What Is Amazon SageMaker?

Amazon SageMaker is a fully managed machine learning service. With SageMaker, data scientists and developers can quickly and easily build and train machine learning models, and then directly deploy them into a production-ready hosted environment. It provides an integrated Jupyter authoring notebook instance for easy access to your data sources for exploration and analysis, so you don't have to manage servers. It also provides common machine learning algorithms that are optimized to run efficiently against extremely large data in a distributed environment. With native support for bring-your-own-algorithms and frameworks, SageMaker offers flexible distributed training options that adjust to your specific workflows. Deploy a model into a secure and scalable environment by launching it with a few clicks from SageMaker Studio or the SageMaker console. Training and hosting are billed by minutes of usage, with no minimum fees and no upfront commitments.

This guide includes information and tutorials on SageMaker features. For additional information, see Amazon SageMaker developer resources.

Topics

- Amazon SageMaker Features (p. 1)
- Amazon SageMaker Pricing (p. 3)
- Are You a First-time User of Amazon SageMaker? (p. 3)

Amazon SageMaker Features

Amazon SageMaker includes the following features:

SageMaker Studio (p. 117)

An integrated machine learning environment where you can build, train, deploy, and analyze your models all in the same application.

SageMaker Canvas (p. 213)

An auto ML service that gives people with no coding experience the ability to build models and make predictions with them.

SageMaker Ground Truth Plus (p. 677)

A turnkey data labeling feature to create high-quality training datasets without having to build labeling applications and manage the labeling workforce on your own.

SageMaker Studio Lab (p. 90)

A free service that gives customers access to AWS compute resources in an environment based on open-source JupyterLab.

SageMaker Training Compiler (p. 2575)

Train deep learning models faster on scalable GPU instances managed by SageMaker.

SageMaker Studio Universal Notebook (p. 984)

Easily discover, connect to, create, terminate and manage Amazon EMR clusters in single account and cross account configurations directly from SageMaker Studio.
SageMaker Serverless Endpoints (p. 2923)

A serverless endpoint option for hosting your ML model. Automatically scales in capacity to serve your endpoint traffic. Removes the need to select instance types or manage scaling policies on an endpoint.

SageMaker Inference Recommender (p. 2712)

Get recommendations on inference instance types and configurations (e.g. instance count, container parameters and model optimizations) to use your ML models and workloads.

SageMaker Model Registry (p. 2982)

Versioning, artifact and lineage tracking, approval workflow, and cross account support for deployment of your machine learning models.

SageMaker Projects (p. 3281)

Create end-to-end ML solutions with CI/CD by using SageMaker projects.

SageMaker Model Building Pipelines (p. 3203)

Create and manage machine learning pipelines integrated directly with SageMaker jobs.

SageMaker ML Lineage Tracking (p. 3309)

Track the lineage of machine learning workflows.

SageMaker Data Wrangler (p. 815)

Import, analyze, prepare, and featurize data in SageMaker Studio. You can integrate Data Wrangler into your machine learning workflows to simplify and streamline data pre-processing and feature engineering using little to no coding. You can also add your own Python scripts and transformations to customize your data prep workflow.

SageMaker Feature Store (p. 1036)

A centralized store for features and associated metadata so features can be easily discovered and reused. You can create two types of stores, an Online or Offline store. The Online Store can be used for low latency, real-time inference use cases and the Offline Store can be used for training and batch inference.

SageMaker JumpStart (p. 45)

Learn about SageMaker features and capabilities through curated 1-click solutions, example notebooks, and pretrained models that you can deploy. You can also fine-tune the models and deploy them.

SageMaker Clarify (p. 6)

Improve your machine learning models by detecting potential bias and help explain the predictions that models make.

SageMaker Edge Manager (p. 3013)

Optimize custom models for edge devices, create and manage fleets and run models with an efficient runtime.

SageMaker Ground Truth (p. 370)

High-quality training datasets by using workers along with machine learning to create labeled datasets.

Amazon Augmented AI (p. 3390)

Build the workflows required for human review of ML predictions. Amazon A2I brings human review to all developers, removing the undifferentiated heavy lifting associated with building human review systems or managing large numbers of human reviewers.
SageMaker Studio Notebooks (p. 129)

The next generation of SageMaker notebooks that include AWS IAM Identity Center (successor to AWS Single Sign-On) (IAM Identity Center) integration, fast start-up times, and single-click sharing.

SageMaker Experiments (p. 2231)

Experiment management and tracking. You can use the tracked data to reconstruct an experiment, incrementally build on experiments conducted by peers, and trace model lineage for compliance and audit verifications.

SageMaker Debugger (p. 2258)

Inspect training parameters and data throughout the training process. Automatically detect and alert users to commonly occurring errors such as parameter values getting too large or small.

SageMaker Autopilot (p. 318)

Users without machine learning knowledge can quickly build classification and regression models.

SageMaker Model Monitor (p. 2853)

Monitor and analyze models in production (endpoints) to detect data drift and deviations in model quality.

SageMaker Neo (p. 3063)

Train machine learning models once, then run anywhere in the cloud and at the edge.

SageMaker Elastic Inference (p. 3129)

Speed up the throughput and decrease the latency of getting real-time inferences.

Reinforcement Learning (p. 2225)

Maximize the long-term reward that an agent receives as a result of its actions.

Preprocessing (p. 1022)

Analyze and preprocess data, tackle feature engineering, and evaluate models.

Batch Transform (p. 2955)

Preprocess datasets, run inference when you don't need a persistent endpoint, and associate input records with inferences to assist the interpretation of results.

Amazon SageMaker Pricing

As with other AWS products, there are no contracts or minimum commitments for using Amazon SageMaker. For more information about the cost of using SageMaker, see SageMaker Pricing.

Are You a First-time User of Amazon SageMaker?

If you are a first-time user of SageMaker, we recommend that you do the following:

1. Read How Amazon SageMaker Works (p. 4) – This section provides an overview of SageMaker, explains key concepts, and describes the core components involved in building AI solutions with SageMaker. We recommend that you read this topic in the order presented.

2. Set Up Amazon SageMaker Prerequisites (p. 33) – This section explains how to set up your AWS account.
3. Amazon SageMaker Autopilot simplifies the machine learning experience by automating machine learning tasks. If you are new to SageMaker, it provides the easiest learning path. It also serves as an excellent ML learning tool that provides visibility into the code with notebooks generated for each of the automated ML tasks. For an introduction to its capabilities, see Automate model development with Amazon SageMaker Autopilot (p. 318). To get started building, training, and deploying machine learning models, Autopilot provides:
   - Samples: Explore modeling with Amazon SageMaker Autopilot (p. 319)
   - Videos: Use Autopilot to automate and explore the machine learning process (p. 320)
   - Tutorials: Get started with Amazon SageMaker Autopilot (p. 321)

4. Get Started with Amazon SageMaker (p. 33) – This section walks you through training your first model using SageMaker Studio, or the SageMaker console and the SageMaker API. You use training algorithms provided by SageMaker.

5. Explore other topics – Depending on your needs, do the following:
   - Submit Python code to train with deep learning frameworks – In SageMaker, you can use your own training scripts to train models. For information, see Use Machine Learning Frameworks, Python, and R with Amazon SageMaker (p. 13).
   - Use SageMaker directly from Apache Spark – For information, see Use Apache Spark with Amazon SageMaker (p. 14).
   - Use SageMaker to train and deploy your own custom algorithms – Package your custom algorithms with Docker so you can train and/or deploy them in SageMaker. To learn how SageMaker interacts with Docker containers, and for the SageMaker requirements for Docker images, see Using Docker containers with SageMaker (p. 3149).

6. View the API Reference – This section describes the SageMaker API operations.

How Amazon SageMaker Works

SageMaker is a fully managed service that enables you to quickly and easily integrate machine learning-based models into your applications. This section provides an overview of machine learning and explains how SageMaker works. If you are a first-time user of SageMaker, we recommend that you read the following sections in order:

1. Machine Learning with Amazon SageMaker (p. 4)
2. Explore, Analyze, and Process Data (p. 6)
3. Train a Model with Amazon SageMaker (p. 9)
4. Deploy a Model in Amazon SageMaker (p. 11)
5. Use Machine Learning Frameworks, Python, and R with Amazon SageMaker (p. 13)
6. Get Started with Amazon SageMaker (p. 33)

Machine Learning with Amazon SageMaker

This section describes a typical machine learning workflow and summarizes how you accomplish those tasks with Amazon SageMaker.

In machine learning, you “teach” a computer to make predictions, or inferences. First, you use an algorithm and example data to train a model. Then you integrate your model into your application to generate inferences in real time and at scale. In a production environment, a model typically learns from millions of example data items and produces inferences in hundreds to less than 20 milliseconds.

The following diagram illustrates the typical workflow for creating a machine learning model:
As the diagram illustrates, you typically perform the following activities:

1. **Generate example data**—To train a model, you need example data. The type of data that you need depends on the business problem that you want the model to solve (the inferences that you want the model to generate). For example, suppose that you want to create a model to predict a number given an input image of a handwritten digit. To train such a model, you need example images of handwritten numbers.

   Data scientists often spend a lot of time exploring and preprocessing, or "wrangling," example data before using it for model training. To preprocess data, you typically do the following:
   a. **Fetch the data**—You might have in-house example data repositories, or you might use datasets that are publicly available. Typically, you pull the dataset or datasets into a single repository.
   b. **Clean the data**—To improve model training, inspect the data and clean it as needed. For example, if your data has a country name attribute with values United States and US, you might want to edit the data to be consistent.
   c. **Prepare or transform the data**—To improve performance, you might perform additional data transformations. For example, you might choose to combine attributes. If your model predicts the conditions that require de-icing an aircraft, instead of using temperature and humidity attributes separately, you might combine those attributes into a new attribute to get a better model.

   In SageMaker, you preprocess example data in a Jupyter notebook on your notebook instance. You use your notebook to fetch your dataset, explore it, and prepare it for model training. For more information, see *Explore, Analyze, and Process Data* (p. 6). For more information about preparing data in AWS Marketplace, see *data preparation*.

2. **Train a model**—Model training includes both training and evaluating the model, as follows:
   - **Training the model**—To train a model, you need an algorithm or a pre-trained base model. The algorithm you choose depends on a number of factors. For a quick, out-of-the-box solution, you might be able to use one of the algorithms that SageMaker provides. For a list of algorithms provided by SageMaker and related considerations, see *Use Amazon SageMaker Built-in Algorithms or Pre-trained Models* (p. 1096). For a UI-based training solution that provides algorithms and models, see *SageMaker JumpStart* (p. 45).
You also need compute resources for training. Depending on the size of your training dataset and how quickly you need the results, you can use resources ranging from a single general-purpose instance to a distributed cluster of GPU instances. For more information, see Train a Model with Amazon SageMaker (p. 9).

- **Evaluating the model**—After you've trained your model, you evaluate it to determine whether the accuracy of the inferences is acceptable. In SageMaker, you use either the AWS SDK for Python (Boto) or the high-level Python library that SageMaker provides to send requests to the model for inferences.

You use a Jupyter notebook in your SageMaker notebook instance to train and evaluate your model.

3. **Deploy the model**—You traditionally re-engineer a model before you integrate it with your application and deploy it. With SageMaker hosting services, you can deploy your model independently, decoupling it from your application code. For more information, see Deploy Models for Inference (p. 2711).

Machine learning is a continuous cycle. After deploying a model, you monitor the inferences, collect "ground truth," and evaluate the model to identify drift. You then increase the accuracy of your inferences by updating your training data to include the newly collected ground truth. You do this by retraining the model with the new dataset. As more and more example data becomes available, you continue retraining your model to increase accuracy.

**Explore, Analyze, and Process Data**

Before using a dataset to train a model, data scientists typically explore, analyze, and preprocess it.

Amazon SageMaker Processing enables running jobs to preprocess and postprocess data, perform feature engineering, and evaluate models on SageMaker easily and at scale. When combined with the other critical machine learning tasks provided by SageMaker, such as training and hosting, Processing provides you with the benefits of a fully managed machine learning environment, including all the security and compliance support built into SageMaker. With Processing, you have the flexibility to use the built-in data processing containers or to bring your own containers and submit custom jobs to run on managed infrastructure. After you submit a job, SageMaker launches the compute instances, processes and analyzes the input data, and releases the resources upon completion. For more information, see Process Data (p. 1022).

- For information about how to run your own data processing scripts, see Data Processing with scikit-learn (p. 1024).
- For information about how to build your own processing container to run scripts, see Build Your Own Processing Container (Advanced Scenario) (p. 1031).
- For information about how to perform exploratory data analysis (EDA) with a visual no-code interface, see Prepare ML Data with Amazon SageMaker Data Wrangler (p. 815).

**What Is Fairness and Model Explainability for Machine Learning Predictions?**

Amazon SageMaker Clarify helps improve your machine learning (ML) models by detecting potential bias and helping explain the predictions that models make. It helps you identify various types of bias.
in pretraining data and in posttraining that can emerge during model training or when the model is in production. SageMaker Clarify helps explain how these models make predictions using a feature attribution approach. It also monitors inferences models make in production for bias or feature attribution drift. The fairness and explainability functionality provided by SageMaker Clarify provides components that help AWS customers build less biased and more understandable machine learning models. It also provides tools to help you generate model governance reports that you can use to inform risk and compliance teams, and external regulators.

Machine learning models and data-driven systems are being increasingly used to help make decisions across domains such as financial services, healthcare, education, and human resources. Machine learning applications provide benefits such as improved accuracy, increased productivity, and cost savings to help meet regulatory requirements, improve business decisions, and provide better insights into data science procedures.

- **Regulatory** – In many situations, it is important to understand why an ML model made a specific prediction and also whether the prediction it made was impacted by any bias, either during training or at inference. Recently, policymakers, regulators, and advocates have raised awareness about the ethical and policy challenges posed by ML and data-driven systems. In particular, they have expressed concerns about the potentially discriminatory impact of such systems (for example, inadvertently encoding of bias into automated decisions).

- **Business** – The adoption of AI systems in regulated domains requires trust, which can be built by providing reliable explanations of the behavior of trained models and how the deployed models make predictions. Model explainability may be particularly important to certain industries with reliability, safety, and compliance requirements, such as financial services, human resources, healthcare, and automated transportation. To take a common financial example, lending applications that incorporate the use of ML models might need to provide explanations about how those models made certain predictions to internal teams of loan officers, customer service representatives, and forecasters, in addition to end users/customers.

- **Data Science** – Data scientists and ML engineers need tools to generate the insights required to debug and improve ML models through better feature engineering, to determine whether a model is making inferences based on noisy or irrelevant features, and to understand the limitations of their models and failure modes their models may encounter.

For a blog that shows how to architect and build a complete machine learning use case involving fraudulent automobile claims that integrates SageMaker Clarify into a SageMaker pipeline, see the [Architect and build the full machine learning lifecycle with AWS: An end-to-end Amazon SageMaker demo](#). This blog discusses how to assess pre and post training bias, how to mitigate the bias, and how the data features impact the prediction. There are links to the relevant code for each task in the ML lifecycle, including the creation of an automated workflow that integrates the fairness and explainability functionality of SageMaker Clarify into a SageMaker Pipeline.

### Best Practices for Evaluating Fairness and Explainability in the ML Lifecycle

**Fairness as a Process** – The notions of bias and fairness are highly dependent on the application. Further, the choice of the attributes for which bias is to be measured, as well as the choice of the bias metrics, may need to be guided by social, legal, and other non-technical considerations. Building consensus and achieving collaboration across key stakeholders (such as product, policy, legal, engineering, and AI/ML teams, as well as end users and communities) is a prerequisite for the successful adoption of fairness-aware ML approaches in practice.

**Fairness and Explainability by Design in the ML Lifecycle** – You should consider fairness and explainability during each stage of the ML lifecycle: problem formation, dataset construction, algorithm selection, model training process, testing process, deployment, and monitoring/feedback. It is important
to have the right tools to do this analysis. To encourage engaging with these considerations, here are a few example questions we recommend you ask during each of these stages.

Sample Notebooks

Amazon SageMaker Clarify provides the following sample notebooks:

- **Explainability and bias detection with Amazon SageMaker Clarify** – Use SageMaker Clarify to create a processing job for the detecting bias and explaining model predictions with feature attributions.

- **Monitoring bias drift and feature attribution drift Amazon SageMaker Clarify** – Use Amazon SageMaker Model Monitor to monitor bias drift and feature attribution drift over time.

- **Fairness and Explainability with SageMaker Clarify (Bring Your Own Container)** – This sample notebook introduces key terms and concepts needed to understand SageMaker Clarify, and it walks you through an end-to-end data science workflow demonstrating how to build your own model and container that can work seamlessly with your Clarify jobs, use the model and SageMaker Clarify to measure bias, explain the importance of the various input features on the model's decision and then access the reports through SageMaker Studio if you have an instance set up.

- **Fairness and Explainability with SageMaker Clarify - Spark Distributed Processing** – This sample notebook walks you through key terms and concepts needed to understand SageMaker Clarify, measures the pre-training bias of a dataset and post-training bias of a model, explains the importance of the various input features on the model's decision, and accesses the reports through SageMaker Studio if you have an instance set up.

- **Mitigate Bias, Train another unbiased Model and Put in the Model Registry** – This notebook describes how to detect bias using SageMaker Clarify, mitigate it with **Synthetic Minority Over-sampling Technique (SMOTE)**, train another model, then put it in the Model Registry along with all the lineage of the artifacts created along the way: data, code and model metadata. This notebook forms part of a series that shows how to integrate SageMaker Clarify into a SageMaker Pipeline that is described in the Architect and build the full machine learning lifecycle with AWS blog.

These notebooks have been verified to run in Amazon SageMaker Studio only. If you need instructions on how to open a notebook in Amazon SageMaker Studio, see [Create or Open an Amazon SageMaker Studio Notebook](p. 133). If you’re prompted to choose a kernel, choose **Python 3 (Data Science)**.

Guide to the SageMaker Clarify Documentation

Bias can occur and be measured in the data at each stage of the machine learning lifecycle: before training a model and after model training. SageMaker Clarify can provide feature attribution...
explanations of model predictions for trained models and for models deployed to production, where models can be monitored for any drift from their baseline explanatory attributions. Clarify calculates baselines when needed. The documentation for SageMaker Clarify is embedded throughout the larger SageMaker documentation set at the relevant ML stages as follows:

- For further information on detecting bias in preprocessing data before it's used to train a model, see [Detect Pretraining Data Bias](#).
- For further information on detecting posttraining data and model bias, see [Detect Posttraining Data and Model Bias with Amazon SageMaker Clarify](#).
- For further information on the model-agnostic feature attribution approach to explain model predictions after training, see [Amazon SageMaker Clarify Model Explainability](#).
- For further information on monitoring for bias in production model inferences due to the drift of data away from the baseline used to train the model, see [Monitor Bias Drift for Models in Production](#).
- For further information on monitoring for the drift of features' contributions away from the baseline that was established during model training, see [Monitor Feature Attribution Drift for Models in Production](#).

## Train a Model with Amazon SageMaker

The following diagram shows how you train and deploy a model with Amazon SageMaker:
The area labeled SageMaker highlights the two components of SageMaker: model training and model deployment.

To train a model in SageMaker, you create a training job. The training job includes the following information:

• The URL of the Amazon Simple Storage Service (Amazon S3) bucket where you've stored the training data.
• The compute resources that you want SageMaker to use for model training. Compute resources are ML compute instances that are managed by SageMaker.
• The URL of the S3 bucket where you want to store the output of the job.
• The Amazon Elastic Container Registry path where the training code is stored. For more information, see Docker Registry Paths and Example Code (p. 1105).

You have the following options for a training algorithm:

• Use an algorithm provided by SageMaker—SageMaker provides dozens of built-in training algorithms and hundreds of pre-trained models. If one of these meets your needs, it's a great out-
of-the-box solution for quick model training. For a list of algorithms provided by SageMaker, see Use Amazon SageMaker Built-in Algorithms or Pre-trained Models (p. 1096). To try an exercise that uses an algorithm provided by SageMaker, see Get Started with Amazon SageMaker (p. 33). You can also use SageMaker JumpStart (p. 45) to use algorithms and models through the Studio UI.

- **Use SageMaker Debugger**—to inspect training parameters and data throughout the training process when working with the TensorFlow, PyTorch, and Apache MXNet learning frameworks or the XGBoost algorithm. Debugger automatically detects and alerts users to commonly occurring errors such as parameter values getting too large or small. For more information about using Debugger, see Debug and Profile Training Jobs Using Amazon SageMaker Debugger (p. 2258). Debugger sample notebooks are available at Amazon SageMaker Debugger Samples.

- **Use Apache Spark with SageMaker**—SageMaker provides a library that you can use in Apache Spark to train models with SageMaker. Using the library provided by SageMaker is similar to using Apache Spark MLLib. For more information, see Use Apache Spark with Amazon SageMaker (p. 14).

- **Submit custom code to train with deep learning frameworks**—You can submit custom Python code that uses TensorFlow, PyTorch, or Apache MXNet for model training. For more information, see Use TensorFlow with Amazon SageMaker (p. 30), Use PyTorch with Amazon SageMaker (p. 26), and Use Apache MXNet with Amazon SageMaker (p. 14).

- **Use your own custom algorithms**—Put your code together as a Docker image and specify the registry path of the image in a SageMaker CreateTrainingJob API call. For more information, see Using Docker containers with SageMaker (p. 3149).

- **Use an algorithm that you subscribe to from AWS Marketplace**—For information, see Find and Subscribe to Algorithms and Model Packages on AWS Marketplace (p. 3492).

After you create the training job, SageMaker launches the ML compute instances and uses the training code and the training dataset to train the model. It saves the resulting model artifacts and other output in the S3 bucket you specified for that purpose.

You can create a training job with the SageMaker console or the API. For information about creating a training job with the API, see the CreateTrainingJob API.

When you create a training job with the API, SageMaker replicates the entire dataset on ML compute instances by default. To make SageMaker replicate a subset of the data on each ML compute instance, you must set the S3DataDistributionType field to ShardedByS3Key. You can set this field using the low-level SDK. For more information, see S3DataDistributionType in S3DataSource.

**Important**

To prevent your algorithm container from contending for memory, we reserve memory for our SageMaker critical system processes on your ML compute instances and therefore you cannot expect to see all the memory for your instance type.

### Deploy a Model in Amazon SageMaker

After you train your machine learning model, you can deploy it using Amazon SageMaker to get predictions in any of the following ways, depending on your use case:

- For persistent, real-time endpoints that make one prediction at a time, use SageMaker real-time hosting services. See Real-time inference (p. 2744).

- Workloads that have idle periods between traffic spurts and can tolerate cold starts, use Serverless Inference. See Serverless Inference (p. 2923).

- Requests with large payload sizes up to 1GB, long processing times, and near-real-time latency requirements, use Amazon SageMaker Asynchronous Inference. See Asynchronous inference (p. 2939).

- To get predictions for an entire dataset, use SageMaker batch transform. See Use Batch Transform (p. 2955).
Validating a Machine Learning Model

After training a model, evaluate it to determine whether its performance and accuracy enable you to achieve your business goals. You might generate multiple models using different methods and evaluate each. For example, you could apply different business rules for each model, and then apply various measures to determine each model's suitability. You might consider whether your model needs to be more sensitive than specific (or vice versa).

You can evaluate your model using historical data (offline) or live data:

- **Offline testing**—Use historical, not live, data to send requests to the model for inferences.

  Deploy your trained model to an alpha endpoint, and use historical data to send inference requests to it. To send the requests, use a Jupyter notebook in your Amazon SageMaker notebook instance and either the AWS SDK for Python (Boto) or the high-level Python library provided by SageMaker.

- **Online testing with live data**—SageMaker supports A/B testing for models in production by using production variants. Production variants are models that use the same inference code and are deployed on the same SageMaker endpoint. You configure the production variants so that a small portion of the live traffic goes to the model that you want to validate. For example, you might choose to send 10% of the traffic to a model variant for evaluation. After you are satisfied with the model's performance, you can route 100% traffic to the updated model. For an example of testing models in production, see Safely update models in production (p. 2819).

For more information, see articles and books about how to evaluate models, for example, Evaluating Machine Learning Models.

Options for offline model evaluation include:

- **Validating using a holdout set**—Machine learning practitioners often set aside a part of the data as a "holdout set." They don't use this data for model training.

  With this approach, you evaluate how well your model provides inferences on the holdout set. You then assess how effectively the model generalizes what it learned in the initial training, as opposed to using model memory. This approach to validation gives you an idea of how often the model is able to infer the correct answer.

In some ways, this approach is similar to teaching elementary school students. First, you provide them with a set of examples to learn, and then test their ability to generalize from their learning. With homework and tests, you pose problems that were not included in the initial learning and determine...
whether they are able to generalize effectively. Students with perfect memories could memorize the problems, instead of learning the rules.

Typically, the holdout dataset is of 20-30% of the training data.

- **k-fold validation**—In this validation approach, you split the example dataset into k parts. You treat each of these parts as a holdout set for k training runs, and use the other k-1 parts as the training set for that run. You produce k models using a similar process, and aggregate the models to generate your final model. The value k is typically in the range of 5-10.

### Monitoring a Model in Production

After you deploy a model into your production environment, use Amazon SageMaker model monitor to continuously monitor the quality of your machine learning models in real time. Amazon SageMaker model monitor enables you to set up an automated alert triggering system when there are deviations in the model quality, such as data drift and anomalies. Amazon CloudWatch Logs collects log files of monitoring the model status and notifies when the quality of your model hits certain thresholds that you preset. CloudWatch stores the log files to an Amazon S3 bucket you specify. Early and pro-active detection of model deviations through AWS model monitor products enables you to take prompt actions to maintain and improve the quality of your deployed model.

For more information about SageMaker model monitoring products, see Monitor models for data and model quality, bias, and explainability (p. 2853).

To start your machine learning journey with SageMaker, sign up for an AWS account at Set Up SageMaker.

### Use Machine Learning Frameworks, Python, and R with Amazon SageMaker

You can use Python and R natively in Amazon SageMaker notebook kernels. There are also kernels that support specific frameworks. A very popular way to get started with SageMaker is to use the Amazon SageMaker Python SDK. It provides open source Python APIs and containers that make it easy to train and deploy models in SageMaker, as well as examples for use with several different machine learning and deep learning frameworks.

For information about using specific frameworks or how to use R in SageMaker, see the following topics.

**Languages SDKs and user guides:**

- Amazon SageMaker Python SDK
- R (p. 26)
- API Reference Guide for Amazon SageMaker (p. 3693)

**Machine learning and deep learning frameworks guides:**

- Apache MXNet (p. 14)
- Apache Spark (p. 14)
- Chainer (p. 23)
- Hugging Face (p. 24)
Use Apache MXNet with Amazon SageMaker

You can use SageMaker to train and deploy a model using custom MXNet code. The Amazon SageMaker Python SDK MXNet estimators and models and the SageMaker open-source MXNet container make writing a MXNet script and running it in SageMaker easier.

What do you want to do?

I want to train a custom MXNet model in SageMaker.

For a sample Jupyter notebook, see the MXNet example notebooks in the Amazon SageMaker Examples GitHub repository.

For documentation, see Train a Model with MXNet.

I have an MXNet model that I trained in SageMaker, and I want to deploy it to a hosted endpoint.

For more information, see Deploy MXNet models.

I have an MXNet model that I trained outside of SageMaker, and I want to deploy it to a SageMaker endpoint

For more information, see Deploy Endpoints from Model Data.

I want to see the API documentation for Amazon SageMaker Python SDK MXNet classes.

For more information, see MXNet Classes.

I want to find the SageMaker MXNet container repository.

For more information, see SageMaker MXNet Container GitHub repository.

I want to find information about MXNet versions supported by AWS Deep Learning Containers.

For more information, see Available Deep Learning Container Images.

For general information about writing MXNet script mode training scripts and using MXNet script mode estimators and models with SageMaker, see Using MXNet with the SageMaker Python SDK.

Use Apache Spark with Amazon SageMaker

This section provides information for developers who want to use Apache Spark for preprocessing data and Amazon SageMaker for model training and hosting. For information about supported versions of Apache Spark, see the Getting SageMaker Spark page in the SageMaker Spark GitHub repository.

SageMaker provides an Apache Spark library, in both Python and Scala, that you can use to easily train models in SageMaker using org.apache.spark.sql.DataFrame data frames in your Spark clusters. After model training, you can also host the model using SageMaker hosting services.

The SageMaker Spark library, com.amazonaws.services.sagemaker.sparksdk, provides the following classes, among others:

• SageMakerEstimator—Extends the org.apache.spark.ml.Estimator interface. You can use this estimator for model training in SageMaker.
Amazon SageMaker Developer Guide
Apache Spark

With SageMaker Studio, you can easily connect to an Amazon EMR cluster. For more information, see Prepare data at Scale with Studio Notebooks.

Download the SageMaker Spark Library

You have the following options for downloading the Spark library provided by SageMaker:

- You can download the source code for both PySpark and Scala libraries from the SageMaker Spark GitHub repository.
- For the Python Spark library, you have the following additional options:
  - Use pip install:

    ```bash
    pip install sagemaker_pyspark
    ```
  - In a notebook instance, create a new notebook that uses either the Sparkmagic (PySpark) or the Sparkmagic (PySpark3) kernel and connect to a remote Amazon EMR cluster.

    **Note**
    The EMR cluster must be configured with an IAM role that has the AmazonSageMakerFullAccess policy attached. For information about configuring roles for an EMR cluster, see Configure IAM Roles for Amazon EMR Permissions to AWS Services in the Amazon EMR Management Guide.

- You can get the Scala library from Maven. Add the Spark library to your project by adding the following dependency to your pom.xml file:

```xml
<dependency>
    <groupId>com.amazonaws</groupId>
    <artifactId>sagemaker-spark_2.11</artifactId>
    <version>spark_2.2.0-1.0</version>
</dependency>
```

Integrate Your Apache Spark Application with SageMaker

The following is high-level summary of the steps for integrating your Apache Spark application with SageMaker.

1. Continue data preprocessing using the Apache Spark library that you are familiar with. Your dataset remains a DataFrame in your Spark cluster. Load your data into a DataFrame and preprocess it so that you have a features column with org.apache.spark.ml.linalg.Vector of Doubles, and an optional label column with values of Double type.

2. Use the estimator in the SageMaker Spark library to train your model. For example, if you choose the k-means algorithm provided by SageMaker for model training, you call the KMeansSageMakerEstimator.fit method.

   Provide your DataFrame as input. The estimator returns a SageMakerModel object.

   **Note**
   SageMakerModel extends the org.apache.spark.ml.Model.
The fit method does the following:

a. Converts the input DataFrame to the protobuf format by selecting the features and label columns from the input DataFrame and uploading the protobuf data to an Amazon S3 bucket. The protobuf format is efficient for model training in SageMaker.

b. Starts model training in SageMaker by sending a SageMaker CreateTrainingJob request. After model training has completed, SageMaker saves the model artifacts to an S3 bucket.

SageMaker assumes the IAM role that you specified for model training to perform tasks on your behalf. For example, it uses the role to read training data from an S3 bucket and to write model artifacts to a bucket.

c. Creates and returns a SageMakerModel object. The constructor does the following tasks, which are related to deploying your model to SageMaker.

   i. Sends a CreateModel request to SageMaker.
   
   ii. Sends a CreateEndpointConfig request to SageMaker.
   
   iii. Sends a CreateEndpoint request to SageMaker, which then launches the specified resources, and hosts the model on them.

3. You can get inferences from your model hosted in SageMaker with the SageMakerModel.transform method.

   Provide an input DataFrame with features as input. The transform method transforms it to a DataFrame containing inferences. Internally, the transform method sends a request to the InvokeEndpoint SageMaker API to get inferences. The transform method appends the inferences to the input DataFrame.

Example 1: Use Amazon SageMaker for Training and Inference with Apache Spark

Topics
- Use Custom Algorithms for Model Training and Hosting on Amazon SageMaker with Apache Spark (p. 20)
- Use the SageMakerEstimator in a Spark Pipeline (p. 21)

Amazon SageMaker provides an Apache Spark library (in both Python and Scala) that you can use to integrate your Apache Spark applications with SageMaker. For example, you might use Apache Spark for data preprocessing and SageMaker for model training and hosting. For more information, see Use Apache Spark with Amazon SageMaker (p. 14). This section provides example code that uses the Apache Spark Scala library provided by SageMaker to train a model in SageMaker using DataFrames in your Spark cluster. The example also hosts the resulting model artifacts using SageMaker hosting services. Specifically, this example does the following:

- Uses the KMeansSageMakerEstimator to fit (or train) a model on data

Because the example uses the k-means algorithm provided by SageMaker to train a model, you use the KMeansSageMakerEstimator. You train the model using images of handwritten single-digit numbers (from the MNIST dataset). You provide the images as an input DataFrame. For your convenience, SageMaker provides this dataset in an S3 bucket.
In response, the estimator returns a `SageMakerModel` object.

- Obtains inferences using the trained `SageMakerModel`

To get inferences from a model hosted in SageMaker, you call the `SageMakerModel.transform` method. You pass a `DataFrame` as input. The method transforms the input `DataFrame` to another `DataFrame` containing inferences obtained from the model.

For a given input image of a handwritten single-digit number, the inference identifies a cluster that the image belongs to. For more information, see K-Means Algorithm (p. 2151).

This is the example code:

```scala
import org.apache.spark.sql.SparkSession
import com.amazonaws.services.sagemaker.sparksdk.IAMRole
import com.amazonaws.services.sagemaker.sparksdk.algorithms
import com.amazonaws.services.sagemaker.sparksdk.algorithms.KMeansSageMakerEstimator
val spark = SparkSession.builder.getOrCreate
// load mnist data as a dataframe from libsvm
val region = "us-east-1"
val trainingData = spark.read.format("libsvm")
  .option("numFeatures", "784")
  .load(s"s3://sagemaker-sample-data-$region/spark/mnist/train/")
val testData = spark.read.format("libsvm")
  .option("numFeatures", "784")
  .load(s"s3://sagemaker-sample-data-$region/spark/mnist/test/")
val roleArn = "arn:aws:iam::<account-id>:role/rolename"
val estimator = new KMeansSageMakerEstimator(
  sagemakerRole = IAMRole(roleArn),
  trainingInstanceType = "ml.p2.xlarge",
  trainingInstanceCount = 1,
  endpointInstanceType = "ml.c4.xlarge",
  endpointInitialInstanceCount = 1)
  .setK(10).setFeatureDim(784)
// train
val model = estimator.fit(trainingData)
val transformedData = model.transform(testData)
transformedData.show
```

The code does the following:

- Loads the MNIST dataset from an S3 bucket provided by SageMaker (awsai-sparksdk-dataset) into a Spark DataFrame (`mnistTrainingDataFrame`):

```scala
// Get a Spark session.
val spark = SparkSession.builder.getOrCreate
// load mnist data as a dataframe from libsvm
```
val region = "us-east-1"
val trainingData = spark.read.format("libsvm")
                   .option("numFeatures", "784")
                   .load(s"s3://sagemaker-sample-data-$region/spark/mnist/train/")
val testData = spark.read.format("libsvm")
              .option("numFeatures", "784")
              .load(s"s3://sagemaker-sample-data-$region/spark/mnist/test/")
val roleArn = "arn:aws:iam::account-id:role/rolename"

trainingData.show()

The show method displays the first 20 rows in the data frame:

```
+-----+--------------------+
|label|            features|
+-----+--------------------+
|  5.0|[784,[152,153,154...|
|  0.0|[784,[127,128,129...|
|  4.0|[784,[160,161,162...|
|  1.0|[784,[158,159,160...|
|  9.0|[784,[208,209,210...|
|  2.0|[784,[155,156,157...|
|  1.0|[784,[124,125,126...|
|  5.0|[784,[151,152,155...|
|  1.0|[784,[152,153,154...|
|  4.0|[784,[134,135,161...|
|  3.0|[784,[123,124,125...|
|  5.0|[784,[216,217,218...|
|  3.0|[784,[143,144,145...|
|  6.0|[784,[72,73,74,99...|
|  1.0|[784,[151,152,153...|
|  7.0|[784,[211,212,213...|
|  2.0|[784,[151,152,153...|
|  8.0|[784,[159,160,161...|
|  6.0|[784,[100,101,102...|
|  9.0|[784,[209,210,211...|
+-----+--------------------+
```

only showing top 20 rows

In each row:

- The label column identifies the image's label. For example, if the image of the handwritten number is the digit 5, the label value is 5.
- The features column stores a vector (org.apache.spark.ml.linalg.Vector) of Double values. These are the 784 features of the handwritten number. (Each handwritten number is a 28 x 28-pixel image, making 784 features.)

- Creates a SageMaker estimator (KMeansSageMakerEstimator)

    The fit method of this estimator uses the k-means algorithm provided by SageMaker to train models using an input DataFrame. In response, it returns a SageMakerModel object that you can use to get inferences.

    **Note**
    The KMeansSageMakerEstimator extends the SageMaker SageMakerEstimator, which extends the Apache Spark Estimator.

val estimator = new KMeansSageMakerEstimator(
    sagemakerRole = IAMRole(roleArn),
    trainingInstanceType = "ml.p2.xlarge",
)
The constructor parameters provide information that is used for training a model and deploying it on SageMaker:

- `trainingInstanceType` and `trainingInstanceCount`—Identify the type and number of ML compute instances to use for model training.

- `endpointInstanceType`—Identifies the ML compute instance type to use when hosting the model in SageMaker. By default, one ML compute instance is assumed.

- `endpointInitialInstanceCount`—Identifies the number of ML compute instances initially backing the endpoint hosting the model in SageMaker.

- `sagemakerRole`—SageMaker assumes this IAM role to perform tasks on your behalf. For example, for model training, it reads data from S3 and writes training results (model artifacts) to S3.

  **Note**
  This example implicitly creates a SageMaker client. To create this client, you must provide your credentials. The API uses these credentials to authenticate requests to SageMaker. For example, it uses the credentials to authenticate requests to create a training job and API calls for deploying the model using SageMaker hosting services.

- After the `KMeansSageMakerEstimator` object has been created, you set the following parameters, are used in model training:
  - The number of clusters that the k-means algorithm should create during model training. You specify 10 clusters, one for each digit, 0 through 9.
  - Identifies that each input image has 784 features (each handwritten number is a 28 x 28-pixel image, making 784 features).

- Calls the estimator `fit` method

```scala
// train
val model = estimator.fit(trainingData)
```

You pass the input `DataFrame` as a parameter. The model does all the work of training the model and deploying it to SageMaker. For more information see, [Integrate Your Apache Spark Application with SageMaker](p. 15). In response, you get a `SageMakerModel` object, which you can use to get inferences from your model deployed in SageMaker.

You provide only the input `DataFrame`. You don't need to specify the registry path to the k-means algorithm used for model training because the `KMeansSageMakerEstimator` knows it.

- Calls the `SageMakerModel.transform` method to get inferences from the model deployed in SageMaker.
The `transform` method takes a DataFrame as input, transforms it, and returns another DataFrame containing inferences obtained from the model.

```scala
val transformedData = model.transform(testData)
transformedData.show
```

For simplicity, we use the same DataFrame as input to the `transform` method that we used for model training in this example. The `transform` method does the following:

- Serializes the `features` column in the input DataFrame to protobuf and sends it to the SageMaker endpoint for inference.
- Deserializes the protobuf response into the two additional columns (`distance_to_cluster` and `closest_cluster`) in the transformed DataFrame.

The `show` method gets inferences to the first 20 rows in the input DataFrame:

<table>
<thead>
<tr>
<th>label</th>
<th>features</th>

<td></td>
<td></td>
</tr>
</tbody>
</table>

You can interpret the data, as follows:

- A handwritten number with the label 5 belongs to cluster 4 (`closest_cluster`).
- A handwritten number with the label 0 belongs to cluster 5.
- A handwritten number with the label 4 belongs to cluster 9.
- A handwritten number with the label 1 belongs to cluster 6.

For more information on how to run these examples, see [https://github.com/aws/sagemaker-spark/blob/master/README.md](https://github.com/aws/sagemaker-spark/blob/master/README.md) on GitHub.

**Use Custom Algorithms for Model Training and Hosting on Amazon SageMaker with Apache Spark**

In Example 1: Use Amazon SageMaker for Training and Inference with Apache Spark (p. 16), you use the `kMeansSageMakerEstimator` because the example uses the k-means algorithm provided by Amazon SageMaker for model training. You might choose to use your own custom algorithm for model training.
training instead. Assuming that you have already created a Docker image, you can create your own SageMakerEstimator and specify the Amazon Elastic Container Registry path for your custom image.

The following example shows how to create a KMeansSageMakerEstimator from the SageMakerEstimator. In the new estimator, you explicitly specify the Docker registry path to your training and inference code images.

```scala
import com.amazonaws.services.sagemaker.sparksdk.IAMRole
import com.amazonaws.services.sagemaker.sparksdk.SageMakerEstimator
import com.amazonaws.services.sagemaker.sparksdk.transformation.serializers.ProtobufRequestRowSerializer
import com.amazonaws.services.sagemaker.sparksdk.transformation.deserializers.KMeansProtobufResponseRowDeserializer

val estimator = new SageMakerEstimator(
  trainingImage = "811284229777.dkr.ecr.us-east-1.amazonaws.com/kmeans:1",
  modelImage = "811284229777.dkr.ecr.us-east-1.amazonaws.com/kmeans:1",
  requestRowSerializer = new ProtobufRequestRowSerializer(),
  responseRowDeserializer = new KMeansProtobufResponseRowDeserializer(),
  hyperParameters = Map("k" -> "10", "feature_dim" -> "784"),
  sagemakerRole = IAMRole(roleArn),
  trainingInstanceType = "ml.p2.xlarge",
  trainingInstanceCount = 1,
  endpointInstanceType = "ml.c4.xlarge",
  endpointInitialInstanceCount = 1,
  trainingSparkDataFormat = "sagemaker")
```

In the code, the parameters in the SageMakerEstimator constructor include:

- **trainingImage** — Identifies the Docker registry path to the training image containing your custom code.
- **modelImage** — Identifies the Docker registry path to the image containing inference code.
- **requestRowSerializer** — Implements `com.amazonaws.services.sagemaker.sparksdk.transformation.RequestRowSerializer`. This parameter serializes rows in the input DataFrame to send them to the model hosted in SageMaker for inference.
- **responseRowDeserializer** — Implements `com.amazonaws.services.sagemaker.sparksdk.transformation.ResponseRowDeserializer`. This parameter deserializes responses from the model, hosted in SageMaker, back into a DataFrame.
- **trainingSparkDataFormat** — Specifies the data format that Spark uses when uploading training data from a DataFrame to S3. For example, "sagemaker" for protobuf format, "csv" for comma-separated values, and "libsvm" for LibSVM format.

You can implement your own RequestRowSerializer and ResponseRowDeserializer to serialize and deserialize rows from a data format that your inference code supports, such as .libsvm or .csv.

**Use the SageMakerEstimator in a Spark Pipeline**

You can use `org.apache.spark.ml.Estimator` estimators and `org.apache.spark.ml.Model` models, and SageMakerEstimator estimators and SageMakerModel models in `org.apache.spark.ml.Pipeline` pipelines, as shown in the following example:

```scala
import org.apache.spark.ml.Pipeline
import org.apache.spark.ml.feature.PCA
```
import org.apache.spark.sql.SparkSession
import com.amazonaws.services.sagemaker.sparksdk.IAMRole
import com.amazonaws.services.sagemaker.sparksdk.algorithms
import com.amazonaws.services.sagemaker.sparksdk.algorithms.KMeansSageMakerEstimator

val spark = SparkSession.builder.getOrCreate

// load mnist data as a dataframe from libsvm
val region = "us-east-1"
val trainingData = spark.read.format("libsvm")
  .option("numFeatures", "784")
  .load(s"s3://sagemaker-sample-data-$region/spark/mnist/train/")
val testData = spark.read.format("libsvm")
  .option("numFeatures", "784")
  .load(s"s3://sagemaker-sample-data-$region/spark/mnist/test/")

// substitute your SageMaker IAM role here
val roleArn = "arn:aws:iam::<account-id>:role/rolename"

val pcaEstimator = new PCA()
  .setInputCol("features")
  .setOutputCol("projectedFeatures")
  .setK(50)

val kMeansSageMakerEstimator = new KMeansSageMakerEstimator(
  sagemakerRole = IAMRole(integTestingRole),
  requestRowSerializer =
    new ProtobufRequestRowSerializer(featuresColumnName = "projectedFeatures"),
  trainingSparkDataFormatOptions = Map("featuresColumnName" -> "projectedFeatures"),
  trainingInstanceType = "ml.p2.xlarge",
  trainingInstanceCount = 1,
  endpointInstanceType = "ml.c4.xlarge",
  endpointInitialInstanceCount = 1)
  .setK(10).setFeatureDim(50)

val pipeline = new Pipeline().setStages(Array(pcaEstimator, kMeansSageMakerEstimator))

// train
val pipelineModel = pipeline.fit(trainingData)
val transformedData = pipelineModel.transform(testData)
transformedData.show()

The parameter trainingSparkDataFormatOptions configures Spark to serialize to protobuf the "projectedFeatures" column for model training. Additionally, Spark serializes to protobuf the "label" column by default. Because we want to make inferences using the "projectedFeatures" column, we pass the column name into the ProtobufRequestRowSerializer.

The following example shows a transformed DataFrame:

+-----+--------------------+--------------------+-------------------+---------------+
|label|            features|   projectedFeatures|distance_to_cluster|closest_cluster|
+-----+--------------------+--------------------+-------------------+---------------+

SDK examples: Use Amazon SageMaker with Apache Spark

The following list is a subset of available examples. Visit the examples website to see more.

- sagemaker-spark: a Spark library for SageMaker
- SageMaker PySpark K-Means Clustering MNIST Example
- Distributed Data Processing using Apache Spark and SageMaker Processing

**Note**
To run the notebooks on a notebook instance, see Example Notebooks (p. 306). To run the notebooks on Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 133).

Use Chainer with Amazon SageMaker

You can use SageMaker to train and deploy a model using custom Chainer code. The SageMaker Python SDK Chainer estimators and models and the SageMaker open-source Chainer container make writing a Chainer script and running it in SageMaker easier.

**What do you want to do?**

I want to train a custom Chainer model in SageMaker.

For a sample Jupyter notebook, see the Chainer example notebooks in the Amazon SageMaker Examples GitHub repository.

For documentation, see Train a Model with Chainer.

I have a Chainer model that I trained in SageMaker, and I want to deploy it to a hosted endpoint.

For more information, see Deploy Chainer models.

I have a Chainer model that I trained outside of SageMaker, and I want to deploy it to a SageMaker endpoint

For more information, see Deploy Endpoints from Model Data.

I want to see the API documentation for Amazon SageMaker Python SDK Chainer classes.

For more information, see Chainer Classes.

I want to find information about SageMaker Chainer containers.

For more information, see the SageMaker Chainer Container GitHub repository.

For information about supported Chainer versions, and for general information about writing Chainer training scripts and using Chainer estimators and models with SageMaker, see Using Chainer with the SageMaker Python SDK.
Use Hugging Face with Amazon SageMaker

Amazon SageMaker enables customers to train, fine-tune, and run inference using Hugging Face models for Natural Language Processing (NLP) on SageMaker. You can use Hugging Face for both training and inference. This functionality is available through the development of Hugging Face AWS Deep Learning Containers. These containers include Hugging Face Transformers, Tokenizers and the Datasets library, which allows you to use these resources for your training and inference jobs. For a list of the available Deep Learning Containers images, see Available Deep Learning Containers Images. These Deep Learning Containers images are maintained and regularly updated with security patches.

To use the Hugging Face Deep Learning Containers with the SageMaker Python SDK for training, see the Hugging Face SageMaker Estimator. With the Hugging Face Estimator, you can use the Hugging Face models as you would any other SageMaker Estimator. However, using the SageMaker Python SDK is optional. You can also orchestrate your use of the Hugging Face Deep Learning Containers with the AWS CLI and AWS SDK for Python (Boto3).

For more information on Hugging Face and the models available in it, see the Hugging Face documentation.

Training

To run training, you can use any of the thousands of models available in Hugging Face and fine-tune them for your specific use case with additional training. With SageMaker, you can use standard training or take advantage of SageMaker Distributed Data and Model Parallel training. As with other SageMaker training jobs using custom code, you can capture your own metrics by passing a metrics definition to the SageMaker Python SDK as shown in Defining Training Metrics (SageMaker Python SDK). The captured metrics are then accessible via CloudWatch and as a Pandas DataFrame via the TrainingJobAnalytics method. Once your model is trained and fine-tuned, you can use it like any other model to run inference jobs.

How to run training with the Hugging Face Estimator

You can implement the Hugging Face Estimator for training jobs using the SageMaker Python SDK. The SageMaker Python SDK is an open source library for training and deploying machine learning models on SageMaker. For more information on the Hugging Face Estimator, see the SageMaker Python SDK documentation.

With the SageMaker Python SDK, you can run training jobs using the Hugging Face Estimator in the following environments:

- **SageMaker Studio**: Amazon SageMaker Studio is the first fully integrated development environment (IDE) for machine learning (ML). SageMaker Studio provides a single, web-based visual interface where you can perform all ML development steps required to prepare, build, train and tune, deploy and manage models. For information on using Jupyter Notebooks in Studio, see Use Amazon SageMaker Studio Notebooks.

- **SageMaker Notebook Instances**: An Amazon SageMaker notebook instance is a machine learning (ML) compute instance running the Jupyter Notebook App. This app lets you run Jupyter Notebooks in your notebook instance to prepare and process data, write code to train models, deploy models to SageMaker hosting, and test or validate your models without SageMaker Studio features like Debugger, Model Monitoring, and a web-based IDE.

- **Locally**: If you have connectivity to AWS and have appropriate SageMaker permissions, you can use the SageMaker Python SDK locally to launch remote training and inference jobs for Hugging Face in SageMaker on AWS. This works on your local machine, as well as other AWS services with a connected SageMaker Python SDK and appropriate permissions.
Inference

For inference, you can use your trained Hugging Face model or one of the pretrained Hugging Face models to deploy an inference job with SageMaker. With this collaboration, you only need one line of code to deploy both your trained models and pretrained models with SageMaker. You can also run inference jobs without having to write any custom inference code. With custom inference code, you can customize the inference logic by providing your own Python script.

How to deploy an inference job using the Hugging Face Deep Learning Containers

You have two options for running inference with SageMaker. You can run inference using a model that you trained, or deploy a pretrained Hugging Face model.

- **Run inference with your trained model**: You have two options for running inference with your own trained model. You can run inference with a model that you trained using an existing Hugging Face model with the SageMaker Hugging Face Deep Learning Containers, or you can bring your own existing Hugging Face model and deploy it using SageMaker. When you run inference with a model that you trained with the SageMaker Hugging Face Estimator, you can deploy the model immediately after training completes or you can upload the trained model to an Amazon S3 bucket and ingest it when running inference later. If you bring your own existing Hugging Face model, you must upload the trained model to an Amazon S3 bucket and ingest that bucket when running inference as shown in Deploy your Hugging Face Transformers for inference example.

- **Run inference with a pretrained Hugging Face model**: You can use one of the thousands of pretrained Hugging Face models to run your inference jobs with no additional training needed. To run inference, you select the pretrained model from the list of Hugging Face models, as outlined in Deploy pre-trained Hugging Face Transformers for inference example.

What do you want to do?

The following Jupyter Notebooks in the Hugging Face notebooks repository illustrate how to use the Hugging Face Deep Learning Containers with SageMaker in various use cases.

I want to train and deploy a text classification model using Hugging Face in SageMaker with PyTorch.

For a sample Jupyter Notebook, see the PyTorch Getting Started Demo.

I want to train and deploy a text classification model using Hugging Face in SageMaker with TensorFlow.

For a sample Jupyter Notebook, see the TensorFlow Getting Started example.

I want to run distributed training with data parallelism using Hugging Face and SageMaker Distributed.

For a sample Jupyter Notebook, see the Distributed Training example.

I want to run distributed training with model parallelism using Hugging Face and SageMaker Distributed.

For a sample Jupyter Notebook, see the Model Parallelism example.

I want to use a spot instance to train and deploy a model using Hugging Face in SageMaker.

For a sample Jupyter Notebook, see the Spot Instances example.

I want to capture custom metrics and use SageMaker Checkpointing when training a text classification model using Hugging Face in SageMaker.

For a sample Jupyter Notebook, see the Training with Custom Metrics example.

I want to train a distributed question-answering TensorFlow model using Hugging Face in SageMaker.

For a sample Jupyter Notebook, see the Distributed TensorFlow Training example.
I want to train a distributed summarization model using Hugging Face in SageMaker.

For a sample Jupyter Notebook, see the Distributed Summarization Training example.

I want to train an image classification model using Hugging Face in SageMaker.

For a sample Jupyter Notebook, see the Vision Transformer Training example.

I want to deploy my trained Hugging Face model in SageMaker.

For a sample Jupyter Notebook, see the Deploy your Hugging Face Transformers for inference example.

I want to deploy a pre-trained Hugging Face model in SageMaker.

For a sample Jupyter Notebook, see the Deploy pre-trained Hugging Face Transformers for inference example.

**Use PyTorch with Amazon SageMaker**

You can use Amazon SageMaker to train and deploy a model using custom PyTorch code. The SageMaker Python SDK PyTorch estimators and models and the SageMaker open-source PyTorch container make writing a PyTorch script and running it in SageMaker easier.

What do you want to do?

I want to train a custom PyTorch model in SageMaker.

For a sample Jupyter notebook, see the PyTorch example notebook in the Amazon SageMaker Examples GitHub repository.

For documentation, see Train a Model with PyTorch.

I have a PyTorch model that I trained in SageMaker, and I want to deploy it to a hosted endpoint.

For more information, see Deploy PyTorch models.

I have a PyTorch model that I trained outside of SageMaker, and I want to deploy it to a SageMaker endpoint.

For more information, see Deploy Endpoints from Model Data.

I want to see the API documentation for Amazon SageMaker Python SDK PyTorch classes.

For more information, see PyTorch Classes.

I want to find the SageMaker PyTorch container repository.

For more information, see SageMaker PyTorch Container GitHub repository.

I want to find information about PyTorch versions supported by AWS Deep Learning Containers.

For more information, see Available Deep Learning Container Images.

For general information about writing PyTorch training scripts and using PyTorch estimators and models with SageMaker, see Using PyTorch with the SageMaker Python SDK.

**R User Guide to Amazon SageMaker**

This document will walk you through ways of leveraging Amazon SageMaker features using R. This guide introduces SageMaker's built-in R kernel, how to get started with R on SageMaker, and finally several example notebooks.
The examples are organized in three levels, Beginner, Intermediate, and Advanced. They start from Getting Started with R on SageMaker, continue to end-to-end machine learning with R on SageMaker, and then finish with more advanced topics such as SageMaker Processing with R script, and Bring-Your-Own (BYO) R algorithm to SageMaker.

For information on how to bring your own custom R image to Studio, see Bring your own SageMaker image (p. 152). For a similar blog article, see Bringing your own R environment to Amazon SageMaker Studio.

RStudio Support in SageMaker

Amazon SageMaker supports RStudio as a fully-managed integrated development environment (IDE) integrated with Amazon SageMaker Domain. With RStudio integration, you can launch an RStudio environment in the Domain to run your RStudio workflows on SageMaker resources. For more information, see RStudio on Amazon SageMaker (p. 182).

R Kernel in SageMaker

SageMaker notebook instances support R using a pre-installed R kernel. Also, the R kernel has the reticulate library, an R to Python interface, so you can use the features of SageMaker Python SDK from within an R script.

- reticulatelibrary: provides an R interface to the Amazon SageMaker Python SDK. The reticulate package translates between R and Python objects.

Get Started with R in SageMaker

- Create a Notebook Instance using the t2.medium instance type and default storage size. You can pick a faster instance and more storage if you plan to continue using the instance for more advanced examples, or create a bigger instance later.
- Wait until the status of the notebook is In Service, and then click Open Jupyter.

- Create a new notebook with R kernel from the list of available environments.
• When the new notebook is created, you should see an R logo in the upper right corner of the notebook environment, and also R as the kernel under that logo. This indicates that SageMaker has successfully launched the R kernel for this notebook.

• Alternatively, when you are in a Jupyter notebook, you can use Kernel menu, and then select R from Change Kernel option.

Example Notebooks

Prerequisites

Getting Started with R on SageMaker: This sample notebook describes how you can develop R scripts using Amazon SageMaker’s R kernel. In this notebook you set up your SageMaker environment and permissions, download the abalone dataset from the UCI Machine Learning Repository, do some basic processing and visualization on the data, then save the data as .csv format to S3.

Beginner Level

SageMaker Batch Transform using R Kernel: This sample Notebook describes how to conduct a batch transform job using SageMaker’s Transformer API and the XGBoost algorithm. The notebook also uses the Abalone dataset.

Intermediate Level

Hyperparameter Optimization for XGBoost in R: This sample notebook extends the previous beginner notebooks that use the abalone dataset and XGBoost. It describes how to do model tuning with hyperparameter optimization. You will also learn how to use batch transform for batching predictions, as well as how to create a model endpoint to make real-time predictions.

Amazon SageMaker Processing with R: SageMaker Processing lets you preprocess, post-process and run model evaluation workloads. This example shows you how to create an R script to orchestrate a Processing job.

Advanced Level
**Train and Deploy Your Own R Algorithm in SageMaker:** Do you already have an R algorithm, and you want to bring it into SageMaker to tune, train, or deploy it? This example walks you through how to customize SageMaker containers with custom R packages, all the way to using a hosted endpoint for inference on your R-origin model.

### Use Scikit-learn with Amazon SageMaker

You can use Amazon SageMaker to train and deploy a model using custom Scikit-learn code. The SageMaker Python SDK Scikit-learn estimators and models and the SageMaker open-source Scikit-learn containers make writing a Scikit-learn script and running it in SageMaker easier.

#### Requirements

Scikit-learn 1.0 has the following dependencies.

<table>
<thead>
<tr>
<th>Dependency</th>
<th>Minimum version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Python</td>
<td>3.7</td>
</tr>
<tr>
<td>NumPy</td>
<td>1.14.6</td>
</tr>
<tr>
<td>SciPy</td>
<td>1.1.0</td>
</tr>
<tr>
<td>joblib</td>
<td>0.11</td>
</tr>
<tr>
<td>threadpoolctl</td>
<td>2.0.0</td>
</tr>
</tbody>
</table>

The SageMaker Scikit-learn container supports the following Scikit-learn versions.

<table>
<thead>
<tr>
<th>Supported Scikit-learn version</th>
<th>Minimum Python version</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.0-1</td>
<td>3.7</td>
</tr>
<tr>
<td>0.23-1</td>
<td>3.6</td>
</tr>
<tr>
<td>0.20.0</td>
<td>2.7 or 3.4</td>
</tr>
</tbody>
</table>

For general information about writing Scikit-learn training scripts and using Scikit-learn estimators and models with SageMaker, see [Using Scikit-learn with the SageMaker Python SDK](#).

### What do you want to do?

**Note**

Matplotlib v2.2.3 or newer is required to run the SageMaker Scikit-learn example notebooks.

I want to use Scikit-learn for data processing, feature engineering, or model evaluation in SageMaker.

For documentation, see [ReadTheDocs](#).

I want to train a custom Scikit-learn model in SageMaker.

I have a Scikit-learn model that I trained in SageMaker, and I want to deploy it to a hosted endpoint. For more information, see Deploy Scikit-learn models.

I have a Scikit-learn model that I trained outside of SageMaker, and I want to deploy it to a SageMaker endpoint. For more information, see Deploy Endpoints from Model Data.

I want to see the API documentation for Amazon SageMaker Python SDK Scikit-learn classes. For more information, see Scikit-learn Classes.

I want to see information about SageMaker Scikit-learn containers. For more information, see SageMaker Scikit-learn Container GitHub repository.

Use SparkML Serving with Amazon SageMaker

The Amazon SageMaker Python SDK SparkML Serving model and predictor and the Amazon SageMaker open-source SparkML Serving container support deploying Apache Spark ML pipelines serialized with MLeeap in SageMaker to get inferences.

For information about using the SparkML Serving container to deploy models to SageMaker, see SageMaker Spark ML Container GitHub repository. For information about the Amazon SageMaker Python SDK SparkML Serving model and predictors, see the SparkML Serving Model and Predictor API documentation.

Use TensorFlow with Amazon SageMaker

Use TensorFlow Version 1.11 and Later

For TensorFlow versions 1.11 and later, the Amazon SageMaker Python SDK supports script mode training scripts.

What do you want to do?

I want to train a custom TensorFlow model in SageMaker.

For a sample Jupyter notebook, see TensorFlow script mode training and serving.

For documentation, see Train a Model with TensorFlow.

I have a TensorFlow model that I trained in SageMaker, and I want to deploy it to a hosted endpoint.

For more information, see Deploy TensorFlow Serving models.

I have a TensorFlow model that I trained outside of SageMaker, and I want to deploy it to a SageMaker endpoint.

For more information, see Deploying directly from model artifacts.

I want to see the API documentation for Amazon SageMaker Python SDK TensorFlow classes.

For more information, see TensorFlow Estimator.
I want to find the SageMaker TensorFlow container repository.

For more information, see SageMaker TensorFlow Container GitHub repository.

I want to find information about TensorFlow versions supported by AWS Deep Learning Containers.

For more information, see Available Deep Learning Container Images.

For general information about writing TensorFlow script mode training scripts and using TensorFlow script mode estimators and models with SageMaker, see Using TensorFlow with the SageMaker Python SDK.

Use TensorFlow Legacy Mode for Versions 1.11 and Earlier

The Amazon SageMaker Python SDK provides a legacy mode that supports TensorFlow versions 1.11 and earlier. Use legacy mode TensorFlow training scripts to run TensorFlow jobs in SageMaker if:

• You have existing legacy mode scripts that you do not want to convert to script mode.
• You want to use a TensorFlow version earlier than 1.11.

For information about writing legacy mode TensorFlow scripts to use with the SageMaker Python SDK, see TensorFlow SageMaker Estimators and Models.

Use Triton Inference Server with Amazon SageMaker

SageMaker enables customers to deploy a model using custom code with NVIDIA Triton Inference Server. This functionality is available through the development of Triton Inference Server Containers. These containers include NVIDIA Triton Inference Server, support for common ML frameworks, and useful environment variables that let you optimize performance on SageMaker. For a list of all available Deep Learning Containers images, see Available Deep Learning Containers Images. Deep Learning Containers images are maintained and regularly updated with security patches.

You can use the Triton Inference Server Container with SageMaker Python SDK as you would any other container in your SageMaker models. However, using the SageMaker Python SDK is optional. You can use Triton Inference Server Containers with the AWS CLI and AWS SDK for Python (Boto3).

For more information on NVIDIA Triton Inference Server see the Triton documentation.

Inference

Note

The Triton Python backend uses shared memory (SHMEM) to connect your code to Triton. SageMaker Inference provides up to half of the instance memory as SHMEM so you can use an instance with more memory for larger SHMEM size.

For inference, you can use your trained ML models with Triton Inference Server to deploy an inference job with SageMaker.

Some of the key features of Triton Inference Server Container are:

• Support for multiple frameworks: Triton can be used to deploy models from all major ML frameworks. Triton supports TensorFlow GraphDef and SavedModel, ONNX, PyTorch TorchScript, TensorRT, and custom Python/C++ model formats.
• Model pipelines: Triton model ensemble represents a pipeline of one model with pre/post processing logic and the connection of input and output tensors between them. A single inference request to an ensemble triggers the execution of the entire pipeline.
• **Concurrent model execution**: Multiple instances of the same model can run simultaneously on the same GPU or on multiple GPUs.

• **Dynamic batching**: For models that support batching, Triton has multiple built-in scheduling and batching algorithms that combine individual inference requests together to improve inference throughput. These scheduling and batching decisions are transparent to the client requesting inference.

• **Diverse CPU and GPU support**: The models can be executed on CPUs or GPUs for maximum flexibility and to support heterogeneous computing requirements.

**What do you want to do?**

I want to deploy my trained PyTorch model in SageMaker.

For a sample Jupyter Notebook, see the [Deploy your PyTorch Resnet50 model with Triton Inference Server example](#).

I want to deploy my trained Hugging Face model in SageMaker.

For a sample Jupyter Notebook, see the [Deploy your PyTorch BERT model with Triton Inference Server example](#).

**Supported Regions and Quotas**

For the AWS Regions supported by Amazon SageMaker and the Amazon Elastic Compute Cloud (Amazon EC2) instance types that are available in each Region, see [Amazon SageMaker Pricing](#).

For a list of the SageMaker service endpoints for each Region, see [Amazon SageMaker endpoints and quotas in the AWS General Reference](#).

Amazon SageMaker Pipelines is available in all the AWS Regions supported by AWS except the AWS GovCloud (US) Regions. SageMaker Projects is available in the AWS regions where CodePipeline is available. For more information about CodePipeline region availability, see the [AWS Regional Services List](#).

The following SageMaker features aren’t available in the Asia Pacific (Osaka) Region:

• Amazon SageMaker Autopilot
• Clarify
• SageMaker Edge Manager
• Ground Truth
• Amazon SageMaker Inference Recommender
• Amazon SageMaker Model Monitor
• Reinforcement learning
• RStudio on Amazon SageMaker

**Quotas**

The **Service Quotas console** provides information about your service quotas. You can use the Service Quotas console to view your default service quotas or to request quota increases. To request a quota increase for adjustable quotas, see [Requesting a quota increase](#).

You can set up a quota request template for your AWS Organization that automatically requests quota increases during account creation. For more information, see [Using Service Quotas request templates](#).
Get Started with Amazon SageMaker

Before you can use Amazon SageMaker, you must sign up for an AWS account and create an IAM admin user by following the steps in Set Up Amazon SageMaker Prerequisites (p. 33).

Amazon SageMaker Studio Lab does not require an AWS account or IAM integration.

After you complete these tasks, continue to one of the following topics, depending on your use case.

- **Onboard to Amazon SageMaker Domain (p. 35):** Follow these steps to create a Domain, which gives you access to Amazon SageMaker Studio and RStudio on Amazon SageMaker. For more information about Domains, see Amazon SageMaker Machine Learning Environments (p. 115).
- **SageMaker JumpStart (p. 45):** Follow these steps to start working with SageMaker JumpStart and learn about SageMaker features and capabilities through curated one-click solutions, example notebooks, and pretrained models that you can deploy. To use SageMaker JumpStart, which is a feature of Amazon SageMaker Studio, you must first onboard to an Amazon SageMaker Domain.
- **Get Started with Amazon SageMaker Notebook Instances (p. 73):** Follow these steps to train and deploy Machine Learning (ML) models using SageMaker notebook instances. SageMaker notebook instances help create the environment by initiating Jupyter servers on Amazon Elastic Compute Cloud (Amazon EC2) and providing preconfigured kernels. For more information, see Use Amazon SageMaker Notebook Instances (p. 291).
- **Amazon SageMaker Studio Lab (p. 90):** Follow these steps to start working with Amazon SageMaker Studio Lab. Studio Lab is a free service that gives you access to AWS compute resources, in an environment based on open-source JupyterLab, without requiring an AWS account.

Topics

- Set Up Amazon SageMaker Prerequisites (p. 33)
- Onboard to Amazon SageMaker Domain (p. 35)
- SageMaker JumpStart (p. 45)
- Get Started with Amazon SageMaker Notebook Instances (p. 73)
- Amazon SageMaker Studio Lab (p. 90)

Set Up Amazon SageMaker Prerequisites

In this section, you sign up for an AWS account and create an AWS Identity and Access Management (IAM) admin user.

If you’re new to SageMaker, we recommend that you read How Amazon SageMaker Works (p. 4).

Topics

- Create an AWS Account (p. 33)
- Create an IAM Administrator User and Group (p. 34)

Create an AWS Account

In this section, you sign up for an AWS account. If you already have an AWS account, skip this step.

When you sign up for Amazon Web Services (AWS), your AWS account is automatically signed up for all AWS services, including SageMaker. You are charged only for the services that you use.
To create an AWS account
2. Follow the online instructions.

Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

When you sign up for an AWS account, an AWS account root user is created. The root user has access to all AWS services and resources in the account. As a security best practice, assign administrative access to an administrative user, and use only the root user to perform tasks that require root user access.

Write down your AWS account ID because you'll need it for the next task.

Create an IAM Administrator User and Group

When you create an AWS account, you get a single sign-in identity that has complete access to all of the AWS services and resources in the account. This identity is called the AWS account root user. Signing in to the AWS console using the email address and password that you used to create the account gives you complete access to all of the AWS resources in your account.

We strongly recommend that you not use the root user for everyday tasks, even the administrative ones. Instead, adhere to the Create Individual IAM Users, an AWS Identity and Access Management (IAM) administrator user. Then securely lock away the root user credentials and use them to perform only a few account and service management tasks.

To create an administrator user
1. Create an administrator user in your AWS account. For instructions, see Creating Your First IAM User and Administrators Group in the IAM User Guide.

   Note
   We assume that you use administrator user credentials for the exercises and procedures in this guide. If you choose to create and use another IAM user, grant that user minimum permissions. For more information, see Authenticating with Identities (p. 3501).

2. Ensure that your administrator user has the AmazonSageMakerFullAccess policy, as well as a policy with the following content needed to create a SageMaker domain. For more information about creating IAM policies, see Creating IAM policies.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "sagemaker:*"
            ],
            "Resource": [
                "arn:aws:sagemaker:*:*:domain/*",
                "arn:aws:sagemaker:*:*:user-profile/*",
                "arn:aws:sagemaker:*:*:app/*",
                "arn:aws:sagemaker:*:*:flow-definition/*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "iam:GetRole",
                "iam:PassRole"
            ],
            "Resource": [
                "arn:aws:iam:::role/*",
                "arn:aws:iam:::instance-profile/*"
            ]
        }
    ]
}
```
Onboard to Amazon SageMaker Domain

An Amazon SageMaker Domain consists of an associated Amazon Elastic File System (Amazon EFS) volume; a list of authorized users; and a variety of security, application, policy, and Amazon Virtual Private Cloud (Amazon VPC) configurations. To use Amazon SageMaker Studio, Amazon SageMaker Studio Notebooks, and RStudio, you must complete the Amazon SageMaker Domain onboarding process using the SageMaker console. For more information about Amazon SageMaker Domains, see Amazon SageMaker Machine Learning Environments (p. 115).

When onboarding, you can choose to use either AWS IAM Identity Center (successor to AWS Single Sign-On) (IAM Identity Center) or AWS Identity and Access Management (IAM) for authentication methods. When you use IAM authentication, you can choose either the Quick setup or the Standard setup procedure. RStudio setup is only available when using the Standard setup procedure.

Note
If you onboard using IAM authentication and want to switch to authentication using IAM Identity Center later, you must delete the Domain that you created. Then, you need to manually re-import all notebooks and other user data that you created. For more information, see Delete an Amazon SageMaker Domain (p. 43).

The simplest way to create an Amazon SageMaker Domain is to follow the Quick setup procedure. Quick setup uses the same default settings as the Standard setup procedures. These settings include shareable notebooks and public internet access. For more control, including the option of using authentication using IAM Identity Center and RStudio, use the Standard setup procedures.

Authentication using IAM Identity Center

To use authentication using IAM Identity Center with Amazon SageMaker Studio and RStudio, you must onboard to an AWS Organizations organization.

Note
The AWS Organizations account must be in the same AWS Region as Amazon SageMaker Studio and RStudio.

Authentication using IAM Identity Center provides the following benefits over IAM authentication:

• Members given access to Studio have a unique sign-in URL that directly opens Studio, and they sign in with their IAM Identity Center credentials. When you use IAM authentication, you must sign in through the SageMaker console.
• Organizations manage their members in IAM Identity Center instead of the Domain. You can assign multiple members access to the Domain at the same time. When you use IAM authentication, you must add and manage members manually, one at time, using the Domain Control Panel.

Topics
• Onboard to Amazon SageMaker Domain Using Quick setup (p. 36)
• Onboard to Amazon SageMaker Domain Using IAM Identity Center (p. 37)
• Onboard to Amazon SageMaker Domain Using IAM (p. 40)
Onboard to Amazon SageMaker Domain Using Quick setup

This topic describes how to onboard to Amazon SageMaker Domain using the Quick setup procedure, which uses AWS Identity and Access Management (IAM) authentication. For information on how to onboard using the standard IAM procedure, see Onboard Using IAM (p. 40).

RStudio support is not currently available when onboarding using the Quick setup procedure.

For information on how to onboard using AWS IAM Identity Center (successor to AWS Single Sign-On) (IAM Identity Center), see Onboard Using IAM Identity Center (p. 37).

To onboard to the Domain using Quick setup

1. Open the SageMaker console.
2. Choose Control Panel at the top left of the page.
4. Under User profile, for Name keep the default name or create a new name. The name can be up to 63 characters. Valid characters: A-Z, a-z, 0-9, and - (hyphen).
5. For Default execution role, choose an option from the role selector. This is the default role that is assigned to the Amazon SageMaker Domain user profile.

   If you choose Enter a custom IAM role ARN, the role must have at a minimum, an attached trust policy that grants SageMaker permission to assume the role. For more information, see SageMaker Roles (p. 3536).

   If you choose Create a new role, the Create an IAM role dialog opens:
   - For S3 buckets you specify, specify additional S3 buckets that users of your notebooks can access. If you don't want to add access to more buckets, choose None.
   - Choose Create role. SageMaker creates a new IAM AmazonSageMaker-ExecutionPolicy role with the AmazonSageMakerFullAccess policy attached.
6. Choose Submit.
7. From the pop-up window, select a Amazon Virtual Private Cloud (Amazon VPC) and subnet to use.
8. Choose Save and continue.

   Note
   If you receive an error message that you need to create a VPC, see Choose a VPC (p. 42).

   When Status is Ready, the user name that you specified is enabled and chosen. The Add user and Delete user buttons, and the Launch app link are also enabled.

   When Studio opens, you can start using it.

Now that you've onboarded to SageMaker Studio, use the following steps to access Studio later.

To access Studio after you onboard

1. Open the SageMaker console.
2. Choose Control Panel at the top left of the page.
3. On the Control Panel, choose your user name and then choose Launch app. Select Studio.

To add more users
1. On the Control Panel, choose Add user.
2. Repeat steps 4 and 5 from the first procedure, “To onboard to Amazon SageMaker Domain using Quick setup.”
3. Choose Submit.

For information about using SageMaker Studio, see SageMaker Studio (p. 117).

Onboard to Amazon SageMaker Domain Using IAM Identity Center

This topic describes how to onboard to Amazon SageMaker Domain using authentication using IAM Identity Center. For information on how to onboard using AWS Identity and Access Management (IAM) authentication, see Onboard Using Quick setup (p. 36) or Onboard Using IAM (p. 40).

To onboard to Domain using IAM Identity Center
1. Open the SageMaker console.
2. Choose Control Panel at the top left of the page.
4. Select Configure.

Step 1: General settings
1. For Authentication, choose AWS IAM Identity Center (successor to AWS Single Sign-On).
2. If you don't have a group in IAM Identity Center in the same Region as your SageMaker Domain, you must create a group in IAM Identity Center in the same Region as your SageMaker Domain before proceeding. To continue to onboard without IAM Identity Center, choose the AWS Identity and Access Management (IAM) authentication method or the Quick setup procedure, which also uses IAM.

For information about setting up IAM Identity Center for use with Domain, see Set Up IAM Identity Center for use with Amazon SageMaker Domain (p. 39).
3. Under Permission, for IAM role, choose an option from the role selector.

If you choose Enter a custom IAM role ARN, the role must have at a minimum, an attached trust policy that grants SageMaker permission to assume the role. For more information, see SageMaker Roles (p. 3536).

If you choose Create a new role, the Create an IAM role dialog opens:

   a. For S3 buckets you specify, specify additional S3 buckets that users of your notebooks can access. If you don't want to add access to more buckets, choose None.
   b. Choose Create role. SageMaker creates a new IAM AmazonSageMaker-ExecutionPolicy role with the AmazonSageMakerFullAccess policy attached.

4. Under Network and storage, specify the following:
   • Your VPC information – For more information, see Choose a VPC (p. 42).
(Optional) **Encryption key** – SageMaker uses an AWS KMS key to encrypt your Amazon Elastic File System (Amazon EFS) and Amazon Elastic Block Store (Amazon EBS) file systems. By default, it uses an AWS managed key. To use a customer managed key, enter its key ID or Amazon Resource Name (ARN). For more information, see Protect Data at Rest Using Encryption (p. 3496).

**Note**
Encryption in transit is only available for Amazon SageMaker Studio.

5. Select **Next**.

**Step 2: Studio settings**

1. Under **Default JupyterLab version**, select a JupyterLab version from the dropdown to use as the default for your domain. For information on selecting a JupyterLab version, see JupyterLab Versioning (p. 120).

2. Under **Notebook Sharing Configuration**, accept the default notebook sharing configuration or customize the options.

3. Under **SageMaker Projects and JumpStart**, accept the default Project and JumpStart settings, or customize whether administrators and users can create projects and use JumpStart. For more information, see SageMaker Studio Permissions Required to Use Projects (p. 3286).

4. Select **Next**.

**Step 3: RStudio settings**

1. Under **RStudio Workbench**, verify that your RStudio license is automatically detected. For more information about getting an RStudio license and activating it with SageMaker, see RStudio license (p. 183).

2. Select an instance type to launch your RStudio Server on. For more information, see RStudioServerPro instance type (p. 186).

3. Under **Permission**, create your role or select an existing role. The role must have the following permissions policy. This policy allows the RStudioServerPro app to access necessary resources and allows Amazon SageMaker to automatically launch an RStudioServerPro app when the existing RStudioServerPro app is in a Deleted or Failed status. For information about adding permissions to a role, see Modifying a role permissions policy (console).

```json

    }
  ]
}
```
4. Under **RStudio Connect**, add the URL for your RStudio Connect server. RStudio Connect is a publishing platform for Shiny applications, R Markdown reports, dashboards, plots, and more. When you onboard to RStudio on SageMaker, an RStudio Connect server is not created. For more information, see **RStudio Connect URL** (p. 186).

5. Under **RStudio Package Manager**, add the URL for your RStudio Package Manager. SageMaker creates a default package repository for the Package Manager when you onboard RStudio. For more information about RStudio Package Manager, see **RStudio Package Manager** (p. 187).

6. Select **Submit**.

**To access the Domain after onboarding**

After you are given access to the Domain, you are sent an email inviting you to create a password and use IAM Identity Center. The email also contains the URL to sign in to the Domain. For more information about signing in and session duration, see **How to sign in to the user portal**.

After you activate your account, go to the Domain URL, sign in, and wait for your user profile to be created. On subsequent visits, you only need to wait for the Studio or RStudio app to load.

Bookmark the URL. The URL is also available in the **Control Panel**.

For information about using SageMaker Studio, see **SageMaker Studio** (p. 117).

For information about using RStudio, see **RStudio on Amazon SageMaker** (p. 182).

**Set Up IAM Identity Center for use with Amazon SageMaker Domain**

To use authentication in IAM Identity Center, you must belong to an AWS Organizations. If you don't belong to an AWS Organizations, you can create one following the steps in **Tutorial: Creating and configuring an organization**.

After you have created your organization and user, you can create a SageMaker Studio user profile for that user in IAM Identity Center as follows.

1. **From the Amazon SageMaker Console**: – You can use the Amazon SageMaker Console to create a user profile for the user in IAM Identity Center. If the user in IAM Identity Center hasn’t already been associated with Studio, it is automatically associated.

2. **Using the AWS CLI or AWS CloudFormation** – A user in IAM Identity Center assigned to Studio can create a Studio user profile using the SageMaker console, AWS CLI or AWS CloudFormation.
   - The user in IAM Identity Center, or a group in IAM Identity Center containing that user, must first be assigned to the Studio application from the IAM Identity Center Console. For more information about application assignment, see **Assign user access**.
   - A user profile can then be created for the user in IAM Identity Center with the AWS CLI or AWS CloudFormation.

**Note**

To simplify administration of access permissions, we recommend assigning groups in IAM Identity Center to the SageMaker Studio application instead of assigning users in IAM Identity Center. Groups allow permissions to be granted or denied to multiple users at once.
A user can be moved out of a group or to a different group if needed. When assigning user access to applications, IAM Identity Center does not currently support users being added to nested groups. If a user is added to a nested group, they may receive a “You do not have any applications” error message during sign-in. Assignments must be made to the immediate group the user is a member of.

Return to the Control Panel to continue to onboard using authentication using IAM Identity Center.

Onboard to Amazon SageMaker Domain Using IAM

This topic describes how to onboard to Amazon SageMaker Domain using the standard setup procedure for AWS Identity and Access Management (IAM) authentication. To onboard faster using IAM, see Onboard Using Quick setup (p. 36).

For information on how to onboard using AWS IAM Identity Center (successor to AWS Single Sign-On) (IAM Identity Center), see Onboard Using IAM Identity Center (p. 37).

To onboard to Domain using IAM

1. Open the SageMaker console.
2. Choose Control Panel at the top left of the page.
4. Select Configure.

Step 1: General settings

1. For Authentication, choose AWS Identity and Access Management (IAM).
2. Under Permission, for IAM role, choose an option from the role selector.
   If you choose Enter a custom IAM role ARN, the role must have at a minimum, an attached trust policy that grants SageMaker permission to assume the role. For more information, see SageMaker Roles (p. 3536).
   If you choose Create a new role, the Create an IAM role dialog opens:
   a. For S3 buckets you specify, specify additional S3 buckets that users of your notebooks can access. If you don't want to add access to more buckets, choose None.
   b. Choose Create role. SageMaker creates a new IAM AmazonSageMaker-ExecutionPolicy role with the AmazonSageMakerFullAccess policy attached.
3. Under Network and storage, specify the following:
   • Your VPC information – For more information, see Choose a VPC (p. 42).
   • (Optional) Storage encryption key – SageMaker uses an AWS KMS key to encrypt your Amazon Elastic File System (Amazon EFS) and Amazon Elastic Block Store (Amazon EBS) file systems. By default, it uses an AWS managed key. To use a customer managed key, enter its key ID or Amazon Resource Name (ARN). For more information, see Protect Data at Rest Using Encryption (p. 3496).
     Note
     Encryption in transit is only available for Amazon SageMaker Studio.
4. Select Next.

Step 2: Studio settings

1. Under Default JupyterLab version, select a JupyterLab version from the dropdown to use as the default for your domain. For information on selecting a JupyterLab version, see JupyterLab Versioning (p. 120).
2. Under **Notebook Sharing Configuration**, accept the default notebook sharing configuration or customize the options.

3. Under **SageMaker Projects and JumpStart**, accept the default Project and JumpStart settings or customize whether administrators and user can create projects and use Jumpstart. For more information, see [SageMaker Studio Permissions Required to Use Projects](p. 3286).

4. Select **Next**.

**Step 3: RStudio settings**

1. Under **RStudio Workbench**, verify that your RStudio license is automatically detected. For more information about getting an RStudio license and activating it with SageMaker, see [RStudio license](p. 183).

2. Select an instance type to launch your RStudio Server on. For more information, see [RStudioServerPro instance type](p. 186).

3. Under **Permission**, create your role or select an existing role. The role must have the following permissions policy. This policy allows the RStudioServerPro app to access necessary resources and allows Amazon SageMaker to automatically launch an RStudioServerPro app when the existing RStudioServerPro app is in a Deleted or Failed status. For information on adding permissions to a role, see [Modifying a role permissions policy (console)].

4. Under **RStudio Connect**, add the URL for your RStudio Connect Server. RStudio Connect is a publishing platform for Shiny applications, R Markdown reports, dashboards, plots, and more. When you onboard to RStudio on Amazon SageMaker, an RStudio Connect server is not created. You must create an RStudio Connect server on an EC2 instance to use Connect with Amazon SageMaker. For more information, see [RStudio Connect URL](p. 186).

5. Under **RStudio Package Manager**, add the URL for your RStudio Package Manager. SageMaker creates a default package repository for the Package Manager when you onboard RStudio. For more information about RStudio Package Manager, see [RStudio Package Manager](p. 187).

6. Select **Submit**.
Choose a VPC

This topic provides detailed information about choosing an Amazon Virtual Private Cloud (VPC) when you onboard to Amazon SageMaker Domain. For more information about onboarding to SageMaker Domain, see Onboard to Amazon SageMaker Domain (p. 35).

By default, SageMaker Domain uses two VPCs. One VPC is managed by Amazon SageMaker and provides direct internet access. You specify the other VPC, which provides encrypted traffic between the Domain and your Amazon Elastic File System (EFS) volume.

You can change this behavior so that SageMaker sends all traffic over your specified VPC. When you choose this option, you must provide the subnets, security groups, and interface endpoints that are necessary to communicate with the SageMaker API and SageMaker runtime, and various AWS services, such as Amazon Simple Storage Service (Amazon S3) and Amazon CloudWatch, that are used by Studio and your Studio notebooks.

When you onboard to SageMaker Domain, you tell SageMaker to send all traffic over your VPC by setting the network access type to VPC only.

To specify the VPC information

When you specify the VPC entities (that is, the VPC, subnet, or security group) in the following procedure, one of three options is presented based on the number of entities you have in the current AWS Region. The behavior is as follows:

- One entity – SageMaker uses that entity. This can't be changed.
- Multiple entities – You must choose the entities from the dropdown list.
- No entities – You must create one or more entities in order to use Domain. Choose Create <entity> to open the VPC console in a new browser tab. After you create the entities, return to the Domain Get started page to continue the onboarding process.

This procedure is part of the Amazon SageMaker Domain onboarding process when you choose Standard setup. Your VPC information is specified under the Network section.

1. Choose the VPC.
2. Choose one or more subnets. If you don't choose any subnets, SageMaker uses all the subnets in the VPC.
3. Select the network access type.
   - Public internet only – Non-EFS traffic goes through a SageMaker managed VPC, which allows internet access. Traffic between the domain and your Amazon EFS volume is through the specified VPC.
• **VPC only** – All SageMaker traffic is through the specified VPC and subnets. Internet access is disabled by default.

4. Choose the security groups. If you chose **Public internet only**, this step is optional. If you chose **VPC only**, this step is required.

   **Note**
   For the maximum number of allowed security groups, see [UserSettings](#).

For VPC requirements in **VPC only** mode, see [Connect SageMaker Studio Notebooks in a VPC to External Resources](#p. 3631).

---

# Delete an Amazon SageMaker Domain

A domain consists of a list of authorized users, configuration settings, and an Amazon Elastic File System (Amazon EFS) volume, which contains data for the users, including notebooks, resources, and artifacts. A user can have multiple applications (apps) which support the reading and execution experience of the user’s notebooks, terminals, and consoles.

You can delete your domain using one of the following:

- AWS console
- AWS Command Line Interface (AWS CLI)
- SageMaker SDK

The following sections give information on the requirements to delete a domain, as well as how to delete the domain.

**Topics**

- Requirements (p. 43)
- EFS files (p. 44)
- Delete a Amazon SageMaker Domain (Console) (p. 44)
- Delete a Amazon SageMaker Domain (CLI) (p. 44)

**Requirements**

You must satisfy the following requirements to delete a domain.

- You must have admin permission to delete a Domain.
- You can only delete an app whose status is InService, which is displayed as **Ready** in the domain. An app whose status is Failed doesn't need to be deleted to delete the containing domain. In the domain, an attempt to delete an app in the failed state results in an error.
- To delete a domain, the domain cannot contain any user profiles. To delete a user profile, the profile cannot contain any non-failed apps.

When you delete these resources, the following occurs:

- **App** – The data (files and notebooks) in a user’s home directory is saved. Unsaved notebook data is lost.
- **User profile** – The user is no longer able to sign in to the Domain and loses access to their home directory, but the data is not deleted. An admin can retrieve the data from the Amazon EFS volume where it is stored under the user’s AWS account.
- You must delete the domain if you want to switch authentication modes from IAM to IAM Identity Center.
EFS files

Your files are kept in an Amazon EFS volume as a backup. This backup includes the files in the mounted directory, which is `/home/sagemaker-user` for Jupyter and `/root` for your kernel. When you delete files from these mounted directories, the kernel or app may move the deleted files into a hidden trash folder. If the trash folder is inside the mounted directory, those files are copied into the Amazon EFS volume and will incur charges. To avoid these Amazon EFS charges, you must identify and clean the trash folder location. The trash folder location for default apps and kernels is `~/.local/`. This may vary depending on the Linux distribution used for custom apps or kernels. For more information about the Amazon EFS volume, see Manage Your EFS Storage Volume in SageMaker Studio (p. 178).

When you use the AWS console to delete the domain, the Amazon EFS volume is detached but not deleted. The same behavior occurs by default when you use the AWS CLI or the SDK to delete the domain. However, when you use the AWS CLI or the SDK, you can set the RetentionPolicy to `HomeEfsFileSystem=Delete` to delete the EFS volume along with the domain.

Delete a Amazon SageMaker Domain (Console)

To delete a domain

1. Open the SageMaker console.
2. Choose Control Panel on the left side of the page.
3. Repeat the following steps for each user in the User name list.
   a. Choose the user.
   b. On the User Details page, for each non-failed app in the Apps list, choose Action.
   c. From the dropdown list, choose Delete.
   d. On the Delete app dialog, choose Yes, delete app, type delete in the confirmation field, and then choose Delete.
   e. When the Status for all apps show as Deleted, choose Edit.
   f. From the Edit User page, choose Delete user.
   g. On the Delete user dialog, choose Yes, delete user, type delete in the confirmation field, and then choose Delete.

   **Important**
   When a user is deleted, they lose access to the Amazon EFS volume that contains their data, including notebooks and other artifacts. The data is not deleted and can be accessed by an administrator.

4. When all users are deleted, choose the domain settings icon (Commit).
5. From the General settings page, choose Delete Domain.
6. On the Delete Domain dialog, choose Yes, delete Domain, type delete in the confirmation field, and then choose Delete.

Delete a Amazon SageMaker Domain (CLI)

To delete a domain

1. Retrieve the list of domains in your account.

   ```bash
   aws --region Region sagemaker list-domains
   ```
2. Retrieve the list of applications for the domain to be deleted.

```bash
aws --region Region sagemaker list-apps \
    --domain-id-equals DomainId
```

3. Delete each application in the list.

```bash
aws --region Region sagemaker delete-app \
    --domain-id DomainId \n    --app-name AppName \n    --app-type AppType \n    --user-profile-name UserProfileName
```

4. Retrieve the list of user profiles in the domain.

```bash
aws --region Region sagemaker list-user-profiles \
    --domain-id-equals DomainId
```

5. Delete each user profile in the list.

```bash
aws --region Region sagemaker delete-user-profile \
    --domain-id DomainId \n    --user-profile-name UserProfileName
```

6. Delete the domain. To also delete the Amazon EFS volume, specify HomeEfsFileSystem=Delete.

```bash
aws --region Region sagemaker delete-domain \
    --domain-id DomainId \n    --retention-policy HomeEfsFileSystem=Retain
```

## SageMaker JumpStart

SageMaker JumpStart provides pre-trained, open-source models for a wide range of problem types to help you get started with machine learning. You can incrementally train and tune these models before deployment. JumpStart also provides solution-templates that set up infrastructure for common use cases, and executable example notebooks for machine learning with SageMaker.

You can access the pre-trained models, solution templates, and examples through the JumpStart landing page in Amazon SageMaker Studio. The following steps show how to access JumpStart models and solutions using Amazon SageMaker Studio.

You can also access the models using the SageMaker Python SDK. For information about how to use JumpStart models programmatically via API, see [Use SageMaker JumpStart Algorithms with Pretrained Models](#).

### Open and use JumpStart

The following sections give information on how to open and use JumpStart from the Amazon SageMaker Studio UI.

#### Open JumpStart

In Amazon SageMaker Studio, open JumpStart by using one of the following:

- The JumpStart launcher in the Get Started section.
Open and use JumpStart

- The JumpStart icon ( ) in the left sidebar.
- The Browse JumpStart button in the launched assets pane.

Important
Before downloading or using third-party content: You are responsible for reviewing and complying with any applicable license terms and making sure that they are acceptable for your use case.

Use JumpStart

From the SageMaker JumpStart landing page, you can browse for solutions, models, notebooks, and other resources. You can also view your currently launched solutions, endpoints, and training jobs. Using the JumpStart search bar, you can search for topics of interest.
You can find JumpStart resources by using search, or by browsing each category that follows the search panel:

- **Featured** – The latest or most used solutions, models, and examples.
- **Solutions** – In one step, launch comprehensive machine learning solutions that tie SageMaker to other AWS services. Select **Explore All Solutions** to view all available solutions.
- **Models** – Find a model that fits your needs from the collection of text, vision, and tabular models. You can filter the collection by problem types, data types, and frameworks. Then, deploy and refine pre-trained models for image classification and object detection in one step. Select **Explore All Models** to view all available models.
- **Resources** – Use example notebooks, blogs, and video tutorials to learn and head start your problem types.
  - **Example notebooks** – Run example notebooks that use SageMaker features like Spot Instance training and experiments over a large variety of model types and use cases.
  - **Blogs** – Read details and solutions from machine learning experts.
  - **Video tutorials** – Watch video tutorials for SageMaker features and machine learning use cases from machine learning experts.
Solution Templates

SageMaker JumpStart provides one-click, end-to-end solutions for many common machine learning use cases. Explore the following use cases for more information on available solution templates.

- Demand forecasting (p. 48)
- Credit rating prediction (p. 49)
- Fraud detection (p. 49)
- Computer vision (p. 50)
- Extract and analyze data from documents (p. 50)
- Predictive maintenance (p. 51)
- Churn prediction (p. 51)
- Personalized recommendations (p. 52)
- Reinforcement learning (p. 52)
- Healthcare and life sciences (p. 52)
- Financial pricing (p. 53)

Choose the solution template that best fits your use case from the JumpStart landing page. When you choose a solution template, JumpStart shows a description of the solution and a Launch button. When you select Launch, JumpStart creates all of the resources that you need to run the solution, including training and model hosting instances. For more information on launching a JumpStart solution, see the section called “Launch a Solution” (p. 53).

After launching the solution, you can explore solution features and any generated artifacts in JumpStart. Select Open Notebook to use provided notebooks and explore the solution’s features. When artifacts are generated during launch or after running the provided notebooks, they’re listed in the Generated Artifacts table. You can delete individual artifacts with the trash icon (Trash). You can delete all of the solution’s resources by choosing Delete solution resources.

Demand forecasting

Demand forecasting uses historical time series data in order to make future estimations in relation to customer demand over a specific period and streamline the supply-demand decision-making process across businesses.

Demand forecasting use cases include predicting ticket sales in the transportation industry, stock prices, number of hospital visits, number of customer representatives to hire for multiple locations in the next month, product sales across multiple regions in the next quarter, cloud server usage for the next day for a video streaming service, electricity consumption for multiple regions over the next week, number of IoT devices and sensors such as energy consumption, and more.

Time series data is categorized as univariate and multi-variate. For example, the total electricity consumption for a single household is a univariate time series over a period of time. When multiple univariate time series are stacked on each other, it’s called a multi-variate time series. For example, the total electricity consumption of 10 different (but correlated) households in a single neighborhood make up a multi-variate time series dataset.

### Computer vision

With the rise of business use cases such as autonomous vehicles, smart video surveillance, healthcare monitoring and various object counting tasks, fast and accurate object detection systems are rising in demand. These systems involve not only recognizing and classifying every object in an image, but localizing each one by drawing the appropriate bounding box around it. In the last decade, the rapid advances of deep learning techniques greatly accelerated the momentum of object detection.

### Churn prediction

Customer churn, or rate of attrition, is a costly problem faced by a wide range of companies. In an effort to reduce churn, companies can identify customers that are likely to leave their service in order to focus their efforts on customer retention. Use a JumpStart churn prediction solution to analyze data sources such as user behavior and customer support chat logs to identify customers that are at a high risk of cancelling a subscription or service.

</tbody>
</table>

**Reinforcement learning**

Reinforcement learning (RL) is a type of learning that is based on interaction with the environment. This type of learning is used by an agent that must learn behavior through trial-and-error interactions with a dynamic environment in which the goal is to maximize the long-term rewards that the agent receives as a result of its actions. Rewards are maximized by trading off exploring actions that have uncertain rewards with exploiting actions that have known rewards.

RL is well-suited for solving large, complex problems, such as supply chain management, HVAC systems, industrial robotics, game artificial intelligence, dialog systems, and autonomous vehicles.

### Launch a Solution

On the page for each solution, JumpStart shows a description of the solution and a Launch button. To launch a solution, select Launch. JumpStart then creates all of the resources needed to run the solution. This includes training and model hosting instances. After you choose a solution, the Launch Solution pane opens.

### Advanced parameters

The solution that you select may have advanced parameters that you can select. Choose Advanced Parameters to specify the AWS Identity and Access Management role for the solution.

Solutions are able to launch resources across 9 AWS services that interact with each other. For the solution to work as expected, newly created components from one service must be able to act on newly created components from another service. We recommend that you use the default IAM role to ensure that all needed permissions are added. For more information about IAM roles, see Identity and Access Management for Amazon SageMaker (p. 3500).

### Default IAM role

If you select this option, the default IAM roles that are required by this solution are used. Each solution requires different resources. The following list describes the default roles that are used for the solutions based on the service needed. For a description of the permissions required for each service, see AWS Managed Policies for SageMaker projects and JumpStart (p. 3593).

- **API Gateway** – AmazonSageMakerServiceCatalogProductsApiGatewayRole
- **CloudFormation** – AmazonSageMakerServiceCatalogProductsCloudformationRole
- **CodeBuild** – AmazonSageMakerServiceCatalogProductsCodeBuildRole
- **CodePipeline** – AmazonSageMakerServiceCatalogProductsCodePipelineRole
Models

JumpStart supports models across fifteen of the most popular problem types. Of the supported problem types, Vision and NLP-related types total thirteen. There are eight problem types that support
incremental training and fine-tuning. For more information about incremental training and hyperparameter tuning, see SageMaker Automatic Model Tuning. JumpStart also supports four popular algorithms for tabular data modeling.

You can search and browse models from the JumpStart landing page in Studio. When you select a model, the model detail page provides information about the model, and you can train and deploy your model in a few steps. The description section describes what you can do with the model, the expected types of inputs and outputs, and the data type needed for fine-tuning your model.

You can also programmatically utilize models with the SageMaker Python SDK.

The list of problem types and links to their example Jupyter notebooks are summarized in the following table. For a complete list of JumpStart models, see JumpStart Available Model Table.

## Deploy a Model

When you deploy a model from JumpStart, SageMaker hosts the model and deploys an endpoint that you can use for inference. JumpStart also provides an example notebook that you can use to access the model after it's deployed.

### Model deployment configuration

After you choose a model, the **Deploy Model** pane opens. Choose **Deployment Configuration** to configure your model deployment.
The default instance type for deploying a model depends on the model. The instance type is the hardware that the training job runs on. In the following example, the \texttt{ml.g4dn.xlarge} instance is the default for this particular BERT model.

You can also change the \textbf{Endpoint name}.
Choose **Security Settings** to specify the AWS Identity and Access Management (IAM) role, Amazon Virtual Private Cloud (Amazon VPC), and encryption keys for the model.
Deploy a pretrained model to an endpoint for inference. Deploying on SageMaker deploys the model on the specified compute instance and creates an internal API endpoint. Just like training, you will provide you an example notebook to access the model after it is deployed. Learn more.

Deployment Configuration

Security Settings

This model runs in network isolation. Learn more.

Specify the IAM role that Amazon SageMaker should use to deploy your model:

- Default IAM role
- Find IAM role
- Input IAM role

Amazon SageMaker will deploy your model using your Studio execution role.

Specify whether your model should connect to a virtual private cloud (VPC).

- No VPC
- Find VPC
- Input VPC

No VPC will be used to access your model container.

Specify the encryption keys to secure your data. Learn more.

- No encryption
- Find encryption keys
- Input encryption keys

Your data will not be fully encrypted. Learn more.
Model deployment security

When you deploy a model with JumpStart, you can specify an IAM role, Amazon VPC, and encryption keys for the model. If you don't specify any values for these entries: The default IAM role is your Studio runtime role; default encryption is used; no Amazon VPC is used.

IAM role

You can select an IAM role that is passed as part of training jobs and hosting jobs. SageMaker uses this role to access training data and model artifacts. If you don't select an IAM role, SageMaker deploys the model using your Studio runtime role. For more information about IAM roles, see Identity and Access Management for Amazon SageMaker (p. 3500).

The role that you pass must have access to the resources that the model needs, and must include all of the following.

- For training jobs: CreateTrainingJob API: Execution Role Permissions.
- For hosting jobs: CreateModel API: Execution Role Permissions.

Note

You can scope down the Amazon S3 permissions granted in each of the following roles. Do this by using the ARN of your Amazon Simple Storage Service (Amazon S3) bucket and the JumpStart Amazon S3 bucket.

```json
{  
    "Effect": "Allow",
    "Action": [
        "s3:GetObject",
        "s3:PutObject",
        "s3:ListMultipartUploadParts"
    ],
    "Resources": [
        "arn:aws:s3::<region>::bucket/jumpstart-cache-prod-<region>/**",
        "arn:aws:s3::<region>::bucket/*",
    ],
},
{  
    "Effect": "Allow",
    "Action": [
        "s3:ListBucket",
    ],
    "Resources": [
        "arn:aws:s3::<region>::bucket/jumpstart-cache-prod-<region>/",
        "arn:aws:s3::<region>::bucket/*",
    ]
}
```

Find IAM role

If you select this option, you must select an existing IAM role from the dropdown list.
Input IAM role

If you select this option, you must manually enter the ARN for an existing IAM role. If your Studio runtime role or Amazon VPC block the `iam: list*` call, you must use this option to use an existing IAM role.

Amazon VPC

All JumpStart models run in network isolation mode. After the model container is created, no more calls can be made. You can select an Amazon VPC that is passed as part of training jobs and hosting jobs. SageMaker uses this Amazon VPC to push and pull resources from your Amazon S3 bucket. This Amazon VPC is different from the Amazon VPC that limits access to the public internet from your Studio instance. For more information about the Studio Amazon VPC, see Connect SageMaker Studio Notebooks in a VPC to External Resources (p. 3631).

The Amazon VPC that you pass does not need access to the public internet, but it does need access to Amazon S3. The Amazon VPC endpoint for Amazon S3 must allow access to at least the following resources that the model needs.

```json
{
  "Effect": "Allow",
  "Action": [
    "s3:GetObject",
    "s3:PutObject",
  ]
}
```
If you do not select an Amazon VPC, no Amazon VPC is used.

Find VPC

If you select this option, you must select an existing Amazon VPC from the dropdown list. After you select an Amazon VPC, you must select a subnet and security group for your Amazon VPC. For more information about subnets and security groups, see Overview of VPCs and subnets.

Input VPC

If you select this option, you must manually select the subnet and security group that compose your Amazon VPC. If your Studio runtime role or Amazon VPC blocks the `ec2:list*` call, you must use this option to select the subnet and security group.
Encryption keys

You can select an AWS KMS key that is passed as part of training jobs and hosting jobs. SageMaker uses this key to encrypt the Amazon EBS volume for the container, and the repackaged model in Amazon S3 for hosting jobs and the output for training jobs. For more information about AWS KMS keys, see AWS KMS keys.

The key that you pass must trust the IAM role that you pass. If you do not specify an IAM role, the AWS KMS key must trust your Studio runtime role.

If you do not select an AWS KMS key, SageMaker provides default encryption for the data in the Amazon EBS volume and the Amazon S3 artifacts.

Find encryption keys

If you select this option, you must select existing AWS KMS keys from the dropdown list.
Input encryption keys

If you select this option, you must manually enter the AWS KMS keys. If your Studio execution role or Amazon VPC block the `kms:list*` call, you must use this option to select existing AWS KMS keys.
Fine-Tune a Model

Fine-tuning trains a pretrained model on a new dataset without training from scratch. This process, also known as transfer learning, can produce accurate models with smaller datasets and less training time.

Fine-Tuning data source

When you fine-tune a model, you can use the default dataset or choose your own data, which is located in an Amazon S3 bucket.

To browse the buckets available to you, choose **Find S3 bucket**. These buckets are limited by the permissions used to set up your Studio account. You can also specify an Amazon S3 URI by choosing **Enter Amazon S3 bucket location**.

**Tip**
To find out how to format the data in your bucket, choose **Learn more**. The description section for the model has detailed information about inputs and outputs.
For text models:

- The bucket must have a data.csv file.
- The first column must be a unique integer for the class label. For example: 1, 2, 3, 4, n
- The second column must be a string.
- The second column should have the corresponding text that matches the type and language for the model.

For vision models:

- The bucket must have as many subdirectories as the number of classes.
- Each subdirectory should contain images that belong to that class in .jpg format.

Note

The Amazon S3 bucket must be in the same AWS Region where you’re running SageMaker Studio because SageMaker doesn’t allow cross-Region requests.

Fine-Tuning deployment configuration

The p3 family is recommended as the fastest for deep learning training, and this is recommended for fine-tuning a model. The following chart shows the number of GPUs in each instance type. There are other available options that you can choose from, including p2 and g4 instance types.

<table>
<thead>
<tr>
<th>Instance type</th>
<th>GPUs</th>
</tr>
</thead>
<tbody>
<tr>
<td>p3.2xlarge</td>
<td>1</td>
</tr>
<tr>
<td>p3.8xlarge</td>
<td>4</td>
</tr>
<tr>
<td>p3.16xlarge</td>
<td>8</td>
</tr>
<tr>
<td>p3dn.24xlarge</td>
<td>8</td>
</tr>
</tbody>
</table>

Hyperparameters

You can customize the hyperparameters of the training job that are used to fine-tune the model.

If you use the default dataset for text models without changing the hyperparameters, you get a nearly identical model as a result. For vision models, the default dataset is different from the dataset used to train the pretrained models, so your model is different as a result.

You have the following hyperparameter options:

- **Epochs** – One epoch is one cycle through the entire dataset. Multiple intervals complete a batch, and multiple batches eventually complete an epoch. Multiple epochs are run until the accuracy of the model reaches an acceptable level, or when the error rate drops below an acceptable level.
- **Learning rate** – The amount that values should be changed between epochs. As the model is refined, its internal weights are being nudged and error rates are checked to see if the model improves. A typical learning rate is 0.1 or 0.01, where 0.01 is a much smaller adjustment and could cause the training to take a long time to converge, whereas 0.1 is much larger and can cause the training to overshoot. It is one of the primary hyperparameters that you might adjust for training your model. Note that for text models, a much smaller learning rate (5e-5 for BERT) can result in a more accurate model.
- **Batch size** – The number of records from the dataset that is to be selected for each interval to send to the GPUs for training.
In an image example, you might send out 32 images per GPU, so 32 would be your batch size. If you choose an instance type with more than one GPU, the batch is divided by the number of GPUs. Suggested batch size varies depending on the data and the model that you are using. For example, how you optimize for image data differs from how you handle language data.

In the instance type chart in the deployment configuration section, you can see the number of GPUs per instance type. Start with a standard recommended batch size (for example, 32 for a vision model). Then, multiply this by the number of GPUs in the instance type that you selected. For example, if you're using a p3.8xlarge, this would be 32(batch size) multiplied by 4 (GPUs), for a total of 128, as your batch size adjusts for the number of GPUs. For a text model like BERT, try starting with a batch size of 64, and then reduce as needed.

### Hyper-parameters

**Epochs**

3

**Learning Rate**

0.00002

**Batch Size**

8

[Reset to default]

**Training output**

When the fine-tuning process is complete, JumpStart provides information about the model: parent model, training job name, training job ARN, training time, and output path. The output path is where you can find your new model in an Amazon S3 bucket. The folder structure uses the model name that you provided and the model file is in an /output subfolder and it's always named model.tar.gz.

Example: s3://bucket/model-name/output/model.tar.gz
Amazon SageMaker JumpStart Industry: Financial

Use SageMaker JumpStart Industry: Financial solutions, models, and example notebooks to learn about SageMaker features and capabilities through curated one-step solutions and example notebooks of industry-focused machine learning (ML) problems. The notebooks also walk through how to use the SageMaker JumpStart Industry Python SDK to enhance industry text data and fine-tune pretrained models.

Topics
- Amazon SageMaker JumpStart Industry Python SDK (p. 69)

Amazon SageMaker JumpStart Industry Python SDK

SageMaker JumpStart provides processing tools for curating industry datasets and fine-tuning pretrained models through its client library called SageMaker JumpStart Industry Python SDK. For detailed API documentation of the SDK, and to learn more about processing and enhancing industry text datasets for improving the performance of state-of-the-art models on SageMaker JumpStart, see the SageMaker JumpStart Industry Python SDK open source documentation.

Amazon SageMaker JumpStart Industry: Financial Solution

SageMaker JumpStart Industry: Financial provides the following solution notebooks:

- **Corporate Credit Rating Prediction – Financial Services**

  This SageMaker JumpStart Industry: Financial solution provides a template for a text-enhanced corporate credit rating model. It shows how to take a model based on numeric features (in this case, Altman’s famous 5 financial ratios) combined with texts from SEC filings to achieve an improvement in the prediction of credit ratings. In addition to the 5 Altman ratios, you can add more variables as needed or set custom variables. This solution notebook shows how SageMaker JumpStart Industry Python SDK helps process NLP scoring of texts from SEC filings. Furthermore, the solution demonstrates how to train a model using the enhanced dataset to achieve a best-in-class model, deploy the model to a SageMaker endpoint for production, and receive improved predictions in real time.

- **Graph-Based Credit Scoring – Financial Services**

  Credit ratings are traditionally generated using models that use financial statement data and market data, which is tabular only (numeric and categorical). This solution constructs a network of firms using SEC filings and shows how to use the network of firm relationships with tabular data to generate accurate rating predictions. This solution demonstrates a methodology to use data on firm linkages to extend the traditionally tabular-based credit scoring models, which have been used by the ratings industry for decades, to the class of machine learning models on networks.

  **Note**
  The solution notebooks are for demonstration purposes only. They should not be relied on as financial or investment advice.
You can find these financial services solutions through the SageMaker JumpStart page in Studio.

**Note**
The SageMaker JumpStart Industry: Financial solutions, model cards, and example notebooks are hosted and runnable only through SageMaker Studio. Log in to the SageMaker console, and launch SageMaker Studio. For more information about how to find the solution card, see the previous topic at SageMaker JumpStart.

## Amazon SageMaker JumpStart Industry: Financial Models

SageMaker JumpStart Industry: Financial provides the following pretrained Robustly Optimized BERT approach (RoBERTa) models:

- RoBERTa-SEC-Base
- RoBERTa-SEC-WIKI-Base
- RoBERTa-SEC-Large
- RoBERTa-SEC-WIKI-Large

The RoBERTa-SEC-Base and RoBERTa-SEC-Large models are the text embedding models based on GluonNLP’s RoBERTa model and pre-trained on S&P 500 SEC 10-K/10-Q reports of the decade of the 2010’s (from 2010 to 2019). In addition to these, SageMaker JumpStart Industry: Financial provides two more RoBERTa variations, RoBERTa-SEC-WIKI-Base and RoBERTa-SEC-WIKI-Large, which are pretrained on the SEC filings and common texts of Wikipedia.

By deploying the model cards through SageMaker JumpStart, you’ll be able to access their corresponding notebooks. The paired notebooks will walk you through how the pretrained models can be fine-tuned for specific classification tasks on multimodal datasets, which are enhanced by the SageMaker JumpStart Industry Python SDK.

**Note**
The model notebooks are for demonstration purposes only. They should not be relied on as financial or investment advice.

The following screenshot shows the pretrained model cards provided through the SageMaker JumpStart page on Studio.
Note
The SageMaker JumpStart Industry: Financial solutions, model cards, and example notebooks are hosted and runnable only through SageMaker Studio. Log in to the SageMaker console, and launch SageMaker Studio. For more information about how to find the model cards, see the previous topic at SageMaker JumpStart.

Amazon SageMaker JumpStart Industry: Financial Example Notebooks

SageMaker JumpStart Industry: Financial provides the following hands-on examples of solving industry-focused ML problems:

- **SEC Filings Retrieval w/ Summarizer and Scoring** – This example introduces how to use the SageMaker JumpStart Industry Python SDK for processing the SEC filings, such as text summarization and scoring texts based on NLP score types and their corresponding word lists. To preview the content of this notebook, see Simple Construction of a Multimodal Dataset from SEC Filings and NLP Scores

- **ML on a TabText (Multimodal) Dataset** – This example shows how to merge different types of datasets into a single dataframe called TabText and perform multimodal ML. To preview the content of this notebook, see Machine Learning on a TabText Dataframe – An Example Based on the Paycheck Protection Program

- **Multi-category ML on SEC filings data** – This example shows how to train an AutoGluon NLP model over the multimodal (TabText) datasets curated from SEC filings for a multiclass classification task. Classify SEC 10K/Q Filings to Industry Codes Based on the MDNA Text Column
Note
The example notebooks are for demonstrative purposes only. They should not be relied on as financial or investment advice.

The following screenshot shows the example notebook cards provided through the SageMaker JumpStart page on Studio.

Note
The SageMaker JumpStart Industry: Financial solutions, model cards, and example notebooks are hosted and runnable only through SageMaker Studio. Log in to the SageMaker console, and launch SageMaker Studio. For more information about how to find the example notebooks, see the previous topic at SageMaker JumpStart.

To preview the content of the example notebooks, see Tutorials – Finance in the SageMaker JumpStart Industry Python SDK documentation.

Amazon SageMaker JumpStart Industry: Financial Blog Posts

Get Started with Amazon SageMaker Notebook Instances

One of the best ways for machine learning (ML) practitioners to use Amazon SageMaker is to train and deploy ML models using SageMaker notebook instances. The SageMaker notebook instances help create the environment by initiating Jupyter servers on Amazon Elastic Compute Cloud (Amazon EC2) and providing preconfigured kernels with the following packages: the Amazon SageMaker Python SDK, AWS SDK for Python (Boto3), AWS Command Line Interface (AWS CLI), Conda, Pandas, deep learning framework libraries, and other libraries for data science and machine learning.

Machine Learning with the SageMaker Python SDK

To train, validate, deploy, and evaluate an ML model in a SageMaker notebook instance, use the SageMaker Python SDK. The SageMaker Python SDK abstracts AWS SDK for Python (Boto3) and SageMaker API operations. It enables you to integrate with and orchestrate other AWS services, such as Amazon Simple Storage Service (Amazon S3) for saving data and model artifacts, Amazon Elastic Container Registry (ECR) for importing and servicing the ML models, Amazon Elastic Compute Cloud (Amazon EC2) for training and inference.

You can also take advantage of SageMaker features that help you deal with every stage of a complete ML cycle: data labeling, data preprocessing, model training, model deployment, evaluation on prediction performance, and monitoring the quality of model in production.

If you're a first-time SageMaker user, we recommend you to use the SageMaker Python SDK, following the end-to-end ML tutorial. To find the open source documentation, see the Amazon SageMaker Python SDK.

Tutorial Overview

This Get Started tutorial walks you through how to create a SageMaker notebook instance, open a Jupyter notebook with a preconfigured kernel with the Conda environment for machine learning, and
Step 1: Create an Amazon SageMaker Notebook Instance

An Amazon SageMaker notebook instance is a fully managed machine learning (ML) Amazon Elastic Compute Cloud (Amazon EC2) compute instance that runs the Jupyter Notebook App. You use the notebook instance to create and manage Jupyter notebooks for preprocessing data and to train and deploy machine learning models.

To create a SageMaker notebook instance

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Choose Notebook instances, and then choose Create notebook instance.
3. On the Create notebook instance page, provide the following information (if a field is not mentioned, leave the default values):
   a. For Notebook instance name, type a name for your notebook instance.
   b. For Notebook Instance type, choose ml.t2.medium. This is the least expensive instance type that notebook instances support, and it suffices for this exercise. If a ml.t2.medium instance type isn't available in your current AWS Region, choose ml.t3.medium.
   c. For Platform Identifier, choose a platform type to create the notebook instance on. This platform type dictates the Operating System and the JupyterLab version that your notebook instance is created with. For information about platform identifier type, see Amazon Linux 2 vs

Topics

- Step 1: Create an Amazon SageMaker Notebook Instance (p. 74)
- Step 2: Create a Jupyter Notebook (p. 76)
- Step 3: Download, Explore, and Transform a Dataset (p. 76)
- Step 4: Train a Model (p. 81)
- Step 5: Deploy the Model to Amazon EC2 (p. 85)
- Step 6: Evaluate the Model (p. 87)
- Step 7: Clean Up (p. 90)
d. For IAM role, choose Create a new role, and then choose Create role. This IAM role automatically gets permissions to access any S3 bucket that has sagemaker in the name. It gets these permissions through the AmazonSageMakerFullAccess policy, which SageMaker attaches to the role.

**Note**
If you want to grant the IAM role permission to access S3 buckets without sagemaker in the name, you need to attach the S3FullAccess policy or limit the permissions to specific S3 buckets to the IAM role. For more information and examples of adding bucket policies to the IAM role, see Bucket Policy Examples.

e. Choose Create notebook instance.

In a few minutes, SageMaker launches an ML compute instance—in this case, a notebook instance—and attaches a 5 GB of Amazon EBS storage volume to it. The notebook instance has a preconfigured Jupyter notebook server, SageMaker and AWS SDK libraries, and a set of Anaconda libraries.

For more information about creating a SageMaker notebook instance, see Create a Notebook Instance.

## (Optional) Change SageMaker Notebook Instance Settings

If you want to change the ML compute instance type or the size of the Amazon EBS storage of a SageMaker notebook instance that’s already created, you can edit the notebook instance settings.

**To change and update the SageMaker Notebook instance type and the EBS volume**

1. On the Notebook instances page in the SageMaker console, choose your notebook instance.
2. Choose Actions, choose Stop, and then wait until the notebook instance fully stops.
3. After the notebook instance status changes to Stopped, choose Actions, and then choose Update settings.
   a. For Notebook instance type, choose a different ML instance type.
   b. For Volume size in GB, type a different integer to specify a new EBS volume size.

**Note**
EBS storage volumes are encrypted, so SageMaker can’t determine the amount of available free space on the volume. Because of this, you can increase the volume size when you update a notebook instance, but you can’t decrease the volume size. If you want to decrease the size of the ML storage volume in use, create a new notebook instance with the desired size.

4. At the bottom of the page, choose Update notebook instance.
5. When the update is complete, Start the notebook instance with the new settings.

For more information about updating SageMaker notebook instance settings, see Update a Notebook Instance.

## (Optional) Advanced Settings for SageMaker Notebook Instances

The following tutorial video shows how to set up and use SageMaker notebook instances through the SageMaker console with advanced options, such as SageMaker lifecycle configuration and importing GitHub repositories. (Length: 26:04)
Step 2: Create a Jupyter Notebook

To start scripting for training and deploying your model, create a Jupyter notebook in the SageMaker notebook instance. Using the Jupyter notebook, you can conduct machine learning (ML) experiments for training and inference while accessing the SageMaker features and the AWS infrastructure.

To create a Jupyter notebook

1. Open the notebook instance as follows:
   b. On the Notebook instances page, open your notebook instance by choosing either Open JupyterLab for the JupyterLab interface or Open Jupyter for the classic Jupyter view.

   Note
   If the notebook instance status shows Pending in the Status column, your notebook instance is still being created. The status will change to InService when the notebook instance is ready for use.

2. Create a notebook as follows:
   • If you opened the notebook in the JupyterLab view, on the File menu, choose New, and then choose Notebook. For Select Kernel, choose conda_python3. This preinstalled environment includes the default Anaconda installation and Python 3.
   • If you opened the notebook in the classic Jupyter view, on the Files tab, choose New, and then choose conda_python3. This preinstalled environment includes the default Anaconda installation and Python 3.

3. Save the notebooks as follows:
   • In the JupyterLab view, choose File, choose Save Notebook As..., and then rename the notebook.
   • In the Jupyter classic view, choose File, choose Save as..., and then rename the notebook.

Step 3: Download, Explore, and Transform a Dataset

In this step, you load the Adult Census dataset to your notebook instance using the SHAP (SHapley Additive exPlanations) Library, review the dataset, transform it, and upload it to Amazon S3. SHAP is a game theoretic approach to explain the output of any machine learning model. For more information about SHAP, see Welcome to the SHAP documentation.

To run the following example, paste the sample code into a cell in your notebook instance.

Load Adult Census Dataset Using SHAP

Using the SHAP library, import the Adult Census dataset as shown following:

```python
import shap
X, y = shap.datasets.adult()
X_display, y_display = shap.datasets.adult(display=True)
feature_names = list(X.columns)
feature_names
```

Note
If the current Jupyter kernel does not have the SHAP library, install it by running the following conda command:
If you're using JupyterLab, you must manually refresh the kernel after the installation and updates have completed. Run the following IPython script to shut down the kernel (the kernel will restart automatically):

```python
import IPython
IPython.Application.instance().kernel.do_shutdown(True)
```

The `feature_names` list object should return the following list of features:

```
['Age',
 'Workclass',
 'Education-Num',
 'Marital Status',
 'Occupation',
 'Relationship',
 'Race',
 'Sex',
 'Capital Gain',
 'Capital Loss',
 'Hours per week',
 'Country']
```

**Tip**
If you're starting with unlabeled data, you can use Amazon SageMaker Ground Truth to create a data labeling workflow in minutes. To learn more, see [Label Data](Label Data).

## Overview the Dataset

Run the following script to display the statistical overview of the dataset and histograms of the numeric features.

```python
display(X.describe())
hist = X.hist(bins=30, sharey=True, figsize=(20, 10))
```
Tip
If you want to use a dataset that needs to be cleaned and transformed, you can simplify and streamline data preprocessing and feature engineering using Amazon SageMaker Data Wrangler. To learn more, see Prepare ML Data with Amazon SageMaker Data Wrangler.

Split the Dataset into Train, Validation, and Test Datasets

Using Sklearn, split the dataset into a training set and a test set. The training set is used to train the model, while the test set is used to evaluate the performance of the final trained model. The dataset is randomly sorted with the fixed random seed: 80 percent of the dataset for training set and 20 percent of it for a test set.

```python
from sklearn.model_selection import train_test_split
X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=0.2, random_state=1)
X_train_display = X_display.loc[X_train.index]
```

Split the training set to separate out a validation set. The validation set is used to evaluate the performance of the trained model while tuning the model's hyperparameters. 75 percent of the training set becomes the final training set, and the rest is the validation set.

```python
X_train, X_val, y_train, y_val = train_test_split(X_train, y_train, test_size=0.25, random_state=1)
X_train_display = X_display.loc[X_train.index]
X_val_display = X_display.loc[X_val.index]
```

Using the pandas package, explicitly align each dataset by concatenating the numeric features with the true labels.
import pandas as pd
train = pd.concat([pd.Series(y_train, index=X_train.index, name='Income>50K', dtype=int), X_train], axis=1)
validation = pd.concat([pd.Series(y_val, index=X_val.index, name='Income>50K', dtype=int), X_val], axis=1)
test = pd.concat([pd.Series(y_test, index=X_test.index, name='Income>50K', dtype=int), X_test], axis=1)

Check if the dataset is split and structured as expected:

Step 3: Download, Explore, and Transform Data

Convert the Train and Validation Datasets to CSV Files

Convert the train and validation dataframe objects to CSV files to match the input file format for the XGBoost algorithm.

```python
# Use 'csv' format to store the data
# The first column is expected to be the output column
train.to_csv('train.csv', index=False, header=False)
validation.to_csv('validation.csv', index=False, header=False)
```

Upload the Datasets to Amazon S3

Using the SageMaker and Boto3, upload the training and validation datasets to the default Amazon S3 bucket. The datasets in the S3 bucket will be used by a compute-optimized SageMaker instance on Amazon EC2 for training.

The following code sets up the default S3 bucket URI for your current SageMaker session, creates a new demo-sagemaker-xgboost-adult-income-prediction folder, and uploads the training and validation datasets to the data subfolder.

```python
import sagemaker, boto3, os
bucket = sagemaker.Session().default_bucket()
prefix = "demo-sagemaker-xgboost-adult-income-prediction"
boto3.Session().resource('s3').Bucket(bucket).Object(os.path.join(prefix, 'data/train.csv')).upload_file('train.csv')
boto3.Session().resource('s3').Bucket(bucket).Object(os.path.join(prefix, 'data/validation.csv')).upload_file('validation.csv')
```

Run the following AWS CLI to check if the CSV files are successfully uploaded to the S3 bucket.

```bash
! aws s3 ls {bucket}/{prefix}/data --recursive
```

This should return the following output:

```
2021-01-14 17:52:00    786285 demo-sagemaker-xgboost-adult-income-prediction/data/train.csv
2021-01-14 17:52:10    262122 demo-sagemaker-xgboost-adult-income-prediction/data/validation.csv
```
Step 4: Train a Model

The Amazon SageMaker Python SDK provides framework estimators and generic estimators to train your model while orchestrating the machine learning (ML) lifecycle accessing the SageMaker features for training and the AWS infrastructures, such as Amazon Elastic Container Registry (Amazon ECR), Amazon Elastic Compute Cloud (Amazon EC2), Amazon Simple Storage Service (Amazon S3). For more information about SageMaker built-in framework estimators, see Frameworks in the Amazon SageMaker Python SDK documentation. For more information about built-in algorithms, see Use Amazon SageMaker Built-in Algorithms or Pre-trained Models (p. 1096).

Topics
- Choose the Training Algorithm (p. 81)
- Create and Run a Training Job (p. 81)

Choose the Training Algorithm

To choose the right algorithm for your dataset, you typically need to evaluate different models to find the most suitable models to your data. For simplicity, the SageMaker XGBoost Algorithm built-in algorithm is used throughout this tutorial without the pre-evaluation of models.

Tip
If you want SageMaker to find an appropriate model for your tabular dataset, use Amazon SageMaker Autopilot that automates a machine learning solution. For more information, see Automate model development with Amazon SageMaker Autopilot (p. 318).

Create and Run a Training Job

After you figured out which model to use, start constructing a SageMaker estimator for training. This tutorial uses the XGBoost built-in algorithm for the SageMaker generic estimator.

To run a model training job

1. Import the Amazon SageMaker Python SDK and start by retrieving the basic information from your current SageMaker session.

   ```python
   import sagemaker
   region = sagemaker.Session().boto_region_name
   print("AWS Region: {0}".format(region))
   role = sagemaker.get_execution_role()
   print("RoleArn: {0}".format(role))
   ```

   This returns the following information:
   - region – The current AWS Region where the SageMaker notebook instance is running.
   - role – The IAM role used by the notebook instance.

   Note
   Check the SageMaker Python SDK version by running sagemaker.__version__. This tutorial is based on sagemaker>=2.20. If the SDK is outdated, install the latest version by running the following command:

   ```bash
   ! pip install -qU sagemaker
   ```
If you run this installation in your exiting SageMaker Studio or notebook instances, you need to manually refresh the kernel to finish applying the version update.

2. Create an XGBoost estimator using the `sagemaker.estimator.Estimator` class. In the following example code, the XGBoost estimator is named `xgb_model`.

```python
from sagemaker.debugger import Rule, rule_configs
from sagemaker.session import TrainingInput
s3_output_location='s3://{}/{}/{}'.format(bucket, prefix, 'xgboost_model')
container=sagemaker.image_uri.retrieve("xgboost", region, "1.2-1")
print(container)
xgb_model=sagemaker.estimator.Estimator(
    image_uri=container,
    role=role,
    instance_count=1,
    instance_type='ml.m4.xlarge',
    volume_size=5,
    output_path=s3_output_location,
    sagemaker_session=sagemaker.Session(),
    rules=[Rule.sagemaker(rule_configs.create_xgboost_report())]
)
```

To construct the SageMaker estimator, specify the following parameters:

- **image_uri** – Specify the training container image URI. In this example, the SageMaker XGBoost training container URI is specified using `sagemaker.image_uri.retrieve`.
- **role** – The AWS Identity and Access Management (IAM) role that SageMaker uses to perform tasks on your behalf (for example, reading training results, call model artifacts from Amazon S3, and writing training results to Amazon S3).
- **instance_count** and **instance_type** – The type and number of Amazon EC2 ML compute instances to use for model training. For this training exercise, you use a single `ml.m4.xlarge` instance, which has 4 CPUs, 16 GB of memory, an Amazon Elastic Block Store (Amazon EBS) storage, and a high network performance. For more information about EC2 compute instance types, see Amazon EC2 Instance Types. For more information about billing, see Amazon SageMaker pricing.
- **volume_size** – The size, in GB, of the EBS storage volume to attach to the training instance. This must be large enough to store training data if you use File mode (File mode is on by default).
- **output_path** – The path to the S3 bucket where SageMaker stores the model artifact and training results.
- **sagemaker_session** – The session object that manages interactions with SageMaker API operations and other AWS service that the training job uses.
- **rules** – Specify a list of SageMaker Debugger built-in rules. In this example, the `create_xgboost_report()` rule creates an XGBoost report that provides insights into the training progress and results. For more information, see SageMaker Debugger XGBoost Training Report (p. 2345).

**Tip**

If you want to run distributed training of large sized deep learning models, such as convolutional neural networks (CNN) and natural language processing (NLP) models, use SageMaker Distributed for data parallelism or model parallelism. For more information, see Amazon SageMaker Distributed Training Libraries (p. 2466).
3. Set the hyperparameters for the XGBoost algorithm by calling the `set_hyperparameters` method of the estimator. For a complete list of XGBoost hyperparameters, see XGBoost Hyperparameters (p. 2044).

```python
xgb_model.set_hyperparameters(
    max_depth = 5,
    eta = 0.2,
    gamma = 4,
    min_child_weight = 6,
    subsample = 0.7,
    objective = "binary:logistic",
    num_round = 1000
)
```

**Tip**
You can also tune the hyperparameters using the SageMaker hyperparameter optimization feature. For more information, see Perform Automatic Model Tuning with SageMaker (p. 2436).

4. Use the `TrainingInput` class to configure a data input flow for training. The following example code shows how to configure `TrainingInput` objects to use the training and validation datasets you uploaded to Amazon S3 in the Split the Dataset into Train, Validation, and Test Datasets (p. 78) section.

```python
from sagemaker.session import TrainingInput

train_input = TrainingInput(
    "s3://{}/{}".format(bucket, prefix, "data/train.csv"), content_type="csv"
)
validation_input = TrainingInput(
    "s3://{}/{}".format(bucket, prefix, "data/validation.csv"), content_type="csv"
)
```

5. To start model training, call the estimator's `fit` method with the training and validation datasets. By setting `wait=True`, the `fit` method displays progress logs and waits until training is complete.

```python
xgb_model.fit({"train": train_input, "validation": validation_input}, wait=True)
```

For more information about model training, see Train a Model with Amazon SageMaker (p. 9). This tutorial training job might take up to 10 minutes.

After the training job has done, you can download an XGBoost training report and a profiling report generated by SageMaker Debugger. The XGBoost training report offers you insights into the training progress and results, such as the loss function with respect to iteration, feature importance, confusion matrix, accuracy curves, and other statistical results of training. For example, you can find the following loss curve from the XGBoost training report which clearly indicates that there is an overfitting problem.
Run the following code to specify the S3 bucket URI where the Debugger training reports are generated and check if the reports exist.

```python
rule_output_path = xgb_model.output_path + "/" + xgb_model.latest_training_job.job_name + "/rule-output"
! aws s3 ls {rule_output_path} --recursive
```

Download the Debugger XGBoost training and profiling reports to the current workspace:

```bash
! aws s3 cp {rule_output_path} ./ --recursive
```

Run the following IPython script to get the file link of the XGBoost training report:

```python
from IPython.display import FileLink, FileLinks
display("Click link below to view the XGBoost Training report",
    FileLink("CreateXgboostReport/xgboost_report.html"))
```

The following IPython script returns the file link of the Debugger profiling report that shows summaries and details of the EC2 instance resource utilization, system bottleneck detection results, and python operation profiling results:

```python
profiler_report_name = [rule["RuleConfigurationName"]
    for rule in xgb_model.latest_training_job.rule_job_summary()
    if "Profiler" in rule["RuleConfigurationName"]][0]

display("Click link below to view the profiler report", FileLink(profiler_report_name + "/profiler-output/profiler-report.html"))
```
Tip
If the HTML reports do not render plots in the JupyterLab view, you must choose Trust HTML at the top of the reports.

To identify training issues, such as overfitting, vanishing gradients, and other problems that prevents your model from converging, use SageMaker Debugger and take automated actions while prototyping and training your ML models. For more information, see Debug and Profile Training Jobs Using Amazon SageMaker Debugger (p. 2258). To find a complete analysis of model parameters, see the Explainability with Amazon SageMaker Debugger example notebook.

You now have a trained XGBoost model. SageMaker stores the model artifact in your S3 bucket. To find the location of the model artifact, run the following code to print the model_data attribute of the xgb_model estimator:

```python
xgb_model.model_data
```

Tip
To measure biases that can occur during each stage of the ML lifecycle (data collection, model training and tuning, and monitoring of ML models deployed for prediction), use SageMaker Clarify. For more information, see Amazon SageMaker Clarify Model Explainability (p. 2652). For an end-to-end example of it, see the Fairness and Explainability with SageMaker Clarify example notebook.

Step 5: Deploy the Model to Amazon EC2

To get predictions, deploy your model to Amazon EC2 using Amazon SageMaker.

Topics
- Deploy the Model to SageMaker Hosting Services (p. 85)
- (Optional) Use SageMaker Predictor to Reuse the Hosted Endpoint (p. 86)
- (Optional) Make Prediction with Batch Transform (p. 86)

Deploy the Model to SageMaker Hosting Services

To host a model through Amazon EC2 using Amazon SageMaker, deploy the model that you trained in Create and Run a Training Job (p. 81) by calling the deploy method of the xgb_model estimator. When you call the deploy method, you must specify the number and type of EC2 ML instances that you want to use for hosting an endpoint.

```python
import sagemaker
from sagemaker.serializers import CSVSerializer
xgb_predictor=xgb_model.deploy(
    initial_instance_count=1,
    instance_type='ml.t2.medium',
    serializer=CSVSerializer()
)
```

- `initial_instance_count` (int) – The number of instances to deploy the model.
- `instance_type` (str) – The type of instances that you want to operate your deployed model.
- `serializer` (int) – Serialize input data of various formats (a NumPy array, list, file, or buffer) to a CSV-formatted string. We use this because the XGBoost algorithm accepts input files in CSV format.
The deploy method creates a deployable model, configures the SageMaker hosting services endpoint, and launches the endpoint to host the model. For more information, see the SageMaker generic Estimator's deploy class method in the Amazon SageMaker Python SDK. To retrieve the name of endpoint that's generated by the deploy method, run the following code:

```python
xgb_predictor.endpoint_name
```

This should return the endpoint name of the xgb_predictor. The format of the endpoint name is "sagemaker-xgboost-YYYY-MM-DD-HH-MM-SS-SSS". This endpoint stays active in the ML instance, and you can make instantaneous predictions at any time unless you shut it down later. Copy this endpoint name and save it to reuse and make real-time predictions elsewhere in SageMaker Studio or SageMaker notebook instances.

**Tip**

To learn more about compiling and optimizing your model for deployment to Amazon EC2 instances or edge devices, see Compile and Deploy Models with Neo.

**(Optional) Use SageMaker Predictor to Reuse the Hosted Endpoint**

After you deploy the model to an endpoint, you can set up a new SageMaker predictor by pairing the endpoint and continuously make real-time predictions in any other notebooks. The following example code shows how to use the SageMaker Predictor class to set up a new predictor object using the same endpoint. Re-use the endpoint name that you used for the xgb_predictor.

```python
import sagemaker
xgb_predictor_reuse = sagemaker.predictor.Predictor(
    endpoint_name="sagemaker-xgboost-YYYY-MM-DD-HH-MM-SS-SSS",
    sagemaker_session=sagemaker.Session(),
    serializer=sagemaker.serializers.CSVSerializer()
)
```

The xgb_predictor_reuse Predictor behaves exactly the same as the original xgb_predictor. For more information, see the SageMaker Predictor class in the Amazon SageMaker Python SDK.

**(Optional) Make Prediction with Batch Transform**

Instead of hosting an endpoint in production, you can run a one-time batch inference job to make predictions on a test dataset using the SageMaker batch transform. After your model training has completed, you can extend the estimator to a transformer object, which is based on the SageMaker Transformer class. The batch transformer reads in input data from a specified S3 bucket and makes predictions.

**To run a batch transform job**

1. Run the following code to convert the feature columns of the test dataset to a CSV file and uploads to the S3 bucket:

   ```python
   X_test.to_csv('test.csv', index=False, header=False)
boto3.Session().resource('s3').Bucket(bucket).Object(os.path.join(prefix, 'test/test.csv')).upload_file('test.csv')
   ```

2. Specify S3 bucket URIs of input and output for the batch transform job as shown following:

   ```python
   # The location of the test dataset
   batch_input = 's3://{}/{}test'.format(bucket, prefix)
   ```
Step 6: Evaluate the Model

Now that you have trained and deployed a model using Amazon SageMaker, evaluate the model to ensure that it generates accurate predictions on new data. For model evaluation, use the test dataset that you created in Step 3: Download, Explore, and Transform a Dataset (p. 76).

Evaluate the Model Deployed to SageMaker Hosting Services

To evaluate the model and use it in production, invoke the endpoint with the test dataset and check whether the inferences you get returns a target accuracy you want to achieve.

To evaluate the model

1. Set up the following function to predict each line of the test set. In the following example code, the `rows` argument is to specify the number of lines to predict at a time. You can change the value of it to perform a batch inference that fully utilizes the instance's hardware resource.

```python
import numpy as np
def predict(data, rows=1000):
    split_array = np.array_split(data, int(data.shape[0] / float(rows) + 1))
    predictions = ''
    for array in split_array:
        predictions = ','.join([predictions, xgb_predictor.predict(array).decode('utf-8')])
```

# The location to store the results of the batch transform job
batch_output = 's3://{}//{}//batch-prediction'.format(bucket, prefix)

3. Create a transformer object specifying the minimal number of parameters: the `instance_count` and `instance_type` parameters to run the batch transform job, and the `output_path` to save prediction data as shown following:

```python
transformer = xgb_model.transformer(
    instance_count=1,
    instance_type='ml.m4.xlarge',
    output_path=batch_output
)
```

4. Initiate the batch transform job by executing the `transform()` method of the transformer object as shown following:

```python
transformer.transform(
    data=batch_input,
    data_type='S3Prefix',
    content_type='text/csv',
    split_type='Line'
)
transformer.wait()
```

5. When the batch transform job is complete, SageMaker creates the `test.csv.out` prediction data saved in the `batch_output` path, which should be in the following format: `s3://sagemaker-<region>-111122223333/demo-sagemaker-xgboost-adult-income-prediction/batch-prediction`. Run the following AWS CLI to download the output data of the batch transform job:

```
! aws s3 cp {batch_output} ./ --recursive
```

This should create the `test.csv.out` file under the current working directory. You'll be able to see the float values that are predicted based on the logistic regression of the XGBoost training job.

Step 6: Evaluate the Model

Now that you have trained and deployed a model using Amazon SageMaker, evaluate the model to ensure that it generates accurate predictions on new data. For model evaluation, use the test dataset that you created in Step 3: Download, Explore, and Transform a Dataset (p. 76).

Evaluate the Model Deployed to SageMaker Hosting Services

To evaluate the model and use it in production, invoke the endpoint with the test dataset and check whether the inferences you get returns a target accuracy you want to achieve.

To evaluate the model

1. Set up the following function to predict each line of the test set. In the following example code, the `rows` argument is to specify the number of lines to predict at a time. You can change the value of it to perform a batch inference that fully utilizes the instance's hardware resource.

```python
import numpy as np
def predict(data, rows=1000):
    split_array = np.array_split(data, int(data.shape[0] / float(rows) + 1))
    predictions = ''
    for array in split_array:
        predictions = ','.join([predictions, xgb_predictor.predict(array).decode('utf-8')])
```
Step 6: Evaluate the Model

2. Run the following code to make predictions of the test dataset and plot a histogram. You need to take only the feature columns of the test dataset, excluding the 0th column for the actual values.

```python
import matplotlib.pyplot as plt
predictions = predict(test.to_numpy()[:, 1:])
plt.hist(predictions)
plt.show()
```

3. The predicted values are float type. To determine True or False based on the float values, you need to set a cutoff value. As shown in the following example code, use the Scikit-learn library to return the output confusion metrics and classification report with a cutoff of 0.5.

```python
import sklearn
cutoff = 0.5
print(sklearn.metrics.confusion_matrix(test.iloc[:, 0], np.where(predictions > cutoff, 1, 0)))
print(sklearn.metrics.classification_report(test.iloc[:, 0], np.where(predictions > cutoff, 1, 0)))
```

This should return the following confusion matrix:

```
[[4670 356]
 [ 480 1007]]
```

<table>
<thead>
<tr>
<th></th>
<th>precision</th>
<th>recall</th>
<th>f1-score</th>
<th>support</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0.91</td>
<td>0.93</td>
<td>0.92</td>
<td>5026</td>
</tr>
<tr>
<td>1</td>
<td>0.74</td>
<td>0.68</td>
<td>0.71</td>
<td>1487</td>
</tr>
</tbody>
</table>

4. To find the best cutoff with the given test set, compute the log loss function of the logistic regression. The log loss function is defined as the negative log-likelihood of a logistic model that returns prediction probabilities for its ground truth labels. The following example code numerically and iteratively calculates the log loss values \(-y \log(p) + (1-y) \log(1-p)\), where y is the true label and p is a probability estimate of the corresponding test sample. It returns a log loss versus cutoff graph.

```python
import matplotlib.pyplot as plt
```
cutoffs = np.arange(0.01, 1, 0.01)
log_loss = []
for c in cutoffs:
    log_loss.append(
        sklearn.metrics.log_loss(test.iloc[:, 0], np.where(predictions > c, 1, 0))
    )
plt.figure(figsize=(15,10))
plt.plot(cutoffs, log_loss)
plt.xlabel("Cutoff")
plt.ylabel("Log loss")
plt.show()

This should return the following log loss curve.

5. Find the minimum points of the error curve using the NumPy `argmin` and `min` functions:

```python
print(
    'Log loss is minimized at a cutoff of ', cutoffs[np.argmin(log_loss)],
    ', and the log loss value at the minimum is ', np.min(log_loss)
)
```

This should return: Log loss is minimized at a cutoff of 0.53, and the log loss value at the minimum is 4.348539186773897.

Instead of computing and minimizing the log loss function, you can estimate a cost function as an alternative. For example, if you want to train a model to perform a binary classification for a business problem such as a customer churn prediction problem, you can set weights to the elements of confusion matrix and calculate the cost function accordingly.

You have now trained, deployed, and evaluated your first model in SageMaker.

**Tip**
To monitor model quality, data quality, and bias drift, use Amazon SageMaker Model Monitor and SageMaker Clarify. To learn more, see Amazon SageMaker Model Monitor, Monitor Data Quality, Monitor Model Quality, Monitor Bias Drift, and Monitor Feature Attribution Drift.
Tip
To get human review of low confidence ML predictions or a random sample of predictions, use Amazon Augmented AI human review workflows. For more information, see Using Amazon Augmented AI for Human Review.

Step 7: Clean Up

To avoid incurring unnecessary charges, use the AWS Management Console to delete the endpoints and resources that you created while running the exercises.

Note
Training jobs and logs cannot be deleted and are retained indefinitely.

Note
If you plan to explore other exercises in this guide, you might want to keep some of these resources, such as your notebook instance, S3 bucket, and IAM role.

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/ and delete the following resources:
   • The endpoint. Deleting the endpoint also deletes the ML compute instance or instances that support it.
     1. Under Inference, choose Endpoints.
     2. Choose the endpoint that you created in the example, choose Actions, and then choose Delete.
   • The endpoint configuration.
     1. Under Inference, choose Endpoint configurations.
     2. Choose the endpoint configuration that you created in the example, choose Actions, and then choose Delete.
   • The model.
     1. Under Inference, choose Models.
     2. Choose the model that you created in the example, choose Actions, and then choose Delete.
   • The notebook instance. Before deleting the notebook instance, stop it.
     1. Under Notebook, choose Notebook instances.
     2. Choose the notebook instance that you created in the example, choose Actions, and then choose Stop. The notebook instance takes several minutes to stop. When the Status changes to Stopped, move on to the next step.
     3. Choose Actions, and then choose Delete.
2. Open the Amazon S3 console at https://console.aws.amazon.com/s3/, and then delete the bucket that you created for storing model artifacts and the training dataset.
3. Open the Amazon CloudWatch console at https://console.aws.amazon.com/cloudwatch/, and then delete all of the log groups that have names starting with /aws/sagemaker/.

Amazon SageMaker Studio Lab

Amazon SageMaker Studio Lab is a free service that gives customers access to AWS compute resources, in an environment based on open-source JupyterLab. It is based on the same architecture and user interface as Amazon SageMaker Studio, but with a subset of Studio capabilities.

With Studio Lab, you can use AWS compute resources to create and run your Jupyter notebooks without signing up for an AWS account. Because Studio Lab is based on open-source JupyterLab, you can take advantage of open-source Jupyter extensions to run your Jupyter notebooks.
Studio Lab compared to Amazon SageMaker Studio

While Studio Lab provides free access to AWS compute resources, Amazon SageMaker Studio provides the following advanced machine learning capabilities that Studio Lab does not support.

- Continuous integration and continuous delivery (SageMaker Pipelines)
- Real-time predictions
- Large-scale distributed training
- Data preparation (Amazon SageMaker Data Wrangler)
- Data labeling (Amazon SageMaker Ground Truth)
- Feature Store
- Bias analysis (Clarify)
- Model deployment
- Model monitoring

Studio also supports fine-grained access control and security by using AWS Identity and Access Management (IAM), Amazon Virtual Private Cloud (Amazon VPC), and AWS Key Management Service (AWS KMS). Studio Lab does not support these Studio features, nor does it support the use of estimators and built-in SageMaker algorithms.

To export your Studio Lab projects for use with Studio, see Export Amazon SageMaker Studio Lab environment to Amazon SageMaker Studio (p. 110).

The following topics give information about Studio Lab and how to use it

Topics
- Amazon SageMaker Studio Lab components overview (p. 91)
- Onboard to Amazon SageMaker Studio Lab (p. 94)
- Manage your account (p. 96)
- Launch your Amazon SageMaker Studio Lab project runtime (p. 97)
- Use Amazon SageMaker Studio Lab starter assets (p. 98)
- Use the Amazon SageMaker Studio Lab project runtime (p. 99)
- Troubleshooting (p. 113)

Amazon SageMaker Studio Lab components overview

Amazon SageMaker Studio Lab consists of the following components. The following topics give more details about these components.

Topics
- Landing page (p. 92)
- User account (p. 92)
- Project overview page (p. 92)
- Preview page (p. 93)
- Project (p. 93)
- Compute instance type (p. 93)
- Project runtime (p. 94)
- Session (p. 94)
Landing page

You can request an account and sign in to an existing account on your landing page. To navigate to the landing page, see the Amazon SageMaker Studio Lab website. For more information about creating a user account, see Onboard to Amazon SageMaker Studio Lab (p. 94).

The following screenshot shows the Studio Lab landing page interface for requesting a user account and signing in.

User account

Your user account gives you access to Studio Lab. For more information about creating a user account, see Onboard to Amazon SageMaker Studio Lab (p. 94).

Project overview page

You can launch a compute instance and view information about your project on this page. To navigate to this page, you must sign in from the Amazon SageMaker Studio Lab website. The URL takes the following format.

https://studiolab.sagemaker.aws/users/<YOUR_USER_NAME>

The following screenshot shows a project overview in the Studio Lab user interface.
Preview page

On this page, you can access a read-only preview of your Jupyter notebook and copy that notebook into your project. To navigate to this page, you must follow the steps in Use GitHub resources (p. 107).

Project

Your project contains all of your files and folders, including your Jupyter notebooks. You have full control over the files in your project. Your project also includes the JupyterLab-based user interface. From this interface, you can interact with your Jupyter notebooks, edit your source code files, integrate with GitHub, and connect to Amazon S3. For more information, see Use the Amazon SageMaker Studio Lab project runtime (p. 99).

The following screenshot shows a Studio Lab project with the file browser open and the Studio Lab Launcher displayed.

Compute instance type

Your Amazon SageMaker Studio Lab project runtime is based on an EC2 instance. You are allotted 15 GB of storage and 16 GB of RAM. Availability of compute instances is not guaranteed and is subject
to demand. If you require additional storage or compute resources, consider switching to Amazon SageMaker Studio.

Amazon SageMaker Studio Lab offers the choice of a CPU (Central Processing Unit) and a GPU (Graphical Processing Unit). The following sections give information about these two options, including selection guidance.

**CPU**

A central processing unit (CPU) is designed to handle a wide range of tasks efficiently, but is limited in how many tasks it can run concurrently. For machine learning, a CPU is recommended for compute intensive algorithms, such as time series, forecasting, and tabular data.

The CPU compute type has 12 hours of compute time.

**GPU**

A graphics processing unit (GPU) is designed to render high-resolution images and video concurrently. A GPU is recommended for deep learning tasks, especially for transformers and computer vision.

The GPU compute type has 4 hours of compute time.

**Compute time**

When compute time for Studio Lab reaches its time limit, the instance stops all running computations. Studio Lab does not support time limit increases.

Studio Lab automatically saves your environment when you update your environment and every time you create a new file. Custom-installed extensions and packages persist even after your runtime has ended.

File edits are periodically saved, but are not saved when your runtime ends. To ensure that you do not lose your progress, save your work manually. If you have content in your Studio Lab project that you don’t want to lose, we recommend that you back up your content elsewhere. For more information about exporting your environment and files, see Export Amazon SageMaker Studio Lab environment to Amazon SageMaker Studio (p. 110).

During long computation, you do not need to keep your project open. For example, you can start training a model, then close your browser. The instance keeps running for up to 12 hours on CPU instances and 4 hours on GPU instances. You can then sign in later to continue your work.

We recommend that you use checkpointing in your deep learning jobs. You can use saved checkpoints to restart a job from the previously saved checkpoint. For more information, see File I/O.

**Project runtime**

The project runtime is the period of time when your compute instance is running.

**Session**

A user session begins every time you launch your project.

**Onboard to Amazon SageMaker Studio Lab**

To onboard to Amazon SageMaker Studio Lab, follow the steps in this guide. In the following sections, you learn how to request a Studio Lab account, create your account, and sign in.
Topics
• Request a Studio Lab account (p. 95)
• Create a Studio Lab account (p. 95)
• Sign in to Studio Lab (p. 95)

Request a Studio Lab account

To use Studio Lab, you must first request approval to create a Studio Lab account. An AWS account cannot be used for onboarding to Studio Lab.

The following steps show how to request a Studio Lab account.

1. Navigate to the Studio Lab landing page.
2. Select Request account.
3. Enter the required information into the form.
4. Select Submit request.
5. If you receive an email to verify your email address, follow the instructions in the email to complete this step.

Your account request must be approved before you can register for a Studio Lab account. Your request will be reviewed within five business days. When your account request is approved, you receive an email with a link to the Studio Lab account registration page. This link expires seven days after your request is approved. If the link expires, you must submit a new account request.

Note: Your account request is denied if your email has been associated with activity that violates our Terms of Service or other agreements.

Referral codes

Studio Lab referral codes enable new account requests to be automatically approved to support machine learning events like workshops, hackathons, and classes. With a referral code, a trusted host can get their participants immediate access to Studio Lab. After an account has been created using a referral code, the account continues to exist after the expiration of the code.

To get a referral code, contact Sales Support. To use a referral code, enter the code as part of the account request form.

Create a Studio Lab account

After your request is approved, complete the following steps to create your Studio Lab account.

1. Select Create account in the account request approval email to open a new page.
2. From the new page, enter your Email, a Password, and a Username.
3. Select Create account.

Sign in to Studio Lab

After you register for your account, you can sign in to Studio Lab.

1. Navigate to the Studio Lab landing page.
2. Select **Sign in** to open a new page.
3. Enter your **Email** or **Username** and **Password**.
4. Select **Sign in** to open a new page to your project.

## Manage your account

The following topic gives information about managing your account, including changing your password, deleting your account, and getting information that we have collected. These topics require that you sign in to your Amazon SageMaker Studio Lab account. For more information, see [Sign in to Studio Lab](p. 95).

### Change your password

Follow these steps to change your Amazon SageMaker Studio Lab password.

1. Navigate to the Studio Lab project overview page. The URL takes the following format.

   ```
   https://studiolab.sagemaker.aws/users/<YOUR_USER_NAME>
   ```

2. From the top-right corner, select your user name to open a dropdown menu.
3. From the dropdown menu, select **Change password** to open a new page.
4. Enter your current password into the **Enter your current password** field.
5. Enter your new password into the **Create a new password** and **Confirm your new password** fields.
6. Select **Submit**.

### Delete your account

Follow these steps to delete your Studio Lab account.

1. Navigate to the Studio Lab project overview page. The URL takes the following format.

   ```
   https://studiolab.sagemaker.aws/users/<YOUR_USER_NAME>
   ```

2. From the top-right corner, select your user name to open a dropdown menu.
3. From the dropdown menu, select **Delete account** to open a new page.
4. Enter your password to confirm the deletion of your Studio Lab account.
5. Select **Delete**.

### Customer information

Studio Lab collects your email address, user name, encrypted password, project files, and metadata. When requesting an account, you can optionally choose to provide your first and last name, country, organization name, occupation, and the reason for your interest in this product. We protect all customer personal data with encryption. For more information about how your personal information is handled, see the [Privacy Notice](#).

When you delete your account, all of your information is deleted immediately. If you have an inquiry about this, submit the [Amazon SageMaker Studio Lab Form](#). For information and support related to AWS compliance, see [Compliance support](#).
Launch your Amazon SageMaker Studio Lab project runtime

The Amazon SageMaker Studio Lab project runtime lets you write and run code directly from your browser. It is based on JupyterLab and has an integrated terminal and console. For more information about JupyterLab, see the JupyterLab Documentation.

The following topic gives information about how to manage your project runtime. These topics require that you sign in to your Amazon SageMaker Studio Lab account. For more information about signing in, see Sign in to Studio Lab (p. 95). For more information about your project, see Amazon SageMaker Studio Lab components overview (p. 91).

Topics

• Start the project runtime (p. 97)
• Stop the project runtime (p. 97)
• View remaining compute time (p. 97)
• Change your compute type (p. 97)

Start the project runtime

To use Studio Lab, you must start your project runtime. This runtime gives you access to the JupyterLab environment.

1. Navigate to the Studio Lab project overview page. The URL takes the following format.

   https://studiolab.sagemaker.aws/users/<YOUR_USER_NAME>

2. Under My Project, select a compute type. For more information about compute types, see Compute instance type (p. 93).
3. Select Start runtime.
4. After the runtime is running, select Open project to open the project runtime environment in a new browser tab.

Stop the project runtime

When you stop your project runtime, your files are not automatically saved. To ensure that you don't lose your work, save all of your changes before stopping your project runtime.

• Under My Project, select Stop runtime.

View remaining compute time

Your project runtime has limited compute time based on the compute type that you select. For more information about compute time in Studio Lab, see Compute instance type (p. 93).

• Under My Project, view Time remaining.

Change your compute type

You can switch your compute type based on your workflow. For more information about compute types, see Compute instance type (p. 93).
Use Amazon SageMaker Studio Lab starter assets

Amazon SageMaker Studio Lab supports the following assets to help machine learning (ML) practitioners get started. This guide shows you how to clone notebooks for your project.

Getting started notebook

Studio Lab comes with a starter notebook that gives general information and guides you through key workflows. When you launch your project runtime for the first time, this notebook automatically opens.

Dive into Deep Learning

Dive into Deep Learning (D2L) is an interactive, open-source book that teaches the ideas, mathematical theory, and code that power machine learning. With over 150 Jupyter notebooks, D2L provides a comprehensive overview of deep learning principles. For more information about D2L, see the D2L website.

The following procedure shows how to clone the D2L Jupyter notebooks to your instance. Your project runtime must be running.

1. Navigate to the Studio Lab project overview page. The URL takes the following format.

   https://studiolab.sagemaker.aws/users/<YOUR_USER_NAME>

2. Under Learn and experiment, find Dive into Deep Learning.

3. From Dive into Deep Learning, select Open D2L notebooks to open a new page with a preview of the notebooks.

4. Select Copy to project.

AWS Machine Learning University

The AWS Machine Learning University (MLU) provides access to the machine learning courses used to train Amazon's own developers. With AWS MLU, any developer can learn how to use machine learning with the learn-at-your-own-pace MLU Accelerator learning series. The MLU Accelerator series is designed to help developers begin their ML journey. It offers three-day foundational courses on these three subjects: Natural Language Processing, Tabular Data, and Computer Vision. For more information, see Machine Learning University.

The following procedure shows how to clone the AWS MLU Jupyter notebooks to your instance. Your project runtime must be running.
1. **Navigate to the Studio Lab project overview page.** The URL takes the following format.

   https://studiolab.sagemaker.aws/users/<YOUR_USER_NAME>

2. **Under Learn and experiment, find AWS Machine Learning University.**

3. **From AWS Machine Learning University, select Open MLU notebooks** to open a new page with a preview of the notebooks.

4. **Select Copy to project.**

**Hugging Face**

Hugging Face models give you the tools to train, fine-tune, and run inference for Natural Language Processing (NLP). For more information, see https://huggingface.co/.

The following procedure shows how to clone the Hugging Face Jupyter notebooks to your instance. Your project runtime must be running.

1. **Navigate to the Studio Lab project overview page.** The URL takes the following format.

   https://studiolab.sagemaker.aws/users/<YOUR_USER_NAME>

2. **Under Resources and community, find Hugging Face.**

3. **From Hugging Face, select Open Hugging Face notebooks** to open a new page with a preview of the notebooks.

4. **Select Copy to project.**

**Use the Amazon SageMaker Studio Lab project runtime**

The following topics give information about using the Amazon SageMaker Studio Lab project runtime. Before you can use the Studio Lab project runtime, you must onboard to Studio Lab by following the steps in Onboard to Amazon SageMaker Studio Lab (p. 94).

**Topics**

- Amazon SageMaker Studio Lab UI overview (p. 99)
- Create or open an Amazon SageMaker Studio Lab notebook (p. 101)
- Use the Amazon SageMaker Studio Lab notebook toolbar (p. 102)
- Manage your environment (p. 104)
- Use external resources in Amazon SageMaker Studio Lab (p. 107)
- Get notebook differences (p. 109)
- Export Amazon SageMaker Studio Lab environment to Amazon SageMaker Studio (p. 110)
- Shut down resources (p. 112)

**Amazon SageMaker Studio Lab UI overview**

Amazon SageMaker Studio Lab extends the JupyterLab interface. Previous users of JupyterLab will notice similarities between the JupyterLab and Studio Lab UI, including the workspace. For an overview of the basic JupyterLab interface, see The JupyterLab Interface.
The following image shows Studio Lab with the file browser open and the Studio Lab Launcher displayed.

![Studio Lab](image)

You will find the *menu bar* at the top of the screen. The *left sidebar* contains icons to open file browsers, resource browsers, and tools. The *status bar* is located at the bottom-left corner of Studio Lab.

The main work area is divided horizontally into two panes. The left pane is the *file and resource browser*. The right pane contains one or more tabs for resources, such as notebooks and terminals.

**Topics**
- Left sidebar (p. 100)
- File and resource browser (p. 101)
- Main work area (p. 101)

**Left sidebar**

The left sidebar includes the following icons. When you hover over an icon, a tooltip displays the icon name. When you choose an icon, the file and resource browser displays the described functionality. For hierarchical entries, a selectable breadcrumb at the top of the browser shows your location in the hierarchy.

<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="Folder" /></td>
<td><strong>File browser</strong></td>
</tr>
</tbody>
</table>

Choose the **Upload Files** icon (↑) to add files to Studio Lab.

Double-click a file to open the file in a new tab.

To have adjacent files open, choose a tab that contains a notebook, Python, or text file, and then choose **New View for File**.

Choose the plus (+) sign on the menu at the top of the file browser to open the Studio Lab Launcher.
Use the Studio Lab project runtime

<table>
<thead>
<tr>
<th>Icon</th>

</tbody>
</table>

File and resource browser

The file and resource browser shows lists of your notebooks and files. On the menu at the top of the file browser, choose the plus (+) sign to open the Studio Lab Launcher. The Launcher allows you to create a notebook or open a terminal.

Main work area

The main work area has multiple tabs that contain your open notebooks and terminals.

Create or open an Amazon SageMaker Studio Lab notebook

When you create a notebook in Amazon SageMaker Studio Lab or open a notebook in Studio Lab, you must select a kernel for the notebook. The following topics describe how to create and open notebooks in Studio Lab.

For information about shutting down the notebook, see Shut down resources (p. 112).

Topics

- Open a Studio Lab notebook (p. 101)
- Create a notebook from the file menu (p. 102)
- Create a notebook from the Launcher (p. 102)

Open a Studio Lab notebook

Studio Lab can only open notebooks listed in the Studio Lab file browser. To clone a notebook into your file browser from an external repository, see Use external resources in Amazon SageMaker Studio Lab (p. 107).

To open a notebook

1. In the left sidebar, choose the **File Browser** icon ( 文件夹 ) to display the file browser.
2. Browse to a notebook file and double-click it to open the notebook in a new tab.
Create a notebook from the file menu

To create a notebook from the File menu

1. From the Studio Lab menu, choose **File**, choose **New**, and then choose **Notebook**.
2. To use the default kernel, in the **Select Kernel** dialog box, choose **Select**. Otherwise, to select a different kernel, use the dropdown menu.

Create a notebook from the Launcher

To create a notebook from the Launcher

1. Open the Launcher by using the keyboard shortcut **Ctrl + Shift + L**.

   Alternatively, you can open Launcher from the left sidebar: Choose the **File Browser** icon, and then choose the plus (+) icon.
2. To use the default kernel from the Launcher, under **Notebook**, choose **default:Python**. Otherwise, select a different kernel.

After you choose the kernel, your notebook launches and opens in a new Studio Lab tab.

To view the notebook's kernel session, in the left sidebar, choose the **Running Terminals and Kernels** icon ( ). You can stop the notebook's kernel session from this view.

Use the Amazon SageMaker Studio Lab notebook toolbar

Amazon SageMaker Studio Lab notebooks extend the JupyterLab interface. For an overview of the basic JupyterLab interface, see [The JupyterLab Interface](#).

The following image shows the toolbar and an empty cell from a Studio Lab notebook.

When you hover over a toolbar icon, a tooltip displays the icon function. You can find additional notebook commands in the Studio Lab main menu. The toolbar includes the following icons:

<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
</table>
| ![Save and checkpoint](#) | **Save and checkpoint**  
Saves the notebook and updates the checkpoint file. |
| ![Insert cell](#) | **Insert cell**  
Inserts a code cell below the current cell. The current cell is noted by the blue vertical marker in the left margin. |
| ![Cut, copy, and paste cells](#) | **Cut, copy, and paste cells**  
Cuts, copies, and pastes the selected cells. |
<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="Run cells" /></td>
<td><strong>Run cells</strong>&lt;br&gt;Runs the selected cells. The cell that follows the last-selected cell becomes the new-selected cell.</td>
</tr>
<tr>
<td><img src="image" alt="Interrupt kernel" /></td>
<td><strong>Interrupt kernel</strong>&lt;br&gt;Interrupts the kernel, which cancels the currently-running operation. The kernel remains active.</td>
</tr>
<tr>
<td><img src="image" alt="Restart kernel" /></td>
<td><strong>Restart kernel</strong>&lt;br&gt;Restarts the kernel. Variables are reset. Unsaved information is not affected.</td>
</tr>
<tr>
<td><img src="image" alt="Restart kernel and re-run notebook" /></td>
<td><strong>Restart kernel and re-run notebook</strong>&lt;br&gt;Restarts the kernel. Variables are reset. Unsaved information is not affected. Then re-runs the entire notebook.</td>
</tr>
<tr>
<td><img src="image" alt="Code" /></td>
<td><strong>Cell type</strong>&lt;br&gt;Displays or changes the current cell type. The cell types are:&lt;br&gt;• Code – Code that the kernel runs.&lt;br&gt;• Markdown – Text rendered as markdown.&lt;br&gt;• Raw – Content, including Markdown markup, that's displayed as text.</td>
</tr>
<tr>
<td><img src="image" alt="Checkpoint diff" /></td>
<td><strong>Checkpoint diff</strong>&lt;br&gt;Opens a new tab that displays the difference between the notebook and the checkpoint file. For more information, see <a href="#">Get notebook differences (p. 109)</a>.</td>
</tr>
<tr>
<td><img src="image" alt="Git diff" /></td>
<td><strong>Git diff</strong>&lt;br&gt;Only enabled if the notebook is opened from a Git repository. Opens a new tab that displays the difference between the notebook and the last Git commit. For more information, see <a href="#">Get notebook differences (p. 109)</a>.</td>
</tr>
<tr>
<td><img src="image" alt="default Kernel" /></td>
<td><strong>Kernel</strong>&lt;br&gt;Displays or changes the kernel that processes the cells in the notebook.&lt;br&gt;No Kernel indicates that the notebook was opened without specifying a kernel. You can edit the notebook, but you can't run any cells.</td>
</tr>
<tr>
<td><img src="image" alt="Kernel busy status" /></td>
<td><strong>Kernel busy status</strong>&lt;br&gt;Displays a kernel's busy status by showing the circle's edge and its interior as the same color. The kernel is busy when it is starting and when it is processing cells. Additional kernel states are displayed in the status bar at the bottom-left corner of Studio Lab.</td>
</tr>
</tbody>
</table>
Manage your environment

Your Amazon SageMaker Studio Lab environment comes with a base image installed that includes key packages and resources. You can customize your environment by adding new packages and libraries to it. You can also create new environments from Studio Lab, import compatible environments, and reset your environment to create space.

**Topics**
- Base image (p. 104)
- Managing conda environments (p. 105)

**Base image**

The default Amazon SageMaker Studio Lab base image includes the following packages.

- Python 3.9
- bzip2
- build-essential
- curl
- git
- libgl1-mesa-glx
- nano
- rsync
- unzip
- wget
- ca-certificates
- pip
- ipykernel-6.4

**Supported ML frameworks and libraries**

Machine learning frameworks simplify machine learning by abstracting complex algorithms and processes. This abstraction helps you get started with machine learning. Libraries are collections of files, programs, and other resources that you can use in your code. Studio Lab supports the following frameworks and libraries, which you must install manually.

- PyTorch 1.9
- TensorFlow 1.15 and 2.6
- MxNet 1.8
- Hugging Face
- AutoGluon 0.3.1
- Scikit-learn 0.24
- PyTorch ecosystem
- OpenCV
- scipy
- numpy

For a list of all of the packages currently installed in your environment, run the following command from your Jupyter notebook.
%pip list

Managing conda environments

The following sections give information about your default conda environment, how to customize it, and how to add new conda environments. For more information about conda environments, see Conda environments. For a list of sample environments that you can install into Studio Lab, see Creating Custom Conda Environments. To use these sample environment YAML files with Studio Lab, see Step 4 – Import your Studio Lab Conda environments in Studio (p. 112).

Your default environment

Studio Lab uses conda environments to encapsulate the software packages that are needed to run notebooks. Your project contains a default conda environment, named default, with the IPython kernel. This environment serves as the default kernel for your Jupyter notebooks.

Customize your environment

You can customize your environment by installing extensions and packages, as needed. You do not need to install your packages every time you work on your project. Any installed extensions and packages persist in your project.

Note

Installed packages count against your 15 GB of instance storage.

To install additional packages to your environment from a Jupyter notebook, insert one of the following commands in a cell at the top of your notebook. These commands install packages in the environment used by that notebook. Any packages that you install are saved in your persistent project directory.

- `%conda install <PACKAGE>`
- `%pip install <PACKAGE>`

We don’t recommend using the `!pip` or `!conda` commands because they can behave in unexpected ways when you have multiple environments. After you install new packages to your environment, restart the kernel to ensure that the packages work in your notebook.

Create and activate new conda environments

If you would like to maintain multiple environments for different use cases, you can create new conda environments in your project. The following sections show how to create and activate new conda environments. For a Jupyter notebook that shows how to create a custom environment, see Setting up a Custom Environment in SageMaker Studio Lab.

Note

Maintaining multiple environments in your project decreases your available memory.

Create

To create a new conda environment, run the following conda command from your terminal. This example creates a new environment with Python 3.9.

```bash
conda create --name <ENVIRONMENT_NAME> python=3.9
```

Activate

To activate any conda environment, run the following command in the terminal.

```bash
conda activate <ENVIRONMENT_NAME>
```
When you run this command, any packages installed using conda or pip are installed in the environment.

To use your new conda environments with notebooks, make sure the ipykernel package is installed in the environment.

```
conda install ipykernel
```

After you have created the environment, you can select it as the kernel for your notebook.

**Using Sample Studio Lab Environments**

Studio Lab provides sample custom environments through the SageMaker Studio Lab Sample Notebooks repository. The following shows how to clone and build these environments.

1. Navigate to your root directory and open the Getting Started notebook.
2. Click the **Clone SageMaker Studio Lab Examples** button to clone the SageMaker Studio Lab Sample Notebooks repository.
3. Navigate to the `studio-lab-examples/custom-environments` directory in File Browser.
4. Open the directory for the environment that you want to build.
5. Right click the `.yml` file in the folder, then select **Build Conda Environment**.
6. After your conda environment has finished building, use the following command to activate it. You can then use the environment.

```
conda activate ENVIRONMENT_NAME
```

**Installing JupyterLab and Jupyter Server extensions**

You can install open-source JupyterLab and Jupyter Server extensions in Studio Lab. These extensions are typically Python packages that are installed using conda or pip.

The following steps show how to install these extensions.

1. Open the terminal and activate the `studiolab` environment.
```
conda activate studiolab
```
2. Install the JupyterLab or Jupyter Server extension.
```
conda install <JUPYTER_EXTENSION>
```
3. Navigate to the Studio Lab project overview page.
4. Select **Stop runtime**.
5. Select **Start runtime**.

**Reset environment**

To remove all of your files and reset your project, run the following command from the terminal.

```
rm -rf */.*
```

The following command deletes a conda environment from your project.

```
conda remove --name <ENVIRONMENT_NAME> --all
```
Use external resources in Amazon SageMaker Studio Lab

With Amazon SageMaker Studio Lab, you can integrate external resources, such as Jupyter notebooks and data, from Git repositories and Amazon S3. You can also add an Open in Amazon SageMaker Studio Lab button to your GitHub repo and notebooks. This button lets you clone your notebooks directly from Studio Lab.

The following topics show how to integrate external resources.

Topics
- Use GitHub resources (p. 107)
- Add an Open in Amazon SageMaker Studio Lab button to your notebook (p. 108)
- Import files from your computer (p. 109)
- Connect to Amazon S3 (p. 109)

Use GitHub resources

Amazon SageMaker Studio Lab offers integration with GitHub. With this integration, you can clone notebooks and repositories directly to your Studio Lab project.

The following topics give information about how to use GitHub resources with Amazon SageMaker Studio Lab.

Amazon SageMaker Studio Lab sample notebooks

To get started with a repository of sample notebooks tailored for Studio Lab, see Amazon SageMaker Studio Lab Sample Notebooks.

This repository provides notebooks for the following use cases and others.

- Computer vision
- Connecting to AWS
- Creating custom environments
- Geospatial data analysis
- Natural language processing
- Using R

Clone a GitHub repo

To clone a GitHub repo to your Amazon SageMaker Studio Lab project, follow these steps.

1. Open the Studio Lab project runtime.
2. From the menu, select Git to open a new dropdown menu.
3. Select Clone Git Repository to open a new window.
4. In the new window, paste the repository's URL.
5. Select Clone.

Clone individual notebooks from GitHub

To open a notebook in Studio Lab, you must have access to the repo that the notebook is in. The following examples describe Studio Lab permission-related behavior in various situations.
If a repo is public, you can automatically clone the notebook into your project from the Studio Lab preview page.

If a repo is private, you are prompted to sign in to GitHub from the Studio Lab preview page. If you have access to a private repo, you can clone the notebook into your project.

If you don't have access to a private repo, you cannot clone the notebook from the Studio Lab preview page.

The following sections show two options for you to copy a GitHub notebook in your Studio Lab project. These options depend on whether the notebook has an **Open in Amazon SageMaker Studio Lab** button.

**Option 1: Copy notebook with an **Open in Amazon SageMaker Studio Lab** button**

The following procedure shows how to copy a notebook that has an **Open in Amazon SageMaker Studio Lab** button. If you want to add this button to your notebook, see **Add an **Open in Amazon SageMaker Studio Lab** button to your notebook** (p. 108).

1. Sign in to Studio Lab following the steps in **Sign in to Studio Lab** (p. 95).
2. In a new browser tab, navigate to the GitHub notebook that you want to clone.
3. In the notebook, select the **Open in Amazon SageMaker Studio Lab** button to open a new page in Studio Lab with a preview of the notebook.
4. If the project runtime is not already running, start it by choosing the **Start runtime** button at the top of the preview page. Wait for the runtime to start before proceeding to the next step.
5. After the project runtime has started, select **Copy to project** to open the project runtime in a new browser tab.
6. In the **Copy from GitHub?** dialog box, select **Copy notebook only**. This copies the notebook file to your project.

**Option 2: Clone any GitHub notebook**

The following procedure shows how to copy any notebook from GitHub.

1. Navigate to the notebook in GitHub.
2. In the browser's address bar, modify the notebook URL, as follows.

```
# Original URL
https://github.com/<PATH_TO_NOTEBOOK>

# Modified URL
https://studiolab.sagemaker.aws/import/github/<PATH_TO_NOTEBOOK>
```

3. Navigate to the modified URL. This opens a preview of the notebook in Studio Lab.
4. If the project runtime is not already running, start it by choosing the **Start runtime** button at the top of the preview page. Wait for the runtime to start before proceeding to the next step.
5. After the project runtime has started, select **Copy to project** to open the project runtime in a new browser tab.
6. In the **Copy from GitHub?** dialog box, select **Copy notebook only** to copy the notebook file to your project.

**Add an **Open in Amazon SageMaker Studio Lab** button to your notebook**

When you add the **Open in Amazon SageMaker Studio Lab** button to your notebooks, others can clone your notebooks or repositories directly to their Studio Lab projects. If you are sharing your notebook within a public GitHub repository, your content will be publicly readable. Do not share private content, such as AWS access keys or AWS Identity and Access Management credentials, in your notebook.
To add the functional **Open in Amazon SageMaker Studio Lab** button to your Jupyter notebook or repository, add the following markdown to the top of your notebook or repository.

```
[![Open In SageMaker Studio Lab](https://studiolab.sagemaker.aws/studiolab.svg)](https://studiolab.sagemaker.aws/import/github/<PATH_TO_YOUR_NOTEBOOK_ON_GITHUB>)
```

### Import files from your computer

The following steps show how to import files from your computer to your Studio Lab project.

1. Open the Studio Lab project runtime.
2. Open the **File Browser** panel.
3. In the actions bar of the **File Browser** panel, select the **Upload Files** button.
4. Select the files that you want to upload from your local machine.
5. Select **Open**.

Alternatively, you can drag and drop files from your computer into the **File Browser** panel.

### Connect to Amazon S3

The AWS CLI enables AWS integration in your Studio Lab project. With this integration, you can pull resources from Amazon S3 to use with your Jupyter notebooks.

To use AWS CLI with Studio Lab, complete the following steps. For a notebook that outlines this integration, see [Using Studio Lab with AWS Resources](#).

1. Install the AWS CLI following the steps in [Installing or updating the latest version of the AWS CLI](#).
2. Configure your AWS credentials by following the steps in [Quick setup](#). The role for your AWS account must have permissions to access the Amazon S3 bucket that you are copying data from.
3. From your Jupyter notebook, clone resources from the Amazon S3 bucket, as needed. The following command shows how to clone all resources from an Amazon S3 path to your project. For more information, see the [AWS CLI Command Reference](#).

```
!aws s3 cp s3://<BUCKET_NAME>/<PATH_TO_RESOURCES>/ <PROJECT_DESTINATION_PATH>/ --recursive
```

### Get notebook differences

You can display the difference between the current notebook and the last checkpoint, or the last Git commit, using the Amazon SageMaker Studio Lab project UI.

**Topics**

- Get the difference between the last checkpoint (p. 109)
- Get the difference between the last commit (p. 110)

### Get the difference between the last checkpoint

When you create a notebook, a hidden checkpoint file that matches the notebook is created. You can view changes between the notebook and the checkpoint file, or revert the notebook to match the checkpoint file.
To save the Studio Lab notebook and update the checkpoint file to match: Choose the **Save notebook and create checkpoint** icon (️). This is located on the Studio Lab menu's left side. The keyboard shortcut for **Save notebook and create checkpoint** is Ctrl + s.

To view changes between the Studio Lab notebook and the checkpoint file: Choose the **Checkpoint diff** icon (️), located in the center of the Studio Lab menu.

To revert the Studio Lab notebook to the checkpoint file: On the main Studio Lab menu, choose **File**, and then **Revert Notebook to Checkpoint**.

### Get the difference between the last commit

If a notebook is opened from a Git repository, you can view the difference between the notebook and the last Git commit.

To view the changes in the notebook from the last Git commit: Choose the **Git diff** icon (️) in the center of the notebook menu.

### Export Amazon SageMaker Studio Lab environment to Amazon SageMaker Studio

Amazon SageMaker Studio offers many features for machine learning and deep learning workflows that are unavailable in Amazon SageMaker Studio Lab. To take advantage of the features offered in Amazon SageMaker Studio, you must first onboard following the steps in **Onboard to Amazon SageMaker Domain** (p. 35).

After you’ve onboarded to Studio, you can migrate your Studio Lab environment and artifacts to Studio.

Studio Lab does not currently support sharing your project with others. However, you may download a copy of your project files to share using the following steps.

#### Topics

- **Step 1 – Export your Studio Lab Conda environment** (p. 110)
- **Step 2 – Export your Studio Lab artifacts to GitHub** (p. 111)
- **Step 3 – Import your Studio Lab artifacts from GitHub to Studio** (p. 111)
- **Step 4 – Import your Studio Lab Conda environments in Studio** (p. 112)

#### Step 1 – Export your Studio Lab Conda environment

When you add libraries to your environment following the steps in **Manage your environment** (p. 104), they become part of your Conda environments. The following procedure shows how to export the definitions of those environments so they can be rebuilt in Studio.

1. From the terminal, list the Conda environments in your Studio Lab.

   ```bash
   conda env list
   ```

   This command outputs a list of the Conda environments and their locations in the file system. When you onboard to Studio Lab, you use the **default-kernel** Conda environment by default.

   ```bash
   # conda environments: #
   default-kernel /home/studio-lab-user/.conda/envs/default-kernel
   ```
We recommend that you do not export the `studiolab` and `base` environments. These environments are not usable in Studio for the following reasons:

- `studiolab`: This sets up the JupyterLab environment for Studio Lab. Studio Lab runs a different major version of JupyterLab than Studio, so it is not usable in Studio.
- `base`: This environment comes with Conda by default. The `base` environment in Studio Lab and the `base` environment in Studio have incompatible versions of many packages.

2. For each Conda environment that you want to migrate to Studio, run the following command. This command exports the Conda environment definition to a YAML file in your Studio Lab home directory.

```
conda env export -n <ENVIRONMENT_NAME> ~/<ENVIRONMENT_NAME>.yml
```

Step 2 – Export your Studio Lab artifacts to GitHub

Next, you must clone your artifacts to a GitHub repository. The repository will be cloned in Studio in Step 3.

The following procedure shows how to synchronize your content with GitHub using the Studio Lab terminal.

1. From the Studio Lab terminal, navigate to your home directory.
2. Initialize the directory as a Git repository using the following command. For more information, see the `git-init` documentation.

```
git init
```

3. Move all of your artifacts, including the Conda environments’ YAML file definitions, to your home directory.
4. Add all relevant files and then commit your changes.

```
git add <FILE_NAME>
git commit -m "<COMMIT_MESSAGE>"
```

5. Push the commit to your remote repository. This repository has the format `https://github.com/<GITHUB_USERNAME>/<REPOSITORY_NAME>` where `<GITHUB_USERNAME>` is your GitHub username and the `<REPOSITORY_NAME>` is your remote repository.

```
git remote add origin git@github.com/<GITHUB_USERNAME>/<REPOSITORY_NAME>
git push -u origin <BRANCH_NAME>
```

Step 3 – Import your Studio Lab artifacts from GitHub to Studio

The following procedure shows how to import your artifacts to Studio from your GitHub repository.

1. Navigate to Studio.
2. From the Launcher, navigate to **Notebooks and compute resources**.
3. For **Select a SageMaker Image**, select **Data Science**. This image comes with Conda preinstalled.
4. Select **Image Terminal**.
5. From the image terminal, run the following command to clone your repository. This command creates a directory named after `<REPOSITORY_NAME>` in your Studio instance. After that, it clones your artifacts in that repository.

```bash
git clone https://github.com/<GITHUB_USERNAME>/<REPOSITORY_NAME>.git
```

**Step 4 – Import your Studio Lab Conda environments in Studio**

After you've cloned your GitHub repository to your Studio instance, you can use the YAML files to recreate your Conda environments in Studio.

For each Conda environment that you want to recreate, run the following commands.

```bash
conda env create --file /<PATH_TO_DIRECTORY>/<ENVIRONMENT_NAME>.yml
conda activate <ENVIRONMENT_NAME>
conda install ipykernel
python -m ipykernel install
```

After these commands are complete, you can select your environment as the kernel for your Studio notebook instances.

**Shut down resources**

In this guide, you will learn how to shut down individual resources, including notebooks, terminals, and kernels. You can also shut down all resources in one of these categories at the same time.

**Topics**

- Shut down an open notebook (p. 112)
- Shut down resources (p. 112)

**Shut down an open notebook**

You can shut down an open notebook from the Amazon SageMaker Studio Lab File menu or from the Running Terminals and Kernels pane.

**Note**

When you shut down a notebook, any unsaved information in the notebook is lost. The notebook is not deleted.

**To shut down an open notebook from the File menu**

1. Save the notebook contents by choosing the icon, located in the notebook menu.
2. Choose File then Close and Shutdown Notebook.
3. Choose OK.

**Shut down resources**

On the left sidebar of Studio Lab, you will find the Running Terminals and Kernels pane and icon. The Running Terminals and Kernels pane has three sections. Each section lists all of the resources...
of that type. You can shut down each resource individually, or shut down all resources in a section simultaneously.

When you shut down all resources in a section, the following occurs:

- **KERNELS** – All kernels, notebooks, and consoles are shut down.
- **TERMINALS** – All terminals are shut down.

**To shut down resources**

1. In the left sidebar, choose the Running Terminals and Kernels icon ( самым).
2. Do either of the following:
   - To shut down a specific resource: Choose the SHUT DOWN icon on the same row as the resource.
   - To shut down all resources in a section: Choose Shut Down All, which is located to the right of the section label. After a confirmation dialog box appears, choose Shut down all to proceed.

**Troubleshooting**

The guide shows common errors that might occur when using Amazon SageMaker Studio Lab. Each error contains a description, as well as a solution to the error.

**Note**

You cannot share your password with multiple users or use Studio Lab to mine cryptocurrency. We don’t recommend using Studio Lab for production tasks because of runtime limits.

**Can't access account**

If you can't access your account, verify that you are using the correct email and password. If you have forgotten your password, use the following steps to reset your password. If you still cannot access your account, you must request and register for a new account using the instructions in Onboard to Amazon SageMaker Studio Lab (p. 94).

**Forgot password**

If you forget your password, you must reset it using the following steps.

1. Navigate to the Studio Lab landing page.
2. Select Sign in.
3. Select Forgot password? to open a new page.
4. Enter the email address that you used to sign up for an account.
5. Select Send reset link to send an email with a password reset link.
6. From the password reset email, select Reset your password.
7. Enter your new password.
8. Select Submit.

**Can't launch project runtime**

If the Studio Lab project runtime does not launch, try launching it again. If this doesn't work, switch the instance type from CPU to GPU (or in reverse). For more information, see Change your compute type (p. 97).
Runtime stopped running unexpectedly

If there is an issue with the environment used to run JupyterLab, then Studio Lab will automatically recreate the environment. Studio Lab does not support manual activation of this process.

Conflicting versions

Because you can add packages and modify your environment as needed, you may run into conflicts between packages in your environment. If there are conflicts between packages in your environment, you must remove the conflicting package.

Environment build fails

When you build an environment from a YAML file, a package-version conflict or file issue might cause a build to fail. To resolve this, remove the environment by running the following command. Do this before attempting to build it again.

```bash
conda remove --name <YOUR_ENVIRONMENT> --all
```

Increasing disk space in your project

If you get a notification that your disk space is full while you're attempting to create or import a file, you can delete files to increase space. For instructions, see Reset environment (p. 106).

Cannot import cv2

If you run into an error when importing cv2 after installing opencv-python, you must uninstall opencv-python and install opencv-python-headless as follows.

```bash
%pip uninstall opencv-python --yes
%pip install opencv-python-headless
```

You can then import cv2 as expected.

Studio Lab becomes unresponsive when opening large files

The Studio Lab IDE may fail to render when large files are opened, resulting in blocked access to Studio Lab resources. To resolve this, reset the Studio Lab workspace using the following procedure.

1. After you open the IDE, copy the URL in your browser's address bar. This URL should be in the https://xxxxxx.studio.us-east-2.sagemaker.aws/studiolab/default/jupyter/lab format. Close the tab.
2. In a new tab, paste the URL and remove anything after https://xxxxxx.studio.us-east-2.sagemaker.aws/studiolab/default/jupyter/lab.
3. Add ?reset to the end of the URL, so it is in the https://xxxxxx.studio.us-east-2.sagemaker.aws/studiolab/default/jupyter/lab?reset format.
4. Navigate to the updated URL. This resets the saved UI state and makes the Studio Lab IDE responsive.
Amazon SageMaker Machine Learning Environments

Amazon SageMaker supports the following machine learning environments.

- **Amazon SageMaker Studio**: Lets you build, train, debug, deploy, and monitor your machine learning models.
- **RStudio on Amazon SageMaker**: RStudio is an IDE for R, with a console, syntax-highlighting editor that supports direct code execution, and tools for plotting, history, debugging and workspace management.
- **Amazon SageMaker Canvas**: Gives you the ability to use machine learning to generate predictions without needing to code.

To use these machine learning environments, you must create an Amazon SageMaker Domain.

**Topics**
- Amazon SageMaker Domain (p. 115)
- Amazon SageMaker Studio (p. 117)
- RStudio on Amazon SageMaker (p. 182)
- Amazon SageMaker Canvas (p. 213)

Amazon SageMaker Domain

Amazon SageMaker Domain supports the SageMaker machine learning environments. SageMaker Domain creates the following entities. For information on the onboarding steps to create a Domain, see Onboard to Amazon SageMaker Domain (p. 35).

- **Domain**: An Amazon SageMaker Domain consists of an associated Amazon Elastic File System (Amazon EFS) volume; a list of authorized users; and a variety of security, application, policy, and Amazon Virtual Private Cloud (Amazon VPC) configurations. An AWS account is limited to one Domain per Region. Users within a Domain can share notebook files and other artifacts with each other.
- **UserProfile**: A user profile represents a single user within a Domain, and is the main way to reference a user for the purposes of sharing, reporting, and other user-oriented features. This entity is created when a user onboards to the Amazon SageMaker Domain.
- **App**: An app represents an application that supports the reading and execution experience of the user’s notebooks, terminals, and consoles. The type of app can be JupyterServer, KernelGateway, RStudioServerPro, or RSession. A user may have multiple Apps active simultaneously.

The following tables describe the status values for the Domain, UserProfile, and App entities. Where applicable, they also give troubleshooting steps.

**Domain status values**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pending</td>
<td>Ongoing creation of Domain.</td>
</tr>
<tr>
<td>Value</td>

Amazon SageMaker Studio

Amazon SageMaker Studio is a web-based, integrated development environment (IDE) for machine learning that lets you build, train, debug, deploy, and monitor your machine learning models. SageMaker Studio provides all the tools you need to take your models from data preparation to experimentation to production while boosting your productivity. In a single unified visual interface, customers can perform the following tasks:

- Write and execute code in Jupyter notebooks
- Prepare data for machine learning
- Build and train machine learning models
- Deploy the models and monitor the performance of their predictions
- Track and debug the machine learning experiments

For information on the onboarding steps to sign in to SageMaker Studio, see Onboard to Amazon SageMaker Domain (p. 35).

For the AWS Regions supported by SageMaker Studio, see Supported Regions and Quotas (p. 32).

Topics

- Studio Features (p. 118)
- Amazon SageMaker Studio UI Overview (p. 118)
- JupyterLab Versioning (p. 120)
- Use the Amazon SageMaker Studio Launcher (p. 127)
- Use Amazon SageMaker Studio Notebooks (p. 129)
- Customize Amazon SageMaker Studio (p. 152)
- Perform Common Tasks in Amazon SageMaker Studio (p. 175)
- Amazon SageMaker Studio Pricing (p. 181)
- Troubleshooting Amazon SageMaker Studio (p. 181)
Studio Features

Studio includes the following features:

- SageMaker Autopilot
- SageMaker Clarify
- SageMaker Data Wrangler
- SageMaker Debugger
- SageMaker Experiments
- SageMaker Feature Store
- SageMaker JumpStart
- Amazon SageMaker Model Building Pipelines
- SageMaker Model Registry
- SageMaker Projects
- SageMaker Studio Notebooks
- SageMaker Studio Universal Notebook

Amazon SageMaker Studio UI Overview

Amazon SageMaker Studio extends the JupyterLab interface. Previous users of JupyterLab will notice the similarity of the user interface, including the workspace. Studio adds many additions to the interface. The most prominent additions are detailed in the following sections. For an overview of the basic JupyterLab interface, see The JupyterLab Interface.

The following image shows SageMaker Studio with the file browser open and the Studio Launcher displayed.

At the top of the screen is the menu bar. At the left of the screen is the left sidebar which contains icons to open file browsers, resource browsers, and tools. At the right of the screen is the right sidebar,
represented by the Settings icon (💰), which displays contextual property settings when open. At the bottom of the screen is the status bar.

Above the Settings icon, there's a button to provide feedback about your experiences with SageMaker Studio.

To the left of the Feedback button there's the notification icon. Choose the icon to view notifications from Studio such as new Studio versions and new SageMaker features. To update to a new version of Studio, see Shut Down and Update SageMaker Studio and Studio Apps (p. 179).

The main work area is divided horizontally into two panes. The left pane is the file and resource browser. The right pane contains one or more tabs for resources such as notebooks, terminals, metrics, and graphs.

Topics
- Left sidebar (p. 119)
- File and resource browser (p. 120)
- Main work area (p. 120)
- Settings (p. 120)

Left sidebar

The left sidebar includes the following icons. When you hover over an icon, a tooltip displays the icon name. When you choose an icon, the file and resource browser displays the described functionality. For hierarchical entries, a selectable breadcrumb at the top of the browser shows your location in the hierarchy.

<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
</table>
| ![Folder](file_browser.png) | **File Browser**
Choose the **Upload Files** icon (⇅) to add files to Studio.
Double-click a file to open the file in a new tab.
To have adjacent files open, choose a tab that contains a notebook, Python, or text file, then choose **New View for File**.
Choose the plus (+) sign on the menu at the top of the file browser to open the Studio Launcher. |
| ![Terminal](running_terminals_and_kernels.png) | **Running Terminals and Kernels**
For more information, see Shut Down Resources (p. 144). |
| ![Git](git.png) | **Git**
You can connect to a Git repository and then access a full range of Git tools and operations. For more information, see Clone a Git Repository in SageMaker Studio (p. 176). |
| ![Commands](commands.png) | **Commands (Ctrl + Shift + C)**
The majority of the menu commands are available here. |
### Icon | Description
--- | ---
Notebook Tools | You can access a notebook's metadata through the Advanced Tools section. This icon is displayed only when a notebook is open.
Open Tabs | Provides a list of open tabs, which is useful if you have multiple open tabs.
SageMaker Jumpstart | Provides a list of solutions, model endpoints, or training jobs created with SageMaker Jumpstart.
SageMaker Components and registries | Provides a list of projects, data wrangler flows, pipelines, experiments, trials, models, or endpoints, or access to the feature store.

### File and resource browser

The file and resource browser displays lists of your notebooks, experiments, trials, trial components, endpoints, and low-code solutions. On the menu at the top of the file browser, choose the plus (+) sign to open the Studio Launcher. The Launcher allows you to create a notebook, launch a Python interactive shell, open a terminal, or create a low-code solution.

### Main work area

The main work area consists of multiple tabs that contain your open notebooks and terminals, and detailed information about your experiments and endpoints, as well as low-code solutions. One commonly used tab is the Trial Component List. This list is referred to as the Leaderboard because it's where you can compare experiments and trials. For more information, see View and Compare Amazon SageMaker Experiments, Trials, and Trial Components (p. 2237).

### Settings

The settings pane allows you to adjust table and chart properties. By default, the pane is hidden on the far right of the screen. To open the pane, choose the Settings icon (⚙️) on the top right of the screen.

### JupyterLab Versioning

The Amazon SageMaker Studio interface is based on JupyterLab, which is a web-based interactive development environment for notebooks, code, and data. Studio now supports using both JupyterLab 1 and JupyterLab 3. The default version of JupyterLab in Studio is JupyterLab 3. If you created your domain and user profile before 08/31/2022, then your Studio instance defaults to JupyterLab 1. After 08/31/2022, JupyterLab version 1 on Amazon SageMaker Studio only receives security fixes. You can choose the version that you want to run. However, you can run only a single instance of JupyterLab at one time. You can't run multiple versions of JupyterLab simultaneously.

### Topics
- JupyterLab 3 (p. 121)
- Restricting default JupyterLab version using an IAM policy condition key (p. 121)
Setting a default JupyterLab version (p. 122)
View and update the JupyterLab version of an app from the console (p. 125)
Installing JupyterLab and Jupyter Server extensions (p. 126)

JupyterLab 3

JupyterLab 3 includes the following features that are not available in previous versions. For more information about these features, see JupyterLab 3.0 is released!

- Visual debugger when using the Base Python 2.0 and Data Science 2.0 kernels.
- File browser filter
- Table of Contents (TOC)
- Multi-language support
- Simple mode
- Single interface mode

Important changes to JupyterLab 3

Consider the following when using JupyterLab 3:

- When setting the JupyterLab version using the AWS CLI, select the corresponding image for your Region and JupyterLab version from the image list in From the AWS CLI (p. 122).
- In JupyterLab 3, you must activate the studio conda environment before installing extensions. For more information, see Installing JupyterLab and Jupyter Server extensions (p. 126).
- Debugger is only supported when using the following images:
  - Base Python 2.0
  - Data Science 2.0

Restricting default JupyterLab version using an IAM policy condition key

You can use IAM policy condition keys to restrict the version of JupyterLab that your users can launch.

The following policy shows how to limit the JupyterLab version at the domain level.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Block users from creating JupyterLab 3 apps at the domain level",
            "Effect": "Deny",
            "Action": [
                "sagemaker:CreateDomain",
                "sagemaker:UpdateDomain"
            ],
            "Resource": "*",
            "Condition": {
                "ForAllValues:StringLike": {
                    "sagemaker:ImageArns": "*image/jupyter-server-3"
                }
            }
        }
    ]
}
```
The following policy shows how to limit the JupyterLab version at the user profile level.

```json
{    "Version": "2012-10-17",    "Statement": [        {            "Sid": "Block users from creating JupyterLab 3 apps at the user profile level",            "Effect": "Deny",            "Action": [                "sagemaker:CreateUserProfile",                "sagemaker:UpdateUserProfile"            ],            "Resource": "*",            "Condition": {                "ForAllValues:StringLike": {                    "sagemaker:ImageArns": "*image/jupyter-server-3"                }            }        }    ]}
```

The following policy shows how to limit the JupyterLab version at the application level.

```json
{    "Version": "2012-10-17",    "Statement": [        {            "Sid": "Block users from creating JupyterLab 3 apps at the application level",            "Effect": "Deny",            "Action": "sagemaker:CreateApp",            "Resource": "*",            "Condition": {                "ForAllValues:StringLike": {                    "sagemaker:ImageArns": "*image/jupyter-server-3"                }            }        }    ]}
```

### Setting a default JupyterLab version

The following sections show how to set a default JupyterLab version for Studio using either the console or the AWS CLI.

#### From the console

You can select the default JupyterLab version to use on either the domain or user profile level during resource creation. To set the default JupyterLab version using the console, see [Onboard to Amazon SageMaker Domain](p. 35).

#### From the AWS CLI

You can select the default JupyterLab version to use on either the domain or user profile level using the AWS CLI.
To set the default JupyterLab version using the AWS CLI, you must include the ARN of the desired default JupyterLab version as part of an AWS CLI command. This ARN differs based on the version and the Region of the SageMaker domain.

The following table lists the ARNs of the available JupyterLab versions for each Region:

<table>
<thead>
<tr>
<th>Region</th>
<th>JL1</th>
<th>JL3</th>
</tr>
</thead>
</table>

The following shows how to create a domain with JupyterLab 3 as the default, using the AWS CLI:

```bash
aws --region <REGION> \
sagemaker create-domain \ 
  --domain-name <NEW_DOMAIN_NAME> \ 
  --auth-mode <AUTHENTICATION_MODE> \ 
  --subnet-ids <SUBNET-IDS> \ 
  --vpc-id <VPC-ID> \ 
  --default-user-settings '{
    "JupyterServerAppSettings": {
      "DefaultResourceSpec": {
        "InstanceType": "system"
      }
    }
  }'
```

The following shows how to update a domain to use JupyterLab 3 as the default, using the AWS CLI:

```bash
aws --region <REGION> \
sagemaker update-domain \ 
  --domain-id <YOUR_DOMAIN_ID> \ 
  --default-user-settings '{
    "JupyterServerAppSettings": {
      "DefaultResourceSpec": {
        "InstanceType": "system"
      }
    }
  }'
```
Create or update user profile

You can set a default JupyterServer version at the user profile level by invoking CreateUserProfile or UpdateUserProfile and passing the UserSettings.JupyterServerAppSettings.DefaultResourceSpec.SageMakerImageArn field.

The following shows how to create a user profile with JupyterLab 3 as the default on an existing domain, using the AWS CLI:

```bash
aws --region <REGION> \
  sagemaker create-user-profile \
  --domain-id <YOUR_DOMAIN_ID> \
  --user-profile-name <NEW_USERPROFILE_NAME> \
  --query UserProfileArn --output text \
  --user-settings '{
    "JupyterServerAppSettings": {
      "DefaultResourceSpec": {
        "InstanceType": "system"
      }
    }
  }'
```

The following shows how to update a user profile to use JupyterLab 3 as the default, using the AWS CLI:

```bash
aws --region <REGION> \
  sagemaker update-user-profile \
  --domain-id <YOUR_DOMAIN_ID> \
  --user-profile-name <EXISTING_USERPROFILE_NAME> \
  --user-settings '{
    "JupyterServerAppSettings": {
      "DefaultResourceSpec": {
        "InstanceType": "system"
      }
    }
  }'
```

View and update the JupyterLab version of an app from the console

The following shows how to view and update the JupyterLab version of an app.

1. Navigate to the SageMaker control panel.
2. Select a user to view their apps.
3. To view the JupyterLab version of an app, select the app's name.
4. To update the JupyterLab version, select Action.
5. From the dropdown menu, select Change JupyterLab version.
6. From the Studio settings page, select the JupyterLab version from the dropdown menu.
7. After the JupyterLab version for the user profile has been successfully updated, restart the JupyterServer app to make the version changes effective.

## Installing JupyterLab and Jupyter Server extensions

The process for installing JupyterLab and Jupyter Server extensions differs depending on the JupyterLab version of your Studio instance. In JupyterLab 1, you can open the terminal and install extensions without activating any conda environment. In JupyterLab 3, you must activate the studio conda environment before installing extensions. The method for this differs if you're installing the extensions from within Studio or using a lifecycle configuration script.

### Installing Extension from within Studio

To install extensions from within Studio, you must activate the studio environment before you install extensions.

```
# Before installing extensions
conda activate studio

# Install your extensions
pip install `<JUPYTER_EXTENSION>`

# After installing extensions
conda deactivate
```

### Installing Extensions using a lifecycle configuration script

If you're installing JupyterLab and Jupyter Server extensions in your lifecycle configuration script, you must modify your script so that it works with JupyterLab 3. The following sections show the code needed for existing and new lifecycle configuration scripts.

#### Existing lifecycle configuration script

If you're reusing an existing lifecycle configuration script that must work with both versions of JupyterLab, use the following code in your script:

```
# Before installing extension
export AWS_SAGEMAKER_JUPYTERSERVER_IMAGE="$(AWS_SAGEMAKER_JUPYTERSERVER_IMAGE:-'jupyter-server')"
if [ "AWS_SAGEMAKER_JUPYTERSERVER_IMAGE" = "jupyter-server-3" ]; then
  eval "$(conda shell.bash hook)"
  conda activate studio
fi;

# Install your extensions
pip install `<JUPYTER_EXTENSION>`

# After installing extension
if [ "AWS_SAGEMAKER_JUPYTERSERVER_IMAGE" = "jupyter-server-3" ]; then
  conda deactivate
fi;
```

#### New lifecycle configuration script

If you're writing a new lifecycle configuration script that only uses JupyterLab 3, you can use the following code in your script:
Use the Amazon SageMaker Studio Launcher

You can use the Amazon SageMaker Studio Launcher to create notebooks and text files, and launch terminals and interactive Python shells.

You can open Studio Launcher in any of the following ways:

- Choose **Amazon SageMaker Studio** at the top-left of Studio.
- Use the keyboard shortcut Ctrl + Shift + L.
- From the Studio menu, choose File and then choose New Launcher.
- If the Studio file browser is open, choose the plus (+) sign on the Studio file browser menu.

The Launcher opens in a new tab in Studio.

The Launcher consists of the following sections:

- **Get started** – Provides material to get started using SageMaker Studio, such as videos and tutorials, and one-click solutions for machine learning problems.
- **ML tasks and components** – Create machine learning tasks and components, such as new feature groups, data flows, and projects.
- **Notebooks and compute resources** – Create a notebook, open an image terminal, or open a Python console.
- **Utilities and files** – Show contextual help from a notebook, create files, or open a system terminal.

Topics

- ML Tasks and Components (p. 127)
- Notebooks and compute resources (p. 128)
- Utilities and files (p. 128)

ML Tasks and Components

The following items are available:

- **New Data Flow**
  
  Launches a new Data Wrangler flow that you can use to import, explore and prepare, and process data for machine learning.

- **New Compilation Job**

  Creates a new compilation job.

- **New Project**
Built-in and custom project templates to organize machine learning components and automate MLOps.

- **New Feature Group**
  Creates a new feature group in the feature store to logically group and manage features.

- **New Autopilot Experiment**
  Creates prediction model from your data in a few clicks.

### Notebooks and compute resources

To create or launch an item, choose the SageMaker image that you want the item to run in from the **SageMaker image** dropdown menu. You can also select the Lifecycle Configuration script that you want to run. For more information, see Use Lifecycle Configurations with Amazon SageMaker Studio (p. 167). Next, choose the item. When you choose an item from this section, you might incur additional usage charges. For more information, see Usage Metering (p. 146).

The following items are available:

- **Notebook**
  Launches the notebook in a kernel session on the chosen SageMaker image. For more information, see Change a Kernel (p. 143).
  Creates the notebook in the folder that you have currently selected in the file browser. To view the file browser, in the left sidebar of Studio, choose the **File Browser** icon ( ).

- **Console**
  Launches the shell in a kernel session on the chosen SageMaker image.
  Opens the shell in the folder that you have currently selected in the file browser.

- **Image terminal**
  Launches the terminal in a terminal session on the chosen SageMaker image.
  Opens the terminal in the root folder for the user (as shown by the Home folder in the file browser).

  **Note**
  CPU instances are launched on a `ml.t3.medium` instance, while GPU instances are launched on a `ml.g4dn.xlarge` instance.

### Utilities and files

Items in this section run in the context of SageMaker Studio and don't incur usage charges.

The following items are available:

- **Show Contextual Help**
  Opens a new tab that displays contextual help for functions in a Studio notebook. To display the help, choose a function in an active notebook. To make it easier to see the help in context, drag the help tab so that it's adjacent to the notebook tab. To open the help tab from within a notebook, press Ctrl + I.

  The following screenshot shows the contextual help for the `Experiment.create` method.
Use Amazon SageMaker Studio Notebooks

Amazon SageMaker Studio notebooks are collaborative notebooks that you can launch quickly because you don’t need to set up compute instances and file storage beforehand. A set of instance types, known as *Fast launch* types are designed to launch in under two minutes. SageMaker Studio notebooks provide persistent storage, which enables you to view and share notebooks even if the instances that the notebooks run on are shut down.

You can share your notebooks with others, so that they can easily reproduce your results and collaborate while building models and exploring your data. You provide access to a read-only copy of the notebook through a secure URL. Dependencies for your notebook are included in the notebook's metadata. When your colleagues copy the notebook, it opens in the same environment as the original notebook.

A SageMaker Studio notebook runs in an environment defined by the following:

- **EC2 instance type** – The hardware configuration the notebook runs on. The configuration includes the number and type of processors (vCPU and GPU), and the amount and type of memory. The instance type determines the pricing rate.
- **SageMaker image** – A container image that is compatible with SageMaker Studio. The image consists of the kernels, language packages, and other files required to run a notebook in Studio. There can be multiple images in an instance. For more information, see Bring your own SageMaker image (p. 152).
- **KernelGateway app** – A SageMaker image runs as a KernelGateway app. The app provides access to the kernels in the image. There is a one-to-one correspondence between a SageMaker image and a SageMaker app.
- **Kernel** – The process that inspects and runs the code contained in the notebook. A kernel is defined by a *kernel spec* in the image. There can be multiple kernels in an image.

You can change any of these resources from within the notebook.

The following diagram outlines how a notebook kernel runs in relation to the KernelGateway App, User, and SageMaker Studio Domain.

Sample SageMaker Studio notebooks are available in the *aws_sagemaker_studio* folder of the Amazon SageMaker example GitHub repository. Each notebook comes with the necessary SageMaker image that opens the notebook with the appropriate kernel.

We recommend that you familiarize yourself with the SageMaker Studio interface and the Studio notebook toolbar before creating or using a Studio notebook. For more information, see Amazon SageMaker Studio UI Overview (p. 118) and Use the SageMaker Studio Notebook Toolbar (p. 134).

**Topics**
- How Are Amazon SageMaker Studio Notebooks Different from Notebook Instances? (p. 131)
- Get Started (p. 131)
- Amazon SageMaker Studio Tour (p. 132)
- Create or Open an Amazon SageMaker Studio Notebook (p. 133)
- Use the SageMaker Studio Notebook Toolbar (p. 134)
- Install External Libraries and Kernels in Amazon SageMaker Studio (p. 136)
- Share and Use an Amazon SageMaker Studio Notebook (p. 138)
- Get Notebook and App Metadata (p. 139)
How Are Amazon SageMaker Studio Notebooks Different from Notebook Instances?

When you're starting a new notebook, we recommend that you create the notebook in Amazon SageMaker Studio instead of launching a notebook instance from the Amazon SageMaker console. There are many benefits to using a SageMaker Studio notebook, including the following:

- Starting a Studio notebook is faster than launching an instance-based notebook. Typically, it is 5-10 times faster than instance-based notebooks.
- Notebook sharing is an integrated feature in SageMaker Studio. Users can generate a shareable link that reproduces the notebook code and also the SageMaker image required to execute it, in just a few clicks.
- SageMaker Studio notebooks come pre-installed with the latest Amazon SageMaker Python SDK.
- SageMaker Studio notebooks are accessed from within Studio. This enables you to build, train, debug, track, and monitor your models without leaving Studio.
- Each member of a Studio team gets their own home directory to store their notebooks and other files. The directory is automatically mounted onto all instances and kernels as they're started, so their notebooks and other files are always available. The home directories are stored in Amazon Elastic File System (Amazon EFS) so that you can access them from other services.
- When using IAM Identity Center, you use your IAM Identity Center credentials through a unique URL to directly access SageMaker Studio. You don't have to interact with the AWS Management Console to run your notebooks.
- Studio notebooks are equipped with a set of predefined SageMaker image settings to get you started faster.

**Note**

Studio notebooks don’t support local mode. However, you can use a notebook instance to train a sample of your dataset locally, and then use the same code in a Studio notebook to train on the full dataset.

When you open a notebook in SageMaker Studio, the view is an extension of the JupyterLab interface. The primary features are the same, so you’ll find the typical features of a Jupyter notebook and JupyterLab. For more information about the Studio interface, see Amazon SageMaker Studio UI Overview (p. 118).

Get Started

To get started, you or your organization's administrator need to complete the Amazon SageMaker Studio onboarding process. For more information, see Onboard to Amazon SageMaker Domain (p. 35).

You can access an SageMaker Studio notebook in any of the following ways:

- You receive an email invitation to access Studio through your organization's IAM Identity Center, which includes a direct link to login to Studio without having to use the Amazon SageMaker console. You can proceed to the the section called “Next Steps” (p. 132).
- You receive a link to a shared Studio notebook, which includes a direct link to log in to Studio without having to use the SageMaker console. You can proceed to the the section called “Next Steps” (p. 132).
• You onboard to Studio and then log in to the SageMaker console. For more information, see Onboard to Amazon SageMaker Domain (p. 35).

Log In from the Amazon SageMaker console

To log in from the SageMaker console

1. Onboard to Amazon SageMaker Studio following the instructions on Onboard to Amazon SageMaker Domain (p. 35). If you've already onboarded, skip to the next step.
2. Open the SageMaker console.
3. Choose Control Panel.
4. The Control Panel opens.
5. In the Control Panel, you'll see a list of user names.

   Next to your user name, choose Open Studio.

Next Steps

Now that you're in Studio, you can try any of the following options:

• Create a SageMaker Studio notebook – Continue to the next section.
• Familiarize yourself with the SageMaker Studio interface – See Amazon SageMaker Studio UI Overview (p. 118).
• Explore Studio end-to-end tutorial notebooks – See Amazon SageMaker Studio Tour (p. 132).

Amazon SageMaker Studio Tour

For a walkthrough that takes you on a tour of the main features of Amazon SageMaker Studio, see the xgboost_customer_churn_studio.ipynb sample notebook from the aws/amazon-sagemaker-examples repository. The code in the notebook trains multiple models and sets up the SageMaker Debugger and SageMaker Model Monitor. The walkthrough shows you how to view the trials, compare the resulting models, show the debugger results, and deploy the best model using the SageMaker Studio UI. You don't need to understand the code to follow this walkthrough.

Prerequisites

To run the notebook for this tour, you need:

• An IAM account to sign in to Studio. For information, see Onboard to Amazon SageMaker Domain (p. 35).
• Basic familiarity with the Studio user interface and Jupyter notebooks. For information, see Amazon SageMaker Studio UI Overview (p. 118).
• A copy of the aws/amazon-sagemaker-examples repository in your Studio environment.

To clone the repository

1. Sign in to SageMaker Studio. For users in IAM Identity Center, sign in using the URL from your invitation email. For IAM users, follow these steps.
   a. Sign in to the SageMaker console.
   b. Choose Control Panel in the left navigation pane.
c. Choose **Launch app** in the row next to your user name.
d. Choose **Studio** from the dropdown menu.

2. On the top menu, choose **File** then **New** then **Terminal**.
3. At the command prompt, run the following command to clone the `aws/amazon-sagemaker-examples` repository.

```
git clone https://github.com/aws/amazon-sagemaker-examples.git
```

### To navigate to the sample notebook

1. From the **File Browser** on the left menu, select **amazon-sagemaker-examples**.
2. Navigate to the example notebook with the following path.
   ```
   ~/amazon-sagemaker-examples/aws_sagemaker_studio/getting_started/
xgboost_customer_churn_studio.ipynb
   ```

**Note**
If you encounter an error when you run the sample notebook, and some time has passed from when you cloned the repository, review the notebook on the remote repository for updates.

### Create or Open an Amazon SageMaker Studio Notebook

When you create a notebook in Amazon SageMaker Studio or open a non-shared notebook in Studio for the first time, you have to select a SageMaker image and kernel for the notebook. SageMaker launches the notebook on a default instance of a type based on the chosen SageMaker image. For CPU based images, the default instance type is `ml.t3.medium` (available as part of the **AWS Free Tier**). For GPU based images, the default instance type is `ml.g4dn.xlarge`.

If you create or open additional notebooks that use the same instance type, whether or not the notebooks use the same kernel, the notebooks run on the same instance of that instance type.

After a notebook is launched, you can change its instance type, and SageMaker image and kernel from within the notebook. For more information, see [Change an Instance Type](p. 142) and [Change a Kernel](p. 143).

You can have only one instance of each instance type. Each instance can have multiple SageMaker images running on it. Each SageMaker image can run multiple kernels or terminal instances.

Billing occurs per instance and starts when the first instance of a given instance type is launched. If you want to create or open a notebook without the risk of incurring charges, open the notebook from the **File** menu and choose **No Kernel** from the **Select Kernel** dialog. You can read and edit a notebook without a running kernel but you can't run cells.

Billing ends when the SageMaker image for the instance is shut down. For more information, see [Usage Metering](p. 146).

For information about shutting down the notebook, see [Shut Down Resources](p. 144).

### Topics

- [Open a Studio notebook](p. 134)
- [Create a Notebook from the File Menu](p. 134)
- [Create a Notebook from the Launcher](p. 134)
Open a Studio notebook

SageMaker Studio can only open notebooks listed in the Studio file browser. For instructions on uploading a notebook to the file browser, see Upload Files to SageMaker Studio (p. 175) or Clone a Git Repository in SageMaker Studio (p. 176).

To open a notebook

1. In the left sidebar, choose the File Browser icon ( ) to display the file browser.
2. Browse to a notebook file and double-click it to open the notebook in a new tab.

Create a Notebook from the File Menu

To create a notebook from the File menu

1. From the Studio menu, choose File, choose New, and then choose Notebook.
2. On the Select Kernel dialog, to use the default kernel, Python 3 (Data Science), choose Select. Otherwise, use the dropdown menu to select a different kernel.

For a list of the available kernels, see Available Amazon SageMaker Kernels (p. 151).

Create a Notebook from the Launcher

To create a notebook from the Launcher

1. To open the Launcher, use the keyboard shortcut Ctrl + Shift + L.
   Alternatively, from the File Browser, choose the plus (+) sign on the left of the menu.
2. On the Launcher, keep the default SageMaker image, Data Science, or use the dropdown menu to select a different image.

For a list of the available images, see Available Amazon SageMaker Images (p. 148).

After you choose the kernel or image, your notebook launches and opens in a new Studio tab. To view the notebook's kernel session, in the left sidebar, choose the Running Terminals, Kernels, and Images icon ( ). You can stop the notebook's kernel session from this view.

Use the SageMaker Studio Notebook Toolbar

Amazon SageMaker Studio notebooks extend the JupyterLab interface. For an overview of the basic JupyterLab interface, see The JupyterLab Interface.

The following image shows the toolbar and an empty cell from a SageMaker Studio notebook.

![SageMaker Studio Notebook Toolbar](image)

When you pause on a toolbar icon, a tooltip displays the icon function. Additional notebook commands are found in the Studio main menu. For a list of available notebook commands and shortcuts, in the left sidebar of Studio, choose the Commands icon ( ), and then scroll to the NOTEBOOK CELL OPERATIONS and NOTEBOOK OPERATIONS sections. The toolbar includes the following icons:
<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="Image" alt="Save and checkpoint icon" /></td>
<td><strong>Save and checkpoint</strong>&lt;br&gt;Saves the notebook and updates the checkpoint file. For more information, see [Get the Difference Between the Last Checkpoint](p. 141).</td>
</tr>
<tr>
<td><img src="Image" alt="Insert cell icon" /></td>
<td><strong>Insert cell</strong>&lt;br&gt;Inserts a code cell below the current cell. The current cell is noted by the blue vertical marker in the left margin.</td>
</tr>
<tr>
<td><img src="Image" alt="Cut, copy, and paste cells icon" /></td>
<td><strong>Cut, copy, and paste cells</strong>&lt;br&gt;Cuts, copies, and pastes the selected cells.</td>

### Amazon SageMaker Developer Guide

#### Use Studio Notebooks

<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
</table>
| ![Icon](image) | Displays or changes the instance type the notebook runs in. The format is as follows:  
*number of vCPUs + amount of memory + number of GPUs*  
Unknown indicates the notebook was opened without specifying a kernel. The notebook runs on the SageMaker Studio instance and doesn't accrue runtime charges. You can't assign the notebook to an instance type. You must specify a kernel and then Studio assigns the notebook to a default type.  
For more information, see [Create or Open an Amazon SageMaker Studio Notebook](p. 133) and [Change an Instance Type](p. 142). |
| ![Icon](image) | Kernel and SageMaker Image  
Displays or changes the kernel that processes the cells in the notebook. The format is as follows:  
*Kernel (SageMaker Image)*  
No Kernel indicates the notebook was opened without specifying a kernel. You can edit the notebook but you can't run any cells.  
For more information, see [Change a Kernel](p. 143). |
| ![Icon](image) | Kernel busy status  
Displays the busy status of the kernel. When the edge of the circle and its interior are the same color, the kernel is busy. The kernel is busy when it is starting and when it is processing cells. Additional kernel states are displayed in the status bar at the bottom-left corner of SageMaker Studio. |
| ![Icon](image) | Share notebook  
Shares the notebook. For more information, see [Share and Use an Amazon SageMaker Studio Notebook](p. 138). |

To select multiple cells, click in the left margin outside of a cell. Hold down the Shift key and use K or the Up key to select previous cells, or use J or the Down key to select following cells.

## Install External Libraries and Kernels in Amazon SageMaker Studio

Amazon SageMaker Studio notebooks come with multiple images already installed. These images contain kernels and Python packages including scikit, Pandas, NumPy, TensorFlow, and MXNet. You can also install your own images that contain your choice of packages and kernels. For more information on installing your own image, see [Bring your own SageMaker image](p. 152).

The different Jupyter kernels in Amazon SageMaker Studio notebooks are separate conda environments. For information about conda environments, see [Managing environments](p. 23).

### Package installation tools

The method that you use to install Python packages from the terminal differs depending on the image. Studio supports the following package installation tools:
• **Notebooks** – The following commands are supported. If one of the following does not work on your image, try the other one.
  • `%conda install`
  • `%pip install`

• **The Jupyter terminal** – You can install packages using pip and conda directly. You can also use `apt-get install` to install system packages from the terminal.

  **Note**
  We do not recommend using `pip install -u` or `pip install --user`, because those commands install packages on the user's Amazon EFS volume and can potentially block JupyterServer app restarts. Instead, use a lifecycle configuration to reinstall the required packages on app restarts as shown in Install packages using lifecycle configurations (p. 138).

We recommend using `%pip` and `%conda` to install packages from within a notebook because they correctly take into account the active environment or interpreter being used. For more information, see Add `%pip` and `%conda` magic functions. You can also use the system command syntax (lines starting with `!`) to install packages. For example, `!pip install` and `!conda install`.

**Conda**

Conda is an open source package management system and environment management system that can install packages and their dependencies. SageMaker supports using conda with either of these two main channels: the default channel or the conda-forge channel. For more information, see Conda channels. The conda-forge channel is a community channel where contributors can upload packages.

  **Note**
  Installing packages from conda-forge can take up to 10 minutes. Timing relates to how conda resolves the dependency graph.

All of the SageMaker provided environments are functional. User installed packages may not function correctly.

Conda has two methods for activating environments: `conda activate` and `source activate`. For more information, see Managing environment.

**Supported conda operations**

• `conda install` of a package in a single environment
• `conda install` of a package in all environments
• Installing a package from the main conda repository
• Installing a package from conda-forge
• Changing the conda install location to use Amazon EBS
• Supporting both `conda activate` and `source activate`

**Pip**

Pip is the tool for installing and managing Python packages. Pip searches for packages on the Python Package Index (PyPI) by default. Unlike conda, pip doesn't have built in environment support. Therefore, pip isn't as thorough as conda when it comes to packages with native or system library dependencies. Pip can be used to install packages in conda environments. You can use alternative package repositories with pip instead of the PyPI.

**Supported pip operations**

• Using pip to install a package without an active conda environment
• Using pip to install a package in a conda environment
• Using pip to install a package in all conda environments
• Changing the pip install location to use Amazon EBS
• Using an alternative repository to install packages with pip

Unsupported

SageMaker aims to support as many package installation operations as possible. However, if the packages were installed by SageMaker and you use the following operations on these packages, it might make your environment unstable:

• Uninstalling
• Downgrading
• Upgrading

Due to potential issues with network conditions or configurations, or the availability of conda or PyPi, packages may not install in a fixed or deterministic amount of time.

Note

Attempting to install a package in an environment with incompatible dependencies can result in a failure. If issues occur, you can contact the library maintainer about updating the package dependencies. When you modify the environment, such as removing or updating existing packages, this may result in instability of that environment.

Install packages using lifecycle configurations

Install custom images and kernels on the Studio instance's Amazon EBS volume so that they persist when you stop and restart the notebook, and that any external libraries you install are not updated by SageMaker. To do that, use a lifecycle configuration that includes both a script that runs when you create the notebook (on-create) and a script that runs each time you restart the notebook (on-start). For more information about using lifecycle configurations with Studio, see Use Lifecycle Configurations with Amazon SageMaker Studio (p. 167). For sample lifecycle configuration scripts, see SageMaker Studio Lifecycle Configuration Samples.

Share and Use an Amazon SageMaker Studio Notebook

You can share your Amazon SageMaker Studio notebooks with your colleagues. The shared notebook is a copy. After you share your notebook, any changes you make to your original notebook aren't reflected in the shared notebook and any changes your colleague's make in their shared copies of the notebook aren't reflected in your original notebook. If you want to share your latest version, you must create a new snapshot and then share it.

Topics

• Share a Notebook (p. 138)
• Use a Shared Notebook (p. 139)

Share a Notebook

The following screenshot shows the menu from a Studio notebook.
To share a notebook

1. In the upper-right corner of the notebook, choose Share.
2. (Optional) In Create shareable snapshot, choose any of the following items:
   • Include Git repo information – Includes a link to the Git repository that contains the notebook. This enables you and your colleague to collaborate and contribute to the same Git repository.
   • Include output – Includes all notebook output that has been saved.

   **Note**
   If you’re an user in IAM Identity Center and you don’t see these options, your IAM Identity Center administrator probably disabled the feature. Contact your administrator.

3. Choose Create.
4. After the snapshot is created, choose Copy link and then choose Close.
5. Share the link with your colleague.

After selecting your sharing options, you are provided with a URL. You can share this link with users that have access to Amazon SageMaker Studio. When the user opens the URL, they're prompted to log in using IAM Identity Center or IAM authentication. This shared notebook becomes a copy, so changes made by the recipient will not be reproduced in your original notebook.

**Use a Shared Notebook**

You use a shared notebook in the same way you would with a notebook that you created yourself. You must first login to your account, then open the shared link. If you don't have an active session, you receive an error.

When you click a link to a shared notebook for the first time, a read-only version of the notebook opens. To edit the shared notebook, choose Create a Copy. This copies the shared notebook to your personal storage.

The copied notebook launches on an instance of the instance type and SageMaker image that the notebook was using when the sender shared it. If you aren't currently running an instance of the instance type, a new instance is started. Customization to the SageMaker image isn't shared. You can also inspect the notebook snapshot by choosing Snapshot Details.

The following are some important considerations about sharing and authentication:

- If you have an active session, you see a read-only view of the notebook until you choose Create a Copy.
- If you don't have an active session, you need to log in.
- If you use IAM to login, after you login, select your user profile then choose Open SageMaker Studio. Then you need to choose the link you were sent.
- If you use IAM Identity Center to login, after you login the shared notebook is opened automatically in Studio.

**Get Notebook and App Metadata**

You can access notebook metadata and App metadata using the Amazon SageMaker UI.

**Topics**

- Get Notebook Metadata (p. 140)
- Get App Metadata (p. 140)
Get Notebook Metadata

Jupyter notebooks contain optional metadata that you can access through the Amazon SageMaker UI.

To view the notebook metadata

1. In the left sidebar, choose the Notebook Tools icon. The icon only displays when there's a notebook available in Studio.
2. Open the Advanced Tools section.

The metadata should look similar to the following.

```
{
  "instance_type": "ml.t3.medium",
  "kernelspec": {
    "display_name": "Python 3 (Data Science)",
    "language": "python",
    "name": "python3__SAGEMAKER_INTERNAL__arn:aws:sagemaker:us-west-2:<acct-id>:image/datascience-1.0"
  },
  "language_info": {
    "codemirror_mode": {
      "name": "ipython",
      "version": 3
    },
    "file_extension": ".py",
    "mimetype": "text/x-python",
    "name": "python",
    "nbconvert_exporter": "python",
    "pygments_lexer": "ipython3",
    "version": "3.7.6"
  }
}
```

Get App Metadata

When you create a notebook in Amazon SageMaker Studio, the App metadata is written to a file named `resource-metadata.json` in the folder `/opt/ml/metadata/`. You can get the App metadata by opening an Image terminal from within the notebook. The metadata gives you the following information, which includes the SageMaker image and instance type the notebook runs in:

- **AppType** – KernelGateway
- **DomainId** – Same as the StudioID
- **UserProfileName** – The profile name of the current user
- **ResourceArn** – The Amazon Resource Name (ARN) of the App, which includes the instance type
- **ResourceName** – The name of the SageMaker image

Additional metadata might be included for internal use by Studio and is subject to change.

To get the App metadata

1. In the center of the notebook menu, choose the Launch Terminal icon. This opens a terminal in the SageMaker image that the notebook runs in.
2. Run the following commands to display the contents of the `resource-metadata.json` file.
The file should look similar to the following.

```json
{
    "AppType": "KernelGateway",
    "DomainId": "d-xxxxxxxxxxxx",
    "UserProfileName": "profile-name",
    "ResourceName": "datascience--1-0-ml"
}
```

**Get Notebook Differences**

You can display the difference between the current notebook and the last checkpoint or the last Git commit using the Amazon SageMaker UI.

The following screenshot shows the menu from a Studio notebook.

**Topics**
- Get the Difference Between the Last Checkpoint (p. 141)
- Get the Difference Between the Last Commit (p. 141)

**Get the Difference Between the Last Checkpoint**

When you create a notebook, a hidden checkpoint file that matches the notebook is created. You can view changes between the notebook and the checkpoint file or revert the notebook to match the checkpoint file.

By default, a notebook is auto-saved every 120 seconds and also when you close the notebook. However, the checkpoint file isn't updated to match the notebook. To save the notebook and update the checkpoint file to match, you must choose the **Save notebook and create checkpoint** icon (rganization) on the left of the notebook menu or use the Ctrl + S keyboard shortcut.

To view the changes between the notebook and the checkpoint file, choose the **Checkpoint diff** icon (organisation) in the center of the notebook menu.

To revert the notebook to the checkpoint file, from the main Studio menu, choose **File** then **Revert Notebook to Checkpoint**.

**Get the Difference Between the Last Commit**

If a notebook is opened from a Git repository, you can view the difference between the notebook and the last Git commit.

To view the changes in the notebook from the last Git commit, choose the **Git diff** icon (organisation) in the center of the notebook menu.
Manage Resources

You can change the instance type, and SageMaker image and kernel from within an Amazon SageMaker Studio notebook. To create a custom kernel to use with your notebooks, see Bring your own SageMaker image (p. 152).

Topics
- Change an Instance Type (p. 142)
- Change a Kernel (p. 143)
- Shut Down Resources (p. 144)

Change an Instance Type

When you open a new Studio notebook for the first time, you are assigned a default Amazon Elastic Compute Cloud (Amazon EC2) instance type to run the notebook. When you open additional notebooks on the same instance type, the notebooks run on the same instance as the first notebook, even if the notebooks use different kernels.

You can change the instance type that your Studio notebook runs on from within the notebook.

The following information only applies to Studio notebooks. For information about how to change the instance type of a Amazon SageMaker notebook instance, see Update a Notebook Instance (p. 299).

Important
If you change the instance type, unsaved information and existing settings for the notebook are lost, and installed packages must be re-installed.

The previous instance type continues to run even if no kernel sessions or apps are active. You must explicitly stop the instance to stop accruing charges. To stop the instance, see Shut Down Resources (p. 144).

The following screenshot shows the menu from a Studio notebook. The processor and memory of the instance type powering the notebook are displayed as 2 vCPU + 4 GiB.

To change the instance type

1. Choose the instance type.
2. In Select instance, choose one of the fast launch instance types that are listed. Or to see all instance types, switch off Fast launch only. The list can be sorted by any column.
3. After choosing a type, choose **Save and continue**.

4. Wait for the new instance to become enabled, and then the new instance type information is displayed.

For a list of the available instance types, see Available SageMaker Studio Instance Types (p. 147).

**Change a Kernel**

With Amazon SageMaker Studio notebooks, you can change the notebook's kernel from within the notebook.

The following screenshot shows the menu from a Studio notebook. The current SageMaker kernel and image are displayed as **Python 3 (Data Science)**, where Python 3 denotes the kernel and Data Science denotes the SageMaker image that contains the kernel. The color of the circle to the right indicates the kernel is idle or busy. The kernel is busy when the center and the edge of the circle are the same color.
To change a notebook's kernel

1. Choose the kernel name.
2. From the drop-down list, choose a kernel.
3. After choosing a kernel, choose Select.
4. Wait for the kernel's status to show as idle, which indicates the kernel has started.

For a list of available SageMaker kernels, see Available Amazon SageMaker Kernels (p. 151).

Shut Down Resources

You can shut down individual resources, including notebooks, terminals, kernels, apps, and instances. You can also shut down all resources in one of these categories at the same time.

Note
Amazon SageMaker Studio does not support shutting down resources from within a notebook.

Topics

- Shut Down an Open Notebook (p. 144)
- Shut Down Resources (p. 144)

Shut Down an Open Notebook

You can shut down an open notebook from the Amazon SageMaker Studio File menu or from the Running Terminal and Kernels pane.

Note
When you shut down a notebook, any unsaved information in the notebook is lost. The notebook is not deleted.

To shut down an open notebook from the File menu

1. Optionally, save the notebook contents by choosing the Disk icon on the left of the notebook menu.
2. Choose File then Close and Shutdown Notebook.
3. Choose OK.

Shut Down Resources

You can reach the Running Terminals and Kernels pane on the left side of Amazon SageMaker Studio with the icon. The Running Terminals and Kernels pane consists of four sections. Each section lists all the resources of that type. You can shut down each resource individually or shut down all the resources in a section at the same time.
When you choose to shut down all resources in a section, the following occurs:

- **RUNNING INSTANCES/RUNNING APPS** – All instances, apps, notebooks, kernel sessions, consoles/shells, and image terminals are shut down. System terminals aren’t shut down.

  **Note**
  When you shutdown the Studio notebook instances, any additional resources, such as SageMaker endpoints, Amazon EMR clusters, and Amazon S3 buckets created from Studio are not deleted. Delete those resources to stop accrual of charges.

- **KERNEL SESSIONS** – All kernels, notebooks and consoles/shells are shut down.

- **TERMINAL SESSIONS** – All image terminals and system terminals are shut down.

**To shut down resources**

1. In the left sidebar, choose the **Running Terminals and Kernels** icon ( ).
2. Do either of the following:

   - To shut down a specific resource, choose the **SHUT DOWN** icon ( ) on the same row as the resource.

     For running instances, a confirmation dialog lists all the resources that will be shut down. For running apps, a confirmation dialog is displayed. Choose **Shut down all** to proceed.

     **Note**
     No confirmation dialog is displayed for kernel sessions or terminal sessions.

   - To shut down all resources in a section, choose the **X** to the right of the section label. A confirmation dialog is displayed. Choose **Shut down all** to proceed.
Usage Metering

There is no additional charge for using Amazon SageMaker Studio. The costs incurred for running Amazon SageMaker Studio notebooks, interactive shells, consoles, and terminals are based on Amazon Elastic Compute Cloud (Amazon EC2) instance usage.

When you run the following resources, you must choose a SageMaker image and kernel:

**From the Studio Launcher**

- Notebook
- Interactive Shell
- Image Terminal

**From the File menu**

- Notebook
- Console

When launched, the resource is run on an Amazon EC2 instance of an instance type based on the chosen SageMaker image and kernel. If an instance of that type was previously launched and is available, the resource is run on that instance.

For CPU based images, the default instance type is `ml.t3.medium`. For GPU based images, the default instance type is `ml.g4dn.xlarge`.

The costs incurred are based on the instance type. You are billed separately for each instance.

Metering starts when an instance is created. Metering ends when all the apps on the instance are shut down, or the instance is shut down. For information about how to shut down an instance, see Shut Down Resources (p. 144).

**Important**

You must shut down the instance to stop incurring charges. If you shut down the notebook running on the instance but don’t shut down the instance, you will still incur charges. When you shut down the Studio notebook instances, any additional resources, such as SageMaker endpoints, Amazon EMR clusters, and Amazon S3 buckets created from Studio are not deleted. Delete those resources to stop accrual of charges.

When you open multiple notebooks on the same instance type, the notebooks run on the same instance even if they’re using different kernels. You are billed only for the time that one instance is running.

You can change the instance type from within the notebook after you open it. For more information, see Change an Instance Type (p. 142).

For information about billing along with pricing examples, see Amazon SageMaker Pricing.

Available Resources

The following sections list the available resources for Amazon SageMaker Studio notebooks.

**Topics**

- Available SageMaker Studio Instance Types (p. 147)
- Available Amazon SageMaker Images (p. 148)
- Available Amazon SageMaker Kernels (p. 151)
Available SageMaker Studio Instance Types

The following Amazon Elastic Compute Cloud (Amazon EC2) instance types are available for use with SageMaker Studio notebooks.

For detailed information on which instance types fit your use case, and their performance capabilities, see Amazon Elastic Compute Cloud Instance types.

For information about available Amazon SageMaker Notebook Instance types, see CreateNotebookInstance.

Note
For most use cases, you should use a ml.t3.medium. This is the default instance type for CPU-based SageMaker images, and is available as part of the AWS Free Tier.

>> Fast launch instances types are optimized to start in under two minutes.

Default instance types

- CPU-based images: ml.t3.medium >> Fast launch
- GPU-based images: ml.g4dn.xlarge >> Fast launch

General purpose (no GPUs)

- ml.t3.medium >> Fast launch
- ml.t3.large
- ml.t3.xlarge
- ml.t3.2xlarge
- ml.m5.large >> Fast launch
- ml.m5.xlarge
- ml.m5.2xlarge
- ml.m5.4xlarge
- ml.m5.8xlarge
- ml.m5.12xlarge
- ml.m5.16xlarge
- ml.m5.24xlarge
- ml.m5d.large
- ml.m5d.xlarge
- ml.m5d.2xlarge
- ml.m5d.4xlarge
- ml.m5d.8xlarge
- ml.m5d.12xlarge
- ml.m5d.16xlarge
- ml.m5d.24xlarge

Compute optimized (no GPUs)

- ml.c5.large >> Fast launch
- ml.c5.xlarge
• ml.c5.2xlarge
• ml.c5.4xlarge
• ml.c5.9xlarge
• ml.c5.12xlarge
• ml.c5.18xlarge
• ml.c5.24xlarge

**Memory optimized (no GPUs)**

• ml.r5.large
• ml.r5.xlarge
• ml.r5.2xlarge
• ml.r5.4xlarge
• ml.r5.8xlarge
• ml.r5.12xlarge
• ml.r5.16xlarge
• ml.r5.24xlarge

**Accelerated computing (1+ GPUs)**

• ml.p3.2xlarge
• ml.p3.8xlarge
• ml.p3.16xlarge
• ml.p3dn.24xlarge
• ml.g4dn.xlarge >> *Fast launch*
• ml.g4dn.2xlarge
• ml.g4dn.4xlarge
• ml.g4dn.8xlarge
• ml.g4dn.12xlarge
• ml.g4dn.16xlarge
• ml.g5.xlarge
• ml.g5.2xlarge
• ml.g5.4xlarge
• ml.g5.8xlarge
• ml.g5.12xlarge
• ml.g5.24xlarge
• ml.g5.48xlarge

**Available Amazon SageMaker Images**

The following SageMaker images are available in Amazon SageMaker Studio. SageMaker images contain the latest Amazon SageMaker Python SDK and the latest version of the kernel. The name in brackets ([ ]) is the resource identifier of the SageMaker image as specified in the Amazon Resource Name (ARN) for the SageMaker image. For more information, see Deep Learning Containers Images.

• *Base Python [python-3.6]*
Use Studio Notebooks

Official Python 3.6 image from DockerHub with boto3 and AWS CLI included.

- **Base Python 2.0** [sagemaker-base-python-38]

Official Python 3.8 image from DockerHub with boto3 and AWS CLI included.

- **Data Science** [datascience-1.0]

  Data Science is a Python 3.7 conda image with the most commonly used Python packages and libraries, such as NumPy and SciKit Learn.

- **Data Science 2.0** [sagemaker-datascience-38]

  Data Science 2.0 is a Python 3.8 conda image with the most commonly used Python packages and libraries, such as NumPy and SciKit Learn.

- **SparkMagic** [sagemaker-sparkmagic]

  Anaconda Individual Edition with PySpark and Spark kernels. For more information, see sparkmagic.

- **MXNet 1.6 Python 3.6 (optimized for CPU)** [mxnet-1.6-cpu-py36]

  The AWS Deep Learning Containers for AWS MX powered by Apache MXNet 1.6 include containers for training on CPU, optimized for performance and scale on AWS. For more information, see AWS Deep Learning Containers for MXNet 1.6.0.

- **MXNet 1.6 Python 3.6 (optimized for GPU)** [mxnet-1.6-gpu-py36]

  The AWS Deep Learning Containers for AWS MX powered by Apache MXNet 1.6 with CUDA 10.1 include containers for training on GPU, optimized for performance and scale on AWS. For more information, see AWS Deep Learning Containers for MXNet 1.6.0.

- **MXNet 1.8 Python 3.7 (optimized for CPU)** [mxnet-1.8-cpu-py37-ubuntu16.04-v1]

  The AWS Deep Learning Containers for AWS MX powered by Apache MXNet 1.8 include containers for training on CPU, optimized for performance and scale on AWS. For more information, see AWS Deep Learning Containers for AWS MX 1.8.0.

- **MXNet 1.8 Python 3.7 (optimized for GPU)** [mxnet-1.8-gpu-py37-ubuntu16.04-v1]

  The AWS Deep Learning Containers for AWS MX powered by Apache MXNet 1.8 with CUDA 11.0 include containers for training on GPU, optimized for performance and scale on AWS. For more information, see AWS Deep Learning Containers for MX MX 1.8.0.

- **MXNet 1.9 Python 3.8 (optimized for CPU)** [mxnet-1.9-cpu-py38-ubuntu20.04-sagemaker-v1.0]

  The AWS Deep Learning Containers for AWS MX powered by Apache MXNet 1.9 include containers for training on CPU, optimized for performance and scale on AWS. For more information, see AWS Deep Learning Containers for MX 1.9.0 on SageMaker.

- **MXNet 1.9 Python 3.8 (optimized for GPU)** [mxnet-1.9-gpu-py38-cu112-ubuntu20.04-sagemaker-v1.0]

  The AWS Deep Learning Containers for AWS MX powered by Apache MXNet 1.9 with CUDA 11.2 include containers for training on GPU, optimized for performance and scale on AWS. For more information, see AWS Deep Learning Containers for MX 1.9.0 on SageMaker.

- **PyTorch 1.10 Python 3.8 (optimized for CPU)** [pytorch-1.10-cpu-py38]

  The AWS Deep Learning Containers for PyTorch 1.10 include containers for training on CPU, optimized for performance and scale on AWS. For more information, see AWS Deep Learning Containers for PyTorch 1.10.2 on SageMaker.

- **PyTorch 1.10 Python 3.8 (optimized for GPU)** [pytorch-1.10-gpu-py38]

  The AWS Deep Learning Containers for PyTorch 1.10 with CUDA 11.3 include containers for training on GPU, optimized for performance and scale on AWS. For more information, see AWS Deep Learning Containers for PyTorch 1.10.2 on SageMaker.
• **PyTorch 1.4 Python 3.6 (optimized for CPU) [pytorch-1.4-cpu-py36]**

The AWS Deep Learning Containers for PyTorch 1.4 include containers for training on CPU, optimized for performance and scale on AWS. For more information, see [AWS Deep Learning Containers v3.2 for PyTorch](https://aws.amazon.com/about-awls/deep-learning-containers/).  

• **PyTorch 1.4 Python 3.6 (optimized for GPU) [pytorch-1.4-gpu-py36]**

The AWS Deep Learning Containers for PyTorch 1.4 with CUDA 10.1 include containers for training on GPU, optimized for performance and scale on AWS. For more information, see [AWS Deep Learning Containers v3.2 for PyTorch](https://aws.amazon.com/about-awls/deep-learning-containers/).  

• **PyTorch 1.6 Python 3.6 (optimized for CPU) [pytorch-1.6-cpu-py36-ubuntu16.04-v1]**

The AWS Deep Learning Containers for PyTorch 1.6 include containers for training on CPU, optimized for performance and scale on AWS. For more information, see [AWS Deep Learning Containers for PyTorch 1.6](https://aws.amazon.com/about-awls/deep-learning-containers/).  

• **PyTorch 1.6 Python 3.6 (optimized for GPU) [pytorch-1.6-gpu-py36-cu110-ubuntu18.04-v3]**

The AWS Deep Learning Containers for PyTorch 1.6 with CUDA 11.0 include containers for training on GPU, optimized for performance and scale on AWS. For more information, see [AWS Deep Learning Containers for PyTorch 1.6.0 with CUDA 11.0](https://aws.amazon.com/about-awls/deep-learning-containers/).  

• **PyTorch 1.8 Python 3.6 (optimized for CPU) [1.8.1-cpu-py36]**

The AWS Deep Learning Containers for PyTorch 1.8 include containers for training on CPU, optimized for performance and scale on AWS. For more information, see [AWS Deep Learning Containers for PyTorch 1.8.0](https://aws.amazon.com/about-awls/deep-learning-containers/).  

• **PyTorch 1.8 Python 3.6 (optimized for GPU) [pytorch-1.8-gpu-py36]**

The AWS Deep Learning Containers for PyTorch 1.8 with CUDA 11.1 include containers for training on GPU, optimized for performance and scale on AWS. For more information, see [AWS Deep Learning Containers for PyTorch 1.8.0](https://aws.amazon.com/about-awls/deep-learning-containers/).  

• **TensorFlow 1.15 Python 3.6 (optimized for CPU) [tensorflow-1.15-cpu-py36]**

The AWS Deep Learning Containers for TensorFlow 1.15 include containers for training on CPU, optimized for performance and scale on AWS. For more information, see [AWS Deep Learning Containers with TensorFlow 1.15.3](https://aws.amazon.com/about-awls/deep-learning-containers/).  

• **TensorFlow 1.15 Python 3.6 (optimized for GPU) [tensorflow-1.15-gpu-py36]**

The AWS Deep Learning Containers for TensorFlow 1.15 with CUDA 10.0 include containers for training on GPU, optimized for performance and scale on AWS. For more information, see [AWS Deep Learning Containers with TensorFlow 1.15.3](https://aws.amazon.com/about-awls/deep-learning-containers/).  

• **TensorFlow 1.15 Python 3.7 (optimized for CPU) [tensorflow-1.15-cpu-py37-ubuntu18.04-v7]**

The AWS Deep Learning Containers for TensorFlow 1.15 include containers for training on CPU, optimized for performance and scale on AWS. For more information, see [AWS Deep Learning Containers v7.0 for TensorFlow](https://aws.amazon.com/about-awls/deep-learning-containers/).  

• **TensorFlow 1.15 Python 3.7 (optimized for GPU) [tensorflow-1.15-gpu-py37-cu110-ubuntu18.04-v8]**

The AWS Deep Learning Containers for TensorFlow 1.15 with CUDA 11.0 include containers for training on GPU, optimized for performance and scale on AWS. For more information, see [AWS Deep Learning Containers v7.0 for TensorFlow](https://aws.amazon.com/about-awls/deep-learning-containers/).  

• **TensorFlow 2.1 Python 3.6 (optimized for CPU) [tensorflow-2.1-cpu-py36]**

The AWS Deep Learning Containers for TensorFlow 2.1 include containers for training on CPU, optimized for performance and scale on AWS. For more information, see [AWS Deep Learning Containers v6.2 for TensorFlow](https://aws.amazon.com/about-awls/deep-learning-containers/).  

• **TensorFlow 2.1 Python 3.6 (optimized for GPU) [tensorflow-2.1-gpu-py36]**
The AWS Deep Learning Containers for TensorFlow 2.1 with CUDA 10.1 include containers for training on GPU, optimized for performance and scale on AWS. For more information, see AWS Deep Learning Containers v6.2 for TensorFlow.

- TensorFlow 2.3 Python 3.7 (optimized for CPU) [tensorflow-2.3-cpu-py37-ubuntu18.04-v1]

The AWS Deep Learning Containers for TensorFlow 2.3 include containers for training on CPU, optimized for performance and scale on AWS. For more information, see AWS Deep Learning Containers with TensorFlow 2.3.0.

- TensorFlow 2.3 Python 3.7 (optimized for GPU) [tensorflow-2.3-gpu-py37-cu110-ubuntu18.04-v3]

The AWS Deep Learning Containers for TensorFlow 2.3 with CUDA 11.0 include containers for training on GPU, optimized for performance and scale on AWS. For more information, see AWS Deep Learning Containers for TensorFlow 2.3.1 with CUDA 11.0.

- TensorFlow 2.6 Python 3.8 (optimized for CPU) [tensorflow-2.6-cpu-py38-ubuntu20.04-v1]

The AWS Deep Learning Containers for TensorFlow 2.6 include containers for training on GPU, optimized for performance and scale on AWS. For more information, see AWS Deep Learning Containers for TensorFlow 2.6.

- TensorFlow 2.6 Python 3.8 (optimized for GPU) [tensorflow-2.6-gpu-py38-cu112-ubuntu20.04-v1]

The AWS Deep Learning Containers for TensorFlow 2.6 with CUDA 11.2 include containers for training on GPU, optimized for performance and scale on AWS. For more information, see AWS Deep Learning Containers for TensorFlow 2.6.

Available Amazon SageMaker Kernels

The following Amazon SageMaker kernels are available in SageMaker Studio. The name in parentheses is the SageMaker image hosting the kernel.

Data Science is a conda image with the most commonly used Python packages and libraries, such as NumPy and scikit-learn.

- Python 3 (Base Python) with Python 3.6
- Python 3 (Base Python 2.0) with Python 3.8
- Python 3 (Data Science) with Python 3.7
- Python 3 (Data Science 2.0) with Python 3.8
- PySpark (SparkMagic) with Python 3.7
- Spark (SparkMagic) with Python 3.7
- Python 3 (MXNet 1.6 Python 3.6 CPU Optimized)
- Python 3 (MXNet 1.6 Python 3.6 GPU Optimized)
- Python 3 (MXNet 1.8 Python 3.7 CPU Optimized)
- Python 3 (MXNet 1.8 Python 3.7 GPU Optimized)
- Python 3 (MXNet 1.8 Python 3.8 CPU Optimized)
- Python 3 (MXNet 1.8 Python 3.8 GPU Optimized)
- Python 3 (PyTorch 1.10 Python 3.8 CPU Optimized)
- Python 3 (PyTorch 1.10 Python 3.8 GPU Optimized)
- Python 3 (PyTorch 1.4 Python 3.6 CPU Optimized)
- Python 3 (PyTorch 1.4 Python 3.6 GPU Optimized)
- Python 3 (PyTorch 1.6 Python 3.6 CPU Optimized)
Amazon SageMaker Developer Guide

Customize Studio

- Python 3 (PyTorch 1.6 Python 3.6 GPU Optimized)
- Python 3 (PyTorch 1.8 Python 3.6 CPU Optimized)
- Python 3 (PyTorch 1.8 Python 3.6 GPU Optimized)
- Python 3 (SageMaker JumpStart Data Science 1.0) with Python 3.7

- Python 3 (TensorFlow 2.3 Python 3.7 GPU Optimized)
- Python 3 (TensorFlow 2.6 Python 3.8 CPU Optimized)
- Python 3 (TensorFlow 2.6 Python 3.8 GPU Optimized)

Customize Amazon SageMaker Studio

There are two options for customizing your Amazon SageMaker Studio environment. You bring your own SageMaker image or use a Lifecycle Configuration script. These two options can be used individually or together.

- Bring your own SageMaker image: A SageMaker image is a file that identifies the kernels, language packages, and other dependencies required to run a Jupyter notebook in Amazon SageMaker Studio. Amazon SageMaker provides many built-in images for you to use. If you need different functionality, you can bring your own custom images to Studio.

- Use Lifecycle Configurations with Amazon SageMaker Studio: Lifecycle Configurations are shell scripts triggered by Amazon SageMaker Studio lifecycle events, such as starting a new Studio notebook. You can use Lifecycle Configurations to automate customization for your Studio environment. For example, you can install custom packages, configure notebook extensions, preload datasets, and set up source code repositories.

The following topics show how to use these two options to customize your Amazon SageMaker Studio environment.

Topics
- Bring your own SageMaker image (p. 152)
- Use Lifecycle Configurations with Amazon SageMaker Studio (p. 167)

Bring your own SageMaker image

A SageMaker image is a file that identifies the kernels, language packages, and other dependencies required to run a Jupyter notebook in Amazon SageMaker Studio. These images are used to create an environment that you then run Jupyter notebooks from. Amazon SageMaker provides many built-in images for you to use. For the list of built-in images, see Available Amazon SageMaker Images (p. 148).
If you need different functionality, you can bring your own custom images to Studio. You can create images and image versions, and attach image versions to your domain, using the SageMaker control panel, the AWS SDK for Python (Boto3), and the AWS Command Line Interface (AWS CLI). You can also create images and image versions using the SageMaker console, even if you haven't onboarded to a SageMaker domain. SageMaker provides sample Dockerfiles to use as a starting point for your custom SageMaker images in the SageMaker Studio Custom Image Samples repository.

The following topics explain how to bring your own image using the SageMaker console or AWS CLI, then launch the image in Studio. For a similar blog article, see Bringing your own R environment to Amazon SageMaker Studio. For notebooks that show how to bring your own image for use in training and inference, see Amazon SageMaker Studio Container Build CLI.

**Key terminology**

The following section defines key terms for bringing your own image to use with Studio.

- **Dockerfile**: A Dockerfile is a file that identifies the language packages and other dependencies for your Docker image.
- **Docker image**: The Docker image is a built Dockerfile. This image is checked into Amazon ECR and serves as the basis of the SageMaker image.
- **SageMaker image**: A SageMaker image is a holder for a set of SageMaker image versions based on Docker images. Each image version is immutable.
- **Image version**: An image version of a SageMaker image represents a Docker image and is stored in an Amazon ECR repository. Each image version is immutable. These image versions can be attached to a domain and used with Studio.

**Topics**

- Custom SageMaker image specifications (p. 153)
- Prerequisites (p. 155)
- Add a Docker image compatible with Studio to Amazon ECR (p. 155)
- Create a custom SageMaker image (p. 156)
- Attach a custom SageMaker image (p. 159)
- Launch a custom SageMaker image in Amazon SageMaker Studio (p. 163)
- Clean up resources (p. 166)

**Custom SageMaker image specifications**

The following specifications apply to the container image that is represented by a SageMaker image version.

**Running the image**

ENTRYPOINT and CMD instructions are overridden to enable the image to run as a KernelGateway app.

Port 8888 in the image is reserved for running the KernelGateway web server.

**Stopping the image**

The DeleteApp API issues the equivalent of a `docker stop` command. Other processes in the container won't get the SIGKILL/SIGTERM signals.

**Kernel discovery**

SageMaker recognizes kernels as defined by Jupyter kernel specs.
You can specify a list of kernels to display before running the image. If not specified, python3 is displayed. Use the DescribeAppImageConfig API to view the list of kernels.

Conda environments are recognized as kernel specs by default.

**File system**

The /opt/.sagemakerinternal and /opt/ml directories are reserved. Any data in these directories might not be visible at runtime.

**User data**

Each user in a domain gets a user directory on a shared Amazon Elastic File System volume in the image. The location of the current user's directory on the Amazon EFS volume is configurable. By default, the location of the directory is /home/sagemaker-user.

SageMaker configures POSIX UID/GID mappings between the image and the host. This defaults to mapping the root user's UID/GID (0/0) to the UID/GID on the host.

You can specify these values using the CreateAppImageConfig API.

**GID/UID limits**

Amazon SageMaker Studio only supports the following DefaultUID and DefaultGID combinations:

- DefaultUID: 1000 and DefaultGID: 100, which corresponds to a non-privileged user.
- DefaultUID: 0 and DefaultGID: 0, which corresponds to root access.

**Metadata**

A metadata file is located at /opt/ml/metadata/resource-metadata.json. No additional environment variables are added to the variables defined in the image. For more information, see Get App Metadata (p. 140).

**GPU**

On a GPU instance, the image is run with the --gpus option. Only the CUDA toolkit should be included in the image not the NVIDIA drivers. For more information, see NVIDIA User Guide.

**Metrics and logging**

Logs from the KernelGateway process are sent to Amazon CloudWatch in the customer’s account. The name of the log group is /aws/sagemaker/studio. The name of the log stream is $domainID/$userProfileName/KernelGateway/$appName.

**Image size**

Limited to 25 GB. To view the size of your image, run docker image ls.

**Sample Dockerfile**

The following sample Dockerfile creates an image based Amazon Linux 2, installs third party packages and the python3 kernel, and sets the scope to the non-privileged user.

```
FROM public.ecr.aws/amazonlinux/amazonlinux:2
ARG NB_USER=sagemaker-user
ARG NB_UID=1000
ARG NB_GID=100
```
Prerequisites

You must satisfy the following prerequisites to bring your own container for use with Amazon SageMaker Studio.

- The Docker application. For information about setting up Docker, see Orientation and setup.
- Install the AWS CLI by following the steps in Getting started with the AWS CLI.
- A local copy of any Dockerfile for creating a Studio compatible image. For sample custom images, see the SageMaker Studio custom image samples repository.
- Permissions to access the Amazon Elastic Container Registry (Amazon ECR) service. For more information, see Amazon ECR Managed Policies.
- An AWS Identity and Access Management execution role that has the AmazonSageMakerFullAccess policy attached. If you have onboarded to Amazon SageMaker domain, you can get the role from the Domain Summary section of the SageMaker control panel.
- Install the Studio image build CLI by following the steps in SageMaker Docker Build. This CLI enables you to build a Dockerfile using AWS CodeBuild.

Add a Docker image compatible with Studio to Amazon ECR

You perform the following steps to add a container image to Amazon ECR:

- Create an Amazon ECR repository.
- Authenticate to Amazon ECR.
- Build a Docker image compatible with Studio.
- Push the image to the Amazon ECR repository.

**Note**
The Amazon ECR repository must be in the same AWS Region as Studio.

To build and add a container image to Amazon ECR

1. Create an Amazon ECR repository using the AWS CLI. To create the repository using the Amazon ECR console, see Creating a repository.

```bash
aws ecr create-repository \
  --repository-name smstudio-custom \
  --image-scanning-configuration scanOnPush=true
```

The response should look similar to the following.

```json
{
  "repository": {
```
2. Build the Dockerfile using the Studio image build CLI. The period (.) specifies that the Dockerfile should be in the context of the build command. This command builds the image and uploads the built image to the ECR repo. It then outputs the image URI.

```bash
sm-docker build . -t smstudio-custom -t <acct-id>.dkr.ecr.<region>.amazonaws.com/smstudio-custom:custom
```

The response should look similar to the following.

```
Image URI: <acct-id>.dkr.ecr.<region>.amazonaws.com/<image_name>
```

Create a custom SageMaker image

This topic describes how you can create a custom SageMaker image using the SageMaker console or AWS CLI.

When you create an image from the console, SageMaker also creates an initial image version. The image version represents a container image in Amazon Elastic Container Registry (ECR). The container image must satisfy the requirements to be used in Amazon SageMaker Studio. For more information, see Custom SageMaker image specifications (p. 153). For information on testing your image locally and resolving common issues, see the SageMaker Studio Custom Image Samples repo.

After you have created your custom SageMaker image, you must attach it to your domain to use it with Studio. For more information, see Attach a custom SageMaker image (p. 159).

Create a SageMaker image from the console

The following section demonstrates how to create a custom SageMaker image from the SageMaker console.

To create an image

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the left navigation pane, choose Images.
3. On the Custom images page, choose Create image.
4. For Image source, enter the registry path to the container image in Amazon ECR. The path is in the following format:

```
acct-id.dkr.ecr.<region>.amazonaws.com/repo-name[:tag] or [@digest]
```
5. Choose Next.
6. Under Image properties, enter the following:
   - Image name – The name must be unique to your account in the current AWS Region.
   - (Optional) Display name – The name displayed in the Studio user interface. When not provided, Image name is displayed.
   - (Optional) Description – A description of the image.
• IAM role – The role must have the AmazonSageMakerFullAccess policy attached. Use the dropdown menu to choose one of the following options:
  • Create a new role – Specify any additional Amazon Simple Storage Service (Amazon S3) buckets that you want users of your notebooks to have access to. If you don’t want to allow access to additional buckets, choose None. SageMaker attaches the AmazonSageMakerFullAccess policy to the role. The role allows users of your notebooks access to the S3 buckets listed next to the checkmarks.
  • Enter a custom IAM role ARN – Enter the Amazon Resource Name (ARN) of your IAM role.
  • Use existing role – Choose one of your existing roles from the list.
  • (Optional) Image tags – Choose Add new tag. You can add up to 50 tags. Tags are searchable using the Studio user interface, the SageMaker console, or the SageMaker Search API.

7. Choose Submit.

The new image is displayed in the Custom images list and briefly highlighted. After the image has been successfully created, you can choose the image name to view its properties or choose Create version to create another version.

To create another image version

1. Choose Create version on the same row as the image.
2. For Image source, enter the registry path to the Amazon ECR container image. The container image shouldn’t be the same image as used in a previous version of the SageMaker image.

Create a SageMaker image from the AWS CLI

You perform the following steps to create a SageMaker image from the container image using the AWS CLI.

• Create an Image.
• Create an ImageVersion.
• Create a configuration file.
• Create an AppImageConfig.

To create the SageMaker image entities

1. Create a SageMaker image.

```
aws sagemaker create-image
  --image-name custom-image
  --role-arn arn:aws:iam::<acct-id>:role/service-role/<execution-role>
```

The response should look similar to the following.

```
{
  "ImageArn": "arn:aws:sagemaker:us-east-2:acct-id:image/custom-image"
}
```

2. Create a SageMaker image version from the container image.

```
aws sagemaker create-image-version
  --image-name custom-image
  --base-image <acct-id>.dkr.ecr.<region>.amazonaws.com/smstudio-custom:custom-image
```

```
The response should look similar to the following.

```json
{
    "ImageVersionArn": "arn:aws:sagemaker:us-east-2:acct-id:image-version/custom-image/1"
}
```

3. Check that the image version was successfully created.

```
aws sagemaker describe-image-version \
   --image-name custom-image \ 
   --version 1
```

The response should look similar to the following.

```json
{
    "ImageVersionStatus": "CREATED"
}
```

**Note**
If the response is "ImageVersionStatus": "CREATED_FAILED", the response also includes the failure reason. A permissions issue is a common cause of failure. You also can check your Amazon CloudWatch logs if you experience a failure when starting or running the KernelGateway app for a custom image. The name of the log group is /aws/sagemaker/studio. The name of the log stream is $domainID/$userProfileName/KernelGateway/$appName.

4. Create a configuration file, named `app-image-config-input.json`. The Name value of KernelSpecs must match the name of the kernelSpec available in the Image associated with this AppImageConfig. This value is case sensitive. You can find the available kernelSpecs in an image by running `jupyter-kernelspec list` from a shell inside the container. MountPath is the path within the image to mount your Amazon Elastic File System (Amazon EFS) home directory. It needs to be different from the path you use inside the container because that path will be overridden when your Amazon EFS home directory is mounted.

**Note**
The following DefaultUID and DefaultGID combinations are the only accepted values:
- DefaultUID: 1000 and DefaultGID: 100
- DefaultUID: 0 and DefaultGID: 0

```json
{
    "AppImageConfigName": "custom-image-config",
    "KernelGatewayImageConfig": {
        "KernelSpecs": [{
            "Name": "python3",
            "DisplayName": "Python 3 (ipykernel)"
        }],
        "FileSystemConfig": {
            "MountPath": "/home/sagemaker-user",
            "DefaultUid": 1000,
            "DefaultGid": 100
        }
    }
}
```
5. Create the AppImageConfig using the file created in the previous step.

```
aws sagemaker create-app-image-config \
   --cli-input-json file://app-image-config-input.json
```

The response should look similar to the following.

```
{
}
```

**Attach a custom SageMaker image**

To use a custom SageMaker image, you must attach a version of the image to your domain. When you attach an image version, it appears in the SageMaker Studio Launcher and is available in the **Select image** dropdown list, which users use to launch an activity or change the image used by a notebook.

To make a custom SageMaker image available to all users within a domain, you attach the image to the domain. To make an image available to a single user, you attach the image to the user's profile. When you attach an image, SageMaker uses the latest image version by default. You can also attach a specific image version. After you attach the version, you can choose the version from the SageMaker Launcher or the image selector when you launch a notebook.

There is a limit to the number of image versions that can be attached at any given time. After you reach the limit, you must detach a version in order to attach another version of the image.

The following sections demonstrate how to attach a custom SageMaker image to your domain using either the SageMaker console or the AWS CLI.

**Attach the SageMaker image using the Console**

This topic describes how you can attach an existing custom SageMaker image version to your domain using the SageMaker control panel. You can also create a custom SageMaker image and image version, and then attach that version to your domain. For the procedure to create an image and image version, see [Create a custom SageMaker image](p. 156).

**To attach an existing image**

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the left navigation pane, choose **Control Panel**.
3. On the **Control Panel**, under **Custom SageMaker Studio images attached to domain**, choose **Attach image**.
4. For **Image source**, choose **Existing image**.
5. Choose an existing image from the list.
6. Choose a version of the image from the list.
7. Choose **Next**.
8. Enter values for **Image name**, **Image display name**, and **Description**.
9. Choose the IAM role. For more information, see [Create a custom SageMaker image](p. 156).
10. (Optional) Add tags for the image.
11. Choose **Next**.
12. Under **Studio configuration**, enter or change the following settings. For information on how to get the kernel information from the image, see [DEVELOPMENT](p. 159) in the SageMaker Studio Custom
Image Samples repository. For more information, see the Kernel discovery and User data sections of Custom SageMaker image specifications (p. 153).

- EFS mount path – The path within the image to mount the user's Amazon Elastic File System (EFS) home directory.
- Kernel:
  - For Kernel name, enter the name of an existing kernel in the image.
  - (Optional) For Kernel display name, enter the display name for the kernel.
  - Choose Add kernel.
  - (Optional) Configuration tags – Choose Add new tag and then add a configuration tag.

13. Choose Submit.

- Wait for the image version to be attached to the domain. When attached, the version is displayed in the Custom images list and briefly highlighted.

Attach the SageMaker image using the AWS CLI

The following sections demonstrate how to attach a custom SageMaker image when creating a new domain or updating your existing domain using the AWS CLI.

Attach the SageMaker image to a new domain

The following section demonstrates how to create a new domain with the version attached. These steps require that you specify the Amazon Virtual Private Cloud (VPC) information and execution role required to create the domain. You perform the following steps to create the domain and attach the custom SageMaker image:

- Get your default VPC ID and subnet IDs.
- Create the configuration file for the domain, which specifies the image.
- Create the domain with the configuration file.

To add the custom SageMaker image to your domain

1. Get your default VPC ID.

   ```bash
   aws ec2 describe-vpcs
   --filters Name=isDefault,Values=true
   --query "Vpcs[0].VpcId" --output text
   
   The response should look similar to the following.
   
   vpc-xxxxxxxx
   
   2. Get your default subnet IDs using the VPC ID from the previous step.

   ```bash
   aws ec2 describe-subnets
   --filters Name=vpc-id,Values=<vpc-id>
   --query "Subnets[*].SubnetId" --output json
   
   The response should look similar to the following.

   ["subnet-b55171dd",
    "subnet-8a5f99c6",
    
   
   160
3. Create a configuration file named `create-domain-input.json`. Insert the VPC ID, subnet IDs, `ImageName`, and `AppImageConfigName` from the previous steps. Because `ImageVersionNumber` isn't specified, the latest version of the image is used, which is the only version in this case.

```json
{
    "DomainName": "domain-with-custom-image",
    "VpcId": "<vpc-id>",
    "SubnetIds": [
        "<subnet-ids>"
    ],
    "DefaultUserSettings": {
        "ExecutionRole": "<execution-role>",
        "KernelGatewayAppSettings": {
            "CustomImages": [
                {
                    "ImageName": "custom-image",
                    "AppImageConfigName": "custom-image-config"
                }
            ]
        }
    },
    "AuthMode": "IAM"
}
```

4. Create the domain with the attached custom SageMaker image.

```bash
aws sagemaker create-domain \
  --cli-input-json file://create-domain-input.json
```

The response should look similar to the following.

```json
{
    "Url": "https://d-xxxxxxxxxxxx.studio.us-east-2.sagemaker.aws/..."
}
```

**Attach the SageMaker image to your current domain**

If you have onboarded to a SageMaker domain, you can attach the custom image to your current domain. For more information about onboarding to a SageMaker domain, see [Onboard to Amazon SageMaker Domain](p. 35). You don't need to specify the VPC information and execution role when attaching a custom image to your current domain. After you attach the version, you must delete all the apps in your domain and reopen Studio. For information about deleting the apps, see [Delete an Amazon SageMaker Domain](p. 43).

**Note**

You can have only one domain. If you have onboarded to SageMaker domain, you must delete your current domain before you can use this method. For more information, see [Delete an Amazon SageMaker Domain](p. 43).

You perform the following steps to add the SageMaker image to your current domain.

- Get your `DomainID` from SageMaker control panel.
- Use the `DomainID` to get the `DefaultUserSettings` for the domain.
- Add the `ImageName` and `AppImageConfig` as a `CustomImage` to the `DefaultUserSettings`.
- Update your domain to include the custom image.
To add the custom SageMaker image to your domain

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. From the top left of the navigation pane, choose Control Panel.
3. From the Control Panel, under Domain, find the DomainId. The ID is in the following format: d-xxxxxxxxxxxxx.

4. Use the domain ID to get the description of the domain.

   ```bash
   aws sagemaker describe-domain \
   --domain-id <d-xxxxxxxxxxxxx>
   ``

   The response should look similar to the following.

   ```json
   {
   "DomainId": "d-xxxxxxxxxxxx",  
   "DefaultUserSettings": {  
   "KernelGatewayAppSettings": {  
   "CustomImages": [    
   ],  
   ...  
   }  
   }
   }
   ```

5. Save the default user settings section of the response to a file named default-user-settings.json.

6. Insert the ImageName and AppImageConfigName from the previous steps as a custom image. Because ImageVersionNumber isn't specified, the latest version of the image is used, which is the only version in this case.

   ```json
   {    
   "DefaultUserSettings": {    
   "KernelGatewayAppSettings": {    
   "CustomImages": [    
   {    
   "ImageName": "string",    
   "AppImageConfigName": "string"    
   }    
   ],    
   ```
7. Use the domain ID and default user settings file to update your domain.

```
aws sagemaker update-domain \
  --domain-id <d-xxxxxxxxxxxx> \
  --cli-input-json file://default-user-settings.json
```

The response should look similar to the following.

```
{
  "DomainArn": "arn:aws:sagemaker:us-east-2:acct-id:domain/d-xxxxxxxxxxxx"
}
```

View the attached image in the SageMaker control panel

After you create the custom SageMaker image and attach it to your domain, the image appears in the custom images list in the control panel.

Launch a custom SageMaker image in Amazon SageMaker Studio

After you create your custom SageMaker image and attach it to your domain, the image appears in the image selector dialog box of the Studio Launcher, and the kernel appears in the kernel selector dialog box.

To launch and select your custom image

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Use the keyboard shortcut Ctrl + Shift + L to open Studio Launcher.
3. Open the **Select a SageMaker image** dropdown menu.

4. Choose your custom image.
5. Launch a notebook or interactive shell in the custom image.

6. In an open notebook, you can switch to the custom kernel by choosing a different kernel in the Select Kernel dialog box.
Note
If you encounter an error when launching the image, check your Amazon CloudWatch logs. The name of the log group is /aws/sagemaker/studio. The name of the log stream is $domainID/$userProfileName/KernelGateway/$appName.

Clean up resources

The following sections show how to clean up the resources you created in the previous sections from the SageMaker console or AWS CLI. You perform the following steps to clean up the resources:

- Detach the image and image versions from your domain.
- Delete the image, image version, and app image config.
- Delete the container image and repository from Amazon ECR. For more information, see Deleting a repository.

Clean up resources from the SageMaker console

The following section shows how to clean up resources from the SageMaker console.

When you detach an image from a domain, all versions of the image are detached. When an image is detached, all users of the domain lose access to the image versions. A running notebook that has a kernel session on an image version when the version is detached, continues to run. When the notebook is stopped or the kernel is shut down, the image version becomes unavailable.
To detach an image

1. In the Control Panel, under Custom SageMaker Studio images attached to domain, choose the image and then choose Detach.
2. (Optional) To delete the image and all versions from SageMaker, select Also delete the selected images .... This does not delete the associated container images from Amazon ECR.
3. Choose Detach.

Clean up resources from the AWS CLI

The following section shows how to clean up resources from the SageMaker console.

To clean up resources

1. Detach the image and image versions from your domain by passing an empty custom image list to the domain. Open the default-user-settings.json file you created in ?? (p. 161).
2. Delete the custom images and then save the file.

   ```json
   "DefaultUserSettings": {
     "KernelGatewayAppSettings": {
       "CustomImages": [],
       ..
       },
     ..
   }
   ``

3. Use the domain ID and default user settings file to update your domain.

   ```bash
   aws sagemaker update-domain \
   --domain-id <d-xxxxxxxxxxxx> \
   --cli-input-json file://default-user-settings.json
   ```

   The response should look similar to the following.

   ```json
   {
     "DomainArn": "arn:aws:sagemaker:us-east-2:acct-id:domain/d-xxxxxxxxxxxx"
   }
   ```

4. Delete the app image config.

   ```bash
   aws sagemaker delete-app-image-config \
   --app-image-config-name custom-image-config
   ```

5. Delete the SageMaker image, which also deletes all image versions. The container images in ECR that are represented by the image versions are not deleted.

   ```bash
   aws sagemaker delete-image \
   --image-name custom-image
   ```

Use Lifecycle Configurations with Amazon SageMaker Studio

Lifecycle Configurations are shell scripts triggered by Amazon SageMaker Studio lifecycle events, such as starting a new Studio notebook. You can use Lifecycle Configurations to automate customization for
Customize Studio

your Studio environment. This customization includes installing custom packages, configuring notebook extensions, preloading datasets, and setting up source code repositories.

Using Lifecycle Configurations gives you flexibility and control to configure Studio to meet your specific needs. For example, you can create a minimal set of base container images with the most commonly used packages and libraries, then use Lifecycle Configurations to install additional packages for specific use cases across your data science and machine learning teams.

For example Lifecycle Configuration scripts, see the Studio Lifecycle Configuration examples repo. For a blog on implementing Lifecycle Configurations, see Customize Amazon SageMaker Studio using Lifecycle Configurations.

Note
Each script has a limit of 16384 characters.

Topics
• Creating and Associating a Lifecycle Configuration (p. 168)
• Setting Default Lifecycle Configurations (p. 172)
• Debugging Lifecycle Configurations (p. 173)
• Updating and deleting Lifecycle Configurations (p. 175)

Creating and Associating a Lifecycle Configuration

Amazon SageMaker Studio provides interactive applications that enable Studio's visual interface, code authoring, and run experience. This series shows how to create a lifecycle configuration and associate it with Amazon SageMaker Studio.

Application types can be either JupyterServer or KernelGateway.

• JupyterServer applications: This application type enables access to the visual interface for Studio. Every user in Studio gets their own Jupyter Server application.
• KernelGateway applications: This application type enables access to the code run environment and kernels for your Studio notebooks and terminals. For more information, see Jupyter Kernel Gateway.

For more information about Studio's architecture and Studio applications, see Use Amazon SageMaker Studio Notebooks.

Topics
• Create a Lifecycle Configuration from the AWS CLI (p. 168)
• Create a Lifecycle Configuration from the SageMaker Console (p. 170)

Create a Lifecycle Configuration from the AWS CLI

The following topic shows how to create a lifecycle configuration using the AWS CLI to automate customization for your Studio environment.

Prerequisites

Before you begin, complete the following prerequisites:

• Update the AWS CLI by following the steps in Installing the current AWS CLI Version.
• From your local machine, run aws configure and provide your AWS credentials. For information about AWS credentials, see Understanding and getting your AWS credentials.
• Onboard to Amazon SageMaker Studio. For more information, see Onboard to Amazon SageMaker Studio.
Step 1: Create a Lifecycle Configuration

The following procedure shows how to create a lifecycle configuration script that prints Hello World.

1. From your local machine, create a file named my-script.sh with the following content.

```bash
#!/bin/bash
set -eux
echo 'Hello World!'
```

2. Convert your my-script.sh file into base64 format. This requirement prevents errors that occur from spacing and line break encoding.

```bash
LCC_CONTENT=`openssl base64 -A -in my-script.sh`
```

3. Create a Studio lifecycle configuration. The following command creates a lifecycle configuration that runs when you launch an associated KernelGateway application.

```bash
aws sagemaker create-studio-lifecycle-config \
--region <your-region> \
--studio-lifecycle-config-name my-studio-lcc \
--studio-lifecycle-config-content $LCC_CONTENT \
--studio-lifecycle-config-app-type KernelGateway
```

Note the ARN of the newly created lifecycle configuration that is returned. This ARN is required to attach the lifecycle configuration to your application.

Step 2: Attach the Lifecycle Configuration to your Studio domain or user profile

To attach the lifecycle configuration, you must update the UserSettings for your Studio domain or an individual user profile. Lifecycle configuration scripts that are associated at the domain level are inherited by all users. However, scripts that are associated at the user profile level are scoped to a specific user.

The following example shows how to create a new user profile with the lifecycle configuration attached. To update an existing user profile, use the update-user-profile command.

Add the lifecycle configuration ARN from the previous step to the settings for the appropriate AppType. For example, place it in the JupyterServerAppSettings of the user. You can add multiple lifecycle configuration at the same time by using a list of lifecycle configuration.

```bash
# Create a new UserProfile
aws sagemaker create-user-profile --domain-id <DOMAIN-ID> \
--user-profile-name <USER-PROFILE-NAME> \
--region <REGION> \
--user-settings '{
"JupyterServerAppSettings": {
  "LifecycleConfigArns":
  ["<LIFECYCLE-CONFIGURATION-ARN-LIST>"
  ]
}
'
```

Step 3: Launch application with Lifecycle Configuration

After you attach a lifecycle configuration to a user profile, the user can select it when launching an application using the AWS CLI. This section describes how to launch an application with an attached lifecycle configuration.
Launch the application and specify the lifecycle configuration ARN in the ResourceSpec argument of the CreateApp API.

- The following example shows how to create a JupyterServer application. When creating the app-type JupyterServer, the app-name must be default.

```
aws sagemaker create-app --domain-id <DOMAIN-ID> \
  --region <YOUR-REGION> \ 
  --user-profile-name <USERPROFILE-NAME> \ 
  --app-type JupyterServer \ 
  --resource-spec LifecycleConfigArn=<LIFECYCLE-CONFIGURATION-ARN> \ 
  --app-name default
```

- The following example shows how to create a KernelGateway application.

```
aws sagemaker create-app --domain-id <DOMAIN-ID> \
  --region <YOUR-REGION> \ 
  --user-profile-name <USERPROFILE-NAME> \ 
  --app-type KernelGateway \ 
  --resource-spec LifecycleConfigArn=<LIFECYCLE-CONFIGURATION-ARN>,SageMakerImageArn=<SAGEMAKER-IMAGE-ARN>,InstanceType=<INSTANCE-TYPE> \ 
  --app-name <APP-NAME>
```

Create a Lifecycle Configuration from the SageMaker Console

The following topic shows how to create a lifecycle configuration from the Amazon SageMaker console to automate customization for your Studio environment.

Prerequisites

Before you can begin this tutorial, complete the following prerequisite:

- Onboard to Amazon SageMaker Studio. For more information, see Onboard to Amazon SageMaker Studio.

Step 1: Create a new Lifecycle Configuration

You can create a lifecycle configuration by entering a script from the Amazon SageMaker console.

The following procedure shows how to create a lifecycle configuration script that prints **Hello World**.

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. From the navigation panel, under SageMaker dashboard, choose Lifecycle configurations.
3. Choose the Studio tab.
4. Choose Create configuration.
5. Under Select configuration type, select the type of application that the lifecycle configuration should be attached to.
6. Choose Next.
7. In the section called Configuration settings, enter a name for your lifecycle configuration.
8. In the Scripts section, enter the following content.

```bash
#!/bin/bash
set -eux
echo 'Hello World!'
```
9. (Optional) Create a tag for your lifecycle configuration.

10. Choose Create Configuration.

**Step 2: Attach the Lifecycle Configuration to Studio domain or user profile**

Lifecycle configuration scripts associated at the domain level are inherited by all users. However, scripts that are associated at the user profile level are scoped to a specific user.

The following sections show how to attach a lifecycle configuration to your domain and user profile.

**Attach to Studio domain**

The following shows how to attach a lifecycle configuration to your existing domain in Studio.

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. From the left navigation panel, choose Control panel.
3. From the Control panel, choose the Lifecycle configurations tab.
4. Choose Attach.
5. Under Source, choose Existing configuration.
6. Under Studio lifecycle configurations, select the lifecycle configuration that you created in the previous step.
7. Select Attach to domain.

**Attach to your user profile**

The following shows how to attach a lifecycle configuration to your existing user profile.

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. From the left navigation panel, choose Control panel.
3. Under Users, select the user profile.
4. From the User Details page, choose Edit.
5. On the left navigation, choose Studio settings.
6. Under Lifecycle configurations attached to user, choose Attach.
7. Under Source, choose Existing configuration.
8. Under Studio lifecycle configurations, select the lifecycle configuration that you created in the previous step.
9. Choose Attach to user profile.

**Step 3: Launch an application with the Lifecycle Configuration**

After you attach a lifecycle configuration to a user profile, the user can select it when launching an application using the Studio Launcher. The following sections describe how to launch an application with an attached lifecycle configuration.

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Launch the Studio Domain. For more information, see Use the Amazon SageMaker Studio Launcher (p. 127).
3. In the launcher, navigate to the Notebooks and compute resources section.
4. Select a SageMaker image.
5. Select a start-up script. If there is no default lifecycle configuration, this value defaults to No script. Otherwise, this value is equal to your default lifecycle configuration. After you select a lifecycle configuration, you can view the entire script.

6. Choose Notebook to launch a new notebook kernel with your selected image and lifecycle configuration.

**Step 4: View logs for a Lifecycle Configuration**

You can view the logs for your lifecycle configuration after it has been attached to a Studio domain or user profile.

1. First, provide access to CloudWatch for your AWS Identity and Access Management (IAM) role. Add read permissions for the following log group /aws/sagemaker/studio and for the following log stream `<Domain>/<UserProfile>/<AppType>/<AppName>/LifecycleConfigOnStart`. For information about adding permissions, see Enabling logging from certain AWS services.

2. From within Studio, navigate to the Running instances tab to monitor your lifecycle configuration.

3. Select an application from the list of running applications. Applications with attached lifecycle configurations have an attached indicator icon.

4. Select the indicator icon for your application. This opens a new panel that lists the lifecycle configuration.

5. From the new panel, select View logs. This opens a new tab that displays the logs.

**Setting Default Lifecycle Configurations**

To set a Lifecycle Configuration as the default for your Domain or UserProfile programatically, you can create a new resource or update an existing resource. To associate a Lifecycle Configuration as a default, you'll first need to create a Lifecycle Configuration following the steps in Creating and Associating a Lifecycle Configuration (p. 168). Default Lifecycle Configurations set up at the domain level are inherited by all users, while those set up at the user level are scoped to a specific user.

**Note**

User level defaults override defaults set up at the domain level.

To set up a default Lifecycle Configuration, it must be added to the DefaultResourceSpec of the appropriate app type. The behavior of your Lifecycle Configuration depends on whether it is added to the DefaultResourceSpec of a JupyterServer or KernelGateway app.

- **JupyterServer apps:** When added to the DefaultResourceSpec of a JupyterServer app, the default Lifecycle Configuration script runs automatically when the user logs into Studio for the first time or restarts Studio. This can be used to automate one-time set-up actions for the Studio developer environment, such as installing notebook extensions or setting up a GitHub repo. For an example of this, see Customize Amazon SageMaker Studio using Lifecycle Configurations.

- **KernelGateway apps:** When added to the DefaultResourceSpec of a KernelGateway app, Studio defaults to selecting the Lifecycle Configuration script from the Studio launcher. Users can launch a notebook or terminal with the default script selected or they can select a different one from the list of Lifecycle Configurations.

**Note**

A default KernelGateway Lifecycle Configuration specified in DefaultResourceSpec applies to all KernelGateway images in the Studio Domain unless the user selects a different script from the list presented in the Studio launcher. The default script also runs if No Script is selected by the user. For more information on selecting a script, see Step 3: Launch an application with the Lifecycle Configuration (p. 171).
Associate a default Lifecycle Configuration when creating a new Domain or UserProfile

To associate a Lifecycle Configuration when creating a new Studio Domain or UserProfile, you need the ARN of the Lifecycle Configuration that you created. This ARN is passed to one of the following API calls:

- `create-user-profile`
- `create-domain`

For example, the following API call creates a new UserProfile with an associated Lifecycle Configuration.

```bash
aws sagemaker create-user-profile --domain-id <DOMAIN-ID> \
--user-profile-name <USER-PROFILE-NAME> \
--region <REGION> \
--user-settings '{
  "KernelGatewayAppSettings": {
    "DefaultResourceSpec": {
      "InstanceType": "ml.t3.medium",
      "LifecycleConfigArn": "<LIFECYCLE-CONFIGURATION-ARN>"
    }
  }
}'
```

Associate a default Lifecycle Configuration when updating a Domain or UserProfile

To associate a Lifecycle Configuration when updating an existing Studio Domain or UserProfile, you need the ARN of the Lifecycle Configuration that you created. This ARN is passed to one of the following API calls:

- `update-user-profile`
- `update-domain`

The Lifecycle Configuration ARN should be placed in 2 places, the DefaultResourceSpec and the LifecycleConfigArns list in KernelGatewayAppSettings. For example, the following API call updates a UserProfile with an associated Lifecycle Configuration.

```bash
aws sagemaker update-user-profile --domain-id <DOMAIN-ID> \
--user-profile-name <USER-PROFILE-NAME> \
--region <REGION> \
--user-settings '{
  "KernelGatewayAppSettings": {
    "DefaultResourceSpec": {
      "InstanceType": "ml.t3.medium",
      "LifecycleConfigArn": "<LIFECYCLE-CONFIGURATION-ARN>"
    }
  }
}'
```

Debugging Lifecycle Configurations

The following topics show how to get information about and debug your Lifecycle Configurations.

Topics

- Verify Lifecycle Configuration Process from Amazon CloudWatch Logs (p. 174)
- JupyterServer App failure (p. 174)
- KernelGateway App failure (p. 174)
- Lifecycle Config timeout (p. 175)
Verify Lifecycle Configuration Process from Amazon CloudWatch Logs

Lifecycle Configurations only log STDOUT and STDERR. STDOUT is the default output for bash scripts, while STDERR can be written to by appending `&2` to the end of a bash command. For example, `echo 'hello' >&2`. Logs for your Lifecycle Configurations are published to your AWS Account via CloudWatch. These logs can be found in the `/aws/sagemaker/studio` Log Stream from the AWS CloudWatch console.

2. Select Logs from the left side. From the dropdown menu, select Log Groups.
4. On the `aws/sagemaker/studio` Log Group screen, navigate to the Log Streams tab.
5. To find the logs for a specific app, search Log Streams using the following format:

   `<DomainId>/< UserProfileName>/<AppType>/<AppName>

   For example, to find the Lifecycle Configuration logs for Domain d-m851cu8vbqzmz, UserProfile i-sonic-js, AppType JupyterServer and AppName test-lcc-echo, use the following search string:

   d-m851cu8vbqzmz/i-sonic-js/JupyterServer/test-lcc-echo

6. Select the log stream appended with `LifecycleConfigOnStart` to view the script execution logs.

**JupyterServer App failure**

If your JupyterServer App crashes because of an issue with the attached Lifecycle Configuration, Studio displays the following error message on the Studio startup screen.

```
Failed to create SageMaker Studio due to start-up script failure
```

Click the View script logs link to view the CloudWatch logs for your JupyterServer app.

In the case where the faulty Lifecycle Configuration is specified in the `DefaultResourceSpec` of your Studio Domain or UserProfile, Studio continues to use the Lifecycle Configuration even after restarting Studio.

To resolve this error, follow the steps in Setting Default Lifecycle Configurations (p. 172) to remove the Lifecycle Configuration script from the `DefaultResourceSpec` or select another script using the AWS CLI. Then launch a new JupyterServer app.

**KernelGateway App failure**

If your KernelGateway App crashes because of an issue with the attached Lifecycle Configuration, Studio displays the error message in your Studio Notebook.

Click the View script logs link to view the CloudWatch logs for your KernelGateway app.

In this case, your Lifecycle Configuration is specified in the Studio Launcher when launching a new Studio Notebook.

To resolve this error, use the Studio launcher to select a different Lifecycle Configuration or select No script.

**Note**

A default KernelGateway Lifecycle Configuration specified in `DefaultResourceSpec` applies to all KernelGateway images in the Studio Domain unless the user selects a different script from
the list presented in the Studio launcher. The default script also runs if No Script is selected by the user. For more information on selecting a script, see Step 3: Launch an application with the Lifecycle Configuration (p. 171).

Lifecycle Config timeout

There is a Lifecycle Configuration timeout limitation of 5 minutes. If a Lifecycle Configuration script takes longer than 5 minutes to run, Studio throws an error.

To resolve this error, ensure that your Lifecycle Configuration script completes in less than 5 minutes.

To help decrease the run time of scripts, try the following:

- Cut down on necessary steps. For example, limit which conda environments to install large packages in.
- Run tasks in parallel processes.
- Use the nohup command in your script.

Updating and deleting Lifecycle Configurations

A Lifecycle Configuration script cannot be changed after it has been created. To update your script, you must create a new Lifecycle Configuration script and use the update-domain and update-user-profile APIs to attach the Lifecycle Configuration script to the respective Domain or UserProfile. For more information, see Creating and Associating a Lifecycle Configuration (p. 168).

To delete an existing Lifecycle Configuration, use the DeleteStudioLifecycleConfig API. To successfully delete a Lifecycle Configuration, no running Apps can be using it.

Perform Common Tasks in Amazon SageMaker Studio

The following sections describe how to perform common tasks in Amazon SageMaker Studio. For an overview of the Studio interface, see Amazon SageMaker Studio UI Overview (p. 118).

Topics

- Upload Files to SageMaker Studio (p. 175)
- Clone a Git Repository in SageMaker Studio (p. 176)
- Stop a Training Job in SageMaker Studio (p. 176)
- Use TensorBoard in Amazon SageMaker Studio (p. 176)
- Manage Your EFS Storage Volume in SageMaker Studio (p. 178)
- Provide Feedback on SageMaker Studio (p. 178)
- Shut Down and Update SageMaker Studio and Studio Apps (p. 179)

Upload Files to SageMaker Studio

When you onboard to Amazon SageMaker Studio, a home directory is created for you in the Amazon Elastic File System (Amazon EFS) volume that was created for your team. Studio can open only files that have been uploaded to your directory. The Studio file browser maps to your home directory.

Note

Studio does not support uploading folders. Only individual files can be uploaded.
To upload files to your home directory

1. In the left sidebar, choose the File Browser icon ( 文件).
2. In the file browser, choose the Upload Files icon ( 文件上传).
3. Select the files you want to upload and then choose Open.
4. Double-click a file to open the file in a new tab in Studio.

Clone a Git Repository in SageMaker Studio

Amazon SageMaker Studio can connect only to a local repository. In this example, you clone the aws/amazon-sagemaker-examples repository (repo).

To clone the repo

1. In the left sidebar, choose the File Browser icon ( 文件).
2. Choose the root folder or the folder you want to clone the repo into.
3. In the left sidebar, choose the Git icon ( Git).
4. Choose Clone a Repository.
5. Enter the URI for the SageMaker examples repo https://github.com/aws/amazon-sagemaker-examples.git.
6. Choose CLONE.
7. If the repo requires credentials, you are prompted to enter your username and personal access token.
8. Wait for the download to finish. After the repo has been cloned, the File Browser opens to display the cloned repo.
9. Double-click the repo to open it.
10. Choose the Git icon to view the Git user interface which now tracks the examples repo.
11. To track a different repo, open the repo in the file browser and then choose the Git icon.

Stop a Training Job in SageMaker Studio

You can stop a training job with the Amazon SageMaker Studio UI. When you stop a training job, its status changes to Stopping at which time billing ceases. An algorithm can delay termination in order to save model artifacts after which the job status changes to Stopped. For more information, see the stop_training_job method in the AWS SDK for Python (Boto3).

To stop a training job

1. Follow the View and Compare Experiments, Trials, and Trial Components (p. 2237) procedure on this page until you open the Describe Trial Component tab.
2. At the upper-right side of the tab, choose Stop training job. The Status at the top left of the tab changes to Stopped.
3. To view the training time and billing time, choose AWS Settings.

Use TensorBoard in Amazon SageMaker Studio

The following doc outlines how to install and run TensorBoard in Amazon SageMaker Studio.
Prerequisites

This tutorial requires an Amazon SageMaker Studio Domain.

Set Up TensorBoardCallback

1. Launch Studio.
2. In the Amazon SageMaker Studio Launcher under Notebooks and compute resources, select the TensorFlow 2.3 Python 3.7(optimized for CPU) Studio Image.
3. Launch a notebook to run the commands in the following steps. You run these commands from within a notebook cell.
4. Import the required packages.

```python
import os
import datetime
import tensorflow as tf
```
5. Create your Keras model.

```python
mnist = tf.keras.datasets.mnist
(x_train, y_train),(x_test, y_test) = mnist.load_data()
x_train, x_test = x_train / 255.0, x_test / 255.0

def create_model():
    return tf.keras.models.Sequential([tf.keras.layers.Flatten(input_shape=(28, 28)),
                                        tf.keras.layers.Dense(512, activation='relu'),
                                        tf.keras.layers.Dropout(0.2),
                                        tf.keras.layers.Dense(10, activation='softmax')])
```
6. Create a directory for your TensorBoard logs

```python
LOG_DIR = os.path.join(os.getcwd(), "logs/fit/" + datetime.datetime.now().strftime("%Y%m%d-%H%M%S"))
```
7. Run training with TensorBoard.

```python
model = create_model()
model.compile(optimizer='adam',
              loss='sparse_categorical_crossentropy',
              metrics=['accuracy'])
tensorboard_callback = tf.keras.callbacks.TensorBoard(log_dir=LOG_DIR,
                                                        histogram_freq=1)
model.fit(x=x_train,
y=y_train,
epochs=5,
validation_data=(x_test, y_test),
callbacks=[tf.keras.callbacks.TensorBoard(log_dir=LOG_DIR)])
```
8. Generate the EFS path for the TensorBoard logs. You use this path to set up your logs from the terminal.

```python
EFS_PATH_LOG_DIR = "".join(LOG_DIR.strip("/").split('/')[1:-1])
print(EFS_PATH_LOG_DIR)
```
Install TensorBoard

1. Click on the Amazon SageMaker Studio button on the top left corner of Studio to open the Amazon SageMaker Studio Launcher. This launcher must be opened from your root directory.
2. In the Launcher under Utilities and files, click System terminal.
3. From the terminal, run the following commands. Copy EFS_PATH_LOG_DIR from the Jupyter notebook. You must run this from the /home/sagemaker-user root directory.

   ```
   pip install tensorboard
tensorboard --logdir <EFS_PATH_LOG_DIR>
   ```

Launch TensorBoard

1. To launch TensorBoard, copy your Studio URL and replace lab? with proxy/6006/ as follows. You must include the trailing / character.

   ```
   https://<YOUR_URL>.studio.region.sagemaker.aws/jupyter/default/proxy/6006/
   ```

2. Navigate to the URL to examine your results.

Manage Your EFS Storage Volume in SageMaker Studio

The first time a user on your team onboards to Amazon SageMaker Studio, Amazon SageMaker creates an Amazon Elastic File System (Amazon EFS) volume for the team. A home directory is created in the volume for each user who onboards to Studio as part of your team. Notebook files and data files are stored in these directories. Users don't have access to other team member's home directories.

**Important**

Don't delete the Amazon EFS volume. If you delete it, the domain will no longer function and all of your users will lose their work.

To find your Amazon EFS volume

1. Open the SageMaker console.
2. Choose Control Panel at the top left of the page.
3. From the Control Panel, under Domain, find the Domain ID. The ID will be in the following format: d-xxxxxxxxxxxx.
4. Pass the Domain ID, as DomainId, to the describe_domain method.
5. In the response from describe_domain, note the value for the HomeEfsFileSystemId key. This is the Amazon EFS file system ID.
6. Open the Amazon EFS console. Make sure the AWS Region is the same Region that's used by Studio.
7. Under File systems, choose the file system ID from the previous step.
8. To verify that you've chosen the correct file system, select the Tags heading. The value corresponding to the ManagedByAmazonSageMakerResourceId key should match the Studio ID.

For information on how to access the Amazon EFS volume, see Using file systems in Amazon EFS.

To delete the Amazon EFS volume, see Deleting an Amazon EFS file system.

Provide Feedback on SageMaker Studio

Amazon SageMaker takes your feedback seriously. We encourage you to provide feedback.
To provide feedback

1. At the upper-right of SageMaker Studio, choose Feedback.
2. Choose a smiley emoji to let us know how satisfied you are with SageMaker Studio and add any feedback you’d care to share with us.
3. Decide whether to share your identity with us, then choose Submit.

Shut Down and Update SageMaker Studio and Studio Apps

The following topics show how to shut down and update SageMaker Studio and Studio Apps.

Amazon SageMaker does not update Amazon SageMaker Studio apps when it is in service.

Studio provides a notification icon in the upper-right corner of the Studio UI. This notification icon displays the number of unread notices. To read the notices, select the icon.

Studio provides two types of notifications:

- Upgrade – Displayed when Studio or one of the Studio apps have released a new version. To update, see Shut Down and Update SageMaker Studio and Studio Apps (p. 179).
- Information – Displayed for new features and other information.

To reset the notification icon, you must select the link in each notice. Read notifications may still display in the icon. This does not indicate that updates are still needed after you have updated Studio and Studio Apps.

To learn how to update Amazon SageMaker Data Wrangler, see Shut down and Update Studio Apps (p. 180).

To ensure that you have the most recent software updates, update Amazon SageMaker Studio and your Studio apps using the methods outlined in the following topics.

Topics

- Shut down and Update SageMaker Studio (p. 179)
- Shut down and Update Studio Apps (p. 180)

Shut down and Update SageMaker Studio

To update Amazon SageMaker Studio to the latest release, you must shut down the JupyterServer app. You can shut down the JupyterServer app from the SageMaker console or from within Studio. After the JupyterServer app is shut down, you must reopen Studio through the SageMaker console which creates a new version of the JupyterServer app.

Any unsaved notebook information is lost in the process. The user data in the Amazon EFS volume isn’t impacted.

Some of the services within Studio, like Data Wrangler, run on their own app. To update these services you must delete the app for that service. To learn more, see Shut down and Update Studio Apps (p. 180).

Note

A JupyterServer app is associated with a single Studio user. When you update the app for one user it doesn’t affect other users.
The following topic shows how to update the JupyterServer App from the SageMaker console or from inside Studio.

**To update the JupyterServer app from the SageMaker console**

2. Choose Control panel.
3. Under Users, select your user name.
5. Choose Yes, delete app.
6. Type delete in the confirmation box.
7. Choose Delete.
8. After the app has been deleted, launch a new Studio app to get the latest version.

**To update the JupyterServer app from inside Studio**

1. Launch Studio.
2. On the top menu, choose File then Shut Down.
3. Choose one of the following options:
   - **Shutdown Server** – Shuts down the JupyterServer app. Terminal sessions, kernel sessions, SageMaker images, and instances aren't shut down. These resources continue to accrue charges.
   - **Shutdown All** – Shuts down all apps, terminal sessions, kernel sessions, SageMaker images, and instances. These resources no longer accrue charges.
4. Close the window.
5. After the app has been deleted, launch a new Studio app to use the latest version.

**Shut down and Update Studio Apps**

To update an Amazon SageMaker Studio app to the latest release, you must first shut down the corresponding KernelGateway app from the SageMaker console. After the KernelGateway app is shut down, you must reopen it through SageMaker Studio by running a new kernel. The kernel automatically updates. Any unsaved notebook information is lost in the process. The user data in the Amazon EFS volume isn't impacted.

**Note**

A KernelGateway app is associated with a single Studio user. When you update the app for one user it doesn't effect other users.

**To update the KernelGateway app**

2. Choose Control panel.
3. Under Users, select your user name.
4. Under Apps, in the row displaying the App name, choose Delete app.

   To update Data Wrangler, delete the app that starts with sagemaker-data-wrang.
5. Choose Yes, delete app.
6. Type delete in the confirmation box.
7. Choose Delete.
8. After the app has been deleted, launch a new kernel from within Studio to use the latest version.

Amazon SageMaker Studio Pricing

When the first member of your team onboards to Amazon SageMaker Studio, Amazon SageMaker creates an Amazon Elastic File System (Amazon EFS) volume for the team. In the SageMaker Control Panel, when the Studio Status displays as Ready, the Amazon EFS volume has been created.

When this member, or any member of the team, opens Studio, a home directory is created in the volume for the member. A storage charge is incurred for this directory. Subsequently, additional storage charges are incurred for the notebooks and data files stored in the member's home directory. For pricing information on Amazon EFS, see Amazon EFS Pricing.

Additional costs are incurred when other operations are run inside Studio, for example, running a notebook, running training jobs, and hosting a model.

For information on the costs associated with using Studio notebooks, see Usage Metering (p. 146).

For information about billing along with pricing examples, see Amazon SageMaker Pricing.

Troubleshooting Amazon SageMaker Studio

The following are common errors that you might run into when using Amazon SageMaker Studio. Each error is followed by a solution to the error.

- **SageMaker Studio core functionalities are not available.**

  If you get this error message when opening Studio, it might be due to Python package version conflicts. This occurs if you used the following commands in a notebook or terminal to install Python packages that have version conflicts with SageMaker package dependencies.

  ```
  !pip install
  pip install --user
  ```

  To resolve this issue, complete the following steps:
  1. Uninstall recently installed Python packages. If you’re not sure which package to uninstall, reach out using the feedback button on the lower left of the AWS Management Console.
  2. Restart Studio:
      a. Shut down Studio from the File menu.
      b. Wait for 1 minute.
      c. Re-open Studio by refreshing the page or opening it from the AWS Management Console.

  The problem should be resolved if you have uninstalled the package which caused the conflict. To install packages without causing this issue again, use `pip install` without the `--user` flag.

  If the issue persists, create a new user profile and set up your environment with that user profile.

  If these solutions don’t fix the issue, reach out using the feedback button on the lower left of the AWS Management Console.

- **Unable to open Studio from the AWS Management Console.**

  If you are continually unable to open Studio, and are unable to make a new running instance with all default settings, reach out using the feedback button on the lower left of the AWS Management Console.
RStudio on Amazon SageMaker

RStudio is an integrated development environment for R, with a console, syntax-highlighting editor that supports direct code execution, and tools for plotting, history, debugging and workspace management. Amazon SageMaker supports RStudio as a fully-managed integrated development environment (IDE) integrated with Amazon SageMaker Domain.

RStudio allows customers to create data science insights using an R environment. With RStudio integration, you can launch an RStudio environment in the Domain to run your RStudio workflows on SageMaker resources. For more information about RStudio, see the RStudio website.

Topics
- RStudio components (p. 182)
- Differences from RStudio Workbench (p. 183)
- Manage RStudio on Amazon SageMaker (p. 183)
- Use RStudio on Amazon SageMaker (p. 211)

SageMaker integrates RStudio through the creation of a RStudioServerPro app.

The following are supported by RStudio on SageMaker.

- R developers use the RStudio IDE interface with popular developer tools from the R ecosystem. Users can launch new RStudio sessions, write R code, install dependencies from RStudio Package Manager, and publish Shiny apps using RStudio Connect.
- R developers can quickly scale underlying compute resources to run large scale data processing and statistical analysis.
- Platform administrators can set up user identities, authorization, networking, storage, and security for their data science teams through AWS IAM Identity Center (successor to AWS Single Sign-On) and AWS Identity and Access Management integration. This includes connection to private Amazon Virtual Private Cloud (Amazon VPC) resources and internet-free mode with AWS PrivateLink.
- Integration with AWS License Manager.

For information on the onboarding steps to create a Domain with RStudio enabled, see Onboard to Amazon SageMaker Domain (p. 35).

For information about the AWS Regions that RStudio on SageMaker is supported in, see Supported Regions and Quotas (p. 32).

RStudio components

- **RStudioServerPro**: The RStudioServerPro app is a multiuser app that is a shared resource among all user profiles in the Domain. Once an RStudio app is created in a Domain, the admin can give permissions to users in the Domain.
- **RStudio user**: RStudio users are users within the Domain that are authorized to use the RStudio license.
- **RStudio admin**: An RStudio on Amazon SageMaker admin can access the RStudio administrative dashboard. RStudio on Amazon SageMaker admins differ from "stock" RStudio Workbench admins because they do not have root access to the instance running the RStudioServerPro app and can't modify the RStudio configuration file.
- **RStudio Server**: The RStudio Server instance is responsible for serving the RStudio UI to all authorized Users. This instance is launched on an Amazon SageMaker instance.
- **RSession**: An RSession is a browser-based interface to the RStudio IDE running on an Amazon SageMaker instance. Users can create and interact with their RStudio projects through the RSession.
• **RSessionGateway**: The RSessionGateway app is used to support an RSession.

• **RStudio administrative dashboard**: This dashboard gives information on the RStudio users in the Amazon SageMaker Domain and their sessions. This dashboard can only be accessed by users that have RStudio admin authorization.

### Differences from RStudio Workbench

RStudio on Amazon SageMaker has some significant differences from RStudio Workbench.

• When using RStudio on SageMaker, users don’t have access to the RStudio configuration files. Amazon SageMaker manages the configuration file and sets defaults. You can modify the RStudio Connect and RStudio Package Manager URLs when creating your RStudio-enabled Amazon SageMaker Domain.

• Project sharing, realtime collaboration, and Job Launcher are not currently supported when using RStudio on Amazon SageMaker.

• When using RStudio on SageMaker, the RStudio IDE runs on Amazon SageMaker instances for on-demand containerized compute resources.

• RStudio on SageMaker only supports the RStudio IDE and does not support other IDEs supported by an RStudio Workbench installation.

### Manage RStudio on Amazon SageMaker

The following topics give information on managing RStudio on Amazon SageMaker. This includes information on your RStudio environment configuration, user sessions, and necessary resources. For information on how to use RStudio on SageMaker, see [Use RStudio on Amazon SageMaker](p. 211).

For information about creating a Amazon SageMaker Domain with RStudio enabled, see [Onboard to Amazon SageMaker Domain](p. 35).

For information about the AWS Regions that RStudio on SageMaker is supported in, see [Supported Regions and Quotas](p. 32).

**Topics**

- RStudio license (p. 183)
- Upgrade the RStudio Version (p. 184)
- Network and Storage (p. 185)
- RStudioServerPro instance type (p. 186)
- RStudio Connect URL (p. 186)
- RStudio Package Manager (p. 187)
- Create an Amazon SageMaker Domain with RStudio using the AWS CLI (p. 187)
- Bring your own image to RStudio on SageMaker (p. 192)
- Manage users (p. 205)
- RStudio administrative dashboard (p. 207)
- Shut down and restart RStudio (p. 208)
- Manage billing and cost (p. 209)
- Diagnose issues and get support (p. 210)

**RStudio license**

RStudio on Amazon SageMaker is a paid product and requires that each user is appropriately licensed. Licenses for RStudio on Amazon SageMaker may be obtained from RStudio PBC directly, or by
purchasing a subscription to RStudio Workbench on AWS Marketplace. For existing customers of RStudio Workbench Enterprise, licenses are issued at no additional cost.

To use an RStudio license with Amazon SageMaker, you must first have a valid RStudio license registered with AWS License Manager. Subscriptions to RStudio Workbench on AWS Marketplace automatically trigger license creation with AWS License Manager. For licenses purchased directly through RStudio PBC, a licenses grant for your AWS Account must be created. Contact RStudio for direct license purchases or to enable existing licenses in AWS License Manager. For more information about registering a license with AWS License Manager, see Seller issued licenses in AWS License Manager.

The following topics show how to acquire and validate a license granted by RStudio PBC.

**Get an RStudio license**

1. If you don't have an RStudio license, you may purchase one at RStudio Pricing or by contacting sales@rstudio.com. When buying or updating an RStudio license, you must provide the AWS Account that will host your Amazon SageMaker Domain.
   
   If you have an existing RStudio license, contact your RStudio Sales representative or sales@rstudio.com to add RStudio on Amazon SageMaker to your existing RStudio Workbench Enterprise license, or to convert your RStudio Workbench Standard license. The RStudio Sales representative will send you the appropriate electronic order form.

2. RStudio grants a RStudio Workbench license to your AWS Account through AWS License Manager in the US East (N. Virginia) Region. Although the RStudio license is granted in the US East (N. Virginia) Region, your license can be consumed in any AWS Region that RStudio on Amazon SageMaker is supported in. You can expect the license grant process to complete within three business days after you share your AWS account ID with RStudio.

3. When this license is granted, you receive an email from your RStudio Sales representative with instructions to accept your license grant.

**Validate your RStudio license to be used with Amazon SageMaker**

1. Log into the AWS License Manager console in the same region as your Amazon SageMaker Domain. If you are using AWS License Manager for the first time, you need to grant permission to use AWS License Manager.

2. Select Create Customer managed license.

3. Select I grant AWS License Manager the required permissions and select Grant Permissions.

4. Navigate to Granted Licenses on the left panel.

5. Select the license grant with RSW-SageMaker as the Product name and select View.

6. From the license detail page, select Accept & activate license.

**RStudio administrative dashboard**

You can use the RStudio administrative dashboard to see the number of users on the license following the steps in RStudio administrative dashboard (p. 207).

**Upgrade the RStudio Version**

In this guide, you'll get information about the latest version update for RStudio on SageMaker. You must update your version to provide continued functionality. To upgrade to the latest RStudio version on Amazon SageMaker, complete the steps in Shut down and restart RStudio (p. 208).

**Latest version updates**

The updated RStudio version is 2022.02.2-485.pro2. This version supports:
• Enhanced R help system, introduced with R 4.2.0.
• Added editor support for the R pipe-bind placeholder (\_).
• Encryption between RStudioServerPro and RSessions. This update requires upgrading existing RStudio-enabled SageMaker domains. For more information, see Upgrade Scenarios (p. 185).

All newly created SageMaker domains with RStudio and RSessions support this new version. To use this new version with existing SageMaker domains with RStudio, you must relaunch your RStudioServerPro application. For more information about the changes in this release, see the RStudio Release Notes.

Upgrade Scenarios

All new RStudio applications are created using the 2022.02.2-485.pro2 release. The RStudioServerPro application is deployed when the domain is created, and it persists unless it's deleted. If you have an existing RStudio-enabled domain, you must upgrade the RStudioServerPro application to support end-to-end encryption with new RSessions. If you create a new domain, you don't need to upgrade.

Your upgrade status is one of the following:

• If you create a new domain with RStudio Enabled: RStudio applications for newly created domains are created using the 2022.02.2-485.pro2 release and support end-to-end encryption. No further action is required.
• You have a pre-existing SageMaker domain with RStudio and update the RStudioServerPro App: This enables end-to-end encryption and requires no further changes for new RSessions. You must delete and re-create your existing RSessions applications.
• You have a pre-existing SageMaker domain with RStudio and do not update the RStudioServerPro App: If you don’t update your application, there is a version mismatch with all new RSessions. There may be functionality issues because of the version mismatch. Traffic encryption between RStudioServerPro and RSessions is also not available. We recommend that you update your RStudioServerPro application to the new version.

Changes to BYOI Images

If you are using a BYOI image with RStudio, you must upgrade your custom images to use the 2022.02.2-485.pro2 release and redeploy your existing RSessions. If you attempt to load a non-compatible image in an RSessions of a domain using the 2022.02.2-485.pro2 version, the RSessions fails because it cannot parse parameters that it receives. Your RSessions will not function properly and will not support end-to-end encryption. You must update all of the deployed custom images in your existing RStudioServerPro app.

Network and Storage

The following topic describes network access and data storage considerations for your RStudio instance. For general information about network access and data storage when using Amazon SageMaker, see Data Protection in Amazon SageMaker (p. 3495).

Encryption

RStudio on Amazon SageMaker supports encryption at rest.

Use RStudio in VPC-only mode

RStudio in Amazon SageMaker supports AWS PrivateLink integration. With this integration, you can use RStudio on SageMaker in VPC-only mode without direct access to the internet. When you use
RStudio in VPC-only mode, your security groups are automatically managed by the service. This includes connectivity between your RServer and your RSessions.

The following are required to use RStudio in VPC-only mode. For more information on selecting a VPC, see Choose a VPC (p. 42).

- A private subnet with either access the internet to make a call to Amazon SageMaker & License Manager, or Amazon Virtual Private Cloud (Amazon VPC) endpoints for both Amazon SageMaker & License Manager.
- A Security Group ID for use with the Domain in Domain Settings. This must allow all outbound access.
- A Security Group ID for use with the Amazon VPC endpoint. This security group must allow inbound traffic from the Domain Security Group ID.
- Amazon VPC Endpoint for sagemaker.api and AWS License Manager. This must be in the same Amazon VPC as the private subnet.

RStudioServerPro instance type

When deciding which Amazon EC2 instance type to use for your RStudioServerPro app, the main factor to consider is bandwidth. Bandwidth is important because the RStudioServerPro instance is responsible for serving the RStudio UI to all users. This includes UI heavy workflows, such as generating figures, animations, and displaying many data rows. Therefore, there may be some UI performance degradation depending on the workload across all users. The following are the available instance types to use for your RStudioServerPro. For pricing information about these instances, see Amazon SageMaker Pricing.

- `ml.t3.medium`: This instance type is recommended for Domains with low UI use and is free to use.
- `ml.c5.4xlarge`: This instance type is recommended for Domains with moderate UI use.
- `ml.c5.9xlarge`: This instance type is recommended for Domains with heavy UI use.

Changing RStudio instance type

To change the instance type of your RStudioServerPro, pass the new instance type as part of a call to the `update-domain` CLI command. You then need to delete the existing RStudioServerPro app using the `delete-app` CLI command and create a new RStudioServerPro app using the `create-app` CLI command.

RStudio Connect URL

RStudio Connect is a publishing platform for Shiny applications, R Markdown reports, dashboards, plots, and more. RStudio Connect makes it easy to surface machine learning and data science insights by making hosting content simple and scalable. If you have an RStudio Connect server, then you can set the server as the default place where apps are published. For more information about RStudio Connect, see RStudio Connect.

When you onboard to RStudio on Amazon SageMaker Domain, an RStudio Connect server is not created. You can create an RStudio Connect server on an Amazon EC2 instance to use Connect with Amazon SageMaker Domain. For information about how to set up your RStudio Connect server, see Host RStudio Connect and Package Manager for ML development in RStudio on Amazon SageMaker.

Add an RStudio Connect URL

If you have an RStudio Connect URL, you can update the default URL so that your RStudio Users can publish to it.

1. Navigate to the Control Panel.
2. Under Domain, choose **Edit Settings**. This opens a new page.
3. From the new page, select **RStudio Settings** on the left side.
4. Under **RStudio Connect URL**, enter the RStudio Connect URL to add.
5. Select **Submit**.

**CLI**

You can set a default RStudio Connect URL when you create your Amazon SageMaker Domain. The only way to update your RStudio Connect URL from the AWS CLI is to delete your Domain and create a new one with the updated RStudio Connect URL.

**RStudio Package Manager**

RStudio Package Manager is a repository management server used to organize and centralize packages across your organization. For more information on RStudio Package Manager, see [RStudio Package Manager](#). If you don’t supply your own Package Manager URL, Amazon SageMaker Domain uses the default Package Manager repository when you onboard RStudio following the steps in [Onboard to Amazon SageMaker Domain](#) (p. 35). For more information, see [Host RStudio Connect and Package Manager for ML development in RStudio on Amazon SageMaker](#).

**Update Package Manager URL**

You can update the Package Manager URL used for your RStudio-enabled Domain as follows.

1. Navigate to the **Control Panel**.
2. Under Domain, select **Edit Settings**. This opens a new page.
3. From the new page, select **RStudio Settings** on the left side.
4. Under **RStudio Package Manager**, enter your RStudio Package Manager URL.
5. Select **Submit**.

**CLI**

The only way to update your Package Manager URL from the AWS CLI is to delete your Domain and create a new one with the updated Package Manager URL.

**Create an Amazon SageMaker Domain with RStudio using the AWS CLI**

The following topic shows how to onboard to Amazon SageMaker Domain with RStudio enabled using the AWS CLI. To onboard using the AWS Management Console, see [Onboard to Amazon SageMaker Domain](#) (p. 35).

**Prerequisites**

- Install and configure **AWS CLI version 2**
- Configure the **AWS CLI** with IAM credentials

**Create DomainExecution role**

To launch the RStudio App, you must provide a DomainExecution role. This role is used to determine whether RStudio needs to be launched as part of Amazon SageMaker Domain creation. This role is also used by Amazon SageMaker to access the RStudio License and push RStudio logs.
Note
The DomainExecution role should have at least AWS License Manager permissions to access RStudio License, and CloudWatch permissions to push logs in your account.

The following procedure shows how to create the DomainExecution role with the AWS CLI.

1. Create a file named assume-role-policy.json with the following content.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Action": "sts:AssumeRole",
         "Effect": "Allow",
         "Principal": {
            "Service": ["sagemaker.amazonaws.com"]
         }
      }
   ]
}
```

2. Create the DomainExecution role. `<REGION>` should be the AWS Region to launch your Domain in.

```bash
aws iam create-role --region <REGION> --role-name DomainExecution --assume-role-policy-document file://assume-role-policy.json
```

3. Create a file named domain-setting-policy.json with the following content. This policy allows the RStudioServerPro app to access necessary resources and allows Amazon SageMaker to automatically launch an RStudioServerPro app when the existing RStudioServerPro app is in a Deleted or Failed status.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "VisualEditor0",
         "Effect": "Allow",
         "Action": ["license-manager:ExtendLicenseConsumption",
                    "license-manager:ListReceivedLicenses",
                    "license-manager:GetLicense",
                    "license-manager:CheckoutLicense",
                    "license-manager:CheckInLicense",
                    "logs:CreateLogDelivery",
                    "logs:CreateLogGroup",
                    "logs:CreateLogStream",
                    "logs:DeleteLogDelivery",
                    "logs:Describe*",
                    "logs:GetLogDelivery",
                    "logs:GetLogEvents",
                    "logs:ListLogDeliveries",
                    "logs:PutLogEvents",
                    "logs:PutResourcePolicy",
                    "logs:UpdateLogDelivery",
                    "sagemaker:CreateApp"
         ],
         "Resource": "**"
      }
   ]
}
```
4. Create the Domain setting policy that is attached to the DomainExecution role. Be aware of the PolicyArn from the response, you will need to enter that ARN in the following steps.

```bash
aws iam create-policy --region <REGION> --policy-name domain-setting-policy --policy-document file://domain-setting-policy.json
```

5. Attach domain-setting-policy to the DomainExecution role. Use the PolicyArn returned in the previous step.

```bash
aws iam attach-role-policy --role-name DomainExecution --policy-arn <POLICY_ARN>
```

### Create Amazon SageMaker Domain with RStudio App

The RStudioServerPro app is launched automatically when you create a Amazon SageMaker Domain using the `create-domain` CLI command with the `RStudioServerProDomainSettings` parameter specified. When launching the RStudioServerPro App, Amazon SageMaker checks for a valid RStudio license in the account and fails Domain creation if the license is not found.

The creation of a Amazon SageMaker Domain differs based on the authentication method and the network type. These options must be used together, with one authentication method and one network connection type selected. For more information about the requirements to create a new Domain, see CreateDomain.

The following authentication methods are supported.

- IAM Auth
- SSO Auth

The following network connection types are supported:

- PublicInternet
- VPCOnly

#### Authentication methods

##### IAM Auth Mode

The following shows how to create a Amazon SageMaker Domain with RStudio enabled and an IAM Auth Network Type. For more information about AWS Identity and Access Management, see What is IAM?

- DomainExecutionRoleArn should be the ARN for the role created in the previous step.
- ExecutionRole is the ARN of the role given to users in the Amazon SageMaker Domain.
- vpc-id should be the ID of your Amazon Virtual Private Cloud. subnet-ids should be a space-separated list of subnet IDs. For information about vpc-id and subnet-ids, see VPCs and subnets.
- RStudioPackageManagerUrl and RStudioConnectUrl are optional and should be set to the URLs of your RStudio Package Manager and RStudio Connect server, respectively.
- app-network-access-type should be either PublicInternetOnly or VPCOnly.

```bash
aws sagemaker create-domain --region <REGION> --domain-name <DOMAIN_NAME> \
--auth-mode IAM \
--default-user-settings ExecutionRole=<DEFAULT_USER_EXECUTIONROLE> \
```
Amazon SageMaker Developer Guide
Manage RStudio on SageMaker

Authentication using IAM Identity Center

The following shows how to create a Amazon SageMaker Domain with RStudio enabled and an SSO Auth Network Type. AWS IAM Identity Center (successor to AWS Single Sign-On) must be enabled for the region that the domain is launched on. For more information about IAM Identity Center, see What is AWS IAM Identity Center (successor to AWS Single Sign-On)?.

- DomainExecutionRoleArn should be the ARN for the role created in the previous step.
- ExecutionRole is the ARN of the role given to users in the Amazon SageMaker Domain.
- vpc-id should be the ID of your Amazon Virtual Private Cloud. subnet-ids should be a space-separated list of subnet IDs. For information about vpc-id and subnet-ids, see VPCs and subnets.
- RStudioPackageManagerUrl and RStudioConnectUrl are optional and should be set to the URLs of your RStudio Package Manager and RStudio Connect server, respectively.
- app-network-access-type should be either PublicInternetOnly or VPCOnly.

```
aws sagemaker create-domain --region <REGION> --domain-name <DOMAIN_NAME> \
--auth-mode SSO \ 
--default-user-settings ExecutionRole=<DEFAULT_USER_EXECUTIONROLE> \ 
--domain-settings 
RStudioServerProDomainSettings={RStudioPackageManagerUrl=<PACKAGE_MANAGER_URL>,RStudioConnectUrl=<CONNECT_URL> \ 
---vpc-id <VPC_ID> \ 
--subnet-ids <SUBNET_IDS> \ 
--app-network-access-type <NETWORK_ACCESS_TYPE>
```

Connection types

PublicInternet/Direct Internet network type

The following shows how to create a Amazon SageMaker Domain with RStudio enabled and a PublicInternet Network Type.

- DomainExecutionRoleArn should be the ARN for the role created in the previous step.
- ExecutionRole is the ARN of the role given to users in the Amazon SageMaker Domain.
- vpc-id should be the ID of your Amazon Virtual Private Cloud. subnet-ids should be a space-separated list of subnet IDs. For information about vpc-id and subnet-ids, see VPCs and subnets.
- RStudioPackageManagerUrl and RStudioConnectUrl are optional and should be set to the URLs of your RStudio Package Manager and RStudio Connect server, respectively.
- auth-mode should be either SSO or IAM.

```
aws sagemaker create-domain --region <REGION> --domain-name <DOMAIN_NAME> \
--auth-mode <AUTH_MODE> \ 
--default-user-settings ExecutionRole=<DEFAULT_USER_EXECUTIONROLE> \ 
--domain-settings 
RStudioServerProDomainSettings={RStudioPackageManagerUrl=<PACKAGE_MANAGER_URL>,RStudioConnectUrl=<CONNECT_URL> \ 
---vpc-id <VPC_ID> \ 
```
VPCOnly mode

The following shows how to launch a Amazon SageMaker Domain with RStudio enabled and a VPCOnly Network Type. For more information about using the VPCOnly network access type, see Connect SageMaker Studio Notebooks in a VPC to External Resources (p. 3631).

- DomainExecutionRoleArn should be the ARN for the role created in the previous step.
- ExecutionRole is the ARN of the role given to users in the Amazon SageMaker Domain.
- vpc-id should be the ID of your Amazon Virtual Private Cloud. subnet-ids should be a space-separated list of subnet IDs. Your private subnet must be able to either access the internet to make a call to Amazon SageMaker, and AWS License Manager or have Amazon VPC endpoints for both Amazon SageMaker and AWS License Manager. For information about Amazon VPC endpoints, see Interface Amazon VPC endpoints For information about vpc-id and subnet-ids, see VPCs and subnets.
- SecurityGroups must allow outbound access to the Amazon SageMaker and AWS License Manager endpoints.
- auth-mode should be either SSO or IAM.

Note
When using Amazon Virtual Private Cloud endpoints, the security group attached to your Amazon Virtual Private Cloud endpoints must allow inbound traffic from the security group you pass as part of the domain-setting parameter of the create-domain CLI call.

With RStudio, Amazon SageMaker manages security groups for you. This means that Amazon SageMaker manages security group rules to ensure RSessions can access RStudioServerPro Apps. Amazon SageMaker creates one security group rule per user profile.

```
aws sagemaker create-domain --region <REGION> --domain-name <DOMAIN_NAME> \
  --auth-mode <AUTH_MODE> \
  --default-user-settings SecurityGroups=<USER_SECURITY_GROUP>,ExecutionRole=<DEFAULT_USER_EXECUTIONROLE> \
  --domain-settings SecurityGroupIds=<DOMAIN_SECURITY_GROUP>,RStudioServerProDomainSettings={DomainExecutionRoleArn=<DOMAINEXECUTION_ROLE_ARN> \
    --vpc-id <VPC_ID> \
    --subnet-ids "<SUBNET_IDS>" \
    --app-network-access-type VPCOnly --app-security-group-management Service
```

Note: The RStudioServerPro app is launched by a special user profile named domain-shared. As a result, this app is not returned as part of list-app API calls by any other user profiles.

You may have to increase the Amazon VPC quota in your account to increase the number of users. For more information, see Amazon VPC quotas.

Verify Domain creation

Use the following command to verify that your Domain has been created with a Status of InService. Your domain-id is appended to the Domains ARN. For example, arn:aws:sagemaker:<REGION>:<ACCOUNT_ID>:domain/<DOMAIN_ID>.

```
aws sagemaker describe-domain --domain-id <DOMAIN_ID> --region <REGION>
```
Bring your own image to RStudio on SageMaker

A SageMaker image is a file that identifies language packages and other dependencies that are required to run RStudio on Amazon SageMaker. SageMaker uses these images to create an environment where you run RStudio. Amazon SageMaker provides a built-in RStudio image for you to use. If you need different functionality, you can bring your own custom images.

The process to bring your own image to use with RStudio on SageMaker takes three steps:

1. Build a custom image from a Dockerfile and push it to a repository in Amazon Elastic Container Registry (Amazon ECR).
2. Create a SageMaker image that points to a container image in Amazon ECR and attach it to your SageMaker domain.
3. Launch a new session in RStudio with your custom image.

You can create images and image versions, and attach image versions to your domain, using the SageMaker control panel, the AWS SDK for Python (Boto3), and the AWS Command Line Interface (AWS CLI). You can also create images and image versions using the SageMaker console, even if you haven’t onboarded to a domain.

The following topics show how to bring your own image to RStudio on SageMaker by creating, attaching, and launching a custom image.

Key terminology

The following section defines key terms for bringing your own image to use with RStudio on SageMaker.

- **Dockerfile**: A Dockerfile is a file that identifies the language packages and other dependencies for your Docker image.
- **Docker image**: The Docker image is a built Dockerfile. This image is checked into Amazon ECR and serves as the basis of the SageMaker image.
- **SageMaker image**: A SageMaker image is a holder for a set of SageMaker image versions based on Docker images.
- **Image version**: An image version of a SageMaker image represents a Docker image that is compatible with RStudio and stored in an Amazon ECR repository. Each image version is immutable. These image versions can be attached to a domain and used with RStudio on SageMaker.

Prerequisites

You must complete the following prerequisites before bringing your own image to use with RStudio on Amazon SageMaker.

- If you have an existing domain with RStudio that was created before April 7, 2022, you must delete your RStudioServerPro application and recreate it. For information about how to delete an application, see Shut down and Update SageMaker Studio (p. 179).
- Install the Docker application. For information about setting up Docker, see Orientation and setup.
- Create a local copy of an RStudio-compatible Dockerfile that works with SageMaker. For information about creating a sample RStudio dockerfile, see Use a custom image to bring your own development environment to RStudio on Amazon SageMaker.
- Use an AWS Identity and Access Management execution role that has the AmazonSageMakerFullAccess policy attached. If you have onboarded to Amazon SageMaker domain, you can get the role from the Domain Summary section of the SageMaker control panel.

Add the following permissions to access the Amazon Elastic Container Registry (Amazon ECR) service to your execution role.
Custom RStudio image specifications

In this guide, you'll learn custom RStudio image specifications to use when you bring your own image. There are two sets of requirements that you must satisfy with your custom RStudio image to use it with Amazon SageMaker. These requirements are imposed by RStudio PBC and the Amazon SageMaker Studio platform. If either of these sets of requirements aren't satisfied, then your custom image won't function properly.

**RStudio PBC requirements**

RStudio PBC requirements are laid out in the Using Docker images with RStudio Workbench / RStudio Server Pro, Launcher, and Kubernetes article. Follow the instructions in this article to create the base of your custom RStudio image.

For instructions about how to install multiple R versions in your custom image, see Installing multiple versions of R on Linux.

**Amazon SageMaker Studio requirements**

Amazon SageMaker Studio imposes the following set of installation requirements for your RStudio image.

- You must use an RStudio base image of at least 2022.02.2-485.pro2. For more information, see Upgrade the RStudio Version (p. 184).
- You must install the following packages:

```bash
yum install -y sudo \
openjdk-11-jdk \
libpng-dev \
```
& & yum clean all \
& & /opt/R/${R_VERSION}/bin/R -e "install.packages('reticulate', repos='https://
packagemanager.rstudio.com/cran/_/centos7/latest')" \
& & /opt/python/${PYTHON_VERSION}/bin/pip install --upgrade \
  'boto3>1.0<2.0' \
  'awscli>1.0<2.0' \
  'sagemaker[local]<3'

- You must provide default values for the RSTUDIO_CONNECT_URL and
  RSTUDIO_PACKAGE_MANAGER_URL environment values.

| ENV RSTUDIO_CONNECT_URL "YOUR_CONNECT_URL" |
| ENV RSTUDIO_PACKAGE_MANAGER_URL "YOUR_PACKAGE_MANAGER_URL" |

The following general specifications apply to the image that is represented by an RStudio image version.

**Running the image**

ENTRYPOINT and CMD instructions are overridden so that the image is run as an RSession application.

**Stopping the image**

The DeleteApp API issues the equivalent of a docker stop command. Other processes in the container won't get the SIGKILL/SIGTERM signals.

**File system**

The /opt/.sagemakerinternal and /opt/ml directories are reserved. Any data in these directories might not be visible at runtime.

**User data**

Each user in a SageMaker domain gets a user directory on a shared Amazon Elastic File System volume in the image. The location of the current user's directory on the Amazon Elastic File System volume is /home/sagemaker-user.

**Metadata**

A metadata file is located at /opt/ml/metadata/resource-metadata.json. No additional environment variables are added to the variables defined in the image. For more information, see Get App Metadata (p. 140).

**GPU**

On a GPU instance, the image is run with the --gpus option. Only the CUDA toolkit should be included in the image, not the NVIDIA drivers. For more information, see NVIDIA User Guide.

**Metrics and logging**

Logs from the RSession process are sent to Amazon CloudWatch in the customer's account. The name of the log group is /aws/sagemaker/studio. The name of the log stream is $domainID/$userProfileName/RSession/$appName.

**Image size**

Image size is limited to 25 GB. To view the size of your image, run docker image ls.

**Create a custom RStudio image**

This topic describes how you can create a custom RStudio image using the SageMaker console and the AWS CLI. If you use the AWS CLI, you must run the steps from your local machine. The following steps do not work from within Amazon SageMaker Studio.
When you create an image, SageMaker also creates an initial image version. The image version represents a container image in Amazon Elastic Container Registry (ECR). The container image must satisfy the requirements to be used in RStudio. For more information, see Custom RStudio image specifications (p. 193).

For information about testing your image locally and resolving common issues, see the SageMaker Studio Custom Image Samples repo.

Topics
- Add a SageMaker-compatible RStudio Docker container image to Amazon ECR (p. 195)
- Create a SageMaker image from the console (p. 196)
- Create an image from the AWS CLI (p. 197)

Add a SageMaker-compatible RStudio Docker container image to Amazon ECR

Use the following steps to add a Docker container image to Amazon ECR:

- Create an Amazon ECR repository.
- Authenticate to Amazon ECR.
- Build a SageMaker-compatible RStudio Docker image.
- Push the image to the Amazon ECR repository.

**Note**
The Amazon ECR repository must be in the same AWS Region as your domain.

To build and add a Docker image to Amazon ECR

1. Create an Amazon ECR repository using the AWS CLI. To create the repository using the Amazon ECR console, see Creating a repository.

   ```bash
   aws ecr create-repository --repository-name rstudio-custom --image-scanning-configuration scanOnPush=true
   ```

   Response:

   ```json
   {
     "repository": {
       "repositoryArn": "arn:aws:ecr:us-east-2:acct-id:repository/rstudio-custom",
       "registryId": "acct-id",
       "repositoryName": "rstudio-custom",
       "repositoryUri": "acct-id.dkr.ecr.us-east-2.amazonaws.com/rstudio-custom",
       ...
     }
   }
   ```

2. Authenticate to Amazon ECR using the repository URI returned as a response from the create-repository command. Make sure that the Docker application is running. For more information, see Registry Authentication.

   ```bash
   aws ecr get-login-password | \
   docker login --username AWS --password-stdin <repository-uri>
   ```

   Response:
3. **Build the Docker image.** Run the following command from the directory that includes your Dockerfile.

   ```bash
docker build .
   ``

4. **Tag your built image with a unique tag.**

   ```bash
docker tag <image-id> "<repository-uri>:<tag>"
   ``

5. **Push the container image to the Amazon ECR repository.** For more information, see ImagePush and Pushing an image.

   ```bash
docker push <repository-uri>:<tag>
   ``

   **Response:**

   ```
The push refers to repository [<account-id>.dkr.ecr.us-east-2.amazonaws.com/rstudio-custom]
r: digest: <digest> size: 3066
   ```

---

**Create a SageMaker image from the console**

**To create an image**

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the left navigation pane, choose **Images**.
3. On the **Custom images** page, choose **Create image**.
4. For **Image source**, enter the registry path to the container image in Amazon ECR. The path is in the following format:

   ```
   acct-id.dkr.ecr.region.amazonaws.com/repo-name[:tag] or [@digest]
   ```

5. Choose **Next**.
6. Under **Image properties**, enter the following:

   - **Image name** – The name must be unique to your account in the current AWS Region.
   - (Optional) **Image display name** – The name displayed in the domain user interface. When not provided, Image name is displayed.
   - (Optional) **Description** – A description of the image.
   - **IAM role** – The role must have the AmazonSageMakerFullAccess policy attached. Use the dropdown menu to choose one of the following options:
     - Create a new role – Specify any additional Amazon Simple Storage Service (Amazon S3) buckets that you want your notebooks users to access. If you don't want to allow access to additional buckets, choose **None**.
     - Enter a custom IAM role ARN – Enter the Amazon Resource Name (ARN) of your IAM role.
     - Use existing role – Choose one of your existing roles from the list.
   - (Optional) **Image tags** – Choose **Add new tag**. You can add up to 50 tags. Tags are searchable using the SageMaker console or the SageMaker Search API.
8. Choose **Submit**.

The new image is displayed in the **Custom images** list and briefly highlighted. After the image has been successfully created, you can choose the image name to view its properties or choose **Create version** to create another version.

**To create another image version**

1. Choose **Create version** on the same row as the image.
2. For **Image source**, enter the registry path to the Amazon ECR image. The image shouldn't be the same image as used in a previous version of the SageMaker image.

To use the custom image in RStudio, you must attach it to your domain. For more information, see **Attach a custom SageMaker image** (p. 198).

**Create an image from the AWS CLI**

This section shows how to create a custom Amazon SageMaker image using the AWS CLI.

Use the following steps to create a SageMaker image:

- Create an Image.
- Create an ImageVersion.
- Create a configuration file.
- Create an AppImageConfig.

**To create the SageMaker image entities**

1. Create a SageMaker image. The role ARN must have at least the AmazonSageMakerFullAccessPolicy policy attached.

   ```bash
   aws sagemaker create-image \
   --image-name rstudio-custom-image \
   --role-arn arn:aws:iam::<acct-id>:role/service-role/<execution-role>
   ```

   **Response:**

   ```json
   {
     "ImageArn": "arn:aws:sagemaker:us-east-2:<acct-id>:image/rstudio-custom-image"
   }
   ```

2. Create a SageMaker image version from the image. Pass the unique tag value that you chose when you pushed the image to Amazon ECR.

   ```bash
   aws sagemaker create-image-version \
   --image-name rstudio-custom-image \
   --base-image <repository-uri>:@<tag>
   ```

   **Response:**

   ```json
   {
   }
   ```
3. Check that the image version was successfully created.

```sh
aws sagemaker describe-image-version \
  --image-name rstudio-custom-image \
  --version 1
```

Response:

```json
{
  "ImageVersionStatus": "CREATED"
}
```

**Note**

If the response is "ImageVersionStatus": "CREATED_FAILED", the response also includes the failure reason. A permissions issue is a common cause of failure. You also can check your Amazon CloudWatch Logs. The name of the log group is /aws/sagemaker/studio. The name of the log stream is $domainID/$userProfileName/KernelGateway/$appName.

4. Create a configuration file, named `app-image-config-input.json`. The app image config is used to configuration for running a SageMaker image as a Kernel Gateway application.

```json
{
  "AppImageConfigName": "rstudio-custom-config"
}
```

5. Create the AppImageConfig using the file that you created in the previous step.

```sh
aws sagemaker create-app-image-config \
  --cli-input-json file://app-image-config-input.json
```

Response:

```json
{
}
```

**Attach a custom SageMaker image**

This guide shows how to attach a custom RStudio image to your domain using the SageMaker console or the AWS Command Line Interface (AWS CLI).

To use a custom SageMaker image, you must attach a custom RStudio image to your domain. When you attach an image version, it appears in the RStudio Launcher and is available in the Select image dropdown list. You use the dropdown to change the image used by RStudio.

There is a limit to the number of image versions that you can attach. After you reach the limit, you must first detach a version so that you can attach a different version of the image.

**Topics**

- Attach an image version to your domain using the console (p. 199)
• Attach an existing image version to your domain using the AWS CLI (p. 199)

Attach an image version to your domain using the console

You can attach a custom SageMaker image version to your domain using the console's control panel. You can also create a custom SageMaker image, and an image version, and then attach that version to your domain.

To attach an existing image

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the left navigation pane, choose Control panel.
4. For Image source, choose Existing image or New image.

   If you select Existing image, choose an image from the Amazon SageMaker image store.

   If you select New image, provide the Amazon ECR registry path for your Docker image. The path must be in the same AWS Region as the domain. The Amazon ECR repo must be in the same account as your domain, or cross-account permissions for SageMaker must be enabled.

5. Choose an existing image from the list.
6. Choose a version of the image from the list.
7. Choose Next.
8. Enter values for Image name, Image display name, and Description.
9. Choose the IAM role. For more information, see Create a custom RStudio image (p. 194).
10. (Optional) Add tags for the image.
11. (Optional) Choose Add new tag, then add a configuration tag.
12. For Image type, select RStudio Image.
13. Choose Submit.

Wait for the image version to be attached to the domain. After the version is attached, it appears in the Custom images list and is briefly highlighted.

Attach an existing image version to your domain using the AWS CLI

Two methods are presented to attach the image version to your domain using the AWS CLI. In the first method, you create a new domain with the version attached. This method is simpler but you must specify the Amazon Virtual Private Cloud (Amazon VPC) information and execution role that's required to create the domain.

If you have already onboarded to the SageMaker domain, you can use the second method to attach the image version to your current domain. In this case, you don't need to specify the Amazon VPC information and execution role. After you attach the version, delete all of the applications in your domain and relaunch RStudio.

Attach the SageMaker image to a new domain

To use this method, you must specify an execution role that has the AmazonSageMakerFullAccess policy attached.

Note
You can have only one domain. If you have onboarded to a SageMaker domain, you must delete your current domain before you can use this method. For more information, see Delete an Amazon SageMaker Domain (p. 43).
Use the following steps to create the domain and attach the custom SageMaker image:

- Get your default VPC ID and subnet IDs.
- Create the configuration file for the domain, which specifies the image.
- Create the domain with the configuration file.

**To add the custom SageMaker image to your domain**

1. Get your default VPC ID.
   
   ```
   aws ec2 describe-vpcs \
   --filters Name=isDefault,Values=true \
   --query "Vpcs[0].VpcId" --output text
   ```
   
   Response:
   
   `vpc-xxxxxxxx`

2. Get your default subnet IDs using the VPC ID from the previous step.

   ```
   aws ec2 describe-subnets \
   --filters Name=vpc-id,Values=<vpc-id> \
   --query "Subnets[*].SubnetId" --output json
   ```
   
   Response:
   
   `[
   "subnet-b55171dd",
   "subnet-8a5f99c6",
   "subnet-e88d1392"
   ]`

3. Create a configuration file named `create-domain-input.json`. Insert the VPC ID, subnet IDs, `ImageName`, and `AppImageConfigName` from the previous steps. Because `ImageVersionNumber` isn’t specified, the latest version of the image is used, which is the only version in this case. Your execution role must satisfy the requirements in Prerequisites (p. 192).

   ```
   {
   "DomainName": "domain-with-custom-r-image",
   "VpcId": "<vpc-id>",
   "SubnetIds": [ "<subnet-ids>" ],
   "DomainSettings": {
   "RStudioServerProDomainSettings": {
   "DomainExecutionRoleArn": "<execution-role>"
   }
   },
   "DefaultUserSettings": {
   "ExecutionRole": "<execution-role>",
   "RSessionAppSettings": {
   "CustomImages": [
   { "AppImageConfigName": "rstudio-custom-config",
   "ImageName": "rstudio-custom-image"
   }]
   }
   }
   ```
4. Create the domain with the attached custom SageMaker image.

```
aws sagemaker create-domain \
   --cli-input-json file://create-domain-input.json
```

Response:

```
{
   "Url": "https://d-xxxxxxxxxxxx.studio.us-east-2.sagemaker.aws/..."
}
```

### Attach the SageMaker image to an existing domain

This method assumes that you've already onboarded to Amazon SageMaker domain. For more information, see [Onboard to Amazon SageMaker Domain](p. 35).

**Note**

You must delete all of the applications in your domain before you update the domain with the new image version. For information about deleting these applications, see [Delete an Amazon SageMaker Domain](p. 45).

Use the following steps to add the SageMaker image to your current domain.

- Get your DomainID from the SageMaker console.
- Use the DomainID to get the DefaultUserSettings for the domain.
- Add the ImageName and AppImageConfig as a CustomImage to the DefaultUserSettings.
- Update your domain to include the custom image.

### To add the custom SageMaker image to your domain

2. From the left navigation pane, choose Control panel.
3. From the Control panel, under Domain, find the Domain ID. The ID is in the following format: d-xxxxxxxxxxxx.
4. Use the domain ID to get the description of the domain.

```bash
aws sagemaker describe-domain \
--domain-id <d-xxxxxxxxxxxxx>
```

Response:

```json
{
  "DomainId": "d-xxxxxxxxxxxxx",
  "DefaultUserSettings": {
    "KernelGatewayAppSettings": {
      "CustomImages": [],
      ...
    },
    ...
  }
}
```

5. Save the `DefaultUserSettings` section of the response to a file named `update-domain-input.json`. 
6. Insert the ImageName and AppImageConfigName from the previous steps as a custom image. Because ImageVersionNumber isn't specified, the latest version of the image is used, which is the only version in this case.

```json
{
    "DefaultUserSettings": {
        "RSessionAppSettings": {
            "CustomImages": [
                {
                    "ImageName": "rstudio-custom-image",
                    "AppImageConfigName": "rstudio-custom-config"
                }
            ]
        }
    }
}
```

7. Use the domain ID and default user settings file to update your domain.

```
aws sagemaker update-domain \
    --domain-id <d-xxxxxxxxxxxx> \
    --cli-input-json file://update-domain-input.json
```

Response:

```json
{
    "DomainArn": "/arn:aws:sagemaker:us-east-2:acct-id:domain/d-xxxxxxxxxxxx"
}
```

8. Delete the RStudioServerPro application. You must restart the RStudioServerPro domain-shared application for the RStudio Launcher UI to pick up the latest changes.

```
aws sagemaker delete-app \
    --domain-id <d-xxxxxxxxxxxx> --user-profile-name domain-shared \
    --app-type RStudioServerPro --app-name default
```

9. Create a new RStudioServerPro application. You must create this application using the AWS CLI.

```
aws sagemaker create-app \
    --domain-id <d-xxxxxxxxxxxx> --user-profile-name domain-shared \
    --app-type RStudioServerPro --app-name default
```

Launch a custom SageMaker image in RStudio

You can use your custom image when launching an RStudio application from the console. After you create your custom SageMaker image and attach it to your domain, the image appears in the image selector dialog box of the RStudio Launcher. To launch a new RStudio app, follow the steps in Open RStudio Launcher and launch RSessions (p. 211) and select your custom image as shown in the following image.
Clean up image resources

This guide shows how to clean up RStudio image resources that you created in the previous sections. To delete an image, complete the following steps using either the SageMaker console or the AWS CLI, as shown in this guide.

- Detach the image and image versions from your domain.
- Delete the image, image version, and app image config.

After you've completed these steps, you can delete the container image and repository from Amazon ECR. For more information about how to delete the container image and repository, see Deleting a repository.

Clean up resources from the SageMaker console

When you detach an image from a domain, all versions of the image are detached. When an image is detached, all users of the domain lose access to the image versions.

To detach an image

1. In the SageMaker control panel, under Custom images attached to domain, choose the image and then choose Detach.
2. (Optional) To delete the image and all versions from SageMaker, select Also delete the selected images .... This does not delete the associated images from Amazon ECR.
3. Choose Detach.

Clean up resources from the AWS CLI

To clean up resources

1. Detach the image and image versions from your domain by passing an empty custom image list to the domain. Open the update-domain-input.json file that you created in ?? (p. 161).
2. Delete the RSessionAppSettings custom images and then save the file. Do not modify the KernelGatewayAppSettings custom images.

```json
{
    "DomainId": "d-xxxxxxxxxxxx",
    "DefaultUserSettings": {
        "KernelGatewayAppSettings": {
            "CustomImages": []
        }
    }
}
```
3. Use the domain ID and default user settings file to update your domain.

```bash
aws sagemaker update-domain \
--domain-id <d-xxxxxxxxxxxx> \
--cli-input-json file://update-domain-input.json
```

Response:

```json
{
  "DomainArn": "arn:aws:sagemaker:us-east-2:acct-id:domain/d-xxxxxxxxxxxx"
}
```

4. Delete the app image config.

```bash
aws sagemaker delete-app-image-config \
--app-image-config-name rstudio-image-config
```

5. Delete the SageMaker image, which also deletes all image versions. The container images in Amazon ECR that are represented by the image versions are not deleted.

```bash
aws sagemaker delete-image \
--image-name rstudio-image
```

### Manage users

After your RStudio-enabled Amazon SageMaker Domain is running, you can add user profiles (UserProfiles) to the Domain. The following topics show how to create user profiles that are authorized to use RStudio, as well as update an existing user profile. For information on how to delete an RStudio App, UserProfile, or Domain, follow the steps in [Delete an Amazon SageMaker Domain](#).

**Note**

The limit for the total number of UserProfiles in a Amazon SageMaker Domain is 60.

There are two types of users:

- Unauthorized: This user cannot access the RStudio app.
- Authorized: This user can access the RStudio app and use one of the RStudio license seats. By default, a new user is Authorized if the Domain is enabled for RStudio.

If a user is authorized, they can be given one of the following levels of access to RStudio:

- RStudio User: This is a standard RStudio user and can access RStudio.
- RStudio Admin: The admin of your Amazon SageMaker Domain has the ability to create users, add existing users, and update the permissions of existing users. Admins can also access the RStudio
Administrative dashboard. However, this admin is not able to update parameters that are managed by Amazon SageMaker.

Methods to create a user

The following topics show how to create a user in your RStudio-enabled Amazon SageMaker Domain.

Create user IAM

The following procedure shows how to add users to a Amazon SageMaker Domain created using IAM. For more information about using IAM with Amazon SageMaker, see How Amazon SageMaker Works with IAM.

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Navigate to the Control Panel.
3. Select Add user. This opens a new User Settings page.
4. Under User profile, enter a name for your user and select an IAM role. You can create a new IAM role or use an existing role. The IAM role must have the AmazonSageMakerFullAccess policy attached.
5. Select Next.
6. Under SageMaker Projects and Jumpstart, select whether to enable Amazon SageMaker project templates and Amazon SageMaker JumpStart for Studio users.
7. Select Next.
8. Under RStudio Workbench, verify that an RStudio Workbench license is detected.
9. Under License Authorization, select whether you want to create the user with one of the following authorizations.
   - Unauthorized
   - RStudio Admin
   - RStudio User
10. Select Submit.

Create user using IAM Identity Center

The following procedure shows how to add users to a Amazon SageMaker Domain created using AWS IAM Identity Center (successor to AWS Single Sign-On). For information about AWS IAM Identity Center (successor to AWS Single Sign-On), see What is AWS IAM Identity Center (successor to AWS Single Sign-On).

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Navigate to the Control Panel.
3. Select Assign users and groups. This opens a new Assign users and groups page.
4. Select a user or group from the list. For information about adding users and groups, see Manage identities in AWS IAM Identity Center.
5. Select Assign users and groups.

Create user CLI

The following command shows how to add users to a Amazon SageMaker Domain with IAM authentication. A User can belong to either the R_STUDIO_USER or R_STUDIO_ADMIN User group.

```bash
aws sagemaker create-user-profile --region <REGION> \
  --domain-id <DOMAIN-ID> \
  --user-profile-name <USER_PROFILE_NAME-ID>
```
The following command shows how to add users to a Amazon SageMaker Domain with authentication using IAM Identity Center. A user can belong to either the R_STUDIO_USER or R_STUDIO_ADMIN User group.

```
aws sagemaker create-user-profile --region <REGION>  
   --domain-id <DOMAIN-ID>  
   --user-profile-name <USER_PROFILE_NAME-ID>  
   --user-settings RStudioServerProAppSettings={UserGroup=<USER-GROUP>}  
   --single-sign-on-user-identifier UserName  
   --single-sign-on-user-value <USER-NAME>
```

**Update existing user**

You cannot update the authorization of an existing user. You must delete the existing user and create a new one with the updated authorization.

**Log in to RStudio as another user**

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Navigate to the Control Panel.
3. Select a user name from the list of users. This opens a new page with details about the user profile and the apps that are running.
5. From the dropdown, select RStudio to launch an RStudio instance.

**Terminate sessions for another user**

1. From the list of running apps, identify the app you want to delete.
2. Click the respective Delete app button for the app you are deleting.

**Delete another user**

You cannot delete a user if the user is running any apps. Delete all apps before attempting to delete a user.

1. From the User Profile page, select Edit. This opens a new General settings page.
2. Under Delete user, select Delete user.

**RStudio administrative dashboard**

This topic shows how to access and use the RStudio administrative dashboard. With the RStudio administrative dashboard, admins can manage users and RSessions, as well as view information about RStudio Server instance utilization and Amazon CloudWatch Logs.

**Launch the RStudio administrative dashboard**

The R_STUDIO_ADMIN authorization allows the user to access the RStudio administrative dashboard. An R_STUDIO_ADMIN user can access the RStudio administrative dashboard by replacing workspaces with admin in their RStudio URL manually. The following shows how to modify the URL to access the RStudio administrative dashboard.

For example, the following RStudio URL:
Can be converted to:

https://<DOMAIN-ID>.studio.us-east-2.sagemaker.aws/rstudio/default/s/<SESSION-ID>/admin

Dashboard tab

This tab gives an overview of your RStudio Server instance utilization, as well as information on the number of active RSessions.

Sessions tab

This tab gives information on the active RSessions, such as the user that launched the RSessions, the time that the RSessions have been running, and their resource utilization.

Users tab

This tab gives information on the RStudio authorized users in the Domain, such as the time that the last RSession was launched and their resource utilization. The following procedure shows how to get information about the user's historical resource utilization.

1. From the list of users, select the user that you want to view information for. This opens a new page that is specific to the user.
2. To view the user's historical resource utilization, select the Stats tab. This tab gives information about the historical CPU and memory usage, as well as the number of active RSessions.
3. To view Amazon CloudWatch Logs specific to the user, select the Logs tab.

Stats tab

This tab gives information on the historical utilization of your RStudio Server instance.

Logs tab

This tab displays Amazon CloudWatch Logs for the RStudio Server instance. For more information about logging events with Amazon CloudWatch Logs, see What is Amazon CloudWatch Logs?.

Shut down and restart RStudio

To shut down and restart your RStudio Workbench and the associated RStudioServerPro app, you must first shut down all of your existing RSessions. You can shut down the RSessionGateway apps from within RStudio. You can then shut down the RStudioServerPro app using the AWS CLI. After the RStudioServerPro app is shut down, you must reopen RStudio through the SageMaker console.

Any unsaved notebook information is lost in the process. The user data in the Amazon EFS volume isn't impacted.

**Note**

If you are using a custom image with RStudio, ensure that your docker image is using an RStudio version that is compatible with the version of RStudio Workbench being used by SageMaker after you restart your RStudioServerPro app.

The following topics show how to shut down the RSessionGateway and RStudioServerPro apps and restart them.
Suspend your RSessions

Complete the following procedure to suspend all of your RSessions.

1. From the RStudio Launcher, identify the RSesson that you want to suspend.
2. Select **Suspend** for the session.
3. Repeat this for all RSessions.

Delete your RSessions

Complete the following procedure to shut down all of your RSessions.

1. From the RStudio Launcher, identify the RSesson that you want to delete.
2. Select **Quit** for the session. This opens a new **Quit Session** window.
3. From the **Quit Session** window, select **Force Quit**, to end all child processes in the session.
4. Select **Quit Session** to confirm deletion of the session.
5. Repeat this for all RSessions.

Delete your RStudioServerPro app

Run the following commands from the AWS CLI to delete and restart your RStudioServerPro app.

1. Delete the RStudioServerPro application by using your current domain id.

   ```bash
   aws sagemaker delete-app \
   --domain-id <domainId> \n   --user-profile-name domain-shared \n   --app-type RStudioServerPro \n   --app-name default
   ```

2. Re-create the RStudioServerPro application.

   ```bash
   aws sagemaker create-app \
   --domain-id <domainId> \n   --user-profile-name domain-shared \n   --app-type RStudioServerPro \n   --app-name default
   ```

Manage billing and cost

To track the costs associated with your RStudio environment, you can use the AWS Billing and Cost Management service. AWS Billing and Cost Management provides useful tools to help you gather information related to your cost and usage, analyze your cost drivers and usage trends, and take action to budget your spending. For more information, see **What is AWS Billing and Cost Management?**.

The following describes components required to run RStudio on Amazon SageMaker and how each component factors into billing for your RStudio instance.

- **RStudio License** – There is no extra charge for using your RStudio license with Amazon SageMaker. For more information about your RStudio license, see RStudio license (p. 183).
- **RSesson** - These are RStudio working sessions launched by end users. You are charged while the RSesson is running.
- **RStudio Server** - A multi-tenant server manages all the RSessions. You can choose the instance type to run RStudio Server on, and pay the related costs. The default instance, "system", is free, but you
can choose to pay for higher tiers. For more information about the available instance types for your RStudio Server, see RStudioServerPro instance type (p. 186).

Tracking billing at user level

To track billing at the user level using Cost Allocation Tags, see Using Cost Allocation Tags.

Diagnose issues and get support

The following sections describe how to diagnose issues with RStudio on Amazon SageMaker. To get support for RStudio on Amazon SageMaker, contact Amazon SageMaker support. For help with purchasing an RStudio license or modifying the number of license seats, contact sales@rstudio.com.

Upgrade your version

If you receive a warning that there is a version mismatch between your RSession and RStudioServerPro apps, then you must upgrade the version of your RStudioServerPro app. For more information, see Upgrade the RStudio Version (p. 184).

View Metrics and Logs

You can monitor your workflow performance while using RStudio on Amazon SageMaker. View data logs and information about metrics with the RStudio administrative dashboard or Amazon CloudWatch.

View your RStudio logs from the RStudio administrative dashboard

You can view metrics and logs directly from the RStudio administrative dashboard.

1. Log in to your Amazon SageMaker Domain.
2. Navigate to the RStudio administrative dashboard following the steps in RStudio administrative dashboard (p. 207).
3. Select the Logs tab.

View your RStudio logs from Amazon CloudWatch Logs

Amazon CloudWatch monitors your AWS resources and the applications that you run on AWS in real time. You can use Amazon CloudWatch to collect and track metrics, which are variables that you can measure for your resources and applications. To ensure that your RStudio apps have permissions for Amazon CloudWatch, you must include the permissions described in Onboard to Amazon SageMaker Domain (p. 35). You don’t need to do any setup to gather Amazon CloudWatch Logs.

The following steps show how to view Amazon CloudWatch Logs for your RSession.

These logs can be found in the /aws/sagemaker/studio log stream from the AWS CloudWatch console.

2. Select Logs from the left side. From the dropdown menu, select Log groups.
3. On the Log groups screen, search for aws/sagemaker/studio. Select the Log group.
4. On the aws/sagemaker/studio Log group screen, navigate to the Log streams tab.
5. To find the logs for your Domain, search Log streams using the following format:

   `<DomainId>/domain-shared/rstudioserverpro/default`
Use RStudio on Amazon SageMaker

With RStudio support in Amazon SageMaker, you can put your production workflows in place and take advantage of SageMaker features. The following topics show how to launch an RStudio session and complete key workflows. For information about managing RStudio on SageMaker, see Manage RStudio on Amazon SageMaker (p. 183).

For information about the onboarding steps to create an Amazon SageMaker Domain with RStudio enabled, see Onboard to Amazon SageMaker Domain (p. 35).

For information about the AWS Regions that RStudio on SageMaker is supported in, see Supported Regions and Quotas (p. 32).

Topics
- Collaborate in RStudio (p. 211)
- Base R image (p. 211)
- Open RStudio Launcher and launch RSessions (p. 211)
- Publish to RStudio Connect (p. 213)
- Access Amazon SageMaker features with RStudio on Amazon SageMaker (p. 213)

Collaborate in RStudio

To share your RStudio project, you can connect RStudio to your Git repo. For information on setting this up, see Version Control with Git and SVN.

Note: Project sharing and realtime collaboration are not currently supported when using RStudio on Amazon SageMaker.

Base R image

When launching your RStudio instance, the Base R image serves as the basis of your instance. This image extends the r-session-complete Docker image.

This Base R image includes the following:
- R v4.0 or higher
- awscli, sagemaker, and boto3 Python packages
- Reticulate package for R SDK integration

Open RStudio Launcher and launch RSessions

The following topics show how to use the RStudio Launcher to launch RSessions.

Open RStudio Launcher

Open RStudio Launcher from the Amazon SageMaker Console

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Navigate to the Control Panel.
3. After your user has been created, select Launch app.
4. Select either Studio or RStudio to launch a new app of that type.
Open RStudio Launcher from the AWS CLI

The procedure to open the RStudio Launcher using the AWS CLI differs depending on the method used to manage your users.

**IAM Identity Center**

1. Use the AWS access portal to open your Amazon SageMaker Domain.
2. Modify the URL path to "/rstudio/default" as follows.

```
# Studio URL
https://<domain-id>.studio.<region>.sagemaker.aws/jupyter/default/lab
# modified URL
https://<domain-id>.studio.<region>.sagemaker.aws/rstudio/default
```

**IAM**

To open the RStudio Launcher from the AWS CLI in IAM mode, complete the following procedure.

1. Create a presigned URL using the following command.

```
aws sagemaker create-presigned-domain-url --region <REGION> \ 
  --domain-id <DOMAIN-ID> \ 
  --user-profile-name <USER-PROFILE-NAME>
```
2. Append &redirect=RStudioServerPro to the generated URL.
3. Navigate to the updated URL.

**Launch RSessions**

After you’ve launched the RStudio Launcher, you can create a new RSession.

1. Select New Session.
2. Enter a Session Name.
3. Select an instance type that your RSession runs on. This defaults to ml.t3.medium.
4. Select an Image that your RSession uses as the kernel.
5. Select Start Session.
6. After your session has been created, you can start it by selecting the name.

**Note**

If you receive a warning that there is a version mismatch between your RSession and RStudioServerPro apps, then you must upgrade the version of your RStudioServerPro app. For more information, see Upgrade the RStudio Version (p. 184).

**Suspend your RSessions**

1. From the RStudio Launcher, identify the RSession that you want to suspend.
2. Select Suspend for the session.

**Delete your RSessions**

1. From the RStudio Launcher, identify the RSession that you want to delete.
2. Select Quit for the session. This opens a new Quit Session window.
3. From the Quit Session window, select Force Quit, to end all child processes in the session.
4. Select Quit Session to confirm deletion of the session.

Publish to RStudio Connect

RStudio Connect enables data scientists to publish insights, dashboard and web applications from RStudio on Amazon SageMaker. For more information, see Host RStudio Connect and Package Manager for ML development in RStudio on Amazon SageMaker.

For more information on RStudio Connect, see the RStudio Connect User Guide.

Access Amazon SageMaker features with RStudio on Amazon SageMaker

One of the benefits of using RStudio on Amazon SageMaker is the integration of Amazon SageMaker features. This includes integration with Amazon SageMaker Studio and Reticulate.

Use Amazon SageMaker Studio JupyterLab and RStudio on Amazon SageMaker

Your Amazon SageMaker Studio JupyterLab and RStudio instances share the same Amazon EFS file system. This means that files that you import and create using JupyterLab can be accessed using RStudio and vice versa. This allows you to work on the same files using both JupyterLab and RStudio without having to move your files between the two. For more information on this workflow, see the Announcing Fully Managed RStudio on Amazon SageMaker for Data Scientists blog.

Use Amazon SageMaker SDK with reticulate

The reticulate package is used as an R interface to Amazon SageMaker Python SDK to make API calls to Amazon SageMaker. The reticulate package translates between R and Python objects, and Amazon SageMaker provides a serverless data science environment to train and deploy Machine Learning (ML) models at scale. For general information about the reticulate package, see R Interface to Python.

For a blog that outlines how to use the reticulate package with Amazon SageMaker, see Using R with Amazon SageMaker.

The following examples show how to use reticulate for specific use cases.

- For a notebook that describes how to use reticulate to do batch transform to make predictions, see Batch Transform Using R with Amazon SageMaker.
- For a notebook that describes how to use reticulate to conduct hyperparameter tuning and generate predictions, see Hyperparameter Optimization Using R with Amazon SageMaker.

Amazon SageMaker Canvas

Amazon SageMaker Canvas gives you the ability to use machine learning to generate predictions without needing to code. The following are some use cases where you can use SageMaker Canvas:

- Reducing employee churn
- Detecting fraud
- Forecasting sales
- Optimizing inventory

In SageMaker Canvas, you do the following:

1. Import your data from one or more data sources.
2. Build a predictive model.
3. Evaluate the model's performance.
4. Import more data.
5. Train another model.

You use the SageMaker Canvas UI to import your data and perform analyses. You can also use it to import your models into Amazon SageMaker, giving you the ability to collaborate with data scientists.

To learn more about pricing, see the SageMaker Canvas pricing page.

SageMaker Canvas is currently available in the following Regions: US East (Ohio), US East (N. Virginia), US West (Oregon), Asia Pacific (Mumbai), Asia Pacific (Seoul), Asia Pacific (Singapore), Asia Pacific (Sydney), Asia Pacific (Tokyo), Europe (Frankfurt), and Europe (Ireland).

Topics
- Are you a first-time SageMaker Canvas user? (p. 214)
- Getting started with using Amazon SageMaker Canvas (p. 214)
- Setting Up and Managing Amazon SageMaker Canvas (for IT Administrators) (p. 227)
- Importing data in Amazon SageMaker Canvas (p. 247)
- Build a model (p. 257)
- Evaluating Your Model's Performance in Amazon SageMaker Canvas (p. 278)
- Making predictions on your data (p. 283)
- Logging out of Amazon SageMaker Canvas (p. 284)
- Time Series Forecasts in Amazon SageMaker Canvas (p. 284)
- Updating a Model in Amazon SageMaker Canvas (p. 288)
- Share your models with data scientists (p. 289)
- Manage billing and cost in SageMaker Canvas (p. 289)

Are you a first-time SageMaker Canvas user?

If you are a first-time user of SageMaker Canvas, we recommend that you begin by reading the following sections:

- For IT administrators – Setting Up and Managing Amazon SageMaker Canvas (for IT Administrators) (p. 227)
- For analysts and individual users – Getting started with using Amazon SageMaker Canvas (p. 214)

Getting started with using Amazon SageMaker Canvas

This guide tells you how to get started with using SageMaker Canvas. If you're an IT administrator, see Setting Up and Managing Amazon SageMaker Canvas (for IT Administrators) (p. 227) to set up SageMaker Canvas for your users.

If you're a business user or analyst, read the following sections.

Topics
- Prerequisites for setting up Amazon SageMaker Canvas (p. 215)
- Step 1: Log in to Amazon SageMaker Canvas as a business user (p. 217)
Prerequisites for setting up Amazon SageMaker Canvas

To set up Amazon SageMaker Canvas, you either contact your administrator or do the following:

- Set up an Amazon SageMaker Domain
- Optional: Give yourself the ability to upload local files
- Optional: Give yourself permissions to do time series forecasts
- Optional: Give yourself permissions to import Amazon Redshift data

**Important**

For you to set up Amazon SageMaker Canvas, your version of Amazon SageMaker Studio must be 3.19.0 or later. For information about updating Amazon SageMaker Studio, see Shut down and Update SageMaker Studio (p. 179).

To onboard to Domain using IAM Identity Center

1. Open the SageMaker console.
2. Choose Control Panel at the top left of the page.
4. Select Configure.

Use the following procedure to configure the general settings.

1. Under Permission, for IAM role, choose an option from the role selector.
   - If you choose Enter a custom IAM role ARN, the role must have at a minimum, an attached trust policy that grants SageMaker permission to assume the role. For more information, see SageMaker Roles (p. 3536).
   - If you choose Create a new role, the Create an IAM role dialog opens:
     - Choose Create role. SageMaker creates a new IAM AmazonSageMaker-ExecutionPolicy role with the AmazonSageMakerFullAccess policy attached.
2. Under Network and storage, specify the following:
   - Your VPC information – For more information, see Choose a VPC (p. 42) and Configure Amazon SageMaker Canvas in a VPC without internet access (p. 244).
   - (Optional) Encryption key – SageMaker uses an AWS KMS key to encrypt your Amazon Elastic File System (Amazon EFS) and Amazon Elastic Block Store (Amazon EBS) file systems. By default, it uses an AWS managed key. To use a customer managed key, enter its key ID or Amazon Resource Name (ARN). For more information, see Protect Data at Rest Using Encryption (p. 3496).

   **Note**
   - Encryption in transit is only available for Amazon SageMaker Studio.
3. Select Next.

Use the following procedure to configure Amazon SageMaker Studio.
1. Under **Notebook Sharing Configuration**, turn on notebook sharing.
2. Select **Next**.

Use the following procedure to configure the SageMaker Canvas settings.

1. For the **Canvas base permissions configuration**, leave the **Enable Canvas base permissions** option turned on (it is turned on by default). This establishes the minimum required permissions to use the SageMaker Canvas app.
2. (Optional) For the **Time series forecasting configuration**, leave the **Enable time series forecasting** option turned on to give your users permissions to do time series forecasting in SageMaker Canvas (it is turned on by default).
3. (Optional) If you left **Enable time series forecasting** turned on, select **Create and use a new execution role**, or select **Use an existing execution role** if you already have an IAM role with the required Amazon Forecast permissions attached (for more information, see the IAM role setup method (p. 239)).
4. (Optional) Add **Tags** to track your cost and usage trends in AWS Billing and Cost Management. SageMaker adds the tags you specify in the Domain to all of the SageMaker Canvas apps you create in the Domain. For more information about billing and tags, see Manage billing and cost in SageMaker Canvas (p. 289).
5. Finish making any other changes to your Domain setup, and then choose **Submit**.

If you encounter an error during post-building analysis that tells you to increase your quota for `ml.m5.2xlarge` instances, use the following information to resolve the issue. To allow SageMaker Canvas to complete post-building analysis of models, you must increase the SageMaker Hosting endpoint limit for the `ml.m5.2xlarge` instance type to a non-zero value in your AWS account. After building a model, SageMaker Canvas hosts the model on a SageMaker Hosting endpoint and uses the endpoint to generate the post-building analysis. If you don't increase the default account limit of 0 for `ml.m5.2xlarge` instances, SageMaker Canvas cannot complete this step and generates an error during post-building analysis.

Use the following procedure to request a limit increase for your account.

1. Open the **AWS Support Center console**.
2. On the **AWS Support Center** page, choose **Create Case** and then choose **Service limit increase**.
3. In the **Case classification** panel under **Limit type**, search for SageMaker.
4. In the **Request** panel, choose the **Region** that you are working in. For **Resource Type**, choose **SageMaker Hosting**.
5. For **Limit**, choose **ml.m5.2xlarge** instances.
6. For **New Limit Value**, verify that the value is at least 1.
7. In **Case description**, provide a brief explanation of why you need the **Service limit increase**. For example, "SageMaker Canvas uses this instance type for model analysis."
8. In **Contact options**, provide some details about how you would like to be contacted by the AWS service support team on the status of your **Service limit increase** request.
9. Choose **Submit**.

You can now access SageMaker Canvas by doing the following.

1. Navigate to the **SageMaker console**.
2. Under **Control Panel**, choose **Canvas**.
3. Choose **Launch app**.
4. Choose **Canvas**.
SageMaker Canvas creates an Amazon S3 bucket with a name that uses the following pattern: sagemaker-Region-your-account-id.

If you'd like to have the ability to upload files from your local machine to SageMaker Canvas, you attach a CORS policy to it.

To attach a CORS policy, use the following procedure.

2. Choose the bucket with the name that uses the following pattern: sagemaker-AWS-Region-AWS-account-id.
3. Choose Permissions.
4. Navigate to Cross-origins resource sharing (CORS).
5. Choose Edit.
6. Add the following CORS policy:

```json
[
  {
    "AllowedHeaders": ["*"],
    "AllowedMethods": ["POST"],
    "AllowedOrigins": ["*"],
    "ExposeHeaders": []
  }
]
```
7. Choose Save changes.

After updating the CORS policy, you still might not be successful in uploading your files. The browser might be caching the CORS settings from a previous upload attempt. If you're running into issues, clear your browser cache and try again.

You might want to give yourself the ability to perform forecasts on time series data. You can add time series forecasting permissions when setting up your Domain, or you can edit the permissions for a user profile after creating your Domain. The required permissions are the AmazonSageMakerCanvasForecastAccess managed policy and a trust relationship with Amazon Forecast to the AWS IAM role you chose when setting up the user profile. For instructions on how to add these permissions to your IAM role, see Give Your Users Permissions to Perform Time Series Forecasting (p. 237).

If you want to import data from Amazon Redshift, you must give yourself additional permissions. You must add the AmazonRedshiftFullAccess managed policy to the AWS IAM role you chose when setting up the user profile. For instructions on how to add the policy to the role, see Give Users Permissions to Import Amazon Redshift Data (p. 243).

**Step 1: Log in to Amazon SageMaker Canvas as a business user**

Contact your administrator to guide you through the process of setting up Amazon SageMaker Canvas. When you log into SageMaker Canvas for the first time, there is a welcome message with quick getting started tutorials that you can follow for a walkthrough of the SageMaker Canvas application.
You can follow the **Get started with Canvas** tutorial for a high-level overview of the SageMaker Canvas application. There are also shorter tutorials that guide you through the individual steps of using SageMaker Canvas. These tutorials show you how to import a dataset, build a model, analyze the results of a built model, and generate predictions with your model. You can revisit the tutorials at any time by choosing the **Help** button and then choosing **Quick tutorials** on the left navigation bar inside the SageMaker Canvas application.
Step 2: Import and manage data

Format your data so that you can analyze it in Amazon SageMaker Canvas by importing it into a dataset. You import data from multiple sources into a single dataset.

You can import data from the following sources:
- Local files
- Amazon S3
- Amazon Redshift
- Snowflake

Use the following procedure to import a dataset.

To import your data, do the following.

1. In the left navigation pane, choose **Datasets**.
2. Choose **Import Data**.
3. Optional: Add a connection to an external data source, such as an external Amazon S3 bucket, Amazon Redshift, or Snowflake. For more information about importing data, see [Use Snowflake with Amazon SageMaker Canvas](p. 250).
4. Select one or more files from your Amazon S3 bucket or your local folder. Your data must meet the following requirements:
   - Your file can't exceed 5 GB.
   - Currently, your file must be in .csv format. Its values must be comma delimited and must not have newline characters except when denoting a new row.
   - Your data can't have more than 1000 columns.
5. Optional: To preview the datasets that you've uploaded and to review the headers, navigate to the section following the datasets that you're uploading.
6. Choose **Import**.

The following images show how SageMaker Canvas previews files that you've uploaded locally by choosing **Preview**.
The following image shows the import page for datasets that are stored on Amazon S3.
The preceding information walks you through how to import the data. For more information, see Importing data in Amazon SageMaker Canvas (p. 247).

Step 3: Build a model

Build a model that you can use to make predictions on new data. To build a model, you choose the **Target column** in your dataset for which you want to make predictions. Amazon SageMaker Canvas looks at the data in the column and makes recommendations for the types of models that you can train. Choose the model type that works best for your use case.

You can choose **Preview model** before you build the model to get a sense of how well the model can make predictions. The prediction accuracy for **Preview model** is generally lower than the actual prediction accuracy of the model you’ve built. However, it is usually similar to the value of the model.

The following information shows you how to build a model and provides you with contextual information. For more information about model building, see Build a model (p. 257).

Use the following procedure to build a model.

1. In the navigation pane, choose Models.
2. Choose New Model and specify a name for the model.
3. Choose the data that you want to use to build a model. If you haven’t imported the data yet, you can choose Import data.
4. Select the target that you would like to predict out of the columns in the dropdown list. SageMaker Canvas automatically chooses the problem type for you.
5. Optional: Choose the checkboxes next to the names of the columns to drop them from the dataset.
6. Optional: Choose Analyze data to get a general sense of the model's performance before you build it.
7. Choose the downward arrow next to Quick build.
8. Choose Quick build or Standard build.

The following image shows the Quick build and Standard build options.
The following image shows the data in a table view. Choosing a column opens descriptive statistics and visualizations for the column.

The following image shows the columns in a dataset. The checkboxes that have been grayed out indicate that they won't be used to build the model. You can see that the unselected boxes appear in the Model Recipe. The model recipe lists the changes that you've made to the dataset that you've provided.
The following image shows how choosing **Preview model** quickly creates an analysis of how well a fully built model may perform and which columns had the most impact on the models predictions.

After you start model building, Amazon SageMaker Canvas automatically cleans and pre-processes your data. It builds up to 250 models and chooses the one that is the most accurate. The time it takes for Amazon SageMaker Canvas to build a model depends on whether you're doing a **Quick build** or a **Standard build** and the size of the dataset. A **Quick build** usually takes 2-20 minutes to build, whereas a **Standard build** usually takes 2-4 hours to build. You can safely navigate away from the model building page and come back to it when SageMaker Canvas finishes building your model.

The following image shows the process of model building.
Step 4: Evaluate your model

Before using your model to make predictions on new data, you can evaluate how well it performed. You can use information such as the impact that each column had on the predictions. The following image shows an example evaluation page with an explanation of the score and the column impact.

You can use the Scoring tab to get visualizations and metrics on your model's ability to make predictions.
Step 5: Make predictions

You can make one of the following types of predictions.

- **Batch** – Predictions for an entire dataset.
- **Single** – Predictions for a single value that you specify.

For each set of predictions, SageMaker Canvas returns the following:

- The predicted values
- The probability of the predicted value being correct
- The dataset that you've specified for generating predictions

Use the following procedure to make a single prediction with your model.

1. Choose **Single prediction**.
2. Change the input values to see how the predicted value changes from the average prediction.
3. Choose **Update** to get the new prediction.
To make batch predictions, choose a dataset and use the following procedure to generate batch predictions.

1. Choose **Batch prediction**.
2. Choose **Select Dataset**.
3. Choose the dataset.
4. Choose **Generate predictions**.

The following images visualize the preceding procedure.
For batch predictions, you can download the model's predictions as a .csv file. When the Status of the predictions output is Ready, you can download the file by choosing the More options icon and then choosing Download. If you dropped any columns when building your model, SageMaker Canvas adds the dropped columns back to the batch predictions.

**Note**
SageMaker Canvas does not add the dropped columns to your batch predictions for time series models.

You might not be able to make predictions on some datasets because they might have incompatible schemas. A schema is the organizational structure. For a dataset, it is the names of the columns and the data type of the data in the columns.

An incompatible schema might happen for one of the following reasons:

- The dataset that you're using to make predictions has fewer columns than the dataset that you're using to build the model.
- The data types in the columns you used to build the dataset might be different from the data types in dataset that you're using to make predictions.
- The dataset that you're using to make predictions and the dataset that you've used to build the model have column names that don't match. The column names are case sensitive. "Column1" is not the same as "column1".

**Setting Up and Managing Amazon SageMaker Canvas (for IT Administrators)**

You can use the information in this section to help your users do the following:

- Optional: Give your users permissions to upload their files locally.
- Set up Okta SSO for your users.
- Update SageMaker Canvas.
- Clean up or delete the installation of SageMaker Canvas.
- Optional: Set up Amazon Forecast so users can do time series forecasting.
- Optional: Set up an Amazon Virtual Private Cloud.
- Optional: Encrypt data using AWS Key Management Service.
- Optional: Give your users permissions to import Redshift data.
You can also set up SageMaker Canvas for your users with AWS CloudFormation. For more information, see AWS::SageMaker::App in the AWS CloudFormation User Guide.

Topics
- Give Your Users Permissions to Upload Local Files (p. 228)
- Set Up SageMaker Canvas for Your Users (p. 230)
- Encrypt Your SageMaker Canvas Data with AWS KMS (p. 234)
- Give Your Users Permissions to Perform Time Series Forecasting (p. 237)
- Update SageMaker Canvas for Your Users (p. 241)
- Request a Quota Increase (p. 242)
- Give Users Permissions to Import Amazon Redshift Data (p. 243)
- Manage apps (p. 243)
- Configure Amazon SageMaker Canvas in a VPC without internet access (p. 244)

Give Your Users Permissions to Upload Local Files

If your users are uploading files from their local machines to SageMaker Canvas, you must attach a CORS configuration to the Amazon S3 bucket that they’re using. When one of your users first accesses SageMaker Canvas, SageMaker creates an Amazon S3 bucket with a name that uses the following pattern: sagemaker-{region}-{account-ID}. SageMaker Canvas adds your users' data to the bucket whenever they upload a file.

To give users permissions to upload local files to the bucket, you can attach a CORS configuration to it using either of the following procedures. You can use the first method when setting up your Domain or editing the existing Domain settings, where you opt in to allow SageMaker to attach the CORS configuration to the default bucket for you. The second method is the manual method, where you can attach the CORS configuration to the bucket yourself.

Domain setup method

To give your users permissions to upload local files, you can choose Enable Canvas permissions when setting up your Domain. This attaches a CORS configuration to the SageMaker Amazon S3 bucket created for your account and gives all users in the Domain permission to upload local files into SageMaker Canvas. By default, the permissions option is turned on when you set up a Domain, but you can turn off this option if you don’t want to give your users permission to upload files.

Note
If you have an existing CORS configuration on the SageMaker Amazon S3 bucket, turning on Enable Canvas permissions overwrites the existing configuration with the new configuration.

The following procedure shows how you can turn on this option when doing a Quick setup for your Domain in the console.

1. In the User profile section, enter a Name for the user.
2. Select an Execution role for the user.
3. Turn on Enable SageMaker Canvas permissions (by default this option is turned on).
4. Finish setting up the Domain.

If you are doing a Standard setup for your Domain, then use the following procedure for the Canvas settings section to turn on local file upload.

1. For Enable and configure Canvas permissions, select Local file upload (it's already checked by default).
2. Choose **Next**.
3. Finish setting up the Domain.

Your users can now upload local files into their SageMaker Canvas application.

You can also turn on or turn off local upload permissions for an existing Domain by using the following procedure.

1. Go to the **Amazon SageMaker console**.
2. In the **Control Panel**, choose **Edit domain settings**.
3. Go to **Canvas settings**.
4. Select or deselect **Local file upload**.
5. Finish any other modifications you want to make to the Domain, and then **Submit** your changes.

### Amazon S3 bucket method

If you want to manually attach the CORS configuration to the SageMaker Amazon S3 bucket, use the following procedure.

2. Choose the bucket with the name that uses the following pattern: `sagemaker-{region}-{account-ID}`.
3. Choose **Permissions**.
4. Navigate to **Cross-origins resource sharing (CORS)**.
5. Choose **Edit**.
6. Add the following CORS policy:

   ```json
   [
     {
       "AllowedHeaders": [
         "*
       ],
       "AllowedMethods": [
         "POST"
       ],
       "AllowedOrigins": [
         "*
       ],
       "ExposeHeaders": []
     }
   ]
   ```

7. Choose **Save changes**.

In the preceding procedure, the CORS policy must have "POST" listed under **AllowedMethods**.

After you've gone through the procedure, you should have:

- An IAM role assigned to each of your users.
- Amazon SageMaker Studio runtime permissions for each of your users. SageMaker Canvas uses Studio to run the commands from your users.
- If the users are uploading files from their local machines, a CORS policy attached to their Amazon S3 bucket.
If your users still can’t upload the local files after you update the CORS policy, the browser might be caching the CORS settings from a previous upload attempt. If they’re running into issues, instruct them to clear their browser cache and try again.

**Set Up SageMaker Canvas for Your Users**

To set up Amazon SageMaker Canvas, do the following:

- Create an Amazon SageMaker Domain.
- Create user profiles for the Domain.
- Set up Okta Single Sign On (Okta SSO) for your users.
- Activate link sharing for models.

Use Okta Single-Sign On (Okta SSO) to give your users access to Amazon SageMaker Canvas. SageMaker Canvas supports SAML 2.0 SSO methods. The following sections guide you through procedures to set up Okta SSO.

To set up a Domain, see [Onboard to Amazon SageMaker Studio Using IAM](#). You can use the following information to help you complete the procedure in the section:

- You can ignore the step about creating projects.
- You don't need to provide access to additional Amazon S3 buckets. Your users can use the default bucket that we provide when we create a role.
- To give your users access to share their notebooks with data scientists, turn on Notebook Sharing Configuration.
- Use Amazon SageMaker Studio version 3.19.0 or later. For information about updating Amazon SageMaker Studio, see [Shut down and Update SageMaker Studio](#) (p. 179).

Use the following procedure to set up Okta. For all of the following procedures, you specify the same IAM role for *IAM-role*.

**Add the SageMaker Canvas Application To Okta**

Set up the sign-on method for Okta.

1. Sign in to the Okta Admin dashboard.
2. Choose Add application. Search for AWS Account Federation.
3. Choose Add.
4. Optional: Change the name to Amazon SageMaker Canvas.
5. Choose Next.
6. Choose SAML 2.0 as the Sign-On method.
7. Choose Identity Provider Metadata to open the metadata XML file. Save the file locally.
8. Choose Done.

**Set Up ID Federation in IAM**

AWS Identity and Access Management (IAM) is the AWS service that you use to gain access to your AWS account. You gain access to AWS through an IAM account.

1. Sign in to the AWS console.
2. Choose AWS Identity and Access Management (IAM).
3. Choose Identity Providers.
4. Choose Create Provider.
5. For Configure Provider, specify the following:
   - **Provider Type** – From the dropdown menu, choose SAML.
   - **Provider Name** – Specify Okta.
   - **Metadata Document** – Upload the XML document that you've saved locally from step 7 of Add the SageMaker Canvas Application To Okta (p. 230).

7. For Roles, choose the IAM role that you're using for Okta SSO access.
8. Under Trust Relationship for the IAM role, choose Edit Trust Relationship.
9. Modify the IAM trust relationship policy by specifying the Provider ARN value that you've copied and add the following policy:

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Principal": {
           "Federated": "arn:aws:iam::123456789012:saml-provider/Okta"
         },
         "Action": [
           "sts:AssumeRoleWithSAML",
           "sts:SetSourceIdentity",
           "sts:TagSession"
         ],
         "Condition": {
           "StringEquals": {
             "SAML:aud": "https://signin.aws.amazon.com/saml"
           }
         }
       }
     ]
   }
   ```

10. For Permissions, add the following policy:

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Sid": "AmazonSageMakerPresignedUrlPolicy",
         "Effect": "Allow",
         "Action": [
           "sagemaker:CreatePresignedDomainUrl",
           "sagemaker:CreatePresignedDomainUrlWithPrincipalTag"
         ],
         "Resource": "*"
       }
     ]
   }
   ```

**Configure SageMaker Canvas in Okta**

The following procedure gives you the ability to configure Amazon SageMaker Canvas in Okta.
To configure Amazon SageMaker Canvas to use Okta, follow the steps in this section. You must specify unique user names for each `SageMakerStudioProfileName` field. For example, you can use `user.login` as a value. If the username is different from the SageMaker Canvas profile name, choose a different uniquely identifying attribute. For example, you can use an employee’s ID number for the profile name.

For an example of values that you can set for Attributes, see the code following the procedure.

2. Add a group with the following pattern: `sagemaker#canvas#IAM-role#AWS-account-id`
3. In Okta, open the AWS Account Federation app integration configuration.
4. Select Sign On for the AWS Account Federation app.
5. Choose Edit and specify the following:
   - SAML 2.0
   - Default Relay State – `https://Region.conso...onsole.aws.amazon.com/sagemaker/home?region=Region#/studio/canvas/open/StudioId`. You can find the studio ID in the console: `https://console.aws.amazon.com/sagemaker/`
6. Choose Attributes.
7. For the `SageMakerStudioProfileName` fields, specify unique values for each username. The usernames must match the usernames that you’ve created in the AWS console.

   Attribute 1:
   Name: https://aws.amazon.com/SAML/Attributes/
   PrincipalTag:SageMakerStudioUserProfileName
   Value: ${user.login}

   Attribute 2:
   Name: https://aws.amazon.com/SAML/Attributes/TransitiveTagKeys
   Value: {"SageMakerStudioUserProfileName"}

8. Select Environment Type. Choose Regular AWS.
   - If your environment type isn’t listed, you can set your ACS URL in the ACS URL field. If your environment type is listed, you don’t need to enter your ACS URL
9. For Identity Provider ARN, specify the ARN you used in step 6 of the preceding procedure.
10. Specify a Session Duration.
11. Choose Join all roles.
12. Turn on Use Group Mapping by specifying the following fields:
   - App Filter – okta
   - Group Filter – ^aws\#\$+$+\(?IAM\-role\[\w\-]+\)\(?accountid\d+\)$
13. Choose Save/Next.
14. Under Assignments, assign the application to the group that you’ve created.

**Add Optional Policies on Access Control in IAM**

In IAM, you can apply the following policy to the administrator user who creates the user profiles.

```json
{
    "Version": "2012-10-17",
```
If you choose to add the preceding policy to the admin user, you must use the following permissions from Set Up ID Federation in IAM (p. 230).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AmazonSageMakerPresignedUrlPolicy",
      "Effect": "Allow",
      "Action": [
        "sagemaker:CreatePresignedDomainUrl",
        "sagemaker:CreatePresignedDomainUrlWithPrincipalTag"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "sagemaker:ResourceTag/studiouserid": "${aws:PrincipalTag/SageMakerStudioUserProfileName}"
        }
      }
    }
  ]
}
```

**Activate link sharing for models**

In order to create shareable links for importing SageMaker Canvas models into Amazon SageMaker Studio, the Amazon SageMaker Domain must turn on the notebook resource sharing option and have a valid Amazon S3 sharing location. If you delete the Amazon S3 sharing location specified in your Domain, or if you specify a nonexistent Amazon S3 location, you cannot create shareable links for SageMaker Canvas models.

If you choose the **Quick setup** when creating your Domain, SageMaker provides a default Amazon S3 location for resource sharing and automatically turns on notebook resource sharing.

If you choose the **Standard setup** when creating your Domain, configure the following options when setting up the **Notebook Sharing Configuration**:

1. For **Shareable notebook resources**, turn on **Enable notebook resource sharing**.
2. For **S3 location for shareable notebook resources**, enter either the default bucket already provided or a valid Amazon S3 path of your choice.
The Notebook Sharing Configuration for your Domain should look like the following screenshot, with Enable notebook resource sharing turned on and an Amazon S3 path entered for the S3 location for shareable notebook resources field.

### Notebook Sharing Configuration

<table>
<thead>
<tr>
<th>Shareable notebook resources</th>
</tr>
</thead>
<tbody>
<tr>
<td>Notebook resources include artifacts such as cell output and Git Repositories</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>S3 location for shareable notebook resources</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use the S3 default location or pick one</td>
</tr>
</tbody>
</table>

- s3://DOC-EXAMPLE-BUCKET/sharing

To find a path, go to Amazon S3

Make sure you update the IAM policy for the S3 bucket to have access with SageMaker Studio.

### Encryption key - optional

Encrypt your data. Choose an existing KMS key or enter a key's ARN.

- No Custom Encryption

### Notebook cell output sharing preference

When sharing notebooks, users can also share the output of cells.

- Allow users to share cell output
- Disable cell output sharing

---

**Encrypt Your SageMaker Canvas Data with AWS KMS**

You might have data that you want to encrypt while using Amazon SageMaker Canvas, such as your private company information or customer data. SageMaker Canvas uses AWS Key Management Service to protect your data. AWS KMS is a service that you can use to create and manage cryptographic keys for encrypting your data. For more information about AWS KMS, see AWS Key Management Service in the AWS KMS Developer Guide.

Amazon SageMaker Canvas provides you with several options for encrypting your data. SageMaker Canvas provides default encryption within the application for tasks such as building your model and generating insights. You can also choose to encrypt data stored in Amazon S3 to protect your data at rest. SageMaker Canvas supports importing encrypted datasets, so you can establish an encrypted end-to-end workflow. The following sections describe how you can use AWS KMS encryption to protect your data while building models with SageMaker Canvas.

**Encrypt your data in SageMaker Canvas**

With SageMaker Canvas, you can use two different AWS KMS encryption keys to encrypt your data in SageMaker Canvas, which you can specify when setting up your Domain. These two keys can be the same or different. SageMaker Canvas uses one key for temporary application storage, visualizations, or compute purposes (such as building models). You can use either the default AWS-managed key or specify your own. You can also specify an optional key that SageMaker Canvas uses for long-term storage of model objects and datasets, which are stored in the Region's default SageMaker S3 bucket for your account.

**Prerequisites**

To use your own KMS key for either of the previously described purposes, you must first give your user's IAM role permission to use the key. Then, you can specify the KMS key when setting up your Domain.
The simplest way to give your role permission to use the key is to modify the key policy. Use the following procedure to give your role the necessary permissions.

1. Open the AWS KMS console.
2. In the Key Policy section, choose Switch to policy view.
3. Modify the key's policy to grant permissions for the kms:GenerateDataKey and kms:Decrypt actions to the IAM role. You can add a statement that's similar to the following:

   ```json
   {
       "Sid": "ExampleStmt",
       "Action": [
           "kms:Decrypt",
           "kms:GenerateDataKey"
       ],
       "Effect": "Allow",
       "Principal": {
           "AWS": "<arn:aws:iam::111122223333:role/Jane>"
       },
       "Resource": "*"
   }
   ```
4. Choose Save changes.

The less preferred method is to modify the user's IAM role to give the user permissions to use or manage the KMS key. If you use this method, the KMS key's policy must also allow access management through IAM. To learn how to give permission to a KMS key through the user's IAM role, see Specifying KMS keys in IAM policy statements in the AWS KMS Developer Guide.

Encrypt your data in the SageMaker Canvas application

The first KMS key you can use in SageMaker Canvas is used for encrypting application data stored on Amazon Elastic Block Store (EBS) volumes and in the Amazon Elastic File System that SageMaker creates in your Domain. SageMaker Canvas encrypts your data with this key in the underlying application and temporary storage systems created when using compute instances for building models and generating insights. SageMaker Canvas passes the key to other AWS services, such as Autopilot, whenever SageMaker Canvas initiates jobs with them to process your data.

**Note**
For time series forecast models, SageMaker Canvas uses an AWS managed KMS key instead of a key that you specify.

You can specify this key by setting the KmsKeyId in the CreateDomain API call or while doing the Standard Domain setup in the console. If you don't specify your own KMS key, SageMaker uses a default AWS managed KMS key to encrypt your data in the SageMaker Canvas application.

To specify your own KMS key for use in the SageMaker Canvas application through the console, first set up your Amazon SageMaker Domain using the Standard setup. Use the following procedure to complete the Network and Storage Section for the Domain.

1. Fill out your desired Amazon VPC settings.
2. For Encryption key, choose Enter a KMS key ARN.
3. For KMS ARN, enter the ARN for your KMS key, which should have a format similar to the following: `arn:aws:kms:example-region-1:123456789098:key/111aa2bb-333c-4d44-5555-a11bb2c33dd`
Encrypt your SageMaker Canvas data saved in Amazon S3

The second KMS key you can specify is used for data that SageMaker Canvas stores to Amazon S3. SageMaker Canvas saves duplicates of your input datasets, application and model data, and output data to the Region’s default SageMaker S3 bucket for your account. The naming pattern for this bucket is `sagemaker-{region}-{account-ID}`, and SageMaker Canvas stores data in the `Canvas/` folder.

1. Turn on Enable notebook resource sharing.
2. For S3 location for shareable notebook resources, leave the default Amazon S3 path. Note that SageMaker Canvas does not use this S3 path; this S3 path is used for Studio notebooks.
3. For Encryption key, choose Enter a KMS key ARN.
4. For KMS ARN, enter the ARN for your KMS key, which should have a format similar to the following:
   ```
   arn:aws:kms:example-region-1:123456789098:key/111aa2bb-333c-4d44-5555-a11bb2c33dd
   ```

Import encrypted datasets from Amazon S3

Your users might have datasets that have been encrypted with a KMS key. While the preceding section shows you how to encrypt data in SageMaker Canvas and data stored to Amazon S3, you must give your user's IAM role additional permissions if you want to import data from Amazon S3 that is already encrypted with AWS KMS.

To give your user permissions to import encrypted datasets from Amazon S3 into SageMaker Canvas, add the following permissions to the IAM execution role that you've used for the user profile.

```
{kms:Encrypt},
{kms:Decrypt},
{kms:ReEncrypt*},
{kms:GenerateDataKey*},
{kms:DescribeKey}
```

To learn how to edit the IAM permissions for a role, see Adding and removing IAM identity permissions in the IAM User Guide. For more information about KMS keys, see Key policies in AWS Key Management Service in the AWS KMS Developer Guide.

FAQs

Refer to the following FAQ items for answers to commonly asked questions about SageMaker Canvas AWS KMS support.

Q: Does SageMaker Canvas retain my KMS key?

A: No. SageMaker Canvas may temporarily cache your key or pass it on to other AWS services (such as Autopilot), but SageMaker Canvas does not retain your KMS key.

Q: I specified a KMS key when setting up my Domain. Why did my dataset fail to import in SageMaker Canvas?

A: Your user’s IAM role may not have permissions to use that KMS key. To give your user permissions, see the Prerequisites (p. 234). Another possible error is that you have a bucket policy on your Amazon S3 bucket that requires the use of a specific KMS key that doesn't match the KMS key you specified in your Domain. Make sure that you specify the same KMS key for your Amazon S3 bucket and your Domain.
Q: How do I find the Region's default SageMaker S3 bucket for my account?
A: The default S3 bucket follows the naming pattern sagemaker-\{region\}-\{account-ID\}. The Canvas folder in this bucket stores your SageMaker Canvas application data.

Q: Can I change the default SageMaker S3 bucket used to store SageMaker Canvas data?
A: No, SageMaker creates this bucket for you.

Q: What does SageMaker Canvas store in the default SageMaker S3 bucket?
A: SageMaker Canvas uses the default SageMaker S3 bucket to store duplicates of your input datasets, model artifacts, and model outputs.

Q: What use cases are supported for using KMS keys with SageMaker Canvas?
A: With SageMaker Canvas, you can use your own encryption keys with AWS KMS for Regression, Multi-class classification, and Binary classification models, as well as batch inference for these models. SageMaker Canvas doesn't currently support using customer-managed encryption keys for time series forecasting models.

Give Your Users Permissions to Perform Time Series Forecasting

In order to perform time series forecasts in Amazon SageMaker Canvas, your users must have the necessary permissions. The preferred method to give your users these permissions is to enable the time series forecasting option when setting up the Amazon SageMaker Domain, or when editing the settings for a specific user profile. You can also use the manual method of attaching a policy and trust relationship for Amazon Forecast to the AWS Identity and Access Management (IAM) role.

Domain setup method

SageMaker provides you with the option to give time series forecasting permissions to users through the Domain settings. You can toggle the permissions for all of the users in your Domain, and SageMaker manages attaching the required IAM policy and trust relationship for you.

If you are setting up your Amazon SageMaker Domain for the first time and want to turn on time series forecasting permissions for all users in the Domain, then use the following procedures.

Quick setup

Use the following procedure to turn on SageMaker Canvas time series forecasting permissions when doing a Quick setup for your Domain.

1. In the Amazon SageMaker Domain Quick setup, fill out the Name and Default execution role fields in the User profile section.
2. Leave the Enable SageMaker Canvas permissions option turned on (it is turned on by default).
3. Choose Submit to finish setting up your Domain.

Standard setup

Use the following procedure to turn on SageMaker Canvas time series forecasting permissions when doing a Standard setup for your Domain.

1. In the Amazon SageMaker Domain Standard setup, fill out the General settings, Studio settings, and RStudio settings pages.
2. Choose the Canvas settings page.
3. For the **Canvas base permissions configuration**, leave the **Enable Canvas base permissions** option turned on (it is turned on by default). These permissions are required in order to turn on time series forecasting permissions.

4. For the **Time series forecasting configuration**, leave the **Enable time series forecasting** option turned on (it is turned on by default).

5. Select **Create and use a new execution role**, or select **Use an existing execution role** if you already have an IAM role with the required Amazon Forecast permissions attached (for more information, see the [IAM role setup method](#)).

6. Finish making any other changes to your Domain setup, and then choose **Submit**.

Your users should now have the necessary permissions to perform time series forecasting in SageMaker Canvas.

**User setup method**

You can configure time series forecasting permissions for individual users in an existing Domain. The user profile settings override the general Domain settings, so you can give permissions to specific users without giving permissions to all of your users. To give time series forecasting permissions to a specific user that doesn't already have permissions, use the following procedure.

2. In the **Control Panel**, in the **Users** panel, select the name of the user whose permissions you want to edit.
3. On the **User Details** page, choose **Edit**.
4. Choose the **Canvas settings** page.
5. Turn on **Enable Canvas base permissions**. These permissions are required in order to turn on time series forecasting permissions.
6. Turn on the **Enable time series forecasting** option.
7. If you want to use a different execution role for the user than the role specified in the Domain, select **Create and use a new execution role**, or **Use an existing execution role** if you already have an IAM role ready to use.

   **Note**
   If you want to use an existing IAM role, make sure that it has the IAM policy `AmazonSageMakerCanvasForecastAccess` attached and has a trust relationship that establishes Amazon Forecast as a service principal. For more information, see the section [IAM role setup method](#).

8. The **Canvas settings** page should look like the following screenshot. Finish making any other changes to your user profile, and then choose **Submit** to save your changes.
Your user should now have permission to do time series forecasting in SageMaker Canvas.

You can also remove permissions from a user by using the preceding procedure and turning off the Enable time series forecasting option.

**IAM role setup method**

You can manually give your users permissions to perform time series forecasting in Amazon SageMaker Canvas by adding additional permissions to the AWS Identity and Access Management (IAM) role specified for the user's profile. The IAM role must have a trust relationship with Amazon Forecast and an attached policy that gives permissions to Forecast.

The following section shows you how to create the trust relationship and attach the AmazonSageMakerCanvasForecastAccess managed policy to your IAM role, which grants the minimum permissions necessary for time series forecasting to work in SageMaker Canvas.

To configure an IAM role with the manual method, use the following procedure.

2. From the list of Users, select the profile of the user to whom you want to give time series forecasting permissions.

3. Under Details, copy or make a note of the name of the user's Execution role. The name of the IAM role should be similar to the following: AmazonSageMaker-ExecutionRole-1111222233334444.

4. Once you have the name of the user's IAM role, go to the IAM console.

5. Choose Roles.

6. Search for the user's IAM role by name from the list of roles and select it.

7. Under Permissions, choose Add permissions.

8. Choose Attach policies.

9. Search for the AmazonSageMakerCanvasForecastAccess managed policy and select it. Choose Attach policies to attach the policy to the role.
After attaching the policy, the role's **Permissions** section should now include `AmazonSageMakerCanvasForecastAccess`.

**10.** Return to the IAM role's page, and under **Trust relationships**, choose *Edit trust policy*.

**11.** In the *Edit trust policy* editor, update the trust policy to add Forecast as a service principal. The policy should look like the following example.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "sagemaker.amazonaws.com",
          "forecast.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

**12.** After editing the trust policy, choose *Update policy*.

You should now have an IAM role that has the policy `AmazonSageMakerCanvasForecastAccess` attached to it and a trust relationship established with Amazon Forecast, giving users permission to perform time series forecasting in SageMaker Canvas. For information about AWS managed policies, see [Managed policies and inline policies](#).

### Update SageMaker Canvas for Your Users

You can update to the latest version of Amazon SageMaker Canvas as either a user or an IT administrator. You can update Amazon SageMaker Canvas for a single user at a time.

To update the Amazon SageMaker Canvas application, you must delete the previous version.

**Important**
Deleting the previous version of Amazon SageMaker Canvas doesn't delete the data or models that the users have created.

Use the following procedure to log in to AWS, open Amazon SageMaker Domain, and update Amazon SageMaker Canvas. The users can start using the SageMaker Canvas application when they log back in.

1. Sign in to the Amazon SageMaker console at [Amazon SageMaker](#).
2. In the navigation pane, choose **Control Panel**.
3. For **Users**, choose a user name.
4. Choose **Delete app**.
5. Complete the dialog box and choose **Confirm action**.

The following images show the workflow from the preceding procedure.
Your users might use AWS resources in amounts that exceed those specified by their quotas. If your users are resource constrained, you can request a quota increase for them.

Amazon SageMaker Canvas uses the following services to process the requests of your users:

- Amazon SageMaker Autopilot
- Amazon SageMaker Studio Domain
- Amazon Forecast

For information about increasing quotas for SageMaker Canvas operations that aren’t used to forecast time series data, see Amazon SageMaker endpoints and quotas.

For information about increasing quotas for SageMaker Canvas operations that are used to forecast time series data, see Amazon Forecast endpoints and quotas.
Give Users Permissions to Import Amazon Redshift Data

Your users might have datasets stored in Amazon Redshift. Before users can import data from Amazon Redshift into SageMaker Canvas, you must add the AmazonRedshiftFullAccess managed policy to the IAM execution role that you've used for the user profile.

To add the AmazonRedshiftFullAccess policy to the user's IAM role, do the following.

1. Go to the IAM console.
2. Choose Roles.
3. In the search box, search for the user's IAM role by name and select it.
4. On the page for the user's role, under Permissions, choose Add permissions.
5. Choose Attach policies.
6. Search for the AmazonRedshiftFullAccess managed policy and select it.
7. Choose Attach policies to attach the policy to the role.

For more information about AWS managed policies, see Managed policies and inline policies in the AWS IAM User Guide.

Manage apps

The following sections describe how you can manage your SageMaker Canvas applications. You can view, delete, or relaunch your apps from the Control Panel in the SageMaker console.

Check for active apps

To check if you have any actively running SageMaker Canvas apps, use the following procedure.

1. Open the SageMaker console.
2. In the navigation pane, select Control panel.
3. Under Users, select the user profile name for the SageMaker Canvas app you want to view.
4. Under Apps, find the app that says Canvas in the App type column.

The Status column displays the status of the app, such as Ready, Pending, or Deleted. If the app is Ready, then your SageMaker Canvas session is active. You can delete the app from the console or log out from the SageMakerCanvas interface to stop the session.

Delete app

If you want to end your SageMaker Canvas session, you can either log out from the SageMaker Canvas app or delete your app from the SageMaker console. A session is the period of time from when you start using SageMaker Canvas to the point when you stop using it. Deleting the app only ends the session. Models and datasets aren't affected, but Quick build tasks are cancelled. The billing for the session also stops.

Use the following procedure to delete your SageMakerCanvas app.

1. Open the SageMaker console.
2. In the navigation pane, select Control panel.
3. Under Users, select the user profile name for the SageMaker Canvas app you want to view.
4. Under Apps, find the app that says Canvas in the App type column.
5. In the Action column, choose Delete app.
6. In the Delete app dialog box, select the Yes, delete app prompt, confirm the deletion by typing delete, and then choose Delete.
After you've successfully deleted the app, the **Status** column says **Deleted**. Otherwise, your app is still active.

You can also end the session by logging out (p. 284) from within the SageMaker Canvas app.

**Relaunch app**

If you delete or log out of your SageMaker Canvas app and want to relaunch the app, use the following procedure.

1. Open the SageMaker console.
2. In the navigation pane, select **Control panel**.
3. Under **Users**, select the user profile name for the SageMaker Canvas app you want to view.
4. Choose **Launch app** and select **Canvas** from the dropdown list.

SageMaker Canvas begins launching the app.

**Configure Amazon SageMaker Canvas in a VPC without internet access**

The Amazon SageMaker Canvas application runs in a container in an AWS managed Amazon Virtual Private Cloud (VPC). If you want to further control access to your resources or run SageMaker Canvas without public internet access, you can configure your Amazon SageMaker Domain and VPC settings. Within your own VPC, you can configure settings such as security groups (virtual firewalls that control inbound and outbound traffic from Amazon EC2 instances) and subnets (ranges of IP addresses in your VPC). To learn more about VPCs, see **How Amazon VPC works**.

When the SageMaker Canvas application is running in the AWS managed VPC, it can interact with other AWS services using either an internet connection or through VPC endpoints created in a customer-managed VPC (without public internet access). SageMaker Canvas applications can access these VPC endpoints through a Studio-created network interface that provides connectivity to the customer-managed VPC. The default behavior of the SageMaker Canvas application is to have internet access. When using an internet connection, the containers for the preceding jobs access AWS resources over the internet, such as the Amazon S3 buckets where you store training data and model artifacts.

However, if you have security requirements to control access to your data and job containers, we recommend that you configure SageMaker Canvas and your VPC so that your data and containers aren’t accessible over the internet. SageMaker uses the VPC configuration settings you specify when setting up your Domain for SageMaker Canvas.

If you want to configure your SageMaker Canvas application without internet access, you must configure your VPC settings when you onboard to Amazon SageMaker Domain (p. 35), set up VPC endpoints, and grant the necessary AWS Identity and Access Management permissions. For information about configuring a VPC in Amazon SageMaker, see **Choose a VPC** (p. 42). The following sections describe how to run SageMaker Canvas in a VPC without public internet access.

**Configure Amazon SageMaker Canvas in a VPC without internet access**

You can send traffic from SageMaker Canvas to other AWS services through your own VPC. If your own VPC doesn’t have public internet access and you’ve set up your Domain in **VPC only** mode, then SageMaker Canvas won’t have public internet access as well. This includes all requests, such as accessing datasets in Amazon S3 or training jobs for standard builds, and the requests go through VPC endpoints in your VPC instead of the public internet. When you onboard to Domain and **Choose a VPC** (p. 42), you can specify your own VPC as the default VPC for the Domain, along with your desired security group and subnet settings. Then, SageMaker creates a network interface in your VPC that SageMaker Canvas uses to access VPC endpoints in your VPC. Note that the security group and subnet settings are set after you finish onboarding to Domain.
When onboarding to Domain, if you choose Public internet only as the network access type, the VPC is SageMaker managed and allows internet access.

You can change this behavior by choosing VPC only so that SageMaker sends all traffic to a network interface that SageMaker creates in your specified VPC. When you choose this option, you must provide the subnets, security groups, and VPC endpoints that are necessary to communicate with the SageMaker API and SageMaker Runtime, and various AWS services, such as Amazon S3 and Amazon CloudWatch, that are used by SageMaker Canvas. Note that you can only import data from Amazon S3 buckets located in the same Region as your VPC.

The following procedures show how you can configure these settings to use SageMaker Canvas without the internet.

**Step 1: Onboard to Amazon SageMaker Domain**

To send SageMaker Canvas traffic to a network interface in your own VPC instead of over the internet, specify the VPC you want to use when onboarding to Amazon SageMaker Domain (p. 35). Choose Standard setup and do the following procedure when configuring the Network and Storage Section for the Domain.

1. Select your desired VPC.
2. Choose one or more Subnets. If you don’t specify a subnet, SageMaker uses all of the subnets.
3. Choose one or more Security group(s).
4. Choose VPC Only to turn off direct internet access in the AWS managed VPC where SageMaker Canvas is hosted.

After disabling internet access, finish the onboarding process to set up your Domain. For more information about the VPC settings for Amazon SageMaker Domain, see Choose a VPC (p. 42).

**Step 2: Configure VPC endpoints**

SageMaker Canvas only accesses other AWS services to manage and store data for its functionality. For example, it connects to Amazon Redshift if your users access an Amazon Redshift database. It can connect to an AWS service such as Amazon Redshift using an internet connection or a VPC endpoint. Use VPC endpoints if you want to set up connections from your VPC to AWS services that don’t use the public internet.

A VPC endpoint creates a private connection to an AWS service that uses a networking path that is isolated from the public internet. For example, if you set up access to Amazon S3 using a VPC endpoint from your own VPC, then the SageMaker Canvas application can access Amazon S3 by going through the network interface in your VPC and then through the VPC endpoint that connects to Amazon S3. The communication between SageMaker Canvas and Amazon S3 is private.

For more information about configuring VPC endpoints for your VPC, see AWS PrivateLink.

The following are the VPC endpoints for each service you can use with SageMaker Canvas:

<table>
<thead>
<tr>
<th>Service</th>
<th>Endpoint</th>
<th>Endpoint type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon Athena</td>
<td>com.amazonaws.Region.athena</td>
<td>Interface</td>
</tr>
<tr>
<td>Amazon SageMaker</td>
<td>com.amazonaws.Region.sagemaker.api</td>
<td>Interface</td>
</tr>
<tr>
<td></td>
<td>com.amazonaws.Region.sagemaker.runtime</td>
<td></td>
</tr>
<tr>
<td></td>
<td>com.amazonaws.Region.notebook</td>
<td></td>
</tr>
</tbody>
</table>
### Step 3: Grant IAM permissions

The SageMaker Canvas user must have the necessary AWS Identity and Access Management permissions to allow connection to the VPC endpoints. The IAM role to which you give permissions must be the same one you used when onboarding to Amazon SageMaker Domain. You can attach the SageMaker managed AmazonSageMakerFullAccess policy to the IAM role for the user to give the user the required permissions. If you require more restrictive IAM permissions and use custom policies instead, then give the user's role the `ec2:DescribeVpcEndpointServices` permission. SageMaker Canvas requires these permissions to verify the existence of the required VPC endpoints for standard build jobs. If it detects these VPC endpoints, then standard build jobs run by default in your VPC. Otherwise, they will run in the default AWS managed VPC.

For instructions on how to attach the AmazonSageMakerFullAccess IAM policy to your user's IAM role, see Adding and removing IAM identity permissions.

To grant your user's IAM role the granular `ec2:DescribeVpcEndpointServices` permission, use the following procedure.

1. Sign in to the AWS Management Console and open the IAM console.
2. In the navigation pane, choose Roles.
3. In the list, choose the name of the role to which you want to grant permissions.
4. Choose the Permissions tab.
5. Choose Add permissions and then choose Create inline policy.
6. Choose the JSON tab and enter the following policy, which grants the `ec2:DescribeVpcEndpointServices` permission:

```json
{
    "Version": "2012-10-17",
    "Statement": [
```
7. Choose **Review policy**, and then enter a **Name** for the policy (for example, VPCEndpointPermissions).

8. Choose **Create policy**.

The user's IAM role should now have permissions to access the VPC endpoints configured in your VPC.

(Optional) **Step 4: Override security group settings for specific users**

If you are an administrator, you might want different users to have different VPC settings, or user-specific VPC settings. When you override the default VPC's security group settings for a specific user, these settings are passed on to the SageMaker Canvas application for that user.

You can override the security groups that a specific user has access to in your VPC when you set up a new user profile in Studio. You can use the `CreateUserProfile` SageMaker API call (or `create_user_profile` with the `AWS CLI`), and then in the `UserSettings`, you can specify the `SecurityGroups` for the user.

**Importing data in Amazon SageMaker Canvas**

You can import data from different data sources into Amazon SageMaker Canvas. The data sources include Amazon S3, your local machine, and external data sources. Currently, you can only import comma delimited `.csv` files. Your `.csv` files must not have newline characters except when denoting a new row. You can use the dataset that you import to build a model and make predictions on other datasets.

You can import data from the following external data sources:

- An Amazon S3 bucket from an external account
- An Amazon Redshift database
- Snowflake

You can import data with the following data types:

- Categorical
- Numeric
- Text
- Datetime

Canvas has the following limits for importing data and building models.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum dataset file size</td>
<td>5 GB</td>
</tr>
<tr>
<td>Maximum number of columns in datasets</td>
<td>1000</td>
</tr>
<tr>
<td>Maximum number of rows for Quick builds</td>
<td>50,000</td>
</tr>
</tbody>
</table>
To import data from an external data source, create a connection. For more information, see Connect to an external data source (p. 248).

To import data from multiple files on your local machine or Amazon S3 locations, you import the data from each data source and join them into a single dataset. For information about joining datasets, see Join data that you’ve imported into SageMaker Canvas (p. 253).

SageMaker Canvas provides several sample datasets in your application to help you get started. To learn more about the SageMaker-provided sample datasets you can experiment with, see Use sample datasets (p. 255).

## Connect to an external data source

Add a connection to an external data source to import data from it. The credentials that you specify depend on the data source that you’re connecting to. For more information, see the following sections.

### Connect to an Amazon Redshift database

You can import data from Amazon Redshift, a data warehouse where your organization keeps its data. Before you can import data from Amazon Redshift, the AWS IAM role you use must have the AmazonRedshiftFullAccess managed policy attached. For instructions on how to attach this policy, see Give Users Permissions to Import Amazon Redshift Data (p. 243).

To import data from Amazon Redshift, you do the following:

1. Create a connection to Amazon Redshift database.
2. Choose the data that you're importing.
3. Import the data.

You can use the Amazon Redshift editor to drag datasets onto the import pane and import them into SageMaker Canvas. For more control over the values returned in the dataset, you can use the following:

- SQL queries
- Joins

SQL queries give you the ability to customize how you import the values in the dataset. For example, you can specify the columns returned in the dataset or the range of values for a column.

You can use joins to combine multiple datasets from Amazon Redshift into a single dataset. You can drag your datasets from Amazon Redshift into the panel that gives you the ability to join the datasets.

You can use the SQL editor to edit the dataset that you've joined and convert the joined dataset into a single node. You can join another dataset to the node. You can import the data that you've selected into SageMaker Canvas.

Use the following procedure to import data from Amazon Redshift.

You can join datasets before you import them into SageMaker Canvas using SQL or the SageMaker Canvas interface. You can consolidate the joins you make into a single node before joining them into another node.
1. Navigate to the import data screen.
2. Choose Add connection.
3. Choose Amazon Redshift.
4. Specify your Amazon Redshift credentials.
5. From the tab that has the name of your connection, drag the .csv file that you’re importing to the Drag and drop table to import pane.
6. Optional: Drag additional tables to the import pane. You can use the GUI to join the tables. For more specificity in your joins, choose **Edit in SQL**.
7. Optional: If you’re using SQL to query the data, you can choose **Context** to add context to the connection by specifying values for the following:
   - Warehouse
   - Database
   - Schema
8. Choose Import.

The following image shows an example of fields specified for an Amazon Redshift connection.

The following image shows the page used to join datasets in Amazon Redshift.

The following image shows a SQL query being used to edit a join in Amazon Redshift.
Use Snowflake with Amazon SageMaker Canvas

You can import data from your Snowflake account by doing the following:

1. Create a connection to the Snowflake database.
2. Choose the data that you're importing by dragging and dropping the table from the left navigation menu into the editor.
3. Import the data.

You can use the Snowflake editor to drag datasets onto the import pane and import them into SageMaker Canvas. For more control over the values returned in the dataset, you can use the following:

- SQL queries
- Joins

SQL queries give you the ability to customize how you import the values in the dataset. For example, you can specify the columns returned in the dataset or the range of values for a column.

You can use joins to combine multiple datasets from Snowflake into a single dataset. You can drag your datasets from Snowflake into the panel that gives you the ability to join the datasets.

You can combine the datasets that you've joined into a single node and join the nodes to a different Snowflake dataset. You can import the data that you've selected into SageMaker Canvas.

Use the following procedure to import data from Snowflake to Amazon SageMaker Canvas.

You can join datasets before you import them into SageMaker Canvas using SQL or the SageMaker Canvas interface. You can edit the joins in SQL and convert the SQL into a single node. You can join other nodes to the node that you've converted.

1. Navigate to the import data screen.
2. Choose Add connection.
3. Choose Snowflake.
4. Specify your Snowflake credentials.
5. From the tab that has the name of your connection, drag the .csv file that you're importing to the Drag and drop table to import pane.
6. Optional: Drag additional tables to the import pane. You can use the user interface to join the tables. For more specificity in your joins, choose **Edit in SQL**.

7. Optional: If you’re using SQL to query the data, you can choose **Context** to add context to the connection by specifying values for the following:
   - **Warehouse**
   - **Database**
   - **Schema**

   Adding context to a connection makes it easier to specify future queries.

8. Choose **Import**.

The following image shows an example of fields specified for a Snowflake connection.

The following image shows the page used to add context to a connection.
The following image shows the page used to join datasets in Snowflake.

The following image shows a SQL query being used to edit a join in Snowflake.
Join data that you've imported into SageMaker Canvas

You can use Amazon SageMaker Canvas to join multiple datasets into a single dataset. A join combines the two datasets. By default, SageMaker Canvas automatically joins the datasets on their matching column names. The option to combine multiple datasets might give you the ability to get more insight from the models that you build.

You can make the following joins for your datasets:

- **Inner** – Returns a dataset with matching values in both datasets.
- **Left** – Returns a dataset that has:
  - All the rows from the dataset to the left of the join.
  - All the rows from the dataset to the right of the join that have matching values with the columns to the left of the join.
- **Right** – Returns a dataset that has:
  - All the rows from the dataset to the right of the join.
  - All the rows from the dataset to the left of the join that have matching values with the columns to the right of the join.
- **Outer** – Returns all the rows when there is a match in either the left or the right dataset. The dataset from an outer join might have null values that SageMaker Canvas might impute when you build a model.

Use the following procedure to join your datasets.

To join datasets, do the following.

1. Navigate to the **Datasets** page.
2. Choose **Join data**.
3. Drag and drop the datasets that you’re joining into the **Drag and drop datasets to join** box.
4. Configure the join. Amazon SageMaker Canvas shows you a preview of the joined data after you configure it.
5. Choose **Save joined data** to save the output of the join.

The following images show the workflow of the preceding procedure.
Use sample datasets

SageMaker Canvas provides sample datasets addressing unique use cases so you can start building, training, and validating models quickly without writing any code. The use cases associated with these datasets highlight the capabilities of SageMaker Canvas, and you can leverage these datasets to get started with building models. You can find the sample datasets in the Datasets page of your SageMaker Canvas application.
Sample datasets

The following datasets are the samples that SageMaker Canvas provides by default. These datasets cover use cases such as predicting house prices, loan defaults, and readmission for diabetic patients; forecasting sales; predicting machine failures to streamline predictive maintenance in manufacturing units; and generating supply chain predictions for transportation and logistics. The datasets are stored in the sample_dataset folder in the default Amazon S3 bucket that SageMaker creates for your account in a Region.

- **canvas-sample-diabetic-readmission.csv:** This dataset contains historical data including over fifteen features with patient and hospital outcomes. You can use this dataset to predict whether high-risk diabetic patients are likely to get readmitted to the hospital within 30 days of discharge, after 30 days, or not at all. Use the **redadmitted** column as the target column, and use the 3+ category prediction model type with this dataset. To learn more about how to build a model with this dataset, see the SageMaker Canvas workshop page. This dataset was obtained from the UCI Machine Learning Repository.

- **canvas-sample-housing.csv:** This dataset contains data on the characteristics tied to a given housing price. You can use this dataset to predict housing prices. Use the **median_house_value** column as the target column, and use the Numeric prediction model type with this dataset. To learn more about building a model with this dataset, see the SageMaker Canvas workshop page. This is the California housing dataset obtained from the StatLib repository.

- **canvas-sample-loans.csv:** This dataset contains complete loan data for all loans issued from 2007–2011, including the current loan status and latest payment information. You can use this dataset to predict whether a customer will repay a loan. Use the **loan_status** column as the target column, and use the 3+ category prediction model type with this dataset. To learn more about how to build a model with this dataset, see the SageMaker Canvas workshop page. This data uses the LendingClub data obtained from Kaggle.

- **canvas-sample-maintenance.csv:** This dataset contains data on the characteristics tied to a given maintenance failure type. You can use this dataset to predict which failure will occur in the future. Use the **Failure Type** column as the target column, and use the 3+ category prediction model type with this dataset. To learn more about how to build a model with this dataset, see the SageMaker Canvas workshop page. This dataset was obtained from the UCI Machine Learning Repository.

- **canvas-sample-shipping-logs.csv:** This dataset contains complete shipping data for all products delivered, including estimated time shipping priority, carrier, and origin. You can use this dataset to predict the estimated time of arrival of the shipment in number of days. Use the **ActualShippingDays** column as the target column, and use the Numeric prediction model type with this dataset. To learn more about how to build a model with this data, see the SageMaker Canvas workshop page. This is a synthetic dataset created by Amazon.

- **canvas-sample-sales-forecasting.csv:** This dataset contains historical time series sales data for retail stores. You can use this dataset to forecast sales for a particular retail store. Use the **sales** column as the target column, and use the Time series forecasting model type with this dataset. To learn more about how to build a model with this dataset, see the SageMaker Canvas workshop page. This is a synthetic dataset created by Amazon.

Re-import a deleted sample dataset

If you no longer wish to use the sample datasets, you can delete them from the Datasets page of your SageMaker Canvas application. However, these datasets are still stored in the default SageMaker-created Amazon S3 bucket for your account, so you can always access them later.

The default Amazon S3 bucket name where the datasets are stored follows the pattern **sagemaker-{region}-{account ID}**. You can find the sample datasets in the directory path **Canvas/sample_dataset**.

If you delete a sample dataset from your SageMaker Canvas application and want to access the sample dataset again, use the following procedure.
1. Navigate to the Datasets page in your SageMaker Canvas application.
2. Choose Import data.
3. From the list of S3 buckets, select the default SageMaker S3 bucket for your account, which follows the naming pattern sagemaker-{region}-{account ID}.
4. Select the Canvas folder.
5. Select the sample_dataset folder, which contains all of the sample datasets for SageMaker Canvas.
6. Select the dataset you want to import, and then choose Import data.

Build a model

Use Amazon SageMaker Canvas to build a model on the dataset that you've imported. Use the model that you've built to make predictions on new data. SageMaker Canvas uses the information in the dataset to build up to 250 models and choose the one that performs the best.

For each model that you build, you choose the Target column. The Target column is the column that contains the information that you want to predict. For example, if you're building a model to predict whether people have cancelled their subscriptions, the Target column contains data points that are either a "yes" or a "no" about someone's cancellation status.

Amazon SageMaker Canvas uses the data in the Target column to automatically recommend one or more Model types. Model types fall into one of the following categories:

- Categorical prediction, known as classification in machine learning
- Numeric prediction, known as regression in machine learning

The following are the types of categorical prediction:

- 2 category prediction. The machine learning term for 2 category prediction is binary classification. Predicting whether someone has cancelled their subscription is an example of 2 category prediction.
- 3+ category prediction. The machine learning term for 3+ category prediction is multiclass classification.

Amazon SageMaker Canvas predicts the value of the Target column by using the information in the rest of the dataset. For categorical prediction, SageMaker Canvas puts each row into one of the categories listed in the Target column. For numeric prediction, SageMaker Canvas uses the information in the dataset to predict the numeric values in the Target column.

The Build page of SageMaker Canvas generates a preview of 100 rows taken from your dataset, or if your dataset has more than 20,000 rows, then SageMaker Canvas selects 100 rows from a random sample of your dataset. To learn more about the random sample and how you can change the sample size, see the following section Random sample (p. 259).

Before building your model, you can filter your data or prepare it using advanced transforms. For more information about preparing your data for model building, see Prepare data with advanced transformations (p. 266).

To build your model, you can choose either a Quick build or a Standard build. The Quick build usually takes 2-20 minutes to build the model, whereas the Standard build usually takes 2-4 hours and generally has a higher accuracy. For a Quick build, your input dataset can have a maximum of 50,000 rows. If you log out while running a Quick build, your build might be interrupted until you log in again. When you log in again, SageMaker Canvas restarts the Quick build.

While Amazon SageMaker Canvas builds the model, it automatically adds missing values for datasets that don't have time series data. SageMaker Canvas uses the values in your dataset to perform a
mathematical approximation for the missing values. For the highest model accuracy, we recommend adding in the missing data if you can find it.

Amazon SageMaker Canvas can make time series forecasts on your data. Time series forecasts are useful for when you make predictions over a period of time. For information about time series forecasts, see Time Series Forecasts in Amazon SageMaker Canvas (p. 284).

Preview a model

Amazon SageMaker Canvas gives you the ability to get insights from your data before you build a model by choosing Preview model. For example, you can see how the data in each column is distributed. For models built using categorical data, you can also choose Preview model to generate an Estimated accuracy prediction of how well the model might analyze your data. The accuracy of a Quick build or a Standard build represents how well the model can perform on real data and is generally higher than the Estimated accuracy.

Amazon SageMaker Canvas automatically handles missing values in your dataset while it builds the model. It infers the missing values by using adjacent values that are present in the dataset.

Validate data

Before you build your model, SageMaker Canvas checks your dataset for issues that will cause your build to fail. If SageMaker Canvas finds any issues, then it warns you on the Build page before you attempt to build a model.

You can choose Validate data to see a list of the issues with your dataset. You can then use the SageMaker Canvas data preparation features (p. 266) and tools, or your own tools, to fix your dataset before starting a build. If you don’t fix the issues with your dataset, then your build will fail.

If you make changes to your dataset to fix the issues, you have the option to re-validate your dataset before attempting a build. We recommend that you re-validate your dataset before building.

The following table shows the issues that SageMaker Canvas checks for in your dataset and how to resolve them.

<table>
<thead>
<tr>
<th>Issue</th>
<th>Resolution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wrong model type for your data</td>
<td>Try another model type or use a different dataset.</td>
</tr>
<tr>
<td>Missing values in your target column</td>
<td>Replace the missing values, drop rows with missing values, or use a different dataset.</td>
</tr>
<tr>
<td>Issue</td>
<td>Resolution</td>
</tr>
<tr>
<td>------------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Too many unique labels in your target column</td>
<td>Verify that you've used the correct column for your target column, or use a different dataset.</td>
</tr>
<tr>
<td>Too many non-numeric values in your target column</td>
<td>Choose a different target column, select another model type, or use a different dataset.</td>
</tr>
<tr>
<td>One or more column names contain double underscores</td>
<td>Rename the columns to remove any double underscores, and try again.</td>
</tr>
<tr>
<td>None of the rows in your dataset are complete</td>
<td>Replace the missing values, or use a different dataset.</td>
</tr>
<tr>
<td>Too many unique labels for the number of rows in your data</td>
<td>Check that you're using the right target column, increase the number of rows in your dataset, consolidate similar labels, or use a different dataset.</td>
</tr>
</tbody>
</table>

### Random sample

SageMaker Canvas uses the random sampling method to sample your dataset. The random sample method means that each row has an equal chance of being picked for the sample. You can choose a column in the preview to get summary statistics for the random sample, such as the mean and the mode.

By default, SageMaker Canvas uses a random sample size of 20,000 rows from your dataset for datasets with more than 20,000 rows. For datasets smaller than 20,000 rows, the default sample size is the number of rows in your dataset. You can increase or decrease the sample size by choosing Random sample in the Build tab of the SageMaker Canvas app. You can use the slider to select your desired sample size, and then choose Update to change the sample size. The maximum sample size you can choose for a dataset is 40,000 rows, and the minimum sample size is 500 rows. If you choose a large sample size, the dataset preview and summary statistics might take a few moments to reload.

The Build page shows a preview of 100 rows from your dataset. If the sample size is the same size as your dataset, then the preview uses the first 100 rows of your dataset. Otherwise, the preview uses the first 100 rows of the random sample.

### Explore your data using visualization techniques

With Amazon SageMaker Canvas, you can explore and visualize your data, helping you to gain advanced insights into your data before building your ML models. You can visualize using scatter plots, bar charts, and box plots, which can help you understand your data and discover the relationships between features that could affect the model accuracy.

In the Build tab of the SageMaker Canvas app, choose Data visualizer to begin creating your visualizations.

You can change the visualization sample size to adjust the size of the random sample taken from your dataset. A sample size that is too large might affect the performance of your data visualizations, so we recommend that you choose an appropriate sample size. To change the sample size, use the following procedure.

1. Choose Visualization sample.
2. Use the slider to select your desired sample size.
3. Choose Update to confirm the change to your sample size.
**Note**
Certain visualization techniques require columns of a specific data type. For example, you can only use numeric columns for the x and y-axes of scatter plots.

**Scatter plot**

To create a scatter plot with your dataset, choose **Scatter plot** in the **Visualization** panel. Then, you can choose the features you want to plot on the x and y-axes from the **Columns** section. You can drag and drop the columns onto the axes, or once an axis has been dropped, you can choose a column from the list of supported columns.

You can use **Color by** to color the data points on the plot with a third feature. You can also use **Group by** to group the data into separate plots based on a fourth feature.

The following image shows a scatter plot that uses **Color by** and **Group by**. In this example, each data point is colored by the **MaritalStatus** feature, and grouping by the **Department** feature results in a scatter plot for the data points of each department.
Bar chart

To create a bar chart with your dataset, choose Bar chart in the Visualization panel. Then, you can choose the features you want to plot on the x and y-axes from the Columns section. You can drag and drop the columns onto the axes, or once an axis has been dropped, you can choose a column from the list of supported columns.

You can use Group by to group the bar chart by a third feature. You can use Stack by to vertically shade each bar based on the unique values of a fourth feature.

The following image shows a bar chart that uses Group by and Stack by. In this example, the bar chart is grouped by the MaritalStatus feature and stacked by the JobLevel feature. For each JobRole on the x axis, there is a separate bar for the unique categories in the MaritalStatus feature, and every bar is vertically stacked by the JobLevel feature.
Box plot

To create a box plot with your dataset, choose Box plot in the Visualization panel. Then, you can choose the features you want to plot on the x and y-axes from the Columns section. You can drag and drop the columns onto the axes, or once an axis has been dropped, you can choose a column from the list of supported columns.

You can use Group by to group the box plots by a third feature.

The following image shows a box plot that uses Group by. In this example, the x and y-axes show JobLevel and JobSatisfaction, respectively, and the colored box plots are grouped by the Department feature.
Prepare data with advanced transformations

Your machine learning dataset might require data preparation before you build your model. You might want to clean your data due to various issues, which might include missing values or outliers, and perform feature engineering to improve the accuracy of your model. Amazon SageMaker Canvas provides ML data transforms with which you can clean, transform, and prepare your data for model building. You can use these transforms on your datasets without any code. SageMaker Canvas adds the transforms you use to the Model recipe, which is a record of the data preparation done on your data before building the model. Any data transforms you use only modify the input data for model building and do not modify your original data source.

The following transforms are available in SageMaker Canvas for you to prepare your data for building.

**Note**
The preview of your dataset shows the first 100 rows of the dataset. If your dataset has more than 20,000 rows, Canvas takes a random sample of 20,000 rows and previews the first 100 rows from that sample. You can only search for and specify values from the previewed rows, and the filter functionality only filters the previewed rows and not the entire dataset.

Functions and operators

You can use mathematical functions and operators to explore and distribute your data. You can use the SageMaker Canvas supported functions or create your own formula with your existing data and create a new column with the result of the formula. For example, you can add the corresponding values of two columns and save the result to a new column.

You can nest statements to create more complex functions. The following are some examples of nested functions that you might use.

- To calculate BMI, you could use the function \( \frac{\text{weight}}{\text{height}^2} \).
- To classify ages, you could use the function \( \text{Case}(\text{age} < 18, \text{'child'}, \text{age} < 65, \text{'adult'}, \text{'senior'}) \).

You can specify functions in the data preparation stage before you build your model. To use a function, do the following.

- In the **Build** tab of the SageMaker Canvas app, choose **Functions** to open up the **Functions** panel.
- In the **Functions** panel, you can choose a **Formula** to add to your **Model Recipe**. Each formula is applied to all of the values in the column(s) you specify. For formulas that accept two or more columns as arguments, use columns with matching data types; otherwise, you will get an error or null values in the new column.
- After you've specified a **Formula**, add a column name in the **New Column Name** field. SageMaker Canvas uses this name for the new column that is created.
- To add the function to your Model Recipe, choose **Add**.

SageMaker Canvas saves the result of your function to a new column using the name you specified in **New Column Name**. You can view or remove functions from the **Model Recipe** panel.

SageMaker Canvas supports the following operators for functions. You can use either the text format or the in-line format to specify your function.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Supported data types</th>
<th>Text format</th>
<th>In-line format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add</td>
<td>Returns the sum of the values</td>
<td>Numeric</td>
<td>Add(sales1, sales2)</td>
<td>sales1 + sales2</td>
</tr>
<tr>
<td>Operator</td>
<td>Description</td>
<td>Supported data types</td>
<td>Text format</td>
<td>In-line format</td>
</tr>

<td>----------</td>
<td>-------------</td>
<td>----------------------</td>
<td>-------------</td>
<td>----------------</td>
</tr>
<tr>
<td>Subtract</td>
<td>Returns the difference between the values</td>
<td>Numeric</td>
<td>Subtract(sales1, sales2)</td>
<td>sales1 - sales2</td>
</tr>
<tr>
<td>Multiply</td>
<td>Returns the product of the values</td>
<td>Numeric</td>
<td>Multiply(sales1, sales2)</td>
<td>sales1 * sales2</td>
</tr>
<tr>
<td>Divide</td>
<td>Returns the quotient of the values</td>
<td>Numeric</td>
<td>Divide(sales1, sales2)</td>
<td>sales1 / sales2</td>
</tr>
<tr>
<td>Mod</td>
<td>Returns the result of the modulo operator (the remainder after dividing the two values)</td>
<td>Numeric</td>
<td>Mod(sales1, sales2)</td>
<td>sales1 % sales2</td>
</tr>
<tr>
<td>Abs</td>
<td>Returns the absolute value of the value</td>
<td>Numeric</td>
<td>Abs(sales1)</td>
<td>N/A</td>
</tr>
<tr>
<td>Negate</td>
<td>Returns the negative of the value</td>
<td>Numeric</td>
<td>Negate(c1)</td>
<td>-c1</td>
</tr>
<tr>
<td>Exp</td>
<td>Returns e (Euler's number) raised to the power of the value</td>
<td>Numeric</td>
<td>Exp(sales1)</td>
<td>N/A</td>
</tr>
<tr>
<td>Log</td>
<td>Returns the logarithm (base 10) of the value</td>
<td>Numeric</td>
<td>Log(sales1)</td>
<td>N/A</td>
</tr>
<tr>
<td>Ln</td>
<td>Returns the natural logarithm (base e) of the value</td>
<td>Numeric</td>
<td>Ln(sales1)</td>
<td>N/A</td>
</tr>
<tr>
<td>Pow</td>
<td>Returns the value raised to a power</td>
<td>Numeric</td>
<td>Pow(sales1, 2)</td>
<td>sales1 ^ 2</td>
</tr>
<tr>
<td>If</td>
<td>Returns a true or false label based on a condition you specify</td>
<td>Boolean, Numeric, Text</td>
<td>If(sales1&gt;7000, 'truelabel', 'falselabel')</td>
<td>N/A</td>
</tr>
<tr>
<td>Or</td>
<td>Returns a boolean value of whether one of the specified values/conditions is true or not</td>
<td>Boolean</td>
<td>Or(fullprice, discount)</td>
<td>fullprice</td>
</tr>
<tr>
<td>And</td>
<td>Returns a boolean value of whether two of the specified values/conditions are true or not</td>
<td>Boolean</td>
<td>And(sales1, sales2)</td>
<td>sales1 &amp;&amp; sales2</td>
</tr>
<tr>
<td>Not</td>
<td>Returns a boolean value that is the opposite of the specified value/conditions</td>
<td>Boolean</td>
<td>Not(sales1)</td>
<td>!sales1</td>
</tr>
<tr>
<td>Case</td>
<td>Returns a boolean value based on conditional statements (returns c1 if cond1 is true, returns c2 if cond2 is true, else returns c3)</td>
<td>Boolean, Numeric, Text</td>
<td>Case(cond1, c1, cond2, c2, c3)</td>
<td>N/A</td>
</tr>
<tr>
<td>Equal</td>
<td>Returns a boolean value of whether two values are equal</td>
<td>Boolean, Numeric, Text</td>
<td>N/A</td>
<td>c1 = c2</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>c1 == c2</td>
</tr>
</tbody>
</table>
### Operator

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Supported data types</th>
<th>Text format</th>
<th>In-line format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Not equal</td>
<td>Returns a boolean value of whether two values are not equal</td>
<td>Boolean, Numeric, Text</td>
<td>N/A</td>
<td>c1 != c2</td>
</tr>
<tr>
<td>Less than</td>
<td>Returns a boolean value of whether c1 is less than c2</td>
<td>Boolean, Numeric, Text</td>
<td>N/A</td>
<td>c1 &lt; c2</td>
</tr>
<tr>
<td>Greater than</td>
<td>Returns a boolean value of whether c1 is greater than c2</td>
<td>Boolean, Numeric, Text</td>
<td>N/A</td>
<td>c1 &gt; c2</td>
</tr>
<tr>
<td>Less than or equal</td>
<td>Returns a boolean value of whether c1 is less than or equal to c2</td>
<td>Boolean, Numeric, Text</td>
<td>N/A</td>
<td>c1 &lt;= c2</td>
</tr>
<tr>
<td>Greater than or equal</td>
<td>Returns a boolean value of whether c1 is greater than or equal to c2</td>
<td>Boolean, Numeric, Text</td>
<td>N/A</td>
<td>c1 &gt;= c2</td>
</tr>
</tbody>
</table>

SageMaker Canvas also supports aggregate operators, which can perform operations such as calculating the sum of all the values or finding the minimum value in a column. You can use aggregate operators in combination with standard operators in your functions. For example, to calculate the difference of values from the mean, you could use the function $\text{Abs} (\text{height} - \text{avg(\text{height})})$. SageMaker Canvas supports the following aggregate operators.

<table>
<thead>
<tr>
<th>Aggregate operator</th>
<th>Description</th>
<th>Format</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>sum</td>
<td>Returns the sum of all the values in a column</td>
<td>sum</td>
<td>sum(c1)</td>
</tr>
<tr>
<td>minimum</td>
<td>Returns the minimum value of a column</td>
<td>min</td>
<td>min(c2)</td>
</tr>
<tr>
<td>maximum</td>
<td>Returns the maximum value of a column</td>
<td>max</td>
<td>max(c3)</td>
</tr>
<tr>
<td>average</td>
<td>Returns the average value of a column</td>
<td>avg</td>
<td>avg(c4)</td>
</tr>
<tr>
<td>std</td>
<td>Returns the sample standard deviation of a column</td>
<td>std</td>
<td>std(c1)</td>
</tr>
<tr>
<td>stddev</td>
<td>Returns the standard deviation of the values in a column</td>
<td>stddev</td>
<td>stddev(c1)</td>
</tr>
<tr>
<td>variance</td>
<td>Returns the unbiased variance of the values in a column</td>
<td>variance</td>
<td>variance(c1)</td>
</tr>
<tr>
<td>approx_count_distinct</td>
<td>Returns the approximate number of distinct items in a column</td>
<td>approx_count_distinct</td>
<td>approx_count_distinct(c1)</td>
</tr>
<tr>
<td>count</td>
<td>Returns the number of items in a column</td>
<td>count</td>
<td>count(c1)</td>
</tr>
<tr>
<td>first</td>
<td>Returns the first value of a column</td>
<td>first</td>
<td>first(c1)</td>
</tr>
</tbody>
</table>
### Aggregate operator

<table>
<thead>
<tr>
<th>Description</th>
<th>Format</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>last Returns the last value of a column</td>
<td>last</td>
<td>last(c1)</td>
</tr>
<tr>
<td>stddev_pop Returns the population standard</td>
<td>stddev_pop</td>
<td>stddev_pop(c1)</td>
</tr>
<tr>
<td>deviation of a column</td>
<td></td>
<td></td>
</tr>
<tr>
<td>variance_pop Returns the population variance of</td>
<td>variance_pop</td>
<td>variance_pop(c1)</td>
</tr>
<tr>
<td>the values in a column</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Datetime extraction

With the datetime extraction transform, you can extract values from a datetime column to a separate column. For example, if you have a column containing dates of purchases, you can extract the month value to a separate column and use the new column when building your model. You can also extract multiple values to separate columns with a single transform.

Your datetime column must use a supported timestamp format. For a list of the formats that SageMaker Canvas supports, see [Time Series Forecasts in Amazon SageMaker Canvas](p. 284). If your dataset does not use one of the supported formats, update your dataset to use a supported timestamp format and re-import it to Amazon SageMaker Canvas before building your model.

To perform a datetime extraction, do the following.

1. In the **Build** tab of the SageMaker Canvas application, choose **Extract**.
2. Choose the **Column** from which you want to extract values.
3. For **Value**, select one or more values to extract from the column. The values you can extract from a timestamp column are **Year**, **Month**, **Day**, **Hour**, **Week of year**, **Day of year**, and **Quarter**.
4. Choose **Add** to add the transform to the **Model recipe**.

SageMaker Canvas creates a new column in the dataset for each of the values you extract. Except for **Year** values, SageMaker Canvas uses a 0-based encoding for the extracted values. For example, if you extract the **Month** value, January is extracted as 0, and February is extracted as 1.

You can see the transform listed in the **Model recipe** section. If you remove the transform from the **Model recipe** section, the new columns are removed from the dataset.
Drop columns

You can exclude a column from your model build by dropping it in the Build tab of the SageMaker Canvas application. Deselect the column you want to drop, and it isn’t included when building the model.

**Note**

If you drop columns and then make batch predictions (p. 225) with your model, SageMaker Canvas adds the dropped columns back to the .csv file available for you to download. However, SageMaker Canvas does not add the dropped columns back for time series models.

Rename columns

With the rename columns transform, you can rename columns in your data. When you rename a column, SageMaker Canvas changes the column name in the model input.

You can rename a column in your dataset by double-clicking on the column name in the Build tab of the SageMaker Canvas application and entering a new name. Pressing the Enter key submits the change, and clicking anywhere outside the input cancels the change. You can also rename a column by clicking the **More options** icon (i), located at the end of the row in list view or at the end of the header cell in grid view, and choosing **Rename**.

Your column name can’t be longer than 32 characters or have double underscores (_), and you can’t rename a column to the same name as another column. You also can’t rename a dropped column.

The following screenshot shows how to rename a column by double-clicking the column name.

When you rename a column, SageMaker Canvas adds the transform in the **Model recipe** section. If you remove the transform from the **Model recipe** section, the column reverts to its original name.

Remove rows

This transform removes rows of data from the dataset where values in a specific column meet conditions that you specify. You can remove rows that have missing values, contain outliers, or meet custom conditions in a column you choose. These rows are not used when building your model.

Remove rows by missing values

Missing values are a common occurrence in machine learning datasets and can impact model accuracy. Use this transform if you want to drop rows with null or empty values in certain columns.

To remove rows that contain missing values in a specified column, do the following.
1. In the Build tab of the SageMaker Canvas application, choose Remove rows by.
2. Choose the Column you want to check for missing values.
3. For the Operation, choose Is missing.
4. Choose Add to add the transform to the Model recipe.

SageMaker Canvas drops rows that contain missing values in the Column you selected. After removing the rows from the dataset, SageMaker Canvas adds the transform in the Model recipe section. If you remove the transform from the Model recipe section, the rows return to your dataset.

Remove rows by outliers

Outliers, or rare values in the distribution and range of your data, can negatively impact model accuracy and lead to longer building times. With SageMaker Canvas, you can detect and remove rows that contain outliers in numeric columns. You can choose to define outliers with either standard deviations or a custom range.

To remove outliers from your data, do the following.
1. In the Build tab of the SageMaker Canvas application, choose Remove rows by.
2. Choose the Column you want to check for outliers.
3. For the Operation, choose Is outlier.
4. Set the Outlier range to either Standard deviation or Custom range.
5. If you choose Standard deviation, specify a SD (standard deviation) value from 1–3. If you choose Custom range, select either Percentile or Number, and then specify the Min and Max values.
6. Choose Add to add the transform to the Model recipe.

The Standard deviation option detects and removes outliers in numeric columns using the mean and standard deviation. You specify the number of standard deviations a value must vary from the mean to be considered an outlier. For example, if you specify 3 for SD, a value must fall more than 3 standard deviations from the mean to be considered an outlier.

The Custom range option detects and removes outliers in numeric columns using minimum and maximum values. Use this method if you know your threshold values that delimit outliers. You can set the Type of the range to either Percentile or Number. If you choose Percentile, the Min and Max values should be the minimum and maximum of the percentile range (0–100) that you want to allow. If you choose Number, the Min and Max values should be the minimum and maximum numeric values that you want to allow in the data.
After removing the rows from the dataset, SageMaker Canvas adds the transform in the **Model recipe** section. If you remove the transform from the **Model recipe** section, the rows return to your dataset.

### Remove rows by custom values

You can remove rows with values that meet custom conditions. For example, you might want to exclude all of the rows with a price value greater than 100 when building your model. With this transform, you can create a rule that removes all rows that exceed the threshold you set.

To use the custom remove transform, do the following.

1. In the **Build** tab of the SageMaker Canvas application, choose **Remove rows by**.
2. Choose the **Column** you want to check.
3. Select the type of **Operation** you want to use, and then specify the value(s) for the selected condition.
4. Choose **Add** to add the transform to the **Model recipe**.

For the **Operation**, you can choose one of the following options. Note that the available operations depend on the data type of the column you choose. For example, you cannot create a “Greater than” operation for a column containing text values.

<table>
<thead>
<tr>
<th>Operation</th>
<th>Supported column type</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Is equal to</td>
<td>Binary, numeric, text, categorical</td>
<td>Removes rows where the value in <strong>Column</strong> equals the values you specify.</td>
</tr>
<tr>
<td>Is not equal to</td>
<td>Binary, numeric, text, categorical</td>
<td>Removes rows where the value in <strong>Column</strong> doesn't equal the values you specify.</td>
</tr>
<tr>
<td>Is less than</td>
<td>Numeric</td>
<td>Removes rows where the value in <strong>Column</strong> is less than the value you specify.</td>
</tr>
<tr>
<td>Is less than or equal to</td>
<td>Numeric</td>
<td>Removes rows where the value in <strong>Column</strong> is less than or equal to the value you specify.</td>
</tr>
<tr>
<td>Is greater than</td>
<td>Numeric</td>
<td>Removes rows where the value in <strong>Column</strong> is greater than the value you specify.</td>
</tr>
<tr>
<td>Is greater than or equal to</td>
<td>Numeric</td>
<td>Removes rows where the value in <strong>Column</strong> is greater than or equal to the value you specify.</td>
</tr>
</tbody>
</table>
### Replace values

This transform replaces values in your dataset where the values in a specific column meet conditions that you specify. You can replace missing values or outliers. SageMaker Canvas uses the replaced values when building your model but doesn't change your original dataset. Note that if you've dropped a column from your dataset using the *Drop columns* transform, you can't replace values in that column.

#### Replace missing values

Missing values are a common occurrence in machine learning datasets and can impact model accuracy. You can choose to drop rows that have missing values, but your model is more accurate if you choose to replace the missing values instead. With this transform, you can replace missing values in numeric columns with the mean or median of the data in a column, or you can also specify a custom value with which to replace missing values. For non-numeric columns, you can replace missing values with the mode (most common value) of the column or a custom value.

Use this transform if you want to replace the null or empty values in certain columns. To replace missing values in a specified column, do the following.

1. In the *Build* tab of the SageMaker Canvas application, choose *Replace*.
2. Choose the *Column* in which you want to replace missing values.
3. For *Values to replace*, choose *Is missing*.  

<table>
<thead>
<tr>
<th>Operation</th>
<th>Supported column type</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Is between</td>
<td>Numeric</td>
<td>Remarks where the value in <em>Column</em> is between or equal to two values you specify.</td>
</tr>
<tr>
<td>Contains</td>
<td>Text, categorical</td>
<td>Remarks where the value in <em>Column</em> contains a values you specify.</td>
</tr>
<tr>
<td>Starts with</td>
<td>Text, categorical</td>
<td>Remarks where the value in <em>Column</em> begins with a value you specify.</td>
</tr>
<tr>
<td>Ends with</td>
<td>Text, categorical</td>
<td>Remarks where the value in <em>Column</em> ends with a value you specify.</td>
</tr>
</tbody>
</table>
4. Set Mode to either Automatic (default) or Manual. If you choose Automatic (default), SageMaker Canvas replaces missing values with imputed values that best fit your data. If you choose Manual, then specify the Replace with value in the next step.

5. (Optional) If you choose the Manual replacement option, set the Replace with value:
   - If your column is numeric, then select Mean, Median, or Custom. Mean replaces missing values with the mean for the column, and Median replaces missing values with the median for the column. If you choose Custom, then you must specify a custom value that you want to use to replace missing values.
   - If your column is non-numeric, then select Mode or Custom. Mode replaces missing values with the mode, or the most common value, for the column. For Custom, specify a custom value that you want to use to replace missing values.

6. Choose Add to add the transform to the Model recipe.

After replacing the missing values in the dataset, SageMaker Canvas adds the transform in the Model recipe section. If you remove the transform from the Model recipe section, the missing values return to the dataset.

Replace outliers

Outliers, or rare values in the distribution and range of your data, can negatively impact model accuracy and lead to longer building times. SageMaker Canvas enables you to detect outliers in numeric columns and replace the outliers with values that lie within an accepted range in your data. You can choose to define outliers with either standard deviations or a custom range, and you can replace outliers with the minimum and maximum values in the accepted range.

To replace outliers in your data, do the following.

1. In the Build tab of the SageMaker Canvas application, choose Replace.
2. Choose the Column in which you want to replace outliers.
3. For Values to replace, choose Is outlier.
4. For Define outliers, choose either Standard deviation or Custom Range.
5. If you choose Standard deviation, specify a SD (standard deviation) value from 1–3. If you choose Custom Range, select either Percentile or Number, and then specify the Min and Max values.
6. For Replace with, select Min/max range.
7. Choose Add to add the transform to the Model recipe.
The **Standard deviation** option detects outliers in numeric columns using the mean and standard deviation. You specify the number of standard deviations a value must vary from the mean to be considered an outlier. For example, if you specify 3 for SD, a value must fall more than 3 standard deviations from the mean to be considered an outlier. SageMaker Canvas replaces outliers with the minimum value or maximum value in the accepted range. For example, if you configure the standard deviations to only include values from 200 to 300, then SageMaker Canvas changes a value of 198 to 200 (the minimum).

The **Custom Range** option detects outliers in numeric columns using minimum and maximum values. Use this method if you know your threshold values that delimit outliers. You can set the **Type** of the custom range to either **Percentile** or **Number**. If you choose **Percentile**, the **Min** and **Max** values should be the minimum and maximum of the percentile range (0-100) that you want to allow. If you choose **Number**, the **Min** and **Max** values should be the minimum and maximum numeric values that you want to allow. SageMaker Canvas replaces any values that fall outside of the minimum and maximum to the minimum and maximum values. For example, if your range only allows values from 1 to 100, then SageMaker Canvas changes a value of 102 to 100 (the maximum).

After replacing the values in the dataset, SageMaker Canvas adds the transform in the **Model recipe** section. If you remove the transform from the **Model recipe** section, the original values return to the dataset.

### Filter rows

The filter functionality filters the previewed rows (the first 100 rows of your dataset) according to conditions that you specify. Filtering rows creates a temporary preview of the data and does not impact the model building. You can filter to preview rows that have missing values, contain outliers, or meet custom conditions in a column you choose.

#### Filter rows by missing values

Missing values are a common occurrence in machine learning datasets. If you have rows with null or empty values in certain columns, you might want to filter for and preview those rows.

To filter missing values from your previewed data, do the following.

1. In the **Build** tab of the SageMaker Canvas application, choose **Filter by rows**.
2. Choose the **Column** you want to check for missing values.
3. For the **Operation**, choose **Is missing**.

SageMaker Canvas filters for rows that contain missing values in the **Column** you selected and provides a preview of the filtered rows.
Filter rows by outliers

Outliers, or rare values in the distribution and range of your data, can negatively impact model accuracy and lead to longer building times. SageMaker Canvas enables you to detect and filter rows that contain outliers in numeric columns. You can choose to define outliers with either standard deviations or a custom range.

To filter for outliers in your data, do the following.

1. In the **Build** tab of the SageMaker Canvas application, choose **Filter by rows** (Y).
2. Choose the **Column** you want to check for outliers.
3. For the **Operation**, choose **Is outlier**.
4. Set the **Outlier range** to either **Standard deviation** or **Custom range**.
5. If you choose **Standard deviation**, specify a **SD** (standard deviation) value from 1–3. If you choose **Custom range**, select either **Percentile** or **Number**, and then specify the **Min** and **Max** values.

The **Standard deviation** option detects and filters for outliers in numeric columns using the mean and standard deviation. You specify the number of standard deviations a value must vary from the mean to be considered an outlier. For example, if you specify 3 for **SD**, a value must fall more than 3 standard deviations from the mean to be considered an outlier.

The **Custom range** option detects and filters for outliers in numeric columns using minimum and maximum values. Use this method if you know your threshold values that delimit outliers. You can set the **Type** of the range to either **Percentile** or **Number**. If you choose **Percentile**, the **Min** and **Max** values should be the minimum and maximum of the percentile range (0-100) that you want to allow. If you choose **Number**, the **Min** and **Max** values should be the minimum and maximum numeric values that you want to filter in the data.
Filter rows by custom values

You can filter for rows with values that meet custom conditions. For example, you might want to preview rows that have a price value greater than 100 before removing them. With this functionality, you can filter rows that exceed the threshold you set and preview the filtered data.

To use the custom filter functionality, do the following.

1. In the Build tab of the SageMaker Canvas application, choose Filter by rows (Y).
2. Choose the Column you want to check.
3. Select the type of Operation you want to use, and then specify the value(s) for the selected condition.

For the Operation, you can choose one of the following options. Note that the available operations depend on the data type of the column you choose. For example, you cannot create a “Greater than” operation for a column containing text values.

<table>
<thead>
<tr>
<th>Operation</th>
<th>Supported column type</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Is equal to</td>
<td>Binary, numeric, text, categorical</td>
<td>Filters rows where the value in Column equals the values you specify.</td>
</tr>
<tr>
<td>Is not equal to</td>
<td>Binary, numeric, text, categorical</td>
<td>Filters rows where the value in Column doesn't equal the values you specify.</td>
</tr>
<tr>
<td>Is less than</td>
<td>Numeric</td>
<td>Filters rows where the value in Column is less than the value you specify.</td>
</tr>
<tr>
<td>Is less than or equal to</td>
<td>Numeric</td>
<td>Filters rows where the value in Column is less than or equal to the value you specify.</td>
</tr>
<tr>
<td>Is greater than</td>
<td>Numeric</td>
<td>Filters rows where the value in Column is greater than the value you specify.</td>
</tr>
<tr>
<td>Is greater than or equal to</td>
<td>Numeric</td>
<td>Filters rows where the value in Column is greater than or equal to the value you specify.</td>
</tr>
<tr>
<td>Is between</td>
<td>Numeric</td>
<td>Filters rows where the value in Column is between or equal to two values you specify.</td>
</tr>
</tbody>
</table>
Evaluating Your Model's Performance in Amazon SageMaker Canvas

You can evaluate how well your model performed on your data before you start using it to make predictions by using the following:

- **Column impact**
- **Scoring**
- **Advanced metrics**

**Column impact** is a percentage score that indicates how much weight a column has in making predictions in relation to the other columns. For a column impact of 25%, SageMaker Canvas weighs the prediction as 25% for the column and 75% for the other columns.

**Scoring** is a section that shows visualizations and figures that you can use to get more insights into your model's performance beyond the overall accuracy metric. For a categorical prediction, you can see the predicted values in contrast to the actual values.

**Advanced metrics** is a section that contains information that you can use for a deeper understanding of your model's performance.
Model Scoring

Amazon SageMaker Canvas provides different scoring information for both numeric and categorical prediction models.

The **Scoring** section for a categorical prediction model gives you the ability to visualize all the predictions. Line segments extend from the left of the page, indicating all the predictions the model has made. In the middle of the page, the line segments converge on a perpendicular segment to indicate the proportion of each prediction to a single category. From the predicted category, the segments branch out to the actual category. You can get a visual sense of how accurate the predictions were by following each line segment from the predicted category to the actual category.

The following image gives you an example **Scoring section** for a 2 category prediction model.

The following image gives you an example **Scoring section** for a 3+ category prediction model.

The **Scoring** section for numeric prediction shows a line to indicate the model's predicted value in relation to the data used to make predictions. The values of the numeric prediction are often +/- the RMSE (root mean squared error) value. The value that the model predicts is often within the range of the RMSE. The width of the purple band around the line indicates the RMSE range. The predicted values often fall within the range.

The following image shows the **Scoring** section for numeric prediction.
Use advanced metrics in your analyses

Amazon SageMaker Canvas uses different advanced performance metrics to give you a sense of how well your model performed. The advanced metrics that SageMaker Canvas shows you depend on whether your model performs numeric, categorical, or time series forecasting predictions on your data.

**Numeric prediction** refers to the mathematical concept of regression. When your **Target column** has values that can be measured, such as yearly revenue or the number of items sold by a department store, Amazon SageMaker Canvas builds a model on your data using regression. For more information about regression, see Metrics for numeric prediction (p. 281).

**Categorical prediction**, such as 2 category prediction or 3 category prediction, refers to the mathematical concept of classification. Categorical prediction can be performed on data that can be put into a category:

- The colors on a color wheel
- Instances where the data is either a 0 or 1
- Instances where the data is either a Yes or a No.
- A list of responses to a survey question.

**Time series forecasting** refers to making predictions that vary over time. You can perform time series forecasts on data with timestamps that correlate to a value you want to predict. For example, you can make a time series forecast that takes daily sales data and makes sales predictions for the next month.

SageMaker Canvas uses confusion matrices to help you visualize when a model makes predictions correctly.

The following image is an example of a confusion matrix for 2 categories.
Evaluating Your Model’s Performance in Amazon SageMaker Canvas

The following image is an example of a confusion matrix for 3+ categories.

Metrics for numeric prediction

The following defines the advanced metrics for numeric prediction in Amazon SageMaker Canvas and gives you information about how you can use them.

- **R2** – The percentage of the difference in the target column that can be explained by the input column.
- **MAE** – Mean absolute error. On average, the prediction for the target column is +/- {MAE} from the actual value.
- **MAPE** – Mean absolute percent error. On average, the prediction for the target column is +/- {MAPE} % from the actual value
- **RMSE** – Root Mean Square Error. The standard deviation of the errors.

The following image shows a graph of the residuals or errors. The horizontal line indicates an error of 0 or a perfect prediction. The blue dots are the errors. Their distance from the horizontal line indicates the magnitude of the errors.
The following image shows an error density plot.

**Metrics for categorical prediction**

The following defines the advanced metrics for categorical prediction in Amazon SageMaker Canvas and gives you information about how you can use them.

- **Missing** – A missing value contains no content or is non-existent. Missing values are automatically inferred.
- **Mismatched** – A mismatched value has a different data type from the type specified for its column. SageMaker Canvas categorizes these values as missing and infers values for them.
- **Unique** – The number and percentage of values that are unique.
- **Target correlation** – A value between -1 and 1 that represents strength of the linear relationship between a column and the target column. 0 represents no detectable relationship. 1 represents a strong positive relationship. -1 represents a strong negative relationship.
- **Column impact** – Identifies the relative impact of the column in predicting the target column.

The following is a list of available metrics for binary classification.
Making predictions on your data

- F1 – A balanced measure of accuracy that takes class balance into account.
- Accuracy – The percentage of correct predictions.
- Precision – Of all the times that {category-1} was predicted, the prediction was correct {precision}% of the time.
- Recall – The model correctly predicted {recall}% to be {category-1} when {target_column} was actually {category-1}.
- AUC – A value between 0 and 1 that indicates how well your model is able to separate the categories in your dataset. A value of 1 indicates that it was able to separate the categories perfectly.

The following is a list of available metrics for multi-classification.

- F1 – A balanced measure of accuracy that takes class balance into account.
- Accuracy – The percentage of correct predictions.
- Precision – Of all the times that {category-1} was predicted, the prediction was correct {precision}% of the time.
- Recall – The model correctly predicted {recall}% to be {category-1} when {target_column} was actually {category-1}.
- AUC – A value between 0 and 1 that indicates how well your model is able to separate the categories in your dataset. A value of 1 indicates that it was able to separate the categories perfectly.
- Average F1 – The F1 averaged for all categories.
- Average Accuracy – The percentage of correct predictions out of all the predictions that are made.
- Average Precision – The precision averaged for all categories.
- Average Recall – The recall averaged for all categories.
- Average AUC – The AUC averaged for all categories.

Metrics for time series forecasts

The following defines the advanced metrics for time series forecasts in Amazon SageMaker Canvas and gives you information about how you can use them.

- Average Weighted Quantile Loss (wQL) – Evaluates the forecast by averaging the accuracy at the P10, P50, and P90 quantiles. A lower value indicates a more accurate model.
- Weighted Absolute Percent Error (WAPE) – The sum of the absolute error normalized by the sum of the absolute target, which measure the overall deviation of forecasted values from observed values. A lower value indicates a more accurate model, where WAPE = 0 is a model with no errors.
- Root Mean Square Error (RMSE) – The square root of the average squared errors. A lower RMSE indicates a more accurate model, where RMSE = 0 is a model with no errors.
- Mean Absolute Percent Error (MAPE) – The percentage error (percent difference of the mean forecasted value versus the actual value) averaged over all time points. A lower value indicates a more accurate model, where MAPE = 0 is a model with no errors.
- Mean Absolute Scaled Error (MASE) – The mean absolute error of the forecast normalized by the mean absolute error of a simple baseline forecasting method. A lower value indicates a more accurate model, where MASE < 1 is estimated to be better than the baseline and MASE > 1 is estimated to be worse than the baseline.

Making predictions on your data

Use the model that you’ve built in Amazon SageMaker Canvas to make predictions with your model. For information about making predictions, see Step 5: Make predictions (p. 225).
Logging out of Amazon SageMaker Canvas

If you're not using Amazon SageMaker Canvas, you can log out of your session. A session starts as soon as you launch SageMaker Canvas from the console. Logging out ends the session. You are only billed for the duration of the session.

When you log out, your models and datasets aren't affected, but SageMaker Canvas cancels any Quick build tasks. If you log out of SageMaker Canvas while running a Quick build, your build might be interrupted until you log back in. When you log back in, SageMaker Canvas automatically restarts the build.

To log out, choose the Log out button (Logout) on the left panel of the SageMaker Canvas app.

You can also log out from the SageMaker Canvas app by deleting the app (p. 243) in the console.

After you log out, SageMaker Canvas tells you to start a new session in a different tab. Logging in takes between 3 minutes and 8 minutes. If you have an administrator who set up SageMaker Canvas for you, use the instructions they gave you to log back in. If don't have an administrator, see the procedure for accessing SageMaker Canvas in Prerequisites for setting up Amazon SageMaker Canvas (p. 215).

Time Series Forecasts in Amazon SageMaker Canvas

Amazon SageMaker Canvas gives you the ability to use machine learning time series forecasts. Time series forecasts give you the ability to make predictions that can vary with time.

You can make a time series forecast for the following examples:

- Forecasting your inventory in the coming months.
- The number of items sold in the next four months.
- The effect of reducing the price on sales during the holiday season.
- Item inventory in the next 12 months.
- The number of customers entering a store in the next several hours.
- Forecasting how a 10% reduction in the price of a product affects sales over a time period.

To make a time series forecast, your dataset must have the following:

- A timestamp column with all values having the datetime type.
- A target column that has the values that you're using to forecast future values.

The datetime values in the timestamp column must use one of the following formats:

- YYYY-MM-DD HH:MM:SS
- YYYY-MM-DDTHH:MM:SSZ
- YYYY-MM-DD
- MM/DD/YY
- MM/DD/YY HH:MM
- MM/DD/YYYY
- YYYY/MM/DD HH:MM:SS
- YYYY/MM/DD
• DD/MM/YYYY
• DD/MM/YY
• DD-MM-YY
• DD-MM-YYYY

You can make forecasts for the following intervals:

• 1 min
• 5 min
• 15 min
• 30 min
• 1 hour
• 1 day
• 1 week
• 1 month
• 1 year

For higher prediction accuracy, your dataset can also have additional columns that can provide data that can explain the variation in the target column. Using the additional explanatory columns might help you forecast future values in the target column more accurately.

For example, you can forecast the amount of ice cream sold by a grocery store. To make a forecast, you must have a timestamp column and a column that indicates how much ice cream the grocery store sold. For a more accurate forecast, your dataset can also include the price, the ambient temperature, the flavor of the ice cream, or a unique identifier for the ice cream.

Ice cream sales might increase when the weather is warmer. A decrease in the price of the ice cream might result in more units sold. Having a column with ambient temperature data and a column with pricing data can improve your ability to forecast the number of units of ice cream the grocery store sells.

You might have missing data for different reasons. The reason for your missing data might inform how you want Amazon SageMaker Canvas to impute it. For example, your organization might use an automatic system that only tracks when a sale happens. If you're using a dataset that comes from this type of automatic system, you have missing values in the target column.

For missing values in the dataset, SageMaker Canvas imputes the missing values for you.

**Important**

If you have missing values in the target column, we recommend using a dataset that doesn't have them. SageMaker Canvas uses the target column to forecast future values. Missing values in the target column can greatly reduce the accuracy of the forecast.

You can make one of the following types of forecasts:

• **Single item**
• **All items**

For a forecast on all the items in your dataset, SageMaker Canvas returns a forecast for the future values for each item in your dataset.

For a single item forecast, you specify the item and SageMaker Canvas returns a forecast for the future values. The forecast includes a line graph that plots the predicted values over time.
Topics

- Gain additional insights from your forecast (p. 286)
- Make a time series forecast (p. 286)

Gain additional insights from your forecast

In Amazon SageMaker Canvas, you can use the following optional methods to get more insights from your forecast:

- Group column
- Holiday schedule
- What-if scenario

You can specify a column in your dataset as a Group column. Amazon SageMaker Canvas groups the forecast by each value in the column. For example, you can group the forecast on columns containing price data or unique item identifiers. Grouping a forecast by a column lets you make more specific forecasts. For example, if you group a forecast on a column containing item identifiers, you can see the forecast for each item.

Overall sales of items might be impacted by the presence of holidays. For example, in the United States, the number of items sold in both November and December might differ greatly from the number of items sold in January. If you use the data from November and December to forecast the sales in January, your results might be inaccurate. Using a holiday schedule prevents you getting inaccurate results. You can use a holiday schedule for 66 countries.

For a forecast on a single item in your dataset, you can use what-if scenarios. A what-if scenario gives you the ability to change values in your data and change the forecast. For example, you can answer the following questions by using a what-if scenario, "What if I lowered prices? How would that affect the number of items sold?"

Make a time series forecast

To make a time series forecast, you choose a target column. The target column contains the data that you want to predict. For example, your target column might have data on the number of items sold. After you select the target column, Amazon SageMaker Canvas selects a Model type. SageMaker Canvas uses the time-series data to automatically choose a time series model that you can use to make predictions on your data. After you build the model, you can evaluate its performance and use it to make predictions on new data.

Use the following procedure to make a time series forecast.

To make a time-series forecast, do the following.

1. Import the data.
2. Choose a target column in your dataset.
3. SageMaker Canvas automatically chooses Time series forecasting as the model type. Choose Set configuration to confirm that you're performing a time series forecast.
4. Specify the following fields:
   - Item ID column – The column that contains unique identifiers for each item in your dataset. For example, an SKU number uniquely identifies an item.
   - Optional: Group column – Groups the time series forecast by values in the column. For example, you can group your forecast for an item by store.
• **Time stamp column** – The column containing the time stamps in your dataset. For a list of the supported date time formats for this column, see *Time Series Forecasts in Amazon SageMaker Canvas* (p. 284).

• **Future timestamp** – A timestamp that indicates a future forecast time. SageMaker Canvas forecasts values up to the point in time specified by the timestamp.

• Optional: **Holiday schedule** – Activate the holiday schedule to use a country's holiday schedule. Use it to make your forecasts with holiday data more accurate.

You can have one of the following types of missing values:

• Missing future values

• Missing values

Missing future values are missing values in the target column. SageMaker Canvas uses the values in the target column to forecast the values in the future. If you have missing values in the target column, your forecast might be less accurate. We highly recommend updating the dataset.

Missing values are values that are missing in any column other than the target column. With missing values that aren't in the target column, it's helpful to note the following:

• They generally don't reduce the accuracy of your forecast as much as missing future values.

• SageMaker Canvas automatically imputes the missing values.

You can evaluate the model by seeing how close the predictions are within the actual value. You can also use the **Column Impact** metric to determine the direction and magnitude of the column's impact on the model's predictions. For example, in the following image, holidays had the largest positive impact on the forecast for demand. Price had the largest negative impact on demand.

![Customer Churn Model](image)

After you've built a model, you can make the following types of forecasts:

• Single item – Make a forecast for a single item in a dataset and a line graph of the values that SageMaker Canvas forecasts. For example, you can see how sales of an item vary over time.
• All items – Make a forecast for all items in a dataset.
• What-if scenario – See how changing values in the dataset can affect the overall forecast for a single item.

The following image shows a single item forecast with a what-if scenario. In a what-if scenario, you have the ability to change values that can vary with time. You can see how changing the values affects the forecast.

The points connected by the solid blue line are the values that the model forecasts. The points connected by the dashed lines show the what-if scenario.

Updating a Model in Amazon SageMaker Canvas

Amazon SageMaker Canvas gives you the ability to update the models that you've built using new data. SageMaker Canvas shows you a model history, so that you can compare the models that you've built recently to those that you've generated in the past.

Each model that you build has a version number. The first model is Version 1.

If you have more than one version of a model, you can delete the versions that aren't useful to you.

You need to build at least one version of a model to add a new version.

Use the following procedure to add a new model version.

To add a new model version, do the following.

1. Choose the dropdown list at the top of the page. If you're on the first version of the model, it says V1 at the beginning.
2. Choose Add version.

The following image visualizes the preceding procedure.
After you choose a new version, you start the process of building another model. The process for building a new version of a model is almost the same as the process for building a model for the first time. For new versions of a model, you can only choose datasets that have the same target column as the target column in Version 1. For more information about building a model, see Step 3: Build a model (p. 221).

You can use the different versions of the model to see changes in prediction accuracy when you've used different model types or data.

**Share your models with data scientists**

You can share the models that you've built with data scientists. They can review the models and give you feedback.

- **Note**
  You can't share Quick build or time series models.

Use the following procedure to share a model.

To share a model, do the following.

1. From the screen showing the models that you've created, choose a model.
2. Choose Share.
3. Choose the versions of the model that you want to share.
4. Optional: For **Include a note with the link (optional)**, write a note giving more context on the model.
5. Choose Create SageMaker Studio Link.
6. Share the link with the data scientist.

**Manage billing and cost in SageMaker Canvas**

To track the costs associated with your SageMaker Canvas application, you can use the AWS Billing and Cost Management service. Billing and Cost Management provides tools to help you gather information related to your cost and usage, analyze your cost drivers and usage trends, and take action to budget your spending. For more information, see What is AWS Billing and Cost Management?.

Billing in SageMaker Canvas consists of the following components:
• Session charges – You are charged for the number of hours that you are logged in to or using SageMaker Canvas.
• Training charges – You are charged for training models based on the size of the dataset you use.

For more information, see SageMaker Canvas pricing.

To help you track your costs in Billing and Cost Management, you can assign custom tags to your SageMaker Canvas app and users. You can track the costs your apps incur, and by tagging individual user profiles, you can track costs based on the user profile. For more information about tags, see Using Cost Allocation Tags.

You can add tags to your SageMaker Canvas app and users by doing the following:

• If you are setting up your Amazon SageMaker Domain and SageMaker Canvas for the first time, follow the Getting Started instructions and add tags when creating your Domain or users. You can add tags either through the General settings in the Domain console setup, or through the APIs (CreateDomain or CreateUserProfile). SageMaker adds the tags specified in your Domain or UserProfile to any SageMaker Canvas apps or users you create after you create the Domain.
• If you want to add tags to apps in an existing Domain, you must add tags to either the Domain or the UserProfile. You can add tags through either the console or the AddTags API. If you add tags through the console, then you must delete and relaunch your SageMaker Canvas app in order for the tags to propagate to the app. If you use the API, the tags are added directly to the app. For more information about deleting and relaunching a SageMaker Canvas app, see Manage apps.

After you add tags to your Domain, it might take up to 24 hours for the tags to appear in the AWS Billing and Cost Management console for activation. After they appear in the console, it takes another 24 hours for the tags to activate.

On the Cost explorer page, you can group and filter your costs by tags and usage types to separate your Session charges from your Training charges. The names of the usage types are as follows:

• Session charges: REGION-Canvas:Session-Hrs (Hrs)
• Training charges:
  • REGION-Canvas:CreateModelRequest-Tier0 (CreateModelRequest)
  • REGION-Canvas:MillionCells-Tier1 (MillionCells)
Use Amazon SageMaker Notebook Instances

An Amazon SageMaker notebook instance is a machine learning (ML) compute instance running the Jupyter Notebook App. SageMaker manages creating the instance and related resources. Use Jupyter notebooks in your notebook instance to prepare and process data, write code to train models, deploy models to SageMaker hosting, and test or validate your models.

SageMaker also provides sample notebooks that contain complete code walkthroughs. These walkthroughs show how to use SageMaker to perform common machine learning tasks. For more information, see Example Notebooks (p. 306).

This video shows you how to setup and use SageMaker notebook instances. (Length: 26:04)

This video is a deep dive on how to use SageMaker notebook instances. (Length: 16:44)

Amazon Linux 2 vs Amazon Linux notebook instances

Amazon SageMaker notebook instances currently support Amazon Linux 2 (AL2) and Amazon Linux (AL1) operating systems. You can select the operating system that your notebook instances is based on when you create the notebook instance. Notebook instances created before 08/18/2021 automatically run on AL1.

Notebook instances based on AL1 will enter a maintenance phase as of 12/01/2022. To replace AL1, you now have the option to create Amazon SageMaker notebook instances with AL2. The AL1 maintenance phase also coincides with the deprecation of Python 2 and Chainer. Notebooks based on AL2 do not have managed Python 2 and Chainer kernels.
AL1 Maintenance Phase Plan

The following table is a timeline for when AL1 enters its extended maintenance phase.

<table>
<thead>
<tr>
<th>Date</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>08/18/2021</td>
<td>Notebook instances based on AL2 are launched. Newly launched notebook instances still default to AL1. AL1 is supported with security patches and updates, but no new features. You can choose between the two operating systems when launching a new notebook instance.</td>
</tr>
<tr>
<td>10/31/2022</td>
<td>The default platform identifier for SageMaker notebook instances changes from Amazon Linux (al1-v1) to Amazon Linux 2 (al2-v2). You can choose between the two operating systems when launching a new notebook instance.</td>
</tr>
<tr>
<td>12/01/2022</td>
<td>AL1 is no longer supported with non-critical security patches and updates. AL1 still receives fixes for critical security-related issues. You can still launch instances on AL1, but assume the risks associated with using an unsupported operating system.</td>
</tr>
<tr>
<td>02/01/2023</td>
<td>AL1 is no longer an available option for new notebook instance creation. After this date, customers can create notebook instances with the AL2 platform identifiers. Existing al1-v1 notebook instances are not be affected.</td>
</tr>
</tbody>
</table>

Available Kernels

notebook-al1-v1: The following kernels are available in notebook instances based on the Amazon Linux platform. These notebook instances support JupyterLab version 1. For information about JupyterLab versions, see JupyterLab versioning (p. 294).

<table>

**Migrating to Amazon Linux 2**

Your existing notebook instance is not automatically migrated to Amazon Linux 2. To upgrade your notebook instance to Amazon Linux 2, you must create a new notebook instance, replicate your code and environment, and delete your old notebook instance. For more information, see the Amazon Linux 2 migration blog.

**JupyterLab versioning**

The Amazon SageMaker notebook instance interface is based on JupyterLab, which is a web-based interactive development environment for notebooks, code, and data. Notebooks now support using either JupyterLab 1 or JupyterLab 3. A single notebook instance can run a single instance of JupyterLab (at most). You can have multiple notebook instances with different JupyterLab versions.

You can configure your notebook to run your preferred JupyterLab version by selecting the appropriate platform identifier. Use either the AWS CLI or the SageMaker console when creating your notebook instance. For more information about platform identifiers, see Amazon Linux 2 vs Amazon Linux notebook instances. If you don't explicitly configure a platform identifier, your notebook instance defaults to running JupyterLab 1.

**Topics**
- JupyterLab 3 (p. 294)
- Creating a notebook with your JupyterLab version (p. 295)
- View the JupyterLab version of a notebook from the console (p. 295)

**JupyterLab 3**

JupyterLab 3 support is available only on the Amazon Linux 2 operating system platform. JupyterLab 3 includes the following features that are not available in JupyterLab 1. For more information about these features, see JupyterLab 3.0 is released!
Important changes to JupyterLab 3

For information about important changes when using JupyterLab 3, see the following JupyterLab change logs:

- v2.0.0
- v3.0.0

Package version changes

JupyterLab 3 has the following package version changes from JupyterLab 1:

- JupyterLab has been upgraded from 1.x to 3.x.
- Jupyter notebook has been upgraded from 5.x to 6.x.
- jupyterlab-git has been updated to version 0.37.1.
- nbserverproxy 0.x (0.3.2) has been replaced with jupyter-server-proxy 3.x (3.2.1).

Creating a notebook with your JupyterLab version

You can select the JupyterLab version when creating your notebook instance from the console following the steps in Create a Notebook Instance (p. 296).

You can also select the JupyterLab version by passing the `platform-identifier` parameter when creating your notebook instance using the AWS CLI as follows:

```
create-notebook-instance --notebook-instance-name <NEW_NOTEBOOK_NAME> \
--instance-type <INSTANCE_TYPE> \
--role-arn <YOUR_ROLE_ARN> \
--platform-identifier <PLATFORM_TO_USE>
```

View the JupyterLab version of a notebook from the console

You can view the JupyterLab version of a notebook using the following procedure:

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Navigate to the Notebook instances page.
3. From the list of notebook instances, select your notebook instance name.
4. On the Notebook instance settings page, view the Platform Identifier to see the JupyterLab version of the notebook.

Create a Notebook Instance

An Amazon SageMaker notebook instance is a ML compute instance running the Jupyter Notebook App. SageMaker manages creating the instance and related resources. Use Jupyter notebooks in your notebook instance to prepare and process data, write code to train models, deploy models to SageMaker hosting, and test or validate your models.

To create a notebook instance, use either the SageMaker console or the CreateNotebookInstance API.

The notebook instance type you choose depends on how you use your notebook instance. You want to ensure that your notebook instance is not bound by memory, CPU, or IO. If you plan to load a dataset into memory on the notebook instance for exploration or preprocessing, we recommend that you choose an instance type with enough RAM memory for your dataset. This would require an instance with at least 16 GB of memory (xlarge or larger). If you plan to use the notebook for compute intensive preprocessing, we recommend you choose a compute-optimized instance such as a c4 or c5.

A best practice when using a SageMaker notebook is to use the notebook instance to orchestrate other AWS services. For example, you can use the notebook instance to manage large dataset processing by making calls to AWS Glue for ETL (extract, transform, and load) services or Amazon EMR for mapping and data reduction using Hadoop. You can use AWS services as temporary forms of computation or storage for your data.

You can store and retrieve your training and test data using an Amazon S3 bucket. You can then use SageMaker to train and build your model, so the instance type of your notebook would have no bearing on the speed of your model training and testing.

After receiving the request, SageMaker does the following:

- **Creates a network interface**—If you choose the optional VPC configuration, SageMaker creates the network interface in your VPC. It uses the subnet ID that you provide in the request to determine which Availability Zone to create the subnet in. SageMaker associates the security group that you provide in the request with the subnet. For more information, see Connect a Notebook Instance in a VPC to External Resources (p. 3633).
- **Launches an ML compute instance**—SageMaker launches an ML compute instance in a SageMaker VPC. SageMaker performs the configuration tasks that allow it to manage your notebook instance, and if you specified your VPC, it enables traffic between your VPC and the notebook instance.
- **Installs Anaconda packages and libraries for common deep learning platforms**—SageMaker installs all of the Anaconda packages that are included in the installer. For more information, see Anaconda package list. In addition, SageMaker installs the TensorFlow and Apache MXNet deep learning libraries.
- **Attaches an ML storage volume**—SageMaker attaches an ML storage volume to the ML compute instance. You can use the volume as a working area to clean up the training dataset or to temporarily store validation, test, or other data. Choose any size between 5 GB and 16384 GB, in 1 GB increments, for the volume. The default is 5 GB. ML storage volumes are encrypted, so SageMaker can't determine the amount of available free space on the volume. Because of this, you can increase the volume size when you update a notebook instance, but you can't decrease the volume size. If you want to decrease the size of the ML storage volume in use, create a new notebook instance with the desired size.

Only files and data saved within the `/home/ec2-user/SageMaker` folder persist between notebook instance sessions. Files and data that are saved outside this directory are overwritten when the notebook instance stops and restarts. Each notebook instance's `/tmp` directory provides a minimum
of 10 GB of storage in an instance store. An instance store is temporary, block-level storage that isn't persistent. When the instance is stopped or restarted, SageMaker deletes the directory's contents. This temporary storage is part of the root volume of the notebook instance.

- **Copies example Jupyter notebooks**— These Python code examples illustrate model training and hosting exercises using various algorithms and training datasets.

**To create a SageMaker notebook instance:**

2. Choose **Notebook instances**, then choose **Create notebook instance**.
3. On the **Create notebook instance** page, provide the following information:
   a. For **Notebook instance name**, type a name for your notebook instance.
   b. For **Notebook instance type**, choose an instance size suitable for your use case. For a list of supported instance types and quotas, see **Amazon SageMaker Service Quotas**.
   c. For **Elastic Inference**, choose an inference accelerator type to associate with the notebook instance if you plan to conduct inferences from the notebook instance, or choose **none**. For information about elastic inference, see **Use Amazon SageMaker Elastic Inference (EI)** (p. 3129).
   d. For **Platform Identifier**, choose a platform type to create the notebook instance on. This platform type dictates the Operating System and the JupyterLab version that your notebook instance is created with. For information about platform identifier type, see **Amazon Linux 2 vs Amazon Linux notebook instances** (p. 291). For information about JupyterLab versions, see **JupyterLab versioning** (p. 294).
   e. (Optional) **Additional configuration** lets advanced users create a shell script that can run when you create or start the instance. This script, called a lifecycle configuration script, can be used to set the environment for the notebook or to perform other functions. For information, see **Customize a Notebook Instance Using a Lifecycle Configuration Script** (p. 299).
   f. (Optional) **Additional configuration** also lets you specify the size, in GB, of the ML storage volume that is attached to the notebook instance. You can choose a size between 5 GB and 16,384 GB, in 1 GB increments. You can use the volume to clean up the training dataset or to temporarily store validation or other data.
   g. (Optional) For **Minimum IMDS Version**, select a version from the dropdown list. If this value is set to v1, both versions can be used with the notebook instance. If v2 is selected, then only IMDSv2 can be used with the notebook instance. For information about IMDSv2, see **Use IMDSv2**.

**Note**
Starting October 31, 2022, the default minimum IMDS Version for SageMaker notebook instances changes from IMDSv1 to IMDSv2. Starting February 1, 2023, IMDSv1 is no longer be available for new notebook instance creation. After this date, you can create notebook instances with a minimum IMDS version of 2.

h. For **IAM role**, choose either an existing IAM role in your account that has the necessary permissions to access SageMaker resources or choose **Create a new role**. If you choose **Create a new role**, SageMaker creates an IAM role named AmazonSageMaker-ExecutionRole-YYYYMMDDTHHnnmSS. The AWS managed policy AmazonSageMakerFullAccess is attached to the role. The role provides permissions that allow the notebook instance to call SageMaker and Amazon S3.

i. For **Root access**, to enable root access for all notebook instance users, choose **Enable**. To disable root access for users, choose **Disable**. If you enable root access, all notebook instance users have administrator privileges and can access and edit all files on it.

j. (Optional) **Encryption key** lets you encrypt data on the ML storage volume attached to the notebook instance using an AWS Key Management Service (AWS KMS) key. If you plan to store sensitive information on the ML storage volume, consider encrypting the information.
k. (Optional) **Network** lets you put your notebook instance inside a Virtual Private Cloud (VPC). A VPC provides additional security and restricts access to resources in the VPC from sources outside the VPC. For more information on VPCs, see *Amazon VPC User Guide*.

To add your notebook instance to a VPC:

i. Choose the **VPC** and a **SubnetId**.

ii. For **Security Group**, choose your VPC's default security group.

iii. If you need your notebook instance to have internet access, enable direct internet access. For **Direct internet access**, choose **Enable**. Internet access can make your notebook instance less secure. For more information, see *Connect a Notebook Instance in a VPC to External Resources* (p. 3633).

l. (Optional) To associate Git repositories with the notebook instance, choose a default repository and up to three additional repositories. For more information, see *Associate Git Repositories with SageMaker Notebook Instances* (p. 309).

m. Choose **Create notebook instance**.

   In a few minutes, Amazon SageMaker launches an ML compute instance—in this case, a notebook instance—and attaches an ML storage volume to it. The notebook instance has a preconfigured Jupyter notebook server and a set of Anaconda libraries. For more information, see the **CreateNotebookInstance** API.

4. When the status of the notebook instance is **InService**, in the console, the notebook instance is ready to use. Choose **Open Jupyter** next to the notebook name to open the classic Jupyter dashboard.

   You can choose **Open JupyterLab** to open the JupyterLab dashboard. The dashboard provides access to your notebook instance and sample SageMaker notebooks that contain complete code walkthroughs. These walkthroughs show how to use SageMaker to perform common machine learning tasks. For more information, see *Example Notebooks* (p. 306). For more information, see *Control root access to a SageMaker notebook instance* (p. 349).

   For more information about Jupyter notebooks, see *The Jupyter notebook*.

### Access Notebook Instances

To access your Amazon SageMaker notebook instances, choose one of the following options:

- Use the console.

Choose **Notebook instances**. The console displays a list of notebook instances in your account. To open a notebook instance with a standard Jupyter interface, choose **Open Jupyter** for that instance. To open a notebook instance with a JupyterLab interface, choose **Open JupyterLab** for that instance.

The console uses your sign-in credentials to send a
CreatePresignedNotebookInstanceUrl API request to SageMaker. SageMaker returns the URL for your notebook instance, and the console opens the URL in another browser tab and displays the Jupyter notebook dashboard.

**Note**
The URL that you get from a call to CreatePresignedNotebookInstanceUrl is valid only for 5 minutes. If you try to use the URL after the 5-minute limit expires, you are directed to the AWS Management Console sign-in page.

- Use the API.

To get the URL for the notebook instance, call the CreatePresignedNotebookInstanceUrl API and use the URL that the API returns to open the notebook instance.

Use the Jupyter notebook dashboard to create and manage notebooks and to write code. For more information about Jupyter notebooks, see http://jupyter.org/documentation.html.

## Update a Notebook Instance

After you create a notebook instance, you can update it using the SageMaker console and UpdateNotebookInstance API operation.

You can update the tags of a notebook instance that is InService. To update any other attribute of a notebook instance, its status must be Stopped.

**To update a notebook instance in the SageMaker console:**

2. Choose Notebook instances.
3. Choose the notebook instance that you want to update by selecting the notebook instance Name from the list.
4. If your notebook Status is not Stopped, select the Stop button to stop the notebook instance.
   - When you do this, the notebook instance status changes to Stopping. Wait until the status changes to Stopped to complete the following steps.
5. Select the Edit button to open the Edit notebook instance page. For information about the notebook properties you can update, see Create a Notebook Instance (p. 296).
6. Update your notebook instance and select the Update notebook instance button at the bottom of the page when you are done to return to the notebook instances page. Your notebook instance status changes to Updating.
   - When the notebook instance update is complete, the status changes to Stopped.

## Customize a Notebook Instance Using a Lifecycle Configuration Script

To install packages or sample notebooks on your notebook instance, configure networking and security for it, or otherwise use a shell script to customize it, use a lifecycle configuration. A lifecycle configuration provides shell scripts that run only when you create the notebook instance or whenever you start one.
When you create a notebook instance, you can create a new lifecycle configuration and the scripts it uses or apply one that you already have.

You can also use a lifecycle configuration script to access AWS services from your notebook. For example, you can create a script that lets you use your notebook to control other AWS resources, such as an Amazon EMR instance.

We maintain a public repository of notebook lifecycle configuration scripts that address common use cases for customizing notebook instances at https://github.com/aws-samples/amazon-sagemaker-notebook-instance-lifecycle-configuration-samples.

**Note**

Each script has a limit of 16384 characters.
The value of the $PATH environment variable that is available to both scripts is /usr/local/sbin:/usr/local/bin:/usr/bin:/usr/sbin:/sbin:/bin. The working directory, which is the value of the $PWD environment variable, is /.

View CloudWatch Logs for notebook instance lifecycle configurations in log group /aws/sagemaker/NotebookInstances in log stream [notebook-instance-name]/[LifecycleConfigHook].

Scripts cannot run for longer than 5 minutes. If a script runs for longer than 5 minutes, it fails and the notebook instance is not created or started. To help decrease the run time of scripts, try the following:

- Cut down on necessary steps. For example, limit which conda environments in which to install large packages.
- Run tasks in parallel processes.
- Use the nohup command in your script.

You can see a list of notebook instance lifecycle configurations you previously created by choosing Lifecycle configuration in the SageMaker console. These notebook instance lifecycle configurations are available when you create a new notebook instance.

**To create a lifecycle configuration**

2. On the left side under SageMaker dashboard, choose Lifecycle configurations.
3. From the Lifecycle configurations page, choose Create configuration.
4. For Name, type a name using alphanumeric characters and “-”, but no spaces. The name can have a maximum of 63 characters.
5. (Optional) To create a script that runs when you create the notebook and every time you start it, choose Start notebook.
6. In the Start notebook editor, type the script.
7. (Optional) To create a script that runs only once, when you create the notebook, choose Create notebook.
8. In the Create notebook editor, type the script configure networking.
9. Choose Create configuration.

**Lifecycle Configuration Best Practices**

The following are best practices for using lifecycle configurations:

**Important**

We do not recommend storing sensitive information in your lifecycle configuration script.
• Lifecycle configurations run as the root user. If your script makes any changes within the /home/ec2-user/SageMaker directory, (for example, installing a package with pip), use the command `sudo -u ec2-user` to run as the ec2-user user. This is the same user that Amazon SageMaker runs as.

• SageMaker notebook instances use conda environments to implement different kernels for Jupyter notebooks. If you want to install packages that are available to one or more notebook kernels, enclose the commands to install the packages with conda environment commands that activate the conda environment that contains the kernel where you want to install the packages.

For example, if you want to install a package only for the python3 environment, use the following code:

```bash
#!/bin/bash
sudo -u ec2-user -i <<'EOF'
# This will affect only the Jupyter kernel called "conda_python3".
source activate python3
# Replace myPackage with the name of the package you want to install.
pip install myPackage
# You can also perform "conda install" here as well.
source deactivate
EOF
```

If you want to install a package in all conda environments in the notebook instance, use the following code:

```bash
#!/bin/bash
sudo -u ec2-user -i <<'EOF'
# Note that "base" is special environment name, include it there as well.
for env in base /home/ec2-user/anaconda3/envs/*; do
  source /home/ec2-user/anaconda3/bin/activate $(basename "$env")
  # Installing packages in the Jupyter system environment can affect stability of your SageMaker Notebook Instance. You can remove this check if you'd like to install Jupyter extensions, etc.
  if [ "$env" = 'JupyterSystemEnv' ]; then
    continue
  fi

  # Replace myPackage with the name of the package you want to install.
  pip install --upgrade --quiet myPackage
  # You can also perform "conda install" here as well.
  source /home/ec2-user/anaconda3/bin/deactivate
done
EOF
```

• You must store all conda environments in the default environments folder (/home/user/anaconda3/envs).

**Important**
When you create or change a script, we recommend that you use a text editor that provides Unix-style line breaks, such as the text editor available in the console when you create a notebook. Copying text from a non-Linux operating system might introduce incompatible line breaks and result in an unexpected error.
Install External Libraries and Kernels in Notebook Instances

Amazon SageMaker notebook instances come with multiple environments already installed. These environments contain Jupyter kernels and Python packages including: scikit, Pandas, NumPy, TensorFlow, and MXNet. These environments, along with all files in the sample-notebooks folder, are refreshed when you stop and start a notebook instance. You can also install your own environments that contain your choice of packages and kernels.

The different Jupyter kernels in Amazon SageMaker notebook instances are separate conda environments. For information about conda environments, see Managing environments in the Conda documentation.

Install custom environments and kernels on the notebook instance's Amazon EBS volume. This ensures that they persist when you stop and restart the notebook instance, and that any external libraries you install are not updated by SageMaker. To do that, use a lifecycle configuration that includes both a script that runs when you create the notebook instance (on-create) and a script that runs each time you restart the notebook instance (on-start). For more information about using notebook instance lifecycle configurations, see Customize a Notebook Instance Using a Lifecycle Configuration Script (p. 299).

There is a GitHub repository that contains sample lifecycle configuration scripts at SageMaker Notebook Instance Lifecycle Config Samples. The examples at https://github.com/aws-samples/amazon-sagemaker-notebook-instance-lifecycle-config-samples/blob/master/scripts/persistent-conda-ebs/on-create.sh and https://github.com/aws-samples/amazon-sagemaker-notebook-instance-lifecycle-config-samples/blob/master/scripts/persistent-conda-ebs/on-start.sh show the best practice for installing environments and kernels on a notebook instance. The on-create script installs the ipykernel library to create custom environments as Jupyter kernels, then uses pip install and conda install to install libraries. You can adapt the script to create custom environments and install libraries that you want. SageMaker does not update these libraries when you stop and restart the notebook instance, so you can ensure that your custom environment has specific versions of libraries that you want. The on-start script installs any custom environments that you create as Jupyter kernels, so that they appear in the dropdown list in the Jupyter New menu.

Package installation tools

SageMaker notebooks support the following package installation tools:

- conda install
- pip install

You can install packages using the following methods:

- Lifecycle configuration scripts.
  
  For example scripts, see SageMaker Notebook Instance Lifecycle Config Samples. For more information on lifecycle configuration, see Customize a Notebook Instance Using a Lifecycle Configuration Script.
- Notebooks – The following commands are supported.
  
  • %conda install
  • %pip install
- The Jupyter terminal – You can install packages using pip and conda directly.

From within a notebook you can use the system command syntax (lines starting with !) to install packages, for example, !pip install and !conda install. More recently, new commands have been
added to IPython: `%pip` and `%conda`. These commands are the recommended way to install packages from a notebook as they correctly take into account the active environment or interpreter being used. For more information, see Add `%pip` and `%conda` magic functions.

**Conda**

Conda is an open source package management system and environment management system, which can install packages and their dependencies. SageMaker supports using Conda with either of the two main channels, the default channel, and the conda-forge channel. For more information, see Conda channels. The conda-forge channel is a community channel where contributors can upload packages.

**Note**

Due to how Conda resolves the dependency graph, installing packages from conda-forge can take significantly longer (in the worst cases, upwards of 10 minutes).

The Deep Learning AMI comes with many conda environments and many packages preinstalled. Due to the number of packages preinstalled, finding a set of packages that are guaranteed to be compatible is difficult. You may see a warning "The environment is inconsistent, please check the package plan carefully". Despite this warning, SageMaker ensures that all the SageMaker provided environments are correct. SageMaker cannot guarantee that any user installed packages will function correctly.

Conda has two methods for activating environments: conda activate/deactivate, and source activate/deactivate. For more information, see Should I use 'conda activate' or 'source activate' in Linux.

SageMaker supports moving Conda environments onto the Amazon EBS volume, which is persisted when the instance is stopped. The environments aren't persisted when the environments are installed to the root volume, which is the default behavior. For an example lifecycle script, see persistent-conda-ebs.

**Supported conda operations (see note at the bottom of this topic)**

- conda install of a package in a single environment
- conda install of a package in all environments
- conda install of a R package in the R environment
- Installing a package from the main conda repository
- Installing a package from conda-forge
- Changing the Conda install location to use EBS
- Supporting both conda activate and source activate

**Pip**

Pip is the de facto tool for installing and managing Python packages. Pip searches for packages on the Python Package Index (PyPI) by default. Unlike Conda, pip doesn't have built in environment support, and is not as thorough as Conda when it comes to packages with native/system library dependencies. Pip can be used to install packages in Conda environments.

You can use alternative package repositories with pip instead of the PyPI. For an example lifecycle script, see on-start.sh.

**Supported pip operations (see note at the bottom of this topic)**

- Using pip to install a package without an active conda environment (install packages system wide)
- Using pip to install a package in a conda environment
- Using pip to install a package in all conda environments
- Changing the pip install location to use EBS
- Using an alternative repository to install packages with pip
Unsupported

SageMaker aims to support as many package installation operations as possible. However, if the packages were installed by SageMaker or DLAMI, and you use the following operations on these packages, it might make your notebook instance unstable:

- Uninstalling
- Downgrading
- Upgrading

We do not provide support for installing packages via yum install or installing R packages from CRAN.

Due to potential issues with network conditions or configurations, or the availability of Conda or PyPi, we cannot guarantee that packages will install in a fixed or deterministic amount of time.

**Note**

We cannot guarantee that a package installation will be successful. Attempting to install a package in an environment with incompatible dependencies can result in a failure. In such a case you should contact the library maintainer to see if it is possible to update the package dependencies. Alternatively you can attempt to modify the environment in such a way as to allow the installation. This modification however will likely mean removing or updating existing packages, which means we can no longer guarantee stability of this environment.

Notebook Instance Software Updates

Amazon SageMaker periodically tests and releases software that is installed on notebook instances. This includes:

- Kernel updates
- Security patches
- AWS SDK updates
- Amazon SageMaker Python SDK updates
- Open source software updates

SageMaker does not update software on a notebook instance when it is in service. To ensure that you have the most recent software updates, stop and restart your notebook instance, either in the SageMaker console or by calling \texttt{StopNotebookInstance}.

You can also manually update software installed on your notebook instance while it is running by using update commands in a terminal or in a notebook.

**Note**

Updating kernels and some packages might depend on whether root access is enabled for the notebook instance. For more information, see Control root access to a SageMaker notebook instance (p. 3495).

Notebook instances do not notify you if you are running outdated software. You can check the Personal Health Dashboard or the security bulletin at Security Bulletins for updates.

Control an Amazon EMR Spark Instance Using a Notebook

You can use a notebook instance created with a custom lifecycle configuration script to access AWS services from your notebook. For example, you can create a script that lets you use your notebook with
Sparkmagic to control other AWS resources, such as an Amazon EMR instance. You can then use the Amazon EMR instance to process your data instead of running the data analysis on your notebook. This allows you to create a smaller notebook instance because you won’t use the instance to process data. This is helpful when you have large datasets that would require a large notebook instance to process the data.

The process requires three procedures using the Amazon SageMaker console:

- Create the Amazon EMR Spark instance
- Create the Jupyter Notebook
- Test the notebook-to-Amazon EMR connection

To create an Amazon EMR Spark instance that can be controlled from a notebook using Sparkmagic

1. Open the Amazon EMR console at https://console.aws.amazon.com/elasticmapreduce/.
2. In the navigation pane, choose Create cluster.
3. On the Create Cluster - Quick Options page, under Software configuration, choose Spark: Spark 2.4.4 on Hadoop 2.8.5 YARN with Ganglia 3.7.2 and Zeppelin 0.8.2.
4. Set additional parameters on the page and then choose Create cluster.
5. On the Cluster page, choose the cluster name that you created. Note the Master Public DNS, the EMR master’s security group, and the VPC name and subnet ID where the EMR cluster was created. You will use these values when you create a notebook.

To create a notebook that uses Sparkmagic to control an Amazon EMR Spark instance

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, under Notebook instances, choose Create notebook.
3. Enter the notebook instance name and choose the instance type.
4. Choose Additional configuration, then, under Lifecycle configuration, choose Create a new lifecycle configuration.
5. Add the following code to the lifecycle configuration script:

```bash
# OVERVIEW
# This script connects an Amazon EMR cluster to an Amazon SageMaker notebook instance that uses Sparkmagic.
#
# Note that this script will fail if the Amazon EMR cluster’s master node IP address is not reachable.
# 1. Ensure that the EMR master node IP is resolvable from the notebook instance. One way to accomplish this is to have the notebook instance and the Amazon EMR cluster in the same subnet.
# 2. Ensure the EMR master node security group provides inbound access from the notebook instance security group.
# 3. Ensure the notebook instance has internet connectivity to fetch the SparkMagic example config.
#
#
# PARAMETERS
EMR_MASTER_IP=your.emr.master.ip
```
Example Notebooks

Your notebook instance contains example notebooks provided by Amazon SageMaker. The example notebooks contain code that shows how to apply machine learning solutions by using SageMaker. Notebook instances use the nbexamples Jupyter extension, which enables you to view a read-only version of an example notebook or create a copy of it so that you can modify and run it. For more information about the nbexamples extension, see https://github.com/danielballan/nbexamples. For information about example notebooks for SageMaker Studio, see Use Amazon SageMaker Studio Notebooks (p. 129).
Note
Example notebooks typically download datasets from the internet. If you disable SageMaker-provided internet access when you create you notebook instance, example notebooks might not work. For more information, see Connect a Notebook Instance in a VPC to External Resources (p. 3653).

Use or View Example Notebooks in Jupyter Classic

To view or use the example notebooks in the classic Jupyter view, choose the SageMaker Examples tab.

To view a read-only version of an example notebook in the Jupyter classic view, on the SageMaker Examples tab, choose Preview for that notebook. To create a copy of an example notebook in the home directory of your notebook instance, choose Use. In the dialog box, you can change the notebook’s name before saving it.

Use or View Example Notebooks in Jupyterlab

To view or use the example notebooks in the Jupyterlab view, choose the examples icon in the left navigation panel.
To view a read-only version of an example notebook, choose the name of the notebook. This opens the notebook as a tab in the main area. To create a copy of an example notebook in the home directory of your notebook instance, choose Create a Copy in the top banner. In the dialog box, type a name for the notebook and then choose CREATE COPY.

For more information about the example notebooks, see the SageMaker examples GitHub repository.

Set the Notebook Kernel

Amazon SageMaker provides several kernels for Jupyter that provide support for Python 2 and 3, Apache MXNet, TensorFlow, and PySpark. To set a kernel for a new notebook in the Jupyter notebook dashboard, choose New, and then choose the kernel from the list.
You can also create a custom kernel that you can use in your notebook instance. For information, see Install External Libraries and Kernels in Notebook Instances (p. 302).

**Associate Git Repositories with SageMaker Notebook Instances**

Associate Git repositories with your notebook instance to save your notebooks in a source control environment that persists even if you stop or delete your notebook instance. You can associate one default repository and up to three additional repositories with a notebook instance. The repositories can be hosted in AWS CodeCommit, GitHub, or on any other Git server. Associating Git repositories with your notebook instance can be useful for:

- **Persistence** - Notebooks in a notebook instance are stored on durable Amazon EBS volumes, but they do not persist beyond the life of your notebook instance. Storing notebooks in a Git repository enables you to store and use notebooks even if you stop or delete your notebook instance.
- **Collaboration** - Peers on a team often work on machine learning projects together. Storing your notebooks in Git repositories allows peers working in different notebook instances to share notebooks and collaborate on them in a source-control environment.
- **Learning** - Many Jupyter notebooks that demonstrate machine learning techniques are available in publicly hosted Git repositories, such as on GitHub. You can associate your notebook instance with a repository to easily load Jupyter notebooks contained in that repository.

There are two ways to associate a Git repository with a notebook instance:

- **Add a Git repository as a resource in your Amazon SageMaker account.** Then, to access the repository, you can specify an AWS Secrets Manager secret that contains credentials. That way, you can access repositories that require authentication.
- **Associate a public Git repository that is not a resource in your account.** If you do this, you cannot specify credentials to access the repository.

**Topics**

- Add a Git Repository to Your Amazon SageMaker Account (p. 310)
- Create a Notebook Instance with an Associated Git Repository (p. 312)
- Associate a CodeCommit Repository in a Different AWS Account with a Notebook Instance (p. 313)
- Use Git Repositories in a Notebook Instance (p. 314)
Add a Git Repository to Your Amazon SageMaker Account

To manage your GitHub repositories, easily associate them with your notebook instances, and associate credentials for repositories that require authentication, add the repositories as resources in your Amazon SageMaker account. You can view a list of repositories that are stored in your account and details about each repository in the SageMaker console and by using the API.

You can add Git repositories to your SageMaker account in the SageMaker console or by using the AWS CLI.

Note
You can use the SageMaker API CreateCodeRepository to add Git repositories to your SageMaker account, but step-by-step instructions are not provided here.

Add a Git Repository to Your SageMaker Account (Console)

To add a Git repository as a resource in your SageMaker account
2. Under Notebook, choose Git repositories, then choose Add repository.
3. To add an CodeCommit repository, choose AWS CodeCommit. To add a GitHub or other Git-based repository, choose GitHub/Other Git-based repo.

To add an existing CodeCommit repository
1. Choose Use existing repository.
2. For Repository, choose a repository from the list.
3. Enter a name to use for the repository in SageMaker. The name must be 1 to 63 characters. Valid characters are a-z, A-Z, 0-9, and - (hyphen).
4. Choose Add repository.

To create a new CodeCommit repository
1. Choose Create new repository.
2. Enter a name for the repository that you can use in both CodeCommit and SageMaker. The name must be 1 to 63 characters. Valid characters are a-z, A-Z, 0-9, and - (hyphen).
3. Choose Create repository.

To add a Git repository hosted somewhere other than CodeCommit
1. Choose GitHub/Other Git-based repo.
2. Enter a name of up to 63 characters. Valid characters include alpha-numeric characters, a hyphen (-), and 0-9.
3. Enter the URL for the repository. Do not provide a user name in the URL. Add the username and password in AWS Secrets Manager as described in the next step.
4. For Git credentials, choose the credentials to use to authenticate to the repository. This is necessary only if the Git repository is private.

Note
If you have two-factor authentication enabled for your Git repository, use a personal access token generated by your Git service provider instead of a password.
a. To use an existing AWS Secrets Manager secret, choose **Use existing secret**, and then choose a secret from the list. For information about creating and storing a secret, see **Creating a Basic Secret** in the *AWS Secrets Manager User Guide*. The name of the secret you use must contain the string `sagemaker`.

**Note**
The secret must have a staging label of `AWSCURRENT` and must be in the following format:

```
{"username": Username, "password": Password}
```

For GitHub repositories, we recommend using a personal access token instead of your account password. For information, see [https://help.github.com/articles/creating-a-personal-access-token-for-the-command-line/](https://help.github.com/articles/creating-a-personal-access-token-for-the-command-line/).

b. To create a new AWS Secrets Manager secret, choose **Create secret**, enter a name for the secret, and then enter the username and password to use to authenticate to the repository. The name for the secret must contain the string `sagemaker`.

**Note**
The IAM role you use to create the secret must have the `secretsmanager:GetSecretValue` permission in its IAM policy. The secret must have a staging label of `AWSCURRENT` and must be in the following format:

```
{"username": Username, "password": Password}
```

For GitHub repositories, we recommend using a personal access token instead of your account password.

c. To not use any credentials, choose **No secret**.

5. Choose **Create secret**.

### Add a Git Repository to Your Amazon SageMaker Account (CLI)

Use the `create-code-repository` AWS CLI command. Specify a name for the repository as the value of the `code-repository-name` argument. The name must be 1 to 63 characters. Valid characters are a-z, A-Z, 0-9, and - (hyphen). Also specify the following:

- The default branch
- The URL of the Git repository

**Note**
Do not provide a user name in the URL. Add the username and password in AWS Secrets Manager as described in the next step.

- The Amazon Resource Name (ARN) of an AWS Secrets Manager secret that contains the credentials to use to authenticate the repository as the value of the `git-config` argument

For information about creating and storing a secret, see **Creating a Basic Secret** in the *AWS Secrets Manager User Guide*. The following command creates a new repository named `MyRepository` in your Amazon SageMaker account that points to a Git repository hosted at `https://github.com/myprofile/my-repo`.

For Linux, OS X, or Unix:

```
```

For Windows:

```
```
aws sagemaker create-code-repository ^
--code-repository-name "MyRepository" ^

Note
The secret must have a staging label of AWSCURRENT and must be in the following format:
{"username": UserName, "password": Password}
For GitHub repositories, we recommend using a personal access token instead of your account password.

Create a Notebook Instance with an Associated Git Repository

You can associate Git repositories with a notebook instance when you create the notebook instance by using the AWS Management Console, or the AWS CLI. If you want to use a CodeCommit repository that is in a different AWS account than the notebook instance, set up cross-account access for the repository. For information, see Associate a CodeCommit Repository in a Different AWS Account with a Notebook Instance (p. 313).

Topics
• Create a Notebook Instance with an Associated Git Repository (Console) (p. 312)
• Create a Notebook Instance with an Associated Git Repository (CLI) (p. 313)

Create a Notebook Instance with an Associated Git Repository (Console)

To create a notebook instance and associate Git repositories in the Amazon SageMaker console

1. Follow the instructions at Step 1: Create an Amazon SageMaker Notebook Instance (p. 74).
2. For Git repositories, choose Git repositories to associate with the notebook instance.
   a. For Default repository, choose a repository that you want to use as your default repository. SageMaker clones this repository as a subdirectory in the Jupyter startup directory at /home/ec2-user/SageMaker. When you open your notebook instance, it opens in this repository. To choose a repository that is stored as a resource in your account, choose its name from the list. To add a new repository as a resource in your account, choose Add a repository to SageMaker (opens the Add repository flow in a new window) and then follow the instructions at Create a Notebook Instance with an Associated Git Repository (Console) (p. 312). To clone a public repository that is not stored in your account, choose Clone a public Git repository to this notebook instance only, and then specify the URL for that repository.
   b. For Additional repository 1, choose a repository that you want to add as an additional directory. SageMaker clones this repository as a subdirectory in the Jupyter startup directory at /home/ec2-user/SageMaker. To choose a repository that is stored as a resource in your account, choose its name from the list. To add a new repository as a resource in your account, choose Add a repository to SageMaker (opens the Add repository flow in a new window) and then follow the instructions at Create a Notebook Instance with an Associated Git Repository (Console) (p. 312). To clone a repository that is not stored in your account, choose Clone a public Git repository to this notebook instance only, and then specify the URL for that repository.
Repeat this step up to three times to add up to three additional repositories to your notebook instance.

Create a Notebook Instance with an Associated Git Repository (CLI)

To create a notebook instance and associate Git repositories by using the AWS CLI, use the `create-notebook-instance` command as follows:

- Specify the repository that you want to use as your default repository as the value of the `default-code-repository` argument. Amazon SageMaker clones this repository as a subdirectory in the Jupyter startup directory at `/home/ec2-user/SageMaker`. When you open your notebook instance, it opens in this repository. To use a repository that is stored as a resource in your SageMaker account, specify the name of the repository as the value of the `default-code-repository` argument. To use a repository that is not stored in your account, specify the URL of the repository as the value of the `default-code-repository` argument.

- Specify up to three additional repositories as the value of the `additional-code-repositories` argument. SageMaker clones this repository as a subdirectory in the Jupyter startup directory at `/home/ec2-user/SageMaker`, and the repository is excluded from the default repository by adding it to the `.git/info/exclude` directory of the default repository. To use repositories that are stored as resources in your SageMaker account, specify the names of the repositories as the value of the `additional-code-repositories` argument. To use repositories that are not stored in your account, specify the URLs of the repositories as the value of the `additional-code-repositories` argument.

For example, the following command creates a notebook instance that has a repository named `MyGitRepo`, that is stored as a resource in your SageMaker account, as a default repository, and an additional repository that is hosted on GitHub:

```bash
aws sagemaker create-notebook-instance
    --notebook-instance-name "MyNotebookInstance" \
    --instance-type "ml.t2.medium" \
    --role-arn "arn:aws:iam::012345678901:role/service-role/AmazonSageMaker-ExecutionRole-20181129T121390" \
    --default-code-repository "MyGitRepo" \
    --additional-code-repositories "https://github.com/myprofile/my-other-repo"
```

**Note**

If you use an AWS CodeCommit repository that does not contain "SageMaker" in its name, add the `codecommit:GitPull` and `codecommit:GitPush` permissions to the role that you pass as the `role-arn` argument to the `create-notebook-instance` command. For information about how to add permissions to a role, see Adding and Removing IAM Policies in the AWS Identity and Access Management User Guide.

Associate a CodeCommit Repository in a Different AWS Account with a Notebook Instance

To associate a CodeCommit repository in a different AWS account with your notebook instance, set up cross-account access for the CodeCommit repository.
To set up cross-account access for a CodeCommit repository and associate it with a notebook instance:

1. In the AWS account that contains the CodeCommit repository, create an IAM policy that allows access to the repository from users in the account that contains your notebook instance. For information, see Step 1: Create a Policy for Repository Access in AccountA in the CodeCommit User Guide.

2. In the AWS account that contains the CodeCommit repository, create an IAM role, and attach the policy that you created in the previous step to that role. For information, see Step 2: Create a Role for Repository Access in AccountA in the CodeCommit User Guide.

3. Create a profile in the notebook instance that uses the role that you created in the previous step:
   a. Open the notebook instance.
   b. Open a terminal in the notebook instance.
   c. Edit a new profile by typing the following in the terminal:

   ```
   vi /home/ec2-user/.aws/config
   ```

   d. Edit the file with the following profile information:

   ```
   [profile CrossAccountAccessProfile]
   region = us-west-2
   role_arn = arn:aws:iam::CodeCommitAccount:role/CrossAccountRepositoryContributorRole
   credential_source=Ec2InstanceMetadata
   output = json
   ```

   Where CodeCommitAccount is the account that contains the CodeCommit repository, CrossAccountAccessProfile is the name of the new profile, and CrossAccountRepositoryContributorRole is the name of the role you created in the previous step.

4. On the notebook instance, configure git to use the profile you created in the previous step:
   a. Open the notebook instance.
   b. Open a terminal in the notebook instance.
   c. Edit the Git configuration file typing the following in the terminal:

   ```
   vi /home/ec2-user/.gitconfig
   ```

   d. Edit the file with the following profile information:

   ```
   [credential]
   helper = !aws codecommit credential-helper --profile CrossAccountAccessProfile @
   UseHttpPath = true
   ```

   Where CrossAccountAccessProfile is the name of the profile that you created in the previous step.

Use Git Repositories in a Notebook Instance

When you open a notebook instance that has Git repositories associated with it, it opens in the default repository, which is installed in your notebook instance directly under /home/ec2-user/SageMaker.
You can open and create notebooks, and you can manually run Git commands in a notebook cell. For example:

```
!git pull origin master
```

To open any of the additional repositories, navigate up one folder. The additional repositories are also installed as directories under `/home/ec2-user/SageMaker`.

If you open the notebook instance with a JupyterLab interface, the jupyter-git extension is installed and available to use. For information about the jupyter-git extension for JupyterLab, see https://github.com/jupyterlab/jupyterlab-git.

When you open a notebook instance in JupyterLab, you see the git repositories associated with it on the left menu:

![git repositories in JupyterLab](image)

You can use the jupyter-git extension to manage git visually, instead of using the command line:
Notebook Instance Metadata

When you create a notebook instance, Amazon SageMaker creates a JSON file on the instance at the location `/opt/ml/metadata/resource-metadata.json` that contains the ResourceName and ResourceArn of the notebook instance. You can access this metadata from anywhere within the notebook instance, including in lifecycle configurations. For information about notebook instance lifecycle configurations, see Customize a Notebook Instance Using a Lifecycle Configuration Script (p. 299).

The `resource-metadata.json` file has the following structure:

```json
{
    "ResourceArn": "NotebookInstanceArn",
    "ResourceName": "NotebookInstanceName"
}
```

You can use this metadata from within the notebook instance to get other information about the notebook instance. For example, the following commands get the tags associated with the notebook instance:

```bash
NOTEBOOK_ARN=$(jq '.ResourceArn' /opt/ml/metadata/resource-metadata.json --raw-output)
aws sagemaker list-tags --resource-arn $NOTEBOOK_ARN
```

The output looks like the following:

```json
{
    "Tags": [
        {
            "Key": "test",
            "Value": "true"
        }
    ]
}
```

Monitor Jupyter Logs in Amazon CloudWatch Logs

Jupyter logs include important information such as events, metrics, and health information that provide actionable insights when running Amazon SageMaker notebooks. By importing Jupyter logs into
CloudWatch Logs, customers can use CloudWatch Logs to detect anomalous behaviors, set alarms, and discover insights to keep the SageMaker notebooks running more smoothly. You can access the logs even when the Amazon EC2 instance that hosts the notebook is unresponsive, and use the logs to troubleshoot the unresponsive notebook. Sensitive information such as AWS account IDs, secret keys, and authentication tokens in presigned URLs are removed so that customers can share logs without leaking private information.

**To view Jupyter logs for a notebook instance:**

2. Choose Notebook instances.
3. In the list of notebook instances, choose the notebook instance for which you want to view Jupyter logs by selecting the Notebook instance Name.
   
   This will bring you to the details page for that notebook instance.
4. Under Monitor on the notebook instance details page, choose View logs.
5. In the CloudWatch console, choose the log stream for your notebook instance. Its name is in the form NotebookInstanceName/jupyter.log.

For more information about monitoring CloudWatch logs for SageMaker, see Log Amazon SageMaker Events with Amazon CloudWatch (p. 3675).
Automate model development with Amazon SageMaker Autopilot

Amazon SageMaker Autopilot is a feature-set that automates key tasks of an automatic machine learning (AutoML) process. It explores your data, selects the algorithms relevant to your problem type, and prepares the data to facilitate model training and tuning. Autopilot applies a cross-validation resampling procedure automatically to all candidate algorithms when appropriate to test their ability to predict data they have not been trained on. It also produces metrics to assess the predictive quality of its machine learning model candidates. It simplifies your machine learning experience by automating these key tasks that constitute an AutoML process. It ranks all of the optimized models tested by their performance. It finds the best performing model that you can deploy at a fraction of the time normally required.

You can use Autopilot in different ways: on autopilot (hence the name) or with various degrees of human guidance, without code through Amazon SageMaker Studio, or with code using one of the AWS SDKs. Autopilot currently supports regression and binary and multiclass classification problem types. It supports tabular data formatted as CSV or Parquet files in which each column contains a feature with a specific data type and each row contains an observation. The column data types accepted include numerical, categorical, text, and time series that consists of strings of comma-separate numbers. Autopilot supports building machine learning models on large datasets up to hundreds of GBs.

Autopilot also helps explain how models make predictions using a feature attribution approach developed for Amazon SageMaker Clarify. Autopilot automatically generates a report that indicates the importance of each feature for the predictions made by the best candidate. This explainability functionality can make machine learning models more understandable to AWS customers. The model governance report generated can be used to inform risk and compliance teams and external regulators.

You get full visibility into how the data was wrangled and how the models were selected, trained, and tuned for each of the candidates tested. This is provided by notebooks that Autopilot generates for each trial that contains the code used to explore the data and find the best candidate. The notebooks also provide educational tools to help you learn about and conduct your own ML experiments. You can learn about the impact of various inputs and trade-offs made in experiments by examining the various data exploration and candidate definition notebooks exposed by Autopilot. You can also conduct further experiments on the higher performing candidates by making your own modifications to the notebooks and rerunning them.

The following graphic outlines the principal tasks of an AutoML process managed by Autopilot.

With Amazon SageMaker, you pay only for what you use. You pay for the underlying compute and storage resources within SageMaker or other AWS services, based on your usage. For more information about the cost of using SageMaker, see Amazon SageMaker Pricing.

Get started with Amazon SageMaker Autopilot

Amazon SageMaker Autopilot provides samples, videos, and tutorials to get started with Amazon SageMaker Autopilot

Topics
• Samples: Explore modeling with Amazon SageMaker Autopilot (p. 319)
• Videos: Use Autopilot to automate and explore the machine learning process (p. 320)
• Tutorials: Get started with Amazon SageMaker Autopilot (p. 321)

Samples: Explore modeling with Amazon SageMaker Autopilot

Amazon SageMaker Autopilot provides the following sample notebooks.

• Direct marketing with Amazon SageMaker Autopilot: This notebook demonstrates how uses the Bank Marketing Data Set to predict whether a customer will enroll for a term deposit at a bank. You can use Autopilot on this dataset to get the most accurate ML pipeline by exploring options contained in various candidate pipelines. Autopilot generates each candidate in a two-step procedure. The first step performs automated feature engineering on the dataset. The second step trains and tunes an algorithm to produce a model. The notebook contains instructions on how to train the model and how to deploy the model to perform batch inference using the best candidate.

• Customer Churn Prediction with Amazon SageMaker Autopilot: This notebook describes using machine learning for the automated identification of unhappy customers, also known as customer churn prediction. The sample shows how to analyze a publicly available dataset and perform feature engineering on it. Next it shows how to tune a model by selecting the best performing pipeline along with the optimal hyperparameters for the training algorithm. Finally, it shows how to deploy the model to a hosted endpoint and how to evaluate its predictions against ground truth. However, ML models rarely give perfect predictions. That's why this notebook also shows how to incorporate the relative costs of prediction mistakes when determining the financial outcome of using ML.

• Top Candidates Customer Churn Prediction with Amazon SageMaker Autopilot and Batch Transform (Python SDK): This notebook also describes using machine learning for the automated identification of unhappy customers, also known as customer churn prediction. This notebook demonstrates how to configure the model to obtain the inference probability, select the top N models, and make Batch Transform on a hold-out test set for evaluation.

  Note
  This notebook works with SageMaker Python SDK >= 1.65.1 released on 6/19/2020.

• Bringing your own data processing code to Amazon SageMaker Autopilot: This notebook demonstrates how to incorporate and deploy custom data processing code when using Amazon SageMaker Autopilot. It adds a custom feature selection step to remove irrelevant variables to an Autopilot job. It
then shows how to deploy both the custom processing code and models generated by Autopilot on a real-time endpoint and, alternatively, for batch processing.

Videos: Use Autopilot to automate and explore the machine learning process

Here is a video series that provides a tour of Amazon SageMaker Autopilot capabilities using Studio. They show how to start an AutoML job, analyze and preprocess data, how to do feature engineering and hyperparameter optimization on candidate models, and how to visualize and compare the resulting model metrics.

Topics
- Start an AutoML job with Amazon SageMaker Autopilot (p. 320)
- Review data exploration and feature engineering automated in Autopilot. (p. 320)
- Tune models to optimize performance (p. 320)
- Choose and deploy the best model (p. 320)
- Amazon SageMaker Autopilot tutorial (p. 320)

Start an AutoML job with Amazon SageMaker Autopilot

This video shows you to how to start an AutoML job with Autopilot. (Length: 8:41)

Amazon SageMaker Studio - AutoML with Amazon SageMaker Autopilot (part 1)

Review data exploration and feature engineering automated in Autopilot.

This video shows you how to review the data exploration and candidate definition notebooks generated by Amazon SageMaker Autopilot. (Length: 10:04)

Amazon SageMaker Studio - AutoML with Amazon SageMaker Autopilot (part 2)

Tune models to optimize performance

This video shows you how to optimize model performance during training using hyperparameter tuning. (Length: 4:59)

SageMaker Studio - AutoML with Amazon SageMaker Autopilot (part 3)

Choose and deploy the best model

This video shows you how to use job metrics to choose the best model and then how to deploy it. (Length: 5:20)

SageMaker Studio - AutoML with Amazon SageMaker Autopilot (part 4)

Amazon SageMaker Autopilot tutorial

This video walks you through an end to end demo where we first build a binary classification model automatically with Amazon SageMaker Autopilot. We see how candidate models have been built and optimized using auto-generated notebooks. We also look at the top candidates with Amazon SageMaker Experiments. Finally, we deploy the top candidate (based on XGBoost), and configure data capture with SageMaker Model Monitor.
End to end demo with AutoML on SageMaker

Tutorials: Get started with Amazon SageMaker Autopilot

Get started tutorials for Autopilot demonstrate how to create a machine learning model automatically without writing code. They show you how Autopilot simplifies the machine learning experience by helping you explore your data and try different algorithms. Autopilot builds the best machine learning model for the problem type using AutoML capabilities while allowing full control and visibility.

- Create a machine learning model automatically with Autopilot: You assume the role of a developer working at a bank in this tutorial. You have been asked to develop a machine learning model to predict if a customer will enroll for a certificate of deposit (CD). This is a binary classification problem. The model is trained on the marketing dataset that contains information on customer demographics, responses to marketing events, and external factors.

Create an Amazon SageMaker Autopilot experiment

This guide shows how to create an Amazon SageMaker Autopilot experiment, so that you can analyze data, and create a notebook with candidate model definitions. This can help you get started with machine learning quickly.

You can use a user interface (UI) to help you populate the input, output, target, and parameters to run and evaluate an Autopilot experiment. The UI has descriptions, toggle switches, drop down menus, radio buttons and more to help you navigate creating your model. You can also view statistics while the experiment is running. After it runs, you can compare trials and delve into the details.

The following instructions show how to create an Amazon SageMaker Autopilot job as a pilot experiment. You will name your experiment, provide locations for the input and output data, and specify which target data to predict. Optionally, you can also specify the type of machine learning problem that you want to solve.

To create an Autopilot experiment

2. When the SageMaker Studio console opens, choose the Launch SageMaker Studio button.
3. Next, select Launch app in the row containing your user name, and choose Studio from the dropdown list.
4. Select the Build models automatically center card from the Studio launcher tab. See the quick setup guide for more information about starting Studio for the first time.
5. A page titled Create an Autopilot experiment opens. The page includes fields for Experiment and data details such as name, Amazon S3 bucket location, split ratio, and target of the experiment.
6. In the Experiment and data details section of the Create an Autopilot experiment page, enter the following information:
   a. Experiment name – Must be unique to your account in the current AWS Region and contain a maximum of 63 alphanumeric characters. Can include hyphens (-) but not spaces.
   b. Input data – Provide the S3 bucket location of your input data. This S3 bucket must be in your current AWS Region. The URL must be in an s3:// format where Amazon SageMaker has write permissions. The file must be in CSV or parquet format and contain at least 500 rows. Select Browse to scroll through available paths and Preview to see a sample of your input data.
c. **Is your S3 input a manifest file?** – A manifest file includes metadata with your input data. The metadata specifies the location of your data in Amazon Simple Storage Service (Amazon S3). It also specifies how the data is formatted and which attributes from the dataset to use when training your model. You can use a manifest file as an alternative to preprocessing when your labeled data is being streamed in *Pipe* mode.

d. **Auto split data?** – Autopilot can split your data into an 80-20% split for training and validation data. If you prefer a custom split, you can choose the **Specify split ratio**. To use a custom dataset for validation, choose **Provide a validation set**.

e. **Output data location (S3 bucket)** – The name of the S3 bucket location where you want to store the output data. The URL for this bucket must be in an Amazon S3 format where Amazon SageMaker has write permissions. The S3 bucket must be in the current AWS Region. Autopilot can also create this for you in the same location as your input data.

7. Select **Next: Target and features**. The **Target and features** tab opens.

8. In the **Target and features** section, select a column to set as a target for model predictions. You can also select features for training and change their data type. The following data types are available: Text, Numerical, Categorical, Datetime, Sequence and Auto. All features are selected by default.

10. In the **Training method** section, select from the following training options: **Ensembling**, **Hyperparameter optimization (HPO)**, or let Autopilot choose it automatically based on the dataset size.

    For more information about these training modes, see the **Autopilot training modes** section in the **Training modes and algorithms** page.

11. Select **Next: Deployment and advanced settings** to open the **Deployment and advanced settings**. Settings include auto display endpoint name, machine learning problem type, and choices for running your experiment.

12. Currently, you are required to have at least two ml.m5.2xlarge instances.

    Automatic deployment will fail for either of these reasons:
    
    - The default resource quota for endpoint instances in a Region exceeds the limit.
    - The customer quota for endpoint instances in a Region exceeds the limit.

    If you encounter a failure related to quotas, you can request a service limit increase for SageMaker endpoint instances.

13. **Deployment settings** – Autopilot can automatically create an endpoint and deploy your model for you.

    a. To auto deploy to an automatically generated endpoint, or to provide an endpoint name for custom deployment, set the toggle to **Yes** under **Auto deploy?** If you are importing data from Amazon SageMaker Data Wrangler, you have additional options to auto deploy the best model with or without the transforms from Data Wrangler.

    **Note**
    
    If your Data Wrangler flow contains multi-row operations such as groupby, join or concatenate, you won't be able to auto deploy with these transforms. For more information see **Automatically Train Models on Your Data Flow**.

    b. **Advanced settings (optional)** – Autopilot provides additional controls to manually set experimental parameters.

    i. **Machine learning problem type** – Autopilot can automatically select the machine learning problem type. If you prefer to choose it manually, use the **Select the machine learning problem type** dropdown menu.
A. **Auto** – Autopilot infers the problem type from the values of the attribute that you want to predict. In some cases, SageMaker is unable to infer accurately. When that happens, you must provide the value for the job to succeed.

B. **Binary classification** – Binary classification is a type of supervised learning that assigns an individual to one of two predefined and mutually exclusive classes, based on their attributes. For example, medical diagnosis based on results of diagnostic tests that determine if someone has a disease.

C. **Regression** – Regression estimates the values of a dependent target variable based on one or more variables or attributes that are correlated with it. For example, house prices based on features, such as square footage and number of bathrooms.

D. **Multiclass classification** – Multiclass classification is a type of supervised learning that assigns an individual to one of several classes based on their attributes. For example, the prediction of the topic most relevant to a text document, such as politics, finance, or philosophy.

ii. Select **Next: Review and create** to get a summary of your Autopilot experiment before you create it.

14. Select **Create experiment**. Autopilot provides status on the course of the experiment, a list of generated models, and the job profile used to create them.

**Note**

To avoid incurring unnecessary charges: If you deploy a model that is no longer needed, delete the endpoints and resources that were created during that deployment. Information about pricing instances by Region is available at [Amazon SageMaker Pricing](#).

---

**Amazon SageMaker Autopilot datasets and problem types**

Amazon SageMaker Autopilot gives you the option in Studio or with the AutoML API of specifying a problem type, such as binary classification or regression, or of detecting it on your behalf based on the data you provide. Autopilot supports tabular data in which each column contains a feature with a specific data type and each row contains an observation.

**Topics**

- Autopilot datasets, data types, and formats (p. 323)
- How to specify training and validation datasets (p. 324)
- How to select features for training (p. 324)
- Amazon SageMaker Autopilot problem types (p. 325)

**Autopilot datasets, data types, and formats**

Autopilot supports tabular data formatted as CSV files or as Parquet files. For tabular data, each column contains a feature with a specific data type and each row contains an observation. The properties of these two file formats differ considerably.

- **CSV** (comma-separated-values) is a row-based file format that stores data in human readable plaintext which a popular choice for data exchange as they are supported by a wide range of applications.
- **Parquet** is a column-based file format where the data is stored and processed more efficiently than row-based file formats. This makes them a better option for big data problems.
The **data types** accepted for columns include numerical, categorical, text, and time series that consists of strings of comma-separate numbers. If Autopilot detects it is dealing with **time series** sequences, it processes them through specialized feature transformers provided by the `tsfresh` library. This library takes the time series as an input and outputs a feature such as the highest absolute value of the time series or descriptive statistics on autocorrelation. These outputted features are then used as inputs to one of the three problem types.

Autopilot supports building machine learning models on large datasets up to hundreds of GBs. For details on the default resource limits for input datasets and how to increase them, see Amazon SageMaker Autopilot quotas (p. 364)

### How to specify training and validation datasets

When using `CreateAutoMLJob` to create an AutoML job, you must use the `InputDataConfig` parameter to specify the `AutoMLChannel` objects that provide input data sources. Each `AutoMLChannel` has a `ChannelType`, which can be set to either `training` or `validation` values that specify how the data is to be used when building a machine learning model. At least one data source must be provided and a maximum of two data sources is allowed: one for training data and one for validation data.

How you split the data into training and validation datasets depends on whether you have one or two data sources.

- **If you only have one data source**, the `ChannelType` is set to `training` by default and must have this value.
  - If the `ValidationFraction` value in `AutoMLDataSplitConfig` is not set, 0.2 (20%) of the data from this source is used for validation by default.
  - If the `ValidationFraction` is set to a value between 0 and 1, the dataset is split based on the value specified, where the value specifies the fraction of the dataset used for validation.
- **If you have two data sources**, the `ChannelType` of one of the `AutoMLChannel` objects must be set to `training`, the default value. The `ChannelType` of the other data source must be set to `validation`. The two data sources must have the same format, either CSV or Parquet, and the same schema. You must not set the value for the `ValidationFraction` in this case because all of the data from each source is used for either training or validation. Setting this value will cause an error.

### How to select features for training

You can manually select the features to be used in training with the `FeatureSpecificiationS3Uri` attribute of `AutoMLCandidateGenerationConfig` within the `CreateAutoMLJob` API with the following format.

```json
{
    "AutoMLJobConfig": {
        "CandidateGenerationConfig": {
            "FeatureSpecificiationS3Uri": "string"
        }
    }
}
```

Selected features should be contained within a JSON file in the following format:

```json
[ "FeatureAttributeNames": ["col1", "col2", ...] ]
```

The values listed in ["col1", "col2", ...] are case sensitive. They should be a list of strings containing unique values that are subsets of the column names in the input data.
Note
The list of columns provided as features cannot include the target column.

Amazon SageMaker Autopilot problem types

You set the type of problem with the `CreateAutoPilot.ProblemType` parameter. This limits the kind of preprocessing and algorithms that Autopilot tries. After the job is finished, if you had set the `CreateAutoPilot.ProblemType`, then the `ResolvedAttribute.ProblemType` will match the `ProblemType` you set. If you keep it blank (or null), the `ProblemType` will be whatever Autopilot decides on your behalf.

Note
In some cases, Autopilot is unable to infer the `ProblemType` with high enough confidence, in which case you must provide the value for the job to succeed.

Your problem type options are as follows:

Regression

Regression estimates the values of a dependent target variable based on one or more other variables or attributes that are correlated with it. An example is the prediction of house prices using features like the number of bathrooms and bedrooms, square footage of the house and garden. Regression analysis can create a model that takes one or more of these features as an input and predicts the price of a house.

Binary classification

Binary classification is a type of supervised learning that assigns an individual to one of two predefined and mutually exclusive classes based on their attributes. It is supervised because the models are trained using examples where the attributes are provided with correctly labelled objects. A medical diagnosis for whether an individual has a disease or not based on the results of diagnostic tests is an example of binary classification.

Multiclass classification

Multiclass classification is a type of supervised learning that assigns an individual to one of several classes based on their attributes. It is supervised because the models are trained using examples where the attributes are provided with correctly labelled objects. An example is the prediction of the topic most relevant to a text document. A document may be classified as being about, say, religion or politics or finance, or about one of several other predefined topic classes.

Training modes and algorithm support

Amazon SageMaker Autopilot supports different training modes and algorithms to address machine learning problems, report on quality and objective metrics, and to use cross-validation automatically, when needed.

Training modes

SageMaker Autopilot can automatically select the training method based on the dataset size, or you can select it manually. The choices are as follows:

- **Ensembling** – Autopilot uses the AutoGluon library to train several base models. To find the best combination for your dataset, ensemble mode runs 10 trials with different model and meta parameter
settings. Then Autopilot combines these models using a stacking ensemble method to create an optimal predictive model. For a list of algorithms that Autopilot supports in ensembling mode, see the following Algorithm support section.

- **Hyperparameter optimization (HPO)** – Autopilot finds the best version of a model by tuning hyperparameters using Bayesian optimization or multi-fidelity optimization while running training jobs on your dataset. HPO mode selects the algorithms that are most relevant to your dataset and selects the best range of hyperparameters to tune your models. To tune your models, HPO mode runs up to 100 trials (default) to find the optimal hyperparameters settings within the selected range. If your dataset size is less than 100 MB, Autopilot uses Bayesian optimization. Autopilot chooses multi-fidelity optimization if your dataset is larger than 100 MB.

In multi-fidelity optimization, metrics are continuously emitted from the training containers. A trial that is performing poorly against a selected objective metric is stopped early. A trial that is performing well is allocated more resources.

For a list of algorithms that Autopilot supports in HPO mode, see the following Algorithm support section.

- **Auto** – Autopilot automatically chooses either ensembling mode or HPO mode based on your dataset size. If your dataset is larger than 100 MB, Autopilot chooses HPO. Otherwise, it chooses ensembling mode. Autopilot can fail to read the size of your dataset in the following cases.
  - If you enable Virtual Private Cloud (VPC) mode, for an AutoML job but the S3 bucket containing the dataset only allows access from the VPC.
  - The input S3DataType of your dataset is a ManifestFile.
  - The input S3Uri contains more than 1000 items.

If Autopilot is unable to read your dataset size, it defaults to choosing HPO mode.

**Note**
For optimal runtime and performance, use ensemble training mode for datasets that are smaller than 100 MB.

## Algorithm support

In **HPO mode**, Autopilot supports the following types of machine learning algorithms:

- **Linear learner** – A supervised learning algorithm that can solve either classification or regression problems.
- **XGBoost** – A supervised learning algorithm that attempts to accurately predict a target variable by combining an ensemble of estimates from a set of simpler and weaker models.
- **Deep learning algorithm** – A multilayer perceptron (MLP) and feedforward artificial neural network. This algorithm can handle data that is not linearly separable.

**Note**
You don’t need to specify an algorithm to use for your machine learning problem. Autopilot automatically selects the appropriate algorithm to train.

In **ensembling mode**, the following are types of machine learning algorithms that Autopilot supports:

- **LightGBM** – An optimized framework that uses tree-based algorithms with gradient boosting. This algorithm uses trees that grow in breadth, rather than depth, and is highly optimized for speed.
- **CatBoost** – A framework that uses tree-based algorithms with gradient boosting. Optimized for handling categorical variables.
- **XGBoost** – A framework that uses tree-based algorithms with gradient boosting that grows in depth, rather than breadth.
• Random Forest – A tree-based algorithm that uses several decision trees on random sub-samples of the data with replacement. The trees are split into optimal nodes at each level. The decisions of each tree are averaged together to prevent overfitting and improve predictions.

• Extra Trees – A tree-based algorithm that uses several decision trees on the entire dataset. The trees are split randomly at each level. The decisions of each tree are averaged to prevent overfitting and to improve predictions. Extra trees add a degree of randomization in comparison to the random forest algorithm.

• Linear Models – A framework that uses a linear equation to model the relationship between two variables in observed data.

• Neural network torch – A neural network model that's implemented using Pytorch.

• Neural network fast.ai – A neural network model that's implemented using fast.ai.

Metrics and validation

This guide shows metrics and validation techniques that you can use to measure machine learning model performance. Amazon SageMaker Autopilot produces metrics that measure the predictive quality of machine learning model candidates. The metrics calculated for candidates are specified using an array of MetricDatum types.

Autopilot Metrics

The following list contains the names of the metrics that are currently available to measure model performance within Autopilot.

Accuracy

The ratio of the number of correctly classified items to the total number of (correctly and incorrectly) classified items. It is used for both binary and multiclass classification. Accuracy measures how close the predicted class values are to the actual values. Values for accuracy metrics vary between zero (0) and one (1). A value of 1 indicates perfect accuracy, and 0 indicates perfect inaccuracy.

AUC

The area under the curve (AUC) metric is used to compare and evaluate binary classification by algorithms that return probabilities, such as logistic regression. To map the probabilities into classifications, these are compared against a threshold value.

The relevant curve is the receiver operating characteristic curve (ROC curve). The ROC curve plots the true positive rate (TPR) of predictions (or recall) against the false positive rate (FPR) as a function of the threshold value, above which a prediction is considered positive. Increasing the threshold results in fewer false positives, but more false negatives.

AUC is the area under this ROC curve. Therefore, AUC provides an aggregated measure of the model performance across all possible classification thresholds. AUC scores vary between 0 and 1. A score of 1 indicates perfect accuracy, and a score of one half (0.5) indicates that the prediction is not better than a random classifier.

BalancedAccuracy

BalancedAccuracy is a metric that measures the ratio of accurate predictions to all predictions. This ratio is calculated after normalizing true positives (TP) and true negatives (TN) by the total number of positive (P) and negative (N) values. It is used in both binary and multiclass classification and is defined as follows: 0.5*((TP/P)+(TN/N)), with values ranging from 0 to 1. BalancedAccuracy
gives a better measure of accuracy when the number of positives or negatives differ greatly from each other in an imbalanced dataset. For example, when only 1% of email is spam.

**F1**

The F1 score is the harmonic mean of the precision and recall, defined as follows: $F1 = 2 \times (\text{precision} \times \text{recall}) / (\text{precision} + \text{recall})$. It is used for binary classification into classes traditionally referred to as positive and negative. Predictions are said to be true when they match their actual (correct) class, and false when they do not.

Precision is the ratio of the true positive predictions to all positive predictions, and it includes the false positives in a dataset. Precision measures the quality of the prediction when it predicts the positive class.

Recall (or sensitivity) is the ratio of the true positive predictions to all actual positive instances. Recall measures how completely a model predicts the actual class members in a dataset.

F1 scores vary between 0 and 1. A score of 1 indicates the best possible performance, and 0 indicates the worst.

**F1macro**

The F1macro score applies F1 scoring to multiclass classification problems. It does this by calculating the precision and recall, and then taking their harmonic mean to calculate the F1 score for each class. Lastly, the F1macro averages the individual scores to obtain the F1macro score. F1macro scores vary between 0 and 1. A score of 1 indicates the best possible performance, and 0 indicates the worst.

**LogLoss**

Log loss, also known as cross-entropy loss, is a metric used to evaluate the quality of the probability outputs, rather than the outputs themselves. It is used in both binary and multiclass classification, neural nets, and is also the cost function for logistic regression. Log loss is an important metric to indicate when a model makes incorrect predictions with high probabilities. Values range from 0 to infinity. A value of 0 represents a model that perfectly predicts the data.

**MAE**

The mean absolute error (MAE) is a measure of how different the predicted and actual values are, when they're averaged over all values. MAE is commonly used in regression analysis to understand model prediction error. If there is linear regression, MAE represents the average distance from a predicted line to the actual value. MAE is defined as the sum of absolute errors divided by the number of observations. Values range from 0 to infinity, with smaller numbers indicating a better model fit to the data.

**MSE**

The mean squared error (MSE) is the average of the squared differences between the predicted and actual values. It is used for regression. MSE values are always positive. The better a model is at predicting the actual values, the smaller the MSE value is.

**Precision**

Precision measures how well an algorithm predicts the true positives (TP) out of all of the positives that it identifies. It is defined as follows: Precision = TP/(TP+FP), with values ranging from zero (0) to one (1), and is used in binary classification. Precision is an important metric when the cost of a false positive is high. For example, the cost of a false positive is very high if an airplane safety system is falsely deemed safe to fly. A false positive (FP) reflects a positive prediction that is actually negative in the data.

**PrecisionMacro**

The precision macro computes precision for multiclass classification problems. It does this by calculating precision for each class and averaging scores to obtain precision for several classes.
PrecisionMacro scores range from zero (0) to one (1). Higher scores reflect the model's ability to predict true positives (TP) out of all of the positives that it identifies, averaged across multiple classes.

**R2**

R², also known as the coefficient of determination, is used in regression to quantify how much a model can explain the variance of a dependent variable. Values range from one (1) to negative one (-1). Higher numbers indicate a higher fraction of explained variability. R2 values close to zero (0) indicate that very little of the dependent variable can be explained by the model. Negative values indicate a poor fit and that the model is outperformed by a constant function. For linear regression, this is a horizontal line.

**Recall**

Recall measures how well an algorithm correctly predicts all of the true positives (TP) in a dataset. A true positive is a positive prediction that is also an actual positive value in the data. Recall is defined as follows: \( \text{Recall} = \frac{TP}{TP+FN} \), with values ranging from 0 to 1. Higher scores reflect a better ability of the model to predict true positives (TP) in the data, and is used in binary classification.

Recall is important when testing for cancer because it's used to find all of the true positives. A false positive (FP) reflects a positive prediction that is actually negative in the data. It is often insufficient to measure only recall, because predicting every output as a true positive will yield a perfect recall score.

**RecallMacro**

The RecallMacro computes recall for multiclass classification problems by calculating recall for each class and averaging scores to obtain recall for several classes. RecallMacro scores range from 0 to 1. Higher scores reflect the model's ability to predict true positives (TP) in a dataset. Whereas, a true positive reflects a positive prediction that is also an actual positive value in the data. It is often insufficient to measure only recall, because predicting every output as a true positive will yield a perfect recall score.

**RMSE**

Root mean squared error (RMSE) measures the square root of the squared difference between predicted and actual values, and it's averaged over all values. It is used in regression analysis to understand model prediction error. It's an important metric to indicate the presence of large model errors and outliers. Values range from zero (0) to infinity, with smaller numbers indicating a better model fit to the data. RMSE is dependent on scale, and should not be used to compare datasets of different sizes.

Metrics that are automatically calculated for a candidate model are determined by the type of problem being addressed.

- **Regression**: MAE, MSE, R2, RMSE
- **Binary classification**: Accuracy, AUC, BalancedAccuracy, F1, LogLoss, Precision, Recall
- **Multiclass classification**: Accuracy, BalancedAccuracy, F1macro, LogLoss, PrecisionMacro, RecallMacro

**Cross-validation in Autopilot**

Cross-validation is used in to reduce overfitting and bias in model selection. It is also used to assess how well a model can predict the values of an unseen validation dataset, if the validation dataset is drawn from the same population. This method is especially important when training on datasets that have a limited number of training instances.
Autopilot uses cross-validation to build models in hyperparameter optimization (HPO) and ensemble training mode. The first step in the Autopilot cross-validation process is to split the data into k-folds.

**K-fold splitting**

K-fold splitting is a method that separates an input training dataset into multiple training and validation datasets. The dataset is split into \( k \) equally-sized sub-samples called folds. Models are then trained on \( k-1 \) folds and tested against the remaining \( k^{\text{th}} \) fold, which is the validation dataset. The process is repeated \( k \) times using a different data set for validation.

The following image depicts k-fold splitting with \( k = 4 \) folds. Each fold is represented as a row. The dark-toned boxes represent the parts of the data used in training. The remaining light-toned boxes indicate the validation datasets.

![4-fold splitting](image)

Autopilot uses k-fold cross-validation for both hyperparameter optimization (HPO) mode and ensembling mode.

You can deploy Autopilot models that are built using cross-validation like you would with any other Autopilot or SageMaker model.

**HPO mode**

K-fold cross-validation uses the k-fold splitting method for cross-validation. In HPO mode, Autopilot automatically implements k-fold cross-validation for small datasets with 50,000 or fewer training instances. Performing cross-validation is especially important when training on small datasets because it protects against overfitting and selection bias.

HPO mode uses a \( k \) value of 5 on each of the candidate algorithms that are used to model the dataset. Multiple models are trained on different splits, and the models are stored separately. When training is complete, validation metrics for each of the models are averaged to produce a single estimation metric. Lastly, Autopilot combines the models from the trial with the best validation metric into an ensemble model. Autopilot uses this ensemble model to make predictions.

The validation metric for the models trained by Autopilot is presented as the objective metric in the model leaderboard. Autopilot uses the default validation metric for each problem type that it handles, unless you specify otherwise. For more information about the metrics that Autopilot uses, see [AutoMLJobObjective](#).

For example, the Boston Housing dataset contains only 861 samples. If you build a model to predict house sale prices using this dataset without cross-validation, you risk training on a dataset that is not representative of the Boston housing stock. If you split the data only once into training and validation subsets, the training fold may only contain data mainly from the suburbs. As a result, you would train on data that isn't representative of the rest of the city. In this example, your model would likely overfit on
Cross-validation in Autopilot

this biased selection. K-fold cross-validation can reduce the risk of this kind of error by making full and randomized use of the available data for both training and validation.

Cross-validation can increase training times by an average of 20%. Training times may also increase significantly for complex datasets.

**Note**

In HPO mode, you can see the training and validation metrics from each fold in your /aws/sagemaker/TrainingJobs CloudWatch Logs. For more information about CloudWatch Logs, see *Log Amazon SageMaker Events with Amazon CloudWatch* (p. 3675).

**Ensembling mode**

In ensemble mode, cross-validation is performed regardless of dataset size. Customers can either provide their own validation dataset and custom data split ratio, or let Autopilot split the dataset automatically into an 80-20% split ratio. The training data is then split into k-folds for cross-validation, where the value of k is determined by the AutoGluon engine. An ensemble consists of multiple machine learning models, where each model is known as the base model. A single base model is trained on (k-1) folds and makes out-of-fold predictions on the remaining fold. This process is repeated for all k folds, and the out-of-fold (OOF) predictions are concatenated to form a single set of predictions. All base models in the ensemble follow this same process of generating OOF predictions.

The following image depicts k-fold validation with k = 4 folds. Each fold is represented as a row. The dark-toned boxes represent the parts of the data used in training. The remaining light-toned boxes indicate the validation datasets.

In the upper part of the image, in each fold, the first base model makes predictions on the validation dataset after training on the training datasets. At each subsequent fold, the datasets change roles. A dataset that was previously used for training is now used for validation, and this also applies in reverse. At the end of k folds, all of the predictions are concatenated to form a single set of predictions called an out-of-fold (OOF) prediction. This process is repeated for each n base models.

The OOF predictions for each base model are then used as features to train a stacking model. The stacking model learns the importance weights for each base model. These weights are used to combine the OOF predictions to form the final prediction. Performance on the validation dataset determines which base or stacking model is the best, and this model is returned as the final model.

In ensemble mode, you can either provide your own validation dataset or let Autopilot split the input dataset automatically into 80% train and 20% validation datasets. The training data is then split into k-folds for cross-validation and produces an OOF prediction and a base model for each fold.

These OOF predictions are used as features to train a stacking model, which simultaneously learns weights for each base model. These weights are used to combine the OOF predictions to form the final prediction. The validation datasets for each fold are used for hyperparameter tuning of all base models and the stacking model. Performance on the validation datasets determines which base or stacking model is the best model, and this model is returned as the final model.
Amazon SageMaker Autopilot model deployment and prediction

This Amazon SageMaker Autopilot guide includes steps for model deployment, setting up real-time inference, and running inference with batch jobs.

After you train your SageMaker Autopilot models, you can deploy them to get predictions in one of two ways:

1. Use Real-time inferencing (p. 332) to set up an endpoint and obtain predictions interactively.
2. Use Batch inferencing (p. 339) to make predictions in parallel on batches of observations on an entire dataset.

Note
To avoid incurring unnecessary charges: After the endpoints and resources that were created from model deployment are longer needed, you can delete them. For information about pricing of instances by Region, see Amazon SageMaker Pricing.

Real-time inferencing

Real-time inference is ideal for inference workloads where you have real-time, interactive, low latency requirements. This section shows how you can use real-time inferencing to obtain predictions interactively from your model.

To deploy the model that produced the best validation metric in an Autopilot experiment, you have several options. For example, when using Autopilot in SageMaker Studio, you can deploy the model automatically or manually. You can also use SageMaker APIs to manually deploy an Autopilot model.

The following tabs show three options for deploying your model. To see the code examples for each option, open each tab.

Deploy using the Autopilot User Interface (UI)

The Autopilot UI contains helpful dropdown menus, toggles, tooltips, and more to help you navigate through model deployment.

- **Automatically**: To automatically deploy the best model from an Autopilot experiment to an endpoint, toggle the Auto deploy value to Yes when creating the experiment in SageMaker Studio.

  Note
  Automatic deployment will fail if either the default resource quota or your customer quota for endpoint instances in a Region is too limited. In hyperparameter optimization (HPO) mode, you are required to have at least two ml.m5.2xlarge instances. In ensembling mode, you are required to have at least one ml.m5.12xlarge instance. If you encounter a failure related to quotas, you can request a service limit increase for SageMaker endpoint instances.

- **Manually**: To manually deploy the best model from an Autopilot experiment to an endpoint, toggle the Auto deploy value to No when creating the experiment in SageMaker Studio.

  After your Autopilot experiment has been created, select the model that you want to deploy under Model name. Then select the orange Deployment and advanced settings button located on the right of the leaderboard. This opens a new tab.

  Configure the endpoint name, instance type, and other optional information. Select the orange Deploy model to deploy to an endpoint.
Check the progress of the endpoint creation process in the https://console.aws.amazon.com/sagemaker/ by navigating to the Endpoints section. That section is located in the Inference dropdown menu in the navigation panel.

After the endpoint status changes from Creating to In Service, return to Studio and invoke the endpoint.

### Deploy using SageMaker APIs

You can also obtain real-time inference by deploying your model using API calls. This section shows the five general steps of this process using AWS Command Line Interface (AWS CLI) code snippets.

For complete code examples for both AWS CLI commands and AWS SDK for Python (Boto3), open the tabs directly following these steps.

1. **Obtain candidate definitions**

   Obtain the candidate container definitions from `InferenceContainers`. These candidate definitions are used to create a SageMaker model.

   The following example uses the `DescribeAutoMLJob` API to obtain candidate definitions for the best model candidate. See the following AWS CLI command as an example.

   ```bash
   aws sagemaker describe-auto-ml-job --auto-ml-job-name <job-name> --region <region>
   ```

2. **List candidates**

   The following example uses the `ListCandidatesForAutoMLJob` API to list all candidates. See the following AWS CLI command as an example.

   ```bash
   aws sagemaker list-candidates-for-auto-ml-job --auto-ml-job-name <job-name> --region <region>
   ```

3. **Create a SageMaker model**

   Use the container definitions from the previous steps to create a SageMaker model by using the `CreateModel` API. See the following AWS CLI command as an example.

   ```bash
   aws sagemaker create-model --model-name '<your-custom-model-name>'
   --containers [<container-definition1>, <container-definition2>, <container-definition3>]
   --execution-role-arn '<execution-role-arn>' --region '<region>'
   ```

4. **Create an endpoint configuration**

   The following example uses the `CreateEndpointConfig` API to create an endpoint configuration. See the following AWS CLI command as an example.

   ```bash
   aws sagemaker create-endpoint-config --endpoint-config-name '<your-custom-endpoint-config-name>'
   --production-variants '<list-of-production-variants>'
   ```
5. Create the endpoint

The following AWS CLI example uses the CreateEndpoint API to create the endpoint.

```
aws sagemaker create-endpoint --endpoint-name '<your-custom-endpoint-name>' \
    --endpoint-config-name '<endpoint-config-name-you-just-created>' \
    --region '<region>
```

Check the progress of your endpoint deployment by using the DescribeEndpoint API. See the following AWS CLI command as an example.

```
aws sagemaker describe-endpoint --endpoint-name '<endpoint-name>' --region '<region>
```

After the EndpointStatus changes to InService, the endpoint is ready to use for real-time inference.

6. Invoke the endpoint

The following command structure invokes the endpoint for real-time inferencing.

```
aws sagemaker invoke-endpoint --endpoint-name '<endpoint-name>' \
    --region '<region>' --body '<your-data>' [--content-type] '<content-type>' <outfile>
```

The following tabs contain complete code examples for deploying a model with AWS SDK for Python (Boto3) or the AWS CLI.

AWS SDK for Python (Boto3)

1. **Obtain the candidate definitions** by using the following code example.

```
import sagemaker
import boto3

session = sagemaker.session.Session()

sagemaker_client = boto3.client('sagemaker', region_name='us-west-2')
job_name = 'test-auto-ml-job'

describe_response = sm_client.describe_auto_ml_job(AutoMLJobName=job_name)
# extract the best candidate definition from DescribeAutoMLJob response
best_candidate = describe_response['BestCandidate']
# extract the InferenceContainers definition from the candidate definition
inference_containers = best_candidate['InferenceContainers']
```

2. **Create the model** by using the following the code example.

```
# Create Model
model_name = 'test-model'
sagemaker_role = 'arn:aws:iam::444455556666:role/sagemaker-execution-role'
create_model_response = sagemaker_client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = sagemaker_role,
    Containers = inference_containers
)
```

3. **Create the endpoint configuration** by using the following the code example.
4. Create the endpoint and deploy the model with the following code example.

```python
# create endpoint and deploy the model
deployment_name = 'test-endpoint'
create_endpoint_response = sagemaker_client.create_endpoint(
    EndpointName=deployment_name,
    EndpointConfigName=endpoint_config_name)
print(create_endpoint_response)
```

Check the status of creating the endpoint by using the following the code example.

```python
# describe endpoint creation status
status = sagemaker_client.describe_endpoint(EndpointName=deployment_name)
status["EndpointStatus"]
```

5. Invoke the endpoint for real-time inferencing by using the following command structure.

```python
# once endpoint status is InService, you can invoke the endpoint for inferencing
if status == "InService":
    sm_runtime = boto3.Session().client('sagemaker-runtime')
    inference_result = sm_runtime.invoke_endpoint(EndpointName='test-endpoint',
                                                ContentType='text/csv', Body='1,2,3,4,class')
```

AWS Command Line Interface (AWS CLI)

1. Obtain the candidate definitions by using the following code example.

```bash
aws sagemaker describe-auto-ml-job --auto-ml-job-name 'test-automl-job' --region us-west-2
```

2. Create the model by using the following code example.

```bash
aws sagemaker create-model --model-name 'test-sagemaker-model'
```

```bash
--containers '{[""
```
Real-time inferencing

3. Create an endpoint configuration by using the following code example.

```bash
aws sagemaker create-endpoint-config --endpoint-config-name 'test-endpoint-config' \
--production-variants '[["VariantName": "variant1", 
  "ModelName": "test-sagemaker-model", 
  "InitialInstanceCount": 1, 
  "InstanceType": "ml.m5.2xlarge" 
  ]]' \
  --region us-west-2
```

The create endpoint configuration command will return a response in the following format.

```json
{
}
```
4. **Create an endpoint** by using the following code example.

```bash
aws sagemaker create-endpoint --endpoint-name 'test-endpoint' \
--endpoint-config-name 'test-endpoint-config' \
--region us-west-2
```

The `create_endpoint` command will return a response in the following format.

```json
{
}
```

Check the progress of the endpoint deployment by using the following `describe-endpoint` CLI code example.

```bash
aws sagemaker describe-endpoint --endpoint-name 'test-endpoint' --region us-west-2
```

The previous progress check will return a response in the following format.

```json
{
   "EndpointName": "test-endpoint",
   "EndpointConfigName": "test-endpoint-config",
   "EndpointStatus": "Creating",
   "CreationTime": 1660251167.595,
   "LastModifiedTime": 1660251167.595
}
```

After the `EndpointStatus` changes to `InService`, the endpoint is ready for use in real-time inference.

5. **Invoke the endpoint** for real-time inferencing by using the following command structure.

```bash
aws sagemaker-runtime invoke-endpoint --endpoint-name 'test-endpoint' \
--region 'us-west-2' \
--body '1,51,3.5,1.4,0.2' \
--content-type 'text/csv' \
/tmp/inference_output
```

For more options, see *invoking an endpoint*.

### Deploy models from different accounts

You can deploy an Autopilot model from a different account than the original account that a model was generated in. To implement cross-account model deployment, this section shows how to do the following:

1. **Grant permission to the deploying account**

   To assume the role in the generating account, you must grant permission to the deploying account. This allows the deploying account to describe Autopilot jobs in the generating account.

   The following example uses a generating account with a trusted `sagemaker-role` entity. The example shows how to give a deploying account with the ID `111122223333` permission to assume the role of the generating account.
"Statement": [
    {
        "Effect": "Allow",
        "Principal": {
            "Service": [
                "sagemaker.amazonaws.com"
            ],
            "AWS": [ "111122223333"
          ],
        "Action": "sts:AssumeRole"
    }

The new account with the ID 111122223333 can now assume the role for the generating account.

Next, call the DescribeAutoMLJob API from the deploying account to obtain a description of the job created by the generating account.

The following code example describes the model from the deploying account.

```python
import sagemaker
import boto3
session = sagemaker.session.Session()
sts_client = boto3.client('sts')
sts_client.assume_role

role = 'arn:aws:iam::111122223333:role/sagemaker-role'
role_session_name = 'role-session-name'
_assumed_role = sts_client.assume_role(RoleArn=role, RoleSessionName=role_session_name)
credentials = _assumed_role["Credentials"]
access_key = credentials["AccessKeyId"]
secret_key = credentials["SecretAccessKey"]
session_token = credentials["SessionToken"]

session = boto3.session.Session()

sm_client = session.client('sagemaker', region_name='us-west-2',
                           aws_access_key_id=access_key,
                           aws_secret_access_key=secret_key,
                           aws_session_token=session_token)

# now you can call describe automl job created in account A

job_name = "test-job"
response= sm_client.describe_auto_ml_job(AutoMLJobName=job_name)
```

2. **Grant access to the deploying account** to the model artifacts in the generating account.

The deploying account only needs access to the model artifacts in the generating account to deploy it. These are located in the **S3OutputPath** that was specified in the original CreateAutoMLJob API call during model generation.

To give the deploying account access to the model artifacts, choose one of the following options:

a. Give access to the ModelDataUrl from the generating account to the deploying account.

    Next, you need to give the deploying account permission to assume the role. follow the real-time inferencing steps to deploy.

b. Copy model artifacts from the generating account's original S3OutputPath to the generating account.
To grant access to the model artifacts, you must define a best_candidate model and reassign model containers to the new account.

The following example shows how to define a best_candidate model and reassign the ModelDataUrl.

```python
best_candidate = automl.describe_auto_ml_job()['BestCandidate']

# reassigning ModelDataUrl for best_candidate containers below
new_model_locations = ['new-container-1-ModelDataUrl', 'new-container-2-ModelDataUrl', 'new-container-3-ModelDataUrl']
new_model_locations_index = 0
for container in best_candidate['InferenceContainers']:
    container['ModelDataUrl'] = new_model_locations[new_model_locations_index++]
```

After this assignment of containers, follow the steps in Deploy using SageMaker APIs (p. 333) to deploy.

**Batch inferencing**

Batch inferencing, also known as offline inferencing, generates model predictions on a batch of observations. Batch inference is a good option if you don’t need an immediate response to a model prediction request.

Offline predictions are suitable for large datasets or when you need to wait a long time for a response. By contrast, online inference, or real-time inferencing, generates predictions in real time.

You can make batch inferences from an Autopilot model using the SageMaker Python SDK, the AWS SDK for Python (Boto3) or AWS CLI.

**Batch inferencing steps**

To use the SageMaker APIs for batch inferencing, there are three general steps:

1. **Obtain candidate definitions**

   Candidate definitions from InferenceContainers are used to create a SageMaker model.

   The following example shows how to use the DescribeAutoMLJob API to obtain candidate definitions for the best model candidate. See the following AWS CLI command as an example.

   ```bash
   aws sagemaker describe-auto-ml-job --auto-ml-job-name <job-name> --region <region>
   ```

   Use the ListCandidatesForAutoMLJob API to list all candidates. See the following AWS CLI command as an example.

   ```bash
   aws sagemaker list-candidates-for-auto-ml-job --auto-ml-job-name <job-name> --region <region>
   ```

2. **Create a SageMaker model**

   Use the container definitions from the previous steps to create a SageMaker model using the CreateModel API. See the following AWS CLI command as an example.

   ```bash
   aws sagemaker create-model --model-name '"<your-custom-model-name>"'
   ```
3. Create a SageMaker transform job

The following example creates a SageMaker transform job with the `CreateTransformJob` API. See the following AWS CLI command as an example.

```bash
aws sagemaker create-transform-job --transform-job-name '<your-custom-transform-job-name>' --model-name '<your-custom-model-name-from-last-step>'
  --transform-input '{
    "DataSource": {
      "S3DataSource": {
        "S3DataType": "S3Prefix",
        "S3Uri": "<your-input-data>"
      }
    },
    "ContentType": "text/csv",
    "SplitType": "Line"
  }
  --transform-output '{
    "S3OutputPath": "<your-output-path>",
    "AssembleWith": "Line"
  }
  --transform-resources '{
    "InstanceType": "<instance-type>",
    "InstanceCount": 1
  }' --region '<region>'
```

Check the progress of your transform job using the `DescribeTransformJob` API. See the following AWS CLI command as an example.

```bash
aws sagemaker describe-transform-job --transform-job-name '<your-custom-transform-job-name>' --region <region>
```

After the job is finished, the predicted result will be available in `<your-output-path>`.

The output file name has the following format: `<input_data_file_name>.out`. As an example, if your input file is `text_x.csv`, the output name will be `text_x.csv.out`.

The following tabs show code examples for SageMaker Python SDK, AWS SDK for Python (Boto3), and AWS CLI.

### SageMaker Python SDK

The following example uses the **SageMaker Python SDK** to make predictions in batches.

```python
from sagemaker import AutoML
sagemaker_session = sagemaker.session.Session()

job_name = 'test-auto-ml-job' # your autopilot job name
automl = AutoML.attach(auto_ml_job_name=job_name)
output_path = 's3://test-auto-ml-job/output'
input_data = 's3://test-auto-ml-job/test_X.csv'

# call DescribeAutoMLJob API to get the best candidate definition
best_candidate = automl.describe_auto_ml_job()['BestCandidate']
best_candidate_name = best_candidate['CandidateName']
```
# create model
model = automl.create_model(name=best_candidate_name,
                           candidate=best_candidate)

# create transformer
transformer = model.transformer(instance_count=1,
                                 instance_type='ml.m5.2xlarge',
                                 assemble_with='Line',
                                 output_path=output_path)

# do batch transform
transformer.transform(data=input_data,
                      split_type='Line',
                      content_type='text/csv',
                      wait=True)

AWS SDK for Python (Boto3)

The following example uses AWS SDK for Python (Boto3) to make predictions in batches.

```python
import sagemaker
import boto3

session = sagemaker.session.Session()

sm_client = boto3.client('sagemaker', region_name='us-west-2')
role = 'arn:aws:iam::1234567890:role/sagemaker-execution-role'
output_path = 's3://test-auto-ml-job/output'
input_data = 's3://test-auto-ml-job/test_X.csv'

best_candidate = sm_client.describe_auto_ml_job(AutoMLJobName=job_name)["BestCandidate"]
best_candidate_containers = best_candidate['InferenceContainers']
best_candidate_name = best_candidate['CandidateName']

# create model
response = sm_client.create_model(
    ModelName = best_candidate_name,
    ExecutionRoleArn = role,
    Containers = best_candidate_containers
)

# Launch Transform Job
response = sm_client.create_transform_job(
    TransformJobName=f'{best_candidate_name}-transform-job',
    ModelName=model_name,
    TransformInput={
        'DataSource': {
            'S3DataSource': {
                'S3DataType': 'S3Prefix',
                'S3Uri': input_data
            }
        },
        'ContentType': "text/csv",
        'SplitType': 'Line'
    },
    TransformOutput={
        'S3OutputPath': output_path,
        'AssembleWith': 'Line'
    },
    TransformResources={
        'InstanceType': 'ml.m5.2xlarge',
        'InstanceCount': 1
    }
)
The batch inference job returns a response in the following format.

```json
'ResponseMetadata': {
'RequestId': '659f97fc-28c4-400b-b957-a49733f7c2f2',
'HTTPStatusCode': 200,
'HTTPHeaders': {'x-amzn-requestid': '659f97fc-28c4-400b-b957-a49733f7c2f2',
'content-type': 'application/x-amz-json-1.1',
'content-length': '96',
'date': 'Thu, 11 Aug 2022 22:23:49 GMT'},
'RetryAttempts': 0}}
```

AWS Command Line Interface (AWS CLI)

1. **Obtain the candidate definitions** by using the following code example.

   ```bash
   aws sagemaker describe-auto-ml-job --auto-ml-job-name 'test-automl-job' --region us-west-2
   ```

2. **Create the model** by using the following code example.

   ```bash
   aws sagemaker create-model --model-name 'test-sagemaker-model' --containers ['{
    "Image": "348316444620.dkr.ecr.us-west-2.amazonaws.com/sagemaker-sklearn-automl:2.5-1-cpu-py3",
    "ModelDataUrl": "s3://test-bucket/out/test-job1/data-processor-models/test-job1-dpp0-1-e569f7ad77f4e55a7e549a/output/model.tar.gz",
    "Environment": {
      "AUTOML_SPARSE_ENCODE_RECORDIO_PROTOBUF": "1",
      "AUTOML_TRANSFORM_MODE": "feature-transform",
      "SAGEMAKER_DEFAULT_INVOCATIONS_ACCEPT": "application/x-recordio-protobuf",
      "SAGEMAKER_PROGRAM": "sagemaker_serve",
      "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code"
    }
  }, {
    "Image": "348316444620.dkr.ecr.us-west-2.amazonaws.com/sagemaker-xgboost:1.3-1-cpu-py3",
    "ModelDataUrl": "s3://test-bucket/out/test-job1/tuning/flicdf10v2-dpp0-xgb/test-job1E9-244-7490a1c0/output/model.tar.gz",
    "Environment": {
      "MAX_CONTENT_LENGTH": "20971520",
      "SAGEMAKER_DEFAULT_INVOCATIONS_ACCEPT": "text/csv",
      "SAGEMAKER_INFERENCE_OUTPUT": "predicted_label",
      "SAGEMAKER_INFERENCE_SUPPORTED": "predicted_label,probability,probabilities"
    }
  }, {
    "Image": "348316444620.dkr.ecr.us-west-2.amazonaws.com/sagemaker-sklearn-automl:2.5-1-cpu-py3",
    "ModelDataUrl": "s3://test-bucket/out/test-job1/data-processor-models/test-job1-dpp0-1-e569f7ad77f4e55a7e549a/output/model.tar.gz",
    "Environment": {
      "AUTOML_TRANSFORM_MODE": "inverse-label-transform",
      "SAGEMAKER_DEFAULT_INVOCATIONS_ACCEPT": "text/csv",
      "SAGEMAKER_INFERENCE_INPUT": "predicted_label",
      "SAGEMAKER_INFERENCE_OUTPUT": "predicted_label",
      "SAGEMAKER_INFERENCE_SUPPORTED": "predicted_label,probability,labels,probabilities",
      "SAGEMAKER_PROGRAM": "sagemaker_serve",
      "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code"
    }
  }]'
   ```
3. Create the transform job by using the following code example.

```bash
code example:
aws sagemaker create-transform-job --transform-job-name 'test-tranform-job'\
  --model-name 'test-sagemaker-model'\n  --transform-input '{
    "DataSource": {
      "S3DataSource": {
        "S3DataType": "S3Prefix",
        "S3Uri": "s3://test-bucket/data.csv"
      }
    },
    "ContentType": "text/csv",
    "SplitType": "Line"
  }'
  --transform-output '{
    "S3OutputPath": "s3://test-bucket/output/",
    "AssembleWith": "Line"
  }'
  --transform-resources '{
    "InstanceType": "ml.m5.2xlarge",
    "InstanceCount": 1
  }'
  --region 'us-west-2'
```

4. Check the progress of the transform job by using the following code example.

```bash
code example:
aws sagemaker describe-transform-job --transform-job-name 'test-tranform-job' --region us-west-2
```

The following is the response from the transform job.

```json
{  
  "TransformJobName": "test-tranform-job",
  "TransformJobStatus": "InProgress",
  "ModelName": "test-model",
  "TransformInput": {
    "DataSource": {
      "S3DataSource": {
        "S3DataType": "S3Prefix",
        "S3Uri": "s3://test-bucket/data.csv"
      }
    },
    "ContentType": "text/csv",
    "CompressionType": "None",
    "SplitType": "Line"
  },
  "TransformOutput": {
    "S3OutputPath": "s3://test-bucket/output/",
    "AssembleWith": "Line",
    "KmsKeyId": ""
  },
  "TransformResources": {
    "InstanceType": "ml.m5.2xlarge",
    "InstanceCount": 1
  },
  "CreationTime": 1662495635.679,
  "TransformStartTimestamp": 1662495847.496,
  "DataProcessing": {
```

Batch inferencing across accounts

To create a batch inferencing job in a different account than the one that the model was generated in, follow the instructions in Deploy models from different accounts (p. 337). Then you can create models and transform jobs by following the Batch inferencing steps (p. 339).

Amazon SageMaker Autopilot explainability

Amazon SageMaker Autopilot uses tools provided by Amazon SageMaker Clarify to help explain how machine learning (ML) models make predictions. These tools can help ML modelers, developers, and other internal stakeholders understand model characteristics before deployment. You can also use tools to debug predictions provided by a model after it's deployed. Transparency about how ML models arrive at their predictions is also critical to consumers and regulators, who must trust the model predictions so they can accept the decisions based on them. The Autopilot explanatory functionality uses a model-agnostic feature attribution approach. You can use this to understand why a model made a prediction after training, and use it to provide per-instance explanation during inference. The implementation includes a scalable and efficient implementation of SHAP. This is based on the concept of a Shapley value from the field of cooperative game theory that assigns each feature an importance value for a particular prediction.

You can use explanations for auditing and meeting regulatory requirements, building trust in the model, supporting human decision-making, and debugging and improving model performance.

For additional information on Shapley values and baselines, see Feature Attributions that Use Shapley Values (p. 2653) and SHAP Baselines for Explainability (p. 2654).

For a guide to the Amazon SageMaker Clarify documentation, see Guide to the SageMaker Clarify Documentation (p. 8).

Models generated by Amazon SageMaker Autopilot

This procedure describes how to view details about Amazon SageMaker Autopilot jobs that you have run. Details provided about the candidate models generated by Autopilot include:

- A plot of the aggregated SHAP values that indicate the importance of each feature to help explain your models predictions.
- The summary statistics for various training and validation metrics, including the objective metric.
- A list of the hyperparameters used to train and tune the model.
Note
This topic assumes that you have already created and run an Autopilot experiment. For information on how to create an Autopilot experiment, see Create an Amazon SageMaker Autopilot experiment (p. 321)

Note
To access the feature importance metrics in this procedure, you must first select File > Shut down, and then restart Studio from the console.

1. To view model details after running an Amazon SageMaker Autopilot job, choose the SageMaker resources icon \( \text{\textdm{\textbullet}} \) from the left sidebar to open the SageMaker resources panel.
2. Select Experiments and trials from the dropdown menu located underneath SageMaker resources.
3. Locate the Autopilot job whose details that you want to examine in the Unassigned trial components list. Right-click over the name of the job and select Describe AutoML Job from the pop-up menu. This opens a new Autopilot job tab.
4. The Autopilot job panel lists the Objective metric values for each model in the job with the Best model at the top of the Trials tab. To review model details, right click over the model that you are interested in and select Open in model details. This opens a new Model Details tab.
5. In Model Details, the top of the Explainability tab contains a plot of aggregated SHAP values that indicate the importance of each feature, followed by hyper parameter values for this model. The Performance tab contains metrics statistics and a confusion matrix. The Artifacts tab contains information about model inputs, outputs and intermediate results. The Network tab summarizes your network isolation and encryption choices.

Note
Feature importance and information in the Performance tab is only generated for the Best model.

For more information about how the SHAP values help explain predictions based on feature importance, scroll down to see the link to the Understanding the model explainability whitepaper in the Explainability tab. Additional information is also available in the Amazon SageMaker Clarify Model Explainability (p. 2652) topic in the SageMaker Developer Guide.

Amazon SageMaker Autopilot notebooks generated to manage AutoML tasks

Amazon SageMaker Autopilot generates the key tasks in an automatic machine learning (AutoML) process. They are implemented by Autopilot with an AutoML job. The AutoML job creates three notebook-based reports that describe the plan that Autopilot follows to generate candidate models. A candidate model consists of a (pipeline, algorithm) pair. First, there’s a data exploration notebook, that describes what Autopilot learned about the data that you provided. Second, there’s a candidate definition notebook, which uses the information about the data to generate candidates. Third, a model insights report that can help detail the performance characteristics of the best model in the leaderboard of an Autopilot experiment.

Topics
- Amazon SageMaker Autopilot Data exploration report (p. 346)
- Candidate definition notebook (p. 353)
- Autopilot Model Insights (p. 354)

You can run these notebooks in Amazon SageMaker or locally if you have installed the Amazon SageMaker Python SDK. You can share the notebooks just like any other SageMaker Studio
notebook. The notebooks are created for you to conduct experiments. For example, you could edit the following items in the notebooks:

- Preprocessors used on the data
- Amount of hyperparameter optimization (HPO) runs and their parallelism
- Algorithms to try
- Instance types used for the HPO jobs
- Hyperparameter ranges

Modifications to the candidate definition notebook are encouraged as a learning tool. With this capability, you learn how the decisions made during the machine learning process impact your results.

**Note**

When you run the notebooks in your default instance, you incur baseline costs. However, when you run HPO jobs from the candidate notebook, these jobs use additional compute resources that incur additional costs.

### Amazon SageMaker Autopilot Data exploration report

Amazon SageMaker Autopilot cleans and pre-processes your dataset automatically. High data quality enables more efficient machine learning and produces models that make more accurate predictions. There are issues with customer-provided datasets that cannot be fixed automatically without the benefit of some domain knowledge. Large outlier values in the target column for regression problems, for example, may cause suboptimal predictions for the non-outlier values. Outliers may need to be removed depending on the modeling objective. If a target column is included by accident as one of the input features, the final model will validate well, but be of little value for future predictions. To help customers discover these sorts of issues, Autopilot provides a data exploration report that contains insights into potential issues with their data and suggests how to handle them.

A data exploration notebook containing the report is generated for every Autopilot job that completes the pipeline recommendation step. The report is stored in an S3 bucket and can be accessed from your output path. The path of the data exploration report usually adheres to the following pattern:

```
[s3 output path]/[name of the automl job]/sagemaker-automl-candidates/[name of processing job used for data analysis]/notebooks/SageMakerAutopilotDataExplorationNotebook.ipynb
```

The location of the data exploration notebook can be obtained from the Autopilot API using the DescribeAutoMLJob operation response, stored in DataExplorationNotebookLocation.

When running Autopilot from SageMaker Studio, you can open the data exploration report by opening UI that describes the Autopilot job, and then selecting Open data exploration notebook from the Autopilot job description page.
The data exploration report is generated from your data before the training process begins. This allows you to stop Autopilot jobs that might lead to meaningless results and address any issues or improvements with your dataset before rerunning Autopilot. This gives you an opportunity to leverage your domain expertise to improve the data quality manually before training a model on a better curated dataset.

The data report generated contains only static markdown and can be opened in any Jupyter environment. The notebook that contains the report can be converted to other formats, such as PDF or HTML. For more information on conversions, see Using the nbconvert script to convert Jupyter notebooks to other formats.

Topics
- Dataset Summary (p. 347)
- Target Analysis (p. 348)
- Data Sample (p. 350)
- Duplicate rows (p. 351)
- Cross column correlations (p. 351)
- Anomalous Rows (p. 352)
- Missing values, cardinality, and descriptive statistics (p. 352)

Dataset Summary

This **Dataset Summary** provides key statistics characterizing your dataset. It is intended to provide you with a quick alert when there are issue with your dataset that Amazon SageMaker Autopilot has detected and that are likely to require your intervention. The insights are surfaced as warnings that are classified as being of either “high” or “low” severity. The classification depends on the level of confidence that the issue will adversely impact the performance of the model.

The high and low severity insights appear in the summary as pop-ups. For most of the insights, recommendations are offered for how to confirm that there is an issue with the dataset that requires your attention. Proposals are also provided for how to resolve the issues.
Autopilot provides additional statistics about missing or not valid target values in our dataset to help you detect other issues that may not be captured by high severity insights. An unexpected number of columns of a particular type might indicate that some columns that you want to use may be missing from the dataset. It could also indicate that there was an issue with how the data was prepared or stored. Fixing these data problems brought to your attention by Autopilot can improve the performance of the machine learning models trained on your data.

### Dataset Summary

<table>

</table>

High severity insights are shown in the summary section and in other relevant sections in the report. Examples of high and low-severity insights are usually given depending on the section of the data report.

### Target Analysis

Various high and low-severity insights are shown in this section related to the distribution of values in the target column. You should check that target column contains the correct values. Incorrect values in target column will likely result in a machine learning model that doesn't serve the intended business purpose. Several data insights of high and low severity are present in this section. Here are several examples.

- **Outlier target values** - Skewed or unusual target distribution for regression, such as heavy tailed targets.

- **High or low target cardinality** - Infrequent number of class labels or a large number of unique classes for classification.

For both regression and classification problem types, not valid values such as numeric infinity, NaN or empty space in target column are surfaced. Depending on the problem type, different dataset statistics are presented. A distribution of target column values for a regression problem allows you to verify if the distribution is what you expected.

The following example shows an Autopilot data report on the distribution of target column values.
Multiple statistics are shown regarding target values and their distribution. If any of the outliers, not valid values, or missing percentages are greater than zero, these values are surfaced so you can investigate why your data contains unusable target values. Some unusable target values are highlighted as a low severity insight warning. In the following example, a ` symbol was added accidentally to the target column, which prevented the numeric value of the target from being parsed.

To help you identify the problematic values and some impacted rows, Autopilot provides examples of rows that contain unusable or outlier target values. Distribution of labels for classification are tabulated and plotted so that you can analyze them as well.
Note
You can find definitions of all the terms presented in this and other sections in Definitions section at the bottom of the report notebook.

Data Sample

To further help you spot issues with your dataset, an actual sample of your data is presented for you to inspect by Amazon SageMaker Autopilot. The sample table scrolls horizontally. It can be used to verify that all the necessary columns are present in the dataset used. If data columns are missing, there may be a preprocessing issue that occurred before importing the dataset that you need to investigate.

A measure of predictive power is calculated by Amazon SageMaker Autopilot and can be used to identify target columns disguised as input columns. It helps focus your attention on the columns that might be important because they have high prediction power. For more information on prediction power, see the Definitions section.

Note
It is not recommended that you use prediction power as a substitute for feature importance, unless you're certain that prediction power is an appropriate measure for your use case.
Duplicate rows

If duplicate rows are present in the dataset, Amazon SageMaker Autopilot displays a sample of them.

**Note**
It is not recommended to balance a dataset by up-sampling before providing it to Autopilot. This may result in inaccurate validation scores for the models trained by Autopilot, and the models that are produced may be unusable.

Cross column correlations

Numeric column correlation is also presented using a standard cross-correlation matrix graphic. You can use this to reduce the number of features in the dataset. A smaller number of features reduces chances of overfitting a model and can reduce the costs of production in two ways. It lessens the Autopilot runtime needed and, for some applications, can make data collection procedures cheaper.

**Note**
Values close to +1 and values close to -1 indicate that two features are highly correlated, positively and negatively, respectively.
Anomalous Rows

Amazon SageMaker Autopilot detects which rows in your dataset might be anomalous. It then assigns an anomaly score to each row. Rows with negative anomaly scores are considered anomalous.

Anomalous Rows

Anomalous rows are detected using the isolation forest algorithm on a sample of 1380 randomly chosen rows after basic preprocessing. The isolation forest algorithm associates an anomaly score to each row of the dataset it is trained on. Rows with negative anomaly scores are usually considered anomalous and rows with positive anomaly scores are considered non-anomalous. When investigating an anomalous row, look for any unusual values - in particular any that might have resulted from errors in the gathering and processing of data. Dissecting whether a row is indeed anomalous, contains errors, or is in fact valid requires domain knowledge and application of business logic.

Inspect the rows below, to see if any of those are anomalous. A subset of rows is presented below. Anomaly score is presented as the leftmost column; Smaller values indicate a higher chance that the row is anomalous.

Missing values, cardinality, and descriptive statistics

Amazon SageMaker Autopilot examines and reports on properties of the individual columns of your dataset. In each section of the data report that presents this analysis, the content is arranged in order, so that you can check the most "suspicious" values first. Using these statistics you can improve contents of individual columns, and improve the quality of the model produced by Autopilot.
Autopilot calculates several statistics on the categorical values in columns that contain them. These include the number of unique entries and, for text, the number of unique words. These are presented in a table for your inspection.

<table>
<thead>
<tr>
<th>Number of Unique Entries</th>
<th>Number of Unique Words (if Text)</th>
</tr>

**Candidate definition notebook**

The candidate definition notebook contains each suggested preprocessing step, algorithm, and hyperparameter ranges.

After you produce the notebook, you can choose which candidates to train and tune. Choose these candidates by running sections of the automatic machine learning (AutoML) job that contain them inside of the notebook. These candidates are optimized automatically to identify a final, best candidate.

When you run all sections of the AutoML job directly, only the best candidate is displayed after job completion.

**Note**

Candidate definition notebooks are not available for ensembling mode.
Autopilot Model Insights

Amazon SageMaker Model Monitor report provides insights and quality information for the model candidates generated in the leaderboard of an Autopilot experiment by an AutoML job. The report provides the model insights charts only for the best classification model candidate. This includes understanding false positives/false negatives, tradeoffs between true positives and false positives, and tradeoffs between precision and recall.

Autopilot also provides scalar metrics for all of your candidate models used to measure their predictive quality. The leaderboard view includes these metrics by default. The metrics automatically calculated for a candidate model are determined by the type of problem being addressed.

- Regression: MSE
- Binary classification: Accuracy, F1, AUC
- Multiclass classification: Accuracy, F1macro

You can sort your model candidates with the relevant metric to help you select and deploy the model that addresses your business needs. For definitions of these metrics, see the Autopilot candidate metrics topic.

The SageMaker model monitor report contains details characterizing the Autopilot job, a metrics table, and several model insights. These include model charts that are relevant to the type of classification problem. You access these reports in SageMaker Studio from the Performance tab on the page that opens to confirm that your AutoML job has completed. For instructions on how to create and run an AutoML job in SageMaker Studio, see Create an Amazon SageMaker Autopilot experiment (p. 321).

Topics
- Model details and metrics tables (p. 354)
- Confusion matrix (p. 355)
- The area under the receiver operating characteristic curve (p. 357)
- Precision-recall curve (p. 358)

Model details and metrics tables

Model details include the following information.

- Autopilot Candidate Name
- Autopilot Job Name
- Problem Type
- Objective Metric
- Optimization Direction

The model quality information is generated by the prebuilt SageMaker Model Monitor container. The contents of the report generated depends on the problem type addressed: regression, binary classification, or multiclass classification. The report specifies the number of rows that were included in the evaluation dataset and the time at which the evaluation occurred.

Here is an example of a metrics table in a Model Monitor report generated by AutoML job for a regression problem.
Here is an example of a metrics table in a Model Monitor report generated by AutoML job for a binary classification problem.

### Confusion matrix

The confusion matrix provides a way to visualize the accuracy of the predictions made by binary and multiclass classification for different classes. The confusion matrix is a table that contains the percentages of correct and incorrect predictions for the actual labels. Each row in the confusion matrix indicates how an actual label was classified by the label predicted by the model. The percentage of accurate predictions is on the diagonal, from the upper-left to the lower-right corner. The off-
diagonal percentages indicate the types of misclassification that the model is predicting. These incorrect predictions are the confusion values.

Here is an example of a confusion matrix for a binary classification problem.

Here is an example of a confusion matrix for a multi-class classification problem.
This report provides a confusion matrix that can accommodate a maximum 15 labels for multiclass classification problem types. The labels are listed in order, from those predicted least accurately to those predicted most accurately. If a row shows Nan, it means that the validation dataset doesn't have a row for that label.

The area under the receiver operating characteristic curve

The area under the receiver operating characteristic curve (AUC ROC curve) represents the trade-off between true positive and false positive rates. The AUC ROC curve is an industry-standard accuracy metric used for binary classification models. AUC measures the ability the model to predict a higher score for positive examples, as compared to negative examples. The AUC metric provides an aggregated measure of the model performance across all possible classification thresholds.

The AUC metric returns a decimal value from zero (0) to one (1). AUC values near 1 indicate an ML model that is highly accurate. Values near 0.5 indicate an ML model that is no better than guessing at random. Values near 0 are unusual to see, and these typically indicate a problem with the data. Essentially, an AUC near 0 says that the ML model has learned the correct patterns, but is using them to make predictions that are as inaccurate as possible. For example, 0s are predicted as 1s, and 1s as 0s. For more information about the AUC metric, see the Receiver operating characteristic article on Wikipedia.

A binary model that classifies no-better-than-random guessing, with equal rates of true and false positives, has an AUC score of 0.5. The curve representing a random binary classifier is a diagonal dotted red line in a receiver operating characteristic graph. The curves of more accurate classification models lie above this random baseline, where the rate of true positives exceeds the rate of false positives.

The false positive rate (FPR) measures the false alarm rate or the fraction of actual negatives that were falsely predicted as positives. The range is 0 to 1. A smaller value indicates better predictive accuracy.

- \( \text{FPR} = \frac{FP}{FP+TN} \)

The true positive rate (TPR) measures the fraction actual positives that were predicted as positives. The range is 0 to 1. A larger value (1 being the largest) indicates better predictive accuracy.

- \( \text{TPR} = \frac{TP}{TP+FN} \)
Where these rates are defined as follows.

- **Correct predictions**
  - **True positive** (TP): The predicted the value is 1, and the true value is 1.
  - **True negative** (TN): The predicted the value is 0, and the true value is 0.

- **Erroneous predictions**
  - **False positive** (FP): The predicted the value is 1, but the true value is 0.
  - **False negative** (FN): The predicted the value is 0, but the true value is 1.

### Precision-recall curve

The precision-recall curve represents the tradeoff between precision and recall for different thresholds used in a binary classification problem. The objective of a binary classification problem is to correctly classify as many of the relevant elements that labeled positive in a training dataset as possible. A system with high recall but low precision returns lots of relevant results, but a high percentage of its predicted labels is of its labels are incorrect when compared to the training labels. A system with high precision but low recall returns fewer relevant results, but a high percentage of predicted is of its labels are correct when compared to the training labels. A perfect system that has both high precision and high recall produces many correctly-labeled results. For more information, see [Precision and recall](https://en.wikipedia.org/wiki/Precision_and_recall) article in Wikipedia.

**Precision** measures the fraction of actual positives that are predicted as positive out of all those predicted as positive. The range is 0 to 1. A larger value indicates better accuracy in the values predicted.

- Precision = $\frac{TP}{TP+FP}$

**Recall** measures the fraction of actual positives that are predicted as positive out of all the actual positives in the sample. This is also known as the sensitivity and as the true positive rate. The range is 0 to 1. A larger value indicates better detection of positive values from the sample.

- Recall = $\frac{TP}{TP+FN}$

Amazon SageMaker Autopilot reports the area under the precision-recall curve (AUPRC). The AUPRC metric provides an aggregated measure of the model performance across all possible classification thresholds.

Here is an example that compares the precision-recall curves and their AUPRC values from four different models trained on the same dataset.
Configure inference output in generated containers

Amazon SageMaker Autopilot generates an ordered `ContainerDefinition` list. This can be used to build a model to deploy in a machine learning pipeline. This model can be used for online hosting and inference.

Customers can access the list of inference container definitions with the `ListCandidateForAutoMLJob` API. The list of inference container definitions that represent the best candidate is also available in the `DescribeAutoMLJob` response.

Topics
- Inference container definitions for regression and classification problem types (p. 359)

Inference container definitions for regression and classification problem types

This section provides details about container definitions for hyperparameter optimization (HPO) mode.

Autopilot generates inference containers specific to the problem type of the job.

- **Regression**: HPO generates two containers:
  1. A feature engineering container that transforms the original features into features that the regression algorithms can train on.
  2. An algorithm container that transforms features and generates a regression score for the dataset.

- **Classification**: HPO generates three containers:
  1. A feature engineering container that transforms the original features into features that the classification algorithms can train on.
2. An algorithm container that generates the `predicted_label` with the highest probability. This container can also produce the various probabilities associated with the classification outcomes in the inference response.

3. A feature engineering container that performs post-processing of the algorithm prediction. For example, it can perform an inverse transform on the predicted label and change it to the original label.

**Container definitions for ensembling mode**

In **ensembling mode**, both regression and classification problem types have only one inference container. This inference container transforms the features and generates the predictions based on problem type.

**Inference responses for classification models**

In this section, you'll learn to select inference responses for Autopilot classification models in ensembling mode.

For classification inference containers, you can select the content of the inference response by using four predefined keys:

- `predicted_label`: The label with the highest probability of predicting the correct label, as determined by Autopilot.
- `probability`: The probability of the `True` class for binary classification. The probability of the `predicted_label` for multiclass classification.
- `probabilities`: The list of probabilities for all corresponding classes.
- `labels`: The list of all labels.

By default, inference containers are configured to generate only the `predicted_label`. To select additional inference content, you can update the `inference_response_keys` parameter to include up to these three environment variables:

- `SAGEMAKER_INFERENCE_SUPPORTED`: This is set to provide hints to you about what content each container supports.
- `SAGEMAKER_INFERENCE_INPUT`: This should be set to the keys that the container expects in input payload.
- `SAGEMAKER_INFERENCE_OUTPUT`: This should be populated with the set of keys that the container outputs.

**Inference responses for classification models in HPO mode**

This section shows how to configure the inference response from classification models using hyperparameter optimization (HPO) mode.

To choose the inference response content in HPO mode: Add the `SAGEMAKER_INFERENCE_INPUT` and `SAGEMAKER_INFERENCE_OUTPUT` variables to the second and third containers that are generated in HPO mode for classification problems.

The keys supported by the second container (algorithm) are `predicted_label`, `probability`, and `probabilities`. Note that `labels` is deliberately not added to `SAGEMAKER_INFERENCE_SUPPORTED`.

The keys supported by the third classification model container are `predicted_label`, `labels`, `probability`, and `probabilities`. Therefore, the `SAGEMAKER_INFERENCE_SUPPORTED` environment includes the names of these keys.
To update the definition of the inference containers to receive predicted_label and probability, use the following code example.

```python
containers[1]['Environment'].update({'SAGEMAKER_INFERENCE_OUTPUT': 'predicted_label, probability'})
containers[2]['Environment'].update({'SAGEMAKER_INFERENCE_INPUT': 'predicted_label, probability'})
containers[2]['Environment'].update({'SAGEMAKER_INFERENCE_OUTPUT': 'predicted_label, probability'})
```

The following code example updates the definition of the inference containers to receive predicted_label, probabilities, and labels. Do not pass the labels to the second container (the algorithm container), because it is generated by the third container independently.

```python
containers[1]['Environment'].update({'SAGEMAKER_INFERENCE_OUTPUT': 'predicted_label, probability'})
containers[2]['Environment'].update({'SAGEMAKER_INFERENCE_INPUT': 'predicted_label, probability'})
containers[2]['Environment'].update({'SAGEMAKER_INFERENCE_OUTPUT': 'predicted_label, probabilities, labels'})
```

The following collapsible sections provide code examples for AWS SDK for Python (Boto3) and for SageMaker SDK for Python. Each section shows how to select the content of the inference responses in HPO mode for the respective code example.

**AWS SDK for Python (Boto3)**

```python
import boto3

sm_client = boto3.client('sagemaker', region_name='<Region>')
role = '<IAM role>'
input_data = '<S3 input uri>'
output_path = '<S3 output uri>'

best_candidate = sm_client.describe_auto_ml_job(AutoMLJobName='<AutoML Job Name>')['BestCandidate']
best_candidate_containers = best_candidate['InferenceContainers']
best_candidate_name = best_candidate['CandidateName']

best_candidate_containers[1]['Environment'].update({'SAGEMAKER_INFERENCE_OUTPUT': 'predicted_label, probability'})
best_candidate_containers[2]['Environment'].update({'SAGEMAKER_INFERENCE_INPUT': 'predicted_label, probability'})
best_candidate_containers[2]['Environment'].update({'SAGEMAKER_INFERENCE_OUTPUT': 'predicted_label, probability'})

# create model
response = sm_client.create_model(
    ModelName = '<Model Name>',
    ExecutionRoleArn = role,
    Containers = best_candidate_containers
)

# Launch Transform Job
response = sm_client.create_transform_job(
    TransformJobName='<Transform Job Name>',
    ModelName = '<Model Name>',
    TransformInput={
        'DataSource': {
            'S3DataSource': {
                'S3DataType': '<S3Prefix>'
            }
        }
    }
)```
Inference container definitions for regression and classification problem types

Inference responses for classification models in ensembling mode

This section shows how to configure the inference response from classification models using ensembling mode.

In **ensembling mode**, to choose the content of the inference response, update the SAGEMAKER_INFERENCE_OUTPUT environment variable.

The keys supported by the classification model container are predicted_label, labels, probability, and probabilities. These keys are included in the SAGEMAKER_INFERENCE_SUPPORTED environment.

To update the inference container definition to receive predicted_label and probability, refer to the following code example.

```
containers[0]['Environment'].update({'SAGEMAKER_INFERENCE_OUTPUT': 'predicted_label, probability'})
```

The following collapsible section provides a code example for selecting the content of the inference responses in ensembling mode. The example uses AWS SDK for Python (Boto3).

**AWS SDK for Python (Boto3)**

```python
import boto3
```
Inference container definitions for regression and classification problem types

```python
sm_client = boto3.client('sagemaker', region_name='Region')
role = IAM_role
input_data = '<S3 input uri>'
output_path = '<S3 output uri>'

best_candidate = sm_client.describe_auto_ml_job(AutoMLJobName='AutoML Job Name')
best_candidate_containers = best_candidate['InferenceContainers']
best_candidate_name = best_candidate['CandidateName']

best_candidate_containers[0]['Environment'].update({"SAGEMAKER_INFERENCE_OUTPUT": 'predicted_label, probability'})

# create model
response = sm_client.create_model(
    ModelName = '<Model Name>',
    ExecutionRoleArn = role,
    Containers = best_candidate_containers
)

# Launch Transform Job
response = sm_client.create_transform_job(
    TransformJobName='Transform Job Name',
    ModelName='<Model Name>',
    TransformInput={
        'DataSource': {
            'S3DataSource': {
                'S3DataType': 'S3Prefix',
                'S3Uri': input_data
            }
        },
        'ContentType': 'text/CSV',
        'SplitType': 'Line'
    },
    TransformOutput={
        'S3OutputPath': output_path,
        'AssembleWith': 'Line',
    },
    TransformResources={
        'InstanceType': 'ml.m4.xlarge',
        'InstanceCount': 1,
    },
)
```

The following collapsible section provides a code example that is identical to the SageMaker SDK for Python example for HPO. It is included for your convenience.

### SageMaker SDK for Python

The following HPO code example uses SageMaker SDK for Python.

```python
from sagemaker import AutoML

aml = AutoML.attach(auto_ml_job_name='AutoML Job Name')
aml_best_model = aml.create_model(name='<Model Name>',
                                   candidate=None,
                                   *inference_response_keys*=['probabilities', 'labels']*)

aml_transformer = aml_best_model.transformer(accept='text/csv',
                                             assemble_with='Line',
                                             instance_type='ml.m5.xlarge',
                                             instance_count=1,)
```

The following collapsible section provides a code example that is identical to the SageMaker SDK for Python example for HPO. It is included for your convenience.

### SageMaker SDK for Python

The following HPO code example uses SageMaker SDK for Python.
Amazon SageMaker Autopilot quotas

There are quotas that limit the resources available to you when using Amazon SageMaker Autopilot. Some of these limits are increasable and some are not.

**Note**
The resource quotas documented in the following sections are valid for versions of Amazon SageMaker Studio 3.22.2 and higher. For information on updating your version of SageMaker Studio, see [Shut Down and Update SageMaker Studio and Studio Apps](#) (p. 179).

**Topics**
- Quotas that you can increase (p. 364)
- Resource quotas (p. 365)

### Quotas that you can increase

There are default limits for the size of the input datasets: file size of a single Parquet file (*), the target dataset size subsampling (**), and the number of concurrent jobs you can run with Amazon SageMaker Autopilot for each AWS account, per AWS Region.

#### Resource limits

<table>
<thead>
<tr>
<th>Resource</th>
<th>Regions</th>
<th>Default limits</th>
<th>Can be increased up to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Size of input dataset</td>
<td>All</td>
<td>100 GB</td>
<td>Hundreds of GBs</td>
</tr>
<tr>
<td>Size of a single Parquet file*</td>
<td>All</td>
<td>2 GB</td>
<td>Tens of GBs</td>
</tr>
<tr>
<td>Target dataset size for subsampling**</td>
<td>All</td>
<td>5 GB</td>
<td>Hundreds of GBs</td>
</tr>
<tr>
<td>Number of concurrent Autopilot jobs</td>
<td>us-east-1, us-east-2, us-west-2, ap-northeast-1, eu-west-1, eu-central-1</td>
<td>4</td>
<td>Hundreds</td>
</tr>
<tr>
<td></td>
<td>ap-northeast-2, ap-southeast-2, eu-west-2, ap-southeast-1</td>
<td>2</td>
<td>Hundreds</td>
</tr>
<tr>
<td></td>
<td>All other Regions</td>
<td>1</td>
<td>Tens</td>
</tr>
</tbody>
</table>

**Note**
*This 2 GB size limit is for a single compressed Parquet file. You can provide a Parquet dataset that includes multiple compressed Parquet files. After the files are decompressed, they may each expand to a larger size.
**Autopilot automatically subsamples input datasets that are larger than the target dataset size while accounting for class imbalance and preserving rare class labels.
You can increase these limits by contacting Support.

To request a quota increase:

1. Open the AWS Support Center page, sign in if necessary, and then choose Create case.
2. On the Create case page, choose Service limit increase.
3. In the Case details panel, select SageMaker AutoML for the Limit Type.
4. On the Requests panel for Request 1, select the Region, the resource Limit to increase and the New Limit value you are requesting. Select Add another request if you have additional requests for quota increases.
5. Provide your preferred Contact options and choose Submit.

Resource quotas

The following table contains the runtime resource limits for an Amazon SageMaker Autopilot job in an AWS Region.

<table>
<thead>
<tr>
<th>Resource</th>
<th>Limit per Autopilot job</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum runtime for an Autopilot job</td>
<td>30 days</td>
</tr>
</tbody>
</table>
Amazon SageMaker provides API reference documentation that describes all of the REST operations and data types used by Autopilot and a higher-level level Amazon SageMaker Python SDK that you can use to create and manage AutoML jobs. It also provides a command line interface (CLI), an AWS SDK for Python (Boto) for clients of SageMaker services, and SDKs for .NET, C++, Go, Java, JavaScript, PHP V3, and Ruby V3. The following sections describe these Autopilot programming interfaces.

Topics
- SageMaker API reference (p. 366)
- Amazon SageMaker Python SDK (p. 367)
- AWS Command Line Interface (CLI) (p. 367)
- AWS SDK for Python (Boto) (p. 367)
- AWS SDK for .NET (p. 368)
- AWS SDK for C++ (p. 368)
- AWS SDK for Go (p. 368)
- AWS SDK for Java (p. 368)
- AWS SDK for JavaScript (p. 369)
- AWS SDK for PHP V3 (p. 369)
- AWS SDK for Ruby V3 (p. 369)

SageMaker API reference

This API provides HTTP service APIs for creating and managing Amazon SageMaker Autopilot resources.

Actions
- CreateAutoMLJob
- DescribeAutoMLJob
- ListAutoMLJobs
- ListCandidatesForAutoMLJob
- StopAutoMLJob

Data Types
- AutoMLCandidate
- AutoMLCandidateStep
- AutoMLChannel
- AutoMLContainerDefinition
- AutoMLDataSource
- AutoMLJobArtifacts
- AutoMLJobCompletionCriteria
- AutoMLJobConfig
- AutoMLJobObjective
For more information on the entire SageMaker REST API, see API and SDK Reference.

Amazon SageMaker Python SDK

This Python library provides several high-level abstractions for working with SageMaker. The following classes can be used to manage AutoML jobs.

- AutoML
- AutoMLInput
- AutoMLJob
- CandidateEstimator
- CandidateStep

For more information how this Python SDK simplifies model training and deployment, see Using the Amazon SageMaker Python SDK.

AWS Command Line Interface (CLI)

The AWS CLI provides APIs for creating and managing SageMaker resources. Here are the AWS CLI for Amazon SageMaker Autopilot commands.

- create-auto-ml-job
- describe-auto-ml-job
- list-auto-ml-jobs
- list-candidates-for-auto-ml-job
- stop-auto-ml-job

AWS SDK for Python (Boto)

Boto is the Amazon Web Services (AWS) SDK for Python. It enables Python developers to create, configure, and manage AWS services such as SageMaker. Boto provides a low-level Client API that maps to the underlying SageMaker service API. Here is a list of the methods used to manage AutoML jobs with the Client class.
• `create_auto_ml_job()`
• `describe_auto_ml_job()`
• `list_auto_ml_jobs()`
• `list_candidates_for_auto_ml_job()`
• `stop_auto_ml_job()`

**AWS SDK for .NET**

The .NET SDK enables developers to create, configure, and manage AWS services such as SageMaker. The API maps to the underlying SageMaker service API. Here is a list of the methods used to manage AutoML jobs with the Client class.

• `CreateAutoMLJob`
• `DescribeAutoMLJob`
• `ListAutoMLJobs`
• `ListCandidatesForAutoMLJob`
• `StopAutoMLJob`

**AWS SDK for C++**

The C++ SDK enables developers to create, configure, and manage AWS services such as SageMaker. The API maps to the underlying SageMaker service API. For information on the methods used to manage AutoML jobs with the Client class, see `Aws::SageMaker::SageMakerClient Class Reference`.

**AWS SDK for Go**

The Go SDK enables developers to create, configure, and manage AWS services such as SageMaker. The API maps to the underlying SageMaker service API. Here is a list of the methods used to manage AutoML jobs with the Client class.

• `CreateAutoMLJob`
• `DescribeAutoMLJob`
• `ListAutoMLJobs`
• `ListCandidatesForAutoMLJob`
• `StopAutoMLJob`

**AWS SDK for Java**

The Java SDK enables developers to create, configure, and manage AWS services such as SageMaker. The API maps to the underlying SageMaker service API. Here is a list of the methods used to manage AutoML jobs with the Client class.

• `createAutoMLJob`
• `describeAutoMLJob`
• `listAutoMLJobs`
• `listCandidatesForAutoMLJob`
• `stopAutoMLJob`
**AWS SDK for JavaScript**

The JavaScript SDK enables developers to create, configure, and manage AWS services such as SageMaker. The API maps to the underlying SageMaker service API. Here is a list of the methods used to manage AutoML jobs with the Client class.

- `createAutoMLJob`
- `describeAutoMLJob`
- `listAutoMLJobs`
- `listCandidatesForAutoMLJob`
- `stopAutoMLJob`

**AWS SDK for PHP V3**

The PHP V3 SDK enables developers to create, configure, and manage AWS services such as SageMaker. The API maps to the underlying SageMaker service API. Here is a list of the methods used to manage AutoML jobs with the Client class.

- `CreateAutoMLJob`
- `DescribeAutoMLJob`
- `ListAutoMLJobs`
- `ListCandidatesForAutoMLJob`
- `StopAutoMLJob`

**AWS SDK for Ruby V3**

The Ruby V3 SDK enables developers to create, configure, and manage AWS services such as SageMaker. The API maps to the underlying SageMaker service API. Here is a list of the methods used to manage AutoML jobs with the Client class.

- `create_auto_ml_job()`
- `describe_auto_ml_job()`
- `list_auto_ml_jobs()`
- `list_candidates_for_auto_ml_job()`
- `stop_auto_ml_job()`
Label Data

To train a machine learning model, you need a large, high-quality, labeled dataset. You can label your
data using Amazon SageMaker Ground Truth. Choose from one of the Ground Truth built-in task types or
create your own custom labeling workflow. To improve the accuracy of your data labels and reduce the
total cost of labeling your data, use Ground Truth enhanced data labeling features like automated data
labeling and annotation consolidation.

Topics
- Use Amazon SageMaker Ground Truth to Label Data (p. 370)
- Use Amazon SageMaker Ground Truth Plus to Label Data (p. 677)
- Use Amazon SageMaker Ground Truth Synthetic Data to Generate and Label Data (p. 687)
- Create and Manage Workforces (p. 694)
- Crowd HTML Elements Reference (p. 720)

Use Amazon SageMaker Ground Truth to Label Data

To train a machine learning model, you need a large, high-quality, labeled dataset. Ground Truth helps
you build high-quality training datasets for your machine learning models. With Ground Truth, you can
use workers from either Amazon Mechanical Turk, a vendor company that you choose, or an internal,
private workforce along with machine learning to enable you to create a labeled dataset. You can use the
labeled dataset output from Ground Truth to train your own models. You can also use the output as a
training dataset for an Amazon SageMaker model.

Depending on your ML application, you can choose from one of the Ground Truth built-in task types
to have workers generate specific types of labels for your data. You can also build a custom labeling
workflow to provide your own UI and tools to workers labeling your data. To learn more about the
Ground Truth built in task types, see Built-in Task Types (p. 542). To learn how to create a custom
labeling workflow, see Creating Custom Labeling Workflows (p. 509).

In order to automate labeling your training dataset, you can optionally use automated data labeling,
a Ground Truth process that uses machine learning to decide which data needs to be labeled by
humans. Automated data labeling may reduce the labeling time and manual effort required. For more
information, see Automate Data Labeling (p. 640). To create a custom labeling workflow, see Creating
Custom Labeling Workflows (p. 509).

Use either pre-built or custom tools to assign the labeling tasks for your training dataset. A labeling UI
template is a webpage that Ground Truth uses to present tasks and instructions to your workers. The
SageMaker console provides built-in templates for labeling data. You can use these templates to get
started, or you can build your own tasks and instructions by using our HTML 2.0 components. For more
information, see Creating Custom Labeling Workflows (p. 509).

Use the workforce of your choice to label your dataset. You can choose your workforce from:
- The Amazon Mechanical Turk workforce of over 500,000 independent contractors worldwide.
• A private workforce that you create from your employees or contractors for handling data within your organization.
• A vendor company that you can find in the AWS Marketplace that specializes in data labeling services.

For more information, see Create and Manage Workforces (p. 694).

You store your datasets in Amazon S3 buckets. The buckets contain three things: The data to be labeled, an input manifest file that Ground Truth uses to read the data files, and an output manifest file. The output file contains the results of the labeling job. For more information, see Use Input and Output Data (p. 572).

Events from your labeling jobs appear in Amazon CloudWatch under the /aws/sagemaker/LabelingJobs group. CloudWatch uses the labeling job name as the name for the log stream.

Are You a First-time User of Ground Truth?

If you are a first-time user of Ground Truth, we recommend that you do the following:

1. Read Getting started (p. 371)—This section walks you through setting up your first Ground Truth labeling job.
2. Explore other topics—Depending on your needs, do the following:
   • Explore built-in task types—Use built-in task types to streamline the process of creating a labeling job. See Built-in Task Types (p. 542) to learn more about Ground Truth built-in task types.
   • Manage your labeling workforce—Create new work teams and manage your existing workforce. For more information, see Create and Manage Workforces (p. 694).
   • Learn about streaming labeling jobs—Create a streaming labeling job and send new dataset objects to workers in real time using a perpetually running labeling job. Workers continuously receive new data objects to label as long as the labeling job is active and new objects are being sent to it. To learn more, see Ground Truth Streaming Labeling Jobs (p. 576).
3. See the Reference—This section describes operations to automate Ground Truth operations.

Getting started

This video shows you how to setup and use Amazon SageMaker Ground Truth. (Length: 9:37)

To get started using Amazon SageMaker Ground Truth, follow the instructions in the following sections. The sections here explain how to use the console to create a labeling job, assign a public or private workforce, and send the labeling job to your workforce. You can also learn how to monitor the progress of a labeling job.

If you want to create a custom labeling workflow, see Creating Custom Labeling Workflows (p. 509) for instructions.

Before you create a labeling job, you must upload your dataset to an Amazon S3 bucket. For more information, see Use Input and Output Data (p. 572).

Topics
• Step 1: Before You Begin (p. 372)
• Step 2: Create a Labeling Job (p. 372)
• Step 3: Select Workers (p. 373)
• Step 4: Configure the Bounding Box Tool (p. 375)
Step 1: Before You Begin

Before you begin using the SageMaker console to create a labeling job, you must set up the dataset for use. Do this:

1. Save two images at publicly available HTTP URLs. The images are used when creating instructions for completing a labeling task. The images should have an aspect ratio of around 2:1. For this exercise, the content of the images is not important.
2. Create an Amazon S3 bucket to hold the input and output files. The bucket must be in the same Region where you are running Ground Truth. Make a note of the bucket name because you use it during step 2.

Ground Truth requires all S3 buckets that contain labeling job input image data have a CORS policy attached. To learn more about this change, see CORS Permission Requirement (p. 649).
3. You can create an IAM role or let SageMaker create a role with the AmazonSageMakerFullAccess IAM policy. Refer to Creating IAM roles and assign the following permissions policy to the user that is creating the labeling job:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "sagemakergroundtruth",
            "Effect": "Allow",
            "Action": [
                "cognito-idp:CreateGroup",
                "cognito-idp:CreateUserPool",
                "cognito-idp:CreateUserPoolDomain",
                "cognito-idp:AdminCreateUser",
                "cognito-idp:CreateUserPoolClient",
                "cognito-idp:AdminAddUserToGroup",
                "cognito-idp:DescribeUserPoolClient",
                "cognito-idp:DescribeUserPool",
                "cognito-idp:UpdateUserPool"
            ],
            "Resource": "*"
        }
    ]
}
```

Next

Step 2: Create a Labeling Job (p. 372)

Step 2: Create a Labeling Job

In this step you use the console to create a labeling job. You tell Amazon SageMaker Ground Truth the Amazon S3 bucket where the manifest file is stored and configure the parameters for the job. For more information about storing data in an Amazon S3 bucket, see Use Input and Output Data (p. 572).

To create a labeling job

2. From the left navigation, choose Labeling jobs.
3. Choose **Create labeling job** to start the job creation process.
4. In the **Job overview** section, provide the following information:
   - **Job name** – Give the labeling job a name that describes the job. This name is shown in your job list. The name must be unique in your account in an AWS Region.
   - **Label attribute name** – Leave this unchecked as the default value is the best option for this introductory job.
   - **Input data setup** – Select **Automated data setup**. This option allows you to automatically connect to your input data in S3.
   - **S3 location for input datasets** – Enter the S3 location where you added the images in step 1.
   - **S3 location for output datasets** – The location where your output data is written in S3.
   - **Data type** – Use the drop down menu to select **Image**. Ground Truth will use all images found in the S3 location for input datasets as input for your labeling job.
   - **IAM role** – Create or choose an IAM role with the AmazonSageMakerFullAccess IAM policy attached.
5. In the **Task type** section, for the **Task category** field, choose **Image**.
6. In the **Task selection** choose **Bounding box**.
7. Choose **Next** to move on to configuring your labeling job.

**Next**

**Step 3: Select Workers (p. 373)**

**Step 3: Select Workers**

In this step you choose a workforce for labeling your dataset. It is recommended that you create a private workforce to test Amazon SageMaker Ground Truth. Use email addresses to invite the members of your workforce. If you create a private workforce in this step you won't be able to import your Amazon Cognito user pool later. If you want to create a private workforce using an Amazon Cognito user pool, see **Manage a Private Workforce (Amazon Cognito) (p. 703)** and use the Mechanical Turk workforce instead in this tutorial.

**Tip**

To learn about the other workforce options you can use with Ground Truth, see **Create and Manage Workforces (p. 694)**.

**To create a private workforce:**

1. In the **Workers** section, choose **Private**.
2. If this is your first time using a private workforce, in the **Email addresses** field, enter up to 100 email addresses. The addresses must be separated by a comma. You should include your own email address so that you are part of the workforce and can see data object labeling tasks.
3. In the **Organization name** field, enter the name of your organization. This information is used to customize the email sent to invite a person to your private workforce. You can change the organization name after the user pool is created through the console.
4. In the **Contact email** field enter an email address that members of the workforce use to report problems with the task.

If you add yourself to the private workforce, you will receive an email that looks similar to the following. **Amazon, Inc.** is replaced by the organization you enter in step 3 of the preceding procedure. Select the link in the email to log in using the temporary password provided. If prompted, change your password. When you successfully log in, you see the worker portal where your labeling tasks appear.
Tip
You can find the link to your private workforce's worker portal in the Labeling workforces section of the Ground Truth area of the SageMaker console. To see the link, select the Private tab. The link is under the Labeling portal sign-in URL header in Private workforce summary.

If you choose to use the Amazon Mechanical Turk workforce to label the dataset, you are charged for labeling tasks completed on the dataset.

To use the Amazon Mechanical Turk workforce:

1. In the Workers section, choose Public.
2. Set a Price per task.
3. If applicable, choose The dataset does not contain adult content to acknowledge that the sample dataset has no adult content. This information enables Amazon SageMaker Ground Truth to warn external workers on Mechanical Turk that they might encounter potentially offensive content in your dataset.
4. Choose the check box next to the following statement to acknowledge that the sample dataset does not contain any personally identifiable information (PII). This is a requirement to use Mechanical Turk with Ground Truth. If your input data does contain PII, use the private workforce for this tutorial.

You understand and agree that the Amazon Mechanical Turk workforce consists of independent contractors located worldwide and that you should not share confidential information, personal information or protected health information with this workforce.

Next
Step 4: Configure the Bounding Box Tool (p. 375)
Step 4: Configure the Bounding Box Tool

Finally you configure the bounding box tool to give instructions to your workers. You can configure a task title that describes the task and provides high-level instructions for the workers. You can provide both quick instructions and full instructions. Quick instructions are displayed next to the image to be labeled. Full instructions contain detailed instructions for completing the task. In this example, you only provide quick instructions. You can see an example of full instructions by choosing Full instructions at the bottom of the section.

To configure the bounding box tool

1. In the Task description field type in brief instructions for the task. For example:

   Draw a box around any objects in the image.

   Replace objects with the name of an object that appears in your images.

2. In the Labels field, type a category name for the objects that the worker should draw a bounding box around. For example, if you are asking the worker to draw boxes around football players, you could use "Football Player" in this field.

3. The Short instructions section enables you to create instructions that are displayed on the page with the image that your workers are labeling. We suggest that you include an example of a correctly drawn bounding box and an example of an incorrectly drawn box. To create your own instructions, use these steps:
   a. Select the text between GOOD EXAMPLE and the image placeholder. Replace it with the following text:

      Draw the box around the object with a small border.

   b. Select the first image placeholder and delete it.

   c. Choose the image button and then enter the HTTPS URL of one of the images that you created in step 1. It is also possible to embed images directly in the short instructions section, however this section has a quota of 100 kilobytes (including text). If your images and text exceed 100 kilobytes, you receive an error.

   d. Select the text between BAD EXAMPLE and the image placeholder. Replace it with the following text:

      Don’t make the bounding box too large or cut into the object.

   e. Select the second image placeholder and delete it.

   f. Choose the image button and then enter the HTTPS URL of the other image that you created in step 1.

4. Select Preview to preview the worker UI. The preview opens in a new tab, and so if your browser blocks pop ups you may need to manually enable the tab to open. When you add one or more annotations to the preview and then select Submit you can see a preview of the output data your annotation would created.

5. After you have configured and verified your instructions, select Create to create the labeling job.

If you used a private workforce, you can navigate to the worker portal that you logged into in Step 3: Select Workers (p. 373) of this tutorial to see your labeling tasks. The tasks may take a few minutes to appear.

Next

Step 5: Monitoring Your Labeling Job (p. 376)
Step 5: Monitoring Your Labeling Job

After you create your labeling job, you see a list of all the jobs that you have created. You can use this list to monitor that status of your labeling jobs. The list has the following fields:

- **Name** – The name that you assigned the job when you created it.
- **Status** – The completion status of the job. The status can be one of Complete, Failed, In progress, or Stopped.
- **Labeled objects/total** – Shows the total number of objects in the labeling job and how many of them have been labeled.
- **Creation time** – The date and time that you created the job.

You can also clone, chain, or stop a job. Select a job and then select one of the following from the Actions menu:

- **Clone** – Creates a new labeling job with the configuration copied from the selected job. You can clone a job when you want to change to the job and run it again. For example, you can clone a job that was sent to a private workforce so that you can send it to the Amazon Mechanical Turk workforce. Or you can clone a job to rerun it against a new dataset stored in the same location as the original job.
- **Chain** – Creates a new labeling job that can build upon the data and models (if any) of a stopped, failed, or completed job. For more information about the use cases and how to use it, see Chaining Labeling Jobs (p. 646).
- **Stop** – Stops a running job. You cannot restart a stopped job. You can clone a job to start over or chain the job to continue from where it left off. Labels for any already labeled objects are written to the output file location. For more information, see Output Data (p. 614).

Label Images

Use Ground Truth to label images. Select one of the following built in task types to learn more about that task type. Each page includes instructions to help you create a labeling job using that task type.

**Tip**
To learn more about supported file types and input data quotas, see Input Data (p. 572).

**Topics**
- Bounding Box (p. 376)
- Image Semantic Segmentation (p. 382)
- Auto-Segmentation Tool (p. 385)
- Image Classification (Single Label) (p. 389)
- Image Classification (Multi-label) (p. 391)
- Image Label Verification (p. 395)

Bounding Box

The images used to train a machine learning model often contain more than one object. To classify and localize one or more objects within images, use the Amazon SageMaker Ground Truth bounding box labeling job task type. In this context, localization means the pixel-location of the bounding box.

You create a bounding box labeling job using the Ground Truth section of the Amazon SageMaker console or the CreateLabelingJob operation.
Important
For this task type, if you create your own manifest file, use "source-ref" to identify the location of each image file in Amazon S3 that you want labeled. For more information, see Input Data (p. 57).

Creating a Bounding Box Labeling Job (Console)

You can follow the instructions Create a Labeling Job (Console) (p. 544) to learn how to create a bounding box labeling job in the SageMaker console. In Step 10, choose Image from the Task category drop down menu, and choose Bounding box as the task type.

Ground Truth provides a worker UI similar to the following for labeling tasks. When you create the labeling job with the console, you specify instructions to help workers complete the job and up to 50 labels that workers can choose from.
Good example

Fit each box tightly around the boundaries of the object.

Bad example

Boxes should not overlap with the boundaries of objects.
Create a Bounding Box Labeling Job (API)

To create a bounding box labeling job, use the SageMaker API operation `CreateLabelingJob`. This API defines this operation for all AWS SDKs. To see a list of language-specific SDKs supported for this operation, review the See Also section of `CreateLabelingJob`.

Follow the instructions on Create a Labeling Job (API) (p. 547) and do the following while you configure your request:

- Pre-annotation Lambda functions for this task type end with `PRE-BoundingBox`. To find the pre-annotation Lambda ARN for your Region, see `PreHumanTaskLambdaArn`.
- Annotation-consolidation Lambda functions for this task type end with `ACS-BoundingBox`. To find the annotation-consolidation Lambda ARN for your Region, see `AnnotationConsolidationLambdaArn`.

The following is an example of an AWS Python SDK (Boto3) request to create a labeling job in the US East (N. Virginia) Region. All parameters in red should be replaced with your specifications and resources.

```python
response = client.create_labeling_job(
    LabelingJobName='example-bounding-box-labeling-job,
    LabelAttributeName='label',
    InputConfig={
        'DataSource': {
            'S3DataSource': {
                'ManifestS3Uri': 's3://bucket/path/manifest-with-input-data.json'
            }
        },
        'DataAttributes': {
            'ContentClassifiers': [
                'FreeOfPersonallyIdentifiableInformation'|'FreeOfAdultContent'
            ]
        }
    },
    OutputConfig={
        'S3OutputPath': 's3://bucket/path/file-to-store-output-data',
        'KmsKeyId': 'string'
    },
    RoleArn='arn:aws:iam::*:role/*',
    LabelCategoryConfigS3Uri='s3://bucket/path/label-categories.json',
    StoppingConditions={
        'MaxHumanLabeledObjectCount': 123,
        'MaxPercentageOfInputDatasetLabeled': 123
    },
    HumanTaskConfig={
        'WorkteamArn': 'arn:aws:sagemaker:region:*:workteam/private-crowd/*',
        'UiConfig': {
            'UiTemplateS3Uri': 's3://bucket/path/worker-task-template.html'
        },
        'PreHumanTaskLambdaArn': 'arn:aws:lambda:us-east-1:432418664414:function:PRE-BoundingBox',
        'TaskKeywords': ['Bounding Box'],
        'TaskTitle': 'Bounding Box task',
        'TaskDescription': 'Draw bounding boxes around objects in an image',
        'NumberOfHumanWorkersPerDataObject': 123,
        'TaskTimeLimitInSeconds': 123,
        'TaskAvailabilityLifetimeInSeconds': 123,
        'MaxConcurrentTaskCount': 123,
        'AnnotationConsolidationConfig': {
            'AnnotationConsolidationLambdaArn': 'arn:aws:lambda:us-east-1:432418664414:function:ACS-BoundingBox'
        }
    }
)
```
Provide a Template for Bounding Box Labeling Jobs

If you create a labeling job using the API, you must supply a worker task template in `UiTemplateS3Uri`. Copy and modify the following template. Only modify the `short-instructions`, `full-instructions`, and `header`. Upload this template to S3, and provide the S3 URI for this file in `UiTemplateS3Uri`.

```html
<crowd-form>
  <crowd-bounding-box
    name="boundingBox"
    src="{{ task.input.taskObject | grant_read_access }}"
    header="please draw box"
    labels="{{ task.input.labels | to_json | escape }}"
  >

  <full-instructions header="Bounding box instructions">
    <ol>
      <li><strong>Inspect</strong> the image</li>
      <li><strong>Determine</strong> if the specified label is/are visible in the picture.</li>
      <li><strong>Outline</strong> each instance of the specified label in the image using the provided "Box" tool.</li>
      <li>Boxes should fit tight around each object</li>
      <li>Do not include parts of the object are overlapping or that cannot be seen, even though you think you can interpolate the whole shape.</li>
      <li>Avoid including shadows.</li>
      <li>If the target is off screen, draw the box up to the edge of the image.</li>
    </ol>

  </full-instructions>

  <short-instructions>
    <h3><span style="color: rgb(0, 138, 0);">Good example</span></h3>
    <p>Enter description of a correct bounding box label and add images</p>

    <h3><span style="color: rgb(230, 0, 0);">Bad example</span></h3>
    <p>Enter description of an incorrect bounding box label and add images</p>
  </short-instructions>

</crowd-bounding-box>
</crowd-form>
```

Bounding Box Output Data

Once you have created a bounding box labeling job, your output data will be located in the Amazon S3 bucket specified in the `S3OutputPath` parameter when using the API or in the `Output dataset location` field of the `Job overview` section of the console.

For example, the output manifest file of a successfully completed single-class bounding box task will contain the following:

```json
[{
    "boundingBox": {
        "boundingBoxes": [
            {
                "height": 2832,
                "label": "bird",
            }
        ]
    }
}]
```
The `boundingBoxes` parameter identifies the location of the bounding box drawn around an object identified as a "bird" relative to the top-left corner of the image which is taken to be the (0,0) pixel-coordinate. In the previous example, `left` and `top` identify the location of the pixel in the top-left corner of the bounding box relative to the top-left corner of the image. The dimensions of the bounding box are identified with `height` and `width`. The `inputImageProperties` parameter gives the pixel-dimensions of the original input image.

When you use the bounding box task type, you can create single- and multi-class bounding box labeling jobs. The output manifest file of a successfully completed multi-class bounding box will contain the following:

```json
[
  {
    "boundingBox": {
      "boundingBoxes": [
        {
          "height": 938,
          "label": "squirrel",
          "left": 316,
          "top": 218,
          "width": 785
        },
        {
          "height": 825,
          "label": "rabbit",
          "left": 1930,
          "top": 2265,
          "width": 540
        },
        {

]
To learn more about the output manifest file that results from a bounding box labeling job, see Bounding Box Job Output (p. 620).

To learn more about the output manifest file generated by Ground Truth and the file structure the Ground Truth uses to store your output data, see Output Data (p. 614).

Image Semantic Segmentation

To identify the contents of an image at the pixel level, use an Amazon SageMaker Ground Truth semantic segmentation labeling task. When assigned a semantic segmentation labeling job, workers classify pixels in the image into a set of predefined labels or classes. Ground Truth supports single and multi-class semantic segmentation labeling jobs.

Images that contain large numbers of objects that need to be segmented require more time. To help workers (from a private or vendor workforce) label these objects in less time and with greater accuracy, Ground Truth provides an AI-assisted auto-segmentation tool. For information, see Auto-Segmentation Tool (p. 385).

You create a semantic segmentation labeling job using the Ground Truth section of the Amazon SageMaker console or the CreateLabelingJob operation.

Important
For this task type, if you create your own manifest file, use "source-ref" to identify the location of each image file in Amazon S3 that you want labeled. For more information, see Input Data (p. 572).

Creating a Semantic Segmentation Labeling Job (Console)

You can follow the instructions Create a Labeling Job (Console) (p. 544) to learn how to create a semantic segmentation labeling job in the SageMaker console. In Step 10, choose Image from the Task category drop down menu, and choose Semantic segmentation as the task type.

Ground Truth provides a worker UI similar to the following for labeling tasks. When you create the labeling job with the console, you specify instructions to help workers complete the job and labels that workers can choose from.
Instructions

View full instructions
View tool guide
How to use the Auto-segment tool

Good example

All pixels in the image that are part of an animal have been colors with the appropriate label color.

Bad example

Some animals in the image have not been colored in completely.

The color for a given animal extends beyond the boundaries of the animal.
Create a Semantic Segmentation Labeling Job (API)

To create a semantic segmentation labeling job, use the SageMaker API operation CreateLabelingJob. This API defines this operation for all AWS SDKs. To see a list of language-specific SDKs supported for this operation, review the See Also section of CreateLabelingJob.

Follow the instructions on Create a Labeling Job (API) (p. 547) and do the following while you configure your request:

- Pre-annotation Lambda functions for this task type end with PRE-SemanticSegmentation. To find the pre-annotation Lambda ARN for your Region, see PreHumanTaskLambdaArn.
- Annotation-consolidation Lambda functions for this task type end with ACS-SemanticSegmentation. To find the annotation-consolidation Lambda ARN for your Region, see AnnotationConsolidationLambdaArn.

The following is an example of an AWS Python SDK (Boto3) request to create a labeling job in the US East (N. Virginia) Region. All parameters in red should be replaced with your specifications and resources.

```python
response = client.create_labeling_job(
    LabelingJobName='example-semantic-segmentation-labeling-job',
    LabelAttributeName='label',
    InputConfig={
        'DataSource': {
            'S3DataSource': {
                'ManifestS3Uri': 's3://bucket/path/manifest-with-input-data.json'
            }
        },
        'DataAttributes': {
            'ContentClassifiers': [
                'FreeOfPersonallyIdentifiableInformation', 'FreeOfAdultContent'
            ]
        }
    },
    OutputConfig={
        'S3OutputPath': 's3://bucket/path/file-to-store-output-data',
        'KmsKeyId': 'string'
    },
    RoleArn='arn:aws:iam::*:role/*',
    LabelCategoryConfigS3Uri='s3://bucket/path/label-categories.json',
    StoppingConditions={
        'MaxHumanLabeledObjectCount': 123,
        'MaxPercentageOfInputDatasetLabeled': 123
    },
    HumanTaskConfig={
        'WorkteamArn': 'arn:aws:sagemaker:region:*:workteam/private-crowd/*',
        'UiConfig': {
            'UiTemplateS3Uri': 's3://bucket/path/worker-task-template.html'
        },
        'TaskKeywords': ['Semantic Segmentation'],
        'TaskTitle': 'Semantic segmentation task',
        'TaskDescription': 'For each category provided, segment out each relevant object using the color associated with that category',
        'NumberOfHumanWorkersPerDataObject': 123,
        'TaskTimeLimitInSeconds': 123,
        'TaskAvailabilityLifetimeInSeconds': 123,
        'MaxConcurrentTaskCount': 123,
        'AnnotationConsolidationConfig': {
```
Provide a Template for Semantic Segmentation Labeling Jobs

If you create a labeling job using the API, you must supply a worker task template in UiTemplateS3Uri. Copy and modify the following template. Only modify the short-instructions, full-instructions, and header.

Upload this template to S3, and provide the S3 URI for this file in UiTemplateS3Uri.

Semantic Segmentation Output Data

Once you have created a semantic segmentation labeling job, your output data will be located in the Amazon S3 bucket specified in the S3OutputPath parameter when using the API or in the Output dataset location field of the Job overview section of the console.

To learn more about the output manifest file generated by Ground Truth and the file structure the Ground Truth uses to store your output data, see Output Data (p. 614).

To see an example of an output manifest file for a semantic segmentation labeling job, see 3D Point Cloud Semantic Segmentation Output (p. 630).

Auto-Segmentation Tool

Image segmentation is the process of dividing an image into multiple segments, or sets of labeled pixels. In Amazon SageMaker Ground Truth, the process of identifying all pixels that fall under a given
label involves applying a colored filler, or "mask", over those pixels. Some labeling job tasks contain images with large numbers of objects that need to be segmented. To help workers label these objects in less time and with greater accuracy, Ground Truth provides an auto-segmentation tool for segmentation tasks assigned to private and vendor workforces. This tool uses a machine learning model to automatically segment individual objects in the image with minimal worker input. Workers can refine the mask generated by the auto-segmentation tool using other tools found in the worker console. This helps workers complete image segmentation tasks faster and more accurately, resulting in lower cost and higher label quality.

**Note**
The auto-segmentation tool is available for segmentation tasks that are sent to a private workforce or vendor workforce. It isn't available for tasks sent to the public workforce (Amazon Mechanical Turk).

**Tool Preview**

When workers are assigned a labeling job that provides the auto-segmentation tool, they are provided with detailed instructions on how to use the tool. For example, a worker might see the following in the worker console:
Use paint brush to paint a mask on each bird in the image.
Amazon SageMaker Developer Guide
Label Images

Workers can use View full instructions to learn how to use the tool. Workers will need to place a point
on four extreme-points ( top-most, bottom-most, left-most, and right-most points ) of the object of
interest, and the tool will automatically generate a mask for the object. Workers can further-reﬁne the
mask using the other tools provided, or by using the auto-segment tool on smaller portions of the object
that were missed.

Tool Availability
The auto-segmentation tool automatically appears in your workers' consoles if you create a semantic
segmentation labeling job using the Amazon SageMaker console. While creating a semantic
segmentation job in the SageMaker console, you will be able to preview the tool while creating worker
instructions. To learn how to create a semantic segmentation labeling job in the SageMaker console, see
Getting started (p. 371).
If you are creating a custom instance segmentation labeling job in the SageMaker console or creating
an instance- or semantic-segmentation labeling job using the Ground Truth API, you need to create a
custom task template to design your worker console and instructions. To include the auto-segmentation
tool in your worker console, ensure that the following conditions are met in your custom task template:
• For semantic segmentation labeling jobs created using the API, the <crowd-semanticsegmentation> is present in the task template. For custom instance segmentation labeling jobs, the
<crowd-instance-segmentation> tag is present in the task template.
• The task is assigned to a private workforce or vendor workforce.
• The images to be labeled are Amazon Simple Storage Service Amazon S3) objects that have been
pre-signed for the Worker so that they can access it. This is true if the task template includes the
grant_read_access ﬁlter. For information about the grant_read_access ﬁlter, see Adding
automation with Liquid (p. 513).
The following is an example of a custom task template for a custom instance segmentation labeling job,
which includes the <crowd-instance-segmentation/> tag and the grant_read_access Liquid
ﬁlter.
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
<crowd-instance-segmentation
name="crowd-instance-segmentation"
src="{{ task.input.taskObject | grant_read_access }}"
labels="['Car','Road']"
<full-instructions header="Segmentation instructions">
Segment each instance of each class of objects in the image.
</full-instructions>
<short-instructions>
<p>Segment each instance of each class of objects in the image.</p>
<h3 style="color: green">GOOD EXAMPLES</h3>
<img src="path/to/image.jpg" style="width: 100%">
<p>Good because A, B, C.</p>
<h3 style="color: red">BAD EXAMPLES</h3>
<img src="path/to/image.jpg" style="width: 100%">
<p>Bad because X, Y, Z.</p>
</short-instructions>
</crowd-instance-segmentation>
</crowd-form>

Image Classification (Single Label)

Use an Amazon SageMaker Ground Truth image classification labeling task when you need workers to classify images using predefined labels that you specify. Workers are shown images and are asked to choose one label for each image.

You can create an image classification labeling job using the Ground Truth section of the Amazon SageMaker console or the `CreateLabelingJob` operation.

**Important**
For this task type, if you create your own manifest file, use "source-ref" to identify the location of each image file in Amazon S3 that you want labeled. For more information, see Input Data (p. 572).

Create an Image Classification Labeling Job (Console)

You can follow the instructions Create a Labeling Job (Console) (p. 544) to learn how to create a image classification labeling job in the SageMaker console. In Step 10, choose Image from the Task category drop down menu, and choose Image Classification (Single Label) as the task type.

Ground Truth provides a worker UI similar to the following for labeling tasks. When you create the labeling job with the console, you specify instructions to help workers complete the job and labels that workers can choose from.

Create an Image Classification Labeling Job (API)

To create an image classification labeling job, use the SageMaker API operation `CreateLabelingJob`. This API defines this operation for all AWS SDKs. To see a list of language-specific SDKs supported for this operation, review the See Also section of `CreateLabelingJob`. 
Follow the instructions on Create a Labeling Job (API) (p. 547) and do the following while you configure your request:

- Pre-annotation Lambda functions for this task type end with PRE-ImageMultiClass. To find the pre-annotation Lambda ARN for your Region, see PreHumanTaskLambdaArn.
- Annotation-consolidation Lambda functions for this task type end with ACS-ImageMultiClass. To find the annotation-consolidation Lambda ARN for your Region, see AnnotationConsolidationLambdaArn.

The following is an example of an AWS Python SDK (Boto3) request to create a labeling job in the US East (N. Virginia) Region. All parameters in red should be replaced with your specifications and resources.

```python
response = client.create_labeling_job(
    LabelingJobName='example-image-classification-labeling-job',
    LabelAttributeName='label',
    InputConfig={
        'DataSource': { 'S3DataSource': { 'ManifestS3Uri': 's3://bucket/path/manifest-with-input-data.json' } },
        'DataAttributes': { 'ContentClassifiers': ['FreeOfPersonallyIdentifiableInformation','FreeOfAdultContent'],
    } },
    OutputConfig={
        'S3OutputPath': 's3://bucket/path/file-to-store-output-data',
        'KmsKeyId': 'string'
    },
    RoleArn='arn:aws:iam::*:role/*',
    LabelCategoryConfigS3Uri='s3://bucket/path/label-categories.json',
    StoppingConditions={
        'MaxHumanLabeledObjectCount': 123,
        'MaxPercentageOfInputDatasetLabeled': 123,
    },
    HumanTaskConfig={
        'WorkteamArn': 'arn:aws:sagemaker:region::workteam/private-crowd/*',
        'UiConfig': { 'UiTemplateS3Uri': 's3://bucket/path/worker-task-template.html' },
        'TaskKeywords': ['Image classification'],
        'TaskTitle': 'Image classification task',
        'TaskDescription': 'Carefully inspect the image and classify it by selecting one label from the categories provided.',
        'NumberOfHumanWorkersPerDataObject': 123,
        'TaskTimeLimitInSeconds': 123,
        'TaskAvailabilityLifetimeInSeconds': 123,
        'MaxConcurrentTaskCount': 123,
        'AnnotationConsolidationConfig': { 'AnnotationConsolidationLambdaArn': 'arn:aws:lambda:us-east-1:432418664414:function:ACS-ImageMultiClass' },
    },
    Tags=[
        { 'Key': 'string', 'Value': 'string' }
    ],
)```
Provide a Template for Image Classification Labeling Jobs

If you create a labeling job using the API, you must supply a worker task template in UiTemplateS3Uri. Copy and modify the following template. Only modify the short-instructions, full-instructions, and header.

Upload this template to S3, and provide the S3 URI for this file in UiTemplateS3Uri.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
  <crowd-image-classifier
    name="crowd-image-classifier"
    src="{{ task.input.taskObject | grant_read_access }}"
    header="please classify"
    categories="{{ task.input.labels | to_json | escape }}"
  >
    <full-instructions header="Image classification instructions">
      <ol>
        <li><strong>Read</strong> the task carefully and inspect the image.</li>
        <li><strong>Read</strong> the options and review the examples provided to understand more about the labels.</li>
        <li><strong>Choose</strong> the appropriate label that best suits the image.</li>
      </ol>
    </full-instructions>
    <short-instructions>
      <h3><span style="color: rgb(0, 138, 0);">Good example</span></h3>
      <p>Enter description to explain the correct label to the workers</p>
      <h3><span style="color: rgb(230, 0, 0);">Bad example</span></h3>
      <p>Enter description of an incorrect label</p>
    </short-instructions>
  </crowd-image-classifier>
</crowd-form>

Image Classification Output Data

Once you have created an image classification labeling job, your output data will be located in the Amazon S3 bucket specified in the S3OutputPath parameter when using the API or in the Output dataset location field of the Job overview section of the console.

To learn more about the output manifest file generated by Ground Truth and the file structure the Ground Truth uses to store your output data, see Output Data (p. 614).

To see an example of an output manifest file from an image classification labeling job, see Classification Job Output (p. 618).

Image Classification (Multi-label)

Use an Amazon SageMaker Ground Truth multi-label image classification labeling task when you need workers to classify multiple objects in an image. For example, the following image features a dog and a cat. You can use multi-label image classification to associate the labels "dog" and "cat" with this image.
When working on a multi-label image classification task, workers should choose all applicable labels, but must choose at least one. When creating a job using this task type, you can provide up to 50 label-categories.

When creating a labeling job in the console, Ground Truth doesn't provide a "none" category for when none of the labels applies to an image. To provide this option to workers, include a label similar to "none" or "other" when you create a multi-label image classification job.

To restrict workers to choosing a single label for each image, use the Image Classification (Single Label) (p. 389) task type.

Important
For this task type, if you create your own manifest file, use "source-ref" to identify the location of each image file in Amazon S3 that you want labeled. For more information, see Input Data (p. 572).

Create a Multi-Label Image Classification Labeling Job (Console)

You can follow the instructions Create a Labeling Job (Console) (p. 544) to learn how to create a multi-label image classification labeling job in the SageMaker console. In Step 10, choose Image from the Task category drop down menu, and choose Image Classification (Multi-label) as the task type.

Ground Truth provides a worker UI similar to the following for labeling tasks. When you create a labeling job in the console, you specify instructions to help workers complete the job and labels that workers can choose from.
Create a Multi-Label Image Classification Labeling Job (API)

To create a multi-label image classification labeling job, use the SageMaker API operation CreateLabelingJob. This API defines this operation for all AWS SDKs. To see a list of language-specific SDKs supported for this operation, review the See Also section of CreateLabelingJob.

Follow the instructions on Create a Labeling Job (API) (p. 547) and do the following while you configure your request:

- Pre-annotation Lambda functions for this task type end with PRE-ImageMultiClassMultiLabel. To find the pre-annotation Lambda ARN for your Region, see PreHumanTaskLambdaArn.
- Annotation-consolidation Lambda functions for this task type end with ACS-ImageMultiClassMultiLabel. To find the annotation-consolidation Lambda ARN for your Region, see AnnotationConsolidationLambdaArn.

The following is an example of an AWS Python SDK (Boto3) request to create a labeling job in the US East (N. Virginia) Region. All parameters in red should be replaced with your specifications and resources.

```python
response = client.create_labeling_job(
    LabelingJobName='example-multi-label-image-classification-labeling-job',
    LabelAttributeName='label',
    InputConfig={
        'DataSource': {
            'S3DataSource': {
                'ManifestS3Uri': 's3://bucket/path/manifest-with-input-data.json'
            }
        },
        'DataAttributes': {
            'ContentClassifiers': [
                'FreeOfPersonallyIdentifiableInformation',
                'FreeOfAdultContent',
            ]
        }
    }
)
```
OutputConfig={
    'S3OutputPath': 's3://bucket/path/file-to-store-output-data',
    'KmsKeyId': 'string'
},
RoleArn='arn:aws:iam::*:role/*,
LabelCategoryConfigS3Uri='s3://bucket/path/label-categories.json',
StoppingConditions={
    'MaxHumanLabeledObjectCount': 123,
    'MaxPercentageOfInputDatasetLabeled': 123
},
HumanTaskConfig={
    'WorkteamArn': 'arn:aws:sagemaker:region:::workteam/private-crowd/*',
    'UiConfig': {
        'UiTemplateS3Uri': 's3://bucket/path/worker-task-template.html'
    },
    'TaskKeywords': ['Image Classification'],
    'TaskTitle': 'Multi-label image classification task',
    'TaskDescription': 'Select all labels that apply to the images shown',
    'NumberOfHumanWorkersPerDataObject': 123,
    'TaskTimeLimitInSeconds': 123,
    'TaskAvailabilityLifetimeInSeconds': 123,
    'MaxConcurrentTaskCount': 123,
    'AnnotationConsolidationConfig': {
        'AnnotationConsolidationLambdaArn': 'arn:aws:lambda:us-east-1:432418664414:function:ACS-ImageMultiClassMultiLabel'
    },
    'Tags':[
        {'Key': 'string', 'Value': 'string'}
    ]
}

Provide a Template for Multi-label Image Classification

If you create a labeling job using the API, you must supply a worker task template in UiTemplateS3Uri. Copy and modify the following template. Only modify the short-instructions, full-instructions, and header.

Upload this template to S3, and provide the S3 URI for this file in UiTemplateS3Uri.

<crowd-form>
<crowd-image-classifier-multi-select
    name="crowd-image-classifier-multi-select"
    src="{{ task.input.taskObject | grant_read_access }}"
    header="Please identify all classes in image"
    categories="{{ task.input.labels | to_json | escape }}"
>
<full-instructions header="Multi Label Image classification instructions">
  <ol><li><strong>Read</strong> the task carefully and inspect the image.</li>
  <li><strong>Read</strong> the options and review the examples provided to understand more about the labels.</li>
  <li><strong>Choose</strong> the appropriate labels that best suit the image.</li></ol>
</full-instructions>
<short-instructions>
  <h3><span style="color: rgb(0, 138, 0);">Good example</span></h3>
  <p>Enter description to explain the correct label to the workers</p>
</short-instructions>
</crowd-image-classifier-multi-select>
</crowd-form>
Multi-label Image Classification Output Data

Once you have created a multi-label image classification labeling job, your output data will be located in the Amazon S3 bucket specified in the S3OutputPath parameter when using the API or in the Output dataset location field of the Job overview section of the console.

To learn more about the output manifest file generated by Ground Truth and the file structure the Ground Truth uses to store your output data, see Output Data (p. 614).

To see an example of output manifest files for multi-label image classification labeling job, see Multi-label Classification Job Output (p. 619).

Image Label Verification

Building a highly accurate training dataset for your machine learning (ML) algorithm is an iterative process. Typically, you review and continuously adjust your labels until you are satisfied that they accurately represent the ground truth, or what is directly observable in the real world.

You can use an Amazon SageMaker Ground Truth image label verification task to direct workers to review a dataset's labels and improve label accuracy. Workers can indicate if the existing labels are correct or rate label quality. They can also add comments to explain their reasoning. Amazon SageMaker Ground Truth supports label verification for Bounding Box (p. 376) and Image Semantic Segmentation (p. 382) labels.

You create an image label verification labeling job using the Ground Truth section of the Amazon SageMaker console or the CreateLabelingJob operation.

Ground Truth provides a worker console similar to the following for labeling tasks. When you create the labeling job with the console, you can modify the images and content that are shown. To learn how to create a labeling job using the Ground Truth console, see Create a Labeling Job (Console) (p. 544).
Use Ground Truth to Label Text

Use Ground Truth to text. Select one of the following built in task types to learn more about that task type. Each page includes instructions to help you create a labeling job using that task type.

Tip
To learn more about supported file types and input data quotas, see Input Data (p. 572).

Topics
- Named Entity Recognition (p. 396)
- Text Classification (Single Label) (p. 400)
- Text Classification (Multi-label) (p. 403)

Named Entity Recognition

To extract information from unstructured text and classify it into predefined categories, use an Amazon SageMaker Ground Truth named entity recognition (NER) labeling task. Traditionally, NER involves sifting through text data to locate noun phrases, called named entities, and categorizing each with a label, such as "person," "organization," or "brand." You can broaden this task to label longer spans of text and categorize those sequences with predefined labels that you specify.

When tasked with a named entity recognition labeling job, workers apply your labels to specific words or phrases within a larger text block. They choose a label, then apply it by using the cursor to highlight the part of the text to which the label applies. The Ground Truth named entity recognition tool supports
overlapping annotations, in-context label selection, and multi-label selection for a single highlight. Also, workers can use their keyboards to quickly select labels.

You can create a named entity recognition labeling job using the Ground Truth section of the Amazon SageMaker console or the CreateLabelingJob operation.

**Important**
If you manually create an input manifest file, use "source" to identify the text that you want labeled. For more information, see Input Data (p. 572).

**Create a Named Entity Recognition Labeling Job (Console)**

You can follow the instructions Create a Labeling Job (Console) (p. 544) to learn how to create a named entity recognition labeling job in the SageMaker console. In Step 10, choose Text from the Task category drop down menu, and choose Named entity recognition as the task type.

Ground Truth provides a worker UI similar to the following for labeling tasks. When you create the labeling job with the console, you specify instructions to help workers complete the job and labels that workers can choose from.

**Create a Named Entity Recognition Labeling Job (API)**

To create a named entity recognition labeling job, using the SageMaker API operation CreateLabelingJob. This API defines this operation for all AWS SDKs. To see a list of language-specific SDKs supported for this operation, review the See Also section of CreateLabelingJob.

Follow the instructions on Create a Labeling Job (API) (p. 547) and do the following while you configure your request:

- Pre-annotation Lambda functions for this task type end with PRE-NamedEntityRecognition. To find the pre-annotation Lambda ARN for your Region, see PreHumanTaskLambdaArn.
• Annotation-consolidation Lambda functions for this task type end with ACS-NamedEntityRecognition. To find the annotation-consolidation Lambda ARN for your Region, see AnnotationConsolidationLambdaArn.

• You must provide the following ARN for HumanTaskUiArn:

```
```

Replace `aws-region` with the AWS Region you use to create the labeling job. For example, use us-west-1 if you create a labeling job in US West (N. California).

• Provide worker instructions in the label category configuration file using the instructions parameter. You can use a string, or HTML markup language in the shortInstruction and fullInstruction fields. For more details, see Provide Worker Instructions in a Label Category Configuration File (p. 399).

```
"instructions": {"shortInstruction":"<h1>Add header</h1><p>Add Instructions</p>"},
"fullInstruction": "<p>Add additional instructions.</p>"}
```

The following is an example of an AWS Python SDK (Boto3) request to create a labeling job in the US East (N. Virginia) Region. All parameters in red should be replaced with your specifications and resources.

```python
response = client.create_labeling_job(
    LabelingJobName='example-ner-labeling-job',
    LabelAttributeName='label',
    InputConfig={
        'DataSource': {
            'S3DataSource': {
                'ManifestS3Uri': 's3://bucket/path/manifest-with-input-data.json'
            }
        },
        'DataAttributes': {
            'ContentClassifiers': [
                'FreeOfPersonallyIdentifiableInformation','FreeOfAdultContent'
            ],
        }
    },
    OutputConfig={
        'S3OutputPath': 's3://bucket/path/file-to-store-output-data',
        'KmsKeyId': 'string'
    },
    RoleArn='arn:aws:iamp:*:role/**',
    LabelCategoryConfigS3Uri='s3://bucket/path/label-categories.json',
    StoppingConditions={
        'MaxHumanLabeledObjectCount': 123,
        'MaxPercentageOfInputDatasetLabeled': 123
    },
    HumanTaskConfig={
        'WorkteamArn': 'arn:aws:sagemaker:region:*:workteam/private-crowd/**',
        'UiConfig': {
            'TaskKeywords': ['Named entity Recognition'],
            'TaskTitle': 'Named entity Recognition task',
            'TaskDescription': 'Apply the labels provided to specific words or phrases within the larger text block.'
        }
    }
)```
Provide Worker Instructions in a Label Category Configuration File

You must provide worker instructions in the label category configuration file you identify with the LabelCategoryConfigS3Uri parameter in CreateLabelingJob. You can use these instructions to provide details about the task you want workers to perform and help them use the tool efficiently.

You provide short and long instructions using shortInstruction and fullInstruction in the instructions parameter, respectively. To learn more about these instruction types, see Creating Instruction Pages (p. 542).

The following is an example of a label category configuration file with instructions that can be used for a named entity recognition labeling job.

```json
{
  "document-version": "2018-11-28",
  "labels": [
    {
      "label": "label1",
      "shortDisplayName": "L1"
    },
    {
      "label": "label2",
      "shortDisplayName": "L2"
    },
    {
      "label": "label3",
      "shortDisplayName": "L3"
    },
    {
      "label": "label4",
      "shortDisplayName": "L4"
    },
    {
      "label": "label5",
      "shortDisplayName": "L5"
    }
  ],
  "instructions": {
    "shortInstruction": "Enter description of the labels that workers have to choose from<br> Add examples to help workers understand the label",
    "fullInstruction": "Read the text carefully.<br> Highlight words, phrases, or sections of the text. Choose the label that best matches what you have highlighted."}
}``
Named Entity Recognition Output Data

Once you have created a named entity recognition labeling job, your output data will be located in the Amazon S3 bucket specified in the S3OutputPath parameter when using the API or in the Output dataset location field of the Job overview section of the console.

To learn more about the output manifest file generated by Ground Truth and the file structure the Ground Truth uses to store your output data, see Output Data (p. 614).

Text Classification (Single Label)

To categorize articles and text into predefined categories, use text classification. For example, you can use text classification to identify the sentiment conveyed in a review or the emotion underlying a section of text. Use Amazon SageMaker Ground Truth text classification to have workers sort text into categories that you define.

You create a text classification labeling job using the Ground Truth section of the Amazon SageMaker console or the CreateLabelingJob operation.

Important

If you manually create an input manifest file, use "source" to identify the text that you want labeled. For more information, see Input Data (p. 572).

Create a Text Classification Labeling Job (Console)

You can follow the instructions Create a Labeling Job (Console) (p. 544) to learn how to create a text classification labeling job in the SageMaker console. In Step 10, choose Text from the Task category drop down menu, and choose Text Classification (Single Label) as the task type.

Ground Truth provides a worker UI similar to the following for labeling tasks. When you create the labeling job with the console, you specify instructions to help workers complete the job and labels that workers can choose from.
Create a Text Classification Labeling Job (API)

To create a text classification labeling job, use the SageMaker API operation `CreateLabelingJob`. This API defines this operation for all AWS SDKs. To see a list of language-specific SDKs supported for this operation, review the See Also section of `CreateLabelingJob`.

Follow the instructions on Create a Labeling Job (API) (p. 547) and do the following while you configure your request:

- Pre-annotation Lambda functions for this task type end with `PRE-TextMultiClass`. To find the pre-annotation Lambda ARN for your Region, see `PreHumanTaskLambdaArn`.
- Annotation-consolidation Lambda functions for this task type end with `ACS-TextMultiClass`. To find the annotation-consolidation Lambda ARN for your Region, see `AnnotationConsolidationLambdaArn`.

The following is an example of an AWS Python SDK (Boto3) request to create a labeling job in the US East (N. Virginia) Region. All parameters in red should be replaced with your specifications and resources.

```python
response = client.create_labeling_job(
    LabelingJobName='example-text-classification-labeling-job',
    LabelAttributeName='label',
    InputConfig={
        'DataSource': {
            'S3DataSource': {
                'ManifestS3Uri': 's3://bucket/path/manifest-with-input-data.json'
            }
        },
        'DataAttributes': {
            'ContentClassifiers': [
                'FreeOfPersonallyIdentifiableInformation', 'FreeOfAdultContent',
            ]
        }
    },
    OutputConfig={
        'S3OutputPath': 's3://bucket/path/file-to-store-output-data',
        'KmsKeyId': 'string'
    })
```
Provide a Template for Text Classification Labeling Jobs

If you create a labeling job using the API, you must supply a worker task template in `UiTemplateS3Uri`. Copy and modify the following template. Only modify the `short-instructions`, `full-instructions`, and `header`.

Upload this template to S3, and provide the S3 URI for this file in `UiTemplateS3Uri`.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
  <crowd-classifier
    name="crowd-classifier"
    categories="{{ task.input.labels | to_json | escape }}"
    header="classify text"
  >
    <classification-target style="white-space: pre-wrap">
      {{ task.input.taskObject }}
    </classification-target>
    <full-instructions header="Classifier instructions">
      <ol>
        <li><strong>Read</strong> the text carefully.</li>
        <li><strong>Read</strong> the examples to understand more about the options.</li>
        <li><strong>Choose</strong> the appropriate labels that best suit the text.</li>
      </ol>
    </full-instructions>
    <short-instructions>
      <p>Enter description of the labels that workers have to choose from</p>
      <p><br></p>
      <p>Add examples to help workers understand the label</p>
    </short-instructions>
</crowd-form>
```
Text Classification Output Data

Once you have created a text classification labeling job, your output data will be located in the Amazon S3 bucket specified in the S3OutputPath parameter when using the API or in the Output dataset location field of the Job overview section of the console.

To learn more about the output manifest file generated by Ground Truth and the file structure the Ground Truth uses to store your output data, see Output Data (p. 614).

To see an example of an output manifest files from a text classification labeling job, see Classification Job Output (p. 618).

Text Classification (Multi-label)

To categorize articles and text into multiple predefined categories, use the multi-label text classification task type. For example, you can use this task type to identify more than one emotion conveyed in text.

When working on a multi-label text classification task, workers should choose all applicable labels, but must choose at least one. When creating a job using this task type, you can provide up to 50 label categories.

Amazon SageMaker Ground Truth doesn't provide a "none" category for when none of the labels applies. To provide this option to workers, include a label similar to "none" or "other" when you create a multi-label text classification job.

To restrict workers to choosing a single label for each document or text selection, use the Text Classification (Single Label) (p. 400) task type.

Important
If you manually create an input manifest file, use "source" to identify the text that you want labeled. For more information, see Input Data (p. 572).

Create a Multi-Label Text Classification Labeling Job (Console)

You can follow the instructions Create a Labeling Job (Console) (p. 544) to learn how to create a multi-label text classification labeling job in the Amazon SageMaker console. In Step 10, choose Text from the Task category drop down menu, and choose Text Classification (Multi-label) as the task type.

Ground Truth provides a worker UI similar to the following for labeling tasks. When you create the labeling job with the console, you specify instructions to help workers complete the job and labels that workers can choose from.
Create a Multi-Label Text Classification Labeling Job (API)

To create a multi-label text classification labeling job, use the SageMaker API operation `CreateLabelingJob`. This API defines this operation for all AWS SDKs. To see a list of language-specific SDKs supported for this operation, review the See Also section of `CreateLabelingJob`.

Follow the instructions on Create a Labeling Job (API) (p. 547) and do the following while you configure your request:

- Pre-annotation Lambda functions for this task type end with `PRE-TextMultiClassMultiLabel`. To find the pre-annotation Lambda ARN for your Region, see `PreHumanTaskLambdaArn`.
- Annotation-consolidation Lambda functions for this task type end with `ACS-TextMultiClassMultiLabel`. To find the annotation-consolidation Lambda ARN for your Region, see `AnnotationConsolidationLambdaArn`.

The following is an example of an AWS Python SDK (Boto3) request to create a labeling job in the US East (N. Virginia) Region. All parameters in red should be replaced with your specifications and resources.

```python
response = client.create_labeling_job(
    LabelingJobName='example-multi-label-text-classification-labeling-job',
    LabelAttributeName='label',
    InputConfig={
        'DataSource': {
            'S3DataSource': {
                'ManifestS3Uri': 's3://bucket/path/manifest-with-input-data.json'
            }
        },
        'DataAttributes': {
            'ContentClassifiers': [
                'FreeOfPersonallyIdentifiableInformation', 'FreeOfAdultContent',
            ]
        }
    },
    OutputConfig={
        'S3OutputPath': 's3://bucket/path/file-to-store-output-data',
        'KmsKeyId': 'string'
    },
)
```
Create a Template for Multi-label Text Classification

If you create a labeling job using the API, you must supply a worker task template in `UiTemplateS3Uri`. Copy and modify the following template. Only modify the `short-instructions`, `full-instructions`, and `header`.

Upload this template to S3, and provide the S3 URI for this file in `UiTemplateS3Uri`.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
<crowd-classifier-multi-select
    name="crowd-classifier-multi-select"
    categories="{{ task.input.labels | to_json | escape }}"
    header="Please identify all classes in the below text"
>
    <classification-target style="white-space: pre-wrap">
        {{ task.input.taskObject }}
    </classification-target>

    <full-instructions header="Classifier instructions">
        <ol>
            <li><strong>Read</strong> the text carefully.</li>
            <li><strong>Read</strong> the examples to understand more about the options.</li>
            <li><strong>Choose</strong> the appropriate labels that best suit the text.</li>
        </ol>
    </full-instructions>

    <short-instructions>
        <p>Enter description of the labels that workers have to choose from</p>
        <p><br></p>
        <p>Add examples to help workers understand the label</p>
    </short-instructions>
</crowd-classifier-multi-select>
</crowd-form>
```
To learn how to create a custom template, see Creating Custom Labeling Workflows (p. 509).

### Multi-label Text Classification Output Data

Once you have created a multi-label text classification labeling job, your output data will be located in the Amazon S3 bucket specified in the S3OutputPath parameter when using the API or in the Output dataset location field of the Job overview section of the console.

To learn more about the output manifest file generated by Ground Truth and the file structure the Ground Truth uses to store your output data, see Output Data (p. 614).

To see an example of output manifest files for multi-label text classification labeling job, see Multi-label Classification Job Output (p. 619).

### Label Videos and Video Frames

You can use Ground Truth to classify videos and annotate video frames (still images extracted from videos) using one of the three built-in video task types. These task types streamline the process of creating video and video frame labeling jobs using the Amazon SageMaker console, API, and language-specific SDKs.

- **Video clip classification** – Enable workers to classify videos into categories you specify. For example, you can use this task type to have workers categorize videos into topics like sports, comedy, music, and education. To learn more, see Video Classification (p. 406).
- **Video frame labeling jobs** – Enable workers to annotate video frames extracted from a video using bounding boxes, polylines, polygons or keypoint annotation tools. Ground Truth offers two built-in task types to label video frames:
  - **Video frame object detection**: Enable workers to identify and locate objects in video frames.
  - **Video frame object tracking**: Enable workers to track the movement of objects across video frames.
  - **Video frame adjustment jobs**: Have workers adjust labels, label category attributes, and frame attributes from a previous video frame object detection or object tracking labeling job.
  - **Video frame verification jobs**: Have workers verify labels, label category attributes, and frame attributes from a previous video frame object detection or object tracking labeling job.

If you have video files, you can use the Ground Truth automatic frame extraction tool to extract video frames from your videos. To learn more, see Video Frame Input Data (p. 608).

**Tip**

To learn more about supported file types and input data quotas, see Input Data (p. 572).

### Video Classification

Use an Amazon SageMaker Ground Truth video classification labeling task when you need workers to classify videos using predefined labels that you specify. Workers are shown videos and are asked to choose one label for each video.

You create a video classification labeling job using the Ground Truth section of the Amazon SageMaker console or the CreateLabelingJob operation.
Your video files must be encoded in a format that is supported by the browser used by the work team that labels your data. It is recommended that you verify that all video file formats in your input manifest file display correctly using the worker UI preview. You can communicate supported browsers to your workers using worker instructions. To see supported file formats, see Supported Data Formats (p. 575).

**Important**
For this task type, if you create your own manifest file, use "source-ref" to identify the location of each video file in Amazon S3 that you want labeled. For more information, see Input Data (p. 572).

**Create a Video Classification Labeling Job (Console)**

You can follow the instructions in Create a Labeling Job (Console) (p. 544) to learn how to create a video classification labeling job in the SageMaker console. In step 10, choose Video from the Task category dropdown list, and choose Video Classification as the task type.

Ground Truth provides a worker UI similar to the following for labeling tasks. When you create a labeling job in the console, you specify instructions to help workers complete the job and labels from which workers can choose.
Instructions

View full instructions

View tool guide

Select a single label that best describes this video clip. Select none of the above if none of the other labels apply.

Select Submit when you are done.
Create a Video Classification Labeling Job (API)

This section covers details you need to know when you create a labeling job using the SageMaker API operation CreateLabelingJob. This API defines this operation for all AWS SDKs. To see a list of language-specific SDKs supported for this operation, review the See Also section of CreateLabelingJob.

Follow the instructions on Create a Labeling Job (API) (p. 547) and do the following while you configure your request:

- Use a pre-annotation Lambda function that ends with PRE-VideoClassification. To find the pre-annotation Lambda ARN for your Region, see PreHumanTaskLambdaArn.
- Use an annotation-consolidation Lambda function that ends with ACS-VideoClassification. To find the annotation-consolidation Lambda ARN for your Region, see AnnotationConsolidationLambdaArn.

The following is an example of an AWS Python SDK (Boto3) request to create a labeling job in the US East (N. Virginia) Region.

```python
response = client.create_labeling_job(
    LabelingJobName='example-video-classification-labeling-job',
    LabelAttributeName='label',
    InputConfig={
        'DataSource': {
            'S3DataSource': {
                'ManifestS3Uri': 's3://bucket/path/manifest-with-input-data.json'
            }
        },
        'DataAttributes': {
            'ContentClassifiers': [
                'FreeOfPersonallyIdentifiableInformation', 'FreeOfAdultContent'
            ]
        }
    },
    OutputConfig={
        'S3OutputPath': 's3://bucket/path/file-to-store-output-data',
        'KmsKeyId': 'string'
    },
    RoleArn='arn:aws:iam::*:role/*',
    LabelCategoryConfigS3Uri='s3://bucket/path/label-categories.json',
    StoppingConditions={
        'MaxHumanLabeledObjectCount': 123,
        'MaxPercentageOfInputDatasetLabeled': 123
    },
    HumanTaskConfig={
        'WorkteamArn': 'arn:aws:sagemaker:region:*:workteam/private-crowd/*',
        'UiConfig': {
            'UiTemplateS3Uri': 's3://bucket/path/worker-task-template.html'
        },
        'PreHumanTaskLambdaArn': 'arn:aws:lambda:us-east-1:432418664414:function:PRE-VideoClassification',
        'TaskKeywords': [
            'Video Classification'
        ],
        'TaskTitle': 'Video classification task',
        'TaskDescription': 'Select a label to classify this video',
        'NumberOfHumanWorkersPerDataObject': 123,
        'TaskTimeLimitInSeconds': 123,
        'TaskAvailabilityLifetimeInSeconds': 123,
        'MaxConcurrentTaskCount': 123,
        'AnnotationConsolidationConfig': {
        }
    }
)
```

Provide a Template for Video Classiﬁcation
If you create a labeling job using the API, you must supply a worker task template in UiTemplateS3Uri.
Copy and modify the following template by modifying the short-instructions, fullinstructions, and header. Upload this template to Amazon S3, and provide the Amazon S3 URI to
this ﬁle in UiTemplateS3Uri.
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
<crowd-classifier
name="crowd-classifier"
categories="{{ task.input.labels | to_json | escape }}"
header="Please classify video"
>
<classification-target>
<video width="100%" controls/>
<source src="{{ task.input.taskObject | grant_read_access }}"
type="video/mp4"/>
<source src="{{ task.input.taskObject | grant_read_access }}"
type="video/webm"/>
<source src="{{ task.input.taskObject | grant_read_access }}"
type="video/ogg"/>
Your browser does not support the video tag.
</video>
</classification-target>
<full-instructions header="Video classification instructions">
<ol><li><strong>Read</strong> the task carefully and inspect the
video.</li>
<li><strong>Read</strong> the options and review the examples
provided to understand more about the labels.</li>
<li><strong>Choose</strong> the appropriate label that best suits
the video.</li></ol>
</full-instructions>

Video Classification Output Data

Once you have created a video classification labeling job, your output data is located in the Amazon S3 bucket specified in the $S3OutputPath parameter when using the API or in the Output dataset location field of the Job overview section of the console.

To learn more about the output manifest file generated by Ground Truth and the file structure the Ground Truth uses to store your output data, see Output Data (p. 614).

To see an example of output manifest files for video classification labeling jobs, see Classification Job Output (p. 618).

Label Video Frames

You can use Ground Truth built-in video frame task types to have workers annotate video frames using bounding boxes, polylines, polygons or keypoints. A video frame is a sequence of images that have been extracted from a video.

If you do not have video frames, you can provide video files (MP4 files) and use the Ground Truth automated frame extraction tool to extract video frames. To learn more, see Provide Video Files (p. 610).

You can use the following built-in video task types to create video frame labeling jobs using the Amazon SageMaker console, API, and language-specific SDKs.

- **Video frame object detection** – Use this task type when you want workers to identify and locate objects in sequences of video frames. You provide a list of categories, and workers can select one category at a time and annotate objects which the category applies to in all frames. For example, you can use this task to ask workers to identify and localize various objects in a scene, such as cars, bikes, and pedestrians.

- **Video frame object tracking** – Use this task type when you want workers to track the movement of instances of objects across sequences of video frames. When a worker adds an annotation to a single frame, that annotation is associated with a unique instance ID. The worker adds annotations associated with the same ID in all other frames to identify the same object or person. For example, a worker can track the movement of a vehicle across a sequences of video frames by drawing bounding boxes associated with the same ID around the vehicle in each frame that it appears.

Use the following topics to learn more about these built-in task types and how to create a labeling job using each task type. See Task Types (p. 420) to learn more about the annotations tools (bounding boxes, polylines, polygons and keypoints) available for these task types.

Before you create a labeling job, we recommend that you review Video Frame Labeling Job Overview (p. 419).

Topics

- Video Frame Object Detection (p. 411)
- Video Frame Object Tracking (p. 415)
- Video Frame Labeling Job Overview (p. 419)

Video Frame Object Detection

You can use the video frame object detection task type to have workers identify and locate objects in a sequence of video frames (images extracted from a video) using bounding boxes, polylines, polygons
or keypoint annotation tools. The tool you choose defines the video frame task type you create. For example, you can use a bounding box video frame object detection task type workers to identify and localize various objects in a series of video frames, such as cars, bikes, and pedestrians.

You can create a video frame object detection labeling job using the Amazon SageMaker Ground Truth console, the SageMaker API, and language-specific AWS SDKs. To learn more, see Create a Video Frame Object Detection Labeling Job (p. 412) and select your preferred method. See Task Types (p. 420) to learn more about the annotations tools you can choose from when you create a labeling job.

Ground Truth provides a worker UI and tools to complete your labeling job tasks: Preview the Worker UI (p. 412).

You can create a job to adjust annotations created in a video object detection labeling job using the video object detection adjustment task type. To learn more, see Create Video Frame Object Detection Adjustment or Verification Labeling Job (p. 415).

Preview the Worker UI

Ground Truth provides workers with a web user interface (UI) to complete your video frame object detection annotation tasks. You can preview and interact with the worker UI when you create a labeling job in the console. If you are a new user, we recommend that you create a labeling job through the console using a small input dataset to preview the worker UI and ensure your video frames, labels, and label attributes appear as expected.

The UI provides workers with the following assistive labeling tools to complete your object detection tasks:

- For all tasks, workers can use the Copy to next and Copy to all features to copy an annotation to the next frame or to all subsequent frames respectively.
- For tasks that include the bounding box tools, workers can use a Predict next feature to draw a bounding box in a single frame, and then have Ground Truth predict the location of boxes with the same label in all other frames. Workers can then make adjustments to correct predicted box locations.

Create a Video Frame Object Detection Labeling Job

You can create a video frame object detection labeling job using the SageMaker console or the CreateLabelingJob API operation.

This section assumes that you have reviewed the Video Frame Labeling Job Overview (p. 419) and have chosen the type of input data and the input dataset connection you are using.

Create a Labeling Job (Console)

You can follow the instructions in Create a Labeling Job (Console) (p. 544) to learn how to create a video frame object tracking job in the SageMaker console. In step 10, choose Video - Object detection from the Task category dropdown list. Select the task type you want by selecting one of the cards in Task selection.
**Task type**  Info

**Task category**
Select the type of data being labeled to view available task templates for it or select 'Custom'.

**Video - Object detection**

**Task selection**
Select the task that a human worker will perform to label objects in your dataset.

- **Bounding box**
  Get workers to draw bounding boxes around specified objects in your video.  Info

- **Polyline**
  Get workers to draw polyline around specified objects in your video.  Info
Create a Labeling Job (API)

You create an object detection labeling job using the SageMaker API operation `CreateLabelingJob`. This API defines this operation for all AWS SDKs. To see a list of language-specific SDKs supported for this operation, review the See Also section of `CreateLabelingJob`.

Create a Labeling Job (API) (p. 547) provides an overview of the CreateLabelingJob operation. Follow these instructions and do the following while you configure your request:

- You must enter an ARN for `HumanTaskUiArn`. Use
  `arn:aws:sagemaker:<region>:394669845002:human-task-ui/VideoObjectDetection`. Replace `<region>` with the AWS Region in which you are creating the labeling job.

  Do not include an entry for the `UiTemplateS3Uri` parameter.

- Your `LabelAttributeName` must end in `-ref`. For example, `video-od-labels-ref`.

- Your input manifest file must be a video frame sequence manifest file. You can create this manifest file using the SageMaker console, or create it manually and upload it to Amazon S3. For more information, see Input Data Setup (p. 610).

- You can only use private or vendor work teams to create video frame object detection labeling jobs.

- You specify your labels, label category and frame attributes, the task type, and worker instructions in a label category configuration file. Specify the task type (bounding boxes, polylines, polygons or keypoint) using `annotationType` in your label category configuration file. For more information, see Create a Labeling Category Configuration File with Label Category and Frame Attributes (p. 557) to learn how to create this file.

- You need to provide pre-defined ARNs for the pre-annotation and post-annotation (ACS) Lambda functions. These ARNs are specific to the AWS Region you use to create your labeling job.

  - To find the pre-annotation Lambda ARN, refer to `PreHumanTaskLambdaArn`. Use the Region in which you are creating your labeling job to find the correct ARN that ends with `PRE-VideoObjectDetection`.

  - To find the post-annotation Lambda ARN, refer to `AnnotationConsolidationLambdaArn`. Use the Region in which you are creating your labeling job to find the correct ARN that ends with `ACS-VideoObjectDetection`.

- The number of workers specified in `NumberOfHumanWorkersPerDataObject` must be 1.

- Automated data labeling is not supported for video frame labeling jobs. Do not specify values for parameters in `LabelingJobAlgorithmsConfig`.

- Video frame object tracking labeling jobs can take multiple hours to complete. You can specify a longer time limit for these labeling jobs in `TaskTimeLimitInSeconds` (up to 7 days, or 604,800 seconds).

The following is an example of an AWS Python SDK (Boto3) request to create a labeling job in the US East (N. Virginia) Region.

```python
response = client.create_labeling_job(
    LabelingJobName='example-video-od-labeling-job,
    LabelAttributeName='label',
    InputConfig={
        'DataSource': {
            'S3DataSource': {

```
Create Video Frame Object Detection Adjustment or Verification Labeling Job

You can create an adjustment and verification labeling job using the Ground Truth console or CreateLabelingJob API. To learn more about adjustment and verification labeling jobs, and to learn how create one, see Verify and Adjust Labels (p. 502).

Output Data Format

When you create a video frame object detection labeling job, tasks are sent to workers. When these workers complete their tasks, labels are written to the Amazon S3 output location you specified when you created the labeling job. To learn about the video frame object detection output data format, see Video Frame Object Detection Output (p. 626). If you are a new user of Ground Truth, see Output Data (p. 614) to learn more about the Ground Truth output data format.

Video Frame Object Tracking

You can use the video frame object tracking task type to have workers track the movement of objects in a sequence of video frames (images extracted from a video) using bounding boxes, polylines, polygons...
Label Videos and Video Frames

or keypoint *annotation tools*. The tool you choose defines the video frame task type you create. For example, you can use a bounding box video frame object tracking task type to ask workers to track the movement of objects, such as cars, bikes, and pedestrians by drawing boxes around them.

You provide a list of categories, and each annotation that a worker adds to a video frame is identified as an *instance* of that category using an instance ID. For example, if you provide the label category car, the first car that a worker annotates will have the instance ID car:1. The second car the worker annotates will have the instance ID car:2. To track an object's movement, the worker adds annotations associated with the same instance ID around to object in all frames.

You can create a video frame object tracking labeling job using the Amazon SageMaker Ground Truth console, the SageMaker API, and language-specific AWS SDKs. To learn more, see Create a Video Frame Object Detection Labeling Job (p. 412) and select your preferred method. See Task Types (p. 420) to learn more about the annotations tools you can choose from when you create a labeling job.

Ground Truth provides a worker UI and tools to complete your labeling job tasks: Preview the Worker UI (p. 412).

You can create a job to adjust annotations created in a video object detection labeling job using the video object detection adjustment task type. To learn more, see Create Video Frame Object Detection Adjustment or Verification Labeling Job (p. 415).

**Preview the Worker UI**

Ground Truth provides workers with a web user interface (UI) to complete your video frame object tracking annotation tasks. You can preview and interact with the worker UI when you create a labeling job in the console. If you are a new user, we recommend that you create a labeling job through the console using a small input dataset to preview the worker UI and ensure your video frames, labels, and label attributes appear as expected.

The UI provides workers with the following assistive labeling tools to complete your object tracking tasks:

- For all tasks, workers can use the **Copy to next** and **Copy to all** features to copy an annotation with the same unique ID to the next frame or to all subsequent frames respectively.
- For tasks that include the bounding box tools, workers can use a **Predict next** feature to draw a bounding box in a single frame, and then have Ground Truth predict the location of boxes with the same unique ID in all other frames. Workers can then make adjustments to correct predicted box locations.

**Create a Video Frame Object Tracking Labeling Job**

You can create a video frame object tracking labeling job using the SageMaker console or the CreateLabelingJob API operation.

This section assumes that you have reviewed the Video Frame Labeling Job Overview (p. 419) and have chosen the type of input data and the input dataset connection you are using.

**Create a Labeling Job (Console)**

You can follow the instructions in Create a Labeling Job (Console) (p. 544) to learn how to create a video frame object tracking job in the SageMaker console. In step 10, choose **Video - Object tracking** from the **Task category** dropdown list. Select the task type you want by selecting one of the cards in **Task selection**.
Task type

Task category
Select the type of data being labeled to view available task templates for it or select 'Custom' for a self-built task.

Video - Object tracking

Task selection
Select the task that a human worker will perform to label objects in your dataset.

Bounding box
Get workers to track specific instances of objects in your video across multiple frames in your bounding boxes.

Polyline
Get workers to track specific instances of objects in your video across multiple frames in your polylines.
Create a Labeling Job (API)

You create an object tracking labeling job using the SageMaker API operation CreateLabelingJob. This API defines this operation for all AWS SDKs. To see a list of language-specific SDKs supported for this operation, review the See Also section of CreateLabelingJob.

Create a Labeling Job (API) (p. 547) provides an overview of the CreateLabelingJob operation. Follow these instructions and do the following while you configure your request:

- You must enter an ARN for HumanTaskUiArn. Use
  Replace <region> with the AWS Region in which you are creating the labeling job.

  Do not include an entry for the UiTemplateS3Uri parameter.
- Your LabelAttributeName must end in -ref. For example, ot-labels-ref.
- Your input manifest file must be a video frame sequence manifest file. You can create this manifest file using the SageMaker console, or create it manually and upload it to Amazon S3. For more information, see Input Data Setup (p. 610). If you create a streaming labeling job, the input manifest file is optional.
- You can only use private or vendor work teams to create video frame object detection labeling jobs.
- You specify your labels, label category and frame attributes, the task type, and worker instructions in a label category configuration file. Specify the task type (bounding boxes, polylines, polygons or keypoint) using annotationType in your label category configuration file. For more information, see Create a Labeling Category Configuration File with Label Category and Frame Attributes (p. 557) to learn how to create this file.
- You need to provide pre-defined ARNs for the pre-annotation and post-annotation (ACS) Lambda functions. These ARNs are specific to the AWS Region you use to create your labeling job.
  - To find the pre-annotation Lambda ARN, refer to PreHumanTaskLambdaArn. Use the Region in which you are creating your labeling job to find the correct ARN that ends with PRE-VideoObjectTracking.
  - To find the post-annotation Lambda ARN, refer to AnnotationConsolidationLambdaArn. Use the Region in which you are creating your labeling job to find the correct ARN that ends with ACS-VideoObjectTracking.
- The number of workers specified in NumberOfHumanWorkersPerDataObject must be 1.
- Automated data labeling is not supported for video frame labeling jobs. Do not specify values for parameters in LabelingJobAlgorithmsConfig.
- Video frame object tracking labeling jobs can take multiple hours to complete. You can specify a longer time limit for these labeling jobs in TaskTimeLimitInSeconds (up to 7 days, or 604,800 seconds).

The following is an example of an AWS Python SDK (Boto3) request to create a labeling job in the US East (N. Virginia) Region.

```python
def create_labeling_job():
    response = client.create_labeling_job(
        LabelingJobName='example-video-ot-labeling-job,
        LabelAttributeName='label',
        InputConfig={
            'DataSource': {
                'S3DataSource': {
                    'ManifestS3Uri': 's3://DOC-EXAMPLE-BUCKET/path/video-frame-sequence-input-manifest.json'
                }
            }
        },
        DataAttributes={
            'ContentClassifiers': ['FreeOfPersonallyIdentifiableInformation','FreeOfAdultContent']
        }
    )
```
Create a Video Frame Object Tracking Adjustment or Verification Labeling Job

You can create an adjustment and verification labeling job using the Ground Truth console or CreateLabelingJob API. To learn more about adjustment and verification labeling jobs, and to learn how create one, see Verify and Adjust Labels (p. 502).

Output Data Format

When you create a video frame object tracking labeling job, tasks are sent to workers. When these workers complete their tasks, labels are written to the Amazon S3 output location you specified when you created the labeling job. To learn about the video frame object tracking output data format, see Video Frame Object Tracking Output (p. 628). If you are a new user of Ground Truth, see Output Data (p. 614) to learn more about the Ground Truth output data format.

Video Frame Labeling Job Overview

Use this page to learn about the object detection and object tracking video frame labeling jobs. The information on this page applies to both of these built-in task types.

The video frame labeling job is unique because of the following:
You can either provide data objects that are ready to be annotated (video frames), or you can provide video files and have Ground Truth automatically extract video frames.

Workers have the ability to save work as they go.

You cannot use the Amazon Mechanical Turk workforce to complete your labeling tasks.

Ground Truth provides a worker UI, as well as assistive and basic labeling tools, to help workers complete your tasks. You do not need to provide a worker task template.

Use the following topics to learn more.

**Topics**

- Input Data (p. 420)
- Job Completion Times (p. 420)
- Task Types (p. 420)
- Workforces (p. 421)
- Worker User Interface (UI) (p. 421)
- Video Frame Job Permission Requirements (p. 423)

**Input Data**

The video frame labeling job uses sequences of video frames. A single sequence is a series of images that have been extracted from a single video. You can either provide your own sequences of video frames, or have Ground Truth automatically extract video frame sequences from your video files. To learn more, see Provide Video Files (p. 610).

Ground Truth uses sequence files to identify all images in a single sequence. All of the sequences that you want to include in a single labeling job are identified in an input manifest file. Each sequence is used to create a single worker task. You can automatically create sequence files and an input manifest file using Ground Truth automatic data setup. To learn more, see Automated Video Frame Input Data Setup (p. 611).

To learn how to manually create sequence files and an input manifest file, see Create a Video Frame Input Manifest File (p. 613).

**Job Completion Times**

Video and video frame labeling jobs can take workers hours to complete. You can set the total amount of time that workers can work on each task when you create a labeling job. The maximum time you can set for workers to work on tasks is 7 days. The default value is 3 days.

We strongly recommend that you create tasks that workers can complete within 12 hours. Workers must keep the worker UI open while working on a task. They can save work as they go and Ground Truth saves their work every 15 minutes.

When using the SageMaker CreateLabelingJob API operation, set the total time a task is available to workers in the TaskTimeLimitInSeconds parameter of HumanTaskConfig.

When you create a labeling job in the console, you can specify this time limit when you select your workforce type and your work team.

**Task Types**

When you create a video object tracking or video object detection labeling job, you specify the type of annotation that you want workers to create while working on your labeling task. The annotation type determines the type of output data Ground Truth returns and defines the task type for your labeling job.
If you are creating a labeling job using the API operation `CreateLabelingJob`, you specify the task type using the label category configuration file parameter `annotationType`. To learn more, see Create a Labeling Category Configuration File with Label Category and Frame Attributes (p. 557).

The following task types are available for both video object tracking or video object detection labeling jobs:

- **Bounding box** – Workers are provided with tools to create bounding box annotations. A bounding box is a box that a worker draws around an objects to identify the pixel-location and label of that object in the frame.

- **Polyline** – Workers are provided with tools to create polyline annotations. A polyline is defined by the series of ordered x, y coordinates. Each point added to the polyline is connected to the previous point by a line. The polyline does not have to be closed (the start point and end point do not have to be the same) and there are no restrictions on the angles formed between lines.

- **Polygon** – Workers are provided with tools to create polygon annotations. A polygon is a closed shape defined by a series of ordered x, y coordinates. Each point added to the polygon is connected to the previous point by a line and there are no restrictions on the angles formed between lines. Two lines (sides) of the polygon cannot cross. The start and end point of a polygon must be the same.

- **Keypoint** – Workers are provided with tools to create keypoint annotations. A keypoint is a single point associated with an x, y coordinate in the video frame.

**Workforces**

When you create a video frame labeling job, you need to specify a work team to complete your annotation tasks. You can choose a work team from a private workforce of your own workers, or from a vendor workforce that you select in the AWS Marketplace. You cannot use the Amazon Mechanical Turk workforce for video frame labeling jobs.

To learn more about vendor workforces, see Managing Vendor Workforces (p. 698).

To learn how to create and manage a private workforce, see Use a Private Workforce (p. 699).

**Worker User Interface (UI)**

Ground Truth provides a worker user interface (UI), tools, and assistive labeling features to help workers complete your video labeling tasks. You can preview the worker UI when you create a labeling job in the console.

When you create a labeling job using the API operation `CreateLabelingJob`, you must provide an ARN provided by Ground Truth in the parameter `HumanTaskUiArn` to specify the worker UI for your task type. You can use `HumanTaskUiArn` with the SageMaker `RenderUiTemplate` API operation to preview the worker UI.

You provide worker instructions, labels, and optionally, attributes that workers can use to provide more information about labels and video frames. These attributes are referred to as label category attributes and frame attributes respectively. They are all displayed in the worker UI.

**Label Category and Frame Attributes**

When you create a video object tracking or video object detection labeling job, you can add one or more `label category attributes` and `frame attributes`:

- **Label category attribute** – A list of options (strings), a free form text box, or a numeric field associated with one or more labels. It is used by workers to provide metadata about a label.

- **Frame attribute** – A list of options (strings), a free form text box, or a numeric field that appears on each video frame a worker is sent to annotate. It is used by workers to provide metadata about video frames.
Additionally, you can use label and frame attributes to have workers verify labels in a video frame label verification job.

Use the following sections to learn more about these attributes. To learn how to add label category and frame attributes to a labeling job, use the Create Labeling Job sections on the task type page (p. 411) of your choice.

**Label Category Attributes**

Add label category attributes to labels to give workers the ability to provide more information about the annotations they create. A label category attribute is added to an individual label, or to all labels. When a label category attribute is applied to all labels it is referred to as a *global label category attribute*.

For example, if you add the label category *car*, you might also want to capture additional data about your labeled cars, such as if they are occluded or the size of the car. You can capture this metadata using label category attributes. In this example, if you added the attribute *occluded* to the car label category, you can assign *partial*, *completely*, *no* to the *occluded* attribute and enable workers to select one of these options.

When you create a label verification job, you add labels category attributes to each label you want workers to verify.

**Frame level Attributes**

Add frame attributes to give workers the ability to provide more information about individual video frames. Each frame attribute you add appears on all frames.

For example, you can add a number-frame attribute to have workers identify the number of objects they see in a particular frame.

In another example, you may want to provide a free-form text box to give workers the ability to provide an answer to a question.

When you create a label verification job, you can add one or more frame attributes to ask workers to provide feedback on all labels in a video frame.

**Worker Instructions**

You can provide worker instructions to help your workers complete your video frame labeling tasks. You might want to cover the following topics when writing your instructions:

- Best practices and things to avoid when annotating objects.
- The label category attributes provided (for object detection and object tracking tasks) and how to use them.
- How to save time while labeling by using keyboard shortcuts.

You can add your worker instructions using the SageMaker console while creating a labeling job. If you create a labeling job using the API operation CreateLabelingJob, you specify worker instructions in your label category configuration file.

In addition to your instructions, Ground Truth provides a link to help workers navigate and use the worker portal. View these instructions by selecting the task type on Worker Instructions (p. 423).

**Declining Tasks**

Workers are able to decline tasks.

Workers decline a task if the instructions are not clear, input data is not displaying correctly, or if they encounter some other issue with the task. If the number of workers per dataset object (NumberOfHumanWorkersPerDataObject) decline the task, the data object is marked as expired and will not be sent to additional workers.
Video Frame Job Permission Requirements

When you create a video frame labeling job, in addition to the permission requirements found in Assign IAM Permissions to Use Ground Truth (p. 650), you must add a CORS policy to your S3 bucket that contains your input manifest file.

Add a CORS Permission Policy to S3 Bucket

When you create a video frame labeling job, you specify buckets in S3 where your input data and manifest file are located and where your output data will be stored. These buckets may be the same. You must attach the following Cross-origin resource sharing (CORS) policy to your input and output buckets. If you use the Amazon S3 console to add the policy to your bucket, you must use the JSON format.

**JSON**

```json
{
  "AllowedHeaders": [
    "*
  ],
  "AllowedMethods": [
    "GET",
    "HEAD",
    "PUT"
  ],
  "AllowedOrigins": [
    "*
  ],
  "ExposeHeaders": [
    "Access-Control-Allow-Origin"
  ],
  "MaxAgeSeconds": 3000
}
```

**XML**

```xml
<?xml version="1.0" encoding="UTF-8"?>
<CORSConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <CORSRule>
    <AllowedOrigin>*</AllowedOrigin>
    <AllowedMethod>GET</AllowedMethod>
    <AllowedMethod>HEAD</AllowedMethod>
    <AllowedMethod>PUT</AllowedMethod>
    <MaxAgeSeconds>3000</MaxAgeSeconds>
    <ExposeHeader>Access-Control-Allow-Origin</ExposeHeader>
  </CORSRule>
</CORSConfiguration>
```

To learn how to add a CORS policy to an S3 bucket, see How do I add cross-domain resource sharing with CORS? in the Amazon Simple Storage Service User Guide.

Worker Instructions

This topic provides an overview of the Ground Truth worker portal and the tools available to complete your video frame labeling task. First, select the type of task you are working on from Topics.

**Important**

It is recommended that you complete your task using a Google Chrome or Firefox web browser.
For adjustment jobs, select the original labeling job task type that produced the labels you are adjusting. Review and adjust the labels in your task as needed.

Topics
- Work on Video Frame Object Tracking Tasks (p. 424)
- Work on Video Frame Object Detection Tasks (p. 431)

Work on Video Frame Object Tracking Tasks

Video frame object tracking tasks require you to track the movement of objects across video frames. A video frame is a still image from a video scene.

You can use the worker UI to navigate between video frames and use the tools provided to identify unique objects and track their movement from one from to the next. Use this page to learn how to navigate your worker UI, use the tools provided, and complete your task.

It is recommended that you complete your task using a Google Chrome or Firefox web browser.

Important
- If you see annotations have already been added to one or more video frames when you open your task, adjust those annotations and add additional annotations as needed.

Topics
- Your Task (p. 424)
- Navigate the UI (p. 426)
- Bulk Edit Label and Frame Attributes (p. 426)
- Tool Guide (p. 427)
- Icons Guide (p. 429)
- Shortcuts (p. 430)
- Release, Stop and Resume, and Decline Tasks (p. 431)
- Saving Your Work and Submitting (p. 431)

Your Task

When you work on a video frame object tracking task, you need to select a category from the Label category menu on the right side of your worker portal to start annotating. After you've chosen a category, use the tools provided to annotate the objects that the category applies to. This annotation will be associated with a unique label ID that should only be used for that object. Use this same label ID to create additional annotations for the same object in all of the video frames that it appears in. Refer to Tool Guide (p. 427) to learn more about the tools provided.

After you've added a label, you may see a downward pointing arrow next to the label in the Labels menu. Select this arrow and then select one option for each label attribute you see to provide more information about that label.

You may see frame attributes under the Labels menu. These attributes will appear on each frame in your task. Use these attribute prompts to enter additional information about each frame.
After you've added a label, you can quickly add and edit a label category attribute value by using the downward pointing arrow next to the label in the Labels menu. If you select the pencil icon next to the label in the Labels menu, the Edit instance menu will appear. You can edit the label ID, label category, and label category attributes using this menu.

To edit an annotation, select the label of the annotation that you want to edit in the Labels menu or select the annotation in the frame. When you edit or delete an annotation, the action will only modify the annotation in a single frame.

If you are working on a task that includes a bounding box tool, use the predict next icon to predict the location of all bounding boxes that you have drawn in a frame in the next frame. If you select a single box and then select the predict next icon, only that box will be predicted in the next frame. If you have not added any boxes to the current frame, you will receive an error. You must add at least one box to the frame before using this feature.
After you've used the predict next icon, review the location of each box in the next frame and make adjustments to the box location and size if necessary.

For all other tools, you can use the **Copy to next** and **Copy to all** tools to copy your annotations to the next or all frames respectively.

**Navigate the UI**

You can navigate between video frames using the navigation bar in the bottom-left corner of your UI.

Use the play button to automatically move through the entire sequence of frames.

Use the next frame and previous frame buttons to move forward or back one frame at a time. You can also input a frame number to navigate to that frame.

You can zoom in to and out of all video frames. Once you have zoomed into a video frame, you can move around in that frame using the move icon. When you set a new view in a single video frame by zooming and moving within that frame, all video frames are set to the same view. You can reset all video frames to their original view using the fit screen icon. For additional view options, see [Icons Guide](#) (p. 429).

When you are in the worker UI, you see the following menus:

- **Instructions** – Review these instructions before starting your task. Additionally, select More instructions and review these instructions.
- **Shortcuts** – Use this menu to view keyboard shortcuts that you can use to navigate video frames and use the tools provided.
- **Help** – Use this option to refer back to this documentation.

**Bulk Edit Label and Frame Attributes**

You can bulk edit label attributes and frame attributes (attributes).

When you bulk edit an attribute, you specify one or more ranges of frames that you want to apply the edit to. The attribute you select is edited in all frames in that range, including the start and end frames you specify. When you bulk edit label attributes, the range you specify must contain the label that the label attribute is attached to. If you specify frames that do not contain this label, you will receive an error.

To bulk edit an attribute you must specify the desired value for the attribute first. For example, if you want to change an attribute from *Yes* to *No*, you must select *No*, and then perform the bulk edit.

You can also specify a new value for an attribute that has not been filled in and then use the bulk edit feature to fill in that value in multiple frames. To do this, select the desired value for the attribute and complete the following procedure.

**To bulk edit a label or attribute:**

1. Use your mouse to right click the attribute you want to bulk edit.
2. Specify the range of frames you want to apply the bulk edit to using a dash (–) in the text box. For example, if you want to apply the edit to frames one through ten, enter `1-10`. If you want to apply the edit to frames two to five, eight to ten and twenty enter `2-5,8-10,20`.
3. Select **Confirm**.

If you get an error message, verify that you entered a valid range and that the label associated with the label attribute you are editing (if applicable) exists in all frames specified.

You can quickly add a label to all previous or subsequent frames using the **Duplicate to previous frames** and **Duplicate to next frames** options in the **Label** menu at the top of your screen.
**Tool Guide**

Your task will include one or more tools. The tool provided dictates the type of annotations you will create to identify and track objects. Use the following table to learn more about each tool provided.

<table>
<thead>
<tr>
<th>Tool</th>

<td><img src="image" alt="Edit Label Icon" /></td>
<td><strong>edit label</strong></td>
<td>Select this icon to open the <strong>Edit instance</strong> menu. Use this menu to edit a label category, ID, and to add or edit label attributes.</td>
</tr>
</tbody>
</table>

**Shortcuts**

The keyboard shortcuts listed in the **Shortcuts** menu can help you quickly select icons, undo and redo annotations, and use tools to add and edit annotations. For example, once you add a bounding box, you can use **P** to quickly predict the location of that box in subsequent frames.

Before you start your task, it is recommended that you review the **Shortcuts** menu and become acquainted with these commands.
Release, Stop and Resume, and Decline Tasks

When you open the labeling task, three buttons on the top right allow you to decline the task (Decline task), release it (Release task), and stop and resume it at a later time (Stop and resume later). The following list describes what happens when you select one of these options:

- **Decline task**: You should only decline a task if something is wrong with the task, such as unclear video frame images or an issue with the UI. If you decline a task, you will not be able to return to the task.

- **Release Task**: Use this option to release a task and allow others to work on it. When you release a task, you lose all work done on that task and other workers on your team can pick it up. If enough workers pick up the task, you may not be able to return to it. When you select this button and then select Confirm, you are returned to the worker portal. If the task is still available, its status will be Available. If other workers pick it up, it will disappear from your portal.

- **Stop and resume later**: You can use the Stop and resume later button to stop working and return to the task at a later time. You should use the Save button to save your work before you select Stop and resume later. When you select this button and then select Confirm, you are returned to the worker portal, and the task status is Stopped. You can select the same task to resume work on it.

Be aware that the person that creates your labeling tasks specifies a time limit in which all tasks must be completed by. If you do not return to and complete this task within that time limit, it will expire and your work will not be submitted. Contact your administrator for more information.

Saving Your Work and Submitting

You should periodically save your work using the Save button. Ground Truth will automatically save your work every 15 minutes.

When you open a task, you must complete your work on it before pressing Submit.

Work on Video Frame Object Detection Tasks

Video frame object detection tasks required you to classify and identify the location of objects in video frames using annotations. A video frame is a still image from a video scene.

You can use the worker UI to navigate between video frames and create annotations to identify objects of interest. Use the sections on this page to learn how to navigate your worker UI, use the tools provided, and complete your task.

It is recommended that you complete your task using a Google Chrome web browser.

**Important**

If you see annotations have already been added to one or more video frames when you open your task, adjust those annotations and add additional annotations as needed.

Topics

- Your Task (p. 432)
- Navigate the UI (p. 433)
- Bulk Edit Label and Frame Attributes (p. 433)
- Tool Guide (p. 434)
- UI Icon Guide (p. 437)
- Shortcuts (p. 438)
- Release, Stop and Resume, and Decline Tasks (p. 438)
- Saving Your Work and Submitting (p. 439)
Your Task

When you work on a video frame object detection task, you need to select a category from the Label category menu on the right side of your worker portal to start annotating. After you've chosen a category, draw annotations around objects that this category applies to. To learn more about the tools you see in your worker UI, refer to the Tool Guide (p. 434).

After you've added a label, you may see a downward pointing arrow next to the label in the Labels menu. Select this arrow and then select one option for each label attribute you see to provide more information about that label.

You may see frame attributes under the Labels menu. These attributes will appear on each frame in your task. Use these attribute prompts to enter additional information about each frame.
To edit an annotation, select the label of the annotation that you want to edit in the **Labels** menu or select the annotation in the frame. When you edit or delete an annotation, the action will only modify the annotation in a single frame.

If you are working on a task that includes a bounding box tool, use the predict next icon to predict the location of all bounding boxes that you have drawn in a frame in the next frame. If you select a single box and then select the predict next icon, only that box will be predicted in the next frame. If you have not added any boxes to the current frame, you will receive an error. You must add at least one box to the frame before using this feature.

**Note**
The predict next feature will not overwrite manually created annotations. It will only add annotations. If you use predict next and as a result have more than one bounding box around a single object, delete all but one box. Each object should only be identified with a single box.

After you've used the predict next icon, review the location of each box in the next frame and make adjustments to the box location and size if necessary.

For all other tools, you can use the **Copy to next** and **Copy to all** tools to copy your annotations to the next or all frames respectively.

**Navigate the UI**

You can navigate between video frames using the navigation bar in the bottom-left corner of your UI.

Use the play button to automatically play through multiple frames.

Use the next frame and previous frame buttons to move forward or back one frame at a time. You can also input a frame number to navigate to that frame.

You can zoom in to and out of all video frames. Once you have zoomed into a video frame, you can move around in that frame using the move icon. When you navigate to a new view in a single video frame by zooming and moving within that frame, all video frames are set to the same view. You can reset all video frames to their original view using the fit screen icon. To learn more, see *UI Icon Guide* (p. 437).

When you are in the worker UI, you see the following menus:

- **Instructions** – Review these instructions before starting your task. Additionally, select **More instructions** and review these instructions.
- **Shortcuts** – Use this menu to view keyboard shortcuts that you can use to navigate video frames and use the annotation tools provided.
- **Help** – Use this option to refer back to this documentation.

If you

**Bulk Edit Label and Frame Attributes**

You can bulk edit label attributes and frame attributes (attributes).

When you bulk edit an attribute, you specify one or more ranges of frames that you want to apply the edit to. The attribute you select is edited in all frames in that range, including the start and end frames you specify. When you bulk edit label attributes, the range you specify must contain the label that the label attribute is attached to. If you specify frames that do not contain this label, you will receive an error.

To bulk edit an attribute you must specify the desired value for the attribute first. For example, if you want to change an attribute from Yes to No, you must select No, and then perform the bulk edit.

You can also specify a new value for an attribute that has not been filled in and then use the bulk edit feature to fill in that value in multiple frames. To do this, select the desired value for the attribute and complete the following procedure.
To bulk edit a label or attribute:

1. Use your mouse to right click the attribute you want to bulk edit.
2. Specify the range of frames you want to apply the bulk edit to using a dash (-) in the text box. For example, if you want to apply the edit to frames one through ten, enter 1-10. If you want to apply the edit to frames two to five, eight to ten and twenty enter 2-5, 8-10, 20.
3. Select Confirm.

If you get an error message, verify that you entered a valid range and that the label associated with the label attribute you are editing (if applicable) exists in all frames specified.

You can quickly add a label to all previous or subsequent frames using the Duplicate to previous frames and Duplicate to next frames options in the Label menu at the top of your screen.

Tool Guide

Your task will include one or more tools. The tool provided dictates the type of annotations you will create to identify and label objects. Use the following table to learn more about the tool or tools you may see in your worker UI.

<table>
<thead>
<tr>
<th>Tool</th>
<th>Icon</th>

**UI Icon Guide**

Use this table to learn about the icons you see in your worker task portal. You can automatically select these icons using the keyboard shortcuts found in the *Shortcuts* menu.

<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="Brightness Icon" /></td>
<td>Choose this icon to adjust the brightness of all video frames.</td>
</tr>
<tr>
<td><img src="image" alt="Contrast Icon" /></td>
<td>Choose this icon to adjust the contrast of all video frames.</td>
</tr>
<tr>
<td><img src="image" alt="Zoom In Icon" /></td>
<td>Choose this icon to zoom into all of the video frames.</td>
</tr>
<tr>
<td><img src="image" alt="Zoom Out Icon" /></td>
<td>Choose this icon to zoom out of all of the video frames.</td>
</tr>
<tr>
<td><img src="image" alt="Move Screen Icon" /></td>
<td>After you've zoomed into a video frame, choose this icon to move around in that video frame. You can move around in the video frame using your mouse by clicking and dragging the frame in the direction you want it to move. This will change the view in all view frames.</td>
</tr>
<tr>
<td><img src="image" alt="Fit Screen Icon" /></td>
<td>Reset all video frames to their original position.</td>
</tr>
</tbody>
</table>
Icon | Description
--- | ---
undo | Undo an action. You can use this icon to remove a bounding box that you just added, or to undo an adjustment you made to a bounding box.
redo | Redo an action that was undone using the undo icon.
delete label | Delete a label. This will delete the bounding box associated with the label in a single frame.
show or hide label | Select this icon to show a label that has been hidden. If this icon has a slash through it, select it to hide the label.

**Shortcuts**

The keyboard shortcuts listed in the **Shortcuts** menu can help you quickly select icons, undo and redo annotations, and use tools to add and edit annotations. For example, once you add a bounding box, you can use P to quickly predict the location of that box in subsequent frames.

Before you start your task, it is recommended that you review the **Shortcuts** menu and become acquainted with these commands.

**Release, Stop and Resume, and Decline Tasks**

When you open the labeling task, three buttons on the top right allow you to decline the task (**Decline task**), release it (**Release task**), and stop and resume it at a later time (**Stop and resume later**). The following list describes what happens when you select one of these options:

- **Decline task**: You should only decline a task if something is wrong with the task, such as unclear video frame images or an issue with the UI. If you decline a task, you will not be able to return to the task.
- **Release Task**: Use this option to release a task and allow others to work on it. When you release a task, you lose all work done on that task and other workers on your team can pick it up. If enough workers pick up the task, you may not be able to return to it. When you select this button and then select **Confirm**, you are returned to the worker portal. If the task is still available, its status will be **Available**. If other workers pick it up, it will disappear from your portal.
- **Stop and resume later**: You can use the **Stop and resume later** button to stop working and return to the task at a later time. You should use the **Save** button to save your work before you select **Stop and resume later**. When you select this button and then select **Confirm**, you are returned to the worker portal, and the task status is **Stopped**. You can select the same task to resume work on it.

Be aware that the person that creates your labeling tasks specifies a time limit in which all tasks must be completed by. If you do not return to and complete this task within that time limit, it will expire and your work will not be submitted. Contact your administrator for more information.
Saving Your Work and Submitting

You should periodically save your work. Ground Truth automatically saves your work every 15 minutes.

When you open a task, you must complete your work before pressing Submit.

Use Ground Truth to Label 3D Point Clouds

Create a 3D point cloud labeling job to have workers label objects in 3D point clouds generated from 3D sensors like Light Detection and Ranging (LiDAR) sensors and depth cameras, or generated from 3D reconstruction by stitching images captured by an agent like a drone.

3D Point Clouds

Point clouds are made up of three-dimensional (3D) visual data that consists of points. Each point is described using three coordinates, typically x, y, and z. To add color or variations in point intensity to the point cloud, points may be described with additional attributes, such as i for intensity or values for the red (r), green (g), and blue (b) 8-bit color channels. When you create a Ground Truth 3D point cloud labeling job, you can provide point cloud and, optionally, sensor fusion data.

The following image shows a single, 3D point cloud scene rendered by Ground Truth and displayed in the semantic segmentation worker UI.
LiDAR

A Light Detection and Ranging (LiDAR) sensor is a common type of sensor used to collect measurements that are used to generate point cloud data. LiDAR is a remote sensing method that uses light in the form of a pulsed laser to measure the distances of objects from the sensor. You can provide 3D point cloud data generated from a LiDAR sensor for a Ground Truth 3D point cloud labeling job using the raw data formats described in Accepted Raw 3D Data Formats (p. 584).

Sensor Fusion

Ground Truth 3D point cloud labeling jobs include a sensor fusion feature that supports video camera sensor fusion for all task types. Some sensors come with multiple LiDAR devices and video cameras that capture images and associate them with a LiDAR frame. To help annotators visually complete your tasks with high confidence, you can use the Ground Truth sensor fusion feature to project annotations (labels) from a 3D point cloud to 2D camera images and vice versa using 3D scanner (such as LiDAR) extrinsic matrix and camera extrinsic and intrinsic matrices. To learn more, see Sensor Fusion (p. 601).

Label 3D Point Clouds

Ground Truth provides a user interface (UI) and tools that workers use to label or annotate 3D point clouds. When you use the object detection or semantic segmentation task types, workers can annotate a single point cloud frame. When you use object tracking, workers annotate a sequence of frames. You can use object tracking to track object movement across all frames in a sequence.

The following demonstrates how a worker would use the Ground Truth worker portal and tools to annotate a 3D point cloud for an object detection task. For similar visual examples of other task types, see 3D Point Cloud Task types (p. 443).
Double click on the point cloud to zoom in.

Double click on the label ID to zoom in the object on point cloud.

**3D Cuboid Controls**
When you are in Edit Cuboid mode

- **C**: Create
- **V**: Edit
- **Cmd + Drag**: Change dimension
- **Option + Drag**: Move cuboid
- **Option + O**: Fit label to points
- **Option + G**: Set to ground
- **Shift + Drag**: Rotate cuboid
- **[**: Previous label
- **]**: Next label
- **Cmd + ,**: Toggle show/hide label
Assistive Labeling Tools for Point Cloud Annotation

Ground Truth offers assistive labeling tools to help workers complete your point cloud annotation tasks faster and with more accuracy. For details about assistive labeling tools that are included in the worker UI for each task type, select a task type (p. 443) and refer to the View the Worker Task Interface section of that page.

Next Steps

You can create six types of tasks when you use Ground Truth 3D point cloud labeling jobs. Use the topics in 3D Point Cloud Task types (p. 443) to learn more about these task types and to learn how to create a labeling job using the task type of your choice.

The 3D point cloud labeling job is different from other Ground Truth labeling modalities. Before creating a labeling job, we recommend that you read 3D Point Cloud Labeling Jobs Overview (p. 468). Additionally, review input data quotas in 3D Point Cloud and Video Frame Labeling Job Quotas (p. 582).

For an end-to-end demo using the SageMaker API and AWS Python SDK (boto 3) to create a 3D point cloud labeling job, see create-3D-pointcloud-labeling-job.ipynb in the SageMaker Examples notebook tab.

Important
If you use a notebook instance created before June 5th, 2020 to run this notebook, you must stop and restart that notebook instance for the notebook to work.

Topics
• 3D Point Cloud Task types (p. 443)
• 3D Point Cloud Labeling Jobs Overview (p. 468)
• Worker Instructions (p. 471)

3D Point Cloud Task types

You can use Ground Truth 3D point cloud labeling modality for a variety of use cases. The following list briefly describes each 3D point cloud task type. For additional details and instructions on how to create a labeling job using a specific task type, select the task type name to see its task type page.

• 3D point cloud object detection – Use this task type when you want workers to locate and classify objects in a 3D point cloud by adding and fitting 3D cuboids around objects.
• 3D point cloud object tracking – Use this task type when you want workers to add and fit 3D cuboids around objects to track their movement across a sequence of 3D point cloud frames. For example, you can use this task type to ask workers to track the movement of vehicles across multiple point cloud frames.
• 3D point cloud semantic segmentation – Use this task type when you want workers to create a point-level semantic segmentation mask by painting objects in a 3D point cloud using different colors where each color is assigned to one of the classes you specify.
• 3D point cloud adjustment task types – Each of the task types above has an associated adjustment task type that you can use to audit and adjust annotations generated from a 3D point cloud labeling job. Refer to the task type page of the associated type to learn how to create an adjustment labeling job for that task.

3D Point Cloud Object Detection

Use this task type when you want workers to classify objects in a 3D point cloud by drawing 3D cuboids around objects. For example, you can use this task type to ask workers to identify different types of objects in a point cloud, such as cars, bikes, and pedestrians.
For this task type, the *data object* that workers label is a single point cloud frame. Ground Truth renders a 3D point cloud using point cloud data you provide. You can also provide camera data to give workers more visual information about scenes in the frame, and to help workers draw 3D cuboids around objects.

Ground Truth provides workers with tools to annotate objects with 9 degrees of freedom \((x,y,z,rx,ry,rz,l,w,h)\) in three dimensions in both 3D scene and projected side views (top, side, and back). If you provide sensor fusion information (like camera data), when a worker adds a cuboid to identify an object in the 3D point cloud, the cuboid shows up and can be modified in the 2D images. After a cuboid has been added, all edits made to that cuboid in the 2D or 3D scene are projected into the other view.

You can create a job to adjust annotations created in a 3D point cloud object detection labeling job using the 3D point cloud object detection adjustment task type.

If you are a new user of the Ground Truth 3D point cloud labeling modality, we recommend you review 3D Point Cloud Labeling Jobs Overview (p. 468). This labeling modality is different from other Ground Truth task types, and this page provides an overview of important details you should be aware of when creating a 3D point cloud labeling job.

**Topics**

- View the Worker Task Interface (p. 444)
- Create a 3D Point Cloud Object Detection Labeling Job (p. 448)
- Create a 3D Point Cloud Object Detection Adjustment or Verification Labeling Job (p. 449)
- Output Data Format (p. 450)

**View the Worker Task Interface**

Ground Truth provides workers with a web portal and tools to complete your 3D point cloud object detection annotation tasks. When you create the labeling job, you provide the Amazon Resource Name (ARN) for a pre-built Ground Truth worker UI in the `HumanTaskUiArn` parameter. When you create a labeling job using this task type in the console, this worker UI is automatically used. You can preview and interact with the worker UI when you create a labeling job in the console. If you are a new user, it is recommended that you create a labeling job using the console to ensure your label attributes, point cloud frames, and if applicable, images, appear as expected.

The following is a GIF of the 3D point cloud object detection worker task interface. If you provide camera data for sensor fusion in the world coordinate system, images are matched up with scenes in the point cloud frame. These images appear in the worker portal as shown in the following GIF.
Hello, chopt@amazon.com

**Shortcuts**

- **Double click on the point cloud to zoom in**
- **Double click on the label ID to zoom in the object on point cloud.**

**3D Cuboid Controls**

When you are in Edit Cuboid mode

- **C**  Create
- **V**  Edit
- **Cmd + Drag**  Change dimension
- **Option + Drag**  Move cuboid
- **Option + O**  Fit label to points
- **Option + G**  Set to ground
- **Shift + Drag**  Rotate cuboid
- **[**  Previous label
- **]**  Next label
- **Cmd + ,**  Toggle show/hide label
Worker can navigate in the 3D scene using their keyboard and mouse. They can:

- Double click on specific objects in the point cloud to zoom into them.
- Use a mouse-scroller or trackpad to zoom in and out of the point cloud.
- Use both keyboard arrow keys and Q, E, A, and D keys to move Up, Down, Left, Right. Use keyboard keys W and S to zoom in and out.

Once a worker places a cuboid in the 3D scene, a side-view will appear with the three projected side views: top, side, and back. These side-views show points in and around the placed cuboid and help workers refine cuboid boundaries in that area. Workers can zoom in and out of each of those side-views using their mouse.

The following video demonstrates movements around the 3D point cloud and in the side-view.
Additional view options and features are available in the View menu in the worker UI. See the worker instruction page for a comprehensive overview of the Worker UI.

**Assistive Labeling Tools**

Ground Truth helps workers annotate 3D point clouds faster and more accurately using machine learning and computer vision powered assistive labeling tools for 3D point cloud object tracking tasks. The following assistive labeling tools are available for this task type:

- **Snapping** – Workers can add a cuboid around an object and use a keyboard shortcut or menu option to have Ground Truth's autofit tool snap the cuboid tightly around the object.
- **Set to ground** – After a worker adds a cuboid to the 3D scene, the worker can automatically snap the cuboid to the ground. For example, the worker can use this feature to snap a cuboid to the road or sidewalk in the scene.
- **Multi-view labeling** – After a worker adds a 3D cuboid to the 3D scene, a side panel displays front, side, and top perspectives to help the worker adjust the cuboid tightly around the object. In all of these views, the cuboid includes an arrow that indicates the orientation, or heading of the object. When the worker adjusts the cuboid, the adjustment will appear in real time on all of the views (that is, 3D, top, side, and front).
- **Sensor fusion** – If you provide data for sensor fusion, workers can adjust annotations in the 3D scenes and in 2D images, and the annotations will be projected into the other view in real time. Additionally, workers will have the option to view the direction the camera is facing and the camera frustum.
- **View options** – Enables workers to easily hide or view cuboids, label text, a ground mesh, and additional point attributes like color or intensity. Workers can also choose between perspective and orthogonal projections.

**Create a 3D Point Cloud Object Detection Labeling Job**

You can create a 3D point cloud labeling job using the SageMaker console or API operation, `CreateLabelingJob`. To create a labeling job for this task type you need the following:

- A single-frame input manifest file. To learn how to create this type of manifest file, see Create a Point Cloud Frame Input Manifest File (p. 586). If you are a new user of Ground Truth 3D point cloud labeling modalities, you may also want to review Accepted Raw 3D Data Formats (p. 584).
- A work team from a private or vendor workforce. You cannot use Amazon Mechanical Turk for video frame labeling jobs. To learn how to create workforces and work teams, see Create and Manage Workforces (p. 694).

Additionally, make sure that you have reviewed and satisfied the Assign IAM Permissions to Use Ground Truth (p. 650).

Use one of the following sections to learn how to create a labeling job using the console or an API.

**Create a Labeling Job (Console)**

You can follow the instructions Create a Labeling Job (Console) (p. 544) in order to learn how to create a 3D point cloud object detection labeling job in the SageMaker console. While you are creating your labeling job, be aware of the following:

- Your input manifest file must be a single-frame manifest file. For more information, see Create a Point Cloud Frame Input Manifest File (p. 586).
- Optionally, you can provide label category and frame attributes. Workers can assign one or more of these attributes to annotations to provide more information about that object. For example, you might want to use the attribute occluded to have workers identify when an object is partially obstructed.
• Automated data labeling and annotation consolidation are not supported for 3D point cloud labeling tasks.

• 3D point cloud object detection labeling jobs can take multiple hours to complete. You can specify a longer time limit for these labeling jobs when you select your work team (up to 7 days, or 604800 seconds).

Create a Labeling Job (API)

This section covers details you need to know when you create a labeling job using the SageMaker API operation CreateLabelingJob. This API defines this operation for all AWS SDKs. To see a list of language-specific SDKs supported for this operation, review the See Also section of CreateLabelingJob.

Create a Labeling Job (API) (p. 547), provides an overview of the CreateLabelingJob operation. Follow these instructions and do the following while you configure your request:

• You must enter an ARN for HumanTaskUiArn. Use arn:aws:sagemaker:<region>:394669845002:human-task-ui/PointCloudObjectDetection. Replace <region> with the AWS Region you are creating the labeling job in.

  There should not be an entry for the UiTemplateS3Uri parameter.

• Your input manifest file must be a single-frame manifest file. For more information, see Create a Point Cloud Frame Input Manifest File (p. 586).

• You specify your labels, label category and frame attributes, and worker instructions in a label category configuration file. To learn how to create this file, see Create a Labeling Category Configuration File with Label Category and Frame Attributes (p. 557).

• You need to provide pre-defined ARNs for the pre-annotation and post-annotation (ACS) Lambda functions. These ARNs are specific to the AWS Region you use to create your labeling job.

  To find the pre-annotation Lambda ARN, refer to PreHumanTaskLambdaArn. Use the Region you are creating your labeling job in to find the correct ARN. For example, if you are creating your labeling job in us-east-1, the ARN will be arn:aws:lambda:us-east-1:432418664414:function:PRE-3DPointCloudObjectDetection.

  To find the post-annotation Lambda ARN, refer to AnnotationConsolidationLambdaArn. Use the Region you are creating your labeling job in to find the correct ARN. For example, if you are creating your labeling job in us-east-1, the ARN will be arn:aws:lambda:us-east-1:432418664414:function:ACS-3DPointCloudObjectDetection.

• The number of workers specified in NumberOfHumanWorkersPerDataObject must be 1.

• Automated data labeling is not supported for 3D point cloud labeling jobs. You should not specify values for parameters in LabelingJobAlgorithmsConfig.

• 3D point cloud object detection labeling jobs can take multiple hours to complete. You can specify a longer time limit for these labeling jobs in TaskTimeLimitInSeconds (up to 7 days, or 604,800 seconds).

Create a 3D Point Cloud Object Detection Adjustment or Verification Labeling Job

You can create an adjustment or verification labeling job using the Ground Truth console or CreateLabelingJob API. To learn more about adjustment and verification labeling jobs, and to learn how create one, see Verify and Adjust Labels (p. 502).

When you create an adjustment labeling job, your input data to the labeling job can include labels, and yaw, pitch, and roll measurements from a previous labeling job or external source. In the adjustment job, pitch, and roll will be visualized in the worker UI, but cannot be modified. Yaw is adjustable.
Ground Truth uses Tait-Bryan angles with the following intrinsic rotations to visualize yaw, pitch and roll in the worker UI. First, rotation is applied to the vehicle according to the z-axis (yaw). Next, the rotated vehicle is rotated according to the intrinsic y’-axis (pitch). Finally, the vehicle is rotated according to the intrinsic x’’-axis (roll).

**Output Data Format**

When you create a 3D point cloud object detection labeling job, tasks are sent to workers. When these workers complete their tasks, labels are written to the Amazon S3 bucket you specified when you created the labeling job. The output data format determines what you see in your Amazon S3 bucket when your labeling job status (`LabelingJobStatus`) is `Completed`.

If you are a new user of Ground Truth, see [Output Data](p. 614) to learn more about the Ground Truth output data format. To learn about the 3D point cloud object detection output data format, see [3D Point Cloud Object Detection Output](p. 632).

### 3D Point Cloud Object Tracking

Use this task type when you want workers to add and fit 3D cuboids around objects to track their movement across 3D point cloud frames. For example, you can use this task type to ask workers to track the movement of vehicles across multiple point cloud frames.

For this task type, the data object that workers label is a sequence of point cloud frames. A **sequence** is defined as a temporal series of point cloud frames. Ground Truth renders a series of 3D point cloud visualizations using a sequence you provide and workers can switch between these 3D point cloud frames in the worker task interface.

Ground Truth provides workers with tools to annotate objects with 9 degrees of freedom: \((x,y,z,rx,ry,rz,l,w,h)\) in three dimensions in both 3D scene and projected side views (top, side, and back). When a worker draws a cuboid around an object, that cuboid is given a unique ID, for example `Car:1` for one car in the sequence and `Car:2` for another. Workers use that ID to label the same object in multiple frames.

You can also provide camera data to give workers more visual information about scenes in the frame, and to help workers draw 3D cuboids around objects. When a worker adds a 3D cuboid to identify an object in either the 2D image or the 3D point cloud, and the cuboid shows up in the other view.

You can adjust annotations created in a 3D point cloud object detection labeling job using the 3D point cloud object tracking adjustment task type.

If you are a new user of the Ground Truth 3D point cloud labeling modality, we recommend you review [3D Point Cloud Labeling Jobs Overview](p. 468). This labeling modality is different from other Ground Truth task types, and this page provides an overview of important details you should be aware of when creating a 3D point cloud labeling job.

**Topics**

- [View the Worker Task Interface](p. 450)
- [Create a 3D Point Cloud Object Tracking Labeling Job](p. 458)
- [Create a 3D Point Cloud Object Tracking Adjustment or Verification Labeling Job](p. 459)
- [Output Data Format](p. 459)

**View the Worker Task Interface**

Ground Truth provides workers with a web portal and tools to complete your 3D point cloud object tracking annotation tasks. When you create the labeling job, you provide the Amazon Resource Name
(ARN) for a pre-built Ground Truth UI in the HumanTaskUiArn parameter. When you create a labeling job using this task type in the console, this UI is automatically used. You can preview and interact with the worker UI when you create a labeling job in the console. If you are a new user, it is recommended that you create a labeling job using the console to ensure your label attributes, point cloud frames, and if applicable, images, appear as expected.

The following is a GIF of the 3D point cloud object tracking worker task interface and demonstrates how the worker can navigate the point cloud frames in the sequence. The annotating tools are a part of the worker task interface. They are not available for the preview interface.
Once workers add a single cuboid, that cuboid is replicated in all frames of the sequence with the same ID. Once workers adjust the cuboid in another frame, Ground Truth will interpolate the movement of that object and adjust all cuboids between the manually adjusted frames. The following GIF demonstrates this interpolation feature. In the navigation bar on the bottom-left, red-areas indicate manually adjusted frames.

If you provide camera data for sensor fusion, images are matched up with scenes in point cloud frames. These images appear in the worker portal as shown in the following GIF.

Worker can navigate in the 3D scene using their keyboard and mouse. They can:

• Double click on specific objects in the point cloud to zoom into them.
• Use a mouse-scroller or trackpad to zoom in and out of the point cloud.
• Use both keyboard arrow keys and Q, E, A, and D keys to move Up, Down, Left, Right. Use keyboard keys W and S to zoom in and out.

Once a worker places a cuboids in the 3D scene, a side-view will appear with the three projected side views: top, side, and back. These side-views show points in and around the placed cuboid and help workers refine cuboid boundaries in that area. Workers can zoom in and out of each of those side-views using their mouse.

The following video demonstrates movements around the 3D point cloud and in the side-view.
Additional view options and features are available. See the worker instruction page for a comprehensive overview of the Worker UI.

Worker Tools

Workers can navigate through the 3D point cloud by zooming in and out, and moving in all directions around the cloud using the mouse and keyboard shortcuts. If workers click on a point in the point cloud, the UI will automatically zoom into that area. Workers can use various tools to draw 3D cuboid around objects. For more information, see Assistive Labeling Tools.

After workers have placed a 3D cuboid in the point cloud, they can adjust these cuboids to fit tightly around cars using a variety of views: directly in the 3D cuboid, in a side-view featuring three zoomed-in perspectives of the point cloud around the box, and if you include images for sensor fusion, directly in the 2D image.

View options that enable workers to easily hide or view label text, a ground mesh, and additional point attributes. Workers can also choose between perspective and orthogonal projections.

Assistive Labeling Tools

Ground Truth helps workers annotate 3D point clouds faster and more accurately using UX, machine learning and computer vision powered assistive labeling tools for 3D point cloud object tracking tasks. The following assistive labeling tools are available for this task type:

- **Label autofill** – When a worker adds a cuboid to a frame, a cuboid with the same dimensions and orientation is automatically added to all frames in the sequence.
- **Label interpolation** – After a worker has labeled a single object in two frames, Ground Truth uses those annotations to interpolate the movement of that object between those two frames.
- **Bulk label and attribute management** – Workers can add, delete, and rename annotations, label category attributes, and frame attributes in bulk.
  - Workers can manually delete annotations for a given object before or after a frame. For example, a worker can delete all labels for an object after frame 10 if that object is no longer located in the scene after that frame.
  - If a worker accidentally bulk deletes all annotations for an object, they can add them back. For example, if a worker deletes all annotations for an object before frame 100, they can bulk add them to those frames.
  - Workers can rename a label in one frame and all 3D cuboids assigned that label are updated with the new name across all frames.
  - Workers can use bulk editing to add or edit label category attributes and frame attributes in multiple frames.
- **Snapping** – Workers can add a cuboid around an object and use a keyboard shortcut or menu option to have Ground Truth's autofit tool snap the cuboid tightly around the object's boundaries.
- **Fit to ground** – After a worker adds a cuboid to the 3D scene, the worker can automatically snap the cuboid to the ground. For example, the worker can use this feature to snap a cuboid to the road or sidewalk in the scene.
- **Multi-view labeling** – After a worker adds a 3D cuboid to the 3D scene, a side-panel displays front and two side perspectives to help the worker adjust the cuboid tightly around the object. Workers can annotation the 3D point cloud, the side panel and the adjustments appear in the other views in real time.
- **Sensor fusion** – If you provide data for sensor fusion, workers can adjust annotations in the 3D scenes and in 2D images, and the annotations will be projected into the other view in real time.
- **Auto-merge cuboids** – Workers can automatically merge two cuboids across all frames if they determine that cuboids with different labels actually represent a single object.
- **View options** – Enables workers to easily hide or view label text, a ground mesh, and additional point attributes like color or intensity. Workers can also choose between perspective and orthogonal projections.
Create a 3D Point Cloud Object Tracking Labeling Job

You can create a 3D point cloud labeling job using the SageMaker console or API operation, `CreateLabelingJob`. To create a labeling job for this task type you need the following:

- A sequence input manifest file. To learn how to create this type of manifest file, see Create a Point Cloud Sequence Input Manifest (p. 592). If you are a new user of Ground Truth 3D point cloud labeling modalities, we recommend that you review Accepted Raw 3D Data Formats (p. 584).
- A work team from a private or vendor workforce. You cannot use Amazon Mechanical Turk for 3D point cloud labeling jobs. To learn how to create workforces and work teams, see Create and Manage Workforces (p. 694).

Additionally, make sure that you have reviewed and satisfied the Assign IAM Permissions to Use Ground Truth (p. 650).

To learn how to create a labeling job using the console or an API, see the following sections.

Create a Labeling Job (API)

This section covers details you need to know when you create a labeling job using the SageMaker API operation `CreateLabelingJob`. This API defines this operation for all AWS SDKs. To see a list of language-specific SDKs supported for this operation, review the See Also section of `CreateLabelingJob`.

`Create a Labeling Job (API)` (p. 547) provides an overview of the `CreateLabelingJob` operation. Follow these instructions and do the following while you configure your request:

- You must enter an ARN for `HumanTaskUiArn`. Use 
  `arn:aws:sagemaker:<region>:394669845002:human-task-ui/PointCloudObjectTracking`. Replace `<region>` with the AWS Region you are creating the labeling job in.

  There should not be an entry for the `UiTemplateS3Uri` parameter.
- Your `LabelAttributeName` must end in `-ref`. For example, `ot-labels-ref`.
- Your input manifest file must be a point cloud frame sequence manifest file. For more information, see Create a Point Cloud Sequence Input Manifest (p. 592).
- You specify your labels, label category and frame attributes, and worker instructions in a label category configuration file. For more information, see Create a Labeling Category Configuration File with Label Category and Frame Attributes (p. 557) to learn how to create this file.
- You need to provide pre-defined ARNs for the pre-annotation and post-annotation (ACS) Lambda functions. These ARNs are specific to the AWS Region you use to create your labeling job.
  - To find the pre-annotation Lambda ARN, refer to `PreHumanTaskLambdaArn`. Use the Region you are creating your labeling job in to find the correct ARN that ends with `PRE-3DPointCloudObjectTracking`.
  - To find the post-annotation Lambda ARN, refer to `AnnotationConsolidationLambdaArn`. Use the Region you are creating your labeling job in to find the correct ARN that ends with `ACS-3DPointCloudObjectTracking`.
- The number of workers specified in `NumberOfHumanWorkersPerDataObject` should be 1.
- Automated data labeling is not supported for 3D point cloud labeling jobs. You should not specify values for parameters in `LabelingJobAlgorithmsConfig`.
- 3D point cloud object tracking labeling jobs can take multiple hours to complete. You can specify a longer time limit for these labeling jobs in `TaskTimeLimitInSeconds` (up to 7 days, or 604,800 seconds).
Create a Labeling Job (Console)

You can follow the instructions Create a Labeling Job (Console) (p. 544) in order to learn how to create a 3D point cloud object tracking labeling job in the SageMaker console. While you are creating your labeling job, be aware of the following:

- Your input manifest file must be a sequence manifest file. For more information, see Create a Point Cloud Sequence Input Manifest (p. 592).
- Optionally, you can provide label category attributes. Workers can assign one or more of these attributes to annotations to provide more information about that object. For example, you might want to use the attribute occluded to have workers identify when an object is partially obstructed.
- Automated data labeling and annotation consolidation are not supported for 3D point cloud labeling tasks.
- 3D point cloud object tracking labeling jobs can take multiple hours to complete. You can specify a longer time limit for these labeling jobs when you select your work team (up to 7 days, or 604800 seconds).

Create a 3D Point Cloud Object Tracking Adjustment or Verification Labeling Job

You can create an adjustment and verification labeling job using the Ground Truth console or CreateLabelingJob API. To learn more about adjustment and verification labeling jobs, and to learn how create one, see Verify and Adjust Labels (p. 502).

When you create an adjustment labeling job, your input data to the labeling job can include labels, and yaw, pitch, and roll measurements from a previous labeling job or external source. In the adjustment job, pitch, and roll will be visualized in the worker UI, but cannot be modified. Yaw is adjustable.

Ground Truth uses Tait-Bryan angles with the following intrinsic rotations to visualize yaw, pitch and roll in the worker UI. First, rotation is applied to the vehicle according to the z-axis (yaw). Next, the rotated vehicle is rotated according to the intrinsic y'-axis (pitch). Finally, the vehicle is rotated according to the intrinsic x''-axis (roll).

Output Data Format

When you create a 3D point cloud object tracking labeling job, tasks are sent to workers. When these workers complete their tasks, their annotations are written to the Amazon S3 bucket you specified when you created the labeling job. The output data format determines what you see in your Amazon S3 bucket when your labeling job status (LabelingJobStatus) is Completed.

If you are a new user of Ground Truth, see Output Data (p. 614) to learn more about the Ground Truth output data format. To learn about the 3D point cloud object tracking output data format, see 3D Point Cloud Object Tracking Output (p. 634).

3D Point Cloud Semantic Segmentation

Semantic segmentation involves classifying individual points of a 3D point cloud into pre-specified categories. Use this task type when you want workers to create a point-level semantic segmentation mask for 3D point clouds. For example, if you specify the classes car, pedestrian, and bike, workers select one class at a time, and color all of the points that this class applies to the same color in the point cloud.

For this task type, the data object that workers label is a single point cloud frame. Ground Truth generates a 3D point cloud visualization using point cloud data you provide. You can also provide camera data to give workers more visual information about scenes in the frame, and to help workers paint objects. When a worker paints an object in either the 2D image or the 3D point cloud, the paint shows up in the other view.
You can adjust annotations created in a 3D point cloud object detection labeling job using the 3D point cloud semantic segmentation adjustment task type.

If you are a new user of the Ground Truth 3D point cloud labeling modality, we recommend you review 3D Point Cloud Labeling Jobs Overview (p. 468). This labeling modality is different from other Ground Truth task types, and this topic provides an overview of important details you should be aware of when creating a 3D point cloud labeling job.

**Topics**

- View the Worker Task Interface (p. 460)
- Create a 3D Point Cloud Semantic Segmentation Labeling Job (p. 466)
- Create a 3D Point Cloud Semantic Segmentation Adjustment or Verification Labeling Job (p. 467)
- Output Data Format (p. 467)

**View the Worker Task Interface**

Ground Truth provides workers with a web portal and tools to complete your 3D point cloud semantic segmentation annotation tasks. When you create the labeling job, you provide the Amazon Resource Name (ARN) for a pre-built Ground Truth UI in the HumanTaskUiArn parameter. When you create a labeling job using this task type in the console, this UI is automatically used. You can preview and interact with the worker UI when you create a labeling job in the console. If you are a new user, it is recommended that you create a labeling job using the console to ensure your label attributes, point cloud frames, and if applicable, images, appear as expected.

The following is a GIF of the 3D point cloud semantic segmentation worker task interface. If you provide camera data for sensor fusion, images are matched with scenes in the point cloud frame. Workers can paint objects in either the 3D point cloud or the 2D image, and the paint appears in the corresponding location in the other medium. These images appear in the worker portal as shown in the following GIF.
Worker can navigate in the 3D scene using their keyboard and mouse. They can:

- Double click on specific objects in the point cloud to zoom into them.
- Use a mouse-scroller or trackpad to zoom in and out of the point cloud.
- Use both keyboard arrow keys and Q, E, A, and D keys to move Up, Down, Left, Right. Use keyboard keys W and S to zoom in and out.

The following video demonstrates movements around the 3D point cloud. Workers can hide and re-expand all side views and menus. In this GIF, the side-views and menus have been collapsed.
The following GIF demonstrates how a worker can label multiple objects quickly, refine painted objects using the Unpaint option and then view only points that have been painted.
Additionally, make sure that you have reviewed and satisfied the Assign IAM Permissions to Use Ground Truth (p. 650).

Use one of the following sections to learn how to create a labeling job using the console or an API.

Create a Labeling Job (Console)

You can follow the instructions Create a Labeling Job (Console) (p. 544) in order to learn how to create a 3D point cloud semantic segmentation labeling job in the SageMaker console. While you are creating your labeling job, be aware of the following:

- Your input manifest file must be a single-frame manifest file. For more information, see Create a Point Cloud Frame Input Manifest File (p. 586).
- Automated data labeling and annotation consolidation are not supported for 3D point cloud labeling tasks.
- 3D point cloud semantic segmentation labeling jobs can take multiple hours to complete. You can specify a longer time limit for these labeling jobs when you select your work team (up to 7 days, or 604800 seconds).
Create a Labeling Job (API)

This section covers details you need to know when you create a labeling job using the SageMaker API operation CreateLabelingJob. This API defines this operation for all AWS SDKs. To see a list of language-specific SDKs supported for this operation, review the See Also section of CreateLabelingJob.

The page, Create a Labeling Job (API) (p. 547), provides an overview of the CreateLabelingJob operation. Follow these instructions and do the following while you configure your request:

- You must enter an ARN for HumanTaskUiArn. Use arn:aws:sagemaker:<region>:394669845002:human-task-ui/PointCloudSemanticSegmentation. Replace <region> with the AWS Region you are creating the labeling job in.

  There should not be an entry for the UiTemplateS3Uri parameter.

- Your LabelAttributeName must end in -ref. For example, ss-labels-ref.

- Your input manifest file must be a single-frame manifest file. For more information, see Create a Point Cloud Frame Input Manifest File (p. 586).

- You specify your labels and worker instructions in a label category configuration file. See Create a Labeling Category Configuration File with Label Category and Frame Attributes (p. 557) to learn how to create this file.

- You need to provide a pre-defined ARNs for the pre-annotation and post-annotation (ACS) Lambda functions. These ARNs are specific to the AWS Region you use to create your labeling job.

  To find the pre-annotation Lambda ARN, refer to PreHumanTaskLambdaArn. Use the Region you are creating your labeling job in to find the correct ARN. For example, if you are creating your labeling job in us-east-1, the ARN will be arn:aws:lambda:us-east-1:432418664414:function:PRE-3DPointCloudSemanticSegmentation.

  To find the post-annotation Lambda ARN, refer to AnnotationConsolidationLambdaArn. Use the Region you are creating your labeling job in to find the correct ARN. For example, if you are creating your labeling job in us-east-1, the ARN will be arn:aws:lambda:us-east-1:432418664414:function:ACS-3DPointCloudSemanticSegmentation.

- The number of workers specified in NumberOfHumanWorkersPerDataObject should be 1.

- Automated data labeling is not supported for 3D point cloud labeling jobs. You should not specify values for parameters in LabelingJobAlgorithmsConfig.

- 3D point cloud semantic segmentation labeling jobs can take multiple hours to complete. You can specify a longer time limit for these labeling jobs in TaskTimeLimitInSeconds (up to 7 days, or 604800 seconds).

Create a 3D Point Cloud Semantic Segmentation Adjustment or Verification Labeling Job

You can create an adjustment and verification labeling job using the Ground Truth console or CreateLabelingJob API. To learn more about adjustment and verification labeling jobs, and to learn how to create one, see Verify and Adjust Labels (p. 502).

Output Data Format

When you create a 3D point cloud semantic segmentation labeling job, tasks are sent to workers. When these workers complete their tasks, their annotations are written to the Amazon S3 bucket you specified when you created the labeling job. The output data format determines what you see in your Amazon S3 bucket when your labeling job status (LabelingJobStatus) is Completed.

If you are a new user of Ground Truth, see Output Data (p. 614) to learn more about the Ground Truth output data format. To learn about the 3D point cloud object detection output data format, see 3D Point Cloud Semantic Segmentation Output (p. 630).
3D Point Cloud Labeling Jobs Overview

This topic provides an overview of the unique features of a Ground Truth 3D point cloud labeling job. You can use the 3D point cloud labeling jobs to have workers label objects in a 3D point cloud generated from a 3D sensors like LiDAR and depth cameras or generated from 3D reconstruction by stitching images captured by an agent like a drone.

Job Pre-processing Time

When you create a 3D point cloud labeling job, you need to provide an input manifest file (p. 584). The input manifest file can be:

- A frame input manifest file that has a single point cloud frame on each line.
- A sequence input manifest file that has a single sequence on each line. A sequence is defined as a temporal series of point cloud frames.

For both types of manifest files, job pre-processing time (that is, the time before Ground Truth starts sending tasks to your workers) depends on the total number and size of point cloud frames you provide in your input manifest file. For frame input manifest files, this is the number of lines in your manifest file. For sequence manifest files, this is the number of frames in each sequence multiplied by the total number of sequences, or lines, in your manifest file.

Additionally, the number of points per point cloud and the number of fused sensor data objects (like images) factor into job pre-processing times. On average, Ground Truth can pre-process 200 point cloud frames in approximately 5 minutes. If you create a 3D point cloud labeling job with a large number of point cloud frames, you might experience longer job pre-processing times. For example, if you create a sequence input manifest file with 4 point cloud sequences, and each sequence contains 200 point clouds, Ground Truth pre-processes 800 point clouds and so your job pre-processing time might be around 20 minutes. During this time, your labeling job status is InProgress.

While your 3D point cloud labeling job is pre-processing, you receive CloudWatch messages notifying you of the status of your job. To identify these messages, search for 3D_POINT_CLOUD_PROCESSING_STATUS in your labeling job logs.

For frame input manifest files, your CloudWatch logs will have a message similar to the following:

```
{
    "labeling-job-name": "example-point-cloud-labeling-job",
    "event-name": "3D_POINT_CLOUD_PROCESSING_STATUS",
    "event-log-message": "datasetObjectId from: 0 to 10, status: IN_PROGRESS"
}
```

The event log message, datasetObjectId from: 0 to 10, status: IN_PROGRESS identifies the number of frames from your input manifest that have been processed. You receive a new message every time a frame has been processed. For example, after a single frame has processed, you receive another message that says datasetObjectId from: 1 to 10, status: IN_PROGRESS.

For sequence input manifest files, your CloudWatch logs will have a message similar to the following:

```
{
    "labeling-job-name": "example-point-cloud-labeling-job",
    "event-name": "3D_POINT_CLOUD_PROCESSING_STATUS",
    "event-log-message": "datasetObjectId: 0, status: IN_PROGRESS"
}
```

The event log message, datasetObjectId from: 0, status: IN_PROGRESS identifies the number of sequences from your input manifest that have been processed. You receive a new message every
time a sequence has been processed. For example, after a single sequence has processed, you receive a message that says datasetObjectId from: 1, status: IN_PROGRESS as the next sequence begins processing.

**Job Completion Times**

3D point cloud labeling jobs can take workers hours to complete. You can set the total amount of time that workers can work on each task when you create a labeling job. The maximum time you can set for workers to work on tasks is 7 days. The default value is 3 days.

It is strongly recommended that you create tasks that workers can complete within 12 hours. Workers must keep the worker UI open while working on a task. They can save work as they go and Ground Truth will save their work every 15 minutes.

When using the SageMaker CreateLabelingJob API operation, set the total time a task is available to workers in the TaskTimeLimitInSeconds parameter of HumanTaskConfig.

When you create a labeling job in the console, you can specify this time limit when you select your workforce type and your work team.

**Workforces**

When you create a 3D point cloud labeling job, you need to specify a work team that will complete your point cloud annotation tasks. You can choose a work team from a private workforce of your own workers, or from a vendor workforce that you select in the AWS Marketplace. You cannot use the Amazon Mechanical Turk workforce for 3D point cloud labeling jobs.

To learn more about vendor workforce, see Managing Vendor Workforces (p. 698).

To learn how to create and manage a private workforce, see Use a Private Workforce (p. 699).

**Worker User Interface (UI)**

Ground Truth provides a worker user interface (UI), tools, and assistive labeling features to help workers complete your 3D point cloud labeling tasks.

You can preview the worker UI when you create a labeling job in the console.

When you create a labeling job using the API operation CreateLabelingJob, you must provide an ARN provided by Ground Truth in the parameter HumanTaskUiArn to specify the worker UI for your task type. You can use HumanTaskUiArn with the SageMaker RenderUiTemplate API operation to preview the worker UI.

You provide worker instructions, labels, and optionally, label category attributes that are displayed in the worker UI.

**Label Category Attributes**

When you create a 3D point cloud object tracking or object detection labeling job, you can add one or more label category attributes. You can add frame attributes to all 3D point cloud task types:

- **Label category attribute** – A list of options (strings), a free form text box, or a numeric field associated with one or more labels. It is used by workers to provide metadata about a label.
- **Frame attribute** – A list of options (strings), a free form text box, or a numeric field that appears on each point cloud frame a worker is sent to annotate. It is used by workers to provide metadata about frames.

Additionally, you can use label and frame attributes to have workers verify labels in a 3D point cloud label verification job.
Use the following sections to learn more about these attributes. To learn how to add label category and frame attributes to a labeling job, use the Create Labeling Job section on the task type page of your choice.

**Label Category Attributes**

Add label category attributes to labels to give workers the ability to provide more information about the annotations they create. A label category attribute is added to an individual label, or to all labels. When a label category attribute is applied to all labels it is referred to as a *global label category attribute*.

For example, if you add the label category `car`, you might also want to capture additional data about your labeled cars, such as if they are occluded or the size of the car. You can capture this metadata using label category attributes. In this example, if you added the attribute `occluded` to the car label category, you can assign `partial`, `completely`, `no` to the `occluded` attribute and enable workers to select one of these options.

When you create a label verification job, you add labels category attributes to each label you want workers to verify.

**Frame Attributes**

Add frame attributes to give workers the ability to provide more information about individual point cloud frames. You can specify up to 10 frame attributes, and these attributes will appear on all frames.

For example, you can add a frame attribute that allows workers to enter a number. You may want to use this attribute to have workers identify the number of objects they see in a particular frame.

In another example, you may want to provide a free-form text box to give workers the ability to provide a free form answer to a question.

When you create a label verification job, you can add one or more frame attributes to ask workers to provide feedback on all labels in a point cloud frame.

**Worker Instructions**

You can provide worker instructions to help your workers complete your point cloud labeling tasks. You might want to use these instructions to do the following:

- Best practices and things to avoid when annotating objects.
- Explanation of the label category attributes provided (for object detection and object tracking tasks), and how to use them.
- Advice on how to save time while labeling by using keyboard shortcuts.

You can add your worker instructions using the SageMaker console while creating a labeling job. If you create a labeling job using the API operation `CreateLabelingJob`, you specify worker instructions in your label category configuration file.

In addition to your instructions, Ground Truth provides a link to help workers navigate and use the worker portal. View these instructions by selecting the task type on Worker Instructions (p. 471).

**Declining Tasks**

Workers are able to decline tasks.

Workers decline a task if the instructions are not clear, input data is not displaying correctly, or if they encounter some other issue with the task. If the number of workers per dataset object (`NumberOfHumanWorkersPerDataObject`) decline the task, the data object is marked as expired and will not be sent to additional workers.
3D Point Cloud Labeling Job Permission Requirements

When you create a 3D point cloud labeling job, in addition to the permission requirements found in Assign IAM Permissions to Use Ground Truth (p. 650), you must add a CORS policy to your S3 bucket that contains your input manifest file.

Add a CORS Permission Policy to S3 Bucket

When you create a 3D point cloud labeling job, you specify buckets in S3 where your input data and manifest file are located and where your output data will be stored. These buckets may be the same. You must attach the following Cross-origin resource sharing (CORS) policy to your input and output buckets. If you use the Amazon S3 console to add the policy to your bucket, you must use the JSON format.

**JSON**

```json
[
  {

Worker Instructions

This topic provides an overview of the Ground Truth worker portal and the tools available to complete your 3D Point Cloud labeling task. First, select the type of task you are working on from Topics.

For adjustment jobs, select the original labeling job task type that produced the labels you are adjusting. Review and adjust the labels in your task as needed.
Important
It is recommended that you complete your task using a Google Chrome or Firefox web browser.

Topics
• 3D Point Cloud Semantic Segmentation (p. 472)
• 3D Point Cloud Object Detection (p. 481)
• 3D Point Cloud Object Tracking (p. 491)

3D Point Cloud Semantic Segmentation
Use this page to become familiarize with the user interface and tools available to complete your 3D point cloud semantic segmentation task.

Topics
• Your Task (p. 472)
• Navigate the UI (p. 477)
• Icon Guide (p. 479)
• Shortcuts (p. 480)
• Release, Stop and Resume, and Decline Tasks (p. 480)
• Saving Your Work and Submitting (p. 481)

Your Task
When you work on a 3D point cloud semantic segmentation task, you need to select a category from the Annotations menu on the right side of your worker portal using the drop down menu Label Categories. After you've selected a category, use the paint brush and polygon tools to paint each object in the 3D point cloud that this category applies to. For example, if you select the category Car, you would use these tools to paint all of the cars in the point cloud. The following video demonstrates how to use the paint brush tool to paint an object.

If you see one or more images in your worker portal, you can paint in the images or paint in the 3D point cloud and the paint will show up in the other medium.

You may see frame attributes under the Labels menu. Use these attribute prompts to enter additional information about the point cloud.
Important
If you see that objects have already been painted when you open the task, adjust those annotations.

The following video includes an image that can be annotated. You may not see an image in your task.
After you've painted one or more objects using a label category, you can select that category from the Label Category menu on the right to only view points painted for that category.
Navigate the UI

You can navigate in the 3D scene using your keyboard and mouse. You can:

- Double click on specific objects in the point cloud to zoom into them.
- Use a mouse-scroller or trackpad to zoom in and out of the point cloud.
- Use both keyboard arrow keys and Q, E, A, and D keys to move Up, Down, Left, Right. Use keyboard keys W and S to zoom in and out.

The following video demonstrates movements around the 3D point cloud and in the side-view. You can hide and re-expand all side views using the full screen icon. In this GIF, the side-views and menus have been collapsed.
When you are in the worker UI, you see the following menus:

- **Instructions** – Review these instructions before starting your task.
- **Shortcuts** – Use this menu to view keyboard shortcuts that you can use to navigate the point cloud and use the annotation tools provided.
- **View** – Use this menu to toggle different view options on and off. For example, you can use this menu to add a ground mesh to the point cloud, and to choose the projection of the point cloud.
- **3D Point Cloud** – Use this menu to add additional attributes to the points in the point cloud, such as color, and pixel intensity. Note that some or all of these options may not be available.
- **Paint** – Use this menu to modify the functionality of the paint brush.

When you open a task, the move scene icon is on, and you can move around the point cloud using your mouse and the navigation buttons in the point cloud area of the screen. To return to the original view you see when you first opened the task, choose the reset scene icon.

After you select the paint icon, you can add paint to the point cloud and images (if included). You must select the move scene icon again to move to another area in the 3D point cloud or image.

To collapse all panels on the right and make the 3D point cloud full screen, select the full screen icon.

For the camera images and side-panels, you have the following view options:

- **C** – View the camera angle on point cloud view.
- **F** – View the frustum, or field of view, of the camera used to capture that image on point cloud view.
- **P** – View the point cloud overlaid on the image.

**Icon Guide**

Use this table to learn about the icons available in your worker task portal.

<table>
<thead>
<tr>
<th>Icon</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="brush" /></td>
<td>brush</td>
<td>Choose this icon to turn on the brush tool. To use with this tool, choose and move over the objects that you want to paint with your mouse. After you choose it, everything you paint be associated with the category you chose.</td>
</tr>
<tr>
<td><img src="image" alt="polygon" /></td>
<td>polygon</td>
<td>Choose this icon to use the polygon paint tool. Use this tool to draw polygons around objects that you want to paint. After you choose it, everything you draw a polygon around will be associated with the category you have chosen.</td>
</tr>
<tr>
<td><img src="image" alt="reset scene" /></td>
<td>reset scene</td>
<td>Choose this icon to reset the view of the point cloud, side panels, and if applicable, all images to their original position when the task was first opened.</td>
</tr>
<tr>
<td><img src="image" alt="move scene" /></td>
<td>move scene</td>
<td>Choose this icon to move the scene. By default, this icon will be selected when you first start a task.</td>
</tr>
</tbody>
</table>
Icon | Name | Description
--- | --- | ---
| | full screen | Choose this icon to make the 3D point cloud visualization full screen, and to collapse all side panels.
| | ruler | Use this icon to measure distances, in meters, in the point cloud. You may want to use this tool if your instructions ask you to annotate all objects in a given distance from the center of the cuboid or the object used to capture data.

When you select this icon, you can place the starting point (first marker) anywhere in the point cloud by selecting it with your mouse. The tool will automatically use interpolation to place a marker on the closest point within threshold distance to the location you select, otherwise the marker will be placed on ground. If you place a starting point by mistake, you can use the Escape key to revert marker placement.

After you place the first marker, you see a dotted line and a dynamic label that indicates the distance you have moved away from the first marker. Click somewhere else on the point cloud to place a second marker. When you place the second marker, the dotted line becomes solid, and the distance is set.

After you set a distance, you can edit it by selecting either marker. You can delete a ruler by selecting anywhere on the ruler and using the Delete key on your keyboard.

**Shortcuts**

The shortcuts listed in the **Shortcuts** menu can help you navigate the 3D point cloud and use the paint tool.

Before you start your task, it is recommended that you review the **Shortcuts** menu and become acquainted with these commands.

**Release, Stop and Resume, and Decline Tasks**

When you open the labeling task, three buttons on the top right allow you to decline the task (**Decline task**), release it (**Release task**), and stop and resume it at a later time (**Stop and resume later**). The following list describes what happens when you select one of these options:

- **Decline task**: You should only decline a task if something is wrong with the task, such as an issue with the 3D point cloud, images or the UI. If you decline a task, you will not be able to return to the task.
- **Release Task**: If you release a task, you loose all work done on that task. When the task is released, other workers on your team can pick it up. If enough workers pick up the task, you may not be able to return to it. When you select this button and then select **Confirm**, you are returned to the worker portal. If the task is still available, its status will be **Available**. If other workers pick it up, it will disappear from your portal.
- **Stop and resume later**: You can use the **Stop and resume later** button to stop working and return to the task at a later time. You should use the **Save** button to save your work before you select **Stop and
**resumelater.** When you select this button and then select **Confirm**, you are returned to the worker portal, and the task status is **Stopped**. You can select the same task to resume work on it.

Be aware that the person that creates your labeling tasks specifies a time limit in which all tasks must be completed by. If you do not return to and complete this task within that time limit, it will expire and your work will not be submitted. Contact your administrator for more information.

**Saving Your Work and Submitting**

You should periodically save your work. Ground Truth will automatically save your work every 15 minutes. When you open a task, you must complete your work on it before pressing **Submit**.

**3D Point Cloud Object Detection**

Use this page to become familiar with the user interface and tools available to complete your 3D point cloud object detection task.

**Topics**

- Your Task (p. 481)
- Navigate the UI (p. 483)
- Icon Guide (p. 489)
- Shortcuts (p. 490)
- Release, Stop and Resume, and Decline Tasks (p. 490)
- Saving Your Work and Submitting (p. 491)

**Your Task**

When you work on a 3D point cloud object detection task, you need to select a category from the **Annotations** menu on the right side of your worker portal using the **Label Categories** menu. After you've chosen a category, use the add cuboid and fit cuboid tools to fit a cuboid around objects in the 3D point cloud that this category applies to. After you place a cuboid, you can modify its dimensions, location, and orientation directly in the point cloud, and the three panels shown on the right.

If you see one or more images in your worker portal, you can also modify cuboids in the images or in the 3D point cloud and the edits will show up in the other medium.

If you see cuboids have already been added to the 3D point cloud when you open your task, adjust those cuboids and add additional cuboids as needed.

To edit a cuboid, including moving, re-orienting, and changing cuboid dimensions, you must use shortcut keys. You can see a full list of shortcut keys in the **Shortcuts** menu in your UI. The following are important key-combinations that you should become familiar with before starting your labeling task.

<table>
<thead>
<tr>
<th>Mac Command</th>
<th>Windows Command</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cmd + Drag</td>
<td>Ctrl + Drag</td>
<td>Modify the dimensions of the cuboid.</td>
</tr>
<tr>
<td>Option + Drag</td>
<td>Alt + Drag</td>
<td>Move the cuboid.</td>
</tr>
<tr>
<td>Shift + Drag</td>
<td>Shift + Drag</td>
<td>Rotate the cuboid.</td>
</tr>
<tr>
<td>Option + O</td>
<td>Alt + O</td>
<td>Fit the cuboid tightly around the points it has been drawn around.</td>
</tr>
</tbody>
</table>

Before using the option, make sure to save your work.
<table>
<thead>
<tr>
<th>Mac Command</th>
<th>Windows Command</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option + G</td>
<td>Alt + G</td>
<td>Set the cuboid to the ground.</td>
</tr>
</tbody>
</table>

Individual labels may have one or more label attributes. If a label has a label attribute associated with it, it will appear when you select the downward pointing arrow next to the label from the `Label Id` menu. Fill in required values for all label attributes.

You may see frame attributes under the `Labels` menu. Use these attribute prompts to enter additional information about each frame.
Navigate the UI

You can navigate in the 3D scene using your keyboard and mouse. You can:

- Double click on specific objects in the point cloud to zoom into them.
- You can use the [ and ] keys on your keyboard to zoom into and move from one label to the next. If no label is selected, when you select [ or ], the UI will zoom into the first label in the Label Id list.
- Use a mouse-scroller or trackpad to zoom in and out of the point cloud.
- Use both keyboard arrow keys and Q, E, A, and D keys to move Up, Down, Left, Right. Use keyboard keys W and S to zoom in and out.

Once you place a cuboids in the 3D scene, a side-view will appear with three projected views: top, side, and back. These side-views show points in and around the placed cuboid and help workers refine cuboid boundaries in that area. Workers can zoom in and out of each of those side-views using their mouse.

The following video demonstrates movements around the 3D point cloud and in the side-view.
When you are in the worker UI, you see the following menus:

- **Instructions** – Review these instructions before starting your task.
- **Shortcuts** – Use this menu to view keyboard shortcuts that you can use to navigate the point cloud and use the annotation tools provided.
- **Label** – Use this menu to modify a cuboid. First, select a cuboid, and then choose an option from this menu. This menu includes assistive labeling tools like setting a cuboid to the ground and automatically fitting the cuboid to the object’s boundaries.
- **View** – Use this menu to toggle different view options on and off. For example, you can use this menu to add a ground mesh to the point cloud, and to choose the projection of the point cloud.
- **3D Point Cloud** – Use this menu to add additional attributes to the points in the point cloud, such as color, and pixel intensity. Note that these options may not be available.

When you open a task, the move scene icon is on, and you can move around the point cloud using your mouse and the navigation buttons in the point cloud area of the screen. To return to the original view you see when you first opened the task, choose the reset scene icon. Resetting the view will not modify your annotations.

After you select the add cuboid icon, you can add cuboids to the 3D point cloud visualization. Once you've added a cuboid, you can adjust it in the three views (top, side, and front) and in the images (if included).
Hello, chopt@amazon.com

**Shortcuts**

Double click on the point cloud to zoom in

Double click on the label ID to zoom in the object on point cloud.

**3D Cuboid Controls**
When you are in Edit Cuboid mode

- **C** Create
- **V** Edit
- **Cmd** + **Drag** Change dimension
- **Option** + **Drag** Move cuboid
- **Option** + **O** Fit label to points
- **Option** + **G** Set to ground
- **Shift** + **Drag** Rotate cuboid
- **[** Previous label
- **]** Next label
- **Cmd** + , Toggle show/hide label
You must choose the move scene icon again to move to another area in the 3D point cloud or image.

To collapse all panels on the right and make the 3D point cloud full-screen, choose the full screen icon.

If camera images are included, you may have the following view options:

- **C** – View the camera angle on point cloud view.
- **F** – View the frustum, or field of view, of the camera used to capture that image on point cloud view.
- **P** – View the point cloud overlaid on the image.
- **B** – View cuboids in the image.

The following video demonstrates how to use these view options. The **F** option is used to view the field of view of the camera (the gray area), the **C** options shows the direction the camera is facing and angle of the camera (blue lines), and the **B** option is used to view the cuboid.
# Icon Guide

<tr>
<td><img src="image" alt="Delete Labels Icon" /></td>
<td>Delete a label.</td>
</tr>
</tbody>
</table>

**Shortcuts**

The shortcuts listed in the **Shortcuts** menu can help you navigate the 3D point cloud and use tools to add and edit cuboids.

Before you start your task, it is recommended that you review the **Shortcuts** menu and become acquainted with these commands. You need to use some of the 3D cuboid controls to edit your cuboid.

**Release, Stop and Resume, and Decline Tasks**

When you open the labeling task, three buttons on the top right allow you to decline the task (**Decline task**), release it (**Release task**), and stop and resume it at a later time (**Stop and resume later**). The following list describes what happens when you select one of these options:

- **Decline task**: You should only decline a task if something is wrong with the task, such as an issue with the 3D point cloud, images or the UI. If you decline a task, you will not be able to return to the task.

- **Release Task**: If you release a task, you loose all work done on that task. When the task is released, other workers on your team can pick it up. If enough workers pick up the task, you may not be able to return to it. When you select this button and then select **Confirm**, you are returned to the worker portal. If the task is still available, its status will be **Available**. If other workers pick it up, it will disappear from your portal.

- **Stop and resume later**: You can use the **Stop and resume later** button to stop working and return to the task at a later time. You should use the **Save** button to save your work before you select **Stop and resume later**. When you select this button and then select **Confirm**, you are returned to the worker portal, and the task status is **Stopped**. You can select the same task to resume work on it.

Be aware that the person that creates your labeling tasks specifies a time limit in which all tasks much be completed by. If you do not return to and complete this task within that time limit, it will expire and your work will not be submitted. Contact your administrator for more information.
Saving Your Work and Submitting

You should periodically save your work. Ground Truth will automatically save your work every 15 minutes.

When you open a task, you must complete your work on it before pressing **Submit**.

3D Point Cloud Object Tracking

Use this page to become familiar with the user interface and tools available to complete your 3D point cloud object detection task.

**Topics**

- Your Task (p. 491)
- Navigate the UI (p. 495)
- Bulk Edit Label Category and Frame Attributes (p. 499)
- Icon Guide (p. 500)
- Shortcuts (p. 501)
- Release, Stop and Resume, and Decline Tasks (p. 501)
- Saving Your Work and Submitting (p. 502)

Your Task

When you work on a 3D point cloud object tracking task, you need to select a category from the **Annotations** menu on the right side of your worker portal using the **Label Categories** menu. After you've selected a category, use the add cuboid and fit cuboid tools to fit a cuboid around objects in the 3D point cloud that this category applies to. After you place a cuboid, you can modify its location, dimensions, and orientation directly in the point cloud, and the three panels shown on the right. If you see one or more images in your worker portal, you can also modify cuboids in the images or in the 3D point cloud and the edits will show up in the other medium.

**Important**

If you see cuboids have already been added to the 3D point cloud frames when you open your task, adjust those cuboids and add additional cuboids as needed.

To edit a cuboid, including moving, re-orienting, and changing cuboid dimensions, you must use shortcut keys. You can see a full list of shortcut keys in the **Shortcuts** menu in your UI. The following are important key-combinations that you should become familiar with before starting your labeling task.

<table>
<thead>
<tr>
<th>Mac Command</th>
<th>Windows Command</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cmd + Drag</td>
<td>Ctrl + Drag</td>
<td>Modify the dimensions of the cuboid.</td>
</tr>
<tr>
<td>Option + Drag</td>
<td>Alt + Drag</td>
<td>Move the cuboid.</td>
</tr>
<tr>
<td>Shift + Drag</td>
<td>Shift + Drag</td>
<td>Rotate the cuboid.</td>
</tr>
<tr>
<td>Option + O</td>
<td>Alt + O</td>
<td>Fit the cuboid tightly around the points it has been drawn around.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Before using the option, make sure the cuboid fully-surrounds the object of interest.</td>
</tr>
<tr>
<td>Option + G</td>
<td>Alt + G</td>
<td>Set the cuboid to the ground.</td>
</tr>
</tbody>
</table>
When you open your task, two frames will be loaded. If your task includes more than two frames, you need to use the navigation bar in the lower-left corner, or the load frames icon to load additional frames. You should annotate and adjust labels in all frames before submitting.

After you fit a cuboid tightly around the boundaries of an object, navigate to another frame using the navigation bar in the lower-left corner of the UI. If that same object has moved to a new location, add another cuboid and fit it tightly around the boundaries of the object. Each time you manually add a cuboid, you see the frame sequence bar in the lower-left corner of the screen turn red where that frame is located temporally in the sequence.

Your UI automatically infers the location of that object in all other frames after you've placed a cuboid. This is called interpolation. You can see the movement of that object, and the inferred and manually created cuboids using the arrows. Adjust inferred cuboids as needed. The following video demonstrates how to navigate between frames. The following video shows how, if you add a cuboid in one frame, and then adjust it in another, your UI will automatically infer the location of the cuboid in all of the frames in-between.
Tip
You can turn off the automatic cuboid interpolation across frames using the 3D Point Cloud menu item. Select 3D Point Cloud from the top-menu, and then select Interpolate Cuboids Across Frames. This will uncheck this option and stop cuboid interpolation. You can reselect this item to turn cuboid interpolation back on.

Turning cuboid interpolation off will not impact cuboids that have already been interpolated across frames.

Individual labels may have one or more label attributes. If a label has a label attribute associated with it, it will appear when you select the downward pointing arrow next to the label from the Label Id menu. Fill in required values for all label attributes.

You may see frame attributes under the Label Id menu. These attributes will appear on each frame in your task. Use these attribute prompts to enter additional information about each frame.

![Frame 1 attributes](image)
Navigate the UI

You can navigate in the 3D scene using your keyboard and mouse. You can:

- Double click on specific objects in the point cloud to zoom into them.
- You can use the [ and ] keys on your keyboard to zoom into and move from one label to the next. If no label is selected, when you select [ or ], the UI will zoom into the first label in the Label Id list.
- Use a mouse-scroller or trackpad to zoom in and out of the point cloud.
- Use both keyboard arrow keys and Q, E, A, and D keys to move Up, Down, Left, Right. Use keyboard keys W and S to zoom in and out.

Once you place a cuboids in the 3D scene, a side-view will appear with three projected views: top, side, and back. These side-views show points in and around the placed cuboid and help workers refine cuboid boundaries in that area. Workers can zoom in and out of each of those side-views using their mouse.

The following video demonstrates movements around the 3D point cloud and in the side-view.
When you are in the worker UI, you see the following menus:

- **Instructions** – Review these instructions before starting your task.
- **Shortcuts** – Use this menu to view keyboard shortcuts that you can use to navigate the point cloud and use the annotation tools provided.
- **Label** – Use this menu to modify a cuboid. First, select a cuboid, and then choose an option from this menu. This menu includes assistive labeling tools like setting a cuboid to the ground and automatically fitting the cuboid to the object's boundaries.
- **View** – Use this menu to toggle different view options on and off. For example, you can use this menu to add a ground mesh to the point cloud, and to choose the projection of the point cloud.
- **3D Point Cloud** – Use this menu to add additional attributes to the points in the point cloud, such as color, and pixel intensity. Note that these options may not be available.

When you open a task, the move scene icon is on, and you can move around the point cloud using your mouse and the navigation buttons in the point cloud area of the screen. To return to the original view you see when you first opened the task, choose the reset scene icon.

After you select the add cuboid icon, you can add cuboids to the point cloud and images (if included). You must select the move scene icon again to move to another area in the 3D point cloud or image.

To collapse all panels on the right and make the 3D point cloud full-screen, choose the full screen icon.

If camera images are included, you may have the following view options:

- **C** – View the camera angle on point cloud view.
- **F** – View the frustum, or field of view, of the camera used to capture that image on point cloud view.
- **P** – View the point cloud overlaid on the image.
- **B** – View cuboids in the image.

The following video demonstrates how to use these view options. The **F** option is used to view the field of view of the camera (the gray area), the **C** options shows the direction the camera is facing and angle of the camera (blue lines), and the **B** option is used to view the cuboid.
Delete Cuboids

You can select a cuboid or label ID and:

- Delete an individual cuboid in the current frame you are viewing.
- Delete all cuboids with that label ID before or after the frame you are viewing.
- Delete all cuboids with that label ID in all frames.

A common use-case for cuboid deletion is if the object leaves the scene.

You can use one or more of these options to delete both manually placed and interpolated cuboids with the same label ID.

- To delete all cuboids before or after the frame you are currently on, select the cuboid, select the Label menu item at the top of the UI and then select one of Delete in previous frames or Delete in next frames. Use the Shortcuts menu to see the shortcut keys you can use for these options.
- To delete a label in all frames, select Delete in all frames from the Labels menu, or use the shortcut Shift + Delete on your keyboard.
- To delete an individual cuboid from a single frame, select the cuboid and either select the trashcan icon next to that label ID in the Label ID sidebar on the right or use the Delete key on your keyboard to delete that cuboid.

If you have manually placed more than one cuboid with the same label in different frames, when you delete one of the manually placed cuboids, all interpolated cuboids adjust. This adjustment happens because the UI uses manually placed cuboids as anchor points when calculating the location of interpolated cuboid. When you remove one of these anchor points, the UI must recalculate the position of interpolated cuboids.

If you delete a cuboid from a frame, but later decide that you want to get it back, you can use the Duplicate to previous frames or Duplicate to next frames options in the Label menu to copy the cuboid into all the previous or all of the following frames, respectively.

Bulk Edit Label Category and Frame Attributes

You can bulk edit label attributes and frame attributes.

When you bulk edit an attribute, you specify one or more ranges of frames that you want to apply the edit to. The attribute you select is edited in all frames in that range, including the start and end frames you specify. When you bulk edit label attributes, the range you specify must contain the label that the label attribute is attached to. If you specify frames that do not contain this label, you will receive an error.

To bulk edit an attribute you must specify the desired value for the attribute first. For example, if you want to change an attribute from Yes to No, you must select No, and then perform the bulk edit.

You can also specify a new value for an attribute that has not been filled in and then use the bulk edit feature to fill in that value in multiple frames. To do this, select the desired value for the attribute and complete the following procedure.

To bulk edit a label or attribute:

1. Use your mouse to right click the attribute you want to bulk edit.
2. Specify the range of frames you want to apply the bulk edit to using a dash (-) in the text box. For example, if you want to apply the edit to frames one through ten, enter 1-10. If you want to apply the edit to frames two to five, eight to ten and twenty enter 2-5, 8-10, 20.
3. Select Confirm.
If you get an error message, verify that you entered a valid range and that the label associated with the label attribute you are editing (if applicable) exists in all frames specified.

You can quickly add a label to all previous or subsequent frames using the **Duplicate to previous frames** and **Duplicate to next frames** options in the **Label** menu at the top of your screen.

### Icon Guide

Use this table to learn about the icons you see in your worker task portal.

<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>add cuboid</td>
<td>Choose this icon to add a cuboid. Each cuboid you add is associated with the category you chose.</td>
</tr>
<tr>
<td>edit cuboid</td>
<td>Choose this icon to edit a cuboid. After you add a cuboid, you can edit its dimensions, location, and orientation. After a cuboid is added, it automatically switches to edit cuboid mode.</td>
</tr>
<tr>
<td>ruler</td>
<td>Use this icon to measure distances, in meters, in the point cloud. You may want to use this tool if your instructions ask you to annotate all objects in a given distance from the center of the cuboid or the object used to capture data. When you select this icon, you can place the starting point (first marker) anywhere in the point cloud by selecting it with your mouse. The tool will automatically use interpolation to place a marker on the closest point within threshold distance to the location you select, otherwise the marker will be placed on ground. If you place a starting point by mistake, you can use the Escape key to revert marker placement. After you place the first marker, you see a dotted line and a dynamic label that indicates the distance you have moved away from the first marker. Click somewhere else on the point cloud to place a second marker. When you place the second marker, the dotted line becomes solid, and the distance is set. After you set a distance, you can edit it by selecting either marker. You can delete a ruler by selecting anywhere on the ruler and using the Delete key on your keyboard.</td>
</tr>
<tr>
<td>reset scene</td>
<td>Choose this icon to reset the view of the point cloud, side panels, and if applicable, all images to their original position when the task was first opened.</td>
</tr>
<tr>
<td>move scene</td>
<td>Choose this icon to move the scene. By default, this icon is chosen when you first start a task.</td>
</tr>
<tr>
<td>Icon</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td>![full screen icon]</td>
<td>Choose this icon to make the 3D point cloud visualization full screen and to collapse all side panels.</td>
</tr>
<tr>
<td>![load frames icon]</td>
<td>Choose this icon to load additional frames.</td>
</tr>
<tr>
<td>![hide labels icon]</td>
<td>Hide labels in the 3D point cloud visualization, and if applicable, in images.</td>
</tr>
<tr>
<td>![show labels icon]</td>
<td>Show labels in the 3D point cloud visualization, and if applicable, in images.</td>
</tr>
<tr>
<td>![delete labels icon]</td>
<td>Delete a label. This option can only be used to delete labels you have manually created or adjusted.</td>
</tr>
</tbody>
</table>

**Shortcuts**

The shortcuts listed in the **Shortcuts** menu can help you navigate the 3D point cloud and use tools to add and edit cuboids.

Before you start your task, it is recommended that you review the **Shortcuts** menu and become acquainted with these commands. You need to use some of the 3D cuboid controls to edit your cuboid.

**Release, Stop and Resume, and Decline Tasks**

When you open the labeling task, three buttons on the top right allow you to decline the task (**Decline task**), release it (**Release task**), and stop and resume it at a later time (**Stop and resume later**). The following list describes what happens when you select one of these options:

- **Decline task**: You should only decline a task if something is wrong with the task, such as an issue with the 3D point clouds, images or the UI. If you decline a task, you will not be able to return to the task.
- **Release Task**: Use this option to release a task and allow others to work on it. When you release a task, you loose all work done on that task and other workers on your team can pick it up. If enough workers pick up the task, you may not be able to return to it. When you select this button and then select **Confirm**, you are returned to the worker portal. If the task is still available, its status will be **Available**. If other workers pick it up, it will disappear from your portal.
- **Stop and resume later**: You can use the **Stop and resume later** button to stop working and return to the task at a later time. You should use the **Save** button to save your work before you select **Stop and resume later**. When you select this button and then select **Confirm**, you are returned to the worker portal, and the task status is **Stopped**. You can select the same task to resume work on it.
Verify and Adjust Labels

Be aware that the person that creates your labeling tasks specifies a time limit in which all tasks must be completed by. If you do not return to and complete this task within that time limit, it will expire and your work will not be submitted. Contact your administrator for more information.

Saving Your Work and Submitting

You should periodically save your work. Ground Truth will automatically save your work every 15 minutes. When you open a task, you must complete your work on it before pressing Submit.

Verify and Adjust Labels

When the labels on a dataset need to be validated, Amazon SageMaker Ground Truth provides functionality to have workers verify that labels are correct or to adjust previous labels.

These types of jobs fall into two distinct categories:

- **Label verification** — Workers indicate if the existing labels are correct, or rate their quality, and can add comments to explain their reasoning. Workers will not be able to modify or adjust labels.

  If you create a 3D point cloud or video frame label adjustment or verification job, you can choose to make label category attributes (not supported for 3D point cloud semantic segmentation) and frame attributes editable by workers.

- **Label adjustment** — Workers adjust prior annotations and, if applicable, label category and frame attributes to correct them.

The following Ground Truth built-in task types support adjustment and verification labeling jobs:

- Bounding box
- Semantic segmentation
- 3D point cloud object detection, 3D point cloud object tracking, and 3D point cloud semantic segmentation
- All video frame object detection and video frame object tracking task types — bounding box, polyline, polygon and keypoint

**Tip**

For 3D point cloud and video frame labeling verification jobs, it is recommended that you add new label category attributes or frame attributes to the labeling job. Workers can use these attribute to verify individual labels or the entire frame. To learn more about label category and frame attributes, see Worker User Interface (UI) (p. 469) for 3D point cloud and Worker User Interface (UI) (p. 421) for video frame.

You can start a label verification and adjustment jobs using the SageMaker console or the API.

**Topics**

- Requirements to Create Verification and Adjustment Labeling Jobs (p. 503)
- Create a Label Verification Job (Console) (p. 503)
- Create a Label Adjustment Job (Console) (p. 505)
- Start a Label Verification or Adjustment Job (API) (p. 506)
- Label Verification and Adjustment Data in the Output Manifest (p. 508)
- Cautions and Considerations (p. 509)
Verify and Adjust Labels

Requirements to Create Verification and Adjustment Labeling Jobs

To create a label verification or adjustment job, the following criteria must be satisfied.

- For non streaming labeling jobs: The input manifest file you use must contain the label attribute name (`LabelAttributeName`) of the labels that you want adjusted. When you chain a successfully completed labeling job, the output manifest file is used as the input manifest file for the new, chained job. To learn more about the format of the output manifest file Ground Truth produces for each task type, see Output Data (p. 614).

- For streaming labeling jobs: The Amazon SNS message you sent to the Amazon SNS input topic of the adjustment or verification labeling job must contain the label attribute name of the labels you want adjusted or verified. To see an example of how you can create an adjustment or verification labeling job with streaming labeling jobs, see this Jupyter Notebook example in GitHub.

- The task type of the verification or adjustment labeling job must be the same as the task type of the original job unless you are using the Image Label Verification (p. 395) task type to verify bounding box or semantic segmentation image labels. See the next bullet point for more details about the video frame task type requirements.

- For video frame annotation verification and adjustment jobs, you must use the same annotation task type used to create the annotations from the previous labeling job. For example, if you create a video frame object detection job to have workers draw bounding boxes around objects, and then you create a video object detection adjustment job, you must specify `bounding boxes` as the annotation task type. To learn more video frame annotation task types, see Task Types (p. 420).

- The task type you select for the adjustment or verification labeling job must support an audit workflow. The following Ground Truth built-in task types support adjustment and verification labeling jobs: bounding box, semantic segmentation, 3D point cloud object detection, 3D point cloud object tracking, and 3D point cloud semantic segmentation, and all video frame object detection and video frame object tracking task types — bounding box, polyline, polygon and keypoint.

Create a Label Verification Job (Console)

Bounding box and semantic segmentation labeling jobs are created by choosing the Label verification task type in the console. To create a verification job for 3D point cloud and video frame task types, you must choose the same task type as the original labeling job and choose to display existing labels. Use one of the following sections to create a label verification job for your task type.

Topics

- Create an Image Label Verification Job (Console) (p. 503)
- Create a Point Cloud or Video Frame Label Verification Job (Console) (p. 504)

Create an Image Label Verification Job (Console)

Use the following procedure to create a bounding box or semantic segmentation verification job using the console. This procedure assumes that you have already created a bounding box or semantic segmentation labeling job and its status is Complete. This the labeling job that produces the labels you want verified.

To create an image label verification job:

2. Start a new labeling job by chaining (p. 646) a prior job or start from scratch, specifying an input manifest that contains labeled data objects.
3. In the **Task type** pane, select **Label verification**.

4. Choose **Next**.

5. In the **Workers** section, choose the type of workforce you would like to use. For more details about your workforce options see [Create and Manage Workforces](p. 694).

6. (Optional) After you’ve selected your workforce, specify the **Task timeout** and **Task expiration time**.

7. In the **Existing-labels display options** pane, the system shows the available label attribute names in your manifest. Choose the label attribute name that identifies the labels that you want workers to verify. Ground Truth tries to detect and populate these values by analyzing the manifest, but you might need to set the correct value.

8. Use the instructions areas of the tool designer to provide context about what the previous labelers were asked to do and what the current verifiers need to check.

   You can add new labels that workers choose from to verify labels. For example, you can ask workers to verify the image quality, and provide the labels **Clear** and **Blurry**. Workers will also have the option to add a comment to explain their selection.

9. Choose **See preview** to check that the tool is displaying the prior labels correctly and presents the label verification task clearly.

10. Select **Create**. This will create and start your labeling job.

### Create a Point Cloud or Video Frame Label Verification Job (Console)

Use the following procedure to create a 3D point cloud or video frame verification job using the console. This procedure assumes that you have already created a labeling job using the task type that produces the types of labels you want to be verified and its status is Complete.

**To create an image label verification job:**

2. Start a new labeling job by chaining (p. 646) a prior job or start from scratch, specifying an input manifest that contains labeled data objects.

3. In the **Task type** pane, select the same task type as the labeling job that you chained. For example, if the original labeling job was a video frame object detection keypoint labeling job, select that task type.

4. Choose **Next**.

5. In the **Workers** section, choose the type of workforce you would like to use. For more details about your workforce options see [Create and Manage Workforces](p. 694).

6. (Optional) After you’ve selected your workforce, specify the **Task timeout** and **Task expiration time**.

7. Toggle on the switch next to **Display existing labels**.

8. Select **Verification**.

9. For **Label attribute name**, choose the name from your manifest that corresponds to the labels that you want to display for verification. You will only see label attribute names for labels that match the task type you selected on the previous screen. Ground Truth tries to detect and populate these values by analyzing the manifest, but you might need to set the correct value.

10. Use the instructions areas of the tool designer to provide context about what the previous labelers were asked to do and what the current verifiers need to check.

   You cannot modify or add new labels. You can remove, modify and add new label category attributes or frame attributes. It is recommended that you add new label category attributes or frame attributes to the labeling job. Workers can use these attribute to verify individual labels or the entire frame.
By default, preexisting label category attributes and frame attributes will not be editable by workers. If you want to make a label category or frame attribute editable, select the Allow workers to edit this attribute check box for that attribute.

To learn more about label category and frame attributes, see Worker User Interface (UI) (p. 469) for 3D point cloud and Worker User Interface (UI) (p. 421) for video frame.

11. Choose See preview to check that the tool is displaying the prior labels correctly and presents the label verification task clearly.

12. Select Create. This will create and start your labeling job.

Create a Label Adjustment Job (Console)

Use one of the following sections to create a label verification job for your task type.

Topics
- Create an Image Label Adjustment Job (Console) (p. 505)
- Create a Point Cloud or Video Frame Label Adjustment Job (Console) (p. 506)

Create an Image Label Adjustment Job (Console)

Use the following procedure to create a bounding box or semantic segmentation adjustment labeling job using the console. This procedure assumes that you have already created a bounding box or semantic segmentation labeling job and its status is Complete. This the labeling job that produces the labels you want adjusted.

To create an image label adjustment job (console)

2. Start a new labeling job by chaining (p. 646) a prior job or start from scratch, specifying an input manifest that contains labeled data objects.
3. Choose the same task type as the original labeling job.
4. Choose Next.
5. In the Workers section, choose the type of workforce you would like to use. For more details about your workforce options see Create and Manage Workforces (p. 694).
6. (Optional) After you've selected your workforce, specify the Task timeout and Task expiration time.
7. Expand Existing-labels display options by selecting the arrow next to the title.
8. Check the box next to I want to display existing labels from the dataset for this job.
9. For Label attribute name, choose the name from your manifest that corresponds to the labels that you want to display for adjustment. You will only see label attribute names for labels that match the task type you selected on the previous screen. Ground Truth tries to detect and populate these values by analyzing the manifest, but you might need to set the correct value.
10. Use the instructions areas of the tool designer to provide context about what the previous labelers were tasked with doing and what the current verifiers need to check and adjust.
11. Choose See preview to check that the tool shows the prior labels correctly and presents the task clearly.
12. Select Create. This will create and start your labeling job.
Create a Point Cloud or Video Frame Label Adjustment Job (Console)

Use the following procedure to create a 3D point cloud or video frame adjustment job using the console. This procedure assumes that you have already created a labeling job using the task type that produces the types of labels you want to be verified and its status is Complete.

**To create a 3D point cloud or video frame label adjustment job (console)**

1. Open the SageMaker console: https://console.aws.amazon.com/sagemaker/ and choose **Labeling jobs**.
2. Start a new labeling job by chaining (p. 646) a prior job or start from scratch, specifying an input manifest that contains labeled data objects.
3. Choose the same task type as the original labeling job.
4. Toggle on the switch next to **Display existing labels**.
5. Select **Adjustment**.
6. For **Label attribute name**, choose the name from your manifest that corresponds to the labels that you want to display for adjustment. You will only see label attribute names for labels that match the task type you selected on the previous screen. Ground Truth tries to detect and populate these values by analyzing the manifest, but you might need to set the correct value.
7. Use the instructions areas of the tool designer to provide context about what the previous labelers were asked to do and what the current adjusters need to check.
   
   You cannot remove or modify existing labels but you can add new labels. You can remove, modify and add new label category attributes or frame attributes.

   Be default, preexisting label category attributes and frame attributes will be editable by workers. If you want to make a label category or frame attribute uneditable, deselect the **Allow workers to edit this attribute** check box for that attribute.

   To learn more about label category and frame attributes, see Worker User Interface (UI) (p. 469) for 3D point cloud and Worker User Interface (UI) (p. 421) for video frame.
8. Choose **See preview** to check that the tool shows the prior labels correctly and presents the task clearly.
9. Select **Create**. This will create and start your labeling job.

Start a Label Verification or Adjustment Job (API)

Start a label verification or adjustment job by chaining a successfully completed job or starting a new job from scratch using the `CreateLabelingJob` operation. The procedure is almost the same as setting up a new labeling job with `CreateLabelingJob`, with a few modifications. Use the following sections to learn what modifications are required to chain a labeling job to create an adjustment or verification labeling job.

When you create an adjustment or verification labeling job using the Ground Truth API, you must use a different LabelAttributeName than the original labeling job. The original labeling job is the job used to create the labels you want adjusted or verified.

**Important**

The label category configuration file you identify for an adjustment or verification job in `LabelCategoryConfigS3Uri` of `CreateLabelingJob` must contain the same labels used in the original labeling job. You can add new labels. For 3D point cloud and video frame jobs, you can add new label category and frame attributes to the label category configuration file.
Bounding Box and Semantic Segmentation

To create a bounding box or semantic segmentation label verification or adjustment job, use the following guidelines to specify API attributes for the CreateLabelingJob operation.

- Use the `LabelAttributeName` parameter to specify the output label name that you want to use for verified or adjusted labels. You must use a different `LabelAttributeName` than the one used for the original labeling job.
- If you are chaining the job, the labels from the previous labeling job to be adjusted or verified will be specified in the custom UI template. To learn how to create a custom template, see Create Custom Worker Task Templates (p. 3448).

Identify the location of the UI template in the `UiTemplateS3Uri` parameter. SageMaker provides widgets that you can use in your custom template to display old labels. Use the initial-value attribute in one of the following crowd elements to extract the labels that need verification or adjustment and include them in your task template:

- `crowd-semantic-segmentation` (p. 779)—Use this crowd element in your custom UI task template to specify semantic segmentation labels that need to be verified or adjusted.
- `crowd-bounding-box` (p. 726)—Use this crowd element in your custom UI task template to specify bounding box labels that need to be verified or adjusted.

The `LabelCategoryConfigS3Uri` parameter must contain the same label categories as the previous labeling job.

- Use the bounding box or semantic segmentation adjustment or verification lambda ARNs for `PreHumanTaskLambdaArn` and `AnnotationConsolidationLambdaArn`:
  - For bounding box, the adjustment labeling job lambda function ARNs end with `AdjustmentBoundingBox` and the verification lambda function ARNs end with `VerificationBoundingBox`.
  - For semantic segmentation, the adjustment labeling job lambda function ARNs end with `AdjustmentSemanticSegmentation` and the verification lambda function ARNs end with `VerificationSemanticSegmentation`.

3D Point Cloud and Video Frame

- Use the `LabelAttributeName` parameter to specify the output label name that you want to use for verified or adjusted labels. You must use a different `LabelAttributeName` than the one used for the original labeling job.
- You must use the human task UI Amazon Resource Name (ARN) (`HumanTaskUiArn`) used for the original labeling job. To see supported ARNs, see `HumanTaskUiArn`.
- In the label category configuration file, you must specify the label attribute name (`LabelAttributeName`) of the previous labeling job that you use to create the adjustment or verification labeling job in the `auditLabelAttributeName` parameter.
- You specify whether your labeling job is a verification or adjustment labeling job using the `editsAllowed` parameter in your label category configuration file identified by the `LabelCategoryConfigS3Uri` parameter.
  - For verification labeling jobs, you must use the `editsAllowed` parameter to specify that all labels cannot be modified. `editsAllowed` must be set to "none" in each entry in `labels`. Optionally, you can specify whether or not label categories attributes and frame attributes can be adjusted by workers.
  - Optionally, for adjustment labeling jobs, you can use the `editsAllowed` parameter to specify labels, label category attributes, and frame attributes that can or cannot be modified by workers. If you do not use this parameter, all labels, label category attributes, and frame attributes will be adjustable.
To learn more about the editsAllowed parameter and configuring your label category configuration file, see Label Category Configuration File Schema (p. 557).

- Use the 3D point cloud or video frame adjustment lambda ARNs for PreHumanTaskLambdaArn and AnnotationConsolidationLambdaArn for both adjustment and verification labeling jobs:
  - For 3D point clouds, the adjustment and verification labeling job lambda function ARNs end with Adjustment3DPointCloudSemanticSegmentation, Adjustment3DPointCloudObjectTracking, and Adjustment3DPointCloudObjectDetection for 3D point cloud semantic segmentation, object detection, and object tracking respectively.
  - For video frames, the adjustment and verification labeling job lambda function ARNs end with AdjustmentVideoObjectDetection and AdjustmentVideoObjectTracking for video frame object detection and object tracking respectively.

Ground Truth stores the output data from a label verification or adjustment job in the S3 bucket that you specified in the S3OutputPath parameter of the CreateLabelingJob operation. For more information about the output data from a label verification or adjustment labeling job, see Label Verification and Adjustment Data in the Output Manifest (p. 508).

**Label Verification and Adjustment Data in the Output Manifest**

Amazon SageMaker Ground Truth writes label verification data to the output manifest within the metadata for the label. It adds two properties to the metadata:

- A type property, with a value of "groundtruth/label-verification."
- A worker-feedback property, with an array of comment values. This property is added when the worker enters comments. If there are no comments, the field doesn't appear.

The following example output manifest shows how label verification data appears:

```json
{
  "source-ref": "S3 bucket location",
  "verify-bounding-box": "1",
  "verify-bounding-box-metadata": {
    "class-name": "bad",
    "confidence": 0.93,
    "type": "groundtruth/label-verification",
    "job-name": "verify-bounding-boxes",
    "human-annotated": "yes",
    "creation-date": "2018-10-18T22:18:13.527256",
    "worker-feedback": [
      {"comment": "The bounding box on the bird is too wide on the right side."},
      {"comment": "The bird on the upper right is not labeled."}
    ]
  }
}
```

The worker output of adjustment tasks resembles the worker output of the original task, except that it contains the adjusted values and an adjustment-status property with the value of adjusted or unadjusted to indicate whether an adjustment was made.

For more examples of the output of different tasks, see Output Data (p. 614).
Cautions and Considerations

To get expected behavior when creating a label verification or adjustment job, carefully verify your input data.

- If you are using image data, verify that your manifest file contains hexadecimal RGB color information.
- To save money on processing costs, filter your data to ensure you are not including unwanted objects in your labeling job input manifest.
- Add required Amazon S3 permissions to ensure your input data is processed correctly.

When you create an adjustment or verification labeling job using the Ground Truth API, you must use a different LabelAttributeName than the original labeling job.

Color Information Requirements for Semantic Segmentation Jobs

To properly reproduce color information in verification or adjustment tasks, the tool requires hexadecimal RGB color information in the manifest (for example, #FFFFFF for white). When you set up a Semantic Segmentation verification or adjustment job, the tool examines the manifest to determine if this information is present. If it can't find it, Amazon SageMaker Ground Truth displays an error message and the ends job setup.

In prior iterations of the Semantic Segmentation tool, category color information wasn't output in hexadecimal RGB format to the output manifest. That feature was introduced to the output manifest at the same time the verification and adjustment workflows were introduced. Therefore, older output manifests aren't compatible with this new workflow.

Filter Your Data Before Starting the Job

Amazon SageMaker Ground Truth processes all objects in your input manifest. If you have a partially labeled data set, you might want to create a custom manifest using an Amazon S3 Select query on your input manifest. Unlabeled objects individually fail, but they don't cause the job to fail, and they might incur processing costs. Filtering out objects you don't want verified reduces your costs.

If you create a verification job using the console, you can use the filtering tools provided there. If you create jobs using the API, make filtering your data part of your workflow where needed.

Creating Custom Labeling Workflows

This document guides you through the process of setting up a workflow with a custom labeling template. To learn more about starting a labeling job, see Getting started (p. 371). In that section, when you choose the Task type, select Custom labeling task, and then follow this section's instructions to configure it.

Topics

- Step 1: Setting up your workforce (p. 510)
- Step 2: Creating your custom worker task template (p. 510)
- Step 3: Processing with AWS Lambda (p. 516)
- Demo Template: Annotation of Images with crowd-bounding-box (p. 530)
- Demo Template: Labeling Intents with crowd-classifier (p. 534)
- Custom Workflows via the API (p. 541)

For more information about creating custom labeling workflows, see Build a custom data labeling workflow with Amazon SageMaker Ground Truth.
Step 1: Setting up your workforce

In this step you use the console to establish which worker type to use and make the necessary sub-selections for the worker type. It assumes you have already completed the steps up to this point in the Getting started (p. 371) section and have chosen the Custom labeling task as the Task type.

To configure your workforce.

1. First choose an option from the Worker types. There are three types currently available:
   - **Public** uses an on-demand workforce of independent contractors, powered by Amazon Mechanical Turk. They are paid on a per-task basis.
   - **Private** uses your employees or contractors for handling data that needs to stay within your organization.
   - **Vendor** uses third party vendors that specialize in providing data labeling services, available via the AWS Marketplace.

2. If you choose the Public option, you are asked to set the number of workers per dataset object. Having more than one worker perform the same task on the same object can help increase the accuracy of your results. The default is three. You can raise or lower that depending on the accuracy you need.

   You are also asked to set a price per task by using a drop-down menu. The menu recommends price points based on how long it will take to complete the task.

   The recommended method to determine this is to first run a short test of your task with a private workforce. The test provides a realistic estimate of how long the task takes to complete. You can then select the range your estimate falls within on the Price per task menu. If your average time is more than 5 minutes, consider breaking your task into smaller units.

Next

Step 2: Creating your custom worker task template (p. 510)

Step 2: Creating your custom worker task template

A worker task template is a file used by Ground Truth to customize the worker user interface (UI), or human task UI. You can create a worker task template using HTML, CSS, JavaScript, Liquid template language, and Crowd HTML Elements. Liquid is used to automate the template, and Crowd HTML Elements can be used to include common annotation tools and provide the logic to submit to Ground Truth.

- Starting with a base template (p. 511)
- Developing templates locally (p. 511)
- Using External Assets (p. 511)
- Track your variables (p. 511)
- A simple sample (p. 512)
- Adding automation with Liquid (p. 513)
- End-to-end demos (p. 515)
- Next (p. 516)

Use the following topics to learn how you can create a worker task template. You can see a repository of example Ground Truth worker task templates on GitHub.
Starting with a base template

You can use a template editor in the Ground Truth console to start creating a template. This editor includes a number of pre-designed base templates and an HTML and Crowd HTML Element autofill feature.

To access the Ground Truth custom template editor:

1. Following the instructions in Create a Labeling Job (Console) (p. 544) and select Custom for the labeling job Task type.
2. When you select Next, you will be able to access the template editor and base templates in the Custom labeling task setup section.
3. (Optional) Select a base template from the drop-down menu under Templates. If you prefer to create a template from scratch, choose Custom from the drop down-menu for a minimal template skeleton.

Developing templates locally

While you need to be in the console to test how your template will process incoming data, you can test the look and feel of your template's HTML and custom elements in your browser by adding this code to the top of your HTML file.

Example

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
```

This loads the necessary code to render the custom HTML elements. Use this if you want to develop your template's look and feel in your preferred editor rather than in the console.

Remember, though, this will not parse your variables. You may want to replace them with sample content while developing locally.

Using External Assets

Amazon SageMaker Ground Truth custom templates allow external scripts and style sheets to be embedded. For example, the following code block demonstrates how you would add a style sheet located at https://www.example.com/my-enhancement-styles.css to your template.

Example

```
<script src="https://www.example.com/my-enhancement-script.js"></script>
<link rel="stylesheet" type="text/css" href="https://www.example.com/my-enhancement-styles.css">
```

If you encounter errors, ensure that your originating server is sending the correct MIME type and encoding headers with the assets.

For example, the MIME and encoding types for remote scripts are: application/javascript;CHARSET=UTF-8.

The MIME and encoding type for remote stylesheets are: text/css;CHARSET=UTF-8.

Track your variables

In the process of building the sample below, there will be a step that adds variables to it to represent the pieces of data that may change from task to task, worker to worker. If you're starting with one of the
sample templates, you will need to make sure you're aware of the variables it already uses. When you
create your pre-annotation AWS Lambda script, its output will need to contain values for any of those
variables you choose to keep.

The values you use for the variables can come from your manifest file. All the key-value pairs in your
data object are provided to your pre-annotation Lambda. If it's a simple pass-through script, matching
keys for values in your data object to variable names in your template is the easiest way to pass those
values through to the tasks forms your workers see.

A simple sample

All tasks begin and end with the `<crowd-form> </crowd-form>` elements. Like standard HTML
<form> elements, all of your form code should go between them.

For a simple tweet-analysis task, use the `<crowd-classifier>` element. It requires the following
attributes:

- `name` - the variable name to use for the result in the form output.
- `categories` - a JSON formatted array of the possible answers.
- `header` - a title for the annotation tool

As children of the `<crowd-classifier>` element, you must have three regions.

- `<classification-target>` - the text the worker will classify based on the options specified in the
categories attribute above.
- `<full-instructions>` - instructions that are available from the "View full instructions" link in the tool.
  This can be left blank, but it is recommended that you give good instructions to get better results.
- `<short-instructions>` - a more brief description of the task that appears in the tool's sidebar. This can be
  left blank, but it is recommended that you give good instructions to get better results.

A simple version of this tool would look like this.

Example of using `crowd-classifier`

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<!--crowd-form-->

<!--crowd-classifier-->

  name="tweetFeeling"
  categories="["positive","negative","neutral", "unclear"]"
  header="Which term best describes this tweet?"
>
  <!--classification-target-->
  My favorite football team won today!
  Bring on the division finals!
  <!--classification-target-->

  <!--full-instructions header="Sentiment Analysis Instructions">-->
  Try to determine the sentiment the author
  of the tweet is trying to express.
  If none seem to match, choose "cannot determine."
  <!--full-instructions-->

  <!--short-instructions-->
  Pick the term best describing the sentiment
  of the tweet.
  <!--short-instructions-->

<!--crowd-classifier-->
</crowd-form>
```
You can copy and paste the code into the editor in the Ground Truth labeling job creation workflow to preview the tool, or try out a demo of this code on CodePen.

Adding automation with Liquid

Our custom template system uses Liquid for automation. It is an open source inline markup language. In Liquid, the text between single curly braces and percent symbols is an instruction or tag that performs an operation like control flow or iteration. Text between double curly braces is a variable or object that outputs its value.

The most common use of Liquid will be to parse the data coming from your pre-annotation Lambda and pull out the relevant variables to create the task. The taskInput object returned by your Pre-annotation Lambda (p. 517) will be available as the task.input object in your templates.

The properties in your manifest's data objects are passed into your Pre-annotation Lambda (p. 517) as the event.dataObject. A simple pass-through script simply returns that object as the taskInput object. You would represent values from your manifest as variables as follows.

Example Manifest data object

```json
{
  "source": "This is a sample text for classification",
  "labels": ["angry", "sad", "happy", "inconclusive"],
  "header": "What emotion is the speaker feeling?"
}
```

Example Sample HTML using variables

```html
<crowd-classifier
     name='tweetFeeling'
     categories='{{ task.input.labels | to_json }}'
     header='{{ task.input.header }}'>
<classification-target>
```
Note the addition of "| to_json" to the labels property above. That's a filter to turn the array into a JSON representation of the array. Variable filters are explained in the next section.

The following list includes two types of Liquid tags that you may find useful to automate template input data processing. If you select one of the following tag-types, you will be redirected to the Liquid documentation.

- **Control flow**: Includes programming logic operators like `if/else`, `unless`, and `case/when`.
- **Iteration**: Enables you to run blocks of code repeatedly using statements like for loops.

For an example of an HTML template that uses Liquid elements to create a for loop, see `translation-review-and-correction.liquid.html` in GitHub.

For more information and documentation, visit the [Liquid homepage](https://liquid.readthedocs.io).

### Variable filters

In addition to the standard Liquid filters and actions, Ground Truth offers a few additional filters. Filters are applied by placing a pipe (|) character after the variable name, then specifying a filter name. Filters can be chained in the form of:

Example

```liquid
{{ <content> | <filter> | <filter> }}
```

**Autoescape and explicit escape**

By default, inputs will be HTML escaped to prevent confusion between your variable text and HTML. You can explicitly add the escape filter to make it more obvious to someone reading the source of your template that the escaping is being done.

**escape_once**

`escape_once` ensures that if you've already escaped your code, it doesn't get re-escaped on top of that. For example, so that `&` doesn't become `&amp;`.

**skip_autoescape**

`skip_autoescape` is useful when your content is meant to be used as HTML. For example, you might have a few paragraphs of text and some images in the full instructions for a bounding box.

**Use skip_autoescape sparingly**

The best practice in templates is to avoid passing in functional code or markup with `skip_autoescape` unless you are absolutely sure you have strict control over what's being passed. If you're passing user input, you could be opening your workers up to a Cross Site Scripting attack.

**to_json**

`to_json` will encode what you feed it to JSON (JavaScript Object Notation). If you feed it an object, it will serialize it.

**grant_read_access**

`grant_read_access` takes an S3 URI and encodes it into an HTTPS URL with a short-lived access token for that resource. This makes it possible to display to workers photo, audio, or video objects stored in S3 buckets that are not otherwise publicly accessible.
Example of the filters

Input

```text
auto-escape: {{ "Have you read 'James & the Giant Peach'" }}
explicit escape: {{ "Have you read 'James & the Giant Peach'" | escape }}
explicit escape_once: {{ "Have you read 'James & the Giant Peach'" | escape_once }}
skip_autoescape: {{ "Have you read 'James & the Giant Peach'" | skip_autoescape }}
to_json: {{ jsObject | to_json }}
grant_read_access: {{ "s3://mybucket/myphoto.png" | grant_read_access }}
```

Example

Output

```text
auto-escape: Have you read 'James & the Giant Peach'?
explicit escape: Have you read 'James & the Giant Peach'?
explicit escape_once: Have you read 'James & the Giant Peach'?
skip_autoescape: Have you read 'James & the Giant Peach'?
to_json: { "point_number": 8, "coords": [ 59, 76 ] }
grant_read_access: https://s3.amazonaws.com/mybucket/myphoto.png?access token and other params>
```

Example of an automated classification template.

To automate the simple text classification sample, replace the tweet text with a variable.

The text classification template is below with automation added. The changes/additions are highlighted in bold.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
  <crowd-classifier
    name="tweetFeeling"
    categories="['positive', 'negative', 'neutral', 'cannot determine']"
    header="Which term best describes this tweet?"
  >
    <classification-target>
      {{ task.input.source }}
    </classification-target>
    <full-instructions header="Analyzing a sentiment">
      Try to determine the feeling the author of the tweet is trying to express.
      If none seem to match, choose "other."
    </full-instructions>
    <short-instructions>
      Pick the term best describing the sentiment of the tweet.
    </short-instructions>
  </crowd-classifier>
</crowd-form>
```

The tweet text that was in the prior sample is now replaced with an object. The entry.taskInput object uses source (or another name you specify in your pre-annotation Lambda) as the property name for the text and it is inserted directly in the HTML by virtue of being between double curly braces.

End-to-end demos

You can view the following end-to-end demos which include sample Lambda function:
Next

Step 3: Processing with AWS Lambda (p. 516)

Step 3: Processing with AWS Lambda

In this step, you learn how to create and specify the two types of AWS Lambda functions that are required to create a custom labeling workflow:

- **Pre-annotation Lambda**: This function initiates for and pre-processes each data object sent to your labeling job prior to sending it to workers.
- **Post-annotation Lambda**: This function processes the results once workers submit a task. If you specify multiple workers per data object, this function may include logic to consolidate annotations.

If you are a new user of Lambda and Ground Truth, we recommend that you use the pages in this section as follows:

1. First, review Pre-annotation and Post-annotation Lambda Function Requirements (p. 516).
2. Then, use the page Required Permissions To Use AWS Lambda With Ground Truth (p. 523) to learn about security and permission requirements to use your pre-annotation and post-annotation Lambda functions in a Ground Truth custom labeling job.
3. Next, you need to visit the Lambda console or use Lambda's APIs to create your functions. Use the section Create Lambda Functions for a Custom Labeling Workflow (p. 527) to learn how to create Lambda functions.
4. To learn how to test your Lambda functions, see Test Pre-Annotation and Post-Annotation Lambda Functions (p. 527).
5. After you create pre-processing and post-processing Lambda functions, select them from the Lambda functions section that comes after the code editor for your custom HTML in the Ground Truth console. To learn how to use these functions in a CreateLabelingJob API request, see Create a Labeling Job (API) (p. 547).

For a custom labeling workflow tutorial that includes example pre-annotation and post-annotation Lambda functions, in the "Demo Template: Annotation of Images with crowd-bounding-box (p. 530)" document.

Topics
- Pre-annotation and Post-annotation Lambda Function Requirements (p. 516)
- Required Permissions To Use AWS Lambda With Ground Truth (p. 523)
- Create Lambda Functions for a Custom Labeling Workflow (p. 527)
- Test Pre-Annotation and Post-Annotation Lambda Functions (p. 527)

Pre-annotation and Post-annotation Lambda Function Requirements

Use this section to learn about the syntax of the requests sent to pre-annotation and post-annotation Lambda functions, and the response syntax that Ground Truth requires to run a custom labeling workflow.

Topics
Pre-annotation Lambda

Before a labeling task is sent to the worker, your pre-annotation Lambda function is invoked.

Ground Truth sends your Lambda function a JSON-formatted request to provide details about the labeling job and the data object. The following table contains the pre-annotation request schemas. Each parameter is described below.

Data object identified with "source-ref"

```json
{
    "version": "2018-10-16",
    "labelingJobArn": "<labelingJobArn>
    "dataObject" : {
        "source-ref": "<s3Uri>
    }
}
```

Data object identified with "source"

```json
{
    "version": "2018-10-16",
    "labelingJobArn": "<labelingJobArn>
    "dataObject" : {
        "source": "<string>
    }
}
```

- **version** (string): This is a version number used internally by Ground Truth.
- **labelingJobArn** (string): This is the Amazon Resource Name, or ARN, of your labeling job. This ARN can be used to reference the labeling job when using Ground Truth API operations such as DescribeLabelingJob.
- The **dataObject** (JSON object): The key contains a single JSON line, either from your input manifest file or sent from Amazon SNS. The JSON line objects in your manifest can be up to 100 kilobytes in size and contain a variety of data. For a very basic image annotation job, the dataObject JSON may just contain a source-ref key, identifying the image to be annotated. If the data object (for example, a line of text) is included directly in the input manifest file, the data object is identified with source. If you create a verification or adjustment job, this line may contain label data and metadata from the previous labeling job.

The following table includes code block examples of a pre-annotation request. Each parameter in these example requests is explained below the tabbed table.

Data object identified with "source-ref"

```json
{
    "version": "2018-10-16",
    "labelingJobArn": "arn:aws:sagemaker:<aws_region>:<aws_account_number>:labeling-job/<labeling_job_name>
    "dataObject" : {
        "source-ref": "s3://<input-data-bucket>/<data-object-file-name>"
    }
}
```
Example of expected return data

```json
{
  "taskInput": <json object>,
  "isHumanAnnotationRequired": <boolean> # Optional
}
```

In the previous example, the `<json object>` needs to contain all the data your custom worker task template needs. If you're doing a bounding box task where the instructions stay the same all the time, it may just be the HTTP(S) or Amazon S3 resource for your image file. If it's a sentiment analysis task and different objects may have different choices, it is the object reference as a string and the choices as an array of strings.

**Implications of isHumanAnnotationRequired**

This value is optional because it defaults to true. The primary use case for explicitly setting it is when you want to exclude this data object from being labeled by human workers.

If you have a mix of objects in your manifest, with some requiring human annotation and some not needing it, you can include a `isHumanAnnotationRequired` value in each data object. You can add logic to your pre-annotation Lambda to dynamically determine if an object requires annotation, and set this boolean value accordingly.

### Examples of Pre-annotation Lambda Functions

The following, basic pre-annotation Lambda function accesses the JSON object in `dataObject` from the initial request, and returns it in the `taskInput` parameter.

```python
import json

def lambda_handler(event, context):
    return {
        "taskInput": event['dataObject']
    }
```

Assuming the input manifest file uses "source-ref" to identify data objects, the worker task template used in the same labeling job as this pre-annotation Lambda must include a Liquid element like the following to ingest `dataObject`:

```liquid
{{ task.input.source-ref | grant_read_access }}
```

If the input manifest file used `source` to identify the data object, the work task template can ingest `dataObject` with the following:
The following pre-annotation Lambda example includes logic to identify the key used in `dataObject`, and to point to that data object using `taskObject` in the Lambda's return statement.

```python
import json
def lambda_handler(event, context):
    # Event received
    print("Received event: " + json.dumps(event, indent=2))

    # Get source if specified
    source = event['dataObject']['source'] if "source" in event['dataObject'] else None

    # Get source-ref if specified
    source_ref = event['dataObject']['source-ref'] if "source-ref" in event['dataObject'] else None

    # if source field present, take that otherwise take source-ref
    task_object = source if source is not None else source_ref

    # Build response object
    output = {
        "taskInput": {
            "taskObject": task_object,
            "humanAnnotationRequired": "true"
        }
    }

    print(output)

    # If neither source nor source-ref specified, mark the annotation failed
    if task_object is None:
        print(" Failed to pre-process {} !".format(event["labelingJobArn"]))
        output["humanAnnotationRequired"] = "false"

    return output
```

Post-annotation Lambda

When all workers have annotated the data object or when `TaskAvailabilityLifetimeInSeconds` has been reached, whichever comes first, Ground Truth sends those annotations to your post-annotation Lambda. This Lambda is generally used for Consolidate Annotations (p. 639).

**Tip**

To see an example of a post-consolidation Lambda function, see `annotation_consolidation_lambda.py` in the aws-sagemaker-ground-truth-recipe GitHub repository.

The following code block contains the post-annotation request schema. Each parameter is described in the following bulleted list.

```json
{
    "version": "2018-10-16",
    "labelingJobArn": <string>,
    "labelCategories": [<string>],
    "labelAttributeName": <string>,
    "roleArn": <string>,
    "payload": {
        "s3Uri": <string>
    }
}
```
• **version** (string): A version number used internally by Ground Truth.
• **labelingJobArn** (string): The Amazon Resource Name, or ARN, of your labeling job. This ARN can be used to reference the labeling job when using Ground Truth API operations such as DescribeLabelingJob.
• **labelCategories** (list of strings): Includes the label categories and other attributes you either specified in the console, or that you include in the label category configuration file.
• **labelAttributeName** (string): Either the name of your labeling job, or the label attribute name you specify when you create the labeling job.
• **roleArn** (string): The Amazon Resource Name (ARN) of the IAM execution role you specify when you create the labeling job.
• **payload** (JSON object): A JSON that includes an `s3Uri` key, which identifies the location of the annotation data for that data object in Amazon S3. The second code block below shows an example of this annotation file.

The following code block contains an example of a post-annotation request. Each parameter in this example request is explained below the code block.

**Example of an post-annotation Lambda request**

```json
{
    "version": "2018-10-16",
    "labelCategories": ["Ex Category1", "Ex Category2", "Ex Category3"],
    "labelAttributeName": "labeling-job-attribute-name",
    "roleArn": "arn:aws:iam::111122223333:role/role-name",
    "payload": {
        "s3Uri": "s3://DOC-EXAMPLE-BUCKET/annotations.json"
    }
}
```

**Note**

If no worker works on the data object and `TaskAvailabilityLifetimeInSeconds` has been reached, the data object is marked as failed and not included as part of post-annotation Lambda invocation.

The following code block contains the payload schema. This is the file that is indicated by the `s3Uri` parameter in the post-annotation Lambda request `payload` JSON object. For example, if the previous code block is the post-annotation Lambda request, the following annotation file is located at `s3://DOC-EXAMPLE-BUCKET/annotations.json`.

Each parameter is described in the following bulleted list.

**Example of an annotation file**

```json
[
    {
        "datasetObjectId": <string>,
        "dataObject": {
            "s3Uri": <string>,
            "content": <string>
        },
        "annotations": [{
            "workerId": <string>,
            "annotationData": {
                "content": <string>
            }
        }]
    }
]
```
• `datasetObjectId` (string): Identifies a unique ID that Ground Truth assigns to each data object you send to the labeling job.

• `dataObject` (JSON object): The data object that was labeled. If the data object is included in the input manifest file and identified using the `source` key (for example, a string), `dataObject` includes a `content` key, which identifies the data object. Otherwise, the location of the data object (for example, a link or S3 URI) is identified with `s3Uri`.

• `annotations` (list of JSON objects): This list contains a single JSON object for each annotation submitted by workers for that `dataObject`. A single JSON object contains a unique `workerId` that can be used to identify the worker that submitted that annotation. The `annotationData` key contains one of the following:
  • `content` (string): Contains the annotation data.
  • `s3Uri` (string): Contains an S3 URI that identifies the location of the annotation data.

The following table contains examples of the content that you may find in payload for different types of annotation.

### Named Entity Recognition Payload

```
[  
  {  
    "datasetObjectId": "1",  
    "dataObject": {  
      "content": "Sift 3 cups of flour into the bowl."
    },  
    "annotations": [  
      {  
        "workerId": "private.us-west-2.ef729f850a3d9d1",  
        "annotationData": {  
          "content": "{"crowd-entity-annotation":{"entities":[{"endOffset":4,\"label\":\"verb\",\"startOffset":0},{\"endOffset\":6,\"label\":\"number\",\"startOffset\":5},{\"endOffset\":20,\"label\":\"object\",\"startOffset\":15},{\"endOffset\":34,\"label\":\"object\",\"startOffset\":30}]}"
        }
      }
    ]
  }
]
```

### Semantic Segmentation Payload

```
[  
  {  
    "datasetObjectId": "2",  
    "dataObject": {  
      "s3Uri": "s3://DOC-EXAMPLE-BUCKET/gt-input-data/images/bird3.jpg"
    },  
    "annotations": [  
      {  
        "workerId": "private.us-west-2.ab1234c5678a919d0",  
        "annotationData": {  
          "content": "{"crowd-semantic-segmentation":{"inputImageProperties":\{"height\":2000,\"width\":3020\},\"labelMappings":{"\"Bird\":\{"\"color\":\"#2ca02c\"\"},\"labeledImage":\{"\"pngImageData\":\"iVBOR\...\"\}"
        }
      }
    ]
  }
]```
Bounding Box Payload

```
[
    {
        "datasetObjectId": "0",
        "dataObject": {
            "s3Uri": "s3://DOC-EXAMPLE-BUCKET/gt-input-data/images/bird1.jpg"
        },
        "annotations": [
            {
                "workerId": "private.us-west-2.ab1234c5678a919d0",
                "annotationData": {
                    "content": "{"boundingBox": [{"height":2052,"label":"Bird","left":583,"top":302,"width":1375}],"inputImageProperties": [{"height":2497,"width":3745}]"
                }
            }
        ]
    }
]
```

Your post-annotation Lambda function may contain logic similar to the following to loop through and access all annotations contained in the request. For a full example, see annotation_consolidation_lambda.py in the aws-sagemaker-ground-truth-recipe GitHub repository. In this GitHub example, you must add your own annotation consolidation logic.

```
for i in range(len(annotations)):
    worker_id = annotations[i]['workerId']
    annotation_content = annotations[i]['annotationData'].get('content')
    annotation_s3_uri = annotations[i]['annotationData'].get('s3Uri')
    annotation = annotation_content if annotation_s3_uri is None else s3_client.get_object_from_s3(annotation_s3_uri)
    annotation_from_single_worker = json.loads(annotation)
    print('{} Received Annotations from worker [{}] is [{}]' .format(log_prefix, worker_id, annotation_from_single_worker))
```

**Tip**
When you run consolidation algorithms on the data, you can use an AWS database service to store results, or you can pass the processed results back to Ground Truth. The data you return to Ground Truth is stored in consolidated annotation manifests in the S3 bucket specified for output during the configuration of the labeling job.

In return, Ground Truth requires a response formatted like the following:

**Example of expected return data**

```
[
    {
        "datasetObjectId": <string>,
        "consolidatedAnnotation": {
            "content": {
                
```
At this point, all the data you're sending to your S3 bucket, other than the datasetObjectId, is in the content object.

When you return annotations in content, this results in an entry in your job's output manifest like the following:

**Example of label format in output manifest**

```json
{
  "source-ref"/"source": "<s3uri or content>",
  "<labelAttributeName>": {
    # ... label content from you
  },
  "<labelAttributeName>-metadata": {
    # This will be added by Ground Truth
    "job_name": "<labelingJobName>",
    "type": "groundTruth/custom",
    "human-annotated": "yes",
    "creation_date": <date> # Timestamp of when received from Post-labeling Lambda
  }
}
```

Because of the potentially complex nature of a custom template and the data it collects, Ground Truth does not offer further processing of the data.

**Required Permissions To Use AWS Lambda With Ground Truth**

You may need to configure some or all the following to create and use AWS Lambda with Ground Truth.

- You need to grant an IAM role or user (collectively, an IAM entity) permission to create the pre-annotation and post-annotation Lambda functions using AWS Lambda, and to choose them when creating the labeling job.
- The IAM execution role specified when the labeling job is configured needs permission to invoke the pre-annotation and post-annotation Lambda functions.
- The post-annotation Lambda functions may need permission to access Amazon S3.

Use the following sections to learn how to create the IAM entities and grant permissions described above.

**Topics**
- Grant Permission to Create and Select an AWS Lambda Function (p. 524)
Grant Permission to Create and Select an AWS Lambda Function

If you do not require granular permissions to develop pre-annotation and post-annotation Lambda functions, you can attach the AWS managed policy AWSLambda_FullAccess to an IAM user or role. This policy grants broad permissions to use all Lambda features, as well as permission to perform actions in other AWS services with which Lambda interacts.

To create a more granular policy for security-sensitive use cases, refer to the documentation Identity-based IAM policies for Lambda in the to AWS Lambda Developer Guide to learn how to create an IAM policy that fits your use case.

Policies to Use the Lambda Console

If you want to grant an IAM entity permission to use the Lambda console, see Using the Lambda console in the AWS Lambda Developer Guide.

Additionally, if you want the user to be able to access and deploy the Ground Truth starter pre-annotation and post-annotation functions using the AWS Serverless Application Repository in the Lambda console, you must specify the `<aws-region>` where you want to deploy the functions (this should be the same AWS Region used to create the labeling job), and add the following policy to the IAM role.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": [
                "serverlessrepo:ListApplicationVersions",
                "serverlessrepo:GetApplication",
                "serverlessrepo:CreateCloudFormationTemplate"
            ],
        },
        {
            "Sid": "VisualEditor1",
            "Effect": "Allow",
            "Action": "serverlessrepo:SearchApplications",
            "Resource": "*"
        }
    ]
}
```

Policies to See Lambda Functions in the Ground Truth Console

To grant an IAM entity permission to view Lambda functions in the Ground Truth console when the user is creating a custom labeling job, the entity must have the permissions described in Grant IAM Permission to Use the Amazon SageMaker Ground Truth Console (p. 651), including the permissions described in the section Custom Labeling Workflow Permissions (p. 654).

Grant IAM Execution Role Permission to Invoke AWS Lambda Functions

If you add the IAM managed policy AmazonSageMakerGroundTruthExecution to the IAM execution role used to create the labeling job, this role has permission to list and invoke Lambda functions with one
of the following strings in the function name: GtRecipe, SageMaker, Sagemaker, sagemaker, or LabelingFunction.

If the pre-annotation or post-annotation Lambda function names do not include one of the terms in the preceding paragraph, or if you require more granular permission than those in the AmazonSageMakerGroundTruthExecution managed policy, you can add a policy similar to the following to give the execution role permission to invoke pre-annotation and post-annotation functions.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "lambda:InvokeFunction",
            "Resource": [
            ]
        }
    ]
}
```

Grant Post-Annotation Lambda Permissions to Access Annotation

As described in Post-annotation Lambda (p. 519), the post-annotation Lambda request includes the location of the annotation data in Amazon S3. This location is identified by the s3Uri string in the payload object. To process the annotations as they come in, even for a simple pass through function, you need to assign the necessary permissions to the post-annotation Lambda execution role to read files from the Amazon S3.

There are many ways that you can configure your Lambda to access annotation data in Amazon S3. Two common ways are:

- Allow the Lambda execution role to assume the SageMaker execution role identified in roleArn in the post-annotation Lambda request. This SageMaker execution role is the one used to create the labeling job, and has access to the Amazon S3 output bucket where the annotation data is stored.
- Grant the Lambda execution role permission to access the Amazon S3 output bucket directly.

Use the following sections to learn how to configure these options.

Grant Lambda Permission to Assume SageMaker Execution Role

To allow a Lambda function to assume a SageMaker execution role, you must attach a policy to the Lambda function's execution role, and modify the trust relationship of the SageMaker execution role to allow Lambda to assume it.

1. Attach the following IAM policy to your Lambda function's execution role to assume the SageMaker execution role identified in Resource. Replace 222222222222 with an AWS account ID. Replace sm-execution-role with the name of the assumed role.

```json
{
    "Version": "2012-10-17",
    "Statement": {
        "Effect": "Allow",
        "Action": "sts:AssumeRole",
```
2. Modify the trust policy of the SageMaker execution role to include the following Statement. Replace `222222222222` with an AWS account ID. Replace `my-lambda-execution-role` with the name of the assumed role.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::222222222222:role/my-lambda-execution-role"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

**Grant Lambda Execution Role Permission to Access S3**

You can add a policy similar to the following to the post-annotation Lambda function execution role to give it S3 read permissions. Replace `DOC-EXAMPLE-BUCKET` with the name of the output bucket you specify when you create a labeling job.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["s3:GetObject"],
      "Resource": "arn:aws:s3:::DOC-EXAMPLE-BUCKET/*"
    }
  ]
}
```

To add S3 read permissions to a Lambda execution role in the Lambda console, use the following procedure.

**Add S3 read permissions to post-annotation Lambda:**

1. Open the Functions page in the Lambda console.
2. Choose the name of the post-annotation function.
3. Choose Configuration and then choose Permissions.
4. Select the Role name and the summary page for that role opens in the IAM console in a new tab.
5. Select Attach policies.
6. Do one of the following:
   - Search for and select AmazonS3ReadOnlyAccess to give the function permission to read all buckets and objects in the account.
   - If you require more granular permissions, select Create policy and use the policy example in the preceding section to create a policy. Note that you must navigate back to the execution role summary page after you create the policy.
7. If you used the AmazonS3ReadOnlyAccess managed policy, select **Attach policy**.

If you created a new policy, navigate back to the Lambda execution role summary page and attach the policy you just created.

**Create Lambda Functions for a Custom Labeling Workflow**

You can create a Lambda function using the Lambda console, the AWS CLI, or an AWS SDK in a supported programming language of your choice. Use the AWS Lambda Developer Guide to learn more about each of these options:

- To learn how to create a Lambda function using the console, see [Create a Lambda function with the console](#).
- To learn how to create a Lambda function using the AWS CLI, see [Using AWS Lambda with the AWS Command Line Interface](#).
- Select the relevant section in the table of contents to learn more about working with Lambda in the language of your choice. For example, select [Working with Python](#) to learn more about using Lambda with the AWS SDK for Python (Boto3).

Ground Truth provides pre-annotation and post-annotation templates through an AWS Serverless Application Repository (SAR) **recipe**. Use the following procedure to select the Ground Truth recipe in the Lambda console.

**Use the Ground Truth SAR recipe to create pre-annotation and post-annotation Lambda functions:**

1. Open the **Functions** page on the Lambda console.
2. Select **Create function**.
3. Select **Browse serverless app repository**.
4. In the search text box, enter `aws-sagemaker-ground-truth-recipe` and select that app.
5. Select **Deploy**. The app may take a couple of minutes to deploy.

Once the app deploys, two functions appear in the **Functions** section of the Lambda console: `serverlessrepo-aws-sagemaker-GtRecipePreHumanTaskFunc-<id>` and `serverlessrepo-aws-sagemaker-GtRecipeAnnotationConsol-<id>`.

6. Select one of these functions and add your custom logic in the **Code** section.
7. When you are finished making changes, select **Deploy** to deploy them.

**Test Pre-Annotation and Post-Annotation Lambda Functions**

You can test your pre-annotation and post annotation Lambda functions in the Lambda console. If you are a new user of Lambda, you can learn how to test, or **invoke**, your Lambda functions in the console using the **Create a Lambda function** tutorial with the console in the AWS Lambda Developer Guide.

You can use the sections on this page to learn how to test the Ground Truth pre-annotation and post-annotation templates provided through an AWS Serverless Application Repository (SAR).

**Topics**

- Prerequisites (p. 528)
- Test the Pre-annotation Lambda Function (p. 528)
- Test the Post-Annotation Lambda Function (p. 529)
Prerequisites

You must do the following to use the tests described on this page.

- You need access to the Lambda console, and you need permission to create and invoke Lambda functions. To learn how to set up these permissions, see Grant Permission to Create and Select an AWS Lambda Function (p. 524).
- If you have not deployed the Ground Truth SAR recipe, use the procedure in Create Lambda Functions for a Custom Labeling Workflow (p. 527) to do so.
- To test the post-annotation Lambda function, you must have a data file in Amazon S3 with sample annotation data. For a simple test, you can copy and paste the following code into a file and save it as sample-annotations.json and upload this file to Amazon S3. Note the S3 URI of this file—you need this information to configure the post-annotation Lambda test.

```json
[{
"datasetObjectId": "0",
"dataObject": {
"content": "To train a machine learning model, you need a large, high-quality, labeled dataset. Ground Truth helps you build high-quality training datasets for your machine learning models."},
"annotations": [
{"workerId": "private.us-west-2.0123456789", "annotationData": {
"content": "{\"crowd-entity-annotation\": {\"entities\": [\n{"endOffset": 8, \"label\": \"verb\", \"startOffset": 3}, {\"endOffset": 27, \"label\": \"adjective\", \"startOffset": 11}, {\"endOffset": 33, \"label\": \"object\", \"startOffset": 28}, {\"endOffset": 51, \"label\": \"adjective\", \"startOffset": 46}, {\"endOffset": 65, \"label\": \"adjective\", \"startOffset": 53}, {\"endOffset": 74, \"label\": \"adjective\", \"startOffset": 69}, {\"endOffset": 82, \"label\": \"adjective\", \"startOffset": 75}, {\"endOffset": 102, \"label\": \"verb\", \"startOffset": 97}, {\"endOffset": 112, \"label\": \"verb\", \"startOffset": 107}, {\"endOffset": 125, \"label\": \"adjective\", \"startOffset": 113}, {\"endOffset": 134, \"label\": \"adjective\", \"startOffset": 126}, {\"endOffset": 143, \"label\": \"object\", \"startOffset": 135}, {\"endOffset": 169, \"label\": \"adjective\", \"startOffset": 153}, {\"endOffset": 176, \"label\": \"object\", \"startOffset": 170}\n\n}]}
],
"datasetObjectId": "1",
"dataObject": {
"content": "Sift 3 cups of flour into the bowl.\n"},
"annotations": [
{"workerId": "private.us-west-2.0123456789", "annotationData": {
"content": "{\"crowd-entity-annotation\": {\"entities\": [\n{"endOffset": 6, \"label\": \"number\", \"startOffset": 5}, {\"endOffset": 20, \"label\": \"object\", \"startOffset": 15}, {\"endOffset": 34, \"label\": \"object\", \"startOffset": 30}\n\n}]}
],
"datasetObjectId": "2",
"dataObject": {
"content": "Jen purchased 10 shares of the stock on January 1st, 2020.\n"},
"annotations": [
{"workerId": "private.us-west-2.0123456789", "annotationData": {
"content": "{\"crowd-entity-annotation\": {\"entities\": [\n{"endOffset": 13, \"label\": \"person\", \"startOffset": 0}, {\"endOffset": 14, \"label\": \"verb\", \"startOffset": 13}, {\"endOffset": 16, \"label\": \"number\", \"startOffset": 14}, {\"endOffset": 58, \"label\": \"date\", \"startOffset": 48}\n\n}]}
],
"datasetObjectId": "3",
"dataObject": {
"content": "The narrative was interesting, however the character development was weak.\n"},
"annotations": [
{"workerId": "private.us-west-2.0123456789", "annotationData": {
"content": "{\"crowd-entity-annotation\": {\"entities\": [\n{"endOffset": 29, \"label\": \"adjective\", \"startOffset": 18}, {\"endOffset": 73, \"label\": \"adjective\", \"startOffset": 69}\n\n}]}
]
]
}

- You must use the directions in Grant Post-Annotation Lambda Permissions to Access Annotation (p. 525) to give your post-annotation Lambda function’s execution role permission to assume the SageMaker execution role you use to create the labeling job. The post-annotation Lambda function uses the SageMaker execution role to access the annotation data file, sample-annotations.json, in S3.

Test the Pre-annotation Lambda Function

Use the following procedure to test the pre-annotation Lambda function created when you deployed the Ground Truth AWS Serverless Application Repository (SAR) recipe.

Test the Ground Truth SAR recipe pre-annotation Lambda function

1. Open the Functions page in the Lambda console.
2. Select the pre-annotation function that was deployed from the Ground Truth SAR recipe. The name of this function is similar to serverlessrepo-aws-sagemaker-GtRecipePreHumanTaskFunc-<id>.

3. In the Code source section, select the arrow next to Test.

4. Select Configure test event.

5. Keep the Create new test event option selected.

7. Give your test an Event name.

8. Select Create.

9. Select the arrow next to Test again and you should see that the test you created is selected, which is indicated with a dot by the event name. If it is not selected, select it.

10. Select Test to run the test.

After you run the test, you can see the Execution results. In the Function logs, you should see a response similar to the following:

```
START RequestId: cd117d38-8365-4e1a-bffb-0dcd631a878f Version: $LATEST
Received event: {
  "version": "2018-10-16",
  "dataObject": {
    "source-ref": "s3://sagemakerexample/object_to_annotate.jpg"
  }
}
{'taskInput': {'taskObject': 's3://sagemakerexample/object_to_annotate.jpg'}, 'isHumanAnnotationRequired': 'true'}
END RequestId: cd117d38-8365-4e1a-bffb-0dcd631a878f
REPORT RequestId: cd117d38-8365-4e1a-bffb-0dcd631a878f Duration: 0.42 ms Billed Duration: 1 ms Memory Size: 128 MB Max Memory Used: 43 MB
```

In this response, we can see the Lambda function's output matches the required pre-annotation response syntax:

```
{'taskInput': {'taskObject': 's3://sagemakerexample/object_to_annotate.jpg'}, 'isHumanAnnotationRequired': 'true'}
```

Test the Post-Annotation Lambda Function

Use the following procedure to test the post-annotation Lambda function created when you deployed the Ground Truth AWS Serverless Application Repository (SAR) recipe.

**Test the Ground Truth SAR recipe post-annotation Lambda**

1. Open the Functions page in the Lambda console.

2. Select the post-annotation function that was deployed from the Ground Truth SAR recipe. The name of this function is similar to serverlessrepo-aws-sagemaker-GtRecipeAnnotationConsol-<id>.

3. In the Code source section, select the arrow next to Test.

4. Select Configure test event.

5. Keep the Create new test event option selected.

7. Give your test an Event name.

8. Modify the template code provided as follows:
• Replace the Amazon Resource Name (ARN) in `roleArn` with the ARN of the SageMaker execution role you used to create the labeling job.
• Replace the S3 URI in `s3Uri` with the URI of the `sample-annotations.json` file you added to Amazon S3.

After you make these modifications, your test should look similar to the following:

```json
{
   "version": "2018-10-16",
   "labelAttributeName": "example-attribute",
   "roleArn": "arn:aws:iam::222222222222:role/sm-execution-role",
   "payload": {
      "s3Uri": "s3://your-bucket/sample-annotations.json"
   }
}
```

9. Select **Create**.
10. Select the arrow next to **Test** again and you should see that the test you created is selected, which is indicated with a dot by the event name. If it is not selected, select it.
11. Select the **Test** to run the test.

After you run the test, you should see a **-- Consolidated Output --** section in the **Function Logs**, which contains a list of all annotations included in `sample-annotations.json`.

**Demo Template: Annotation of Images with crowd-bounding-box**

When you chose to use a custom template as your task type in the Amazon SageMaker Ground Truth console, you reach the **Custom labeling task panel**. There you can choose from multiple base templates. The templates represent some of the most common tasks and provide a sample to work from as you create your customized labeling task's template. If you are not using the console, or as an additional recourse, see **Amazon SageMaker Ground Truth Sample Task UIs** for a repository of demo templates for a variety of labeling job task types.

This demonstration works with the **BoundingBox** template. The demonstration also works with the AWS Lambda functions needed for processing your data before and after the task. In the Github repository above, to find templates that work with AWS Lambda functions, look for `{{ task.input.<property name> }}` in the template.

**Topics**

- Starter Bounding Box custom template (p. 530)
- Your own Bounding Box custom template (p. 531)
- Your manifest file (p. 532)
- Your pre-annotation Lambda function (p. 533)
- Your post-annotation Lambda function (p. 533)
- The output of your labeling job (p. 534)

**Starter Bounding Box custom template**

This is the starter bounding box template that is provided.
Your own Bounding Box custom template

As an example, assume you have a large collection of animal photos in which you know the kind of animal in an image from a prior image-classification job. Now you want to have a bounding box drawn around it.

In the starter sample, there are three variables: taskObject, header, and labels.

Each of these would be represented in different parts of the bounding box.

- **taskObject** is an HTTP(S) URL or S3 URI for the photo to be annotated. The added | grant_read_access is a filter that will convert an S3 URI to an HTTPS URL with short-lived access to that resource. If you're using an HTTP(S) URL, it's not needed.
- **header** is the text above the photo to be labeled, something like "Draw a box around the bird in the photo."
• labels is an array, represented as ['item1', 'item2', ...]. These are labels that can be assigned by the worker to the different boxes they draw. You can have one or many.

Each of the variable names come from the JSON object in the response from your pre-annotation Lambda. The names above are merely suggested, Use whatever variable names make sense to you and will promote code readability among your team.

Only use variables when necessary
If a field will not change, you can remove that variable from the template and replace it with that text, otherwise you have to repeat that text as a value in each object in your manifest or code it into your pre-annotation Lambda function.

Example: Final Customized Bounding Box Template
To keep things simple, this template will have one variable, one label, and very basic instructions. Assuming your manifest has an "animal" property in each data object, that value can be re-used in two parts of the template.

Note the re-use of {{ task.input.animal }} throughout the template. If your manifest had all of the animal names beginning with a capital letter, you could use {{ task.input.animal | downcase }}, incorporating one of Liquid's built-in filters in sentences where it needed to be presented lowercase.

Your manifest file
Your manifest file should provide the variable values you're using in your template. You can do some transformation of your manifest data in your pre-annotation Lambda, but if you don't need to, you maintain a lower risk of errors and your Lambda will run faster. Here's a sample manifest file for the template.

["source-ref": "<S3 image URI>", "animal": "horse"}
{"source-ref": "<S3 image URI>", "animal": "bird"}
{"source-ref": "<S3 image URI>", "animal": "dog"}
{"source-ref": "<S3 image URI>", "animal": "cat"}
Your pre-annotation Lambda function

As part of the job set-up, provide the ARN of an AWS Lambda function that can be called to process your manifest entries and pass them to the template engine.

**Naming your Lambda function**

The best practice in naming your function is to use one of the following four strings as part of the function name: SageMaker, Sagemaker, sagemaker, or LabelingFunction. This applies to both your pre-annotation and post-annotation functions.

When you're using the console, if you have AWS Lambda functions that are owned by your account, a drop-down list of functions meeting the naming requirements will be provided to choose one.

In this very basic example, you're just passing through the information from the manifest without doing any additional processing on it. This sample pre-annotation function is written for Python 3.7.

```python
import json

def lambda_handler(event, context):
    return {
        "taskInput": event['dataObject']
    }
```

The JSON object from your manifest will be provided as a child of the `event` object. The properties inside the `taskInput` object will be available as variables to your template, so simply setting the value of `taskInput` to `event['dataObject']` will pass all the values from your manifest object to your template without having to copy them individually. If you wish to send more values to the template, you can add them to the `taskInput` object.

Your post-annotation Lambda function

As part of the job set-up, provide the ARN of an AWS Lambda function that can be called to process the form data when a worker completes a task. This can be as simple or complex as you want. If you want to do answer consolidation and scoring as it comes in, you can apply the scoring and/or consolidation algorithms of your choice. If you want to store the raw data for offline processing, that is an option.

**Provide permissions to your post-annotation Lambda**

The annotation data will be in a file designated by the `s3Uri` string in the `payload` object. To process the annotations as they come in, even for a simple pass through function, you need to assign S3Readonly access to your Lambda so it can read the annotation files.

In the Console page for creating your Lambda, scroll to the **Execution role** panel. Select **Create a new role from one or more templates**. Give the role a name. From the **Policy templates** drop-down, choose **Amazon S3 object read-only permissions**. Save the Lambda and the role will be saved and selected.

The following sample is in Python 2.7.

```python
import json
import boto3
from urlparse import urlparse

def lambda_handler(event, context):
    consolidated_labels = []

    parsed_url = urlparse(event['payload']['s3Uri']);
    s3 = boto3.client('s3')
    textFile = s3.get_object(Bucket = parsed_url.netloc, Key = parsed_url.path[1:])
    filecont = textFile['Body'].read()
    annotations = json.loads(filecont);

    for dataset in annotations:
        for annotation in dataset['annotations']:
```
The post-annotation Lambda will often receive batches of task results in the event object. That batch will be the payload object the Lambda should iterate through. What you send back will be an object meeting the API contract (p. 516).

The output of your labeling job

You'll find the output of the job in a folder named after your labeling job in the target S3 bucket you specified. It will be in a subfolder named manifests.

For a bounding box task, the output you find in the output manifest will look a bit like the demo below. The example has been cleaned up for printing. The actual output will be a single line per record.

Example : JSON in your output manifest

```json
{
"source-ref":"<URL>",
"<label attribute name>":
{
"workerId":"<URL>",
"imageSource":"<image URL>",
"boxesInfo":{"boundingBox":[["height":878, "label":"bird ", "left":208, "top":6, "width":809]},"inputImageProperties":{"height":924, "width":1280}}],
"<label attribute name>-metadata":
{
"type":"groundTruth/custom",
"job_name":"<Labeling job name>",
"human-annotated":"yes"
},
"animal" : "bird"
}
```

Note how the additional animal attribute from your original manifest is passed to the output manifest on the same level as the source-ref and labeling data. Any properties from your input manifest, whether they were used in your template or not, will be passed to the output manifest.

Demo Template: Labeling Intents with crowd-classifier

If you choose a custom template, you'll reach the Custom labeling task panel. There you can select from multiple starter templates that represent some of the more common tasks. The templates provide a starting point to work from in building your customized labeling task's template.

In this demonstration, you work with the Intent Detection template, which uses the crowd-classifier (p. 734) element, and the AWS Lambda functions needed for processing your data before and after the task.
Starter Intent Detection custom template

This is the intent detection template that is provided as a starting point.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <crowd-classifier
    name="intent"
    categories="{{ task.input.labels | to_json | escape }}"
    header="Pick the most relevant intention expressed by the below text"
  >
    <classification-target>
      {{ task.input.utterance }}
    </classification-target>
  
    <full-instructions header="Intent Detection Instructions">
      <p>Select the most relevant intention expressed by the text.</p>
      <div>
        <p><strong>Example: </strong>I would like to return a pair of shoes</p>
        <p><strong>Intent: </strong>Return</p>
      </div>
    </full-instructions>

    <short-instructions>
      Pick the most relevant intention expressed by the text
    </short-instructions>

</crowd-classifier>
</crowd-form>
```

The custom templates use the **Liquid template language**, and each of the items between double curly braces is a variable. The pre-annotation AWS Lambda function should provide an object named `taskInput` and that object's properties can be accessed as `{{ task.input.<property name> }}` in your template.

Your Intent Detection custom template

In the starter template, there are two variables: the `task.input.labels` property in the `crowd-classifier` element opening tag and the `task.input.utterance` in the `classification-target` region's content.

Unless you need to offer different sets of labels with different utterances, avoiding a variable and just using text will save processing time and creates less possibility of error. The template used in this demonstration will remove that variable, but variables and filters like `to_json` are explained in more detail in the **crowd-bounding-box demonstration** article.

Styling Your Elements

Two parts of these custom elements that sometimes get overlooked are the `<full-instructions>` and `<short-instructions>` regions. Good instructions generate good results.
In the elements that include these regions, the `<short-instructions>` appear automatically in the "Instructions" pane on the left of the worker's screen. The `<full-instructions>` are linked from the "View full instructions" link near the top of that pane. Clicking the link opens a modal pane with more detailed instructions.

You can not only use HTML, CSS, and JavaScript in these sections, you are encouraged to if you believe you can provide a strong set of instructions and examples that will help workers complete your tasks with better speed and accuracy.

**Example Try out a sample with JSFiddle**

![JSFiddle](image.png)

Try out an example `<crowd-classifier>` task. The example is rendered by JSFiddle, therefore all the template variables are replaced with hard-coded values. Click the "View full instructions" link to see a set of examples with extended CSS styling. You can fork the project to experiment with your own changes to the CSS, adding sample images, or adding extended JavaScript functionality.

**Example : Final Customized Intent Detection Template**

This uses the example `<crowd-classifier>` task, but with a variable for the `<classification-target>`. If you are trying to keep a consistent CSS design among a series of different labeling jobs, you can include an external stylesheet using a `<link rel...>` element the same way you'd do in any other HTML document.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <crowd-classifier
    name="intent"
    categories="['buy', 'eat', 'watch', 'browse', 'leave']"
    header="Pick the most relevant intent expressed by the text below"
  >
  <classification-target>
```
In the statements and questions provided in this exercise, what category of action is the speaker interested in doing?

<table>
<thead>
<tr>
<th>Example Utterance</th>
<th>Good Choice</th>
</tr>
</thead>
<tbody>
<tr>
<td>When is the Seahawks game on?</td>
<td>watch, browse</td>
</tr>
<tr>
<td>When is the Seahawks game on?</td>
<td>buy, eat, watch</td>
</tr>
</tbody>
</table>

What is the speaker expressing they would like to do next?
Example: Your manifest file

If you are preparing your manifest file manually for a text-classification task like this, have your data formatted in the following manner.

```json
["source": "Roses are red"]
["source": "Violets are Blue"]
["source": "Ground Truth is the best"]
["source": "And so are you"]
```

This differs from the manifest file used for the "Demo Template: Annotation of Images with crowd-bounding-box (p. 530)" demonstration in that source-ref was used as the property name instead of source. The use of source-ref designates S3 URIs for images or other files that must be converted to HTTP. Otherwise, source should be used like it is with the text strings above.
Your pre-annotation Lambda function

As part of the job set-up, provide the ARN of an AWS Lambda that can be called to process your manifest entries and pass them to the template engine.

This Lambda function is required to have one of the following four strings as part of the function name: SageMaker, Sagemaker, sagemaker, or LabelingFunction.

This applies to both your pre-annotation and post-annotation Lambdas.

When you're using the console, if you have Lambdas that are owned by your account, a drop-down list of functions meeting the naming requirements will be provided to choose one.

In this very basic sample, where you have only one variable, it's primarily a pass-through function. Here's a sample pre-labeling Lambda using Python 3.7.

```python
import json

def lambda_handler(event, context):
    return {
        "taskInput": event['dataObject']
    }
```

The dataObject property of the event contains the properties from a data object in your manifest.

In this demonstration, which is a simple pass through, you just pass that straight through as the taskInput value. If you add properties with those values to the event['dataObject'] object, they will be available to your HTML template as Liquid variables with the format `{{ task.input.<property name> }}`.

Your post-annotation Lambda function

As part of the job set up, provide the ARN of an Lambda function that can be called to process the form data when a worker completes a task. This can be as simple or complex as you want. If you want to do answer-consolidation and scoring as data comes in, you can apply the scoring or consolidation algorithms of your choice. If you want to store the raw data for offline processing, that is an option.

**Set permissions for your post-annotation Lambda function**

The annotation data will be in a file designated by the s3Uri string in the payload object. To process the annotations as they come in, even for a simple pass through function, you need to assign S3ReadOnly access to your Lambda so it can read the annotation files.

In the Console page for creating your Lambda, scroll to the Execution role panel. Select Create a new role from one or more templates. Give the role a name. From the Policy templates drop-down, choose Amazon S3 object read-only permissions. Save the Lambda and the role will be saved and selected.

The following sample is for Python 3.7.

```python
import json
import boto3
from urllib.parse import urlparse

def lambda_handler(event, context):
    consolidated_labels = []

    parsed_url = urlparse(event['payload']['s3Uri']);
    s3 = boto3.client('s3')
    textFile = s3.get_object(Bucket = parsed_url.netloc, Key = parsed_url.path[1:])
    filecont = textFile['Body'].read()
    annotations = json.loads(filecont);

    for dataset in annotations:
        consolidated_labels.append(dataset)
```

539
for annotation in dataset['annotations']:
    new_annotation = json.loads(annotation['annotationData']['content'])
    label = {
        'datasetObjectId': dataset['datasetObjectId'],
        'consolidatedAnnotation': {
            'content': {
                event['labelAttributeName']: {
                    'workerId': annotation['workerId'],
                    'result': new_annotation,
                    'labeledContent': dataset['dataObject']
                }
            }
        }
    }
    consolidated_labels.append(label)
return consolidated_labels

Your labeling job output

The post-annotation Lambda will often receive batches of task results in the event object. That batch will be the payload object the Lambda should iterate through.

You'll find the output of the job in a folder named after your labeling job in the target S3 bucket you specified. It will be in a subfolder named manifests.

For an intent detection task, the output in the output manifest will look a bit like the demo below. The example has been cleaned up and spaced out to be easier for humans to read. The actual output will be more compressed for machine reading.

Example: JSON in your output manifest

```json
[
    {
        "datasetObjectId": "<Number representing item's place in the manifest>",
        "consolidatedAnnotation": {
            "content": {
                "<name of labeling job>": {
                    "workerId": "private.us-east-1.XXXXXXXXXXXXXXXXXXX",
                    "result": {
                        "intent": {
                            "label": "<label chosen by worker>
                        
                    },
                    "labeledContent": {
                        "content": "<text content that was labeled>
                    }
                }
            }
        }
    },
    {
        "datasetObjectId": "<Number representing item's place in the manifest>",
        "consolidatedAnnotation": {
            "content": {
                "<name of labeling job>": {
                    "workerId": "private.us-east-1.XXXXXXXXXXXXXXXXXXX",
                    "result": {
                        "intent": {
                            "label": "<label chosen by worker>
                        
                    },
                    "labeledContent": {
                        "content": "<text content that was labeled>
                    }
                }
            }
        }
    }
]```
This should help you create and use your own custom template.

**Custom Workflows via the API**

When you have created your custom UI template (Step 2) and processing Lambda functions (Step 3), you should place the template in an Amazon S3 bucket with a file name format of: `<FileName>.liquid.html`

Use the `CreateLabelingJob` action to configure your task. You'll use the location of a custom template (Step 2: Creating your custom worker task template (p. 510)) stored in a `<filename>.liquid.html` file on S3 as the value for the `UiTemplateS3Uri` field in the `UiConfig` object within the `HumanTaskConfig` object.

For the AWS Lambda tasks described in Step 3: Processing with AWS Lambda (p. 516), the post-annotation task's ARN will be used as the value for the `AnnotationConsolidationLambdaArn` field, and the pre-annotation task will be used as the value for the `PreHumanTaskLambdaArn`.

**Create a Labeling Job**

You can create a labeling job in the Amazon SageMaker console and by using an AWS SDK in your preferred language to run `CreateLabelingJob`. After a labeling job has been created, you can track worker metrics (for private workforces) and your labeling job status using `CloudWatch`.

Before you create a labeling job it is recommended that you review the following pages, as applicable:

- You can specify our input data using an automatic data setup in the console, or an input manifest file in either the console or when using `CreateLabelingJob` API. For automated data setup, see Automated Data Setup (p. 574). To learn how to create an input manifest file, see Use an Input Manifest File (p. 573).
- Review labeling job input data quotas: Input Data Quotas (p. 580).

After you have chosen your task type, use the topics on this page to learn how to create a labeling job.

If you are a new Ground Truth user, we recommend that you start by walking through the demo in Getting started (p. 371).

**Important**

Ground Truth requires all S3 buckets that contain labeling job input image data to have a CORS policy attached. To learn more, see CORS Permission Requirement (p. 649).
Topics

- Built-in Task Types (p. 542)
- Creating Instruction Pages (p. 542)
- Create a Labeling Job (Console) (p. 544)
- Create a Labeling Job (API) (p. 547)
- Create a Streaming Labeling Job (p. 552)
- Create a Labeling Category Configuration File with Label Category and Frame Attributes (p. 557)

Built-in Task Types

Amazon SageMaker Ground Truth has several built-in task types. Ground Truth provides a worker task template for built-in task types. Additionally, some built-in task types support Automate Data Labeling (p. 640). The following topics describe each built-in task type and demo the worker task templates that are provided by Ground Truth in the console. To learn how to create a labeling job in the console using one of these task types, select the task type page.

<table>
<thead>
<tr>
<th>Label Images</th>
<th>Label Text</th>
<th>Label Videos and Video Frames</th>
<th>Label 3D Point Clouds</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Bounding Box (p. 376)</td>
<td>• Named Entity Recognition (p. 396)</td>
<td>• Video Classification (p. 406)</td>
<td>• 3D Point Cloud Object Detection (p. 443)</td>
</tr>
<tr>
<td>• Image Classification (Single Label) (p. 389)</td>
<td>• Text Classification (Single Label) (p. 400)</td>
<td>• Video Frame Object Detection (p. 411)</td>
<td>• 3D Point Cloud Object Tracking (p. 450)</td>
</tr>
<tr>
<td>• Image Classification (Multi-label) (p. 391)</td>
<td>• Text Classification (Multi-label) (p. 403)</td>
<td>• Video Frame Object Tracking (p. 415)</td>
<td>• 3D Point Cloud Semantic Segmentation (p. 459)</td>
</tr>
<tr>
<td>• Image Semantic Segmentation (p. 382)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Verify and Adjust Labels (p. 502)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Note

Each of the video frame and 3D point cloud task types has an adjustment task type that you use to verify and adjust labels from a previous labeling job. Select a video frame or 3D point cloud task type page above to learn how to adjust labels created using that task type.

Creating Instruction Pages

Create custom instructions for labeling jobs to improve your worker’s accuracy in completing their task. You can modify the default instructions that are provided in the console or you can create your own. The instructions are shown to the worker on the page where they complete their labeling task.

There are two kinds of instructions:

- Short instructions—instructions that are shown on the same webpage where the worker completes their task. These instructions should provide an easy reference to show the worker the correct way to label an object.
- Full instructions—instructions that are shown on a dialog box that overlays the page where the worker completes their task. We recommend that you provide detailed instructions for completing the task with multiple examples showing edge cases and other difficult situations for labeling objects.
Create instructions in the console when you are creating your labeling job. Start with the existing instructions for the task and use the editor to modify them to suit your labeling job.

**Note**

Once you create your labeling job, it will automatically start and you will not be able to modify your worker instructions. If you need to change your worker instructions, stop the labeling job that you created, clone it, and modify your worker instructions before creating a new job. You can clone a labeling job in the console by selecting the labeling job and then selecting **Clone** in the **Actions** menu.

To clone a labeling job using the Amazon SageMaker API or your preferred Amazon SageMaker SDK, make a new request to the `CreateLabelingJob` operation with the same specifications as your original job after modifying your worker instructions.

### Short Instructions

Short instructions appear on the same web page that workers use to label your data object. For example, the following is the editing page for a bounding box task. The short instructions panel is on the left.

Keep in mind that a worker will only spend seconds looking at the short instructions. Workers must be able to scan and understand your information quickly. In all cases it should take less time to understand the instructions than it takes to complete the task. Keep these points in mind:

- Your instructions should be clear and simple.
• Pictures are better than words. Create a simple illustration of your task that your workers can
immediately understand.
• If you must use words, use short, concise examples.
• Your short instructions are more important than your full instructions.

The Amazon SageMaker Ground Truth console provides an editor so that you can create your short
instructions. Replace the placeholder text and images with instructions for your task. Preview the
worker’s task page by choosing Preview. The preview will open in a new window, be sure to turn off pop-
up blocking so that the window will show.

Full Instructions

You can provide additional instructions for your workers in a dialog box that overlays the page where
workers label your data objects. Use full instructions to explain more complex tasks and to show workers
the proper way to label edge cases or other difficult objects.

You can create full instructions using an editor in the Ground Truth console. As with quick instructions,
keep the following in mind:

• Workers will want detailed instruction the first few times that the complete your task. Any information
  that they must have should be in the quick instructions.
• Pictures are more important than words.
• Text should be concise.
• Full instructions should supplement the short instructions. Don’t repeat information that appears in
  the short instructions.

The Ground Truth console provides an editor so that you can create your full instructions. Replace the
placeholder text and images with instructions for your task. Preview the full instruction page by choosing
Preview. The preview will open in a new window, be sure to turn off pop-up blocking so that the window
will show.

Add example images to your instructions

Images provide useful examples for your workers. To add a publicly accessible image to your instructions:

• Place the cursor where the image should go in the instructions editor.
• Click the image icon in the editor toolbar.
• Enter the URL of your image.

If your instruction image in Amazon S3 is not publicly accessible:

• As the image URL, enter: {{ 'https://s3.amazonaws.com/your-bucket-name/image-file-
  name' | grant_read_access }}.
• This renders the image URL with a short-lived, one-time access code appended so the worker’s browser
can display it. A broken image icon is displayed in the instructions editor, but previewing the tool
displays the image in the rendered preview.

Create a Labeling Job (Console)

You can use the Amazon SageMaker console to create a labeling job for all of the Ground Truth built-in
task types and custom labeling workflows. For built-in task types, we recommend that you use this page
alongside the page for your task type. Each task type page includes specific details on creating a labeling
job using that task type.
You need to provide the following to create a labeling job in the SageMaker console:

- An input manifest file in Amazon S3. You can place your input dataset in Amazon S3 and automatically generate a manifest file using the Ground Truth console (not supported for 3D point cloud labeling jobs).

  Alternatively, you can manually create an input manifest file. To learn how, see Input Data (p. 572).
- An Amazon S3 bucket to store your output data.
- An IAM role with permission to access your resources in Amazon S3 and with a SageMaker execution policy attached. For a general solution, you can attach the managed policy, AmazonSageMakerFullAccess, to an IAM role and include sagemaker in your bucket name.

  For more granular policies, see the section called “IAM Permissions” (p. 650).
- 3D point cloud task types have additional security considerations. Learn more.
- A work team. You create a work team from a workforce made up of Amazon Mechanical Turk workers, vendors, or your own private workers. To learn more, see Create and Manage Workforces (p. 694).

  You cannot use the Mechanical Turk workforce for 3D point cloud or video frame labeling jobs.
- If you are using a custom labeling workflow, you must save a worker task template in Amazon S3 and provide an Amazon S3 URI for that template. For more information, see Step 2: Creating your custom worker task template (p. 510).
- (Optional) An AWS KMS key ARN if you want SageMaker to encrypt the output of your labeling job using your own AWS KMS encryption key instead of the default Amazon S3 service key.
- (Optional) Existing labels for the dataset you use for your labeling job. Use this option if you want workers to adjust, or approve and reject labels.
- If you want to create an adjustment or verification labeling job, you must have an output manifest file in Amazon S3 that contains the labels you want adjusted or verified. This option is only supported for bounding box and semantic segmentation image labeling jobs and 3D point cloud and video frame labeling jobs. It is recommended that you use the instructions on Verify and Adjust Labels (p. 502) to create a verification or adjustment labeling job.

  **Important**
  Your work team, input manifest file, output bucket, and other resources in Amazon S3 must be in the same AWS Region you use to create your labeling job.

When you create a labeling job using the SageMaker console, you add worker instructions and labels to the worker UI that Ground Truth provides. You can preview and interact with the worker UI while creating your labeling job in the console. You can also see a preview of the worker UI on your built-in task type page.

### To create a labeling job (console)

2. In the left navigation pane, choose **Labeling jobs**.
3. On the **Labeling jobs** page, choose **Create labeling job**.
4. For **Job name**, enter a name for your labeling job.
5. (Optional) If you want to identify your labels with a key, select **I want to specify a label attribute name different from the labeling job name**. If you do not select this option, the labeling job name you specified in the previous step will be used to identify your labels in your output manifest file.
6. Choose a data setup to setup to set up a connection between your input dataset and Ground Truth.

   - For **Automated data setup**:
     - Follow the instructions in Automated Data Setup (p. 574) for image, text, and video clip labeling jobs.
• Follow the instructions in Automated Video Frame Input Data Setup (p. 611) for video frame labeling jobs.

• For Manual data setup:
  • For Input dataset location, provide the location in Amazon S3 in which your input manifest file is located. For example, if your input manifest file, manifest.json, is located in example-bucket, enter s3://example-bucket/manifest.json.
  • For Output dataset location, provide the location in Amazon S3 where you want Ground Truth to store the output data from your labeling job.

7. For IAM Role, choose an existing IAM role or create an IAM role with permission to access your resources in Amazon S3, to write to the output Amazon S3 bucket specified above, and with a SageMaker execution policy attached.

8. (Optional) For Additional configuration, you can specify how much of your dataset you want workers to label, and if you want SageMaker to encrypt the output data for your labeling job using an AWS KMS encryption key. To encrypt your output data, you must have the required AWS KMS permissions attached to the IAM role you provided in the previous step. For more details, see the section called “IAM Permissions” (p. 650).

9. In the Task type section, under Task category, use the dropdown list to select your task category.

10. In Task selection, choose your task type.

11. (Optional) Provide tags for your labeling job to make it easier to find in the console later.

12. Choose Next.

13. In the Workers section, choose the type of workforce you would like to use. For more details about your workforce options see Create and Manage Workforces (p. 694).

14. (Optional) After you've selected your workforce, specify the Task timeout. This is the maximum amount of time a worker has to work on a task.

   For 3D point cloud annotation tasks, the default task timeout is 3 days. The default timeout for text and image classification and label verification labeling jobs is 5 minutes. The default timeout for all other labeling jobs is 60 minutes.

15. (Optional) For bounding box, semantic segmentation, video frame, and 3D point cloud task types, you can select Display existing labels if you want to display labels for your input data set for workers to verify or adjust.

   For bounding box and semantic segmentation labeling jobs, this will create an adjustment labeling job.

   For 3D point cloud and video frame labeling jobs:

   • Select Adjustment to create an adjustment labeling job. When you select this option, you can add new labels but you cannot remove or edit existing labels from the previous job. Optionally, you can choose label category attributes and frame attributes that you want workers to edit. To make an attribute editable, select the check box Allow workers to edit this attribute for that attribute.

   Optionally, you can add new label category and frame attributes.

   • Select Verification to create an adjustment labeling job. When you select this option, you cannot add, modify, or remove existing labels from the previous job. Optionally, you can choose label category attributes and frame attributes that you want workers to edit. To make an attribute editable, select the check box Allow workers to edit this attribute for that attribute.

   We recommend that you can add new label category attributes to the labels that you want workers to verify, or add one or more frame attributes to have workers provide information about the entire frame.

For more information, see Verify and Adjust Labels (p. 502).
16. Configure your workers' UI:

- If you are using a built-in task type, specify workers instructions and labels.
  - For image classification and text classification (single and multi-label) you must specify at least two label categories. For all other built-in task types, you must specify at least one label category.
  - (Optional) If you are creating a 3D point cloud or video frame labeling job, you can specify label category attributes (not supported for 3D point cloud semantic segmentation) and frame attributes. Label category attributes can be assigned to one or more labels. Frame attributes will appear on each point cloud or video frame workers label. To learn more, see Worker User Interface (UI) (p. 469) for 3D point cloud and Worker User Interface (UI) (p. 421) for video frame.

- (Optional) Add **Additional instructions** to help your worker complete your task.

- If you are creating a custom labeling workflow you must:
  - Enter a custom template in the code box. Custom templates can be created using a combination of HTML, the Liquid templating language and our pre-built web components. Optionally, you can choose a base-template from the drop-down menu to get started.
  - Specify pre-annotation and post-annotation lambda functions. To learn how to create these functions, see Step 3: Processing with AWS Lambda (p. 516).

17. (Optional) You can select See preview to preview your worker instructions, labels, and interact with the worker UI. Make sure the pop-up blocker of the browser is disabled before generating the preview.

18. Choose **Create**.

After you've successfully created your labeling job, you are redirected to the **Labeling jobs** page. The status of the labeling job you just created is **In progress**. This status progressively updates as workers complete your tasks. When all tasks are successfully completed, the status changes to **Completed**.

If an issue occurs while creating the labeling job, its status changes to **Failed**.

To view more details about the job, choose the labeling job name.

**Next Steps**

After your labeling job status changes to **Completed**, you can view your output data in the Amazon S3 bucket that you specified while creating that labeling job. For details about the format of your output data, see **Output Data** (p. 614).

**Create a Labeling Job (API)**

To create a labeling job using the Amazon SageMaker API, you use the **CreateLabelingJob** operation. For specific instructions on creating a labeling job for a built-in task type, see that task type page. To learn how to create a streaming labeling job, which is a labeling job that runs perpetually, see Create a Streaming Labeling Job (p. 552).

To use the **CreateLabelingJob** operation, you need the following:

- A worker task template (UiTemplateS3Uri) or human task UI ARN (HumanTaskUiArn) in Amazon S3.
- For 3D point cloud jobs, video object detection and tracking jobs, and NER jobs, use the ARN listed in HumanTaskUiArn for your task type.
- If you are using a built-in task type other than 3D point cloud tasks, you can add your worker instructions to one of the pre-built templates and save the template (using a .html or .liquid extension) in your S3 bucket. Find the pre-build templates on your task type page.
• If you are using a custom labeling workflow, you can create a custom template and save the template in your S3 bucket. To learn how to build a custom worker template, see Step 2: Creating your custom worker task template (p. 510). For custom HTML elements that you can use to customize your template, see Crowd HTML Elements Reference (p. 720). For a repository of demo templates for a variety of labeling tasks, see Amazon SageMaker Ground Truth Sample Task UIs.

• An input manifest file that specifies your input data in Amazon S3. Specify the location of your input manifest file in ManifestS3Uri. For information about creating an input manifest, see Input Data (p. 572). If you create a streaming labeling job, this is optional. To learn how to create a streaming labeling job, see Create a Streaming Labeling Job (p. 552).

• An Amazon S3 bucket to store your output data. You specify this bucket, and optionally, a prefix in S3OutputPath.

• A label category configuration file. Each label category name must be unique. Specify the location of this file in Amazon S3 using the LabelCategoryConfigS3Uri parameter. The format and label categories for this file depend on the task type you use:
  • For image classification and text classification (single and multi-label) you must specify at least two label categories. For all other task types, the minimum number of label categories required is one.
  • For named entity recognition tasks, you must provide worker instructions in this file. See Provide Worker Instructions in a Label Category Configuration File (p. 399) for details and an example.
  • For 3D point cloud and video frame task type, use the format in Create a Labeling Category Configuration File with Label Category and Frame Attributes (p. 557).
  • For all other built-in task types and custom tasks, your label category configuration file must be a JSON file in the following format. Identify the labels you want to use by replacing label_1, label_2,...,label_n with your label categories.

```json
{
   "document-version": "2018-11-28",
   "labels": [
      {"label": "label_1"},
      {"label": "label_2"},
      ...
      {"label": "label_n"}
   ]
}
```

• An AWS Identity and Access Management (IAM) role with the AmazonSageMakerGroundTruthExecution managed IAM policy attached and with permissions to access your S3 buckets. Specify this role in RoleArn. To learn more about this policy, see Use IAM Managed Policies with Ground Truth (p. 650). If you require more granular permissions, see the section called "IAM Permissions" (p. 650).

If your input or output bucket name does not contain sagemaker, you can attach a policy similar to the following to the role that is passed to the CreateLabelingJob operation.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": ["s3:GetObject"],
         "Resource": ["arn:aws:s3:::my_input_bucket/*"]
      },
      {
         "Effect": "Allow",
         "Action": [
```
• A pre-annotation and post-annotation (or annotation-consolidation) AWS Lambda function Amazon Resource Name (ARN) to process your input and output data.

• Lambda functions are predefined in each AWS Region for built-in task types. To find the pre-annotation Lambda ARN for your Region, see PreHumanTaskLambdaArn. To find the annotation-consolidation Lambda ARN for your Region, see AnnotationConsolidationLambdaArn.

• For custom labeling workflows, you must provide a custom pre- and post-annotation Lambda ARN. To learn how to create these Lambda functions, see Step 3: Processing with AWS Lambda (p. 516).

• A work team ARN that you specify in WorkteamArn. You receive a work team ARN when you subscribe to a vendor workforce or create a private workteam. If you are creating a labeling job for a video frame or point cloud task type, you cannot use the Amazon Mechanical Turk workforce. For all other task types, to use the Mechanical Turk workforce, use the following ARN. Replace region with the AWS Region you are using to create the labeling job.

  arn:aws:sagemaker:region:394669845002:workteam/public-crowd/default

If you use the Amazon Mechanical Turk workforce, use the ContentClassifiers parameter in DataAttributes of InputConfig to declare that your content is free of personally identifiable information and adult content.

Ground Truth requires that your input data is free of personally identifiable information (PII) if you use the Mechanical Turk workforce. If you use Mechanical Turk and do not specify that your input data is free of PII using the FreeOfPersonallyIdentifiableInformation flag, your labeling job will fail. Use the FreeOfAdultContent flag to declare that your input data is free of adult content. SageMaker may restrict the Amazon Mechanical Turk workers that can view your task if it contains adult content.

To learn more about work teams and workforces, see Create and Manage Workforces (p. 694).

• If you use the Mechanical Turk workforce, you must specify the price you’ll pay workers for performing a single task in PublicWorkforceTaskPrice.

• To configure the task, you must provide a task description and title using TaskDescription and TaskTitle respectively. Optionally, you can provide time limits that control how long the workers have to work on an individual task (TaskTimeLimitInSeconds) and how long tasks remain in the worker portal, available to workers (TaskAvailabilityLifetimeInSeconds).

• (Optional) For some task types, you can have multiple workers label a single data object by inputting a number greater than one for the NumberOfHumanWorkersPerDataObject parameter. For more information about annotation consolidation, see Consolidate Annotations (p. 639).

• (Optional) To create an automated data labeling job, specify one of the ARNs listed in LabelingJobAlgorithmSpecificationArn in LabelingJobAlgorithmsConfig. This ARN identifies the algorithm used in the automated data labeling job. The task type associated with this ARN must match the task type of the PreHumanTaskLambdaArn and AnnotationConsolidationLambdaArn you specify. Automated data labeling is supported for the following task types: image classification, bounding box, semantic segmentation, and text classification. The minimum number of objects allowed for automated data labeling is 1,250, and we strongly suggest providing a minimum of 5,000 objects. To learn more about automated data labeling jobs, see Automate Data Labeling (p. 640).

• (Optional) You can provide StoppingConditions that cause the labeling job to stop if one the conditions is met. You can use stopping conditions to control the cost of the labeling job.
Examples

The following code examples demonstrate how to create a labeling job using `CreateLabelingJob`. For additional examples, we recommend you use one of the Ground Truth Labeling Jobs Jupyter notebooks in the SageMaker Examples section of a SageMaker notebook instance. To learn how to use a notebook example from the SageMaker Examples, see Example Notebooks (p. 306). You can also see these example notebooks on GitHub in the SageMaker Examples repository.

AWS SDK for Python (Boto3)

The following is an example of an AWS Python SDK (Boto3) request to create a labeling job for a built-in task type in the US East (N. Virginia) Region using a private workforce. Replace all red-italized text with your labeling job resources and specifications.

```python
response = client.create_labeling_job(
    LabelingJobName="example-labeling-job",
    LabelAttributeName="label",
    InputConfig={
        'DataSource': {
            'S3DataSource': {
                'ManifestS3Uri': "s3://bucket/path/manifest-with-input-data.json"
            }
        },
        'DataAttributes': {
            'ContentClassifiers': [
                "FreeOfPersonallyIdentifiableInformation","FreeOfAdultContent",
            ]
        }
    },
    OutputConfig={
        'S3OutputPath': "s3://bucket/path/file-to-store-output-data",
        'KmsKeyId': "string"
    },
    RoleArn="arn:aws:iam::*:role/*",
    LabelCategoryConfigS3Uri="s3://bucket/path/label-categories.json",
    StoppingConditions={
        'MaxHumanLabeledObjectCount': 123,
        'MaxPercentageOfInputDatasetLabeled': 123
    },
    HumanTaskConfig={
        'WorkteamArn': "arn:aws:sagemaker:region::*:workteam/private-crowd/*",
        'UiConfig': {

AWS CLI

The following is an example of an AWS CLI request to create a labeling job for a built-in task type in the US East (N. Virginia) Region using the Amazon Mechanical Turk workforce. For more information, see `start-human-loop` in the AWS CLI Command Reference. Replace all *red-italized text* with your labeling job resources and specifications.

```bash
$ aws --region us-east-1 sagemaker create-labeling-job \
--labeling-job-name "example-labeling-job" \
--label-attribute-name "label" \
--role-arn "arn:aws:iam::account-id:role/role-name" \
--input-config '{
    "DataAttributes": {
        "ContentClassifiers": [
            "FreeOfPersonallyIdentifiableInformation",
            "FreeOfAdultContent"
        ],
    },
    "DataSource": {
        "S3DataSource": {
            "ManifestS3Uri": "s3://bucket/path/manifest-with-input-data.json"
        }
    }
} \
--output-config '{
    "KmsKeyId": '',
    "S3OutputPath": "s3://bucket/path/file-to-store-output-data"
} \
--human-task-config '{
    "AnnotationConsolidationConfig": {
        "AnnotationConsolidationLambdaArn": "arn:aws:lambda:us-east-1:432418664414:function:ACS-
    },
    "TaskAvailabilityLifetimeInSeconds": 21600,
    "TaskTimeLimitInSeconds": 3600,
    "NumberOfHumanWorkersPerDataObject": 1,

    }
}
```

Create a Labeling Job

For more information about this operation, see CreateLabelingJob. For information about how to use other language-specific SDKs, see See Also in the CreateLabelingJobs topic.

Create a Streaming Labeling Job

Streaming labeling jobs enable you to send individual data objects in real time to a perpetually running, streaming labeling job. To create a streaming labeling job, you must create an Amazon SNS input topic and specify this topic in CreateLabelingJob parameters InputConfig of SnsDataSource. Optionally, you can also create an Amazon SNS output topic and specify it in OutputConfig if you want to receive label data in real time.

Important
If you are a new user of Ground Truth streaming labeling jobs, it is recommended that you review Ground Truth Streaming Labeling Jobs (p. 576) before creating a streaming labeling job.

Use the following sections to create the resources that you need and can use to create a streaming labeling job:

- Learn how to create SNS topics with the permissions required for Ground Truth streaming labeling jobs by following the steps in Create Amazon SNS Input and Output Topics (p. 552). Your SNS topics must be created in the same AWS Region as your labeling job.
- See Subscribe an Endpoint to Your Amazon SNS Output Topic (p. 554) to learn how to set up an endpoint to receive labeling task output data at a specified endpoint each time a labeling task is completed.
- To learn how to configure your Amazon S3 bucket to send notifications to your Amazon SNS input topic, see Set up Amazon S3 Bucket Event Notifications (p. 555).
- Optionally, add data objects that you want to have labeled as soon as the labeling job starts to your input manifest. For more information, see Create a Manifest File (Optional) (p. 555).
- There are other resources required to create a labeling job, such as an IAM role, Amazon S3 bucket, a worker task template and label categories. These are described in the Ground Truth documentation on creating a labeling job. For more information, see Create a Labeling Job (p. 541).

Important
When you create a labeling job you must provide an IAM execution role. Attach the AWS managed policy AmazonSageMakerGroundTruthExecution to this role to ensure it has required permissions to execute your labeling job.

When you submit a request to create a streaming labeling job, the state of your labeling job is Initializing. Once the labeling job is active, the state changes to InProgress. Do not send new data objects to your labeling job or attempt to stop your labeling job while it is in the Initializing state. Once the state changes to InProgress, you can start sending new data objects using Amazon SNS and the Amazon S3 configuration.

Topics
- Create Amazon SNS Input and Output Topics (p. 552)
- Set up Amazon S3 Bucket Event Notifications (p. 555)
- Create a Manifest File (Optional) (p. 555)
- Example: Use SageMaker API To Create Streaming Labeling Job (p. 555)
- Stop a Streaming Labeling Job (p. 556)

Create Amazon SNS Input and Output Topics

You need to create an Amazon SNS input to create a streaming labeling job. Optionally, you may provide an Amazon SNS output topic.
When you create an Amazon SNS topic to use in your streaming labeling job, note down the topic Amazon Resource Name (ARN). The ARN will be the input values for the parameter SnsTopicArn in InputConfig and OutputConfig when you create a labeling job.

Create an Input Topic

Your input topic is used to send new data objects to Ground Truth. To create an input topic, follow the instructions in Creating an Amazon SNS topic in the Amazon Simple Notification Service Developer Guide.

Note down your input topic ARN and use it as input for the CreateLabelingJob parameter SnsTopicArn in InputConfig.

Create an Output Topic

If you provide an output topic, it is used to send notifications when a data object is labeled. When you create a topic, you have the option to add an encryption key. Use this option to add an AWS Key Management Service customer managed key to your topic to encrypt the output data of your labeling job before it is published to your output topic.

To create an output topic, follow the instructions in Creating an Amazon SNS topic in the Amazon Simple Notification Service Developer Guide.

If you add encryption, you must attach additional permission to the topic. See Add Encryption to Your Output Topic (Optional) (p. 553) for more information.

Important
To add a customer managed key to your output topic while creating a topic in the console, do not use the (Default) alias/aws/sns option. Select a customer managed key that you created.

Note down your input topic ARN and use it in your CreateLabelingJob request in the parameter SnsTopicArn in OutputConfig.

Add Encryption to Your Output Topic (Optional)

To encrypt messages published to your output topic, you need to provide an AWS KMS customer managed key to your topic. Modify the following policy and add it to your customer managed key to give Ground Truth permission to encrypt output data before publishing it to your output topic.

Replace <account_id> with the ID of the account that you are using to create your topic. To learn how to find your AWS account ID, see Finding Your AWS Account ID.

```json
{
  "Id": "key-console-policy",
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Enable IAM User Permissions",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::<account_id>:root"
      },
      "Action": "kms:*",
      "Resource": "*"
    },
    {
      "Sid": "Allow access for Key Administrators",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::<account_id>:role/Admin"
      }
    }
  ]
}
```
Additionally, you must modify and add the following policy to the execution role that you use to create your labeling job (the input value for `RoleArn`).

Replace `<account_id>` with the ID of the account that you are using to create your topic. Replace `<region>` with the AWS Region you are using to create your labeling job. Replace `<key_id>` with your customer managed key ID.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "sid1",
      "Effect": "Allow",
      "Action": [
        "kms:Decrypt",
        "kms:GenerateDataKey"
      ],
      "Resource": "arn:aws:kms:<region>:<account_id>:key/<key_id>"
    }
  ]
}
```

For more information on creating and securing keys, see Creating Keys and Using Key Policies in the AWS Key Management Service Developer Guide.

**Subscribe an Endpoint to Your Amazon SNS Output Topic**

When a worker completes a labeling job task from a Ground Truth streaming labeling job, Ground Truth uses your output topic to publish output data to one or more endpoints that you specify. To receive notifications when a worker finishes a labeling task, you must subscribe an endpoint to your Amazon SNS output topic.

To learn how to add endpoints to your output topic, see Subscribing to an Amazon SNS topic in the Amazon Simple Notification Service Developer Guide.

To learn more about the output data format that is published to these endpoints, see Output Data (p. 614).

**Important**

If you do not subscribe an endpoint to your Amazon SNS output topic, you will not receive notifications when new data objects are labeled.
Set up Amazon S3 Bucket Event Notifications

You can add an event notification to your Amazon S3 bucket using the Amazon S3 console, API, and language specific AWS SDKs, or the AWS Command Line Interface. Set up this event to send notifications to the same Amazon SNS input topic that you specify using SnsTopicArn in InputConfig when you create a labeling job. Do not set up event notifications using the same Amazon S3 location that you specified for S3OutputPath in OutputConfig – doing so may result in unwanted data objects being processed by Ground Truth for labeling.

You decide the types of events that you want to send to your Amazon SNS topic. Ground Truth creates a labeling job when you send object creation events.

The event structure sent to your Amazon SNS input topic must be a JSON message formatted using the same structure found in Event message structure.

To see examples of how you can set up an event notification for your Amazon S3 bucket using the Amazon S3 console, AWS SDK for .NET, and AWS SDK for Java, follow this walkthrough, Walkthrough: Configure a bucket for notifications (SNS topic or SQS queue) in the Amazon Simple Storage Service User Guide.

Create a Manifest File (Optional)

When you create a streaming labeling job, you have the one time option to add objects (such as images or text) to an input manifest file that you specify in ManifestS3Uri of CreateLabelingJob. When the streaming labeling job starts, these objects are sent to workers or added to the Amazon SQS queue if the total number of objects exceed MaxConcurrentTaskCount. The results are added to the Amazon S3 path that you specify when creating the labeling job periodically as workers complete labeling tasks. Output data is sent to any endpoint that you subscribe to your output topic.

If you want to provide initial objects to be labeled, create a manifest file that identifies these objects and place it in Amazon S3. Specify the S3 URI of this manifest file in ManifestS3Uri within InputConfig.

To learn how to format your manifest file, see Input Data (p. 572). To use the SageMaker console to automatically generate a manifest file (not supported for 3D point cloud task types), see Automated Data Setup (p. 574).

Example: Use SageMaker API To Create Streaming Labeling Job

The following is an example of an AWS Python SDK (Boto3) request that you can use to start a streaming labeling job for a built-in task type in the US East (N. Virginia) Region. For more details about each parameter below see CreateLabelingJob. To learn how you can create a labeling job using this API and associated language specific SDKs, see Create a Labeling Job (API).

In this example, note the following parameters:

- SnsDataSource – This parameter appears in InputConfig and OutputConfig and is used to identify your input and output Amazon SNS topics respectively. To create a streaming labeling job, you are required to provide an Amazon SNS input topic. Optionally, you can also provide an Amazon SNS output topic.
- S3DataSource – This parameter is optional. Use this parameter if you want to include an input manifest file of data objects that you want labeled as soon as the labeling job starts.
- StoppingConditions – This parameter is ignored when you create a streaming labeling job. To learn more about stopping a streaming labeling job, see Stop a Streaming Labeling Job (p. 556).
- Streaming labeling jobs do not support automated data labeling. Do not include the LabelingJobAlgorithmsConfig parameter.

```python
response = client.create_labeling_job(
```
LabelingJobName= 'example-labeling-job',
LabelAttributeName='label',
InputConfig={
  'DataSource': {
    'S3DataSource': {
      'ManifestS3Uri': 's3://bucket/path/manifest-with-input-data.json'
    },
    'SnsDataSource': {
      'SnsTopicArn': 'arn:aws:sns:us-east-1:123456789012:your-sns-input-topic'
    }
  },
  'DataAttributes': {
    'ContentClassifiers': ['FreeOfPersonallyIdentifiableInformation', 'FreeOfAdultContent']
  }
},
OutputConfig={
  'S3OutputPath': 's3://bucket/path/file-to-store-output-data',
  'KmsKeyId': 'string',
  'SnsTopicArn': 'arn:aws:sns:us-east-1:123456789012:your-sns-output-topic'
},
RoleArn='arn:aws:iam::*:role/*',
LabelCategoryConfigS3Uri='s3://bucket/path/label-categories.json',
HumanTaskConfig={
  'WorkteamArn': 'arn:aws:sagemaker:us-east-1:*:workteam/private-crowd/*',
  'UiConfig': {
    'UiTemplateS3Uri': 's3://bucket/path/custom-worker-task-template.html'
  },
  'TaskKeywords': [],
  'TaskTitle': 'Multi-label image classification task',
  'TaskDescription': 'Select all labels that apply to the images shown',
  'NumberOfHumanWorkersPerDataObject': 123,
  'TaskTimeLimitInSeconds': 123,
  'TaskAvailabilityLifetimeInSeconds': 123,
  'MaxConcurrentTaskCount': 123,
  'AnnotationConsolidationConfig': {
    'AnnotationConsolidationLambdaArn': 'arn:aws:lambda:us-east-1:432418664414:function:ACS-tasktype'
  },
  Tags=[
    {
      'Key': 'string',
      'Value': 'string'
    }
  ]
},
Stop a Streaming Labeling Job

You can manually stop your streaming labeling job using the operation StopLabelingJob.

If your labeling job remains idle for over 10 days, it is automatically stopped by Ground Truth. In this context, a labeling job is considered idle if no objects are sent to the Amazon SNS input topic and no objects remain in your Amazon SQS queue, waiting to be labeled. For example, if no data objects are fed to the Amazon SNS input topic and all the objects fed to the labeling job are already labeled, Ground Truth starts a timer. After the timer starts, if no items are received within a 10 day period, the labeling job is stopped.

If this 10 day limit poses a problem for your business use case, please contact AWS Support.
When a labeling job is stopped, its status is STOPPING while Ground Truth cleans up labeling job resources and unsubscribes your Amazon SNS topic from your Amazon SQS queue. The Amazon SQS is not deleted by Ground Truth because this queue may contain unprocessed data objects. You should manually delete the queue if you want to avoid incurring additional charges from Amazon SQS. To learn more, see Amazon SQS pricing.

Create a Labeling Category Configuration File with Label Category and Frame Attributes

When you create a 3D point cloud or video frame labeling job using the Amazon SageMaker API operation CreateLabelingJob, you use a label category configuration file to specify your labels and worker instructions. Optionally, you can also provide the following in your label category attribute file:

- You can provide **label category attributes** for video frame and 3D point cloud object tracking and object detection task types. Workers can use one or more attributes to give more information about an object. For example, you may want to use the attribute *occluded* to have workers identify when an object is partially obstructed. You can either specify a label category attribute for a single label using the `categoryAttributes` parameter, or for all labels using the `categoryGlobalAttributes` parameter.

- You can provide **frame attributes** for video frame and 3D point cloud object tracking and object detection task types using `frameAttributes`. When you create a frame attribute, it appears on each frame or point cloud in the worker task. In video frame labeling jobs, these are attributes that workers assign to an entire video frame. For 3D point cloud labeling jobs, these attributes are applied to a single point cloud. Use frame attributes to have workers provide more information about the scene in a specific frame or point cloud.

- For video frame labeling jobs, you use the label category configuration file to specify the task type (bounding box, polyline, polygon, or keypoint) sent to workers.

For workers, specifying values for label category attributes and frame attributes will be optional.

**Important**
You should only provide a label attribute name in `auditLabelAttributeName` if you are running an audit job to verify or adjust labels. Use this parameter to input the `LabelAttributeName` used in the labeling job that generated the annotations you want your worker to adjust. When you create a labeling job in the console, if you did not specify a label attribute name, the Name of your job is used as the LabelAttributeName.

**Topics**
- Label Category Configuration File Schema (p. 557)
- Example: Label Category Configuration Files for 3D Point Cloud Labeling Jobs (p. 564)
- Example: Label Category Configuration Files for Video Frame Labeling Jobs (p. 568)
- Creating Worker Instructions (p. 571)

**Label Category Configuration File Schema**

The following table lists elements you can and must include in your label category configuration file.

**Note**
The parameter `annotationType` is only supported for video frame labeling jobs.

<table>
<thead>
<tr>
<th>Parameter</th>

</tr>
</tbody>
</table>

The following table describes the parameters that you can and must use to create a list of Labels. Each parameter should be included in a JSON object.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Accepted Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>label</td>
<td>Yes</td>
<td>String</td>
<td>The name of the label category that is displayed to workers. Each label category name must be unique.</td>
</tr>
<tr>
<td>categoryAttributes</td>
<td>No</td>
<td>A list of JSON objects. Required Parameters in each JSON Object: name, type minimum and maximum required if type is &quot;number&quot; Optional Parameters in each JSON Object: description, enum, editsAllowed, isRequired Use this parameter to add label category attributes to specific labels you specify in labels. To add one or more label category attributes to a label, include the categoryAttributes JSON object in the same labels JSON object as that label. See the following table for more information.</td>
<td></td>
</tr>
<tr>
<td>editsAllowed</td>
<td>No</td>
<td>String</td>
<td>Specifies whether or not a label can be edited by workers. Supported Values: &quot;none&quot;: no modifications are not allowed. or &quot;any&quot; (Default): all modifications are allowed. For video frame or 3D point cloud adjustment labeling jobs, add this parameter to one or more JSON objects in the labels list to specify whether or not a worker can edit a label. For 3D point cloud and video frame verification labeling jobs, add this parameter with the value &quot;none&quot; to each JSON object in the labels list. This will make all labels uneditable.</td>
</tr>
</tbody>
</table>

The following table describes the parameters that you can and must use to create a frame attributes using frameAttributes and label category attribute using the categoryGlobalAttributes and categoryAttributes parameters.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Accepted Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Yes</td>
<td>String</td>
<td>Use this parameter to assign a name to your label category or frame attribute. This is the attribute name that workers see. Each label category attribute name in your label category configuration file must be unique. Global label category attributes and label specific label category attributes cannot have the same name.</td>
</tr>
<tr>
<td>type</td>
<td>Yes</td>
<td>String</td>
<td>Use this parameter to define the label category or frame attribute type. If you specify &quot;string&quot; for type and provide an enum value for this attribute, workers will be able to choose from one of the choices you provide. If you specify &quot;string&quot; for type and do not provide an enum value, workers can enter free form text. If you specify number for type, worker can enter a number between the minimum and maximum numbers you specify.</td>
</tr>
<tr>
<td>enum</td>
<td>No</td>
<td>List of strings</td>
<td>Use this parameter to define options that workers can choose from for this label category or frame attribute. Workers can choose one value specified in enum. For example, if you specify [&quot;foo&quot;, &quot;buzz&quot;,</td>
</tr>
<tr>
<td>Parameter</td>
<td>Required</td>
<td>Accepted Values</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>----------</td>
<td>-----------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>&quot;bar&quot;] for enum, workers can choose one of foo, buzz, or bar.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>You must specify &quot;string&quot; for type to use an enum list.</td>
</tr>
<tr>
<td>description</td>
<td>frameAttributes: String Yes</td>
<td>categoryAttributes or categoryGlobalAttributes: No</td>
<td>Use this parameter to add a description of the label category or frame attribute. You can use this field to give workers more information about the attribute. This field is only required for frame attributes.</td>
</tr>
<tr>
<td>minimum and maximum</td>
<td>Required if attribute type is &quot;number&quot;</td>
<td>Integers</td>
<td>Use these parameters to specify minimum and maximum (inclusive) values workers can enter for numeric label category or frame attributes. You must specify &quot;number&quot; for type to use minimum and maximum.</td>
</tr>
<tr>
<td>editsAllowed</td>
<td>No</td>
<td>String</td>
<td>Specifies whether or not a label category or frame attribute can be edited by workers. For video frame or 3D point cloud adjustment and verification labeling jobs, add this parameter to label category and frame attribute JSON objects to specify whether or not a worker can edit an attribute.</td>
</tr>
</tbody>
</table>
### Parameter

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Accepted Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>isRequired</td>
<td>No</td>
<td>Boolean</td>
<td>Specifies whether workers are required to annotate an attribute. Workers cannot submit the job until all required attributes are annotated.</td>
</tr>
</tbody>
</table>

### Label and label category attribute quotas

You can specify up to 10 label category attributes per class. This 10-attribute quotas includes global label category attributes. For example, if you create four global label category attributes, and then assign three label category attributes to label X, that label will have $4+3=7$ label category attributes in total. For all label category and label category attribute limits, refer to the following table.

<table>
<thead>
<tr>
<th>Type</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>Labels (Labels)</td>
<td>1</td>
<td>30</td>
</tr>
<tr>
<td>Label name character quota</td>
<td>1</td>
<td>16</td>
</tr>
<tr>
<td>Label category attributes per label (sum of categoryAttributes and categoryGlobalAttributes)</td>
<td>0</td>
<td>10</td>
</tr>
<tr>
<td>Free form text entry label category attributes per label (sum of categoryAttributes and categoryGlobalAttributes)</td>
<td>0</td>
<td>5</td>
</tr>
<tr>
<td>Frame attributes</td>
<td>0</td>
<td>10</td>
</tr>
<tr>
<td>Free form text entry attributes in frameAttributes</td>
<td>0</td>
<td>5</td>
</tr>
<tr>
<td>Attribute name character quota (name)</td>
<td>1</td>
<td>16</td>
</tr>
<tr>
<td>Attribute description character quota (description)</td>
<td>0</td>
<td>128</td>
</tr>
<tr>
<td>Attribute type characters quota (type)</td>
<td>1</td>
<td>16</td>
</tr>
<tr>
<td>Allowed values in the enum list for a string attribute</td>
<td>1</td>
<td>10</td>
</tr>
<tr>
<td>Character quota for a value in enum list</td>
<td>1</td>
<td>16</td>
</tr>
<tr>
<td>Maximum characters in free form text response for free form text frameAttributes</td>
<td>0</td>
<td>1000</td>
</tr>
</tbody>
</table>
Create a Labeling Job

<table>
<thead>
<tr>
<th>Type</th>
<th>Min</th>
<th>Max</th>

Example: Label Category Configuration Files for 3D Point Cloud Labeling Jobs

Select a tab in the following tables to see examples of 3D point cloud label category configuration files for object detection, object tracking, semantic segmentation, adjustment, and verification labeling jobs.

3D Point Cloud Object Tracking and Object Detection

The following is an example of a label category configuration file that includes label category attributes for a 3D point cloud object detection or object tracking labeling job. This example includes a two frame attributes, which will be added to all point clouds submitted to the labeling job. The Car label will include four label category attributes—X, Y, Z, and the global attribute, W.

```json
{
    "documentVersion": "2020-03-01",
    "frameAttributes": [
        {
            "name": "count players",
            "description": "How many players do you see in the scene?",
            "type": "number"
        },
        {
            "name": "select one",
            "description": "Describe the scene",
            "type": "string",
            "enum": ["clear", "blurry"],
            "isRequired": true
        }
    ],
    "categoryGlobalAttributes": [
        {
            "name": "W",
            "description": "label-attributes-for-all-labels",
            "type": "string",
            "enum": ["foo", "buzz", "biz"]
        }
    ],
    "labels": [
        {
            "label": "Car",
            "categoryAttributes": [
                {
                    "name": "X",
                    "description": "Enter a number",
                    "type": "number",
                },
                {
                    "name": "Y",
                    "description": "Select an option",
                    "type": "string",
                    "enum": ["y1", "y2"]
                },
                {
                    "name": "Z",
                    "description": "Submit a free-form response",
                    "type": "string",
                }
            ]
        }
    ]
}
```
3D Point Cloud Semantic Segmentation

The following is an example of a label category configuration file for a 3D point cloud semantic segmentation labeling job.

Label category attributes are not supported for 3D point cloud semantic segmentation task types. Frame attributes are supported. If you provide label category attributes for a semantic segmentation labeling job, they will be ignored.

```json
{
  "documentVersion": "2020-03-01",
  "frameAttributes": [
    {
      "name": "count players",
      "description": "How many players do you see in the scene?",
      "type": "number"
    },
    {
      "name": "select one",
      "description": "Describe the scene",
      "type": "string",
      "enum": ["clear", "blurry"]
    }
  ],
  "labels": [
    {
      "label": "Car"
    },
    {
      "label": "Pedestrian"
    },
    {
      "label": "Cyclist"
    }
  ],
  "instructions": {
    "shortInstruction": "Select the appropriate label and paint all objects in the point cloud that it applies to the same color",
    "fullInstruction": "<html markup>"
  }
}
```

Select a tab in the following table to see an example of a label category configuration file for 3D point cloud verification or adjustment labeling jobs.

3D Point Cloud Adjustment

The following is an example of a label category configuration file for a 3D point cloud object detection or object tracking adjustment labeling job. For 3D point cloud semantic segmentation adjustment labeling jobs, categoryGlobalAttributes and categoryAttributes are not supported.
You must include `auditLabelAttributeName` to specify the label attribute name of the previous labeling job that you use to create the adjustment labeling job. Optionally, you can use the `editsAllowed` parameter to specify whether or not a label or frame attribute can be edited.

```json
{
  "documentVersion": "2020-03-01",
  "frameAttributes": [
    {
      "name": "count players",
      "description": "How many players do you see in the scene?",
      "type": "number"
    },
    {
      "name": "select one",
      "editsAllowed": "none",
      "description": "describe the scene",
      "type": "string",
      "enum": ["clear", "blurry"]
    }
  ],
  "categoryGlobalAttributes": [
    {
      "name": "W",
      "editsAllowed": "any",
      "description": "label-attributes-for-all-labels",
      "type": "string",
      "enum": ["foo", "buzz", "biz"]
    }
  ],
  "labels": [
    {
      "label": "Car",
      "editsAllowed": "any",
      "categoryAttributes": [
        {
          "name": "X",
          "description": "enter a number",
          "type": "number"
        },
        {
          "name": "Y",
          "description": "select an option",
          "type": "string",
          "enum": ["y1", "y2"],
          "editsAllowed": "any"
        },
        {
          "name": "Z",
          "description": "submit a free-form response",
          "type": "string",
          "editsAllowed": "none"
        }
      ]
    },
    {
      "label": "Pedestrian",
      "categoryAttributes": [...]}
  ],
  "instructions": {"shortInstruction": "Draw a tight Cuboid", "fullInstruction": "<html markup>",
  // include auditLabelAttributeName for label adjustment jobs
  "auditLabelAttributeName": "myPrevJobLabelAttributeName"
}
```
3D Point Cloud Verification

The following is an example of a label category configuration file you may use for a 3D point cloud object detection or object tracking verification labeling job. For a 3D point cloud semantic segmentation verification labeling job, categoryGlobalAttributes and categoryAttributes are not supported.

You must include auditLabelAttributeName to specify the label attribute name of the previous labeling job that you use to create the verification labeling job. Additionally, you must use the editsAllowed parameter to specify that no labels can be edited.

```json
{
    "documentVersion": "2020-03-01",
    "frameAttributes": [
        {
            "name": "count players",
            "editsAllowed": "any",
            "description": "How many players do you see in the scene?",
            "type": "number"
        },
        {
            "name": "select one",
            "editsAllowed": "any",
            "description": "describe the scene",
            "type": "string",
            "enum": ["clear", "blurry"
        }
    ],
    "categoryGlobalAttributes": [
        {
            "name": "W",
            "editsAllowed": "none",
            "description": "label-attributes-for-all-labels",
            "type": "string",
            "enum": ["foo", "buzz", "biz"],
        }
    ],
    "labels": [
        {
            "label": "Car",
            "editsAllowed": "none",
            "categoryAttributes": [
                {
                    "name": "X",
                    "description": "enter a number",
                    "type": "number",
                    "editsAllowed": "none"
                },
                {
                    "name": "Y",
                    "description": "select an option",
                    "type": "string",
                    "enum": ["y1", "y2"],
                    "editsAllowed": "any"
                },
                {
                    "name": "Z",
                    "description": "submit a free-form response",
                    "type": "string",
                    "editsAllowed": "none"
                }
            ]
        }
    ]
}
```
Example: Label Category Configuration Files for Video Frame Labeling Jobs

The annotation tools available to your worker and task type used depends on the value you specify for annotationType. For example, if you want workers to use key points to track changes in the pose of specific objects across multiple frames, you would specify Keypoint for the annotationType. If you do not specify an annotation type, BoundingBox will be used by default.

The following is an example of a video frame keypoint label category configuration file with label category attributes. This example includes two frame attributes, which will be added to all frames submitted to the labeling job. The Car label will include four label category attributes—X, Y, Z, and the global attribute, W.

```json
{
  "documentVersion": "2020-03-01",
  "frameAttributes": [
    {
      "name": "count players",
      "description": "How many players do you see in the scene?",
      "type": "number"
    },
    {
      "name": "select one",
      "description": "Describe the scene",
      "type": "string",
      "enum": ["clear", "blurry"]
    }
  ],
  "categoryGlobalAttributes": [
    {
      "name": "W",
      "description": "label-attributes-for-all-labels",
      "type": "string",
      "enum": ["foo", "buz", "buz2"]
    }
  ],
  "labels": [
    {
      "label": "Car",
      "categoryAttributes": [
        {
          "name": "X",
          "description": "Enter a number",
          "type": "number"
        },
        {
          "name": "Y",
          "description": "Select an option",
          "type": "string",
          "enum": ["y1", "y2"]
        }
      ]
    }
  ]
}
```
Select a tab from the following table to see examples of label category configuration files for video frame adjustment and verification labeling jobs.

**Video Frame Adjustment**

The following is an example of a label category configuration file you may use for a video frame adjustment labeling job.

You must include `auditLabelAttributeName` to specify the label attribute name of the previous labeling job that you use to create the verification labeling job. Optionally, you can use the `editsAllowed` parameter to specify whether or not labels, label category attributes, or frame attributes can be edited.

```json
{
    "documentVersion": "2020-03-01",
    "frameAttributes": [
        {
            "name": "count players",
            "editsAllowed": "none",
            "description": "How many players to you see in the scene?",
            "type": "number"
        },
        {
            "name": "select one",
            "description": "describe the scene",
            "type": "string",
            "enum": ["clear", "blurry"]
        }
    ],
    "categoryGlobalAttributes": [
        {
            "name": "W",
            "editsAllowed": "any",
            "description": "label-attributes-for-all-labels",
            "type": "string",
            "enum": ["foo", "buz", "buz2"]
        }
    ],
    "labels": [
        {
            "label": "Car",
            "editsAllowed": "any",
            "categoryAttributes": [
                {
                    "name": "X",
                    "description": "enter a number",
                    "type": "number",
                    "editsAllowed": "any"
                }
            ]
        }
    ]
}
```
Video Frame Verification

The following is an example of a label category configuration file for a video frame labeling job.

You must include `auditLabelAttributeName` to specify the label attribute name of the previous labeling job that you use to create the verification labeling job. Additionally, you must use the `editsAllowed` parameter to specify that no labels can be edited.

```json
{
  "documentVersion": "2020-03-01",
  "frameAttributes": [
    {
      "name": "count players",
      "editsAllowed": "none",
      "description": "How many players do you see in the scene?",
      "type": "number"
    },
    {
      "name": "select one",
      "editsAllowed": "any",
      "description": "describe the scene",
      "type": "string",
      "enum": ["clear", "blurry"]
    }
  ],
  "categoryGlobalAttributes": [
    {
      "name": "W",
      "editsAllowed": "none",
      "description": "label-attributes-for-all-labels",
      "type": "string",
      "enum": ["foo", "buz", "buz2"]
    }
  ],
  "labels": [
    {
      "name": "Y",
      "description": "select an option",
      "type": "string",
      "enum": ["y1", "y2"],
      "editsAllowed": "any"
    },
    {
      "name": "Z",
      "description": "submit a free-form response",
      "type": "string",
      "editsAllowed": "none"
    }
  ]
}
```
Creating Worker Instructions

Create custom instructions for labeling jobs to improve your worker's accuracy in completing their task. Your instructions are accessible when workers select the Instructions menu option in the worker UI. Short instructions must be under 255 characters and long instruction must be under 2,048 characters.

There are two kinds of instructions:

- **Short instructions** – These instructions are shown to workers when they select Instructions in the worker UI menu. They should provide an easy reference to show the worker the correct way to label an object.

- **Full instructions** – These instructions are shown when workers select More Instructions in instructions the pop-up window. We recommend that you provide detailed instructions for completing the task with multiple examples showing edge cases and other difficult situations for labeling objects.

For 3D point cloud and video frame labeling jobs, you can add worker instructions to your label category configuration file. You can use a single string to create instructions or you can add HTML mark up to customize the appearance of your instructions and add images. Make sure that any images you include in your instructions are publicly available, or if your instructions are in Amazon S3, that your workers have read-access so that they can view them.
Use Input and Output Data

The input data that you provide to Amazon SageMaker Ground Truth is sent to your workers for labeling. You choose the data to send to your workers by creating a single manifest file that defines all of the data that requires labeling or by sending input data objects to an ongoing, streaming labeling job to be labeled in real time.

The output data is the result of your labeling job. The output data file, or augmented manifest file, contains label data for each object you send to the labeling job and metadata about the label assigned to data objects.

When you use image classification (single and multi-label), text classification (single and multi-label), object detection, and semantic segmentation built in task types to create a labeling job, you can use the resulting augmented manifest file to launch a SageMaker training job. For a demonstration of how to use an augmented manifest to train an object detection machine learning model with Amazon SageMaker, see object_detection_augmented_manifest_training.ipynb. For more information, see Provide Dataset Metadata to Training Jobs with an Augmented Manifest File (p. 2700).

Topics
- Input Data (p. 572)
- 3D Point Cloud Input Data (p. 584)
- Video Frame Input Data (p. 608)
- Output Data (p. 614)

Input Data

The input data are the data objects that you send to your workforce to be labeled. There are two ways to send data objects to Ground Truth for labeling:

- Send a list of data objects that require labeling using an input manifest file.
- Send individual data objects in real time to a perpetually running, streaming labeling job.

If you have a dataset that needs to be labeled one time, and you do not require an ongoing labeling job, create a standard labeling job using an input manifest file.

If you want to regularly send new data objects to your labeling job after it has started, create a streaming labeling job. When you create a streaming labeling job, you can optionally use an input manifest file to specify a group of data that you want labeled immediately when the job starts. You can continuously send new data objects to a streaming labeling job as long as it is active.

Note

Streaming labeling jobs are only supported through the SageMaker API. You cannot create a streaming labeling job using the SageMaker console.

The following task types have special input data requirements and options:

- For 3D point cloud labeling job input data requirements, see 3D Point Cloud Input Data (p. 584).
- For video frame labeling job input data requirements, see Video Frame Input Data (p. 608).

Topics
- Use an Input Manifest File (p. 573)
- Automated Data Setup (p. 574)
- Supported Data Formats (p. 575)
- Ground Truth Streaming Labeling Jobs (p. 576)
Use an Input Manifest File

Each line in an input manifest file is an entry containing an object, or a reference to an object, to label. An entry can also contain labels from previous jobs and for some task types, additional information.

Input data and the manifest file must be stored in Amazon Simple Storage Service (Amazon S3). Each has specific storage and access requirements, as follows:

- The Amazon S3 bucket that contains the input data must be in the same AWS Region in which you are running Amazon SageMaker Ground Truth. You must give Amazon SageMaker access to the data stored in the Amazon S3 bucket so that it can read it. For more information about Amazon S3 buckets, see Working with Amazon S3 buckets.
- The manifest file must be in the same AWS Region as the data files, but it doesn't need to be in the same location as the data files. It can be stored in any Amazon S3 bucket that is accessible to the AWS Identity and Access Management (IAM) role that you assigned to Ground Truth when you created the labeling job.

**Note**

3D point cloud and video frame task types have different input manifest requirements and attributes. For 3D point cloud task types, refer to Create an Input Manifest File for a 3D Point Cloud Labeling Job (p. 586). For video frame task types, refer to Create a Video Frame Input Manifest File (p. 613).

The manifest is a UTF-8 encoded file in which each line is a complete and valid JSON object. Each line is delimited by a standard line break, \n or \r\n. Because each line must be a valid JSON object, you can't have unescaped line break characters. For more information about data format, see JSON Lines.

Each JSON object in the manifest file can be no larger than 100,000 characters. No single attribute within an object can be larger than 20,000 characters. Attribute names can't begin with $ (dollar sign).

Each JSON object in the manifest file must contain one of the following keys: source-ref or source. The value of the keys are interpreted as follows:

- **source-ref** – The source of the object is the Amazon S3 object specified in the value. Use this value when the object is a binary object, such as an image.
- **source** – The source of the object is the value. Use this value when the object is a text value.

The following is an example of a manifest file for files stored in an Amazon S3 bucket:

```json
{"source-ref": "s3 bucket location 1"},
{"source-ref": "s3 bucket location 2"}, 
...
{"source-ref": "s3 bucket location n"}
```

Use the source-ref key for image files for bounding box, image classification (single and multi-label), semantic segmentation, and video clips for video classification labeling jobs. 3D point cloud and video frame labeling jobs also use the source-ref key but these labeling jobs require additional information in the input manifest file. For more information see 3D Point Cloud Input Data (p. 584) and Video Frame Input Data (p. 608).

The following is an example of a manifest file with the input data stored in the manifest:
Use the `source` key for single and multi-label text classification and named entity recognition labeling jobs.

You can include other key-value pairs in the manifest file. These pairs are passed to the output file unchanged. This is useful when you want to pass information between your applications. For more information, see Output Data (p. 614).

Automated Data Setup

You can use the automated data setup to create manifest files for your labeling jobs in the Ground Truth console using images, videos, video frames, text (.txt) files, and comma-separated value (.csv) files stored in Amazon S3. When you use automated data setup, you specify an Amazon S3 location where your input data is stored and the input data type, and Ground Truth looks for the files that match that type in the location you specify.

**Note**

Ground Truth does not use an AWS KMS key to access your input data or write the input manifest file in the Amazon S3 location that you specify. The IAM user or role that creates the labeling job must have permissions to access your input data objects in Amazon S3.

Before using the following procedure, ensure that your input images or files are correctly formatted:

- **Image files** – Image files must comply with the size and resolution limits listed in the tables found in Input File Size Quota (p. 580).
- **Text files** – Text data can be stored in one or more .txt files. Each item that you want labeled must be separated by a standard line break.
- **CSV files** – Text data can be stored in one or more .csv files. Each item that you want labeled must be in a separate row.
- **Videos** – Video files can be any of the following formats: .mp4, .ogg, and .webm. If you want to extract video frames from your video files for object detection or object tracking, see Provide Video Files (p. 610).
- **Video frames** – Video frames are images extracted from a video. All images extracted from a single video are referred to as a sequence of video frames. Each sequence of video frames must have unique prefix keys in Amazon S3. See Provide Video Frames (p. 609). For this data type, see Automated Video Frame Input Data Setup (p. 611)

**Important**

For video frame object detection and video frame object tracking labeling jobs, see Automated Video Frame Input Data Setup (p. 611) to learn how to use the automated data setup.

Use these instructions to automatically set up your input dataset connection with Ground Truth.

**Automatically connect your data in Amazon S3 with Ground Truth**

   
   This link puts you in the North Virginia (us-east-1) AWS Region. If your input data is in an Amazon S3 bucket in another Region, switch to that Region. To change your AWS Region, on the navigation bar, choose the name of the currently displayed Region.

2. Select Create labeling job.

3. Enter a Job name.
4. In the section **Input data setup**, select **Automated data setup**.
5. Enter an Amazon S3 URI for **S3 location for input datasets**.
6. Specify your **S3 location for output datasets**. This is where your output data is stored.
7. Choose your **Data type** using the dropdown list.
8. Use the drop down menu under **IAM Role** to select an execution role. If you select **Create a new role**, specify the Amazon S3 buckets that you want grant this role permission to access. This role must have permission to access the S3 buckets you specified in Steps 5 and 6.
9. Select **Complete data setup**.

The following GIF demonstrates how to use the automated data setup for image data. This example will create a file, dataset-\texttt{YYMMDDTHHHMMSS}.manifest in the Amazon S3 bucket example-groundtruth-images where \texttt{YYMMDDTHHHMMSS} indicates the year (YY), month (MM), day (DD) and time in hours (HH), minutes (mm) and seconds (ss), that the input manifest file was created.

### Supported Data Formats

When you create an input manifest file for a **built-in task types** manually, your input data must be in one of the following support file formats for the respective input data type. To learn about automated data setup, see Automated Data Setup (p. 574).

**Tip**

When you use the automated data setup, additional data formats can be used to generate an input manifest file for video frame and text based task types.

Ground Truth Streaming Labeling Jobs

If you want to perpetually send new data objects to Amazon SageMaker Ground Truth to be labeled, use a streaming labeling job. Streaming labeling jobs allow you to:

- Send new dataset objects to workers in real time using a perpetually running labeling job. Workers continuously receive new data objects to label as long as the labeling job is active and new objects are being sent to it.
- Gain visibility into the number of objects that have been queued and are waiting to be labeled. Use this information to control the flow of data objects sent to your labeling job.
- Receive label data for individual data objects in real time as workers finish labeling them.

Ground Truth streaming labeling jobs remain active until they are manually stopped or have been idle for more than 10 days. You can intermittently send new data objects to workers while the labeling job is active.

If you are a new user of Ground Truth streaming labeling jobs, it is recommended that you review How It Works (p. 576).

Use Create a Streaming Labeling Job (p. 552) to learn how to create a streaming labeling job.

Note
Ground Truth streaming labeling jobs are only supported through the SageMaker API.

Topics
- How It Works (p. 576)
- Send Data to a Streaming Labeling Job (p. 576)
- Manage Labeling Requests with an Amazon SQS Queue (p. 578)
- Receive Output Data from a Streaming Labeling Job (p. 578)
- Duplicate Message Handling (p. 578)

How It Works

When you create a Ground Truth streaming labeling job, the job remains active until it is manually stopped, remains idle for more than 10 days, or is unable to access input data sources. You can intermittently send new data objects to workers while it is active. A worker can continue to receive new data objects in real time as long as the total number of tasks currently available to the worker is less than the value in MaxConcurrentTaskCount. Otherwise, the data object is sent to a queue that Ground Truth creates on your behalf in Amazon Simple Queue Service (Amazon SQS) for later processing. These tasks are sent to workers as soon as the total number of tasks currently available to a worker falls below MaxConcurrentTaskCount. If a data object is not sent to a worker after 14 days, it expires. You can view the number of tasks pending in the queue and adjust the number of objects you send to the labeling job. For example, you may decrease the speed at which you send objects to the labeling job if the backlog of pending objects moves above a threshold.

Send Data to a Streaming Labeling Job

You can optionally submit input data to a streaming labeling job one time when you create the labeling job using an input manifest file. Once the labeling job has started and the state is InProgress, you
can submit new data objects to your labeling job in real time using your Amazon SNS input topic and Amazon S3 event notifications.

**Submit Data Objects When you Start the Labeling Job (One Time):**

- **Use an Input Manifest File** – You can optionally specify an input manifest file Amazon S3 URI in `ManifestS3Uri` when you create the streaming labeling job. Ground Truth sends each data object in the manifest file to workers for labeling as soon as the labeling job starts. To learn more, see Create a Manifest File (Optional) (p. 555).

After you submit a request to create the streaming labeling job, its status will be **Initializing**. Once the labeling job is active, the state changes to **InProgress** and you can start using the real-time options to submit additional data objects for labeling.

**Submit Data Objects in Real Time:**

- **Send data objects using Amazon SNS messages** – You can send Ground Truth new data objects to label by sending an Amazon SNS message. You will send this message to an Amazon SNS input topic that you create and specify when you create your streaming labeling job. For more information, see Send Data Objects Using Amazon SNS (p. 577).

- **Send data objects by placing them in an Amazon S3 bucket** – Each time you add a new data object to an Amazon S3 bucket, you can prompt Ground Truth to process that object for labeling. To do this, you add an event notification to the bucket so that it notifies your Amazon SNS input topic each time a new object is added to (or created in) that bucket. For more information, see Send Data Objects using Amazon S3 (p. 578). This option is not available for text-based labeling jobs such as text classification and named entity recognition.

  **Important**
  If you use the Amazon S3 configuration, do not use the same Amazon S3 location for your input data configuration and your output data. You specify the S3 prefix for your output data when you create a labeling job.

**Send Data Objects Using Amazon SNS**

You can send data objects to your streaming labeling job using Amazon Simple Notification Service (Amazon SNS). Amazon SNS is a web service that coordinates and manages the delivery of messages to and from endpoints (for example, an email address or AWS Lambda function). An Amazon SNS topic acts as a communication channel between two or more endpoints. You use Amazon SNS to send, or publish, new data objects to the topic specified in the `CreateLabelingJob` parameter `SnsTopicArn` in `InputConfig`. The format of these messages is the same as a single line from an input manifest file.

For example, you may send a piece of text to an active text classification labeling job by publishing it to your input topic. The message that you publish may look similar to the following:

```json
{"source": "Lorem ipsum dolor sit amet"}
```

To send a new image object to an image classification labeling job, your message may look similar to the following:

```json
{"source-ref": "s3://awsexamplebucket/example-image.jpg"}
```

**Note**

You can also include custom deduplication IDs and deduplication keys in your Amazon SNS messages. To learn more, see Duplicate Message Handling (p. 578).

When Ground Truth creates your streaming labeling job, it subscribes to your Amazon SNS input topic.
Send Data Objects using Amazon S3

You can send one or more new data objects to a streaming labeling job by placing them in an Amazon S3 bucket that is configured with an Amazon SNS event notification. You can set up an event to notify your Amazon SNS input topic anytime a new object is created in your bucket. You must specify this same Amazon SNS input topic in the `CreateLabelingJob` parameter `SnsTopicArn` in `InputConfig`.

Anytime you configure an Amazon S3 bucket to send notifications to Amazon SNS, Ground Truth will publish a test event, "s3:TestEvent", to ensure that the topic exists and that the owner of the Amazon S3 bucket specified has permission to publish to the specified topic. It is recommended that you set up your Amazon S3 connection with Amazon SNS before starting a streaming labeling job. If you do not, this test event may register as a data object and be sent to Ground Truth for labeling.

**Important**
- If you use the Amazon S3 configuration, do not use the same Amazon S3 location for your input data configuration and your output data. You specify the S3 prefix for your output data when you create a labeling job.
- For image-based labeling jobs, Ground Truth requires all S3 buckets to have a CORS policy attached. To learn more, see CORS Permission Requirement (p. 649).

Once you have configured your Amazon S3 bucket and created your labeling job, you can add objects to your bucket and Ground Truth either sends that object to workers or places it on your Amazon SQS queue.

To learn more, see Set up Amazon S3 Bucket Event Notifications (p. 555).

**Important**
- This option is not available for text-based labeling jobs such as text classification and named entity recognition.

Manage Labeling Requests with an Amazon SQS Queue

When Ground Truth creates your streaming labeling job, it creates an Amazon SQS queue in the AWS account used to create the labeling job. The queue name is `GroundTruth-labeling_job_name` where `labeling_job_name` is the name of your labeling job, in lowercase letters. When you send data objects to your labeling job, Ground Truth either sends the data objects directly to workers or places the task in your queue to be processed at a later time. If a data object is not sent to a worker after 14 days, it expires and is removed from the queue. You can setup an alarm in Amazon SQS to detect when objects expire and use this mechanism to control the volume of objects you send to your labeling job.

**Important**
- Modifying, deleting, or sending objects directly to the Amazon SQS queue associated with your streaming labeling job may lead to job failures.

Receive Output Data from a Streaming Labeling Job

Your Amazon S3 output bucket is periodically updated with new output data from your streaming labeling job.

Optionally, you can specify an Amazon SNS output topic. Each time a worker submits a labeled object, a notification with the output data is sent to that topic. You can subscribe an endpoint to your SNS output topic to receive notifications or trigger events when you receive output data from a labeling task. Use an Amazon SNS output topic if you want to do real time chaining to another streaming job and receive an Amazon SNS notifications each time a data object is submitted by a worker.

To learn more, see Subscribe an Endpoint to Your Amazon SNS Output Topic (p. 554).

Duplicate Message Handling

For data objects sent in real time, Ground Truth guarantees idempotency by ensuring each unique object is only sent for labeling once, even if the input message referring to that object is received multiple
times (duplicate messages). To do this, each data object sent to a streaming labeling job is assigned a deduplication ID, which is identified with a deduplication key.

If you send your requests to label data objects directly through your Amazon SNS input topic using Amazon SNS messages, you can optionally choose a custom deduplication key and deduplication IDs for your objects. For more information, see Specify A Deduplication Key and ID in an Amazon SNS Message (p. 579).

If you do not provide your own deduplication key, or if you use the Amazon S3 configuration to send data objects to your labeling job, Ground Truth uses one of the following for the deduplication ID:

- For messages sent directly to your Amazon SNS input topic, Ground Truth uses the SNS message ID.
- For messages that come from an Amazon S3 configuration, Ground Truth creates a deduplication ID by combining the Amazon S3 URI of the object with the sequencer token in the message.

Specify A Deduplication Key and ID in an Amazon SNS Message

When you send a data object to your streaming labeling job using an Amazon SNS message, you have the option to specify your deduplication key and deduplication ID in one of the following ways. In all of these scenarios, identify your deduplication key with dataset-objectid-attribute-name.

Bring Your Own Deduplication Key and ID

Create your own deduplication key and deduplication ID by configuring your Amazon SNS message as follows. Replace byo-key with your key and UniqueId with the deduplication ID for that data object.

```json
{
   "source-ref": "s3://bucket/prefix/object1",
   "dataset-objectid-attribute-name": "byo-key",
   "byo-key": "UniqueId"
}
```

Your deduplication key can be up to 140 characters. Supported patterns include: "^[a-zA-Z0-9](-*[a-zA-Z0-9])*".

Your deduplication ID can be up to 1,024 characters. Supported patterns include: ^((https|s3)://([^/]+)?(.*))$.

Use an Existing Key for your Deduplication Key

You can use an existing key in your message as the deduplication key. When you do this, the value associated with that key is used for the deduplication ID.

For example, you can specify use the source-ref key as your deduplication key by formatting your message as follows:

```json
{
   "source-ref": "s3://bucket/prefix/object1",
   "dataset-objectid-attribute-name": "source-ref"
}
```

In this example, Ground Truth uses "s3://bucket/prefix/object1" for the deduplication id.

Find Deduplication Key and ID in Your Output Data

You can see the deduplication key and ID in your output data. The deduplication key is identified by dataset-objectid-attribute-name.
When you use your own custom deduplication key, your output contains something similar to the following:

```
"dataset-objectid-attribute-name": "byo-key",
"byo-key": "UniqueId",
```

When you do not specify a key, you can find the deduplication ID that Ground Truth assigned to your data object as follows. The `$label-attribute-name-object-id` parameter identifies your deduplication ID.

```
{
  "source-ref":"s3://bucket/prefix/object1",
  "dataset-objectid-attribute-name":"$label-attribute-name-object-id"
  "label-attribute-name" :0,
  "label-attribute-name-metadata": {...},
  "$label-attribute-name-object-id":"<service-generated-key>"
}
```

For `<service-generated-key>`, if the data object came through an Amazon S3 configuration, Ground Truth adds a unique value used by the service and emits a new field keyed by `$sequencer` which shows the Amazon S3 sequencer used. If object was fed to SNS directly, Ground Truth use the SNS message ID.

**Note**

Do not use the `$` character in your label attribute name.

### Input Data Quotas

Input datasets used in semantic segmentation labeling jobs have a quota of 20,000 items. For all other labeling job types, the dataset size quota is 100,000 items. To request an increase to the quota for labeling jobs other than semantic segmentation jobs, review the procedures in [AWS Service Quotas](https://aws.amazon.com/servicequotas) to request a quota increase.

Input image data for active and non-active learning labeling jobs must not exceed size and resolution quotas. *Active learning* refers to labeling job that use automated data labeling. *Non-active learning* refers to labeling jobs that don't use automated data labeling.

Additional quotas apply for label categories for all task types, and for input data and labeling category attributes for 3D point cloud and video frame task types.

### Input File Size Quota

Input files can't exceed the following size- quotas for both active and non-active learning labeling jobs. There is no input file size quota for videos used in *video classification* labeling jobs.

<table>
<thead>
<tr>
<th>Labeling Job Task Type</th>
<th>Input File Size Quota</th>
</tr>
</thead>
<tbody>
<tr>
<td>Image classification</td>
<td>40 MB</td>
</tr>
<tr>
<td>Bounding box (Object detection)</td>
<td>40 MB</td>
</tr>
<tr>
<td>Semantic segmentation</td>
<td>40 MB</td>
</tr>
<tr>
<td>Bounding box (Object detection) label adjustment</td>
<td>40 MB</td>
</tr>
<tr>
<td>Semantic segmentation label adjustment</td>
<td>40 MB</td>
</tr>
<tr>
<td>Bounding box (Object detection) label verification</td>
<td>40 MB</td>
</tr>
<tr>
<td>Semantic segmentation label verification</td>
<td>40 MB</td>
</tr>
</tbody>
</table>
Input Image Resolution Quotas

Image file resolution refers to the number of pixels in an image, and determines the amount of detail an image holds. Image resolution quotas differ depending on the labeling job type and the SageMaker built-in algorithm used. The following table lists the resolution quotas for images used in active and non-active learning labeling jobs.

<table>
<thead>
<tr>
<th>Labeling Job Task Type</th>
<th>Resolution Quota - Non Active Learning</th>
<th>Resolution Quota - Active Learning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Image classification</td>
<td>100 million pixels</td>
<td>3840 x 2160 pixels (4 K)</td>
</tr>
<tr>
<td>Bounding box (Object detection)</td>
<td>100 million pixels</td>
<td>3840 x 2160 pixels (4 K)</td>
</tr>
<tr>
<td>Semantic segmentation</td>
<td>100 million pixels</td>
<td>1920 x 1080 pixels (1080 p)</td>
</tr>
<tr>
<td>Object detection label adjustment</td>
<td>100 million pixels</td>
<td>3840 x 2160 pixels (4 K)</td>
</tr>
<tr>
<td>Semantic segmentation label adjustment</td>
<td>100 million pixels</td>
<td>1920 x 1080 pixels (1080 p)</td>
</tr>
<tr>
<td>Object detection label verification</td>
<td>100 million pixels</td>
<td>Not available</td>
</tr>
<tr>
<td>Semantic segmentation label verification</td>
<td>100 million pixels</td>
<td>Not available</td>
</tr>
</tbody>
</table>

Label Category Quotas

Each labeling job task type has a quota for the number of label categories you can specify. Workers select label categories to create annotations. For example, you may specify label categories car, pedestrian, and biker when creating a bounding box labeling job and workers will select the car category before drawing bounding boxes around cars.

**Important**

Label category names cannot exceed 256 characters.
All label categories must be unique. You cannot specify duplicate label categories.

The following label category limits apply to labeling jobs. Quotas for label categories depend on whether you use the SageMaker API operation CreateLabelingJob or the console to create a labeling job.

<table>
<thead>
<tr>
<th>Labeling Job Task Type</th>
<th>Label Category Quota - API</th>
<th>Label Category Quota - Console</th>
</tr>
</thead>
<tbody>
<tr>
<td>Image classification (Multi-label)</td>
<td>50</td>
<td>50</td>
</tr>
<tr>
<td>Image classification (Single label)</td>
<td>Unlimited</td>
<td>30</td>
</tr>
<tr>
<td>Bounding box (Object detection)</td>
<td>50</td>
<td>50</td>
</tr>
<tr>
<td>Label verification</td>
<td>Unlimited</td>
<td>30</td>
</tr>
<tr>
<td>Semantic segmentation (with active learning)</td>
<td>20</td>
<td>10</td>
</tr>
<tr>
<td>Semantic segmentation (without active learning)</td>
<td>Unlimited</td>
<td>10</td>
</tr>
</tbody>
</table>
Use Input and Output Data

Labeling Job Task Type | Label Category Quota - API | Label Category Quota - Console
--- | --- | ---
Named entity recognition | Unlimited | 30
Text classification (Multi-label) | 50 | 50
Text classification (Single label) | Unlimited | 30
Video classification | 30 | 30
Video frame object detection | 30 | 30
Video frame object tracking | 30 | 30
3D point cloud object detection | 30 | 30
3D point cloud object tracking | 30 | 30
3D point cloud semantic segmentation | 30 | 30

3D Point Cloud and Video Frame Labeling Job Quotas

The following quotas apply for 3D point cloud and video frame labeling job input data.

<table>
<thead>
<tr>
<th>Labeling Job Task Type</th>
<th>Input Data Quota</th>
</tr>
</thead>
<tbody>
<tr>
<td>Video frame object detection</td>
<td>2,000 video frames (images) per sequence</td>
</tr>
<tr>
<td>Video frame object detection</td>
<td>10 video frame sequences per manifest file</td>
</tr>
<tr>
<td>Video frame object tracking</td>
<td>2,000 video frames (images) per sequence</td>
</tr>
<tr>
<td>Video frame object tracking</td>
<td>10 video frame sequences per manifest file</td>
</tr>
<tr>
<td>3D point cloud object detection</td>
<td>100,000 point cloud frames per labeling job</td>
</tr>
<tr>
<td>3D point cloud object tracking</td>
<td>100,000 point cloud frame sequences per labeling job</td>
</tr>
<tr>
<td>3D point cloud object tracking</td>
<td>500 point cloud frames in each sequence file</td>
</tr>
</tbody>
</table>

When you create a video frame or 3D point cloud labeling job, you can add one or more label category attributes to each label category that you specify to have workers provide more information about an annotation.

Each label category attribute has a single label category attribute name, and a list of one or more options (values) to choose from. To learn more, see Worker User Interface (UI) (p. 469) for 3D point cloud labeling jobs and Worker User Interface (UI) (p. 421) for video frame labeling jobs.

The following quotas apply to the number of label category attributes names and values you can specify for labeling jobs.
Filter and Select Data for Labeling

You can use the Amazon SageMaker console to select a portion of your dataset for labeling. The data must be stored in an Amazon S3 bucket. You have three options:

- Use the full dataset.
- Choose a randomly selected sample of the dataset.
- Specify a subset of the dataset using a query.

The following options are available in the Labeling jobs section of the SageMaker console after selecting Create labeling job. To learn how to create a labeling job in the console, see Getting started (p. 371). To configure the dataset that you use for labeling, in the Job overview section, choose Additional configuration.

Use the Full Dataset

When you choose to use the Full dataset, you must provide a manifest file for your data objects. You can provide the path of the Amazon S3 bucket that contains the manifest file or use the SageMaker console to create the file. To learn how to create a manifest file using the console, see Automated Data Setup (p. 574).

Choose a Random Sample

When you want to label a random subset of your data, select Random sample. The dataset is stored in the Amazon S3 bucket specified in the Input dataset location field.

After you have specified the percentage of data objects that you want to include in the sample, choose Create subset. SageMaker randomly picks the data objects for your labeling job. After the objects are selected, choose Use this subset.

SageMaker creates a manifest file for the selected data objects. It also modifies the value in the Input dataset location field to point to the new manifest file.

Specify a Subset

You can specify a subset of your data objects using an Amazon S3 SELECT query on the object file names.

The SELECT statement of the SQL query is defined for you. You provide the WHERE clause to specify which data objects should be returned.

For more information about the Amazon S3 SELECT statement, see Selecting Content from Objects. Choose Create subset to start the selection, and then choose Use this subset to use the selected data.

SageMaker creates a manifest file for the selected data objects. It also updates the value in the Input dataset location field to point to the new manifest file.

3D Point Cloud Input Data

To create a 3D point cloud labeling job, you must create an input manifest file. Use this topic to learn the formatting requirements of the input manifest file for each task type. To learn about the raw input data formats Ground Truth accepts for 3D point cloud labeling jobs, see the section Accepted Raw 3D Data Formats (p. 584).

Use your labeling job task type to choose a topics on Create an Input Manifest File for a 3D Point Cloud Labeling Job (p. 586) to learn about the formatting requirements for each line of your input manifest file.

Topics
- Accepted Raw 3D Data Formats (p. 584)
- Create an Input Manifest File for a 3D Point Cloud Labeling Job (p. 586)
- Understand Coordinate Systems and Sensor Fusion (p. 599)

Accepted Raw 3D Data Formats

Ground Truth uses your 3D point cloud data to render a 3D scenes that workers annotate. This section describes the raw data formats that are accepted for point cloud data and sensor fusion data for a point cloud frame. To learn how to create an input manifest file to connect your raw input data files with Ground Truth, see Create an Input Manifest File for a 3D Point Cloud Labeling Job (p. 586).

For each frame, Ground Truth supports Compact Binary Pack Format (.bin) and ASCII (.txt) files. These files contain information about the location (x, y, and z coordinates) of all points that make up that frame, and, optionally, information about the pixel color of each point for colored point clouds. When you create a 3D point cloud labeling job input manifest file, you can specify the format of your raw data in the format parameter.

The following table lists elements that Ground Truth supports in point cloud frame files to describe individual points.

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>The x coordinate of the point.</td>
</tr>
<tr>
<td>y</td>
<td>The y coordinate of the point.</td>
</tr>
<tr>
<td>z</td>
<td>The z coordinate of the point.</td>
</tr>
<tr>
<td>i</td>
<td>The intensity of the point.</td>
</tr>
<tr>
<td>r</td>
<td>The red color channel component. An 8-bit value (0-255).</td>
</tr>
<tr>
<td>g</td>
<td>The green color channel component. An 8-bit value (0-255)</td>
</tr>
<tr>
<td>b</td>
<td>The blue color channel component. An 8-bit value (0-255)</td>
</tr>
</tbody>
</table>

Ground Truth assumes the following about your input data:
- All of the positional coordinates (x, y, z) are in meters.
- All the pose headings (qx, qy, qz, qw) are measured in Spatial Quaternions.
Compact Binary Pack Format

The Compact Binary Pack Format represents a point cloud as an ordered set of a stream of points. Each point in the stream is an ordered binary pack of 4-byte float values in some variant of the form xyzirgb. The x, y, and z elements are required and additional information about that pixel can be included in a variety of ways using i, r, g, and b.

To use a binary file to input point cloud frame data to a Ground Truth 3D point cloud labeling job, enter binary/ in the format parameter for your input manifest file and replace with the order of elements in each binary pack. For example, you may enter one of the following for the format parameter.

- `binary/xyzi` – When you use this format, your point element stream would be in the following order: x1y1z1i1x2y2z2i2...
- `binary/xyzrgb` – When you use this format, your point element stream would be in the following order: x1y1z1r1g1b1x2y2z2r2g2b2...
- `binary/xyzirgb` – When you use this format, your point element stream would be in the following order: x1y1z1i1r1g1b1x2y2z2i2r2g2b2...

When you use a binary file for your point cloud frame data, if you do not enter a value for format, the default pack format binary/xyzi is used.

ASCII Format

The ASCII format uses a text file to represent a point cloud, where each line in the ASCII point cloud file represents a single point. Each point is a line the text file and contains white space separated values, each of which is a 4-byte float ASCII values. The x, y, and z elements are required for each point and additional information about that point can be included in a variety of ways using i, r, g, and b.

To use a text file to input point cloud frame data to a Ground Truth 3D point cloud labeling job, enter text/ in the format parameter for your input manifest file and replace with the order of point elements on each line.

For example, if you enter text/xyzi for format, your text file for each point cloud frame should look similar to the following:

```
x1 y1 z1 i1
x2 y2 z2 i2
...
```

If you enter text/xyzrgb, your text file should look similar to the following:

```
x1 y1 z1 r1 g1 b1
x2 y2 z2 r2 g2 b1
...
```

When you use a text file for your point cloud frame data, if you do not enter a value for format, the default format text/xyzi will be used.

Point Cloud Resolution Limits

Ground Truth does not have a resolution limit for 3D point cloud frames. However, we recommend that you limit each point cloud frame to 500K points for optimal performance. When Ground Truth renders the 3D point cloud visualization, it must be viewable on your workers' computers, which depends on workers' computer hardware. Point cloud frames that are larger than 1 million points may not render on standard machines, or may take too long to load.
Create an Input Manifest File for a 3D Point Cloud Labeling Job

When you create a labeling job, you provide an input manifest file where each line of the manifest describes a unit of task to be completed by annotators. The format of your input manifest file depends on your task type.

- If you are creating a 3D point cloud **object detection** or **semantic segmentation** labeling job, each line in your input manifest file contains information about a single 3D point cloud frame. This is called a **point cloud frame input manifest**. To learn more, see Create a Point Cloud Frame Input Manifest File (p. 586).

- If you are creating a 3D point cloud **object tracking** labeling job, each line of your input manifest file contains a sequence of 3D point cloud frames and associated data. This is called a **point cloud sequence input manifest**. To learn more, see Create a Point Cloud Sequence Input Manifest File (p. 592).

Create a Point Cloud Frame Input Manifest File

The manifest is a UTF-8 encoded file in which each line is a complete and valid JSON object. Each line is delimited by a standard line break, \n or \n\n. Because each line must be a valid JSON object, you can't have unescaped line break characters. In the single-frame input manifest file, each line in the manifest contains data for a single point cloud frame. The point cloud frame data can either be stored in binary or ASCII format (see Accepted Raw 3D Data Formats (p. 584)). This is the manifest file formatting required for 3D point cloud object detection and semantic segmentation. Optionally, you can also provide camera sensor fusion data for each point cloud frame.

Ground Truth supports point cloud and video camera sensor fusion in the **world coordinate system** (p. 599) for all modalities. If you can obtain your 3D sensor extrinsic (like a LiDAR extrinsic), we recommend that you transform 3D point cloud frames into the world coordinate system using the extrinsic. For more information, see Sensor Fusion (p. 601).

However, if you cannot obtain a point cloud in world coordinate system, you can provide coordinates in the original coordinate system that the data was captured in. If you are providing camera data for sensor fusion, it is recommended that you provide LiDAR sensor and camera pose in the world coordinate system.

To create a single-frame input manifest file, you will identify the location of each point cloud frame that you want workers to label using the **source-ref** key. Additionally, you must use the **source-ref-metadata** key to identify the format of your dataset, a timestamp for that frame, and, optionally, sensor fusion data and video camera images.

The following example demonstrates the syntax used for an input manifest file for a single-frame point cloud labeling job. The example includes two point cloud frames. For details about each parameter, see the table following this example.

**Important**

Each line in your input manifest file must be in **JSON Lines** format. The following code block shows an input manifest file with two JSON objects. Each JSON object is used to point to and provide details about a single point cloud frame. The JSON objects have been expanded for readability, but you must minimize each JSON object to fit on a single line when creating an input manifest file. An example is provided under this code block.

```
{
"source-ref": "s3://awsexamplebucket/examplefolder/frame1.bin",
"source-ref-metadata":{

"cx": 576.2129134707038,
When you create an input manifest file, you must collapse your JSON objects to fit on a single line. For example, the code block above would appear as follows in an input manifest file:

```
{"source-ref":"s3://awsexamplebucket/examplefolder/frame1.bin","source-ref-metadata":
{"format":"binary/xyzi","unix-timestamp":1566861644.759115,"ego-vehicle-pose":{"position":
{"x":-2.7161461413869947,"y":116.2582228140078,"z":1.8348751887989483},"heading":
{"qx":-0.02111296123795955,"qy":-0.006495469416730261,"qz":-0.008024565904865688,"qw":0.9997181912290868},"prefix":"s3://awsexamplebucket/lidar_singleframe_dataset/someprefix/"},"images":
[{"image-path":"images/frame300.bin_camera0.jpg","unix-timestamp":1566861644.759115,"fx":847.7962624528487,"fy":850.0340893791985,"cx":576.2129134707038,"cy":317.2423573573745,"k1":0,"k2":0,"k3":0,"k4":0,"p1":0,"p2":0,"skew":0,"position":
{"x":-2.272215189268138,"y":116.86003310568965,"z":1.45641668542299},
"heading":
{"qx":0.75914754093069037,"qy":0.02181790885672969,"qz":-0.0246172523310356,"qw":-0.6496916273040025},
"camera-model":"pinhole"}]
}]
```

The following table shows the parameters you can include in your input manifest file:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Accepted Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source-ref</td>

</tr>
</thead>
</table>
| prefix    | No       | String          | The location in Amazon S3 where your metadata, such as camera images, is stored for this frame. The prefix must end with a forward slash: /.
| images    | No       | List            | A list of parameters describing color camera images used for sensor fusion. You can include up to 8 images in this list. For more information about the parameters required for each image, see Include Camera Data in Your Input Manifest (p. 591). |

Include Vehicle Pose Information in Your Input Manifest

Use the ego-vehicle location to provide information about the location of the vehicle used to capture point cloud data. Ground Truth use this information to compute LiDAR extrinsic matrix.

Ground Truth uses extrinsic matrices to project labels to and from the 3D scene and 2D images. For more information, see Sensor Fusion (p. 601).

The following table provides more information about the position and orientation (heading) parameters that are required when you provide ego-vehicle information.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Accepted Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<td></td>
<td>Required Parameters: qx, qy, qz, and qw. Enter numbers for these parameters.</td>
<td></td>
</tr>
</tbody>
</table>
Include Camera Data in Your Input Manifest

If you want to include video camera data with a frame, use the following parameters to provide information about each image. The **Required** column below applies when the images parameter is included in the input manifest file under `source-ref-metadata`. You are not required to include images in your input manifest file.

If you include camera images, you must include information about the camera position and heading used to capture the images in the world coordinate system.

If your images are distorted, Ground Truth can automatically undistort them using information you provide about the image in your input manifest file, including distortion coefficients ($k_1$, $k_2$, $k_3$, $k_4$, $p_1$, $p_1$), the camera model and the camera intrinsic matrix. The intrinsic matrix is made up of focal length ($f_x$, $f_y$), and the principal point ($c_x$, $c_y$). See [Intrinsic Matrix](#) to learn how Ground Truth uses the camera intrinsic. If distortion coefficients are not included, Ground Truth will not undistort an image.

<table>

<tr>
<td>position</td>
<td>Yes</td>
<td>JSON object</td>
<td>The location or origin of the frame of reference of the camera mounted on the vehicle capturing images.</td>
</tr>
<tr>
<td>heading</td>
<td>Yes</td>
<td>JSON Object</td>
<td>The orientation of the frame of reference of the camera mounted on the vehicle capturing images, measured using quaternions, ((qx, qy, qz, qw)), in the world coordinate system.</td>
</tr>
</tbody>
</table>

#### Point Cloud Frame Limits

You can include up to 100,000 point cloud frames in your input manifest file. 3D point cloud labeling job have longer pre-processing times than other Ground Truth task types. For more information, see Job Pre-processing Time (p. 468).

#### Create a Point Cloud Sequence Input Manifest

The manifest is a UTF-8 encoded file in which each line is a complete and valid JSON object. Each line is delimited by a standard line break, \n or \n\n. Because each line must be a valid JSON object, you can't have unescaped line break characters. In the point cloud sequence input manifest file, each line in the manifest contains a sequence of point cloud frames. The point cloud data for each frame in the sequence can either be stored in binary or ASCII format. For more information, see Accepted Raw 3D Data Formats (p. 584). This is the manifest file formatting required for 3D point cloud object tracking. Optionally, you can also provide point attribute and camera sensor fusion data for each point cloud frame. When you create a sequence input manifest file, you must provide LiDAR and video camera sensor fusion data in a world coordinate system (p. 599).

The following example demonstrates the syntax used for an input manifest file when each line in the manifest is a sequence file. Each line in your input manifest file must be in JSON Lines format.

```json
{"source-ref": "s3://awsexamplebucket/example-folder/seq1.json"}
{"source-ref": "s3://awsexamplebucket/example-folder/seq2.json"}
```

The data for each sequence of point cloud frames needs to be stored in a JSON data object. The following is an example of the format you use for a sequence file. Information about each frame is included as a JSON object and is listed in the \frames list. This is an example of a sequence file with two point cloud frame files, \texttt{frame300.bin} and \texttt{frame303.bin}. The \ldots is used to indicated where you should include information for additional frames. Add a JSON object for each frame in the sequence.

The following code block includes a JSON object for a single sequence file. The JSON object has been expanded for readability.
The following table provides details about the top-level parameters of a sequence file. For detailed information about the parameters required for individual frames in the sequence file, see Parameters for Individual Point Cloud Frames (p. 594).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Accepted Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>seq-no</td>
<td>Yes</td>
<td>Integer</td>
<td>The ordered number of the sequence.</td>
</tr>
</tbody>
</table>
| prefix        | Yes      | String          | The Amazon S3 location where the sequence files are located. The prefix must end with a forward slash: /.
| number-of-frames | Yes    | Integer         | The total number of frames included in the sequence file. This number must match the total number of frames listed in the frames parameter in the next row. |
| frames        | Yes      | List of JSON objects | A list of frame data. The length of the list must equal number-of-frames. In the worker UI, frames in a sequence will be the same as the order of frames in this array. For details about the format of each frame, see Parameters for Individual Point Cloud Frames (p. 594). |

Parameters for Individual Point Cloud Frames

The following table shows the parameters you can include in your input manifest file.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Accepted Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>frame-no</td>
<td>No</td>
<td>Integer</td>
<td>A frame number. This is an optional identifier specified by the customer to identify the frame within a sequence. It is not used by Ground Truth.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Required</td>
<td>Accepted Values</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>----------</td>
<td>-----------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>

<td>Required</td>
<td>Accepted Values</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>----------</td>
<td>--------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>format</td>
<td>No</td>
<td>String</td>
<td>Use this parameter to specify the format of your point cloud data. For more information, see Accepted Raw 3D Data Formats (p. 584).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Accepted string values: &quot;binary/xyz&quot;, &quot;binary/xyzirgb&quot;, &quot;binary/xyzrgb&quot;, &quot;binary/xyzirgb&quot;, &quot;text/xyz&quot;, &quot;text/xyzirgb&quot;, &quot;text/xyzrgb&quot;, &quot;text/xyzirgb&quot;</td>
<td></td>
</tr>
<tr>
<td>ego-vehicle-pose</td>
<td>No</td>
<td>JSON object</td>
<td>The pose of the device used to collect the point cloud data. For more information about this parameter, see Include Vehicle Pose Information in Your Input Manifest (p. 597).</td>
</tr>
<tr>
<td>prefix</td>
<td>No</td>
<td>String</td>
<td>The location in Amazon S3 where your metadata, such as camera images, is stored for this frame. The prefix must end with a forward slash: /.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Accepted string value format:</td>
<td></td>
</tr>
<tr>
<td>images</td>
<td>No</td>
<td>List</td>
<td>A list parameters describing color camera images used for sensor fusion. You can include up to 8 images in this list. For more information about the parameters required for each image, see Include Camera Data in Your Input Manifest (p. 597).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>s3://&lt;bucket-name&gt;/&lt;folder-name&gt;/</td>
<td></td>
</tr>
</tbody>
</table>
Include Vehicle Pose Information in Your Input Manifest

Use the ego-vehicle location to provide information about the pose of the vehicle used to capture point cloud data. Ground Truth uses this information to compute LiDAR extrinsic matrices.

Ground Truth uses extrinsic matrices to project labels to and from the 3D scene and 2D images. For more information, see Sensor Fusion (p. 601).

The following table provides more information about the position and orientation (heading) parameters that are required when you provide ego-vehicle information.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Accepted Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>position</td>
<td>Yes</td>
<td>JSON object</td>
<td>The translation vector of the ego vehicle in the world coordinate system.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Required Parameters:</strong></td>
<td>x, y, and z. Enter numbers for these parameters.</td>
</tr>
<tr>
<td>heading</td>
<td>Yes</td>
<td>JSON Object</td>
<td>The orientation of the frame of reference of the device or sensor mounted on the vehicle sensing the surrounding, measured in quaternions, ((q_x, q_y, q_z, q_w)) in the a coordinate system.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Required Parameters:</strong></td>
<td>q_x, q_y, q_z, and q_w. Enter numbers for these parameters.</td>
</tr>
</tbody>
</table>

Include Camera Data in Your Input Manifest

If you want to include color camera data with a frame, use the following parameters to provide information about each image. The Required column in the following table applies when the images parameter is included in the input manifest file. You are not required to include images in your input manifest file.

If you include camera images, you must include information about the position and orientation (heading) of the camera used to capture the images.

If your images are distorted, Ground Truth can automatically undistort them using information you provide about the image in your input manifest file, including distortion coefficients \((k_1, k_2, k_3, k_4, p_1, p_1)\), camera model and focal length \((f_x, f_y)\), and the principal point \((c_x, c_y)\). To learn more about these coefficients and undistorting images, see Camera calibration With OpenCV. If distortion coefficients are not included, Ground Truth will not undistort an image.

### Sequence File and Point Cloud Frame Limits

You can include up to 100,000 point cloud frame sequences in your input manifest file. You can include up to 500 point cloud frames in each sequence file.
Keep in mind that 3D point cloud labeling job have longer pre-processing times than other Ground Truth task types. For more information, see Job Pre-processing Time (p. 468).

**Understand Coordinate Systems and Sensor Fusion**

Point cloud data is always located in a coordinate system. This coordinate system may be local to the vehicle or the device sensing the surroundings, or it may be a world coordinate system. When you use Ground Truth 3D point cloud labeling jobs, all the annotations are generated using the coordinate system of your input data. For some labeling job task types and features, you must provide data in a world coordinate system.

In this topic, you'll learn the following:

- When you are required to provide input data in a world coordinate system or global frame of reference.
- What a world coordinate is and how you can convert point cloud data to a world coordinate system.
- How you can use your sensor and camera extrinsic matrices to provide pose data when using sensor fusion.

**Coordinate System Requirements for Labeling Jobs**

If your point cloud data was collected in a local coordinate system, you can use an extrinsic matrix of the sensor used to collect the data to convert it to a world coordinate system or a global frame of reference. If you cannot obtain an extrinsic for your point cloud data and, as a result, cannot obtain point clouds in a world coordinate system, you can provide point cloud data in a local coordinate system for 3D point cloud object detection and semantic segmentation task types.

For object tracking, you must provide point cloud data in a world coordinate system. This is because when you are tracking objects across multiple frames, the ego vehicle itself is moving in the world and so all of the frames need a point of reference.

If you include camera data for sensor fusion, it is recommended that you provide camera poses in the same world coordinate system as the 3D sensor (such as a LiDAR sensor).

**Using Point Cloud Data in a World Coordinate System**

This section explains what a world coordinate system (WCS), also referred to as a *global frame of reference*, is and explains how you can provide point cloud data in a world coordinate system.

**What is a World Coordinate System?**

A WCS or global frame of reference is a fixed universal coordinate system in which vehicle and sensor coordinate systems are placed. For example, if multiple point cloud frames are located in different coordinate systems because they were collected from two sensors, a WCS can be used to translate all of the coordinates in these point cloud frames into a single coordinate system, where all frames have the same origin, (0,0,0). This transformation is done by translating the origin of each frame to the origin of the WCS using a translation vector, and rotating the three axes (typically x, y, and z) to the right orientation using a rotation matrix. This rigid body transformation is called a *homogeneous transformation*.

A world coordinate system is important in global path planning, localization, mapping, and driving scenario simulations. Ground Truth uses the right-handed Cartesian world coordinate system such as the one defined in ISO 8855, where the x axis is forward toward the car's movement, y axis is left, and the z axis points up from the ground.

The global frame of reference depends on the data. Some datasets use the LiDAR position in the first frame as the origin. In this scenario, all the frames use the first frame as a reference and device heading and position will be near the origin in the first frame. For example, KITTI datasets have the first frame as a reference for world coordinates. Other datasets use a device position that is different from the origin.
Note that this is not the GPS/IMU coordinate system, which is typically rotated by 90 degrees along the z-axis. If your point cloud data is in a GPS/IMU coordinate system (such as OxTS in the open source AV KITTI dataset), then you need to transform the origin to a world coordinate system (typically the vehicle's reference coordinate system). You apply this transformation by multiplying your data with transformation metrics (the rotation matrix and translation vector). This will transform the data from its original coordinate system to a global reference coordinate system. Learn more about this transformation in the next section.

Convert 3D Point Cloud Data to a WCS

Ground Truth assumes that your point cloud data has already been transformed into a reference coordinate system of your choice. For example, you can choose the reference coordinate system of the sensor (such as LiDAR) as your global reference coordinate system. You can also take point clouds from various sensors and transform them from the sensor's view to the vehicle's reference coordinate system view. You use the a sensor's extrinsic matrix, made up of a rotation matrix and translation vector, to convert your point cloud data to a WCS or global frame of reference.

Collectively, the translation vector and rotation matrix can be used to make up an extrinsic matrix, which can be used to convert data from a local coordinate system to a WCS. For example, your LiDAR extrinsic matrix may be composed as follows, where R is the rotation matrix and T is the translation vector:

\[
\text{LiDAR\_extrinsic} = \begin{bmatrix} R & T \\ 0 & 0 & 0 & 1 \end{bmatrix}
\]

For example, the autonomous driving KITTI dataset includes a rotation matrix and translation vector for the LiDAR extrinsic transformation matrix for each frame. The pykitti python module can be used for loading the KITTI data, and in the dataset dataset.oxts[i].T_w_imu gives the LiDAR extrinsic transform for the i\textsuperscript{th} frame with can be multiplied with points in that frame to convert them to a world frame - np.matmul(lidar_transform_matrix, points). Multiplying a point in LiDAR frame with a LiDAR extrinsic matrix transforms it into world coordinates. Multiplying a point in the world frame with the camera extrinsic matrix gives the point coordinates in the camera's frame of reference.

The following code example demonstrates how you can convert point cloud frames from the KITTI dataset into a WCS.

```python
import pykitti
import numpy as np

basedir = '/Users/nameofuser/kitti-data'
date = '2011_09_26'
drive = '0079'

# The 'frames' argument is optional - default: None, which loads the whole dataset.
# Calibration, timestamps, and IMU data are read automatically.
# Camera and velodyne data are available via properties that create generators
# when accessed, or through getter methods that provide random access.
data = pykitti.raw(basedir, date, drive, frames=range(0, 50, 5))

i = 0

# lidar extrinsic for the ith frame
lidar_extrinsic_matrix = data.oxts[i].T_w_imu

# velodyne raw point cloud in lidar scanners own coordinate system
points = data.get_velo(i)

# transform points from lidar to global frame using lidar_extrinsic_matrix
def generate_transformed_pcd_from_point_cloud(points, lidar_extrinsic_matrix):
    tps = []
    for point in points:
        tps.append(np.matmul(lidar_extrinsic_matrix, point))
    return np.array(tps)

transformed_points = generate_transformed_pcd_from_point_cloud(points, lidar_extrinsic_matrix)
```
transformed_points = np.matmul(lidar_extrinsic_matrix, np.array([point[0],
point[1], point[2], 1], dtype=np.float32).reshape(4,1)).tolist()
    if len(point) > 3 and point[3] is not None:
        tps.append([transformed_points[0][0], transformed_points[1][0],
        transformed_points[2][0], point[3]])
    return tps

# customer transforms points from lidar to global frame using lidar_extrinsic_matrix
transformed_pcl = generate_transformed_pcd_from_point_cloud(points, lidar_extrinsic_matrix)

**Sensor Fusion**

Ground Truth supports sensor fusion of point cloud data with up to 8 video camera inputs. This feature allows human labellers to view the 3D point cloud frame side-by-side with the synchronized video frame. In addition to providing more visual context for labeling, sensor fusion allows workers to adjust annotations in the 3D scene and in 2D images and the adjustment are projected into the other view. The following video demonstrates a 3D point cloud labeling job with LiDAR and camera sensor fusion.
For best results, when using sensor fusion, your point cloud should be in a WCS. Ground Truth uses your sensor (such as LiDAR), camera, and ego vehicle pose information to compute extrinsic and intrinsic matrices for sensor fusion.

**Extrinsic Matrix**

Ground Truth uses sensor (such as LiDAR) extrinsic and camera extrinsic and intrinsic matrices to project objects to and from the point cloud data's frame of reference to the camera's frame of reference.

For example, in order to project a label from the 3D point cloud to camera image plane, Ground Truth transforms 3D points from LiDAR's own coordinate system to the camera's coordinate system. This is typically done by first transforming 3D points from LiDAR's own coordinate system to a world coordinate system (or a global reference frame) using the LiDAR extrinsic matrix. Ground Truth then uses the camera inverse extrinsic (which converts points from a global frame of reference to the camera's frame of reference) to transform the 3D points from world coordinate system obtained in previous step into the camera image plane. The LiDAR extrinsic matrix can also be used to transform 3D data into a world coordinate system. If your 3D data is already transformed into world coordinate system then the first transformation doesn't have any impact on label translation, and label translation only depends on the camera inverse extrinsic. A view matrix is used to visualize projected labels. To learn more about these transformations and the view matrix, see [Ground Truth Sensor Fusion Transformations](#).

Ground Truth computes these extrinsic matrices by using LiDAR and camera pose data that you provide: heading (in quaternions: qx, qy, qz, and qw) and position (x, y, z). For the vehicle, typically the heading and position are described in vehicle's reference frame in a world coordinate system and are called a *ego vehicle pose*. For each camera extrinsic, you can add pose information for that camera. For more information, see [Pose](#).

**Intrinsic Matrix**

Ground Truth use the camera extrinsic and intrinsic matrices to compute view metrics to transform labels to and from the 3D scene to camera images. Ground Truth computes the camera intrinsic matrix using camera focal length (fx, fy) and optical center coordinates (cx, cy) that you provide. For more information, see [Intrinsic and Distortion](#).

**Image Distortion**

Image distortion can occur for a variety of reasons. For example, images may be distorted due to barrel or fish-eye effects. Ground Truth uses intrinsic parameters along with distortion co-efficient to undistort images you provide when creating 3D point cloud labeling jobs. If a camera image is already been undistorted, all distortion coefficients should be set to 0.

For more information about the transformations Ground Truth performs to undistort images, see [Camera Calibrations: Extrinsic, Intrinsic and Distortion](#).

**Ego Vehicle**

To collect data for autonomous driving applications, the measurements used to generate point cloud data and are taken from sensors mounted on a vehicle, or the *ego vehicle*. To project label adjustments to and from the 3D scene and 2D images, Ground Truth needs your ego vehicle pose in a world coordinate system. The ego vehicle pose is comprised of position coordinates and orientation quaternion.

Ground Truth uses your ego vehicle pose to compute rotation and transformations matrices. Rotations in 3 dimensions can be represented by a sequence of 3 rotations around a sequence of axes. In theory, any three axes spanning the 3D Euclidean space are enough. In practice, the axes of rotation are chosen to be the basis vectors. The three rotations are expected to be in a global frame of reference (extrinsic). Ground Truth does not a support body centered frame of reference (intrinsic) which is attached to, and moves with, the object under rotation. To track objects, Ground Truth needs to measure from a global reference where all vehicles are moving. When using Ground Truth 3D point cloud labeling jobs, z specifies the axis of rotation (extrinsic rotation) and yaw Euler angles are in radians (rotation angle).
Pose

Ground Truth uses pose information for 3D visualizations and sensor fusion. Pose information you input through your manifest file is used to compute extrinsic matrices. If you already have an extrinsic matrix, you can use it to extract sensor and camera pose data.

For example in the autonomous driving KITTI dataset, the pykitti python module can be used for loading the KITTI data. In the dataset dataset.oxts[i].T_w_imu gives the LiDAR extrinsic transform for the i-th frame and it can be multiplied with the points to get them in a world frame - matmul(lidar_transform_matrix, points). This transform can be converted into position (translation vector) and heading (in quaternion) of LiDAR for the input manifest file JSON format. Camera extrinsic transform for cam0 in i-th frame can be calculated by

```python
inv(matmul(dataset.calib.T_cam0_velo, inv(dataset.oxts[i].T_w_imu)))
```

This can be converted into heading and position for cam0.

```python
import numpy
rotation = [[ 9.96714314e-01, -8.09890350e-02,  1.16333982e-03],
             [ 8.09967396e-02,  9.96661051e-01, -1.03090934e-02],
             [-3.24531964e-04,  1.03694477e-02,  9.99946183e-01]]
origin= [1.71104606e+00,
         5.80000039e-01,
         9.43144935e-01]

from scipy.spatial.transform import Rotation as R

# position is the origin
position = origin
r = R.from_matrix(np.asarray(rotation))

# heading in WCS using scipy
heading = r.as_quat()
print(f"pose: {position}\nheading: {heading}"
```

Position

In the input manifest file, position refers to the position of the sensor with respect to a world frame. If you are unable to put the device position in a world coordinate system, you can use LiDAR data with local coordinates. Similarly, for mounted video cameras you can specify the position and heading in a world coordinate system. For camera, if you do not have position information, please use (0, 0, 0).

The following are the fields in the position object:

1. x (float) – x coordinate of ego vehicle, sensor, or camera position in meters.
2. y (float) – y coordinate of ego vehicle, sensor, or camera position in meters.
3. z (float) – z coordinate of ego vehicle, sensor, or camera position in meters.

The following is an example of a position JSON object:

```json
{
  "position": {
    "x": 311.21505956090624,
    "y": -152.77584902657554,
    "z": -10.854137529636024
  }
}
```
**Heading**

In the input manifest file, heading is an object that represents the orientation of a device with respect to world frame. Heading values should be in quaternion. A quaternion is a representation of the orientation consistent with geodesic spherical properties. If you are unable to put the sensor heading in world coordinates, please use the identity quaternion \((q_x = 0, q_y = 0, q_z = 0, q_w = 1)\). Similarly, for cameras, specify the heading in quaternions. If you are unable to obtain extrinsic camera calibration parameters, please also use the identity quaternion.

Fields in heading object are as follows:

1. \(q_x\) (float) - x component of ego vehicle, sensor, or camera orientation.
2. \(q_y\) (float) - y component of ego vehicle, sensor, or camera orientation.
3. \(q_z\) (float) - z component of ego vehicle, sensor, or camera orientation.
4. \(q_w\) (float) - w component of ego vehicle, sensor, or camera orientation.

The following is an example of a heading JSON object:

```
{
    "heading": {
        "qy": -0.7046155108831117,
        "qx": 0.034278837280808494,
        "qz": 0.7070617895701465,
        "qw": -0.04904659893885366
    }
}
```

To learn more, see Compute Orientation Quaternions and Position (p. 605).

**Compute Orientation Quaternions and Position**

Ground Truth requires that all orientation, or heading, data be given in quaternions. A quaternion is a representation of the orientation consistent with geodesic spherical properties that can be used to approximate of rotation. Compared to Euler angles they are simpler to compose and avoid the problem of gimbal lock. Compared to rotation matrices they are more compact, more numerically stable, and more efficient.

You can compute quaternions from a rotation matrix or a transformation matrix.

If you have a rotation matrix (made up of the axis rotations) and translation vector (or origin) in world coordinate system instead of a single 4x4 rigid transformation matrix, then you can directly use the rotation matrix and translation vector to compute quaternions. Libraries like scipy and pyqaternion can help. The following code-block shows an example using these libraries to compute quaternion from a rotation matrix.

```
import numpy

rotation = [[ 9.96714314e-01, -8.0990350e-02,  1.16333982e-03],
            [ 8.09967396e-02,  9.96661051e-01, -1.03090934e-02],
            [-3.24531964e-04,  1.03694477e-02,  9.99946183e-01]]

origin = [1.71104606e+00,
          5.80000039e-01,
          9.43144955e-01]

from scipy.spatial.transform import Rotation as R

# position is the origin
position = origin
```
A UI tool like 3D Rotation Converter can also be useful.

If you have a 4x4 extrinsic transformation matrix, note that the transformation matrix is in the form \([R \ 0 \ 0 \ 1]\) where \(R\) is the rotation matrix and \(T\) is the origin translation vector. That means you can extract rotation matrix and translation vector from the transformation matrix as follows.

```python
import numpy as np
transformation = [[9.96714314e-01, -8.0990350e-02, 1.16333982e-03, 1.71104606e+00],
                  [8.09967396e-02, 9.9661051e-01, -1.03090934e-02, 5.80000039e-01],
                  [-3.24531964e-04, 1.03694477e-02, 9.99946183e-01, 9.43144935e-01],
                  [0, 0, 0, 1]]
transformation = np.array(transformation)
rotation = transformation[0:3, 0:3]
translation = transformation[0:3, 3]
from scipy.spatial.transform import Rotation as R
# position is the origin translation
position = translation
r = R.from_matrix(np.asarray(rotation))
# heading in WCS using scipy
heading = r.as_quat()
print(f"position: {position}
heading: {heading}"
)
```

With your own setup, you can compute an extrinsic transformation matrix using the GPS/IMU position and orientation (latitude, longitude, altitude and roll, pitch, yaw) with respect to the LiDAR sensor on the ego vehicle. For example, you can compute pose from KITTI raw data using `convertOxtsToPose(oxts)` to transform the oxts data into a local euclidean poses, specified by 4x4 rigid transformation matrices. You can then transform this pose transformation matrix to a global reference frame using the reference frames transformation matrix in the world coordinate system.

```c
struct Quaternion
{
    double w, x, y, z;
};

Quaternion ToQuaternion(double yaw, double pitch, double roll) // yaw (Z), pitch (Y), roll (X)
{
    // Abbreviations for the various angular functions
    double cy = cos(yaw * 0.5);
    double sy = sin(yaw * 0.5);
    double cp = cos(pitch * 0.5);
    double sp = sin(pitch * 0.5);
    double cr = cos(roll * 0.5);
    double sr = sin(roll * 0.5);

    Quaternion q;
    q.w = cr * cp * cy + sr * sp * sy;
    q.x = sr * cp * cy - cr * sp * sy;
    q.y = cr * sp * cy + sr * cp * sy;
    q.z = cr * cp * sy - sr * sp * cy;

    return q;
}
```
Ground Truth Sensor Fusion Transformations

The following sections go into greater detail about the Ground Truth sensor fusion transformations that are performed using the pose data you provide.

LiDAR Extrinsic

In order to project to and from a 3D LiDAR scene to a 2D camera image, Ground Truth computes the rigid transformation projection metrics using the ego vehicle pose and heading. Ground Truth computes rotation and translation of a world coordinates into the 3D plane by doing a simple sequence of rotations and translation.

Ground Truth computes rotation metrics using the heading quaternions as follows:

\[
M = \begin{pmatrix}
1 - 2y^2 - 2z^2 & 2xy + 2zw & 2xz - 2yw \\
2xy - 2zw & 1 - 2x^2 - 2z^2 & 2yz + 2xw \\
2xz + 2yw & 2yz - 2xw & 1 - 2x^2 - 2y^2
\end{pmatrix}
\]

Here, \([x, y, z, w]\) corresponds to parameters in the heading JSON object, \([qx, qy, qz, qw]\). Ground Truth computes the translation column vector as \(T = [\text{poseX}, \text{poseY}, \text{poseZ}]\). Then the extrinsic metrics is simply as follows:

\[
\text{LiDAR}_{\text{extrinsic}} = [R \ T; 0 \ 0 \ 0 \ 1]
\]

Camera Calibrations: Extrinsic, Intrinsic and Distortion

Geometric camera calibration, also referred to as camera resectioning, estimates the parameters of a lens and image sensor of an image or video camera. You can use these parameters to correct for lens distortion, measure the size of an object in world units, or determine the location of the camera in the scene. Camera parameters include intrinsics and distortion coefficients.

Camera Extrinsic

If the camera pose is given, then Ground Truth computes the camera extrinsic based on a rigid transformation from the 3D plane into the camera plane. The calculation is the same as the one used for the LiDAR Extrinsic (p. 607), except that Ground Truth uses camera pose (position and heading) and computes the inverse extrinsic.

\[
\text{camera}_{\text{inverse extrinsic}} = \text{inv}([Rc \ Tc; 0 \ 0 \ 0 \ 1]) \ #\text{where Rc and Tc are camera pose components}
\]

Intrinsic and Distortion

Some cameras, such as pinhole or fisheye cameras, may introduce significant distortion in photos. This distortion can be corrected using distortion coefficients and the camera focal length. To learn more, see Camera calibration With OpenCV in the OpenCV documentation.

There are two types of distortion Ground Truth can correct for: radial distortion and tangential distortion.

Radial distortion occurs when light rays bend more near the edges of a lens than they do at its optical center. The smaller the lens, the greater the distortion. The presence of the radial distortion manifests in form of the barrel or fish-eye effect and Ground Truth uses Formula 1 to undistort it.

Formula 1:

\[
x_{\text{corrected}} = x(1 + k_1r^2 + k_2r^4 + k_3r^6)
\]

\[
y_{\text{corrected}} = y(1 + k_1r^2 + k_2r^4 + k_3r^6)
\]
Tangential distortion occurs because the lenses used to take the images are not perfectly parallel to the imaging plane. This can be corrected with Formula 2.

**Formula 2:**

\[
\begin{align*}
x_{\text{corrected}} &= x + [2p_1 xy + p_2 (r^2 + 2x^2)] \\
y_{\text{corrected}} &= y + [p_1 (r^2 + 2y^2) + 2p_2 xy]
\end{align*}
\]

In the input manifest file, you can provide distortion coefficients and Ground Truth will undistort your images. All distortion coefficients are floats.

- \(k_1, k_2, k_3, k_4\) – Radial distortion coefficients. Supported for both fisheye and pinhole camera models.
- \(p_1, p_2\) – Tangential distortion coefficients. Supported for pinhole camera models.

If images are already undistorted, all distortion coefficients should be 0 in your input manifest.

In order to correctly reconstruct the corrected image, Ground Truth does a unit conversion of the images based on focal lengths. If a common focal length is used with a given aspect ratio for both axes, such as 1, in the upper formula we will have a single focal length. The matrix containing these four parameters is referred to as the **in camera intrinsic calibration matrix**.

\[
\begin{bmatrix}
x \\
y \\
w
\end{bmatrix} = \begin{bmatrix}
f_x & 0 & c_x \\
0 & f_y & c_y \\
0 & 0 & 1
\end{bmatrix} \begin{bmatrix}
X \\
Y \\
Z
\end{bmatrix}
\]

While the distortion coefficients are the same regardless of the camera resolutions used, these should be scaled with the current resolution from the calibrated resolution.

The following are float values.

- \(fx\) - focal length in x direction.
- \(fy\) - focal length in y direction.
- \(cx\) - x coordinate of principal point.
- \(cy\) - y coordinate of principal point.

Ground Truth use the camera extrinsic and camera intrinsic to compute view metrics as shown in the following code block to transform labels between the 3D scene and 2D images.

```python
def generate_view_matrix(intrinsic_matrix, extrinsic_matrix):
    intrinsic_matrix = np.c_[intrinsic_matrix, np.zeros(3)]
    view_matrix = np.matmul(intrinsic_matrix, extrinsic_matrix)
    view_matrix = np.insert(view_matrix, 2, np.array((0, 0, 0, 1)), 0)
    return view_matrix
```

**Video Frame Input Data**

When you create a video frame object detection or object tracking labeling job, you can choose video files (MP4 files) or video frames for input data. All worker tasks are created using video frames, so if you choose video files, use the Ground Truth frame extraction tool to extract video frames (images) from your video files.
For both of these options, you can use the **Automated data setup** option in the Ground Truth section of the Amazon SageMaker console to set up a connection between Ground Truth and your input data in Amazon S3 so that Ground Truth knows where to look for your input data when creating your labeling tasks. This creates and stores an input manifest file in your Amazon S3 input dataset location. To learn more, see Automated Video Frame Input Data Setup (p. 611).

Alternatively, you can manually create sequence files for each sequence of video frames that you want labeled and provide the Amazon S3 location of an input manifest file that references each of these sequences files using the `source-ref` key. To learn more, see Create a Video Frame Input Manifest File (p. 613).

**Topics**
- Choose Video Files or Video Frames for Input Data (p. 609)
- Input Data Setup (p. 610)

### Choose Video Files or Video Frames for Input Data

When you create a video frame object detection or object tracking labeling job, you can provide a sequence of video frames (images) or you can use the Amazon SageMaker console to have Ground Truth automatically extract video frames from your video files. Use the following sections to learn more about these options.

#### Provide Video Frames

Video frames are sequences of images extracted from a video file. You can create a Ground Truth labeling job to have workers label multiple sequences of video frames. Each sequence is made up of images extracted from a single video.

To create a labeling job using video frame sequences, you must store each sequence using a unique **key name prefix** in Amazon S3. In the Amazon S3 console, key name prefixes are folders. So in the Amazon S3 console, each sequence of video frames must be located in its own folder in Amazon S3.

For example, if you have two sequences of video frames, you might use the key name prefixes `sequence1/` and `sequence2/` to identify your sequences. In this example, your sequences may be located in `s3://DOC-EXAMPLE-BUCKET/video-frames/sequence1/` and `s3://DOC-EXAMPLE-BUCKET/video-frames/sequence2/`.

If you are using the Ground Truth console to create an input manifest file, all of the sequence key name prefixes should be in the same location in Amazon S3. For example, in the Amazon S3 console, each sequence could be in a folder in `s3://DOC-EXAMPLE-BUCKET/video-frames/`. In this example, your first sequence of video frames (images) may be located in `s3://DOC-EXAMPLE-BUCKET/video-frames/sequence1/` and your second sequence may be located in `s3://DOC-EXAMPLE-BUCKET/video-frames/sequence2/`.

**Important**

Even if you only have a single sequence of video frames that you want workers to label, that sequence must have a **key name prefix** in Amazon S3. If you are using the Amazon S3 console, this means that your sequence is located in a folder. It cannot be located in the root of your S3 bucket.

When creating worker tasks using sequences of video frames, Ground Truth uses one sequence per task. In each task, Ground Truth orders your video frames using **UTF-8** binary order.

For example, video frames might be in the following order in Amazon S3:

```
[0001.jpg, 0002.jpg, 0003.jpg, ..., 0011.jpg]
```
They are arranged in the same order in the worker’s task: 0001.jpg, 0002.jpg, 0003.jpg, ..., 0011.jpg.

Frames might also be ordered using a naming convention like the following:

```
[frame1.jpg, frame2.jpg, ..., frame11.jpg]
```

In this case, frame10.jpg and frame11.jpg come before frame2.jpg in the worker task. Your worker sees your video frames in the following order: frame1.jpg, frame10.jpg, frame11.jpg, frame2.jpg, ..., frame9.jpg.

**Provide Video Files**

You can use the Ground Truth frame splitting feature when creating a new labeling job in the console to extract video frames from video files (MP4 files). A series of video frames extracted from a single video file is referred to as a sequence of video frames.

You can either have Ground Truth automatically extract all frames, up to 2,000, from the video, or you can specify a frequency for frame extraction. For example, you can have Ground Truth extract every 10th frame from your videos.

You can provide up to 50 videos when you use automated data setup to extract frames, however your input manifest file cannot reference more than 10 video frame sequence files when you create a video frame object tracking and video frame object detection labeling job. If you use the automated data setup console tool to extract video frames from more than 10 video files, you will need to modify the manifest file the tool generates or create a new one to include 10 video frame sequence files or less. To learn more about these quotas, see 3D Point Cloud and Video Frame Labeling Job Quotas (p. 582).

To use the video frame extraction tool, see Automated Video Frame Input Data Setup (p. 611).

When all of your video frames have been successfully extracted from your videos, you will see the following in your S3 input dataset location:

- A key name prefix (a folder in the Amazon S3 console) named after each video. Each of these prefixes leads to:
  - A sequence of video frames extracted from the video used to name that prefix.
  - A sequence file used to identify all of the images that make up that sequence.
- An input manifest file with a .manifest extension. This identifies all of the sequence files that will be used to create your labeling job.

All of the frames extracted from a single video file are used for a labeling task. If you extract video frames from multiple video files, multiple tasks are created for your labeling job, one for each sequence of video frames.

Ground Truth stores each sequence of video frames that it extracts in your Amazon S3 location for input datasets using a unique key name prefix. In the Amazon S3 console, key name prefixes are folders.

**Input Data Setup**

When you create a video frame labeling job, you need to let Ground Truth know where to look for your input data. You can do this in one of two ways:

- You can store your input data in Amazon S3 and have Ground Truth automatically detect the input dataset used for your labeling job. See Automated Video Frame Input Data Setup (p. 611) to learn more about this option.
- You can create an input manifest file and sequence files and upload them to Amazon S3. See Manual Input Data Setup (p. 613) to learn more about this option.
Automated Video Frame Input Data Setup

You can use the Ground Truth automated data setup to automatically detect video files in your Amazon S3 bucket and extract video frames from those files. To learn how, see Provide Video Files (p. 610).

If you already have video frames in Amazon S3, you can use the automated data setup to use these video frames in your labeling job. For this option, all video frames from a single video must be stored using a unique prefix. To learn about the requirements to use this option, see Provide Video Frames (p. 609).

Select one of the following sections to learn how to set up your automatic input dataset connection with Ground Truth.

Provide Video Files and Extract Frames

Use the following procedure to connect your video files with Ground Truth and automatically extract video frames from those files for video frame object detection and object tracking labeling jobs.

Note
If you use the automated data setup console tool to extract video frames from more than 10 video files, you will need to modify the manifest file the tool generates or create a new one to include 10 video frame sequence files or less. To learn more, see Provide Video Files (p. 610).

Make sure your video files are stored in an Amazon S3 bucket in the same AWS Region that you perform the automated data setup in.

Automatically connect your video files in Amazon S3 with Ground Truth and extract video frames:

   Your input and output S3 buckets must be located in the same AWS Region that you create your labeling job in. This link puts you in the North Virginia (us-east-1) AWS Region. If your input data is in an Amazon S3 bucket in another Region, switch to that Region. To change your AWS Region, on the navigation bar, choose the name of the currently displayed Region.

2. Select Create labeling job.

3. Enter a Job name.

4. In the section Input data setup, select Automated data setup.

5. Enter an Amazon S3 URI for S3 location for input datasets. An S3 URI looks like the following: s3://DOC-EXAMPLE-BUCKET/path-to-files/. This URI should point to the Amazon S3 location where your video files are stored.

6. Specify your S3 location for output datasets. This is where your output data is stored. You can choose to store your output data in the Same location as input dataset or Specify a new location and entering the S3 URI of the location that you want to store your output data.

7. Choose Video Files for your Data type using the dropdown list.

8. Choose Yes, extract frames for object tracking and detection tasks.

   • When you choose Use all frames extracted from the video to create a labeling task, Ground Truth extracts all frames from each video in your S3 location for input datasets, up to 2,000
frames. If a video in your input dataset contains more than 2,000 frames, the first 2,000 are extracted and used for that labeling task.

- When you choose **Use every x frame from a video to create a labeling task**, Ground Truth extracts every \( x \)th frame from each video in your S3 location for input datasets.

For example, if your video is 2 seconds long, and has a frame rate of 30 frames per second, there are 60 frames in your video. If you specify 10 here, Ground Truth extracts every 10th frame from your video. This means the 1st, 10th, 20th, 30th, 40th, 50th, and 60th frames are extracted.

10. Choose or create an IAM execution role. Make sure that this role has permission to access your Amazon S3 locations for input and output data specified in steps 5 and 6.

11. Select **Complete data setup**.

**Provide Video Frames**

Use the following procedure to connect your sequences of video frames with Ground Truth for video frame object detection and object tracking labeling jobs.

Make sure your video frames are stored in an Amazon S3 bucket in the same AWS Region that you perform the automated data setup in. Each sequence of video frames should have a unique prefix. For example, if you have two sequences stored in s3://DOC-EXAMPLE-BUCKET/video-frames/sequences/, each should have a unique prefix like sequence1 and sequence2 and should both be located directly under the /sequences/ prefix. In the example above, the locations of these two sequences is: s3://DOC-EXAMPLE-BUCKET/video-frames/sequences/sequence1/ and s3://DOC-EXAMPLE-BUCKET/video-frames/sequences/sequence2/.

**Automatically connect your video frame in Amazon S3 with Ground Truth:**

1. Navigate to the **Create labeling job** page in the Amazon SageMaker console: https://console.aws.amazon.com/sagemaker/groundtruth.

   Your input and output S3 buckets must be located in the same AWS Region that you create your labeling job in. This link puts you in the North Virginia (us-east-1) AWS Region. If your input data is in an Amazon S3 bucket in another Region, switch to that Region. To change your AWS Region, on the **navigation bar**, choose the name of the currently displayed Region.

2. Select **Create labeling job**.

3. Enter a **Job name**.

4. In the section **Input data setup**, select **Automated data setup**.

5. Enter an Amazon S3 URI for **S3 location for input datasets**.

   This should be the Amazon S3 location where your sequences are stored. For example, if you have two sequences stored in s3://DOC-EXAMPLE-BUCKET/video-frames/sequences/sequence1/, s3://DOC-EXAMPLE-BUCKET/video-frames/sequences/sequence2/, enter s3://DOC-EXAMPLE-BUCKET/video-frames/sequences/here.

6. Specify your **S3 location for output datasets**. This is where your output data is stored. You can choose to store your output data in the **Same location as input dataset** or **Specify a new location** and entering the S3 URI of the location that you want to store your output data.

7. Choose **Video frames** for your **Data type** using the dropdown list.

8. Choose or create an IAM execution role. Make sure that this role has permission to access your Amazon S3 locations for input and output data specified in steps 5 and 6.

9. Select **Complete data setup**.

These procedures will create an input manifest in the Amazon S3 location for input datasets that you specified in step 5. If you are creating a labeling job using the SageMaker API or, AWS CLI, or an AWS SDK, use the Amazon S3 URI for this input manifest file as input to the parameter ManifestS3Uri.
Manual Input Data Setup

Choose the manual data setup option if you have created sequence files for each of your video frame sequences, and a manifest file listing references to those sequences files.

Create a Video Frame Input Manifest File

Ground Truth uses the input manifest file to identify the location of your input dataset when creating labeling tasks. For video frame object detection and object tracking labeling jobs, each line in the input manifest file identifies the location of a video frame sequence file. Each sequence file identifies the images included in a single sequence of video frames.

Use this page to learn how to create a video frame sequence file and an input manifest file for video frame object tracking and object detection labeling jobs.

If you want Ground Truth to automatically generate your sequence files and input manifest file, see Automated Video Frame Input Data Setup (p. 611).

Create a Video Frame Sequence Input Manifest

In the video frame sequence input manifest file, each line in the manifest is a JSON object, with a "source-ref" key that references a sequence file. Each sequence file identifies the location of a sequence of video frames. This is the manifest file formatting required for all video frame labeling jobs.

The following example demonstrates the syntax used for an input manifest file:

```json
["source-ref": "s3://DOC-EXAMPLE-BUCKET/example-folder/seq1.json"],
["source-ref": "s3://DOC-EXAMPLE-BUCKET/example-folder/seq2.json"]
```

Create a Video Frame Sequence File

The data for each sequence of video frames needs to be stored in a JSON data object. The following is an example of the format you use for a sequence file. Information about each frame is included as a JSON object and is listed in the frames list. The following JSON has been expanded for readability.

```json
{
    "seq-no": 1,
    "prefix": "s3://mybucket/prefix/video1/",
    "number-of-frames": 3,
    "frames": [
        {
            "frame-no": 1,
            "unix-timestamp": 1566861644,
            "frame": "frame0001.jpg"
        },
        {
            "frame-no": 2,
            "unix-timestamp": 1566861644,
            "frame": "frame0002.jpg"
        },
        {
            "frame-no": 3,
            "unix-timestamp": 1566861644,
            "frame": "frame0003.jpg"
        }
    ]
}
```

The following table provides details about the parameters shown in the this code example.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Accepted Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>seq-no</td>
<td>Yes</td>
<td>Integer</td>
<td>The ordered number of the sequence.</td>
</tr>
<tr>
<td>prefix</td>
<td>Yes</td>
<td>String</td>
<td>The Amazon S3 location where the sequence files are located.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Accepted Values:</strong></td>
<td>s3://&lt;bucket-name&gt;/&lt;prefix&gt;/</td>
</tr>
<tr>
<td>Parameter</td>
<td>Required</td>
<td>Accepted Values</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>----------</td>
<td>-----------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>number-of-frames</td>
<td>Yes</td>
<td>Integer</td>
<td>The total number of frames included in the sequence file. This number must match the total number of frames listed in the frames parameter in the next row.</td>
</tr>
<tr>
<td>frames</td>
<td>Yes</td>
<td>List of JSON objects</td>
<td>A list of frame data. The length of the list must equal number-of-frames. In the worker UI, frames in a sequence are ordered in UTF-8 binary order. To learn more about this ordering, see Provide Video Frames (p. 609).</td>
</tr>
<tr>
<td>frame-no</td>
<td>Yes</td>
<td>Integer</td>
<td>The frame order number. This will determine the order of a frame in the sequence.</td>
</tr>
<tr>
<td>unix-timestamp</td>
<td>No</td>
<td>Integer</td>
<td>The unix timestamp of a frame. The number of seconds since January 1st, 1970 until the UTC time when the frame was captured.</td>
</tr>
<tr>
<td>frame</td>
<td>Yes</td>
<td>String</td>
<td>The name of a video frame image file.</td>
</tr>
</tbody>
</table>

**Output Data**

The output from a labeling job is placed in the Amazon S3 location that you specified in the console or in the call to the CreateLabelingJob operation. Output data appears in this location when the workers have submitted one or more tasks, or when tasks expire. Note that it may take a few minutes for output data to appear in Amazon S3 after the worker submits the task or the task expires.

Each line in the output data file is identical to the manifest file with the addition of an attribute and value for the label assigned to the input object. The attribute name for the value is defined in the console or in the call to the CreateLabelingJob operation. You can't use -metadata in the label attribute name. If you are running an image semantic segmentation, 3D point cloud semantic segmentation, or 3D point cloud object tracking job, the label attribute must end with -ref. For any other type of job, the attribute name can't end with -ref.

The output of the labeling job is the value of the key-value pair with the label. The label and the value overwrites any existing JSON data in the input file with the new value.
For example, the following is the output from an image classification labeling job where the input data files were stored in an Amazon S3 `AWSDOC-EXAMPLE-BUCKET` and the label attribute name was defined as `sport`. In this example the JSON object is formatted for readability, in the actual output file the JSON object is on a single line. For more information about the data format, see JSON Lines.

```json
{
    "source-ref": "s3://AWSDOC-EXAMPLE-BUCKET/image_example.png",
    "sport": 0,
    "sport-metadata":
        {
            "class-name": "football",
            "confidence": 0.00,
            "type": "groundtruth/image-classification",
            "job-name": "identify-sport",
            "human-annotated": "yes",
            "creation-date": "2018-10-18T22:18:13.527256"
        }
}
```

The value of the label can be any valid JSON. In this case the label's value is the index of the class in the classification list. Other job types, such as bounding box, have more complex values.

Any key-value pair in the input manifest file other than the label attribute is unchanged in the output file. You can use this to pass data to your application.

The output from a labeling job can be used as the input to another labeling job. You can use this when you are chaining together labeling jobs. For example, you can send one labeling job to determine the sport that is being played. Then you send another using the same data to determine if the sport is being played indoors or outdoors. By using the output data from the first job as the manifest for the second job, you can consolidate the results of the two jobs into one output file for easier processing by your applications.

The output data file is written to the output location periodically while the job is in progress. These intermediate files contain one line for each line in the manifest file. If an object is labeled, the label is included. If the object hasn't been labeled, it is written to the intermediate output file identically to the manifest file.

**Output Directories**

Ground Truth creates several directories in your Amazon S3 output path. These directories contain the results of your labeling job and other artifacts of the job. The top-level directory for a labeling job is given the same name as your labeling job; the output directories are placed beneath it. For example, if you named your labeling job `find-people`, your output would be in the following directories:

```
s3://AWSDOC-EXAMPLE-BUCKET/find-people/activelearning
s3://AWSDOC-EXAMPLE-BUCKET/find-people/annotations
s3://AWSDOC-EXAMPLE-BUCKET/find-people/inference
s3://AWSDOC-EXAMPLE-BUCKET/find-people/manifests
s3://AWSDOC-EXAMPLE-BUCKET/find-people/training
```

Each directory contains the following output:

**Active Learning Directory**

The `activelearning` directory is only present when you are using automated data labeling. It contains the input and output validation set for automated data labeling, and the input and output folder for automatically labeled data.
Annotations Directory

The annotations directory contains all of the annotations made by the workforce. These are the responses from individual workers that have not been consolidated into a single label for the data object.

There are three subdirectories in the annotations directory.

- The first, worker-response, contains the responses from individual workers. This contains a subdirectory for each iteration, which in turn contains a subdirectory for each data object in that iteration. The worker response data for each data object is stored in a timestamped JSON file that contains the answers submitted by each worker for that data object, and if you use a private workforce, metadata about those workers. To learn more about this metadata, see Worker Metadata (p. 617).
- The second, consolidated-annotation, contains information required to consolidate the annotations in the current batch into labels for your data objects.
- The third, intermediate, contains the output manifest for the current batch with any completed labels. This file is updated as the label for each data object is completed.

Note

We recommend that you do not use files that are not mentioned in the documentation.

Inference Directory

The inference directory is only present when you are using automated data labeling. This directory contains the input and output files for the SageMaker batch transform used while labeling data objects.

Manifest Directory

The manifest directory contains the output manifest from your labeling job. There is one subdirectory in the manifest directory, output. The output directory contains the output manifest file for your labeling job. The file is named output.manifest.

Training Directory

The training directory is only present when you are using automated data labeling. This directory contains the input and output files used to train the automated data labeling model.

Confidence Score

When you have more than one worker annotate a single task, your label results from annotation consolidation. Ground Truth calculates a confidence score for each label. A confidence score is a number between 0 and 1 that indicates how confident Ground Truth is in the label. You can use the confidence score to compare labeled data objects to each other, and to identify the least or most confident labels.

You should not interpret the value of a confidence score as an absolute value, or compare confidence scores across labeling jobs. For example, if all of the confidence scores are between 0.98 and 0.998, you should only compare the data objects with each other and not rely on the high confidence scores.

You should not compare the confidence scores of human-labeled data objects and auto-labeled data objects. The confidence scores for humans are calculated using the annotation consolidation function for the task, while the confidence scores for automated labeling are calculated using a model that incorporates object features. The two models generally have different scales and average confidence.

For a bounding box labeling job, Ground Truth calculates a confidence score per box. You can compare confidence scores within one image or across images for the same labeling type (human or auto). You can’t compare confidence scores across labeling jobs.
If a single worker annotates a task (NumberOfHumanWorkersPerDataObject is set to 1 or in the console, you enter 1 for **Number of workers per dataset object**), the confidence score is set to 0.00.

**Worker Metadata**

Ground Truth provides information that you can use to track individual workers in task output data. The following data is located in the directories under the worker-response located in the Annotations Directory (p. 616):

- The **acceptanceTime** is the time that the worker accepted the task. The format of this date and time stamp is YYYY-MM-DDTHH:MM:SS.mmmZ for the year (YYYY), month (MM), day (DD), hour (HH), minute (MM), second (SS) and millisecond (mmm). The date and time are separated by a T.
- The **submissionTime** is the time that the worker submitted their annotations using the Submit button. The format of this date and time stamp is YYYY-MM-DDTHH:MM:SS.mmmZ for the year (YYYY), month (MM), day (DD), hour (HH), minute (MM), second (SS) and millisecond (mmm). The date and time are separated by a T.
- **timeSpentInSeconds** reports the total time, in seconds, that a worker actively worked on that task. This metric does not include time when a worker paused or took a break.
- The **workerId** is unique to each worker.
- If you use a **private workforce**, in workerMetadata, you see the following.
  - The **identityProviderType** is the service used to manage the private workforce.
  - The **issuer** is the Cognito user pool or OIDC Identity Provider (IdP) issuer associated with the work team assigned to this human review task.
  - A unique sub identifier refers to the worker. If you create a workforce using Amazon Cognito, you can retrieve details about this worker (such as the name or user name) using this ID using Amazon Cognito. To learn how, see Managing and Searching for User Accounts in Amazon Cognito Developer Guide.

The following is an example of the output you may see if you use Amazon Cognito to create a private workforce. This is identified in the identityProviderType.

```json
"submissionTime": "2020-12-28T18:59:38.321Z",
"acceptanceTime": "2020-12-28T18:59:15.191Z",
"timeSpentInSeconds": 40.543,
"workerId": "a12b3cdefg4h5i67",
"workerMetadata": {
  "identityData": {
    "identityProviderType": "Cognito",
    "sub": "aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee"
  }
}
```

The following is an example of the workerMetadata you may see if you use your own OIDC IdP to create a private workforce:

```json
"workerMetadata": {  
  "identityData": {  
    "identityProviderType": "Oidc",
    "issuer": "https://example-oidc-ipd.com/adfs",
    "sub": "aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee"
  }
}
```

To learn more about using private workforces, see Use a Private Workforce (p. 699).
Output Metadata

The output from each job contains metadata about the label assigned to data objects. These elements are the same for all jobs with minor variations. The following example shows the metadata elements:

```
"confidence": 0.00,
"type": "groundtruth/image-classification",
"job-name": "identify-animal-species",
"human-annotated": "yes",
"creation-date": "2020-10-18T22:18:13.527256"
```

The elements have the following meaning:

- **confidentce** – The confidence that Ground Truth has that the label is correct. For more information, see Confidence Score (p. 616).
- **type** – The type of classification job. For job types, see Built-in Task Types (p. 542).
- **job-name** – The name assigned to the job when it was created.
- **human-annotated** – Whether the data object was labeled by a human or by automated data labeling. For more information, see Automate Data Labeling (p. 640).
- **creation-date** – The date and time that the label was created.

Classification Job Output

The following are sample outputs (output manifest files) from an image classification job and a text classification job. They include the label that Ground Truth assigned to the data object, the value for the label, and metadata that describes the label.

In addition to the standard metadata elements, the metadata for a classification job includes the text value of the label's class. For more information, see Image Classification - MXNet (p. 2172).

The red, italicized text in the examples below depends on labeling job specifications and output data.

```
{  
   "source-ref":"s3://AWSDOC-EXAMPLE-BUCKET/example_image.jpg",
   "species":"0",
   "species-metadata":
   {
      "class-name": "dog",
      "confidence": 0.00,
      "type": "groundtruth/image-classification",
      "job-name": "identify-animal-species",
      "human-annotated": "yes",
      "creation-date": "2018-10-18T22:18:13.527256"
   }
}
```

```
{  
   "source":"The food was delicious",
   "mood":"1",
   "mood-metadata":
   {
      "class-name": "positive",
      "confidence": 0.8,
      "type": "groundtruth/text-classification",
      "job-name": "label-sentiment",
      "human-annotated": "yes",
      "creation-date": "2020-10-18T22:18:13.527256"
   }
}
```
Multi-label Classification Job Output

The following are example output manifest files from a multi-label image classification job and a multi-label text classification job. They include the labels that Ground Truth assigned to the data object (for example, the image or piece of text) and metadata that describes the labels the worker saw when completing the labeling task.

The label attribute name parameter (for example, image-label-attribute-name) contains an array of all of the labels selected by at least one of the workers who completed this task. This array contains integer keys (for example, [1, 0, 8]) that correspond to the labels found in class-map. In the multi-label image classification example, bicycle, person, and clothing were selected by at least one of the workers who completed the labeling task for the image, exampleimage.jpg.

The confidence-map shows the confidence score that Ground Truth assigned to each label selected by a worker. To learn more about Ground Truth confidence scores, see Confidence Score (p. 616).

The red, italicized text in the examples below depends on labeling job specifications and output data.

The following is an example of a multi-label image classification output manifest file.

```
{
    "source-ref": "s3://AWSDOC-EXAMPLE-BUCKET/example_image.jpg",
    "image-label-attribute-name":[1,0,8],
    "image-label-attribute-name-metadata":
    {
        "job-name":"labeling-job/image-label-attribute-name",
        "class-map":
        {
            "1":"bicycle","0":"person","8":"clothing"
        },
        "human-annotated":"yes",
        "creation-date":"2020-02-27T21:36:25.000201",
        "confidence-map":
        {
            "1":0.95,"0":0.77,"8":0.2
        },
        "type":"groundtruth/image-classification-multilabel"
    }
}
```

The following is an example of a multi-label text classification output manifest file. In this example, approving, sad and critical were selected by at least one of the workers who completed the labeling task for the object exampltext.txt found in AWSDOC-EXAMPLE-BUCKET.

```
{
    "source-ref": "AWSDOC-EXAMPLE-BUCKET/text_file.txt",
    "text-label-attribute-name":[1,0,4],
    "text-label-attribute-name-metadata":
    {
        "job-name":"labeling-job/text-label-attribute-name",
        "class-map":
        {
            "1":"approving","0":"sad","4":"critical"
        },
        "human-annotated":"yes",
        "creation-date":"2020-02-20T21:36:25.000201",
        "confidence-map":
        {
            "1":0.95,"0":0.77,"4":0.2
        }
    }
}
```
Bounding Box Job Output

The following is sample output (output manifest file) from a bounding box job. For this task, three bounding boxes are returned. The label value contains information about the size of the image, and the location of the bounding boxes.

The class_id element is the index of the box's class in the list of available classes for the task. The class-map metadata element contains the text of the class.

The metadata has a separate confidence score for each bounding box. The metadata also includes the class-map element that maps the class_id to the text value of the class. For more information, see Object Detection - MXNet (p. 2196).

The red, italicized text in the examples below depends on labeling job specifications and output data.

```json
{
  "source-ref": "s3://AWSDOC-EXAMPLE-BUCKET/example_image.png",
  "bounding-box-attribute-name":
  {
    "image_size": [{ "width": 500, "height": 400, "depth": 3 }],
    "annotations":
    [
      { "class_id": 0, "left": 111, "top": 134, "width": 61, "height": 128 },
      { "class_id": 5, "left": 131, "top": 250, "width": 30, "height": 30 },
      { "class_id": 5, "left": 20, "top": 20, "width": 30, "height": 30 }
    ],
    "bounding-box-attribute-name-metadata":
    {
      "objects":
      [
        { "confidence": 0.8 },
        { "confidence": 0.9 },
        { "confidence": 0.9 }
      ],
      "class-map":
      {
        "0": "dog",
        "5": "bone"
      },
      "type": "groundtruth/object-detection",
      "human-annotated": "yes",
      "creation-date": "2018-10-18T22:18:13.527256",
      "job-name": "identify-dogs-and-toys"
    }
  }
}
```

The output of a bounding box adjustment job looks like the following JSON. Note that the original JSON is kept intact and two new jobs are listed, each with "adjust-" prepended to the original attribute's name.

```json
{
  "source-ref": "S3 bucket location",
  "bounding-box-attribute-name":
  {
    "image_size": [{ "width": 500, "height": 400, "depth": 3 }],
    "annotations":
    [
      { "class_id": 0, "left": 111, "top": 134, "width": 61, "height": 128 },
      { "class_id": 5, "left": 131, "top": 250, "width": 30, "height": 30 },
      { "class_id": 5, "left": 20, "top": 20, "width": 30, "height": 30 }
    ],
    "bounding-box-attribute-name-metadata":
    {
      "objects":
      [
        { "confidence": 0.8 },
        { "confidence": 0.9 },
        { "confidence": 0.9 }
      ],
      "class-map":
      {
        "0": "dog",
        "5": "bone"
      },
      "type": "groundtruth/object-detection",
      "human-annotated": "yes",
      "creation-date": "2018-10-18T22:18:13.527256",
      "job-name": "identify-dogs-and-toys"
    }
  }
}
```
In this output, the job's type doesn't change, but an adjustment-status field is added. This field has the value of adjusted or unadjusted. If multiple workers have reviewed the object and at least one adjusted the label, the status is adjusted.
Named Entity Recognition

The following is an example output manifest file from a named entity recognition (NER) labeling task. For this task, seven entities are returned.

In the output manifest, the JSON object, annotations, includes a list of the labels (label categories) that you provided.

Worker responses are in a list named entities. Each entity in this list is a JSON object that contains a label value that matches one in the labels list, an integer startOffset value for labeled span's starting Unicode offset, and an integer endOffset value for the ending Unicode offset.

The metadata has a separate confidence score for each entity. If a single worker labeled each data object, the confidence value for each entity will be zero.

The red, italicized text in the examples below depends on labeling job inputs and worker responses.

```json
{
  "source": "Amazon SageMaker is a cloud machine-learning platform that was launched in November 2017. SageMaker enables developers to create, train, and deploy machine-learning (ML) models in the cloud. SageMaker also enables developers to deploy ML models on embedded systems and edge-devices",
  "ner-labeling-job-attribute-name": {
    "annotations": {
      "labels": [
        {
          "label": "Date",
          "shortDisplayName": "dt"
        },
        {
          "label": "Verb",
          "shortDisplayName": "vb"
        },
        {
          "label": "Thing",
          "shortDisplayName": "tng"
        },
        {
          "label": "People",
          "shortDisplayName": "ppl"
        }
      ],
      "entities": [
        {
          "label": "Thing",
          "startOffset": 22,
          "endOffset": 53
        },
        {
          "label": "Thing",
          "startOffset": 269,
          "endOffset": 281
        },
        {
          "label": "Verb",
          "startOffset": 63,
          "endOffset": 71
        },
        {
          "label": "Verb",
          "startOffset": 228,
          "endOffset": 234
        }
      ]
    }
  }
}```
Label Verification Job Output

The output (output manifest file) of a bounding box verification job looks different than the output of a bounding box annotation job. That's because the workers have a different type of task. They're not labeling objects, but evaluating the accuracy of prior labeling, making a judgment, and then providing that judgment and perhaps some comments.

If human workers are verifying or adjusting prior bounding box labels, the output of a verification job would look like the following JSON. The red, italicized text in the examples below depends on labeling job specifications and output data.

```json
{
    "source-ref": "s3://AWSDOC-EXAMPLE-BUCKET/image_example.png",
    "bounding-box-attribute-name": {
        "image_size": [
            ["width": 500, "height": 400, "depth": 3]
```
Although the type on the original bounding box output was `groundtruth/object-detection`, the new type is `groundtruth/label-verification`. Also note that the `worker-feedback` array provides worker comments. If the worker doesn't provide comments, the empty fields are excluded during consolidation.

**Semantic Segmentation Job Output**

The following is the output manifest file from a semantic segmentation labeling job. The value of the label for this job is a reference to a PNG file in an Amazon S3 bucket.

In addition to the standard elements, the metadata for the label includes a color map that defines which color is used to label the image, the class name associated with the color, and the confidence score for each color. For more information, see [Semantic Segmentation Algorithm](p. 2215).

The red, italicized text in the examples below depends on labeling job specifications and output data.

```json
{
  "source-ref": "s3://AWSDOC-EXAMPLE-BUCKET/example_city_image.png",
  "city-streets-ref": "S3 bucket location"
}
```
Confidence is scored on a per-image basis. Confidence scores are the same across all classes within an image.

The output of a semantic segmentation adjustment job looks similar to the following JSON.

```json
{
   "source-ref": "s3://AWSDOC-EXAMPLE-BUCKET/example_city_image.png",
   "city-streets-ref": "S3 bucket location",
   "city-streets-ref-metadata": {
      "internal-color-map": {
         "0": {
            "class-name": "BACKGROUND",
            "confidence": 0.9,
            "hex-color": "#ffffff"
         },
         "1": {
            "class-name": "buildings",
            "confidence": 0.9,
            "hex-color": "#2acf59"
         },
         "2": {
            "class-name": "road",
            "confidence": 0.9,
            "hex-color": "#f28333"
         }
      },
      "type": "groundtruth/semantic-segmentation",
      "human-annotated": "yes",
      "creation-date": "2018-10-18T22:18:13.527256",
      "job-name": "label-city-streets",
      "verify-city-streets-ref": "1",
      "verify-city-streets-ref-metadata": {
         "class-name": "bad",
         "confidence": 0.93,
         "type": "groundtruth/label-verification",
         "job-name": "verify-city-streets",
         "human-annotated": "yes",
         "creation-date": "2018-11-20T22:18:13.527256",
         "worker-feedback": [{
            "comment": "The mask on the leftmost building is assigned the wrong side of the road.",
            "comment": "The curb of the road is not labeled but the instructions say otherwise."
         }]
      }
   }
}
```
Video Frame Object Detection Output

The following is the output manifest file from a video frame object detection labeling job. The red, italicized text in the examples below depends on labeling job specifications and output data.

In addition to the standard elements, the metadata includes a class map that lists each class that has at least one label in the sequence. The metadata also includes job-name which is the name you assigned to the labeling job. For adjustment tasks, if one or more bounding boxes were modified, there is an adjustment-status parameter in the metadata for audit workflows that is set to adjusted.

```
{
  "source-ref": "s3://DOC-EXAMPLE-BUCKET/example-path/input-manifest.json",
  "CarObjectDetection-ref": "s3://AWSDOC-EXAMPLE-BUCKET/output/labeling-job-name/annotations/consolidated-annotation/output/0/SeqLabel.json",
  "CarObjectDetection-ref-metadata": {
    "class-map": {
      "0": "car",
      "1": "bus"
    },
    "job-name": "labeling-job/labeling-job-name",
    "human-annotated": "yes",
    "creation-date": "2021-09-29T05:50:35.566000",
    "type": "groundtruth/video-object-detection"
  }
}
```

Ground Truth creates one output sequence file for each sequence of video frames that was labeled. Each output sequence file contains the following:
• All annotations for all frames in a sequence in the detection-annotations list of JSON objects.
• For each frame that was annotated by a worker, the frame file name (frame), number (frame-no), a list of JSON objects containing annotations (annotations), and if applicable, frame-attributes. The name of this list is defined by the task type you use: polylines, polygons, keypoints, and for bounding boxes, annotations.

Each JSON object contains information about a single annotation and associated label. The following table outlines the parameters you'll see for each video frame type.

<table>
<thead>
<tr>
<th>Task Type</th>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bounding Box</td>
<td>Box dimensions: height and width</td>
</tr>
<tr>
<td></td>
<td>Box top, left corner pixel location: top and left</td>
</tr>
<tr>
<td>Keypoint</td>
<td>Keypoint vertices: { &quot;x&quot;: int, &quot;y&quot;: int }</td>
</tr>
<tr>
<td>Polygon</td>
<td>A list of polygon vertices: vertices</td>
</tr>
<tr>
<td></td>
<td>Polygon vertices: { &quot;x&quot;: int, &quot;y&quot;: int }</td>
</tr>
<tr>
<td></td>
<td>A polygon is a closed shape and so the first point will also represent the last point.</td>
</tr>
<tr>
<td>Polyline</td>
<td>A list of polyline vertices: vertices</td>
</tr>
<tr>
<td></td>
<td>Polyline vertices: { &quot;x&quot;: int, &quot;y&quot;: int }</td>
</tr>
</tbody>
</table>

In addition to task type specific values, you will see the following in each JSON object:
• Values of any label-category-attributes that were specified for that label.
• The class-id of the box. Use the class-map in the output manifest file to see which label category this ID maps to.

The following is an example of a SeqLabel.json file from a bounding box video frame object detection labeling job. This file will be located under s3://your-output-bucket/output-prefix/annotations/consolidated-annotation/output/annotation-number/.

```json
{
  "detection-annotations": [
    {
      "annotations": [
        {
          "height": 41,
          "width": 53,
          "top": 152,
          "left": 339,
          "class-id": "1",
          "label-category-attributes": {
            "occluded": "no",
            "size": "medium"
          }
        },
        {
          "height": 24,
          "width": 37,
          "top": 148,
          "left": 183,
          "class-id": "0",
          "label-category-attributes": {
```
Video Frame Object Tracking Output

The following is the output manifest file from a video frame object tracking labeling job. The red, italicized text in the examples below depends on labeling job specifications and output data.

In addition to the standard elements, the metadata includes a class map that lists each class that has at least one label in the sequence of frames. The metadata also includes job-name which is the name you assigned to the labeling job. For adjustment tasks, if one or more bounding boxes were modified, there is an adjustment-status parameter in the metadata for audit workflows that is set to adjusted.

```json
{
  "source-ref": "s3://DOC-EXAMPLE-BUCKET/example-path/input-manifest.json",
  "CarObjectTracking-ref": "s3://AWSDOC-EXAMPLE-BUCKET/output labeling-job-name/annotations/consolidated-annotation/output/0/SeqLabel.json",
  "CarObjectTracking-ref-metadata": {
    "class-map": {
      "0": "car",
      "1": "bus"
    },
    "job-name": "labeling-job labeling-job-name",
    "human-annotated": "yes",
    "creation-date": "2021-09-29T05:50:35.566000",
    "type": "groundtruth/video-object-tracking"
  }
}```
Ground Truth creates one output sequence file for each sequence of video frames that was labeled. Each output sequence file contains the following:

- All annotations for all frames in a sequence in the tracking-annotations list of JSON objects.
- For each frame that was annotated by a worker, the frame (frame), number (frame-no), a list of JSON objects containing annotations (annotations), and if applicable, frame attributes (frame-attributes). The name of this list is defined by the task type you use: polylines, polygons, keypoints, and for bounding boxes, annotations.

Each JSON object contains information about a single annotation and associated label. The following table outlines the parameters you'll see for each video frame task type.

<table>
<thead>
<tr>
<th>Task Type</th>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bounding Box</td>
<td>Box dimensions: height and width</td>
</tr>
<tr>
<td></td>
<td>Box top, left corner pixel location: top and left</td>
</tr>
<tr>
<td>Keypoint</td>
<td>Keypoint vertices: { &quot;x&quot;: int, &quot;y&quot;: int }</td>
</tr>
<tr>
<td>Polygon</td>
<td>A list of polygon vertices: vertices</td>
</tr>
<tr>
<td></td>
<td>Polygon vertices: { &quot;x&quot;: int, &quot;y&quot;: int }</td>
</tr>
<tr>
<td></td>
<td>A polygon is a closed shape and so the first point will also represent the last point.</td>
</tr>
<tr>
<td>Polyline</td>
<td>A list of polyline vertices: vertices</td>
</tr>
<tr>
<td></td>
<td>Polyline vertices: { &quot;x&quot;: int, &quot;y&quot;: int }</td>
</tr>
</tbody>
</table>

In addition to task type specific values, you will see the following in each JSON object:

- Values of any label-category-attributes that were specified for that label.
- The class-id of the box. Use the class-map in the output manifest file to see which label category this ID maps to.
- An object-id which identifies an instance of a label. This ID will be the same across frames if a worker identified the same instance of an object in multiple frames. For example, if a car appeared in multiple frames, all bounding boxes uses to identify that car would have the same object-id.
- The object-name which is the instance ID of that annotation.

The following is an example of a SeqLabel.json file from a bounding box video frame object tracking labeling job. This file will be located under s3://your-output-bucket/output-prefix/annotations/consolidated-annotation/output/annotation-number/:

```json
[
  "tracking-annotations": [
    {
      "annotations": [
        {
          "height": 36,
          "width": 46,
          "top": 178,
          "left": 315,
          "class-id": "0",
          "label-category-attributes": {
            "occluded": "no"
          },
          "object-id": "480dc450-c0ca-11ea-961f-a9b1c5c97972",
```
3D Point Cloud Semantic Segmentation Output

The following is the output manifest file from a 3D point cloud semantic segmentation labeling job.

In addition to the standard elements, the metadata for the label includes a color map that defines which color is used to label the image, the class name associated with the color, and the confidence score for each color. Additionally, there is an adjustment-status parameter in the metadata for audit workflows that is set to adjusted if the color mask is modified. If you added one or more frameAttributes to your label category configuration file, worker responses for frame attributes are in the JSON object, dataset-object-attributes.

The your-label-attribute-ref parameter contains the location of a compressed file with a .zlib extension. When you uncompess this file, it contains an array. Each index in the array corresponds to the index of an annotated point in the input point cloud. The value of the array at a given index gives the class of the point at the same index in the point cloud, based on the semantic color map found in the color-map parameter of the metadata.

You can use Python code similar to the following to decompress a .zlib file:

```python
import zlib
from array import array
```
```python
# read the label file
compressed_binary_file = open(zlib_file_path/file.zlib, 'rb').read()

# uncompress the label file
binary_content = zlib.decompress(compressed_binary_file)

# load labels to an array
my_int_array_data = array('B', binary_content);
print(my_int_array_data)
```

The code block above will produce an output similar to the following. Each element of the printed array contains the class of a point at the that index in the point cloud. For example, `my_int_array_data[0] = 1` means point[0] in the input point cloud has a class 1. In the following output manifest file example, class 0 corresponds with "Background", 1 with Car, and 2 with Pedestrian.

```python
>> array('B', [1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 0, 0, 0, 0, 0, 0, 0, 0, 0, 2, 2, 2, 2, 2, 2, 2])
```

The following is an example of a semantic segmentation 3D point cloud labeling job output manifest file. The red, italicized text in the examples below depends on labeling job specifications and output data.

```json
{
    "source-ref": "s3://AWSDOC-EXAMPLE-BUCKET/examplefolder/frame1.bin",
    "source-ref-metadata": {
        "format": "binary/xyz",
        "unix-timestamp": 1566861644.759115,

        'job-name': 'labeling-job-name',
        // only present for adjustment audit workflow
        "adjustment-status": "adjusted", // "adjusted" means the label was adjusted
```

631
3D Point Cloud Object Detection Output

The following is sample output from a 3D point cloud objected detection job. For this task type, the data about 3D cuboids is returned in the `3d-bounding-box` parameter, in a list named `annotations`. In this list, each 3D cuboid is described using the following information.

- Each class, or label category, that you specify in your input manifest is associated with a `class-id`. Use the `class-map` to identify the class associated with each class ID.
- These classes are used to give each 3D cuboid an `object-name` in the format `<class>:<integer>` where `integer` is a unique number to identify that cuboid in the frame.
- `center-x`, `center-y`, and `center-z` are the coordinates of the center of the cuboid, in the same coordinate system as the 3D point cloud input data used in your labeling job.
- `length`, `width`, and `height` describe the dimensions of the cuboid.
- `yaw` is used to describe the orientation (heading) of the cuboid in radians.

**Note**
yaw is now in the right-handed Cartesian system. Since this feature was added on September 02, 2022 19:02:17 UTC, you can convert the yaw measurement in the output data prior to that using the following (all units are in radians):

\[
\text{old\_yaw\_in\_output} = \pi - \text{yaw}
\]

- In our definition, +x is to the right, +y is to the forward, and +z is up from the ground plane. The rotation order is x - y - z. The roll, pitch and yaw are represented in the right-handed Cartesian system. In 3D space, roll is along the x-axis, pitch is along the y-axis and yaw is along the z-axis. All three are counterclockwise.
- If you included label attributes in your input manifest file for a given class, a `label-category-attributes` parameter is included for all cuboids for which workers selected label attributes.

If one or more cuboids were modified, there is an `adjustment-status` parameter in the metadata for audit workflows that is set to `adjusted`. If you added one or more `frameAttributes` to your label category configuration file, worker responses for frame attributes are in the JSON object, `dataset-object-attributes`.

The red, italicized text in the examples below depends on labeling job specifications and output data. The ellipses (...), denote a continuation of that list, where additional objects with the same format as the proceeding object can appear.

```json

3D Point Cloud Object Tracking Output

The following is an example of an output manifest file from a 3D point cloud object tracking labeling job. The red, italicized text in the examples below depends on labeling job specifications and output data. The ellipses (…) denote a continuation of that list, where additional objects with the same format as the proceeding object can appear.

In addition to the standard elements, the metadata includes a class map that lists each class that has at least one label in the sequence. If one or more cuboids were modified, there is an adjustment-status parameter in the metadata for audit workflows that is set to adjusted.

```json
{
  "source-ref": "s3://AWSDOC-EXAMPLE-BUCKET/myfolder/seq1.json",
  "lidar-label-attribute-ref": "s3://<CustomerOutputLocation>/<labelingJobName>/annotations/consolidated-annotation/output/<datasetObjectId>/SeqLabel.json",
  "lidar-label-attribute-ref-metadata": {

  }
}
```

In the above example, the cuboid data for each frame in seq1.json is in SeqLabel.json in the Amazon S3 location, s3://<customerOutputLocation>/<labelingJobName>/annotations/
consolidated-annotation/output/<datasetObjectId>/SeqLabel.json. The following is an example of this label sequence file.

For each frame in the sequence, you see the frame-number, frame-name, if applicable, frame-attributes, and a list of annotations. This list contains 3D cuboids that were drawn for that frame. Each annotation includes the following information:

- An object-name in the format `<class>:<integer>` where class identifies the label category and integer is a unique ID across the dataset.
- When workers draw a cuboid, it is associated with a unique object-id which is associated with all cuboids that identify the same object across multiple frames.
- Each class, or label category, that you specified in your input manifest is associated with a class-id. Use the class-map to identify the class associated with each class ID.
- center-x, center-y, and center-z are the coordinates of the center of the cuboid, in the same coordinate system as the 3D point cloud input data used in your labeling job.
- length, width, and height describe the dimensions of the cuboid.
- yaw is used to describe the orientation (heading) of the cuboid in radians.

**Note**
yaw is now in the right-handed Cartesian system. Since this feature was added on September 02, 2022 19:02:17 UTC, you can convert the yaw measurement in the output data prior to that using the following (all units are in radians):

\[
\text{old}_\text{yaw}\text{in}\text{output} = \pi - \text{yaw}
\]

- In our definition, +x is to the right, +y is to the forward, and +z is up from the ground plane. The rotation order is x - y - z. The roll, pitch and yaw are represented in the right-handed Cartesian system. In 3D space, roll is along the x-axis, pitch is along the y-axis and yaw is along the z-axis. All three are counterclockwise.
- If you included label attributes in your input manifest file for a given class, a label-category-attributes parameter is included for all cuboids for which workers selected label attributes.

Enhanced Data Labeling

Amazon SageMaker Ground Truth manages sending your data objects to workers to be labeled. Labeling each data object is a task. Workers complete each task until the entire labeling job is complete. Ground Truth divides the total number of tasks into smaller batches that are sent to workers. A new batch is sent to workers when the previous one is finished.

Ground Truth provides two features that help improve the accuracy of your data labels and reduce the total cost of labeling your data:

- **Annotation consolidation** helps to improve the accuracy of your data object labels. It combines the results of multiple workers' annotation tasks into one high-fidelity label.
- **Automated data labeling** uses machine learning to label portions of your data automatically without having to send them to human workers.

**Topics**

- Control the Flow of Data Objects Sent to Workers (p. 637)
- Consolidate Annotations (p. 639)
- Automate Data Labeling (p. 640)
- Chaining Labeling Jobs (p. 646)

**Control the Flow of Data Objects Sent to Workers**

Depending on the type of labeling job you create, Amazon SageMaker Ground Truth sends data objects to workers in batches or in a streaming fashion. You can control the flow of data objects to workers in the following ways:
• For both types of labeling jobs, you can use MaxConcurrentTaskCount to control the total number of data objects available to all workers at a given point in time when the labeling job is running.
• For streaming labeling jobs, you can control the flow of data objects to workers by monitoring and controlling the number of data objects sent to the Amazon SQS associated with your labeling job.

Use the following sections to learn more about these options. To learn more about streaming labeling jobs, see Ground Truth Streaming Labeling Jobs (p. 576).

Topics
• Use MaxConcurrentTaskCount to Control the Flow of Data Objects (p. 638)
• Use Amazon SQS to Control the Flow of Data Objects to Streaming Labeling Jobs (p. 638)

Use MaxConcurrentTaskCount to Control the Flow of Data Objects

MaxConcurrentTaskCount defines the maximum number of data objects that can be labeled by human workers at the same time. If you use the console, this parameter is set to 1,000. If you use CreateLabelingJob, you can set this parameter to any integer between 1 and 1,000, inclusive.

When you start a labeling job using an input manifest file, Ground Truth does the following:

1. For each data object listed in your input manifest file, one or more tasks are created, depending on the value you specify for NumberOfHumanWorkersPerDataObject. For example, if you set the number of workers per data object to 3, 3 tasks will be created for each dataset object. To be marked as successfully labeled, at least one worker must label the object. Alternatively, the tasks can expire or be declined.
2. If you are using the Mechanical Turk workforce, Ground Truth first sends a batch of 10 dataset objects to your workers. It uses this small batch to set up the labeling job and to make sure that the job is correctly configured.
3. Next, Ground Truth sends MaxConcurrentTaskCount number of dataset objects to workers. For example, if you have 2,000 input data objects in your input manifest file and have set the number of workers per data object to 3 and set MaxConcurrentTaskCount to 900, the first 900 data objects in your input manifest are sent to workers, corresponding to 2,700 tasks (900 x 3). This is the first full-sized set of objects sent to workers.
4. What happens next depends on the type of labeling job you create. This step assumes one or more dataset objects in your input manifest file, or sent using an Amazon SNS input data source (in a streaming labeling job) were not include in the set sent to workers in step 3.
   - **Streaming labeling job:** As long as the total number of objects available to workers is equal to MaxConcurrentTaskCount, all remaining dataset objects on your input manifest file and that you send in real time using Amazon SNS are placed on an Amazon SQS queue. When the total number of objects available to workers falls below MaxConcurrentTaskCount minus NumberOfHumanWorkersPerDataObject, a new data object from the queue is used to create NumberOfHumanWorkersPerDataObject-tasks, which are sent to workers in real time.
   - **Non-streaming labeling job:** As workers finish labeling one set of objects, up to MaxConcurrentTaskCount times NumberOfHumanWorkersPerDataObject number of new tasks will be sent to workers. This process is repeated until all data objects in the input manifest file are labeled.

Use Amazon SQS to Control the Flow of Data Objects to Streaming Labeling Jobs

When you create a streaming labeling job, an Amazon SQS queue is automatically created in your account. Data objects are only added to the Amazon SQS queue when the total number of objects sent to workers is above MaxConcurrentTaskCount. Otherwise, objects are sent directly to workers.
You can use this queue to manage the flow of data objects to your labeling job. To learn more, see Manage Labeling Requests with an Amazon SQS Queue (p. 578).

**Consolidate Annotations**

An *annotation* is the result of a single worker's labeling task. *Annotation consolidation* combines the annotations of two or more workers into a single label for your data objects. A label, which is assigned to each object in the dataset, is a probabilistic estimate of what the true label should be. Each object in the dataset typically has multiple annotations, but only one label or set of labels.

You decide how many workers annotate each object in your dataset. Using more workers can increase the accuracy of your labels, but also increases the cost of labeling. To learn more about Ground Truth pricing, see Amazon SageMaker Ground Truth pricing.

If you use the Amazon SageMaker console to create a labeling job, the following are the defaults for the number of workers who can annotate objects:

- Text classification—3 workers
- Image classification—3 workers
- Bounding boxes—5 workers
- Semantic segmentation—3 workers
- Named entity recognition—3 workers

When you use the `CreateLabelingJob` operation, you set the number of workers to annotate each data object with the `NumberOfHumanWorkersPerDataObject` parameter. You can override the default number of workers that annotate a data object using the console or the `CreateLabelingJob` operation.

Ground Truth provides an annotation consolidation function for each of its predefined labeling tasks: bounding box, image classification, name entity recognition, semantic segmentation, and text classification. These are the functions:

- Multi-class annotation consolidation for image and text classification uses a variant of the Expectation Maximization approach to annotations. It estimates parameters for each worker and uses Bayesian inference to estimate the true class based on the class annotations from individual workers.
- Bounding box annotation consolidates bounding boxes from multiple workers. This function finds the most similar boxes from different workers based on the Jaccard index, or intersection over union, of the boxes and averages them.
- Semantic segmentation annotation consolidation treats each pixel in a single image as a multi-class classification. This function treats the pixel annotations from workers as "votes," with more information from surrounding pixels incorporated by applying a smoothing function to the image.
- Named entity recognition clusters text selections by Jaccard similarity and calculates selection boundaries based on the mode, or the median if the mode isn't clear. The label resolves to the most assigned entity label in the cluster, breaking ties by random selection.

You can use other algorithms to consolidate annotations. For information, see Create Your Own Annotation Consolidation Function (p. 639).

**Create Your Own Annotation Consolidation Function**

You can choose to use your own annotation consolidation function to determine the final labels for your labeled objects. There are many possible approaches for writing a function and the approach that you take depends on the nature of the annotations to consolidate. Broadly, consolidation functions look at the annotations from workers, measure the similarity between them, and then use some form of probabilistic judgment to determine what the most probable label should be.
If you want to use other algorithms to create annotation consolidations functions, you can find the worker responses in the `[project-name]/annotations/worker-response` folder of the Amazon S3 bucket where you direct the job output.

**Assess Similarity**

To assess the similarity between labels, you can use one of the following strategies, or you can use one that meets your data labeling needs:

- For label spaces that consist of discrete, mutually exclusive categories, such as multi-class classification, assessing similarity can be straightforward. Discrete labels either match or do not match.
- For label spaces that don't have discrete values, such as bounding box annotations, find a broad measure of similarity. For bounding boxes, one such measure is the Jaccard index. This measures the ratio of the intersection of two boxes with the union of the boxes to assess how similar they are. For example, if there are three annotations, then there can be a function that determines which annotations represent the same object and should be consolidated.

**Assess the Most Probable Label**

With one of the strategies detailed in the previous sections in mind, make some sort of probabilistic judgment on what the consolidated label should be. In the case of discrete, mutually exclusive categories, this can be straightforward. One of the most common ways to do this is to take the results of a majority vote between the annotations. This weights the annotations equally.

Some approaches attempt to estimate the accuracy of different annotators and weight their annotations in proportion to the probability of correctness. An example of this is the Expectation Maximization method, which is used in the default Ground Truth consolidation function for multi-class annotations.

For more information about creating an annotation consolidation function, see Step 3: Processing with AWS Lambda (p. 516).

**Automate Data Labeling**

If you choose, Amazon SageMaker Ground Truth can use active learning to automate the labeling of your input data for certain built-in task types. *Active learning* is a machine learning technique that identifies data that should be labeled by your workers. In Ground Truth, this functionality is called automated data labeling. Automated data labeling helps to reduce the cost and time that it takes to label your dataset compared to using only humans. When you use automated labeling, you incur SageMaker training and inference costs.

We recommend using automated data labeling on large datasets because the neural networks used with active learning require a significant amount of data for every new dataset. Typically, as you provide more data, the potential for high accuracy predictions goes up. Data will only be auto-labeled if the neural network used in the auto-labeling model can achieve an acceptably high level of accuracy. Therefore, with larger datasets, there is more potential to automatically label the data because the neural network can achieve high enough accuracy for auto-labeling. Automated data labeling is most appropriate when you have thousands of data objects. The minimum number of objects allowed for automated data labeling is 1,250, but we strongly suggest providing a minimum of 5,000 objects.

Automated data labeling is available only for the following Ground Truth built-in task types:

- Image Classification (Single Label) (p. 389)
- Image Semantic Segmentation (p. 382)
- Object detection (Bounding Box (p. 376))
- Text Classification (Single Label) (p. 400)
Streaming labeling jobs do not support automated data labeling.

To learn how to create a custom active learning workflow using your own model, see Set up an active learning workflow with your own model (p. 646).

Input data quotas apply for automated data labeling jobs. See Input Data Quotas (p. 580) for information about dataset size, input data size and resolution limits.

Note  
Before you use an the automated-labeling model in production, you need to fine-tune or test it, or both. You might fine-tune the model (or create and tune another supervised model of your choice) on the dataset produced by your labeling job to optimize the model's architecture and hyperparameters. If you decide to use the model for inference without fine-tuning it, we strongly recommend making sure that you evaluate its accuracy on a representative (for example, randomly selected) subset of the dataset labeled with Ground Truth and that it matches your expectations.

How it Works

You enable automated data labeling when you create a labeling job. This is how it works:

1. When Ground Truth starts an automated data labeling job, it selects a random sample of input data objects and sends them to human workers. If more than 10% of these data objects fail, the labeling job will fail. If the labeling job fails, in addition to reviewing any error message Ground Truth returns, check that your input data is displaying correctly in the worker UI, instructions are clear, and that you have given workers enough time to complete tasks.

2. When the labeled data is returned, it is used to create a training set and a validation set. Ground Truth uses these datasets to train and validate the model used for auto-labeling.

3. Ground Truth runs a batch transform job, using the validated model for inference on the validation data. Batch inference produces a confidence score and quality metric for each object in the validation data.

4. The auto labeling component will use these quality metrics and confidence scores to create a confidence score threshold that ensures quality labels.

5. Ground Truth runs a batch transform job on the unlabeled data in the dataset, using the same validated model for inference. This produces a confidence score for each object.

6. The Ground Truth auto labeling component determines if the confidence score produced in step 5 for each object meets the required threshold determined in step 4. If the confidence score meets the threshold, the expected quality of automatically labeling exceeds the requested level of accuracy and that object is considered auto-labeled.

7. Step 6 produces a dataset of unlabeled data with confidence scores. Ground Truth selects data points with low confidence scores from this dataset and sends them to human workers.

8. Ground Truth uses the existing human-labeled data and this additional labeled data from human workers to update the model.

9. The process is repeated until the dataset is fully labeled or until another stopping condition is met. For example, auto-labeling stops if your human annotation budget is reached.

The preceding steps happen in iterations. Select each tab in the following table to see an example of the processes that happen in each iteration for an object detection automated labeling job. The number of data objects used in a given step in these images (for example, 200) is specific to this example. If there are fewer than 5,000 objects to label, the validation set size is 20% of the whole dataset. If there are more than 5,000 objects in your input dataset, the validation set size is 10% of the whole dataset. You can control the number of human labels collected per active learning iteration by changing the value for MaxConcurrentTaskCount when using the API operation CreateLabelingJob. This value is set to 1,000 when you create a labeling job using the console. In the active learning flow illustrated under the Active Learning tab, this value is set to 200.
Model Training

Iterations 1, 2, and 3: Model training

Unlabeled images

Send randomly selected images to annotators

Iteration 3: 20 labeled, 20 valid
Automated Labeling

Iteration 4: Automated Labeling

- 200 human-annotated validation labels
- Compare human-annotated and automated labels
- Trained model
- 200 automated validation labels with confidence scores
- Unlabeled images
- Trained model
**Active Learning**

**Accuracy of Automated Labels**

The definition of *accuracy* depends on the built-in task type that you use with automated labeling. For all task types, these accuracy requirements are pre-determined by Ground Truth and cannot be manually configured.

- For image classification and text classification, Ground Truth uses logic to find a label-prediction confidence level that corresponds to at least 95% label accuracy. This means Ground Truth expects the accuracy of the automated labels to be at least 95% when compared to the labels that human labelers would provide for those examples.
- For bounding boxes, the expected mean *Intersection Over Union (IoU)* of the auto-labeled images is 0.6. To find the mean IoU, Ground Truth calculates the mean IoU of all the predicted and missed boxes on the image for every class, and then averages these values across classes.
- For semantic segmentation, the expected mean IoU of the auto-labeled images is 0.7. To find the mean IoU, Ground Truth takes the mean of the IoU values of all the classes in the image (excluding the background).

At every iteration of Active Learning (steps 3-6 in the list above), the confidence threshold is found using the human-annotated validation set so that the expected accuracy of the auto-labeled objects satisfies certain predefined accuracy requirements.

**Create an Automated Data Labeling Job (Console)**

To create a labeling job that uses automated labeling in the SageMaker console, use the following procedure.

**To create an automated data labeling job (console)**

2. Using Create a Labeling Job (Console) (p. 544) as a guide, complete the *Job overview* and *Task type* sections. Note that auto labeling is not supported for custom task types.
4. In the same section, choose **Enable automated data labeling**.
5. Using Step 4: Configure the Bounding Box Tool (p. 375) as a guide, create worker instructions in the section **Task Type labeling tool**. For example, if you chose **Semantic segmentation** as your labeling job type, this section is called **Semantic segmentation labeling tool**.
6. To preview your worker instructions and dashboard, choose **Preview**.
7. Choose **Create**. This creates and starts your labeling job and the auto labeling process.

You can see your labeling job appear in the **Labeling jobs** section of the SageMaker console. Your output data appears in the Amazon S3 bucket that you specified when creating the labeling job. For more information about the format and file structure of your labeling job output data, see **Output Data** (p. 614).

**Create an Automated Data Labeling Job (API)**

To create an automated data labeling job using the SageMaker API, use the **LabelingJobAlgorithmsConfig** parameter of the **CreateLabelingJob** operation. To learn how to start a labeling job using the **CreateLabelingJob** operation, see **Create a Labeling Job (API)** (p. 547).

Specify the Amazon Resource Name (ARN) of the algorithm that you are using for automated data labeling in the **LabelingJobAlgorithmSpecificationArn** parameter. Choose from one of the four Ground Truth built-in algorithms that are supported with automated labeling:

- Image Classification (Single Label) (p. 389)
- Image Semantic Segmentation (p. 382)
- Object detection (Bounding Box (p. 376))
- Text Classification (Single Label) (p. 400)

When an automated data labeling job finishes, Ground Truth returns the ARN of the model it used for the automated data labeling job. Use this model as the starting model for similar auto-labeling job types by providing the ARN, in string format, in the **InitialActiveLearningModelArn** parameter. To retrieve the model's ARN, use an AWS Command Line Interface (AWS CLI) command similar to the following.

```
# Fetch the mARN of the model trained in the final iteration of the previous labeling job. Ground Truth
pretrained_model_arn = sagemaker_client.describe_labeling_job(LabelingJobName=job_name)
['LabelingJobOutput']['FinalActiveLearningModelArn']
```

To encrypt data on the storage volume attached to the ML compute instance(s) that are used in automated labeling, include an AWS Key Management Service (AWS KMS) key in the **VolumeKmsKeyId** parameter. For information about AWS KMS keys, see **What is AWS Key Management Service?** in the **AWS Key Management Service Developer Guide**.

For an example that uses the **CreateLabelingJob** operation to create an automated data labeling job, see the **object_detection_tutorial** example in the **SageMaker Examples, Ground Truth Labeling Jobs** section of a SageMaker notebook instance. To learn how to create and open a notebook instance, see **Create a Notebook Instance** (p. 296). To learn how to access SageMaker example notebooks, see Example Notebooks (p. 306).

**Amazon EC2 Instances Required for Automated Data Labeling**

The following table lists the Amazon Elastic Compute Cloud (Amazon EC2) instances that you need to run automated data labeling for training and batch inference jobs.
Automated Data Labeling Job Type | Training Instance Type | Inference Instance Type
--- | --- | ---
Image classification | ml.p3.2xlarge* | ml.c5.xlarge
Object detection (bounding box) | ml.p3.2xlarge* | ml.c5.4xlarge
Text classification | ml.c5.2xlarge | ml.m4.xlarge
Semantic segmentation | ml.p3.2xlarge* | ml.p3.2xlarge*  

* In the Asia Pacific (Mumbai) Region (ap-south-1) use ml.p2.8xlarge instead.

Ground Truth manages the instances that you use for automated data labeling jobs. It creates, configures, and terminates the instances as needed to perform your job. These instances don't appear in your Amazon EC2 instance dashboard.

**Set up an active learning workflow with your own model**

You can create an active learning workflow with your own algorithm to run training and inferences in that workflow to auto-label your data. The notebook `bring_your_own_model_for_sagemaker_labeling_workflows_with_active_learning.ipynb` demonstrates this using the SageMaker built-in algorithm, BlazingText. This notebook provides an AWS CloudFormation stack that you can use to execute this workflow using AWS Step Functions. You can find the notebook and supporting files in this GitHub repository.

You can also find this notebook in the SageMaker Examples repository. See Use Example Notebooks to learn how to find an Amazon SageMaker example notebook.

**Chaining Labeling Jobs**

Amazon SageMaker Ground Truth can reuse datasets from prior jobs in two ways: cloning and chaining.

**Cloning** copies the setup of a prior labeling job and allows you to make additional changes before setting it to run.

**Chaining** uses not only the setup of the prior job, but also the results. This allows you to continue an incomplete job and add labels or data objects to a completed job. Chaining is a more complex operation.

For data processing:

- Cloning uses the prior job's *input* manifest, with optional modifications, as the new job's input manifest.
- Chaining uses the prior job's *output* manifest as the new job's input manifest.

Chaining is useful when you need to:

- Continue a labeling job that was manually stopped.
- Continue a labeling job that failed mid-job, after fixing issues.
- Switch to automated data labeling after manually labeling part of a job (or the other way around).
- Add more data objects to a completed job and start the job from there.
- Add another annotation to a completed job. For example, you have a collection of phrases labeled for topic, then want to run the set again, categorizing them by the topic's implied audience.
In Amazon SageMaker Ground Truth you can configure a chained labeling job with either the console or the API.

**Key Term: Label Attribute Name**

The *label attribute name* (LabelAttributeName in the API) is a string used as the key for the key-value pair formed with the label that a worker assigns to the data object.

The following rules apply for the label attribute name:

- It can't end with `-metadata`.
- The names `source` and `source-ref` are reserved and can't be used.
- For semantic segmentation labeling jobs, it must end with `-ref`. For all other labeling jobs, it *can't* end with `-ref`. If you use the console to create the job, Amazon SageMaker Ground Truth automatically appends `-ref` to all label attribute names except for semantic segmentation jobs.
- For a chained labeling job, if you're using the same label attribute name from the originating job and you configure the chained job to use auto-labeling, then if it had been in auto-labeling mode at any point, Ground Truth uses the model from the originating job.

In an output manifest, the label attribute name appears similar to the following.

```json
"source-ref": "<S3 URI>",
"<label attribute name>": {
  "annotations": [{
    "class_id": 0,
    "width": 99,
    "top": 87,
    "height": 62,
    "left": 175
  }],
  "image_size": [{
    "width": 344,

```

If you're creating a job in the console and don't explicitly set the label attribute name value, Ground Truth uses the job name as the label attribute name for the job.

**Start a Chained Job (Console)**

Choose a stopped, failed, or completed labeling job from the list of your existing jobs. This enables the **Actions** menu.

From the **Actions** menu, choose **Chain**.
Job Overview Panel

In the Job overview panel, a new Job name is set based on the title of the job from which you are chaining this one. You can change it.

You may also specify a label attribute name different from the labeling job name.

If you're chaining from a completed job, the label attribute name uses the name of the new job you're configuring. To change the name, select the check box.

If you're chaining from a stopped or failed job, the label attribute name uses the name of the job from which you're chaining. It's easy to see and edit the value because the name check box is checked.

Attribute label naming considerations

- The default uses the label attribute name Ground Truth has selected. All data objects without data connected to that label attribute name are labeled.
- Using a label attribute name not present in the manifest causes the job to process all the objects in the dataset.

The input dataset location in this case is automatically selected as the output manifest of the chained job. The input field is not available, so you cannot change it.

Adding data objects to a labeling job

You cannot specify an alternate manifest file. Manually edit the output manifest from the previous job to add new items before starting a chained job. The Amazon S3 URI helps you locate where you are storing the manifest in your Amazon S3 bucket. Download the manifest file from there, edit it locally on your computer, and then upload the new version to replace it. Make sure you are not introducing errors during editing. We recommend you use JSON linter to check your JSON. Many popular text editors and IDEs have linter plugins available.

Start a Chained Job (API)

The procedure is almost the same as setting up a new labeling job with CreateLabelingJob, except for two primary differences:

- Manifest location: Rather than use your original manifest from the prior job, the value for the ManifestS3Uri in the DataSource should point to the Amazon S3 URI of the output manifest from the prior labeling job.
- Label attribute name: Setting the correct LabelAttributeName value is important here. This is the key portion of a key-value pair where labeling data is the value. Sample use cases include:
  - Adding new or more specific labels to a completed job — Set a new label attribute name.
  - Labeling the unlabeled items from a prior job — Use the label attribute name from the prior job.

Use a Partially Labeled Dataset

You can get some chaining benefits if you use an augmented manifest that has already been partially labeled. Check the Label attribute name check box and set the name so that it matches the name in your manifest.

If you're using the API, the instructions are the same as those for starting a chained job. However, be sure to upload your manifest to an Amazon S3 bucket and use it instead of using the output manifest from a prior job.

The Label attribute name value in the manifest has to conform to the naming considerations discussed earlier.
Ground Truth Security and Permissions

Use the topics on this page to learn about Ground Truth security features and how to configure AWS Identity and Access Management (IAM) permissions to allow an IAM user or role to create a labeling job. Additionally, learn how to create an execution role. An execution role is the role that you specify when you create a labeling job. This role is used to start your labeling job.

If you are a new user and want to get started quickly, or if you do not require granular permissions, see Use IAM Managed Policies with Ground Truth (p. 650).

For more information about IAM users and roles, see Identities (Users, Groups, and Roles) in the IAM User Guide.

To learn more about using IAM with SageMaker, see Identity and Access Management for Amazon SageMaker (p. 3500).

Topics

- CORS Permission Requirement (p. 649)
- Assign IAM Permissions to Use Ground Truth (p. 650)
- Using Amazon SageMaker Ground Truth in an Amazon Virtual Private Cloud (p. 661)
- Output Data and Storage Volume Encryption (p. 672)
- Workforce Authentication and Restrictions (p. 673)

CORS Permission Requirement

Earlier in 2020, widely used browsers like Chrome and Firefox changed their default behavior for rotating images based on image metadata, referred to as EXIF data. Previously, browsers would always display images in exactly the manner in which they are stored on disk, which is typically unrotated. After the change, images now rotate according to a piece of image metadata called orientation value. This has important implications for the entire machine learning (ML) community. For example, if applications that annotate images do not consider the EXIF orientation, they may display images in unexpected orientations, resulting in incorrect labels.

Starting with Chrome 89, AWS can no longer automatically prevent the rotation of images because the web standards group W3C has decided that the ability to control rotation of images violates the web’s Same-origin Policy. Therefore, to ensure human workers annotate your input images in a predictable orientation when you submit requests to create a labeling job, you must add a CORS header policy to the Amazon S3 buckets that contain your input images.

Important
If you do not add a CORS configuration to the Amazon S3 buckets that contain your input data, labeling tasks for those input data objects will fail.

If you create a job through the Ground Truth console, CORS is enabled by default. If all of your input data is not located in the same Amazon S3 bucket as your input manifest file, you must add a CORS configuration to all Amazon S3 buckets that contain input data using the following instructions.

If you are using the CreateLabelingJob API to create a Ground Truth labeling job, you can add a CORS policy to an Amazon S3 bucket that contains input data in the S3 console. To set the required CORS headers on the Amazon S3 bucket that contain your input images in the Amazon S3 console, follow the directions detailed in How do I add cross-domain resource sharing with CORS?. Use the following CORS configuration code for the buckets that host your images. If you use the Amazon S3 console to add the policy to your bucket, you must use the JSON format.

Important
If you create a 3D point cloud or video frame labeling job, you must add additional rules to your CORS configuration. To learn more, see 3D Point Cloud Labeling Job Permission Requirements (p. 471) and Video Frame Job Permission Requirements (p. 423) respectively.
Assign IAM Permissions to Use Ground Truth

Use the topics in this section to learn how to use AWS Identity and Access Management (IAM) managed and custom policies to manage access to Ground Truth and associated resources.

You can use the sections on this page to learn the following:

• How to create IAM policies that grant an IAM user or role permission to create a labeling job. Administrators can use IAM policies to restrict access to Amazon SageMaker and other AWS services that are specific to Ground Truth.
• How to create a SageMaker execution role. An execution role is the role that you specify when you create a labeling job. The role is used to start and manage your labeling job.

The following is an overview of the topics you’ll find on this page:

• If you are getting started using Ground Truth, or you do not require granular permissions for your use case, it is recommended that you use the IAM managed policies described in Use IAM Managed Policies with Ground Truth (p. 650).
• Learn about the permissions required to use the Ground Truth console in Grant IAM Permission to Use the Amazon SageMaker Ground Truth Console (p. 651). This section includes policy examples that grant an IAM entity permission to create and modify private work teams, subscribe to vendor work teams, and create custom labeling workflows.
• When you create a labeling job, you must provide an execution role. Use Create a SageMaker Execution Role for a Ground Truth Labeling Job (p. 655) to learn about the permissions required for this role.

Use IAM Managed Policies with Ground Truth

SageMaker and Ground Truth provide AWS managed policies that you can use to create a labeling job. If you are getting started using Ground Truth and you do not require granular permissions for your use case, it is recommended that you use the following policies:

• AmazonSageMakerFullAccess – Use this policy to give an IAM user or role permission to create a labeling job. This is a broad policy that grants an IAM entity permission to use SageMaker features, as well as features of necessary AWS services through the console and API. This policy gives the IAM entity permission to create a labeling job and to create and manage workforces using Amazon Cognito. To learn more, see AmazonSageMakerFullAccess Policy.
• **AmazonSageMakerGroundTruthExecution** – To create an execution role, you can attach the policy AmazonSageMakerGroundTruthExecution to an IAM role. An execution role is the role that you specify when you create a labeling job and it is used to start your labeling job. This policy allows you to create both streaming and non-streaming labeling jobs, and to create a labeling job using any task type. Note the following limits of this managed policy.

- **Amazon S3 permissions**: This policy grants an execution role permission to access Amazon S3 buckets with the following strings in the name: GroundTruth, Groundtruth, groundtruth, SageMaker, Sagemaker, and sagemaker or a bucket with an object tag that includes SageMaker in the name (case insensitive). Make sure your input and output bucket names include these strings, or add additional permissions to your execution role to grant it permission to access your Amazon S3 buckets. You must give this role permission to perform the following actions on your Amazon S3 buckets: AbortMultipartUpload, GetObject, and PutObject.

- **Custom Workflows**: When you create a custom labeling workflow, this execution role is restricted to invoking AWS Lambda functions with one of the following strings as part of the function name: GtRecipe, SageMaker, Sagemaker, sagemaker, or LabelingFunction. This applies to both your pre-annotation and post-annotation Lambda functions. If you choose to use names without those strings, you must explicitly provide lambda:InvokeFunction permission to the execution role used to create the labeling job.

To learn how to attach an AWS managed policy to an IAM user or role (identity), refer to Adding and removing IAM identity permissions in the IAM User Guide.

### Grant IAM Permission to Use the Amazon SageMaker Ground Truth Console

To use the Ground Truth area of the SageMaker console, you need to grant permission to an IAM entity to access SageMaker and other AWS services that Ground Truth interacts with. Required permissions to access other AWS services depends on your use-case:

- **Amazon S3 permissions** are required for all use cases. These permissions must grant access to the Amazon S3 buckets that contain input and output data.
- **AWS Marketplace permissions** are required to use a vendor workforce.
- **Amazon Cognito permission** are required for private work team setup.
- **AWS KMS permissions** are required to view available AWS KMS keys that can be used for output data encryption.
- **IAM permissions** are required to either list pre-existing execution roles, or to create a new one. Additionally, you must use add a PassRole permission to allow SageMaker to use the execution role chosen to start the labeling job.

The following sections list policies you may want to grant to an IAM role to use one or more functions of Ground Truth.

### Topics

- Ground Truth Console Permissions (p. 651)
- Custom Labeling Workflow Permissions (p. 654)
- Private Workforce Permissions (p. 655)
- Vendor Workforce Permissions (p. 655)

### Ground Truth Console Permissions

To grant permission to an IAM user or role to use the Ground Truth area of the SageMaker console to create a labeling job, attach the following policy to the user or role. The following policy will give an IAM role permission to create a labeling job using a built-in task type task type. If you want to create
a custom labeling workflow, add the policy in Custom Labeling Workflow Permissions (p. 654) to the following policy. Each Statement included in the following policy is described below this code block.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "SageMakerApis",
      "Effect": "Allow",
      "Action": [
        "sagemaker:*"
      ],
      "Resource": "*"
    },
    {
      "Sid": "KmsKeysForCreateForms",
      "Effect": "Allow",
      "Action": [
        "kms:DescribeKey",
        "kms:ListAliases"
      ],
      "Resource": "*"
    },
    {
      "Sid": "AccessAwsMarketplaceSubscriptions",
      "Effect": "Allow",
      "Action": [
        "aws-marketplace:ViewSubscriptions"
      ],
      "Resource": "*"
    },
    {
      "Sid": "SecretsManager",
      "Effect": "Allow",
      "Action": [
        "secretsmanager:CreateSecret",
        "secretsmanager:DescribeSecret",
        "secretsmanager:ListSecrets"
      ],
      "Resource": "*"
    },
    {
      "Sid": "ListAndCreateExecutionRoles",
      "Effect": "Allow",
      "Action": [
        "iam:ListRoles",
        "iam:CreateRole",
        "iam:CreatePolicy",
        "iam:AttachRolePolicy"
      ],
      "Resource": "*"
    },
    {
      "Sid": "PassRoleForExecutionRoles",
      "Effect": "Allow",
      "Action": [
        "iam:PassRole"
      ],
      "Resource": "*"
    },
    {
      "Sid": "SecretsManager",
      "Effect": "Allow",
      "Action": [
        "secretsmanager:GetSecretValue"
      ],
      "Resource": "*"
    },
    {
      "Sid": "AccessKmsKeys",
      "Effect": "Allow",
      "Action": [
        "kms:Encrypt",
        "kms:Decrypt",
        "kms:ReEncryptTo",
        "kms:ReEncryptFrom",
        "kms:GenerateDataKey",
        "kms:GenerateDataKeyoi",
        "kms:ReEncrypt",
        "kms:CancelPendingKeyDeletion",
        "kms:ListKeyHistory",
        "kms:DescribeKey",
        "kms:ListAliases"
      ],
      "Resource": "*"
    }
  ]
}
```
This policy includes the following statements. You can scope down any of these statements by adding specific resources to the Resource list for that statement.

**SageMakerApi**

This statement includes `sagemaker:*`, which allows the user to perform all SageMaker API actions. You can reduce the scope of this policy by restricting users from performing actions that are not used to create and monitoring a labeling job.

**KmsKeysForCreateForms**

You only need to include this statement if you want to grant a user permission to list and select AWS KMS keys in the Ground Truth console to use for output data encryption. The policy above grants a user permission to list and select any key in the account in AWS KMS. To restrict the keys that a user can list and select, specify those key ARNs in Resource.

**SecretsManager**

This statement gives the user permission to describe, list, and create resources in AWS Secrets Manager required to create the labeling job.

**ListAndCreateExecutionRoles**

This statement gives a user permission to list (ListRoles) and create (CreateRole) IAM roles in your account. It also grants the user permission to create (CreatePolicy) policies and attach
(AttachRolePolicy) policies to IAM entities. These are required to list, select, and if required, create an 
execution role in the console.

If you have already created an execution role, and want to narrow the scope of this statement so that 
users can only select that role in the console, specify the ARNs of the IAM roles you want the user to 
have permission to view in Resource and remove the actions CreateRole, CreatePolicy, and 
AttachRolePolicy.

AccessAwsMarketplaceSubscriptions

These permissions are required to view and choose vendor work teams that you are already subscribed 
to when creating a labeling job. To give the user permission to subscribe to vendor work teams, add the 
statement in Vendor Workforce Permissions (p. 655) to the policy above

PassRoleForExecutionRoles

This is required to give the labeling job creator permission to preview the worker UI and verify that input 
data, labels, and instructions display correctly. This statement gives an IAM entity permissions to pass 
the IAM execution role used to create the labeling job to SageMaker to render and preview the worker UI. 
To narrow the scope of this policy, add the role ARN of the execution role used to create the labeling job 
under Resource.

GroundTruthConsole

• groundtruthlabeling – This allows a user to perform actions required to use certain features 
of the Ground Truth console. These include permissions to describe the labeling job status 
(DescribeConsoleJob), list all dataset objects in the input manifest file (ListDatasetObjects), 
filter the dataset if dataset sampling is selected (RunFilterOrSampleDatasetJob), and to generate 
input manifest files if automated data labeling is used (RunGenerateManifestByCrawlingJob). 
These actions are only available when using the Ground Truth console and cannot be called directly 
using an API.
• lambda:InvokeFunction and lambda:ListFunctions – these actions give users permission to list 
and invoke Lambda functions that are used to run a custom labeling workflow.
• s3:* – All Amazon S3 permissions included in this statement are used to view Amazon S3 buckets 
for automated data setup (ListAllMyBuckets), access input data in Amazon S3 (ListBucket, 
GetObject), check for and create a CORS policy in Amazon S3 if needed (GetBucketCors and 
PutBucketCors), and write labeling job output files to S3 (PutObject).
• cognito-idp – These permissions are used to create, view and manage a private workforce using 
Amazon Cognito. To learn more about these actions, refer to the Amazon Cognito API References.

Custom Labeling Workflow Permissions

Add the following statement to a policy similar to the one in Ground Truth Console 
Permissions (p. 651) to give an IAM user permission to select pre-existing pre-annotation and post-
annotation Lambda functions while creating a custom labeling workflow.

```
{
  "Sid": "GroundTruthConsoleCustomWorkflow",
  "Effect": "Allow",
  "Action": [
    "lambda:InvokeFunction",
    "lambda:ListFunctions"
  ],
  "Resource": "*"
}
```

To learn how to give an IAM entity permission to create and test pre-annotation and post-annotation 
Lambda functions, see Required Permissions To Use Lambda With Ground Truth.
Private Workforce Permissions

When added to a permissions policy, the following permission grants access to create and manage a private workforce and work team using Amazon Cognito. These permissions are not required to use an OIDC IdP workforce.

```
{
    "Effect": "Allow",
    "Action": [
        "cognito-idp:AdminAddUserToGroup",
        "cognito-idp:AdminCreateUser",
        "cognito-idp:AdminDeleteUser",
        "cognito-idp:AdminDisableUser",
        "cognito-idp:AdminEnableUser",
        "cognito-idp:AdminRemoveUserFromGroup",
        "cognito-idp:CreateGroup",
        "cognito-idp:CreateUserPool",
        "cognito-idp:CreateUserPoolClient",
        "cognito-idp:CreateUserPoolDomain",
        "cognito-idp:DescribeUserPool",
        "cognito-idp:DescribeUserPoolClient",
        "cognito-idp:DescribeUserPoolDomain",
        "cognito-idp:ListGroups",
        "cognito-idp:ListIdentityProviders",
        "cognito-idp:ListUsers",
        "cognito-idp:ListUsersInGroup",
        "cognito-idp:ListUserPoolClients",
        "cognito-idp:ListUserPools",
        "cognito-idp:UpdateUserPool",
        "cognito-idp:UpdateUserPoolClient"
    ],
    "Resource": "*"
}
```

To learn more about creating private workforce using Amazon Cognito, see Create and Manage Amazon Cognito Workforce (p. 700).

Vendor Workforce Permissions

You can add the following statement to the policy in Grant IAM Permission to Use the Amazon SageMaker Ground Truth Console (p. 651) to grant an IAM entity permission to subscribe to a vendor workforce.

```
{
    "Sid": "AccessAwsMarketplaceSubscriptions",
    "Effect": "Allow",
    "Action": [
        "aws-marketplace:Subscribe",
        "aws-marketplace:Unsubscribe",
        "aws-marketplace:ViewSubscriptions"
    ],
    "Resource": "*"
}
```

Create a SageMaker Execution Role for a Ground Truth Labeling Job

When you configure your labeling job, you need to provide an execution role, which is a role that SageMaker has permission to assume to start and run your labeling job.

This role must give Ground Truth permission to access the following:

- Amazon S3 to retrieve your input data and write output data to an Amazon S3 bucket. You can either grant permission for an IAM role to access an entire bucket by providing the bucket ARN, or you can
grant access to the role to access specific resources in a bucket. For example, the ARN for a bucket may look similar to arn:aws:s3:::awsexamplebucket1 and the ARN of a resource in an Amazon S3 bucket may look similar to arn:aws:s3:::awsexamplebucket1/prefix/file-name.png. To apply an action to all resources in an Amazon S3 bucket, you can use the wild card: *. For example, arn:aws:s3:::awsexamplebucket1/prefix/*. For more information, see Amazon S3 Resources in the Amazon Simple Storage Service User Guide.

- CloudWatch to log worker metrics and labeling job statuses.
- AWS KMS for data encryption. (Optional)
- AWS Lambda for processing input and output data when you create a custom workflow.

Additionally, if you create a streaming labeling job, this role must have permission to access:

- Amazon SQS to create an interact with an SQS queue used to manage labeling requests.
- Amazon SNS to subscribe to and retrieve messages from your Amazon SNS input topic and to send messages to your Amazon SNS output topic.

All of these permissions can be granted with the AmazonSageMakerGroundTruthExecution managed policy except:

- Data and storage volume encryption of your Amazon S3 buckets. To learn how to configure these permissions, see Encrypt Output Data and Storage Volume with AWS KMS (p. 660).
- Permission to select and invoke Lambda functions that do not include GtRecipe, SageMaker, Sagemaker, sagemaker, or LabelingFunction in the function name.
- Amazon S3 buckets that do not include either GroundTruth, Groundtruth, groundtruth, SageMaker, Sagemaker, and sagemaker in the prefix or bucket name or an object tag that includes SageMaker in the name (case insensitive).

If you require more granular permissions than the ones provided in AmazonSageMakerGroundTruthExecution, use the following policy examples to create an execution role that fits your specific use case.

Topics
- Built-In Task Types (Non-streaming) Execution Role Requirements (p. 656)
- Built-In Task Types (Streaming) Execution Role Requirements (p. 657)
- Execution Role Requirements for Custom Task Types (p. 659)
- Automated Data Labeling Permission Requirements (p. 659)

Built-In Task Types (Non-streaming) Execution Role Requirements

The following policy grants permission to create a labeling job for a built-in task type. This execution policy does not include permissions for AWS KMS data encryption or decryption. Replace each red, italicized ARN with your own Amazon S3 ARNs.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "S3ViewBuckets",
      "Effect": "Allow",
      "Action": [
        "s3:ListBucket",
        "s3:GetBucketLocation"
      ]
    }
  ]
}
```
Built-In Task Types (Streaming) Execution Role Requirements

If you create a streaming labeling job, you must add a policy similar to the following to the execution role you use to create the labeling job. To narrow the scope of the policy, replace the * in Resource with specific AWS resources that you want to grant the IAM role permission to access and use.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:AbortMultipartUpload",
        "s3:GetObject",
        "s3:PutObject"
      ],
      "Resource": [
        "arn:aws:s3:::<input-bucket-name>/*",
        "arn:aws:s3:::<output-bucket-name>/*"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject"
      ],
      "Resource": "*",
      "Condition": {
        "StringEqualsIgnoreCase": {
          "s3:ExistingObjectTag/SageMaker": "true"
        }
      }
    }
  ]
}
```

Execution Role Requirements for Custom Task Types

If you want to create a custom labeling workflow, add the following statement to an execution role policy like the ones found in ??? (p. 656) or Built-In Task Types (Streaming) Execution Role Requirements (p. 657).

This policy gives the execution role permission to Invoke your pre-annotation and post-annotation Lambda functions.

```
    "Sid": "LambdaFunctions",
    "Effect": "Allow",
    "Action": [
      "lambda:InvokeFunction"
    ],
    "Resource": [
      "arn:aws:lambda:<region>:<account-id>:function:<post-annotation-lambda-name>"
    ]
}
```

Automated Data Labeling Permission Requirements

If you want to create a labeling job with automated data labeling enabled, you must 1) add one policy to the IAM policy attached to the execution role and 2) update the trust policy of the execution role.

The following statement allows the IAM execution role to be passed to SageMaker so that it can be used to run the training and inference jobs used for active learning and automated data labeling respectively. Add this statement to an execution role policy like the ones found in ??? (p. 656) or Built-In Task Types (Streaming) Execution Role Requirements (p. 657). Replace `arn:aws:iam::<account-number>:role/<role-name>` with the execution role ARN. You can find your IAM role ARN in the IAM console under Roles.

```
    "Effect": "Allow",
    "Action": [
      "iam:PassRole"
    ],
    "Resource": "arn:aws:iam::<account-number>:role/<execution-role-name>",
    "Condition": {
      "StringEquals": {
        "iam:PassedToService": [
          "sagemaker.amazonaws.com"
        ]
      }
    }
}
```
The following statement allows SageMaker to assume the execution role to create and manage the SageMaker training and inference jobs. This policy must be added to the trust relationship of the execution role. To learn how to add or modify an IAM role trust policy, see Modifying a role in the IAM User Guide.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Principal": {
      "Service": "sagemaker.amazonaws.com"
    },
    "Action": "sts:AssumeRole"
  }
}
```

## Encrypt Output Data and Storage Volume with AWS KMS

You can use AWS Key Management Service (AWS KMS) to encrypt output data from a labeling job by specifying a customer managed key when you create the labeling job. If you use the API operation CreateLabelingJob to create a labeling job that uses automated data labeling, you can also use a customer managed key to encrypt the storage volume attached to the ML compute instances to run the training and inference jobs.

This section describes the IAM policies you must attach to your customer managed key to enable output data encryption and the policies you must attach to your customer managed key and execution role to use storage volume encryption. To learn more about these options, see Output Data and Storage Volume Encryption (p. 672).

### Encrypt Output Data using KMS

If you specify an AWS KMS customer managed key to encrypt output data, you must add an IAM policy similar to the following to that key. This policy gives the IAM execution role that you use to create your labeling job permission to use this key to perform all of the actions listed in "Action". To learn more about these actions, see AWS KMS permissions in the AWS Key Management Service Developer Guide.

To use this policy, replace the IAM service-role ARN in "Principal" with the ARN of the execution role you use to create the labeling job. When you create a labeling job in the console, this is the role you specify for IAM Role under the Job overview section. When you create a labeling job using CreateLabelingJob, this is ARN you specify for RoleArn.

```
{
  "Sid": "AllowUseOfKmsKey",
  "Effect": "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::111122223333:role/service-role/example-role"
  },
  "Action": [
    "kms:Encrypt",
    "kms:Decrypt",
    "kms:ReEncrypt*",
    "kms:GenerateDataKey*",
    "kms:DescribeKey"
  ],
  "Resource": "*"
}
```
Encrypt Automated Data Labeling ML Compute Instance Storage Volume

If you specify a `VolumeKmsKeyId` to encrypt the storage volume attached to the ML compute instance used for automated data labeling training and inference, you must do the following:

- Attach permissions described in Encrypt Output Data using KMS (p. 660) to the customer managed key.
- Attach a policy similar to the following to the IAM execution role you use to create your labeling job. This is the IAM role you specify for `RoleArn` in `CreateLabelingJob`. To learn more about the "kms:CreateGrant" action that this policy permits, see `CreateGrant` in the AWS Key Management Service API Reference.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["kms:CreateGrant"],
      "Resource": "*"
    }
  ]
}
```

To learn more about Ground Truth storage volume encryption, see Use Your KMS Key to Encrypt Automated Data Labeling Storage Volume (API Only) (p. 673).

Using Amazon SageMaker Ground Truth in an Amazon Virtual Private Cloud

Amazon Virtual Private Cloud (Amazon VPC) is a service with which you can launch AWS resources in a logically isolated virtual network that you define. You can create and run a Ground Truth labeling job inside of an Amazon VPC instead of connecting over the internet. When you launch a labeling job in an Amazon VPC, communication between your VPC and Ground Truth is conducted entirely and securely within the AWS network.

This guide shows how you can use Ground Truth in an Amazon VPC in the following ways:

1. Run an Amazon SageMaker Ground Truth Labeling Job in an Amazon Virtual Private Cloud (p. 661)
2. Use Amazon VPC Mode from a Private Worker Portal (p. 667)

Run an Amazon SageMaker Ground Truth Labeling Job in an Amazon Virtual Private Cloud

Amazon SageMaker Ground Truth supports the following functionalities.

- You can use Amazon S3 bucket policies to control access to buckets from specific Amazon VPC endpoints, or specific VPCs. If you launch a labeling job and your input data is located in an Amazon S3 bucket with access restricted to users in your VPC, you can add a bucket policy to also grant a Ground Truth endpoint permission to access the bucket. To learn more, see Allow Ground Truth to Access VPC Restricted Amazon S3 Buckets (p. 662).
- You can launch an automated data labeling job in your VPC. You use a VPC configuration to specify VPC subnets and security groups. SageMaker uses this configuration to launch the training and
inference jobs used for automated data labeling in your VPC. To learn more, see Create an Automated Data Labeling Job in a VPC (p. 666).

You may want to use these options in any of the following ways.

- You can use both of these methods to launch a labeling job using a VPC-protected Amazon S3 bucket with automated data labeling enabled.
- You can launch a labeling job using any built-in task type using a VPC-protected bucket.
- You can launch a custom labeling workflow using a VPC-protected bucket. Ground Truth interacts with your pre-annotation and post-annotation Lambda functions using an AWS PrivateLink endpoint.

We recommend that you review Prerequisites to Run a Ground Truth Labeling Job in a VPC (p. 662) before you create a labeling job in an Amazon VPC.

Prerequisites to Run a Ground Truth Labeling Job in a VPC

Review the following prerequisites before you create a Ground Truth labeling job in an Amazon VPC.

- If you are a new user of Ground Truth, review Getting started to learn how to create a labeling job.
- If your input data is located in a VPC-protected Amazon S3 bucket, your workers must access the worker portal from your VPC.

  **Note**
  When you launch a labeling job in your VPC, you must use a private work team. To learn more about creating a private work team, see Use a Private Workforce.

- If you want to launch an automated data labeling job in your VPC, review the following prerequisites.
  - Use the instructions in Create an Amazon S3 VPC Endpoint. Training and inference containers used in the automated data labeling workflow use this endpoint to communicate with your buckets in Amazon S3.
  - Review Automate Data Labeling to learn more about this feature. Note that automated data labeling is supported for the following built-in task types: Image Classification (Single Label), Image Semantic Segmentation, Bounding Box, and Text Classification (Single Label). Streaming labeling jobs do not support automated data labeling.

  - Review the Ground Truth Security and Permissions section and ensure that you have met the following conditions.
    - The user creating the labeling job has all necessary permissions
    - You have created an IAM execution role with required permissions. If you do not require fine-tuned permissions for your use case, we recommend you use the IAM managed policies described in Grant General Permissions To Get Started Using Ground Truth.
    - Allow your VPC to have access to the sagemaker-labeling-data-region and sm-bxcb-region-saved-task-states S3 buckets. These are system owned regionalized S3 buckets that are accessed from worker portal when worker is working on a task. We use these buckets to interact with system managed data.

Allow Ground Truth to Access VPC Restricted Amazon S3 Buckets

The following sections provide details about the permissions Ground Truth requires to launch labeling jobs using Amazon S3 buckets that have access restricted to your VPC and VPC endpoints. To learn how to restrict access to an Amazon S3 bucket to a VPC, see Controlling access from VPC endpoints with bucket policies in the Amazon Simple Storage Service User Guide guide. To learn how to add a policy to an S3 bucket, see Adding a bucket policy using the Amazon S3 console.
Note
Modifying policies on existing buckets can cause IN_PROGRESS Ground Truth jobs to fail. We recommend you start new jobs using a new bucket. If you want to continue using the same bucket, you can do one of the following.

- Wait for an IN_PROGRESS job to finish.
- Terminate the job using the console or the AWS CLI.

You can restrict Amazon S3 bucket access to users in your VPC using an AWS PrivateLink endpoint. For example, the following S3 bucket policy allows access to a specific bucket, `<bucket-name>`, from `<vpc>` and the endpoint `<vpc-endpoint>` only. When you modify this policy, you must replace all *red-italicized text* with your resources and specifications.

**Note**
The following policy *denies* all entities *other than* users within a VPC to perform the actions listed in *Action*. If you do not include actions in this list, they are still accessible to any entity that has access to this bucket and permission to perform those actions. For example, if an IAM user has permission to perform GetBucketLocation on your Amazon S3 bucket, the policy below does not restrict the user from performing this action outside of your VPC.

```
{
   "Version": "2012-10-17",
   "Id": "Policy1415115909152",
   "Statement": [
      {
         "Sid": "Access-to-specific-VPCE-only",
         "Principal": "*",
         "Action": ["s3:GetObject", "s3:PutObject"],
         "Effect": "Deny",
         "Resource": ["arn:aws:s3:::<bucket-name>", "arn:aws:s3:::<bucket-name>/*"],
         "Condition": {
            "StringNotEquals": {
               "aws:sourceVpce": ["<vpc-endpoint>", "<vpc>"
            ]
            }
         }
      }
   ]
}
```

Ground Truth must be able to perform the following Amazon S3 actions on the S3 buckets you use to configure the labeling job.

```
"s3:AbortMultipartUpload",
"s3:GetObject",
"s3:PutObject",
"s3:ListBucket",
"s3:GetBucketLocation"
```

You can do this by adding a Ground Truth endpoint to the bucket policy like the one previously mentioned. The following table includes Ground Truth service endpoints for each AWS Region. Add an endpoint in the same AWS Region you use to run your labeling job to your bucket policy.
For example, the following policy restricts GetObject and PutObject actions on:

- An Amazon S3 bucket to users in a VPC (<vpc>)
- A VPC endpoint (<vpc-endpoint>)
- A Ground Truth service endpoint (<ground-truth-endpoint>)

```
{
   "Version": "2012-10-17",
   "Id": "1",
   "Statement": [
      {
         "Sid": "DenyAccessFromNonGTandCustomerVPC",
         "Effect": "Deny",
         "Principal": "*",
         "Action": [
            "s3:GetObject",
            "s3:PutObject"
         ],
         "Resource": [
            "arn:aws:s3:::<bucket-name>",
            "arn:aws:s3:::<bucket-name>/*"
         ],
         "Condition": {
            "ForAllValues:StringNotEquals": {
               "aws:sourceVpce": [
                  "<vpc-endpoint>",
                  "<ground-truth-endpoint>"
               ],
               "aws:SourceVpc": "<vpc>"
            }
         }
      }
   ]
}
```
If you want an IAM user to have permission to launch a labeling job using the Ground Truth console, you must also add the IAM user's ARN to the bucket policy using the `aws:PrincipalArn` condition. This user must also have permission to perform the following Amazon S3 actions on the bucket you use to launch the labeling job.

```
"s3:GetObject",
"s3:PutObject",
"s3:ListBucket",
"s3:GetBucketCors",
"s3:PutBucketCors",
"s3:ListAllMyBuckets",
```

The following code is an example of a bucket policy that restricts permission to perform the actions listed in `Action` on the S3 bucket `<bucket-name>` to the following.

- `<role-name>`
- The VPC endpoints listed in `aws:sourceVpce`
- Users within the VPC named `<vpc>`

```json
{
  "Version": "2012-10-17",
  "Id": "1",
  "Statement": [
    {
      "Sid": "DenyAccessFromNonGTandCustomerVPC",
      "Effect": "Deny",
      "Principal": "*",
      "Action": [
        "s3:GetObject",
        "s3:PutObject"
      ],
      "Resource": [
        "arn:aws:s3::<bucket-name>/**",
        "arn:aws:s3::<bucket-name>"
      ],
      "Condition": {
        "ForAllValues:StringNotEquals": {
          "aws:sourceVpc": ["<vpc-endpoint>", "<ground-truth-endpoint>"],
          "aws:PrincipalArn": "arn:aws:iam::<aws-account-id>:role/<role-name>",
          "aws:SourceVpc": "<vpc>"
        }
      }
    }
  ]
}
```

**Note**

The Amazon VPC interface endpoints and the protected Amazon S3 buckets you use for input and output data must be located in the same AWS Region that you use to create the labeling job.

After you have granted Ground Truth permission to access your Amazon S3 buckets, you can use one of the topics in Create a Labeling Job to launch a labeling job. Specify the VPC-restricted Amazon S3 buckets for your input and output data buckets.
Create an Automated Data Labeling Job in a VPC

To create an automated data labeling job using an Amazon VPC, you provide a VPC configuration using the Ground Truth console or CreateLabelingJob API operation. SageMaker uses the subnets and security groups you provide to launch the training and inferences jobs used for automated labeling.

**Important**
Before you launch an automated data labeling job with a VPC configuration, make sure you have created an Amazon S3 VPC endpoint using the VPC you want to use for the labeling job. To learn how, see [Create an Amazon S3 VPC Endpoint](#). Additionally, if you create an automated data labeling job using a VPC-restricted Amazon S3 bucket, you must follow the instructions in [Allow Ground Truth to Access VPC Restricted Amazon S3 Buckets](#) to give Ground Truth permission to access the bucket.

Use the following procedures to learn how to add a VPC configuration to your labeling job request.

**Add a VPC configuration to an automated data labeling job (console):**

1. Follow the instructions in [Create a Labeling Job (Console)](#) and complete each step in the procedure, up to step 15.
2. In the Workers section, select the checkbox next to Enable automated data labeling.
3. Maximize the VPC configuration section of the console by selecting the arrow.
4. Specify the [Virtual private cloud (VPC)](#) that you want to use for your automated data labeling job.
5. Choose the dropdown list under Subnets and select one or more subnets.
6. Choose the dropdown list under Security groups and select one or more groups.
7. Complete all remaining steps of the procedure in [Create a Labeling Job (Console)](#).

**Add a VPC configuration to an automated data labeling job (API):**

To configure a labeling job using the Ground Truth API operation, CreateLabelingJob, follow the instructions in [Create an Automated Data Labeling Job (API)](#) to configure your request. In addition to the parameters described in this documentation, you must include a VpcConfig parameter in LabelingJobResourceConfig to specify one or more subnets and security groups using the following schema.

```json
"LabelingJobAlgorithmsConfig": {
   "InitialActiveLearningModelArn": "string",
   "LabelingJobAlgorithmSpecificationArn": "string",
   "LabelingJobResourceConfig": {
      "VolumeKmsKeyId": "string",
      "VpcConfig": {
         "SecurityGroupIds": [ "string" ],
         "Subnets": [ "string" ]
      }
   }
}
```

The following is an example of an AWS Python SDK (Boto3) request to create an automated data labeling job in the US East (N. Virginia) Region using a private workforce. Replace all red-italicized text with your labeling job resources and specifications. To learn more about the CreateLabelingJob operation, see the [Create a Labeling Job (API)](#) tutorial and [CreateLabelingJob](#) API documentation.

```python
import boto3
client = boto3.client(service_name='sagemaker')

response = client.create_labeling_job(
   LabelingJobName="example-labeling-job",
   LabelAttributeName="label",
)`
Use Amazon VPC Mode from a Private Worker Portal

To restrict worker portal access to labelers working inside of your Amazon VPC, you can add a VPC configuration when you create a Ground Truth private workforce. You can also add a VPC configuration to an existing private workforce. Ground Truth automatically creates VPC interface endpoints in your VPC and sets up AWS PrivateLink between your VPC endpoint and the Ground Truth services. The worker portal URL associated with the workforce can be accessed from your VPC. The worker portal URL can also
be accessed from public internet until you set the restriction on the public internet. When you delete the workforce or remove the VPC configuration from your workforce, Ground Truth automatically deletes the VPC endpoints associated with the workforce.

**Note**
There can be only one VPC supported for a workforce.

**Point Cloud** and **video** tasks do not support loading through a VPC.

The guide demonstrates how to complete the necessary steps to add and delete an Amazon VPC configuration to your workforce, and satisfy the prerequisites.

**Prerequisites**

To run a Ground Truth labeling job in Amazon VPC, review the following prerequisites.

- You have an Amazon VPC configured that you can use. If you have not configured a VPC, follow these instructions for [creating a VPC](#).
- Depending on how a Worker Task Template is written, labeling data stored in an Amazon S3 bucket may be accessed directly from Amazon S3 during labeling tasks. In these cases, the VPC network must be configured to allow traffic from the device used by the human labeler to the S3 bucket containing labeling data.
- Follow [View and update DNS attributes for your VPC](#) to enable DNS hostnames and DNS resolution for your VPC.

**Note**
There are two ways to configure your VPC for your workforce. You can do this through the console or the AWS SageMaker CLI.

**Using the SageMaker console to manage a VPC config**

You can use the SageMaker console to add or remove a VPC configuration. You can also delete an existing workforce.

**Adding a VPC configuration to your workforce**

**Create a private workforce**

- Create a private workforce using Amazon Cognito
- Create a private workforce using OpenID Connect (OIDC) Identity Provider(IdP).

After you have created your private workforce, add a VPC configuration to it.

1. Navigate to Amazon SageMaker in your console.
2. Select **Labeling workforces** in the left panel.
3. Select **Private** to access your private workforce. After your Workforce status is **Active**, select Add next to VPC.
4. When you are prompted to configure your VPC, provide the following:
   a. Your VPC
   b. **Subnets**
      i. Ensure that your VPC has an existing subnet
   c. **Security groups**
      i. **Note**
         You cannot select more than 5 security groups.
   d. After filling in this information, choose Confirm.
5. After you choose Confirm, you are redirected back to the Private page under Labeling workforces. You should see a green banner at the top that reads Your private workforce update with VPC configuration was successfully initialized. The workforce status is Updating. Next to the Delete workforce button is the Refresh button, which can be used to retrieve the latest Workforce status. After the workforce status has changed to Active, the VPC endpoint ID is updated as well.

Removing a VPC configuration from your workforce

Use the following information to remove a VPC configuration from your workforce using the console.

1. Navigate to Amazon SageMaker in your console.
2. Select Labeling workforces in the left panel.
3. Find and select your workforce.
4. Under Private workforce summary, find VPC and choose Remove next to it.
5. Select Remove.

Deleting a workforce through the console

If you delete a workforce, you should not have any teams associated with it. You can delete a workforce only if the workforce status is Active or Failed.

Use the following information to delete a workforce using the console.

1. Navigate to Amazon SageMaker in your console.
2. Select Labeling workforces in the left panel.
3. Find and select your workforce.
5. Choose Delete.

Using the SageMaker AWS API to manage a VPC config

Download the following files to use a new VpcConfig parameter into to the SageMaker workforce CLI:

- sagemaker-2017-07-24.normal.json
- sagemaker-2017-07-24.paginators.json
- sagemaker-2017-07-24.waiters-2.json

After downloading the files, run the following commands in your CLI:

```
aws configure add-model --service-model file://./sagemaker-2017-07-24.normal.json --service-name sagemaker

```

You can now test your API changes using AWS CLI. You can either create a new workforce with a VPC configuration or update an existing workforce to add a VPC configuration. You can also remove a VPC configuration from an existing workforce.
Create a workforce with a VPC configuration

If the account already has a workforce, then you must delete it first. You can also update the workforce with VPC configuration.

```bash
aws sagemaker create-workforce --cognito-config '{"ClientId": "app-client-id","UserPool": "Pool_ID",}' --workforce-vpc-config "{"VpcId": "vpc-id", "SecurityGroupIds": ["sg-0123456789abcdef0"], "Subnets": ["subnet-0123456789abcdef0"]}" --workforce-name workforce-name

{ "WorkforceArn": "arn:aws:sagemaker:us-west-2:xxxxxxxxx:workforce/workforce-name"
}

Describe the workforce and make sure the status is Initializing.

```bash
aws sagemaker describe-workforce --workforce-name workforce-name

}
```

Navigate to the Amazon VPC console. Select Endpoints from the left panel. There should be two VPC endpoints created in your account.

Adding a VPC configuration your workforce

Update a non-VPC private workforce with a VPC configuration using the following command.

```bash
aws sagemaker update-workforce --workforce-name workforce-name
--workforce-vpc-config "{"VpcId": "vpc-id", "SecurityGroupIds": ["sg-0123456789abcdef0"], "Subnets": ["subnet-0123456789abcdef0"]}"

Describe the workforce and make sure the status is Updating.

```bash
aws sagemaker describe-workforce --workforce-name workforce-name

}
```
aws sagemaker describe-workforce --workforce-name workforce-name
{
  "Workforce": {
    "WorkforceName": "workforce-name",
    "LastUpdatedDate": 1622151252.451,
    "SourceIpConfig": {
      "Cidrs": []
    },
    "SubDomain": "subdomain.us-west-2.sagemaker.aws.com",
    "CognitoConfig": {
      "UserPool": "Pool_ID",
      "ClientId": "app-client-id"
    },
    "CreateDate": 1622151252.451,
    "WorkforceVpcConfig": {
      "VpcId": "vpc-id",
      "SecurityGroupIds": [
        "sg-0123456789abcdef0"
      ],
      "Subnets": [
        "subnet-0123456789abcdef0"
      ],
      "Status": "Updating"
    }
  }
}

Navigate to your Amazon VPC console. Select Endpoints from the left panel. There should be two VPC endpoints created in your account.

Removing a VPC configuration from your workforce

Update a VPC private workforce with an empty VPC configuration to remove VPC resources.

aws sagemaker update-workforce --workforce-name workforce-name\ --workforce-vpc-config "{}"

Describe the workforce and make sure the status is Updating.

aws sagemaker describe-workforce --workforce-name workforce-name
{
  "Workforce": {
    "WorkforceName": "workforce-name",
    "LastUpdatedDate": 1622151252.451,
    "SourceIpConfig": {
      "Cidrs": []
    },
    "SubDomain": "subdomain.us-west-2.sagemaker.aws.com",
    "CognitoConfig": {
      "UserPool": "Pool_ID",
      "ClientId": "app-client-id"
    },
    "CreateDate": 1622151252.451,
    "Status": "Updating"
  }
}
Navigate to your Amazon VPC console. Select **Endpoints** from the left panel. The two VPC endpoints should be deleted.

**Restrict public access to the worker portal while maintaining access through a VPC**

The workers in a VPC or non-VPC worker portal are be able to see the labeling job tasks assigned to them. The assignment comes from assigning workers in a work team through OIDC groups. It is the customer’s responsibility to restrict the access to their public worker portal by setting the `sourceIpConfig` in their workforce.

**Note**
You can restrict access to the worker portal only through the SageMaker API. This cannot be done through the console.

Use the following command to restrict public access to the worker portal.

```bash
aws sagemaker update-workforce --region us-west-2 \
--workforce-name workforce-demo --source-ip-config '{"Cidrs": ["0.0.0.0/0"]}'
```

After the `sourceIpConfig` is set on the workforce, the workers can access the worker portal in VPC but not through public internet.

**Note**
You can not set the `sourceIP` restriction for worker portal in VPC.

**Output Data and Storage Volume Encryption**

With Amazon SageMaker Ground Truth, you can label highly sensitive data, stay in control of your data, and employ security best practices. While your labeling job is running, Ground Truth encrypts data in transit and at rest. Additionally, you can use AWS Key Management Service (AWS KMS) with Ground Truth to do the following:

- Use a **customer managed key** to encrypt your output data.
- Use AWS KMS customer managed key with your automated data labeling job to encrypt the storage volume attached to the compute instance used for model training and inference.

Use the topics on this page to learn more about these Ground Truth security features.

**Use Your KMS Key to Encrypt Output Data**

Optionally, you can provide an AWS KMS customer managed key when you create a labeling job, which Ground Truth uses to encrypt your output data.

If you don’t provide a customer managed key, Amazon SageMaker uses the default AWS managed key for Amazon S3 for your role's account to encrypt your output data.

If you provide a customer managed key, you must add the required permissions to the key described in *Encrypt Output Data and Storage Volume with AWS KMS* (p. 660). When you use the API operation `CreateLabelingJob`, you can specify your customer managed key ID using the parameter `KmsKeyId`. See the following procedure to learn how to add a customer managed key when you create a labeling job using the console.

**To add an AWS KMS key to encrypt output data (console):**

1. Complete the first 7 steps in *Create a Labeling Job (Console)* (p. 544).
2. In step 8, select the arrow next to **Additional configuration** to expand this section.
3. For **Encryption key**, select the AWS KMS key that you want to use to encrypt output data.
4. Complete the rest of steps in **Create a Labeling Job (Console)** (p. 544) to create a labeling job.

**Use Your KMS Key to Encrypt Automated Data Labeling Storage Volume (API Only)**

When you create a labeling job with automated data labeling using the CreateLabelingJob API operation, you have the option to encrypt the storage volume attached to the ML compute instances that run the training and inference jobs. To add encryption to your storage volume, use the parameter `VolumeKmsKeyId` to input an AWS KMS customer managed key. For more information about this parameter, see **LabelingJobResourceConfig**.

If you specify a key ID or ARN for `VolumeKmsKeyId`, your SageMaker execution role must include permissions to call `kms:CreateGrant`. To learn how to add this permission to an execution role, see **Create a SageMaker Execution Role for a Ground Truth Labeling Job** (p. 655).

**Note**

If you specify an AWS KMS customer managed key when you create a labeling job in the console, that key is *only* used to encrypt your output data. It is not used to encrypt the storage volume attached to the ML compute instances used for automated data labeling.

**Workforce Authentication and Restrictions**

Ground Truth enables you to use your own private workforce to work on labeling jobs. A *private workforce* is an abstract concept which refers to a set of people who work for you. Each labeling job is created using a work team, composed of workers in your workforce. Ground Truth supports private workforce creation using Amazon Cognito.

A Ground Truth workforce maps to a Amazon Cognito user pool. A Ground Truth work team maps to a Amazon Cognito user group. Amazon Cognito manages the worker authentication. Amazon Cognito supports Open ID connection (OIDC) and customers can set up Amazon Cognito federation with their own identity provider (IdP).

Ground Truth only allows one workforce per account per AWS Region. Each workforce has a dedicated Ground Truth work portal login URL.

You can also restrict workers to a Classless Inter-Domain Routing (CIDR) block/IP address range. This means annotators must be on a specific network to access the annotation site. You can add up to ten CIDR blocks for one workforce. To learn more, see **Manage Private Workforce Using the Amazon SageMaker API** (p. 716).

To learn how you can create a private workforce, see **Create a Private Workforce (Amazon Cognito)** (p. 700).

**Restrict Access to Workforce Types**

Amazon SageMaker Ground Truth work teams fall into one of three *workforce types*: public (with Amazon Mechanical Turk), private, and vendor. To restrict IAM user access to a specific work team using one of these types or the work team ARN, use the `sagemaker:WorkteamType` and/or the `sagemaker:WorkteamArn` condition keys. For the `sagemaker:WorkteamType` condition key, use string condition operators. For the `sagemaker:WorkteamArn` condition key, use Amazon Resource Name (ARN) condition operators. If the user attempts to create a labeling job with a restricted work team, SageMaker returns an access denied error.

The policies below demonstrate different ways to use the `sagemaker:WorkteamType` and `sagemaker:WorkteamArn` condition keys with appropriate condition operators and valid condition values.
The following example uses the sagemaker:WorkteamType condition key with the StringEquals condition operator to restrict access to a public work team. It accepts condition values in the following format: workforcetype-crowd, where workforcetype can equal public, private, or vendor.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "RestrictWorkteamType",
            "Effect": "Deny",
            "Action": "sagemaker:CreateLabelingJob",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "sagemaker:WorkteamType": "public-crowd"
                }
            }
        }
    ]
}
```

The following policies show how to restrict access to a public work team using the sagemaker:WorkteamArn condition key. The first shows how to use it with a valid IAM regex-variant of the work team ARN and the ArnLike condition operator. The second shows how to use it with the ArnEquals condition operator and the work team ARN.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "RestrictWorkteamType",
            "Effect": "Deny",
            "Action": "sagemaker:CreateLabelingJob",
            "Resource": "*",
            "Condition": {
                "ArnLike": {
                    "sagemaker:WorkteamArn": "arn:aws:sagemaker:*:*:workteam/public-crowd/*"
                }
            }
        }
    ]
}
```

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "RestrictWorkteamType",
            "Effect": "Deny",
            "Action": "sagemaker:CreateLabelingJob",
            "Resource": "*",
            "Condition": {
                "ArnEquals": {
                }
            }
        }
    ]
}
```
Monitor Labeling Job Status

To monitor the status of your labeling jobs, you can set up an Amazon CloudWatch Events (CloudWatch Events) rule for Amazon SageMaker Ground Truth (Ground Truth) to send an event to CloudWatch Events when a labeling job status changes to Completed, Failed, or Stopped or when a worker accepts, declines, submits, or returns a task.

Once you create a rule, you can add a target to it. CloudWatch Events uses this target to invoke another AWS service to process the event. For example, you can create a target using a Amazon Simple Notification Service (Amazon SNS) topic to send a notification to your email when a labeling job status changes.

Prerequisites:

To create a CloudWatch Events rule, you will need an AWS Identity and Access Management (IAM) role with an events.amazonaws.com trust policy attached. The following is an example of an events.amazonaws.com trust policy.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": ["events.amazonaws.com"
      ],
      "Action": "sts:AssumeRole"
    }
  ]
}
```

Topics

- Send Events to CloudWatch Events (p. 675)
- Set Up a Target to Process Events (p. 676)
- Labeling Job Expiration (p. 677)
- Declining Tasks (p. 677)

Send Events to CloudWatch Events

To configure a CloudWatch Events rule to get status updates, or events, for your Ground Truth labeling jobs, use the AWS Command Line Interface (AWS CLI) put-rule command. You can filter events that are sent to your rule by status change. For example, you can create a rule that notifies you only if a labeling job status changes to Completed. When using the put-rule command, specify the following to receive labeling job statuses:

- "source": ["aws.sagemaker"]
- "detail-type": ["SageMaker Ground Truth Labeling Job State Change"]

To configure a CloudWatch Events rule to watch for all status changes, use the following command and replace the placeholder text. For example, replace "GLabelingJobStateChanges" with a unique CloudWatch Events rule name and "arn:aws:iam::111122223333:role/MyRoleForThisRule"
with the Amazon Resource Number (ARN) of an IAM role with an events.amazonaws.com trust policy attached.

```bash
aws events put-rule --name "GTLabelingJobStateChanges"  
--event-pattern "{"source": ["aws.sagemaker"], "detail-type": ["SageMaker Ground Truth Labeling Job State Change"]}"  
--role-arn "arn:aws:iam::111122223333:role/MyRoleForThisRule"  
--region "region"
```

To filter by job status, use the "detail":{"LabelingJobStatus":["Status"]}" syntax. Valid values for Status are Completed, Failed, and Stopped.

The following example creates a CloudWatch Events rule that notifies you when a labeling job in us-west-2 (Oregon) changes to Completed.

```bash
aws events put-rule --name "LabelingJobCompleted"  
--event-pattern "{"source": ["aws.sagemaker"], "detail-type": ["SageMaker Ground Truth Labeling Job State Change"], "detail":{"LabelingJobStatus": ["Completed"]}"  
--role-arn "arn:aws:iam::111122223333:role/MyRoleForThisRule"  
--region us-west-2
```

The following example creates a CloudWatch Events rule that notifies you when a labeling job in us-east-1 (Virginia) changes to Completed or Failed.

```bash
aws events put-rule --name "LabelingJobCompletedOrFailed"  
--event-pattern "{"source": ["aws.sagemaker"], "detail-type": ["SageMaker Ground Truth Labeling Job State Change"], "detail":{"LabelingJobStatus": ["Completed", "Failed"]}"  
--role-arn "arn:aws:iam::111122223333:role/MyRoleForThisRule"  
--region us-east-1
```

To learn more about the put-rule request, see Event Patterns in CloudWatch Events in the Amazon CloudWatch Events User Guide.

### Set Up a Target to Process Events

After you have created a rule, events similar to the following are sent to CloudWatch Events. In this example, the labeling job test-labeling-job's status changed to Completed.

```json
{
  "version": "0",
  "id": "111e1111-11d1-111f-b111-1111b11dcb11",
  "detail-type": "SageMaker Ground Truth Labeling Job State Change",
  "source": "aws.sagemaker",
  "account": "111122223333",
  "time": "2018-10-06T12:26:13Z",
  "region": "us-east-1",
  "resources": [
  ],
  "detail": {
    "LabelingJobStatus": "Completed"
  }
}
```

To process events, you need to set up a target. For example, if you want to receive an email when your labeling job status changes, use a procedure in Setting Up Amazon SNS Notifications in the Amazon CloudWatch User Guide to set up an Amazon SNS topic and subscribe your email to it. Once you have create a topic, you can use it to create a target.
To add a target to your CloudWatch Events rule

1. Open the CloudWatch console: https://console.aws.amazon.com/cloudwatch/home
2. In the navigation pane, choose Rules.
3. Choose the rule that you want to add a target to.
4. Choose Actions, and then choose Edit.
5. Under Targets, choose Add Target and choose the AWS service you want to act when a labeling job status change event is detected.
6. Configure your target. For instructions, see the topic for configuring a target in the AWS documentation for that service.
7. Choose Configure details.
8. For Name, enter a name and, optionally, provide details about the purpose of the rule in Description.
9. Make sure that the check box next to State is selected so that your rule is listed as Enabled.
10. Choose Update rule.

Labeling Job Expiration

If your labeling job is not completed after 30 days, it will expire. If your labeling job expires, you can chain the job to create a new labeling job that will only send unlabeled data to workers. For more information, and to learn how to create a labeling job using chaining, see Chaining Labeling Jobs (p. 646).

Declining Tasks

Workers are able to decline tasks.

Workers decline a task if the instructions are not clear, input data is not displaying correctly, or if they encounter some other issue with the task. If the number of workers per dataset object (NumberOfHumanWorkersPerDataObject) decline the task, the data object is marked as expired and will not be sent to additional workers.

Use Amazon SageMaker Ground Truth Plus to Label Data

Amazon SageMaker Ground Truth Plus is a turnkey data labeling service that uses an expert workforce to deliver high-quality annotations quickly and reduces costs by up to 40%. Using Ground Truth Plus, data scientists and business managers, such as data operations managers and program managers, can create high-quality training datasets without having to build labeling applications and manage labeling workforces on their own. You can get started with Amazon SageMaker Ground Truth Plus by uploading data along with the labeling requirements in Amazon S3.

Why use Ground Truth Plus?

To train a machine learning (ML) model, data scientists need large, high-quality, labeled datasets. As ML adoption grows, labeling needs increase. This forces data scientists to spend weeks on building data labeling workflows and managing a data labeling workforce. Unfortunately, this slows down innovation and increases cost. To ensure data scientists can spend their time building, training, and deploying ML models, data scientists typically task other in-house teams consisting of data operations managers and program managers to produce high-quality training datasets. However, these teams typically don't have access to skills required to deliver high-quality training datasets, which affects ML results. As a result, you
look for a data labeling partner that can help them create high-quality training datasets at scale without consuming their in-house resources.

When you upload the data, Ground Truth Plus sets up the data labeling workflows and operates them on your behalf. From there, an expert workforce trained on a variety of machine learning (ML) tasks performs data labeling. Ground Truth Plus currently offers two types of expert workforce: an Amazon employed workforce and a curated list of third-party vendors. Ground Truth Plus provides you with the flexibility to choose the labeling workforce. AWS experts select the best labeling workforce based on your project requirements. For example, if you need people proficient in labeling audio files, specify that in the guidelines provided to Ground Truth Plus, and the service automatically selects labelers with those skills.

**Note**

Ground Truth Plus does not support PHI, PCI or FedRAMP certified data, and you should not provide this data to Ground Truth Plus.

**How does it work?**

There are five main components to the Ground Truth Plus workflow.

- Requesting a pilot
- Sharing the data to be labeled
- Creating a project team
- Accessing the project portal to monitor progress of training datasets and review labeled data
- Receiving the labeled data

**How do I use Ground Truth Plus?**

If you are a first-time user of Ground Truth Plus, we recommend that you follow the procedures outlined in the [Getting Started with Amazon SageMaker Ground Truth Plus](#). (p. 678) section.

**Getting Started with Amazon SageMaker Ground Truth Plus.**

The guide demonstrates how to complete the necessary steps to start an Amazon SageMaker Ground Truth Plus project, review labels, and satisfy Ground Truth Plus prerequisites.

To get started using Ground Truth Plus, review Set Up Amazon SageMaker Ground Truth Plus Prerequisites (p. 678) and Core Components of Amazon SageMaker Ground Truth Plus (p. 679).

**Set Up Amazon SageMaker Ground Truth Plus Prerequisites**

Use the following information to sign up for an AWS account. If you already have an AWS account, skip this step.
When you sign up for Amazon Web Services (AWS), your AWS account is automatically signed up for all AWS services, including SageMaker. You are charged only for the services that you use.

**To create an AWS account**

2. Follow the online instructions.

Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

When you sign up for an AWS account, an **AWS account root user** is created. The root user has access to all AWS services and resources in the account. As a security best practice, assign administrative access to an administrative user, and use only the root user to perform tasks that require root user access.

Write down your AWS account ID because you need it for the next task.

AWS sends you a confirmation email after the sign up process is complete. At any time, you can view your current account activity and manage your account by going to [https://aws.amazon.com/](https://aws.amazon.com/) and choosing My Account.

**Core Components of Amazon SageMaker Ground Truth Plus**

The following terms are key to understanding the capabilities of Ground Truth Plus:

- **Project**: Each qualified engagement with an AWS expert results in a Ground Truth Plus project. A project can be in the pilot or production stage.
- **Batch**: A batch is a collection of similar recurring data objects such as images, video frames and text to be labeled. A project can have multiple batches.
- **Metrics**: Metrics are data about your Ground Truth Plus project for a specific date or over a date range.
- **Data type**: Ground Truth Plus currently supports five task types for data labeling. These include text, image, video, audio, and 3D point cloud.
- **Data objects**: Individual items that are to be labeled.

**Request a Pilot**

To get started with Amazon SageMaker Ground Truth Plus, go to the SageMaker console and complete the intake form.
Once you submit the intake form in the AWS console, the status of your pilot changes to submitted on your Ground Truth Plus console. An AWS expert from the Ground Truth Plus team will reach out to discuss your data labeling project requirements and pricing.

**Share Data with Amazon SageMaker Ground Truth Plus**

After the initial consultation call with the AWS expert, you can share your data in a secure Amazon S3 bucket to start the pilot.

**To share data from your Amazon S3 bucket:**

1. Once your project is approved, ask your AWS expert for your Ground Truth Plus account ID.
   
   Write down your Ground Truth Plus account ID since you will need it in the next step.

2. Create an Amazon S3 bucket for storing your input and output data. To create a bucket, follow the instructions in Create a Bucket in the Amazon Simple Storage Service Console User Guide.

3. We recommend using the following naming convention while storing your data in an Amazon S3 bucket.
   
   a. The *project-name* should contain fewer than 63 characters.
b. The `project-name` can include hyphens, but no spaces and underscores.

c. Batches can be named as `batch1`, `batch2`, `batch3`, and so on.

d. Store your input data in the Amazon S3 bucket under the following prefix (directory):

   ```
s3://your-bucket-name/ground-truth-plus/input/project-name/batch-name/..
   ```

e. Ground Truth Plus currently accepts videos in .mp4 format.

f. Video frames can be in .jpg, .jpeg, or .png format. The frames can be in a folder, sorted with UTF-8 ordering.

4. In the **Buckets** list, choose the name of the bucket you created.

5. Choose **Permissions**.

6. In the **Bucket policy** section, choose **Edit**.

7. Copy the **policy** shown below and enter `your-ground-truth-plus-account-id` and `your-bucket-name`:

   ```json
   {
   "Version": "2012-10-17",
   "Statement": [
   {
   "Effect": "Allow",
   "Principal": {
   "AWS": ["your-ground-truth-plus-account-id"]
   // Ex: ["999999999999"]
   },
   "Action": [
   "s3:GetObject",
   "s3:GetBucketLocation",
   "s3:ListBucket",
   "s3:PutObject"
   ],
   "Resource": [
   "arn:aws:s3:::your-bucket-name",
   "arn:aws:s3:::your-bucket-name/*"
   //Ex: "arn:aws:s3:::input-data-to-label/*"
   ]
   }
   ]
   }
   ```

8. Choose **Save changes**.

**Note**

If you have additional requirements for accessing your data in an Amazon S3 bucket, please contact your AWS expert.

---

## Create a Project Team

A project team provides access to the members from your organization or team to track projects, view metrics, and review annotations. You can create a Ground Truth Plus project team once you have shared your data in an Amazon S3 bucket.

To add team members using Amazon Cognito, you have two options:

1. Create a new Amazon Cognito user group
a. Enter an **Amazon Cognito user group name**. This name cannot be changed.

b. Enter the email addresses of up to 50 team members in the **Email addresses** field. The addresses must be separated by a comma.

c. Choose **Create project team**.

d. Your team members receive an email inviting them to join the Ground Truth Plus project team as shown in the following image.

2. Import team members from existing Amazon Cognito user groups.

   a. Choose a user pool that you have created. User pools require a domain and an existing user group. If you get an error that the domain is missing, set it in the **Domain name** options on the **App integration** page of the Amazon Cognito console for your group.

   b. Choose an app client. We recommend using a client generated by Amazon SageMaker.

   c. Choose a user group from your pool to import its members.

   d. Choose **Create project team**.

You can view and manage the list of team members through the AWS console.

**To add team members after creating the project team:**

1. Choose **Invite new members** in the **Members** section.
2. Enter the email addresses of up to 50 team members in the **Email addresses** field. The addresses must be separated by a comma.

3. Choose **Invite new members**

**To delete existing team members:**

1. Choose the team member to be deleted in the **Members** section.
2. Choose **Delete**.

Once you have added members to your project team, you can open the project portal to access your projects.

### Open the Project Portal

Once you have successfully submitted the intake form and created a project team, you can access the Ground Truth Plus project by clicking the **Open project portal** button on the AWS console.

Each project consists of one or more batches. A **batch** is a collection of recurring similar data objects (text, image, video frame, and point cloud) to be labeled. The project portal provides you with transparency into the data labeling process. You can stay updated about the project, review the progress of the datasets across multiple projects, and track and analyze project metrics. The project portal also allows you to review a subset of the labeled data and provide feedback.

You can use the Ground Truth Plus project portal to track the following details about your project.

**Project name**: Each project is identified using a unique name.

**Status**: A Ground Truth Plus project has one of the following status types:

1. **Consultation**: An AWS expert collects all the project requirements.
2. **Workflow design and setup progress**: An AWS expert is setting up your project.
3. **Pilot in-progress**: Object labeling for the project in the pilot stage is currently in progress.
4. **Pilot complete**: Object labeling is complete and the labeled data is stored in your Amazon S3 bucket.
5. **Pricing complete**: An AWS expert shares the pricing for the production project with you.
6. **Contract executed**: The contract is complete.
7. **Production in-progress**: Labeling for the project in the production stage is in progress.
8. **Production complete**: Object labeling is complete and the labeled data is stored in your Amazon S3 bucket.
9. **Paused**: Project is currently paused at your request.

**Task type**: Ground Truth Plus lets you label five types of tasks that include text, image, video, audio, and point cloud.
Batches: Total number of batches within a project.

Project creation date: Starting date of a project.

Total objects: Total number of objects to be labeled across all batches.

Objects completed: Number of labeled objects.

Remaining objects: Number of objects left to be labeled.

Failed objects: Number of objects that cannot be labeled due to an issue with the input data.

Review Metrics

Metrics are data about your Ground Truth Plus project for a specific date or over a date range.

You can review metrics for all batches or choose a batch of your choice as shown in the following image.

You can review the following metrics about the batch:

Total objects: Total number of objects in a batch or across all batches.

Objects completed by day: Total numbers of objects labeled on a specific date or over a date range.

Labels completed by day: Total numbers of labels completed on a specific date or over a date range. An object can have more than one label.

Review Batches

Every Amazon SageMaker Ground Truth Plus project consists of one or more batches. Each batch is made up of data objects to be labeled. You can view all the batches for your project using the project portal as shown in the following image.
You can use the Ground Truth Plus project portal to track the following details about every batch:

**Batch name**: Each batch is identified with a unique batch name.

**Status**: A Ground Truth Plus batch has one of the following status types:

1. **Waiting for data**: The AWS expert is awaiting data from you.
2. **Data received**: We have received your unlabeled input data.
3. **In-progress**: Data labeling is in-progress.
4. **Ready for review**: Data labeling is completed. A subset of labeled objects from the batch are ready for you to review. This is an optional step.
5. **Review submission in-progress**: Review feedback is currently being processed.
6. **Review complete**: You have successfully reviewed the batch. Next, you have to accept or reject it. This action can not be undone.
7. **Accepted**: You have accepted the labeled data and will receive it in your Amazon S3 bucket shortly.
8. **Rejected**: Labeled data needs to be reworked.
9. **Data delivered**: Object labeling is complete and the labeled data is stored in your Amazon S3 bucket.
10. **Paused**: Batch is paused at your request.

**Task type**: Ground Truth Plus lets you label five types of tasks that include text, image, video, audio, and point cloud.

**Batch creation date**: Date when the batch was created.

**Total objects**: Total number of objects to be labeled across a batch.

**Completed objects**: Number of labeled objects.

**Remaining objects**: Number of objects left to be labeled

**Failed objects**: Number of objects that cannot be labeled due to an issue with the input data.

**Objects to review**: Number of objects that are ready for your review.

**Objects with feedback**: Number of objects that have gotten feedback from the team members.

Ground Truth Plus lets you review a sample set of your labeled data (determined during the initial consultation call) through the review UI shown in the following image.
Hello,

Instructions  Shortcuts  Help

Instructions

Please review the following sample set of the batch selected and provide your feedback.

Feedback
Provide feedback for each object. The Feedback section is in the lower right panel.

Navigation
Use the arrow controls in the lower left panel to navigate through the images.

Submit
Choose Submit to submit feedback for all data objects.

Image controls
Use the image controls in the bottom tray to zoom, pan, control brightness and, contrast.

Save
Choose Save to save your progress. It's also autosaved every 15 minutes.

Close
To exit the review UI, choose the Close button on the upper right corner.

Verify the label attributes and frame attributes on each frame. You can't create new objects or modify existing objects in this task.
The portal allows your project team members and you to review a small sample set of the labeled objects for each batch. You can provide feedback for each labeled object within that subset through this UI. The review UI allows you to navigate across the subset of labeled objects and provide feedback for those labeled objects.

You can perform the following actions using the review UI.

- Use the arrow controls on the bottom left to navigate through the data objects.
- You can provide feedback for each object. The Feedback section is in the right panel. Choose Submit to submit feedback for all images.
- Use the image controls in the bottom tray to zoom, pan, and control contrast.
- If you plan on returning to finish up your review, choose Stop and resume later on the top right.
- Choose Save to save your progress. It is also autosaved every 15 minutes.
- To exit the review UI, choose Close on the upper right corner of the review UI.
- You can verify the Label attributes and Frame attributes on each frame using the panel on the right. You cannot create new objects or modify existing objects in this task.

**Accept or Reject Batches**

After you have reviewed a batch, you must choose to accept or reject it.

If you accept a batch, the output from that labeling job is placed in the Amazon S3 bucket that you specify. Once the data is delivered to your S3 bucket, the status of your batch changes from Accepted to Data delivered.

If you reject a batch, you can provide feedback and explain your reasons for rejecting the batch.

Ground Truth Plus allows you to provide feedback at the data object level as well as the batch level. You can provide feedback for data objects through the review UI. You can use the project portal to provide feedback for each batch. When you reject a batch, an AWS expert contacts you to determine the rework process and the next steps for the batch.

**Note**

Accepting or rejecting a batch is a one-time action and cannot be undone. It is necessary to either accept or reject every batch of the project.

**Use Amazon SageMaker Ground Truth Synthetic Data to Generate and Label Data**

Amazon SageMaker Ground Truth synthetic data is a turnkey data generation and labeling service that makes it quicker and more cost effective for machine learning (ML) scientists to acquire images that are used to train computer vision (CV) models. To train a CV model, ML scientists need large, high-quality, labeled datasets. With Ground Truth synthetic data, ML scientists can generate and label thousands of images within days. Ground Truth synthetic data uses computer-generated 3D models to create virtual environments representing real-world scenarios, generates synthetic images captured from these environments, and automatically annotates each image with labels. You can use the labeled synthetic images with AWS's CV model training services such as Amazon SageMaker and Amazon Lookout for Vision.

**Why use Ground Truth Synthetic Data?**
Collecting and labeling data in dynamic environments with variations in object size, shape, color, position, background, and lighting is often a time-consuming and expensive process. To effectively train a model to operate in a dynamic environment, ML scientists must collect a large set of real-world images to represent all possible scenarios, a process that can take months. For scenarios that don’t occur frequently, such as rare product defects and faulty product placement, it can take years to capture a sufficient number of images to train a CV model. To acquire images with product defects, ML scientists may intentionally damage products in order to acquire defective images. Ground Truth synthetic data makes it faster and more cost effective for ML scientists to quickly acquire labeled images that represent real-world scenarios, a core requirement for training CV models. Ground Truth synthetic data can use Ground Truth synthetic data to generate thousands of synthetic images from 3D virtual environments representing real world scenarios in hours instead of months. Ground Truth provides a synthetic image fidelity and diversity report and a manifest file along with the labeled synthetic data. The synthetic image fidelity and diversity report provides statistics and plots that help you better understand the generated synthetic images. The manifest file contains information about the images and image labels that you can use to train and test a model.

Note
Ground Truth synthetic data does not support PHI, PCI, or FedRAMP certified data, and you should not provide this data to Ground Truth synthetic data.

How do I use Ground Truth Synthetic Data?

If you are a first-time user of Ground Truth synthetic data, we recommend that you follow the procedures outlined in the Getting Started with Amazon SageMaker Ground Truth Synthetic Data (p. 688) section.

Getting Started with Amazon SageMaker Ground Truth Synthetic Data

The guide demonstrates how to complete the necessary steps to satisfy the prerequisites, start a Ground Truth synthetic data project, and review labels.

To get started using synthetic data, review Set Up Amazon SageMaker Ground Truth Synthetic Data Prerequisites (p. 688) and Core Components of Amazon SageMaker Ground Truth Synthetic Data (p. 689).

Set Up Amazon SageMaker Ground Truth Synthetic Data Prerequisites

To use Ground Truth synthetic data, you need an AWS account. If you already have an AWS account, skip this step.

When you sign up for Amazon Web Services (AWS), your AWS account is automatically signed up for all AWS services, including SageMaker. You are charged only for the services that you use.

To create an AWS account

2. Follow the online instructions.

Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

When you sign up for an AWS account, an AWS account root user is created. The root user has access to all AWS services and resources in the account. As a security best practice, assign administrative
access to an administrative user, and use only the root user to perform tasks that require root user access.

Write down your AWS account ID because you need it for the next task.

AWS sends you a confirmation email after the sign-up process is complete. At any time, you can view your current account activity and manage your account by going to https://aws.amazon.com/ and choosing My Account.

Core Components of Amazon SageMaker Ground Truth Synthetic Data

The following terms are key to understanding the capabilities of Ground Truth synthetic data:

- **Project:** Each qualified engagement with an AWS expert results in a Ground Truth synthetic data project.
- **Batch:** A batch is a collection of similar labeled images. A project can have multiple batches. A batch can be in the test or production stage. A project can have multiple batches.
- **Synthetic Image Fidelity and Diversity Report:** Ground Truth synthetic data provides a metrics report that helps you compare the generated synthetic images with your typical dataset.

Request a Project

To get started with Amazon SageMaker Ground Truth synthetic data, go to the SageMaker console and complete the intake form.

Once you submit the intake form in the AWS console, an AWS expert from the Ground Truth synthetic data team reaches out to discuss your data labeling project requirements and pricing.

Share Data from Your Amazon S3 Bucket

After an AWS expert reaches out to discuss your project, you may be required to fill out an intake form with questions specific to your synthetic data requirements. The intake form, along with assets shared with Ground Truth synthetic data, allows the Ground Truth synthetic data team to evaluate your project and the estimated work required to complete your project.

Create an Amazon S3 bucket to share your project assets with Ground Truth synthetic data and store your project’s output data.

**To create an Amazon S3 bucket and share it with us:**

1. Follow the instructions in Create a Bucket in the Amazon Simple Storage Service Console User Guide.
2. We recommend using the following naming convention while storing your data in an Amazon S3 bucket.
   a. The *bucket-name* should contain fewer than 63 characters.
   b. The *bucket-name* can include hyphens, but no spaces and underscores.
3. In the Buckets list, choose the name of the bucket you created.
4. Choose Permissions.
5. In the Bucket policy section, choose Edit.
6. Confirm that ACLs disabled is selected.

**Note**

Under Object Ownership should have ACLs disabled as shown in the image below.
7. Choose **Save changes**.

**Note**

If you have additional requirements for accessing your data in an Amazon S3 bucket, please contact your AWS expert.

To share your project assets with the Ground Truth synthetic data team for project evaluation, work estimation, and synthetic data generation, follow the steps in the **Send Project Data to Ground Truth Synthetic Data** (p. 690) section below.

After receiving your intake form and project assets, we return a statement of work (SOW) within 5 business days. The SOW outlines your engagement with Ground Truth synthetic data generation and labeling. After you approve the SOW, the Ground Truth synthetic data team produces a test batch consisting of 50 synthetic images. An AWS expert meets with you to review the test batch, approve or reject images, and complete the final production. The timeline for this is based on the responses in your intake form.

**Send Project Data to Ground Truth Synthetic Data**

After an AWS expert has been assigned to your project, you can send project data to the Ground Truth synthetic data team to assist in project evaluation, work estimation, and synthetic data generation.

**To send project data to Ground Truth synthetic data:**

1. Under the **Project data transfers** table in the project portal, choose **Send project data**.
2. Enter the name of your S3 bucket from which you would like to send project data as the Amazon S3 source location of the project data transfer.
3. Select an IAM role for the project data transfer. If you select **Automatic**, Ground Truth synthetic data creates an IAM role in your account with the required permissions to run the project data transfer and call other services on your behalf (recommended). If you select an existing IAM role in your account, Ground Truth synthetic data uses that IAM role to run the project data transfer and call other services on your behalf.
4. Choose **Create** to create and start the project data transfer.

After creating a project data transfer, you can view the status of the transfer in the **Project data transfers** table on the project details page in the project portal. When the project data transfer status is **Completed**, the project data is available to the Ground Truth synthetic data team.
Project Portal

Each project consists of one or more batches. A batch is a collection of similar generated and labeled images. The project portal provides you access to the projects you have contracted with Ground Truth synthetic data. You can view the status of your projects and access completed batches along with the synthetic image fidelity and diversity report. You also review your batches to accept or reject them through the project portal.

You can use the Ground Truth synthetic data project portal to track the following details about your project:

**Project name**: Each project is identified using a unique name.

**Status**: A Ground Truth synthetic data project has one of the following status types:

1. **Request submitted**: You have successfully submitted the project request form. Next, an AWS expert schedules a call with you to discuss the details for your project.
2. **Review in progress**: We are reviewing your project. An AWS expert has been assigned to your project.
3. **Production in progress**: We are currently working on generating labeled data for your project.
4. **Data ready for review**: At least one batch is ready for your review.
5. **Project complete**: We have completed the generation of the required labeled images. The images are stored in your Amazon S3 bucket.

**Batches**: Total number of batches within a project.

**Project start date**: Starting date of a project.

**Total images**: Number of images you requested.

**Completed images**: Number of labeled images generated across all accepted production batches.

**Delete a Project**

You can delete a project using the console if the project status is **Request submitted** or **Project complete**. To delete a project with any other status, contact your AWS expert. Deleting a Ground Truth synthetic data project does not delete your data from the Amazon S3 buckets and can be subject to charge.

You can delete a project based on its status as follows:
• **Request submitted**: Deleting a requested project deletes all the project and customer information from the Ground Truth synthetic data database.

• **Review in progress / Production in progress / Data ready for review**: You can request your AWS expert to delete a project having one of these statuses. Deleting a project deletes all the project and personal information from Ground Truth synthetic data database and S3 buckets.

• **Project complete**: Once a project is marked as **Project complete**, we delete all customer information from the Ground Truth synthetic data database and S3 buckets. You can view the project and batches as long as you want, or delete them using the console.

**Note**
Deleting a project does not delete the images from your S3 bucket. To learn more about deleting images from your S3 bucket, refer to Deleting Amazon S3 objects.

**Review Batches**

Every Amazon SageMaker Ground Truth synthetic data project consists of one or more batches. Each batch is made up of labeled synthetic images. Batches are of two types, **Test Batch** and **Production Batch**. A test batch provides a small preview of how the synthetic images look using your 3D assets and environment. Images in the test batch are not counted towards the total number of synthetic images you contract. After you approve the test batch for a specific configuration of images, Ground Truth synthetic data starts generating images for your production batch. Images in a production batch are counted towards the total required images.

For every batch, Ground Truth synthetic data provides a **Synthetic Image Fidelity and Diversity Report**. This report provides image and object level statistics and plots that help you make sense of the generated synthetic images. The statistics are used to describe the diversity and the fidelity of the synthetic images and compare them with real images. Examples of the statistics and plots provided are the distributions of object classes, object sizes, image brightness, image contrast, as well as the plots evaluating the indistinguishability between synthetic and real images. The raw data for all the computed dataset statistics is also provided as CSV files to help you accelerate model debugging and enable further analyses.
You can view all the batches for your project using the project portal.

You can use the Ground Truth synthetic data project portal to track the following details about every batch:

- **Batch name**: Each batch is identified with a unique batch name.
- **Status**: A Ground Truth synthetic data batch has one of the following status types:
  1. **In progress**: We are currently generating labeled images for this batch. It will soon be ready for your review.
  2. **Ready for review**: A batch of labeled synthetic images is now ready for your review. Follow the steps in the Transfer Batch Data to Your Amazon S3 bucket (p. 693) section to view the images and review the batch.
  3. **Accepted**: You have accepted this batch.
  4. **Rejected**: You have rejected this batch and it needs to be reworked. When you reject a batch, an AWS expert contacts you to discuss this further.

- **Batch type**: A batch can either be a test batch or a production batch.
- **Creation date**: Date when the batch was created.
- **Images**: Total number of images in the batch.

**Transfer Batch Data to Your Amazon S3 bucket**

When the batch status is **Ready for review**, you must transfer the batch data to your S3 bucket to view the images and review the batch.

**To transfer batch data to your S3 bucket:**

1. On the batch details page in the project portal, choose **Get batch data**.
2. Under **S3 destination location**, enter the name of the S3 bucket where you would like to receive your batch data.
3. Select an IAM role for the project data transfer. If you select **Automatic**, Ground Truth synthetic data creates an IAM role in your account with the required permissions to run the project data transfer and call other services on your behalf (recommended). If you select an existing IAM role in your account, Ground Truth synthetic data uses that IAM role to run the project data transfer and call other services on your behalf.
4. Choose **Create** to create and start the batch data transfer.
After creating a batch data transfer, you can view the status of the transfer in the **Batch data transfers** table on the batch details page in the project portal. When the batch data transfer status is **Completed**, the batch data is available in your S3 bucket, the batch images are viewable on the batch details page in the project portal, and you can proceed to review the batch.

### Accept or Reject Batches

After you have reviewed a batch, you can choose to accept or reject it from the project portal as shown below.

Accepting a batch informs your AWS expert to continue or complete the project, based on the number of remaining images you contracted.

When you reject a batch, an AWS expert contacts you to determine the rework process and the next steps for the batch.

Accepting or rejecting a batch is a one-time action and can only be undone by contacting your AWS expert. It is necessary to either accept or reject every batch of the project.

### Create and Manage Workforces

A *workforce* is the group of workers that you have selected to label your dataset. You can choose either the Amazon Mechanical Turk workforce, a vendor-managed workforce, or you can create your own private workforce to label or review your dataset. Whichever workforce type you choose, Amazon SageMaker takes care of sending tasks to workers.

When you use a private workforce, you also create *work teams*, a group of workers from your workforce that are assigned to specific *jobs*—Amazon SageMaker Ground Truth labeling jobs or Amazon Augmented AI human review tasks. You can have multiple work teams and can assign one or more work teams to each job.

You can use Amazon Cognito or your own private OpenID Connect (OIDC) Identity Provider (IdP) to manage your private workforce and work teams. For more information about the permissions required to manage your workforce this way, see Permissions Required to Use the Amazon SageMaker Ground Truth Console (p. 3510).

**Topics**

- Using the Amazon Mechanical Turk Workforce (p. 695)
Using the Amazon Mechanical Turk Workforce

The Amazon Mechanical Turk (Mechanical Turk) workforce provides the most workers for your Amazon SageMaker Ground Truth labeling job and Amazon Augmented AI human review task. The Amazon Mechanical Turk workforce is a world-wide resource. Workers are available 24 hours a day, 7 days a week. You typically get the fastest turnaround for your human review tasks and labeling jobs when you use the Amazon Mechanical Turk workforce.

Any Amazon Mechanical Turk workforce billing is handled as part of your Ground Truth or Amazon Augmented AI billing. You do not need to create a separate Mechanical Turk account to use the Amazon Mechanical Turk workforce.

**Important**

You should not share confidential information, personal information, or protected health information with this workforce. You should not use the Amazon Mechanical Turk workforce when you use Amazon A2I in conjunction with AWS HIPAA-eligible services, such as Amazon Textract and Amazon Rekognition, for workloads containing protected health information.

You can choose Mechanical Turk as your workforce when you create a Ground Truth labeling job or Amazon A2I human review workflow (flow definition). You can create a labeling job and a human review workflow using the SageMaker console and API.

When you use an API operation to create a labeling job or human review workflow, you use the following ARN for the Amazon Mechanical Turk workforce for your WorkteamArn. Replace `region` with the AWS Region you are using to create the labeling job or human loops. For example, if you create a labeling job in US West (Oregon), replace `region` with `us-west-2`.

```
arn:aws:sagemaker:region:394669845002:workteam/public-crowd/default
```

Ground Truth and Amazon A2I require that your input data is free of personally identifiable information (PII) when you use Mechanical Turk. If you use the Mechanical Turk workforce and do not specify that your input data is free of PII, your Ground Truth labeling jobs and Augmented AI tasks will fail. You specify that your input data is free of PII when you create a Ground Truth labeling job and when you create a Amazon A2I human loop using a built-in integration or the StartHumanLoop operation.

Use the following sections to learn how to use Mechanical Turk with these services.

**Topics**

- Use Mechanical Turk with Ground Truth (p. 695)
- Use Mechanical Turk with Amazon A2I (p. 697)
- When is Mechanical Turk Not Supported? (p. 698)

**Use Mechanical Turk with Ground Truth**

You can use Mechanical Turk with Ground Truth when you create a labeling job using the console, or the CreateLabelingJob operation.

When you create a labeling job, we recommend you adjust the number of workers that annotate each data object based on the complexity of the job and the quality that you need. Amazon SageMaker Ground Truth uses annotation consolidation to improve the quality of the labels. More workers can make
a difference in the quality of the labels for more complex labeling jobs, but might not make a difference for simpler jobs. For more information, see Consolidate Annotations (p. 639). Note that annotation consolidation is not supported for Amazon A2I human review workflows.

To use Mechanical Turk when you create a labeling job (console):

1. Use the following to create a labeling job using the Ground Truth area of the SageMaker console: Create a Labeling Job (Console) (p. 544).
2. When you are selecting Worker types in the Workers section, select Amazon Mechanical Turk.
3. Specify the total amount of time workers have to complete a task using Task timeout.
4. Specify the total amount of time a task remains available to workers in Task expiration. This is how long workers have to pick up a task before it fails.
5. Select the Price per task using the dropdown list. This is the amount of money a worker receives for completing a single task.
6. (Optional) If applicable, select The dataset does not contain adult content. SageMaker may restrict the Mechanical Turk workers that can view your task if it contains adult content.
7. You must read and confirm the following statement by selecting the check box to use the Mechanical Turk workforce. If your input data contains confidential information, personal information, or protected health information, you must select another workforce.

   You understand and agree that the Mechanical Turk workforce consists of independent contractors located worldwide and that you should not share confidential information, personal information, or protected health information with this workforce.
8. (Optional) Select the check box next to Enable automated data labeling if you want to enable automated data labeling. To learn more about this feature, see Automate Data Labeling (p. 640).
9. You can specify the Number of workers per dataset object under Additional configuration. For example, if you enter 3 in this field, each data object will be labeled by 3 workers.

When you create your labeling job by selecting Create, your labeling tasks are sent to Mechanical Turk workers.

To use Mechanical Turk when you create a labeling job (API):

1. Use the following to create a labeling job using the CreateLabelingJob operation: Create a Labeling Job (API) (p. 547).
2. Use the following for the WorkteamArn. Replace region with the AWS Region you are using to create the labeling job.

   arn:aws:sagemaker:region:394669845002:workteam/public-crowd/default
3. Use TaskTimeLimitInSeconds to specify the total amount of time workers have to complete a task.
4. Use TaskAvailabilityLifetimeInSeconds to specify the total amount of time a task remains available to workers. This is how long workers have to pick up a task before it fails.
5. Use NumberOfHumanWorkersPerDataObject to specify the number of workers per dataset object.
6. Use PublicWorkforceTaskPrice to set the price per task. This is the amount of money a worker receives for completing a single task.
7. Use DataAttributes to specify that your input data is free of confidential information, personal information, or protected health information.

   Ground Truth requires that your input data is free of personally identifiable information (PII) if you use the Mechanical Turk workforce. If you use Mechanical Turk and do not specify that your input data...
data is free of PII using the `FreeOfPersonallyIdentifiableInformation` flag, your labeling job will fail.

Use the `FreeOfAdultContent` flag to declare that your input data is free of adult content. SageMaker may restrict the Mechanical Turk workers that can view your task if it contains adult content.

You can see examples of how to use this API in the following notebooks, found on GitHub: [Ground Truth Jupyter Notebook Examples](https://github.com/aws-samples/amazon-sagemaker-ground-truth). You can access these notebooks under the SageMaker Example Notebooks (p. 306) in a notebook instance.

**Use Mechanical Turk with Amazon A2I**

You can specify that you want to use Mechanical Turk with Amazon A2I when you create a human review workflow, also referred to as a flow definition, in the console, or with the `CreateFlowDefinition` API operation. When you use this human review workflow to configure human loops, you must specify that your input data is free of PII.

**To use Mechanical Turk when you create a human review workflow (console):**

1. Use the following to create a human review workflow in the Augmented AI section of the SageMaker console: [Create a Human Review Workflow (Console)](https://docs.aws.amazon.com/sagemaker/latest/dg/how-to-human-review-workflow-console.html) (p. 3420).
2. When you are selecting **Worker types** in the **Workers** section, select Amazon Mechanical Turk.
3. Select the **Price per task** using the dropdown list. This is the amount of money a worker receives for completing a single task.
4. (Optional) You can specify the **Number of workers per dataset object** under **Additional configuration**. For example, if you enter 3 in this field, each data object will be labeled by 3 workers.
5. (Optional) Specify the total amount of time workers have to complete a task using **Task timeout**.
6. (Optional) Specify the total amount of time a task remains available to workers in **Task expiration**. This is how long workers have to pick up a task before it fails.
7. Once you have created your human review workflow, you can use it to configure a human loop by providing its Amazon Resource Name (ARN) in the parameter `FlowDefinitionArn`. You configure a human loop using one of the API operations of a built-in task type, or the Amazon A2I runtime API operation, `StartHumanLoop`. To learn more, see [Create and Start a Human Loop](https://docs.aws.amazon.com/sagemaker/latest/dg/how-to-human-review-workflow-api.html) (p. 3438).

When you configure your human loop, you must specify that your input data is free of personally identifiable information (PII) using the `FreeOfPersonallyIdentifiableInformation` content classifier in `DataAttributes`. If you use Mechanical Turk and do not specify that your input data is free of PII, your human review tasks will fail.

Use the `FreeOfAdultContent` flag to declare that your input data is free of adult content. SageMaker may restrict the Mechanical Turk workers that can view your task if it contains adult content.

**To use Mechanical Turk when you create a human review workflow (API):**

1. Use the following to create a human review workflow using the `CreateFlowDefinition` operation: [Create a Human Review Workflow (API)](https://docs.aws.amazon.com/sagemaker/latest/dg/how-to-human-review-workflow-api.html) (p. 3422).
2. Use the following for the `WorkteamArn`. Replace `region` with the AWS Region you are using to create the labeling job.

   `arn:aws:sagemaker:region:394669845002:workteam/public-crowd/default`

3. Use `TaskTimeLimitInSeconds` to specify the total amount of time workers have to complete a task.
4. Use `TaskAvailabilityLifetimeInSeconds` to specify the total amount of time a task remains available to workers. This is how long workers have to pick up a task before it fails.

5. Use `TaskCount` to specify the number of workers per dataset object. For example, if you specify 3 for this parameter, each data object will be labeled by 3 workers.

6. Use `PublicWorkforceTaskPrice` to set the price per task. This is the amount of money a worker receives for completing a single task.

7. Once you have created your human review workflow, you can use it to configure a human loop by providing its Amazon Resource Name (ARN) in the parameter `FlowDefinitionArn`. You configure a human loop using one of the API operations of a built-in task type, or the Amazon A2I runtime API operation, `StartHumanLoop`. To learn more, see Create and Start a Human Loop (p. 3438).

When you configure your human loop, you must specify that your input data is free of personally identifiable information (PII) using the `FreeOfPersonallyIdentifiableInformation` classifier in `DataAttributes`. If you use Mechanical Turk and do not specify that your input data is free of PII, your human review tasks will fail.

Use the `FreeOfAdultContent` flag to declare that your input data is free of adult content. SageMaker may restrict the Mechanical Turk workers that can view your task if it contains adult content.

You can see examples of how to use this API in the following notebooks, found on GitHub: Amazon A2I Jupyter Notebook Examples.

**When is Mechanical Turk Not Supported?**

This workforce is not supported under the following scenarios. In each scenario, you must use a private or vendor workforce.

- This workforce is not supported for Ground Truth video frame labeling jobs and 3D point cloud labeling jobs.
- You cannot use this workforce if your input data contains personally identifiable information (PII).
- Mechanical Turk is not available in some of the AWS special regions. If applicable, refer to the documentation for your special region for more information.

**Managing Vendor Workforces**

You can use a vendor-managed workforce to label your data using Amazon SageMaker Ground Truth (Ground Truth) and Amazon Augmented AI (Amazon A2I). Vendors have extensive experience in providing data labeling services for the purpose of machine learning. Vendor workforces for these two services must be created and managed separately through the Amazon SageMaker console.

Vendors make their services available via the AWS Marketplace. You can find details of the vendor's services on their detail page, such as the number of workers and the hours that they work. You can use these details to make estimates of how much the labeling job will cost and the amount of time that you can expect the job to take. Once you have chosen a vendor you subscribe to their services using the AWS Marketplace.

A subscription is an agreement between you and the vendor. The agreement spells out the details of the agreement, such as price, schedule, or refund policy. You work directly with the vendor if there are any issues with your labeling job.

You can subscribe to any number of vendors to meet your data annotation needs. When you create a labeling job or human review workflow you can specify that the job be routed to a specific vendor.
Important
Before you send sensitive data to a vendor, check the vendor's security and compliance practices on their detail page and review the end user license agreement (EULA) that is part of your subscription agreement. You are responsible for ensuring that the vendor meets your compliance requirements for personal or confidential information. Do not share protected health information with this workforce.

You must use the console to subscribe to a vendor workforce. Once you have a subscription, you can use the `ListSubscribedWorkteams` operation to list your subscribed vendors.

**To subscribe to a vendor workforce**

2. Choose the appropriate page in the SageMaker console.
   - For Ground Truth labeling jobs, choose Labeling workforces, choose Vendor, and then choose Find data labeling services.
   - For Amazon A2I human review workflows, choose Human review workforces, choose Vendor, and then choose Find human review services.
3. The console opens the AWS Marketplace with:
   - data labeling services category selected for Ground Truth
   - human review services category selected for Amazon A2I

   Here you see a list of the vendor services available for this service.
4. Choose a vendor. The AWS Marketplace shows detailed information about the data labeling or human review service. Use this information to determine if the vendor meets your requirements for your task.
5. If the vendor meets your requirements, choose Continue to subscribe.
6. Review the details of the subscription. If you agree to the terms, choose Subscribe to complete your subscription to the service.

**Use a Private Workforce**

A private workforce is a group of workers that you choose. These can be employees of your company or a group of subject matter experts from your industry. For example, if the task is to label medical images, you could create a private workforce of people knowledgeable about the images in question.

Each AWS account has access to a single private workforce per region, and the owner has the ability to create multiple private work teams within that workforce. A single private work team is used to complete a labeling job or human review task, or a job. You can assign each work team to a separate job or use a single team for multiple jobs. A single worker can be in more than one work team.

Your private workforce can either be created and managed using Amazon Cognito or your own private OpenID Connect (OIDC) Identity Provider (IdP).

If you are a new user of Amazon SageMaker Ground Truth or Amazon Augmented AI and do not require your workers to be managed with your own IdP, it is recommended that you use Amazon Cognito to create and manage your private workforce.

After you create a workforce, in addition to creating and managing work teams, you can do the following:

- Track worker performance
- Create and manage Amazon SNS topics to notify workers when labeling tasks are available
Use a Private Workforce

- Manage Private Workforce Access to Tasks Using IP Addresses

**Note**
Your private workforce is shared between Ground Truth and Amazon A2I. To create and manage private work teams used by Augmented AI, use the Ground Truth section of the SageMaker console.

**Topics**
- Create and Manage Amazon Cognito Workforce (p. 700)
- Create and Manage OIDC IdP Workforce (p. 707)
- Manage Private Workforce Using the Amazon SageMaker API (p. 716)
- Track Worker Performance (p. 717)
- Create and manage Amazon SNS topics for your work teams (p. 719)

**Create and Manage Amazon Cognito Workforce**

Create and manage your private workforce using Amazon Cognito when you want to create your workforce using the Amazon SageMaker console or you don’t want the overhead of managing worker credentials and authentication. When you create a private workforce with Amazon Cognito, it provides authentication, authorization, and user management for your private workers.

**Topics**
- Create a Private Workforce (Amazon Cognito) (p. 700)
- Manage a Private Workforce (Amazon Cognito) (p. 703)

**Create a Private Workforce (Amazon Cognito)**

When you use Amazon Cognito, you can create a private workforce in one of the following ways:

- Create a new workforce while you are creating your labeling job. To learn how, see Create an Amazon Cognito Workforce When Creating a Labeling Job (p. 701).
- Create a new workforce before you create your labeling job. To learn how, see Create an Amazon Cognito Workforce Using the Labeling Workforces Page (p. 701).
- Import an existing workforce after creating a user pool in the Amazon Cognito console. To learn how, see Create a Private Workforce (Amazon Cognito Console) (p. 702).

Once you create a private workforce, that workforce and all work teams and workers associated with it are available to use for all Ground Truth labeling job tasks and Amazon Augmented AI human review workflows tasks.

If you are new to Amazon SageMaker and want to test Ground Truth or Amazon A2I, we suggest that you create a private work team consisting of people from your organization using the console. Use this work team when creating labeling or human review workflows (flow definitions) to test your worker UI and job workflow.

**Topics**
- Create a Private Workforce (Amazon SageMaker Console) (p. 700)
- Create a Private Workforce (Amazon Cognito Console) (p. 702)

**Create a Private Workforce (Amazon SageMaker Console)**

You can create a private workforce in the Amazon SageMaker console in one of two ways:
When creating a labeling job in the **Labeling jobs** page of the Amazon SageMaker Ground Truth section.

- Using the **Labeling workforces** page of the Amazon SageMaker Ground Truth section. If you are creating a private workforce for an Amazon A2I human review workflow, use this method.

Both of these methods also create a default work team containing all of the members of the workforce. This private workforce is available to use for both Ground Truth and Amazon Augmented AI jobs.

When you create a private workforce using the console, SageMaker uses Amazon Cognito as an identity provider for your workforce. If you want to use your own OpenID Connect (OIDC) Identity Provider (IdP) to create and manage your private workforce, you must create a workforce using the SageMaker API operation **CreateWorkforce**. To learn more, see [Create a Private Workforce (OIDC IdP)](p. 707).

### Create an Amazon Cognito Workforce When Creating a Labeling Job

If you haven't created a private workforce when you create your labeling job and you choose to use private workers, you are prompted to create a work team. This will create a private workforce using Amazon Cognito.

#### To create a workforce while creating a labeling job (console)

2. In the navigation pane, choose **Labeling jobs** and fill in all required fields. For instructions on how to start a labeling job, see [Getting started](p. 371). Choose Next.
3. Choose **Private** for the workforce type.
4. In the **Workers** section, enter:
   a. The **Team name**.
   b. Email addresses for up to 100 workforce members. Email addresses are case sensitive. Your workers must log in using the same case used when the address was initially entered. You can add additional workforce members after the job has been created.
   c. The name of your organization. SageMaker uses this to customize the email sent to the workers.
   d. A contact email address for workers to report issues related to the task.

When you create the labeling job, an email is sent to each worker inviting them to join the workforce. After creating the workforce, you can add, delete, and disable workers using the SageMaker console or the Amazon Cognito console.

### Create an Amazon Cognito Workforce Using the Labeling Workforces Page

To create and manage your private workforce using Amazon Cognito, you can use the **Labeling workforces** page. When following the instructions below, you have the option to create a private workforce by entering worker emails importing a pre-existing workforce from an Amazon Cognito user pool. To import a workforce, see [Create a Private Workforce (Amazon Cognito Console)](p. 702).

#### To create a private workforce using worker emails

2. In the navigation pane, choose **Labeling workforces**.
3. Choose **Private**, then choose **Create private team**.
4. Choose **Invite new workers by email**.
5. Paste or type a list of up to 50 email addresses, separated by commas, into the email addresses box.
6. Enter an organization name and contact email.

7. Optionally, choose an SNS topic to which to subscribe the team so workers are notified by email when new Ground Truth labeling jobs become available. Amazon SNS notifications are supported by Ground Truth and are not supported by Augmented AI. If you subscribe workers to receive SNS notifications, they only receive notifications about Ground Truth labeling jobs. They do not receive notifications about Augmented AI tasks.

8. Click the Create private team button.

After you import your private workforce, refresh the page. On the Private workforce summary page, you can see information about the Amazon Cognito user pool for your workforce, a list of work teams for your workforce, and a list of all of the members of your private workforce.

**Note**

If you delete all of your private work teams, you have to repeat this process to use a private workforce in that region.

Create a Private Workforce (Amazon Cognito Console)

Amazon Cognito is used to define and manage your private workforce and your work teams. It is a service that you can use to create identities for your workers and authenticate these identities with identity providers. A private workforce corresponds to a single Amazon Cognito user pool. Private work teams correspond to Amazon Cognito user groups within that user pool.

Example identity providers supported by Amazon Cognito:

- Social sign-in providers such as Facebook and Google
- OpenID Connect (OIDC) providers
- Security Assertion Markup Language (SAML) providers such as Active Directory
- The Amazon Cognito built-in identity provider

For more information, see What Is Amazon Cognito?

To create a private workforce using Amazon Cognito, you must have an existing Amazon Cognito user pool containing at least one user group. See Tutorial: Creating a User Pool to learn how to create a user pool. See Adding Groups to a User Pool to learn how to add a user group to a pool.

Once your user pool has been created, follow the steps below to create a private workforce by importing that user pool into Amazon SageMaker.

**To create a private workforce by importing a Amazon Cognito user pool**

2. In the navigation pane, choose Labeling workforces.
3. Choose Private.
4. Choose Create private team. This creates a private workforce and a work team.
5. Choose Import workers from existing Amazon Cognito user groups.
6. Choose a user pool that you have created. User pools require a domain and an existing user group. If you get an error that the domain is missing, set it in the Domain name options on the App integration page of the Amazon Cognito console for your group.
7. Choose an app client. We recommend using a client generated by SageMaker.
8. Choose a user group from your pool to import its members.
9. Optionally choose an Amazon Simple Notification Service (Amazon SNS) topic to which to subscribe the team so that workers are notified by email when new labeling jobs become available. Amazon
SNS notifications are supported by Ground Truth and are not supported by Augmented AI. If you subscribe workers to receive SNS notifications, they only receive notifications about Ground Truth labeling jobs. They do not receive notifications about Augmented AI tasks.

10. Choose Create private team.

Important
After you create a workforce using an Amazon Cognito user pool, it should not be deleted without first deleting all work teams associated with that pool in the SageMaker console.

After you import your private workforce, refresh the page to see the Private workforce summary page. On this page, you can see information about the Amazon Cognito user pool for your workforce, a list of work teams for your workforce, and a list of all of the members of your private workforce. This workforce is now available to use in both Amazon Augmented AI and Amazon SageMaker Ground Truth for human review tasks and data labeling jobs respectively.

Manage a Private Workforce (Amazon Cognito)

After you have created a private workforce using Amazon Cognito, you can create and manage work teams using the Amazon SageMaker console and API operations.

You can do the following using either the SageMaker console or Amazon Cognito console.

- Add and delete work teams.
- Add workers to your workforce and one or more work teams.
- Disable or remove workers from your workforce and one or more work teams. If you add workers to a workforce using the Amazon Cognito console, you must use the same console to remove the worker from the workforce.

You can restrict access to tasks to workers at specific IP addresses using the SageMaker API. For more information, see Manage Private Workforce Using the Amazon SageMaker API (p. 716).

Topics
- Manage a Workforce (Amazon SageMaker Console) (p. 703)
- Manage a Private Workforce (Amazon Cognito Console) (p. 705)

Manage a Workforce (Amazon SageMaker Console)

You can use the Amazon SageMaker console to create and manage the work teams and individual workers that make up a private workforce.

Use a work team to assign members of your private workforce to a labeling or human review job. When you create your workforce using the SageMaker console, there is a work team called Everyone-in-private-workforce that enables you to assign your entire workforce to a job. Because an imported Amazon Cognito user pool may contain members that you don’t want to include in your work teams, a similar work team is not created for Amazon Cognito user pools.

You have two choices to create a new work team:

- You can create a work team in the SageMaker console and add members from your workforce to the team.
- You can create a user group by using the Amazon Cognito console and then create a work team by importing the user group. You can import more than one user group into each work team. You manage the members of the work team by updating the user group in the Amazon Cognito console. See Manage a Private Workforce (Amazon Cognito Console) (p. 705) for more information.
Create a Work Team Using the SageMaker Console

You can create a new Amazon Cognito user group or import an existing user group using the SageMaker console, on the Labeling workforces page. For more information on creating a user group in the Amazon Cognito console, see Manage a Private Workforce (Amazon Cognito Console) (p. 705).

To create a work team using the SageMaker console

2. Choose Labeling workforces from the left menu.
3. Under Private, choose Create private team.
4. Under Team details, enter a Team name. The name must be unique in your account in an AWS Region.
5. Under Add workers, choose a method to add workers to the team using a user group.
   - If you chose Create a team by adding workers to a new Amazon Cognito user group, select the workers to add to the team.
   - If you chose Create a team by importing existing Amazon Cognito user groups, choose the user groups that are part of the new team.
6. If you select an SNS topic, all workers added to the team are subscribed to the Amazon SNS topic and notified when new work items are available to the team. Select from a list of your existing Ground Truth related Amazon SNS topics or select Create new topic to open a topic-creation dialog.

Amazon SNS notifications are supported by Ground Truth and are not supported by Augmented AI. If you subscribe workers to receive SNS notifications, they only receive notifications about Ground Truth labeling jobs. They do not receive notifications about Augmented AI tasks.

Workers in a workteam subscribed to a topic receive notifications when a new Ground Truth labeling job for that team becomes available and when one is about to expire.

Read Create and manage Amazon SNS topics for your work teams (p. 719) for more information about using Amazon SNS topic.

Subscriptions

After you have created a work team, you can see more information about the team and change or set the Amazon SNS topic to which its members are subscribed by visiting the Amazon Cognito console. If you added any team members before you subscribed the team to a topic, you need to manually subscribe those members to that topic. Read Create and manage Amazon SNS topics for your work teams for more information on creating and managing the Amazon SNS topic.

Add or Remove Workers

A work team is a group of workers within your workforce to whom you can assign jobs. A worker can be added to more than one work team. Once a worker has been added to a work team, that worker can be disabled or removed.

Add Workers to the Workforce

Adding a worker to the workforce enables you to add that worker to any work team within that workforce.

To add workers using the private workforce summary page

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Choose Labeling workforces to navigate to your private workforce summary page.
3. Choose Private.
4. Choose **Invite new workers.**
5. Paste or type a list of email addresses, separated by commas, into the email addresses box. You can have up to 50 email addresses in this list.

**Add a Worker to a Work Team**

A worker must be added to the workforce before being added to a work team. To add a worker to a work team, first navigate to the **Private workforce summary** page using the steps above.

**To add a worker to a work team from the private workforce summary page**

1. In the **Private teams** section, choose the team to which you want to add the workers.
2. Choose the **Workers** tab.
3. Choose **Add workers to team** and choose the boxes next to the workers that you want to add.
4. Click **Add workers to team.**

**Disable and Remove a Worker from the Workforce**

Disabling a worker stops the worker from receiving a job. This action does not remove the worker from the workforce, or from any work team with which the worker is associated. To disable or remove a worker from a work team, first navigate to the private workforce summary page using the steps above.

**To deactivate a worker using the private workforce summary page**

1. In the **Workers** section, choose the worker that you would like to disable.
2. Choose **Disable.**

If desired, you can subsequently **Enable** a worker after they have been disabled.

You can remove workers from your private workforce directly in the SageMaker console if that worker was added in this console. If you added the worker (user) in the Amazon Cognito console, see **Manage a Private Workforce (Amazon Cognito Console)** (p. 705) to learn how to remove the worker in the Amazon Cognito console.

**To remove a worker using the private workforce summary page**

1. In the **Workers** section, choose the worker that you would like to delete.
2. If the worker has not been disabled, choose **Disable.**
3. Select the worker and choose **Delete.**

**Manage a Private Workforce (Amazon Cognito Console)**

A private workforce corresponds to a single **Amazon Cognito user pool.** Private work teams correspond to **Amazon Cognito user groups** within that user pool. Workers correspond to **Amazon Cognito users** within those groups.

After your workforce has been created, you can add work teams and individual workers through the Amazon Cognito console. You can also delete workers from your private workforce or remove them from individual teams in the Amazon Cognito console.

**Important**

You can't delete work teams from the Amazon Cognito console. Deleting a Amazon Cognito user group that is associated with an Amazon SageMaker work team will result in an error. To remove work teams, use the SageMaker console.
Create Work Teams (Amazon Cognito Console)

You can create a new work team to complete a job by adding a Amazon Cognito user group to the user pool associated with your private workforce. To add a Amazon Cognito user group to an existing worker pool, see Adding groups to a User Pool.

To create a work team using an existing Amazon Cognito user group

2. In the navigation pane, choose Workforces.
3. For Private teams, choose Create private team.
4. Under Team details, give the team a name. The name must be unique in your account in an AWS Region.
5. For Add workers, choose Import existing Amazon Cognito user groups, and choose one or more user groups that are part of the new team.
6. If you choose an SNS topic, all workers added to the team are subscribed to the Amazon Simple Notification Service (Amazon SNS) topic and notified when new work items are available to the team. Choose from a list of your existing SNS topics related to SageMaker Ground Truth or Amazon Augmented AI or choose Create new topic to create one.

   Note
   Amazon SNS notifications are supported by Ground Truth and are not supported by Augmented AI. If you subscribe workers to receive SNS notifications, they only receive notifications about Ground Truth labeling jobs. They do not receive notifications about Augmented AI tasks.

Subscriptions

After you have created a work team, you can see more information about the team and change or set the SNS topic to which its members are subscribed using the Amazon Cognito console. If you added any team members before you subscribed the team to a topic, you need to manually subscribe those members to that topic. For more information, see Create and manage Amazon SNS topics for your work teams (p. 719).

Add and Remove Workers (Amazon Cognito Console)

When using the Amazon Cognito console to add workers to a work team, you must add a user to the user pool associated with the workforce before adding that user to a user group. Users can be added to a user pool in various ways. For more information, see Signing Up and Confirming User Accounts.

Add a Worker to a Work Team

After a user has been added to a pool, the user can be associated with user groups inside of that pool. After a user has been added to a user group, that user becomes a worker on any work team created using that user group.

To add a user to a user group

1. Open the Amazon Cognito console: https://console.aws.amazon.com/cognito/.
2. Choose Manage User Pools.
3. Choose the user pool associated with your SageMaker workforce.
4. Under General Settings, choose Users and Groups and do one of the following:
   • Choose Groups, choose the group that you want to add the user to, and choose Add users. Choose the users that you want to add by choosing the plus-icon to the right of the user’s name.
   • Choose Users, choose the user that you want to add to the user group, and choose Add to group. From the dropdown menu, choose the group and choose Add to group.
Disable and Remove a Worker From a Work Team

Disabling a worker stops the worker from receiving jobs. This action doesn't remove the worker from the workforce, or from any work team the worker is associated with. To remove a user from a work team in Amazon Cognito, you remove the user from the user group associated with that team.

To deactivate a worker (Amazon Cognito console)

1. Open the Amazon Cognito console: https://console.aws.amazon.com/cognito/.
2. Choose Manage User Pools.
3. Choose the user pool associated with your SageMaker workforce.
4. Under General Settings, choose Users and Groups.
5. Choose the user that you want to disable.
6. Choose Disable User.

You can enable a disabled user by choosing Enable User.

To remove a user from a user group (Amazon Cognito console)

1. Open the Amazon Cognito console: https://console.aws.amazon.com/cognito/.
2. Choose Manage User Pools.
3. Choose the user pool associated with your SageMaker workforce.
4. Under General Settings, choose Users and Groups.
5. For User tab, choose the X icon to the right of the group from which you want to remove the user.

Create and Manage OIDC IdP Workforce

Create a private workforce using an OpenID Connect (OIDC) Identity Provider (IdP) when you want to manage and authenticate your workers using your own OIDC IdP. Individual worker credentials and other data will be kept private. Ground Truth and Amazon A2I will only have visibility into worker information you provide through the claims that you send to these services. To create a workforce using an OIDC IdP, your IdP must support groups because Ground Truth and Amazon A2I map one or more groups in your IdP to a work team. To learn more, see Send Required and Optional Claims to Ground Truth and Amazon A2I (p. 708).

If you are a new user of Ground Truth or Amazon A2I, you can test your worker UI and job workflow by creating a private work team and adding yourself as a worker. Use this work team when you create a labeling job or human review workflow. First, create a private OIDC IdP workforce using the instructions in Create a Private Workforce (OIDC IdP) (p. 707). Next, refer to Manage a Private Workforce (OIDC IdP) (p. 713) to learn how to create a work team.

Topics

- Create a Private Workforce (OIDC IdP) (p. 707)
- Manage a Private Workforce (OIDC IdP) (p. 713)

Create a Private Workforce (OIDC IdP)

Create a private workforce using an OpenID Connect (OIDC) Identity Provider (IdP) when you want to authenticate and manage workers using your own identity provider. Use this page to learn how to configure your IdP to communicate with Amazon SageMaker Ground Truth (Ground Truth) or Amazon Augmented AI (Amazon A2I) and to learn how to create a workforce using your own IdP.

To create a workforce using an OIDC IdP, your IdP must support groups because Ground Truth and Amazon A2I use one or more groups that you specify to create work teams. You use work teams to
specify workers for your labeling jobs and human review tasks. Because groups are not a standard claim, your IdP may have a different naming convention for a group of users (workers). Therefore, you must identify one or more user groups to which a worker belongs using the custom claim `sagemaker:groups` that is sent to Ground Truth or Amazon A2I from your IdP. To learn more, see Send Required and Optional Claims to Ground Truth and Amazon A2I (p. 708).

You create an OIDC IdP workforce using the SageMaker API operation `CreateWorkforce`. Once you create a private workforce, that workforce and all work teams and workers associated with it are available to use for all Ground Truth labeling job tasks and Amazon A2I human review workflows tasks. To learn more, see Create an OIDC IdP Workforce (p. 710).

Send Required and Optional Claims to Ground Truth and Amazon A2I

When you use your own IdP, Ground Truth and Amazon A2I use your Issuer, ClientId, and ClientSecret to authenticate workers by obtaining an authentication CODE from your AuthorizationEndpoint.

Ground Truth and Amazon A2I will use this CODE to obtain a custom claim from either your IdP’s TokenEndpoint or UserInfoEndpoint. You can either configure TokenEndpoint to return a JSON web token (JWT) or UserInfoEndpoint to return a JSON object. The JWT or JSON object must contain required and optional claims that you specify. A claim is a key-value pair that contains information about a worker or metadata about the OIDC service. The following table lists the claims that must be included, and that can optionally be included in the JWT or JSON object that your IdP returns.

**Note**

Some of the parameters in the following table can be specified using a : or a -. For example, you can specify the groups a worker belongs to using `sagemaker:groups` or `sagemaker-groups` in your claim.

<table>
<thead>
<tr>
<th>Name</th>
<th>Required</th>
<th>Accepted Format and Values</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sagemaker:groups</code> or <code>sagemaker-groups</code></td>
<td>Yes</td>
<td>Data type: If a worker belongs to a single group, identify the group using a string. If a worker belongs to multiple groups, use a list of up to 10 strings.</td>
<td>Assigns a worker to one or more groups. Groups are used to map the worker into work teams.</td>
<td>Example of worker that belongs to a single group: &quot;work_team1&quot; Example of a worker that belongs to more than one groups: [&quot;work_team1&quot;, &quot;work_team2&quot;]</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Allowable characters:</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Regex: \p{L}\p{M}\p{S}\p{N}\p{P}+</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Quotas: 10 groups per worker 63 characters per group name</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>sagemaker:sub</code> or <code>sagemaker-sub</code></td>
<td>Yes</td>
<td>Data type: String</td>
<td>This is mandatory to track a worker identity inside the</td>
<td>&quot;111011101-123456789-3687056437-1111&quot;</td>

</tr>
<tr>
<td>---------------------------</td>
<td>----------</td>
<td>-----------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td>sagemaker:client_id</td>
<td>Yes</td>
<td>Data type: String</td>
<td>A client ID. All tokens must be issued for this client ID.</td>
<td>&quot;00b600bb-1f00-05d0-bd00-00be00fbd0e0&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Allowable characters:</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Regex: [\w+-]+</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Quotes: 128 characters</td>
<td></td>
<td></td>
</tr>
<tr>
<td>sagemaker:name</td>
<td>Yes</td>
<td>Data type: String</td>
<td>The worker name to be displayed in the worker portal.</td>
<td>&quot;Jane Doe&quot;</td>
</tr>
<tr>
<td>or sagemaker-name</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>email</td>
<td>No</td>
<td>Data type: String</td>
<td>The worker email. Ground Truth uses this email to notify workers that they have been invited to work on labeling tasks. Ground Truth will also use this email to notify your workers when labeling tasks become available if you set up an Amazon SNS topic for a work team that this worker is on.</td>
<td>&quot;<a href="mailto:example-email@domain.com">example-email@domain.com</a>&quot;</td>
</tr>
<tr>
<td>email_verified</td>
<td>No</td>
<td>Data type: Bool</td>
<td>Indicates if the user email was verified or not.</td>
<td>True</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Accepted Values: True, False</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The following an example of the JSON object syntax your UserInfoEndpoint can return.

```json
{
  "sub":"122",
  "exp":10000,
  "sagemaker-groups":["group1","group2"]
}```
Ground Truth or Amazon A2I compares the groups listed in sagemaker:groups or sagemaker-groups to verify that your worker belongs to the work team specified in the labeling job or human review task. After the work team has been verified, labeling or human review tasks are sent to that worker.

**Create an OIDC IdP Workforce**

You can create a workforce using the SageMaker API operation CreateWorkforce and associated language-specific SDKs. Specify a WorkforceName and information about your OIDC IDP in the parameter OidcConfig. It is recommended that you configure your OIDC with a place-holder redirect URI, and then update the URI with the worker portal URL after you create the workforce. To learn more, see Configure your OIDC IdP (p. 710).

The following shows an example of the request. See CreateWorkforce to learn more about each parameter in this request.

```json
CreateWorkforceRequest: {
    #required fields
    WorkforceName: "example-oidc-workforce",
    OidcConfig: {
        ClientId: "clientId",
        ClientSecret: "secret",
        Issuer: "https://example-oidc-idp.com/adfs",
        TokenEndpoint: "https://example-oidc-idp.com/adfs/oauth2/token",
        UserInfoEndpoint: "https://example-oidc-idp.com/adfs/oauth2/userInfo",
        JwksUri: "https://example-oidc-idp.com/adfs/discovery/keys"
    },
    SourceIpConfig: {
        Cidrs: ["string", "string"]
    }
}
```

**Configure your OIDC IdP**

How you configure your OIDC IdP depends on the IdP you use, and your business requirements.

When you configure your IdP, you must to specify a callback or redirect URI. After Ground Truth or Amazon A2I authenticates a worker, this URI will redirect the worker to the worker portal where the workers can access labeling or human review tasks. To create a worker portal URL, you need to create a workforce with your OIDC IdP details using the CreateWorkforce API operation. Specifically, you must configure your OIDC IdP with required custom sagemaker claims (see the next section for more details). Therefore, it is recommended that you configure your OIDC with a place-holder redirect URI, and then update the URI after you create the workforce. See Create an OIDC IdP Workforce (p. 710) to learn how to create a workforce using this API.

You can view your worker portal URL in the SageMaker Ground Truth console, or using the SageMaker API operation, DescribeWorkforce. The worker portal URL is in the SubDomain parameter in the response.

**Important**

Make sure you add the workforce subdomain to your OIDC IdP allow list. When you add the subdomain to your allow list, it must end with /oauth2/idpresponse.

**To view your worker portal URL after creating a private workforce (Console):**

2. In the navigation pane, choose **Labeling workforces**.
3. Select the **Private** tab.
4. In **Private workforce summary** you will see **Labeling portal sign-in URL**. This is your worker portal URL.

**To view your worker portal URL after creating a private workforce (API):**

When you create a private workforce using **CreateWorkforce**, you specify a **WorkforceName**. Use this name to call **DescribeWorkforce**. The following table includes examples of requests using the AWS CLI and AWS SDK for Python (Boto3).

**SDK for Python (Boto3)**

```python
response = client.describe_workforce(WorkforceName='string')
print(f'The workforce subdomain is: {response['SubDomain']}'
```

**AWS CLI**

```
$ C:\> describe-workforce --workforce-name 'string'
```

**Validate Your OIDC IdP Workforce Authentication Response**

After you have created your OIDC IdP workforce, you can use the following procedure to validate its authentication workflow using cURL. This procedure assumes you have access to a terminal, and that you have cURL installed.

**To validate your OIDC IdP authorization response:**

1. Get an authorization code using a URI configured as follows:

   `{AUTHORIZE ENDPOINT}?client_id={CLIENT ID}&redirect_uri={REDIRECT URI}&scope={SCOPE}&response_type=code`  

   a. Replace `{AUTHORIZE ENDPOINT}` with the authorize endpoint for your OIDC IdP.
   b. Replace `{CLIENT ID}` with the Client ID from your OAuth client.
   c. Replace `{REDIRECT URI}` with the worker portal URL. If it is not already present, you must add `/oauth2/idpresponse` to the end of the URL.
   d. If you have a custom scope, use it to replace `{SCOPE}`. If you do not have a custom scope, replace `{SCOPE}` with `openid`.

   The following is an example of a URI after the modifications above are made:

   ```text
   ```

2. Copy and paste the modified URI from step 1 into your browser and press Enter on your keyboard.
3. Authenticate using your IdP.
4. Copy the authentication code query parameter in the URI. This parameter beings with `code=`. The following is an example of what the response might look like. In this example, copy `code=MCNYDB...` and everything thereafter.
5. Open a terminal and enter the following command after making required modifications listed below:

```
curl --request POST \
--url '{TOKEN ENDPOINT}' \
--header 'content-type: application/x-www-form-urlencoded' \
--data grant_type=authorization_code \
--data 'client_id={CLIENT ID}' \
--data client_secret={CLIENT SECRET} \
--data code={CODE} \
--data 'redirect_uri={REDIRECT URI}'
```

- Replace `{TOKEN ENDPOINT}` with the token endpoint for your OIDC IdP.
- Replace `{CLIENT ID}` with the Client ID from your OAuth client.
- Replace `{CLIENT SECRET}` with the Client Secret from your OAuth client.
- Replace `{CODE}` with the authentication code query parameter you copied in step 4.
- Replace `{REDIRECT URI}` with the worker portal URL.

The following is an example of the cURL request after making the modifications described above:

```
curl --request POST \
--url 'https://example.com/token' \
--header 'content-type: application/x-www-form-urlencoded' \
--data grant_type=authorization_code \
--data 'client_id=f490a907-9bf1-4471-97aa-6bfd159f81ac' \
--data client_secret=client-secret \
--data code=MCNYDB... \
--data 'redirect_uri=https://example.labeling.sagemaker.aws/oauth2/idpresponse'
```

6. This step depends on the type of access_token your IdP returns, a plain text access token or a JWT access token.

- If your IdP does not support JWT access tokens, `access_token` may be plain text (for example, a UUID). The response you see may look similar to the following. In this case, move to step 7.

```
{
    "access_token":"179c144b-fccb-4d96-a28f-eea060f39c13",
    "token_type":"Bearer",
    "expires_in":3600,
    "refresh_token":"ef43e52e-9b4f-410c-8d4c-d5c5ee57631a",
    "scope":"openid"
}
```

- If your IdP supports JWT access tokens, step 5 should generate an access token in JWT format. For example, the response may look similar to the following:

```
{
    "access_token":"eyJh...JV_adQssw5c",
    "refresh_token":"i6mapTIAVSp2oJkgUnCACKKfZxt_H5MBLiqcybBBd04",
    "refresh_token_expires_in":6327,
    "scope":"openid",
    "id_token":"eyJ0eXAiOiJK9...-rDaQzUHl6cQQWNiDpW01_lxJqQEvQ"
}
```
Copy the JWT and decode it. You can use python script or a third party website to decode it. For example, you can go to the website https://jwt.io/ and paste the JWT into the Encoded box to decode it.

Make sure the decoded response contains the following:

- The **Required** SageMaker claims in the table found in Send Required and Optional Claims to Ground Truth and Amazon A2I (p. 708). If it does not, you must reconfigure your OICD IdP to contain these claims.
- The **Issuer** you specified when you set up the IdP workforce.

7. In a terminal and enter the following command after making required modifications listed below:

```
curl -X POST -H 'Authorization: Bearer {ACCESS_TOKEN}' -d '' -k -v {USERINFO ENDPOINT}
```

   a. Replace `{USERINFO ENDPOINT}` with the user info endpoint for your OICD IdP.
   b. Replace `{ACCESS_TOKEN}` with the access token in the response you received in step 7. This is the entry for the "access_token" parameter.

The following is an example of the cURL request after making the modifications described above:

```
curl -X POST -H 'Authorization: Bearer eyJ0eX...' -d '' -k -v https://example.com/userinfo
```

8. The response to the final step in the procedure above may look similar to the following code block.

If the access_token returned in step 6 was plain text, you must verify that this response contains required information. In this case, the response must contain the **Required** SageMaker claims in the table found in Send Required and Optional Claims to Ground Truth and Amazon A2I (p. 708). For example, `sagemaker-groups`, `sagemaker-name`.

```
{
    "sub" : "122",
    "exp" : "10000",
    "sagemaker-groups" : ["group1","group2"],
    "sagemaker-name" : "name",
    "sagemaker-sub" : "122",
    "sagemaker-client_id" : "123456"
}
```

**Next Steps**

Once you've created a private workforce using your IdP and verified your IdP authentication response, you can create work teams using your IdP groups. To learn more, see Manage a Private Workforce (OIDC IdP) (p. 713).

You can restrict worker access to tasks to specific IP addresses, and update or delete your workforce using the SageMaker API. To learn more, see Manage Private Workforce Using the Amazon SageMaker API (p. 716).

**Manage a Private Workforce (OIDC IdP)**

Once you've created a private workforce using your OpenID Connect (OIDC) Identity Provider (IdP), you can manage your workers using your IdP. For example, you can add, remove, and group workers directly through your IdP.
To add workers to an Amazon SageMaker Ground Truth (Ground Truth) labeling job or Amazon Augmented AI (Amazon A2I) human review task, you create work teams using 1-10 IdP groups and assign that work team to the job or task. You assign a work team to a job or task by specifying that work team when you create a labeling job (Ground Truth) or a human review workflow (Amazon A2I).

You can only assign one team to each labeling job or human review workflow. You can use the same team to create multiple labeling jobs or human review tasks. You can also create multiple work teams to work on different labeling jobs or human review tasks.

**Prerequisites**

To create and manage private work teams using your OIDC IdP groups, first you must create a workforce using the SageMaker API operation `CreateWorkforce`. To learn more, see Create a Private Workforce (OIDC IdP) (p. 707).

**Add work teams**

You can use the SageMaker console to create a private work team using your OIDC IdP workforce on the Labeling workforces page under Ground Truth. If you are creating a Ground Truth labeling job, you can also create a private work team while creating a labeling job.

**Note**

You create and manage work teams for Amazon A2I in the Ground Truth area of the SageMaker console.

You can also use the SageMaker API and associated language-specific SDKs to create a private work team.

Use the following procedures to learn how to create a private work team using the SageMaker console and API.

**To create a private work team on the Labeling workforces page (console)**

2. Select Labeling workforces.
3. Select Private.
4. In the Private teams section, select Create private team.
5. In the Team details section, enter a Team name.
6. In the Add workers section, enter the name of a single user group. All workers associated with this group in your IdP are added to this work team.
7. To add more than one user group, select Add new user group and enter the names of the user groups you want to add to this work team. Enter one user group per line.
8. (Optional) For Ground Truth labeling jobs, if you provide an email for workers in your JWT, Ground Truth notifies workers when a new labeling task is available if you select an SNS topic.
9. Select Create private team.

**To create a private work team while creating a Ground Truth labeling job (console)**

2. Select Labeling jobs.
3. Use the instructions in Create a Labeling Job (Console) (p. 544) to create a labeling job. Stop when you get to the Workers section on the second page.
4. Select Private for your worker type.
5. Enter a **Team name**.
6. In the **Add workers** section, enter the name of a single user group under **User groups**. All workers associated with this group in your IdP are added to this work team.

   **Important**
   The group names you specify for **User groups** must match the group names specified in your OIDC IdP.

7. To add more than one user group, select **Add new user group** and enter the names of the user groups you want to add to this work team. Enter one user group per line.
8. Complete all remaining steps to create your labeling job.

The private team that you create is used for this labeling job, and is listed in the **Labeling workforces** section of the SageMaker console.

**To create a private work team using the SageMaker API**

You can create a private work team using the SageMaker API operation **CreateWorkteam**.

When you use this operation, list all user groups that you want included in the work team in the **OidcMemberDefinition** parameter **Groups**.

   **Important**
   The group names you specify for **Groups** must match the group names specified in your OIDC IdP.

For example, if your user group names are group1, group2, and group3 in your OIDC IdP, configure **OidcMemberDefinition** as follows:

```
"OidcMemberDefinition": {
   "Groups": ["group1", "group2", "group3"]
}
```

Additionally, you must give the work team a name using the **WorkteamName** parameter.

**Add or remove IdP groups from work teams**

After you've created a work team, you can use the SageMaker API to manage that work team. Use the **UpdateWorkteam** operation to update the IdP user groups included in that work team.

- Use the **WorkteamName** parameter to identify the work team that you want to update.
- When you use this operation, list all user groups that you want included in the work team in the **OidcMemberDefinition** parameter **Groups**. If a user group is associated with a work team and you do not include it in this list, that user group is no longer associated with this work team.

**Delete a work team**

You can delete a work team using the SageMaker console and SageMaker API.

**To delete a private work team in the SageMaker console**

2. Select **Labeling workforces**.
3. Select **Private**.
4. In the **Private teams** section, select the work team that you want to delete.
5. **Select Delete.**

To delete a private work team (API)

You can delete a private work team using the SageMaker API operation `DeleteWorkteam`.

Manage Individual Workers

When you create a workforce using your own OIDC IdP, you cannot use Ground Truth or Amazon A2I to manage individual workers.

- To add a worker to a work team, add that worker to a group associated with that work team.
- To remove a worker from a work team, remove that worker from all user groups associated with that work team.

Update, Delete, and Describe Your Workforce

You can update, delete, and describe your OIDC IdP workforce using the SageMaker API. The following is a list of API operations that you can use to manage your workforce. For additional details, including how you can locate your workforce name, see Manage Private Workforce Using the Amazon SageMaker API (p. 716).

- **UpdateWorkforce** – You may want to update a workforce created using your own OIDC IdP to specify a different authorization endpoint, token endpoint, or issuer. You can update any parameter found in `OidcConfig` using this operation.

You can only update your OIDC IdP configuration when there are no work teams associated with your workforce. To learn how to delete work teams, see Delete a work team (p. 715).

- **DeleteWorkforce** – Use this operation to delete your private workforce. If you have any work teams associated with your workforce, you must delete those work teams before you delete your work force. For more information, see Delete a work team (p. 715).

- **DescribeWorkforce** – Use this operation to list private workforce information, including workforce name, Amazon Resource Name (ARN), and, if applicable, allowed IP address ranges (CIDRs).

Manage Private Workforce Using the Amazon SageMaker API

You can use Amazon SageMaker API operations to manage, update, and delete your private workforce. For each API operation linked on this page, you can find a list of supported language-specific SDKs and their documentation in the See Also section of the API documentation.

Find Your Workforce Name

Some of the SageMaker workforce-related API operations require your workforce name as input. You can see your Amazon Cognito or OIDC IdP private and vendor workforce names in an AWS Region using the `ListWorkforces` API operation in that AWS Region.

If you created your workforce using your own OIDC IdP, you can find your workforce name in the Ground Truth area of the SageMaker console.

To find your workforce name in the SageMaker console

2. Select Labeling workforces.
3. Select Private.

4. In the Private workforce summary section, locate your workforce ARN. Your workforce name is located at the end of this ARN. For example, if the ARN is arn:aws:sagemaker:us-east-2:111122223333:workforce/example-workforce, the workforce name is example-workforce.

Restrict Worker Access to Tasks to Allowable IP Addresses

By default, a workforce isn't restricted to specific IP addresses. You can use the UpdateWorkforce operation to require that workers use a specific range of IP addresses (CIDRs) to access tasks. If you specify one or more CIDRs, workers who attempt to access tasks using any IP address outside the specified ranges are denied and will get a HTTP 204 No Content error message on the worker portal. You can specify up to 10 CIDR values using UpdateWorkforce.

After you have restricted your workforce to one or more CIDRs, the output of UpdateWorkforce lists all allowable CIDRs. You can also use the DescribeWorkforce operation to view all allowable CIDRs for a workforce.

Update OIDC Identity Provider Workforce Configuration

You may want to update a workforce created using your own OIDC IdP to specify a different authorization endpoint, token endpoint, or issuer. You can update any parameter found in OidcConfig using the UpdateWorkforce operation.

Important
You can only update your OIDC IdP configuration when there are no work teams associated with your workforce. You can delete a private work team using the DeleteWorkteam operation.

Delete a Private Workforce

You can only have one private workforce in each AWS Region. You may want to delete your private workforce in an AWS Region when:

- You want to create a workforce using a new Amazon Cognito user pool.
- You have already created a private workforce using Amazon Cognito and you want to create a workforce using your own OpenID Connect (OIDC) Identity Provider (IdP).

To delete a private workforce, use the DeleteWorkforce API operation. If you have any work teams associated with your workforce, you must delete those work teams before you delete your workforce. You can delete a private work team using the DeleteWorkteam operation.

Track Worker Performance

Amazon SageMaker Ground Truth logs worker events to Amazon CloudWatch, such as when a worker starts or submits a task. Use Amazon CloudWatch metrics to measure and track throughput across a team or for individual workers.

Important
Worker event tracking is not available for Amazon Augmented AI human review workflows.

Enable Tracking

During the set-up process for a new work team, the permissions for Amazon CloudWatch logging of worker events are created. Since this feature was added in August 2019, work teams created prior to that may not have the correct permissions. If all of your work teams were created before August 2019, create
a new work team. It does not need any members and may be deleted after creation, but by creating it, you establish the permissions and apply them to all of your work teams, regardless of when they were created.

Examine Logs

After tracking is enabled, the activity of your workers is logged. Open the Amazon CloudWatch console and choose Logs in the navigation pane. You should see a log group named `aws/sagemaker/groundtruth/WorkerActivity`.

Each completed task is represented by a log entry, which contains information about the worker, their team, the job, when the task was accepted, and when it was submitted.

Example Log entry

```json
{
  "worker_id": "cd449a289e129409",
  "cognito_user_pool_id": "us-east-2_IpicJXXX",
  "cognito_sub_id": "d6947aeb-0650-447a-ab5d-894db61017fd",
  "task_accepted_time": "Wed Aug 14 16:00:59 UTC 2019",
  "task_submitted_time": "Wed Aug 14 16:01:04 UTC 2019",
  "task_returned_time": "",
  "task_declined_time": "",
  "workteam_arn": "arn:aws:sagemaker:us-east-2:############:workteam/private-crowd/Sample-labeling-team",
  "labeling_job_arn": "arn:aws:sagemaker:us-east-2:############:labeling-job/metrics-demo",
  "work_requester_account_id": "############",
  "job_reference_code": "############",
  "job_type": "Private",
  "event_type": "TasksSubmitted",
  "event_timestamp": "1565798464"
}
```

A useful data point in each event is the `cognito_sub_id`. You can match that to an individual worker.

2. Under the Ground Truth section, choose Workforces.
3. Choose Private.
4. Choose the name of a team in the Private teams section.
5. In the Team summary section, choose the user group identified under Amazon Cognito user group. That will take you to the group in the Amazon Cognito console.
6. The Group page lists the users in the group. Choose any user's link in the Username column to see more information about the user, including a unique sub ID.

To get information about all of the team's members, use the ListUsers action (examples) in the Amazon Cognito API.

Use Log Metrics

If you don't want to write your own scripts to process and visualize the raw log information, Amazon CloudWatch metrics provide insights into worker activity for you.

To view metrics

2. In the navigation pane, choose Metrics.
3. Choose the AWS/SageMaker/Workteam name space, then explore the available metrics (p. 3663). For example, selecting the Workteam and Workforce metrics lets you calculate the average time per submitted task for a specific labeling job.

For more information, see Using Amazon CloudWatch Metrics.

Create and manage Amazon SNS topics for your work teams

Use the procedures in this topic when you want to:

- Create a topic to which you want an existing work team to subscribe.
- Create a topic before you've created a work team.
- Create or modify the work team with an API call, and specify a topic Amazon Resource Name (ARN).

If you create a work team using the console, the console provides an option to create a new topic for the team so that you don't have to perform these steps.

**Important**
The Amazon SNS feature is not supported by Amazon A2I. If you subscribe your work team to an Amazon SNS topic, workers will only receive notifications about Ground Truth labeling jobs. Workers will not receive notifications about new Amazon A2I human review tasks.

Create the Amazon SNS topic

The steps for creating Amazon SNS topics for work team notifications are similar to the steps in Getting Started in the Amazon SNS Developer Guide, with one significant addition—you must add an access policy so that Amazon SageMaker can publish messages to the topic on your behalf.

**To add the policy when you create the topic**

2. In Create topic, enter the name of your topic and then choose Next steps.
4. In the JSON editor, find the Resource property, which displays the topic's ARN.
5. Copy the Resource ARN value.
6. Before the final closing brace (}), add the following policy.

```json
, {
  "Sid": "AwsSagemaker_SnsAccessPolicy",
  "Effect": "Allow",
  "Principal": {
    "Service": "sagemaker.amazonaws.com"
  },
  "Action": "sns:Publish",
  "Resource": "arn:partition:sns:region:111122223333:MyTopic", # ARN of the topic you copied in the previous step
  "Condition": {
    " ArnLike": {
      "aws:SourceArn": "arn:partition:sagemaker:region:111122223333:workteam/*" # Workteam ARN
    },
    "StringEquals": {
      "aws:SourceAccount": "111122223333" # SNS topic account
    }
  }
}
```
7. Create the topic.

After you create the topic, it appears in your Topics summary screen. For more information about creating topics, see Creating a Topic in the Amazon SNS Developer Guide.

Manage worker subscriptions

If you subscribe a work team to a topic after you’ve already created the work team, the individual work team members who were added to the team when the work team was created are not automatically subscribed to the topic. For information about subscribing workers’ email addresses to the topic, see Subscribing an Endpoint to an Amazon SNS Topic in the Amazon SNS Developer Guide.

The only situation in which workers are automatically subscribed to your topic is when you create or import an Amazon Cognito user group at the time that you create a work team and set up the topic subscription when you create that work team. For more information about creating and managing your workteams with Amazon Cognito, see Create Work Teams (Amazon Cognito Console) (p. 706).

Crowd HTML Elements Reference

Crowd HTML Elements are web components, a web standard that abstracts HTML markup, CSS, and JavaScript functionality into an HTML tag or set of tags. Amazon SageMaker provides customers with the ability to design their own custom task templates in HTML.

As a starting point, you can use a template built using Crowd HTML Elements from one of the following GitHub repositories:

- Example task UIs for Amazon SageMaker Ground Truth
- Over 60 example task UIs for Amazon Augmented AI (A2I)

These repositories include templates designed for audio, image, text, video, and other types of data labeling and annotation tasks.

For more information about how to implement custom templates in Amazon SageMaker Ground Truth, see Creating Custom Labeling Workflows (p. 509). To learn more about custom templates in Amazon Augmented AI, see Create Custom Worker Task Templates (p. 3448).

SageMaker Crowd HTML Elements

The following is a list of Crowd HTML Elements that make building a custom template easier and provide a familiar UI for workers. These elements are supported in Ground Truth, Augmented AI, and Mechanical Turk.

Topics

- crowd-alert (p. 721)
- crowd-badge (p. 723)
- crowd-button (p. 724)
- crowd-bounding-box (p. 726)
- crowd-card (p. 730)
- crowd-checkbox (p. 732)
- crowd-classifier (p. 734)
• crowd-classifier-multi-select (p. 736)
• crowd-entity-annotation (p. 738)
• crowd-fab (p. 741)
• crowd-form (p. 742)
• crowd-icon-button (p. 743)
• crowd-image-classifier (p. 745)
• crowd-image-classifier-multi-select (p. 748)
• crowd-input (p. 750)
• crowd-instance-segmentation (p. 753)
• crowd-instructions (p. 756)
• crowd-keypoint (p. 758)
• crowd-line (p. 762)
• crowd-modal (p. 765)
• crowd-polygon (p. 766)
• crowd-polyline (p. 771)
• crowd-radio-button (p. 775)
• crowd-radio-group (p. 777)
• crowd-semantic-segmentation (p. 779)
• crowd-slider (p. 782)
• crowd-tab (p. 784)
• crowd-tabs (p. 785)
• crowd-text-area (p. 787)
• crowd-toast (p. 789)
• crowd-toggle-button (p. 790)

**crowd-alert**

A message that alerts the worker to a current situation.

See an interactive example of an HTML template that uses this Crowd HTML Element in [CodePen](https://codepen.io).

The following is an example of a Liquid template that uses the `<crowd-alert>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <div id="errorBox"></div>

  <crowd-keypoint
    src="{{ task.input.taskObject | grant_read_access }}"
    labels="['Item A', 'Item B', 'Item C']"
    header="Please locate the centers of each item."
    name="annotatedResult">
    <short-instructions>
      Describe your task briefly here and give examples
    </short-instructions>
    <full-instructions>
      Give additional instructions and good/bad examples here
  </crowd-keypoint>
</crowd-form>
```
Attributes

The following attributes are supported by this element.

**dismissible**

A Boolean switch that, if present, allows the message to be closed by the worker.

**type**

A string that specifies the type of message to be displayed. The possible values are "info" (the default), "success", "error", and "warning".
Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 742)
- **Child elements**: none

See Also

For more information, see the following.

- Use Amazon SageMaker Ground Truth to Label Data (p. 370)
- Crowd HTML Elements Reference (p. 720)

crowd-badge

An icon that floats over the top right corner of another element to which it is attached.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a template that uses the `<crowd-badge>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <crowd-image-classifier
    name="crowd-image-classifier"
    src="https://unsplash.com/photos/NLUkAA-nDdE"
    header="Choose the correct category for this image."
    categories="["Person", "Umbrella", "Chair", "Dolphin"]"
  >
    <full-instructions header="Classification Instructions">
      <p>Read the task carefully and inspect the image.</p>
      <p>Choose the appropriate label that best suits the image.</p>
    </full-instructions>

    <short-instructions id="short-instructions">
      <p>Read the task carefully and inspect the image.</p>
      <p>Choose the appropriate label that best suits the image.</p>
      <crowd-badge icon="star" for="short-instructions"/>
    </short-instructions>
  </crowd-image-classifier>
</crowd-form>
```

Attributes

The following attributes are supported by this element.

**for**

A string that specifies the ID of the element to which the badge is attached.

**icon**

A string that specifies the icon to be displayed in the badge. The string must be either the name of an icon from the open-source `iron-icons` set, which is pre-loaded, or the URL to a custom icon.
This attribute overrides the label attribute.

The following is an example of the syntax that you can use to add an iron-icon to a <crowd-badge> HTML element. Replace icon-name with the name of the icon you'd like to use from this [Icons set].

```html
<crowd-badge icon="icon-name" for="short-instructions"/>
```

**label**

The text to display in the badge. Three characters or less is recommended because text that is too large will overflow the badge area. An icon can be displayed instead of text by setting the icon attribute.

**Element Hierarchy**

This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 742)
- **Child elements**: none

**See Also**

For more information, see the following.

- Use Amazon SageMaker Ground Truth to Label Data (p. 370)
- Crowd HTML Elements Reference (p. 720)

**crowd-button**

A styled button that represents some action.

See an interactive example of an HTML template that uses this Crowd HTML Element in [CodePen](https://codepen.io).

The following is an example of a template that uses the <crowd-button> element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <crowd-image-classifier
    name="crowd-image-classifier"
    src="https://unsplash.com/photos/NLUkAA-nDdE"
    header="Please select the correct category for this image"
    categories="[Person', 'Umbrella', 'Chair', 'Dolphin']"
  >
    <full-instructions header="Classification Instructions">
      <p>Read the task carefully and inspect the image.</p>
      <p>Choose the appropriate label that best suits the image.</p>
    </full-instructions>
    <short-instructions>
      <p>Read the task carefully and inspect the image.</p>
      <p>Choose the appropriate label that best suits the image.</p>
    </short-instructions>
  </crowd-image-classifier>
</crowd-form>
```
Attributes

The following attributes are supported by this element.

disabled

A Boolean switch that, if present, displays the button as disabled and prevents clicks.

form-action

A switch that either submits its parent crowd-form (p. 742) element, if set to "submit", or resets its parent <crowd-form> element, if set to "reset".

href

The URL to an online resource. Use this property if you need a link styled as a button.

icon

A string that specifies the icon to be displayed next to the button's text. The string must be the name of an icon from the open-source iron-icons set, which is pre-loaded. For example, to insert the search iron-icon, use the following:

```
<crowd-button>
  <iron-icon icon="search"/>
</crowd-button>
```

The icon is positioned to either the left or the right of the text, as specified by the icon-align attribute.

To use a custom icon see icon-url.

icon-align

The left or right position of the icon relative to the button's text. The default is "left".

icon-url

A URL to a custom image for the icon. A custom image can be used in place of a standard icon that is specified by the icon attribute.

loading

A Boolean switch that, if present, displays the button as being in a loading state. This attribute has precedence over the disabled attribute if both attributes are present.

target

When you use the href attribute to make the button act as a hyperlink to a specific URL, the target attribute optionally targets a frame or window where the linked URL should load.

variant

The general style of the button. Use "primary" for primary buttons, "normal" for secondary buttons, "link" for tertiary buttons, or "icon" to display only the icon without text.
Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 742)
- **Child elements**: none

See Also

For more information, see the following.

- Use Amazon SageMaker Ground Truth to Label Data (p. 370)
- Crowd HTML Elements Reference (p. 720)

crowd-bounding-box

A widget for drawing rectangles on an image and assigning a label to the portion of the image that is enclosed in each rectangle.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that uses the `<crowd-bounding-box>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template. For more examples, see this GitHub repository.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <crowd-bounding-box
    name="annotatedResult"
    src="{{ task.input.taskObject | grant_read_access }}"
    header="Draw bounding boxes around all the cats and dogs in this image"
    labels=["'Cat', 'Dog']"
  >
    <full-instructions header="Bounding Box Instructions">
      <p>Use the bounding box tool to draw boxes around the requested target of interest:</p>
      <ol>
        <li>Draw a rectangle using your mouse over each instance of the target.</li>
        <li>Make sure the box does not cut into the target, leave a 2 - 3 pixel margin</li>
        <li>When targets are overlapping, draw a box around each object, include all contiguous parts of the target in the box. Do not include parts that are completely overlapped by another object.</li>
        <li>Do not include parts of the target that cannot be seen, even though you think you can interpolate the whole shape of the target.</li>
        <li>Avoid shadows, they're not considered as a part of the target.</li>
        <li>If the target goes off the screen, label up to the edge of the image.</li>
      </ol>
    </full-instructions>
    <short-instructions>
      Draw boxes around the requested target of interest.
    </short-instructions>
  </crowd-bounding-box>
</crowd-form>
```
Attributes

The following attributes are supported by this element.

header

The text to display above the image. This is typically a question or simple instruction for the worker.

initial-value

An array of JSON objects, each of which sets a bounding box when the component is loaded. Each JSON object in the array contains the following properties. Bounding boxes set via the initial-value property can be adjusted and whether or not a worker answer was adjusted is tracked via an initialValueModified boolean in the worker answer output.

- **height** – The height of the box in pixels.
- **label** – The text assigned to the box as part of the labeling task. This text must match one of the labels defined in the labels attribute of the <crowd-bounding-box> element.
- **left** – Distance of the top-left corner of the box from the left side of the image, measured in pixels.
- **top** – Distance of the top-left corner of the box from the top of the image, measured in pixels.
- **width** – The width of the box in pixels.

You can extract the bounding box initial value from a manifest file of a previous job in a custom template using the Liquid templating language:

```liquid
initial-value="[
{% for box in task.input.manifestLine.label-attribute-name-from-prior-job.annotations %}
  {% capture class_id %}{{ box.class_id }}{% endcapture %}
  {% assign label = task.input.manifestLine.label-attribute-name-from-prior-job
  metadata.class-map[class_id] %}
  {
    label: {{label | to_json}},
    left: {{box.left}},
    top: {{box.top}},
    width: {{box.width}},
    height: {{box.height}},
  },
{% endfor %}
]"
```

labels

A JSON formatted array of strings, each of which is a label that a worker can assign to the image portion enclosed by a rectangle. **Limit:** 10 labels.

name

The name of this widget. It's used as a key for the widget's input in the form output.

src

The URL of the image on which to draw bounding boxes.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements:** crowd-form (p. 742)
• **Child elements**: full-instructions (p. 728), short-instructions (p. 728)

**Regions**

The following regions are required by this element.

**full-instructions**

General instructions about how to draw bounding boxes.

**short-instructions**

Important task-specific instructions that are displayed in a prominent place.

**Output**

The following output is supported by this element.

**boundingBoxes**

An array of JSON objects, each of which specifies a bounding box that has been created by the worker. Each JSON object in the array contains the following properties.

- **height** – The height of the box in pixels.
- **label** – The text assigned to the box as part of the labeling task. This text must match one of the labels defined in the `labels` attribute of the `<crowd-bounding-box>` element.
- **left** – Distance of the top-left corner of the box from the left side of the image, measured in pixels.
- **top** – Distance of the top-left corner of the box from the top of the image, measured in pixels.
- **width** – The width of the box in pixels.

**inputImageProperties**

A JSON object that specifies the dimensions of the image that is being annotated by the worker. This object contains the following properties.

- **height** – The height, in pixels, of the image.
- **width** – The width, in pixels, of the image.

**Example: Sample Element Outputs**

The following are samples of outputs from common use scenarios for this element.

**Single Label, Single Box / Multiple Label, Single Box**

```
[
  {
    "annotatedResult": {
      "boundingBoxes": [
        {
          "height": 401,
          "label": "Dog",
          "left": 243,
          "top": 117,
          "width": 187
        }
      ],
      "inputImageProperties": {
        "height": 533,
        "width": 728
      }
    }
  ]
```
Single Label, Multiple Box

[
  {
    "annotatedResult": {
      "boundingBoxes": [
        {
          "height": 401,
          "label": "Dog",
          "left": 243,
          "top": 117,
          "width": 187
        },
        {
          "height": 283,
          "label": "Dog",
          "left": 684,
          "top": 120,
          "width": 116
        }
      ],

**crowd-card**

A box with an elevated appearance for displaying information.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a template designed for sentiment analysis tasks that uses the `<crowd-card>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<style>
  h3 {
    margin-top: 0;
  }

  crowd-card {
    width: 100%;
  }

  .card {
    margin: 10px;
  }

  .left {
    width: 70%;
    margin-right: 10px;
    display: inline-block;
    height: 200px;
  }

  .right {
    width: 20%;
    height: 200px;
    display: inline-block;
  }
</style>

<crowd-form>
  <short-instructions>
    Your short instructions here.
  </short-instructions>

  <full-instructions>
    Your full instructions here.
  </full-instructions>

  <div class="left">
    <h3>What sentiment does this text convey?</h3>
    <crowd-card>
      <div class="card">
        730
      </div>
    </crowd-card>
  </div>
</crowd-form>
```
Nothing is great.
</div>
</crowd-card>
</div>

<div class="right">
<h3>Select an option</h3>
<select name="sentiment1" style="font-size: large" required>
<option value="">(Please select)</option>
<option>Negative</option>
<option>Neutral</option>
<option>Positive</option>
<option>Text is empty</option>
</select>
</div>

<div class="left">
<h3>What sentiment does this text convey?</h3>
</div>
</crowd-form>

Attributes

The following attributes are supported by this element.

heading

The text displayed at the top of the box.

image

A URL to an image to be displayed within the box.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 742)
- **Child elements**: none

See Also

For more information, see the following.
crowd-checkbox

A UI component that can be checked or unchecked allowing a user to select multiple options from a set.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that uses the `<crowd-checkbox>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  
  <p>Find the official website for: <strong>{{ task.input.company }}</strong></p>
  <p>Do not give Yelp pages, LinkedIn pages, etc.</p>
  <p>Include the http:// prefix from the website</p>
  <crowd-input name="website" placeholder="http://example.com"></crowd-input>

  <crowd-checkbox name="website-found">Website Found</crowd-checkbox>

</crowd-form>
```

**Attributes**

The following attributes are supported by this element.

**checked**

A Boolean switch that, if present, displays the check box as checked.

The following is an example of the syntax used to check a checkbox by default.

```html
<crowd-checkbox name="checkBox" value="checked" checked>This box is checked</crowd-checkbox>
```

**disabled**

A Boolean switch that, if present, displays the check box as disabled and prevents it from being checked.

The following is an example of the syntax used to disable a checkbox.

```html
<crowd-checkbox name="disabledCheckBox" value="Disabled" disabled>Cannot be selected</crowd-checkbox>
```

**name**

A string that is used to identify the answer submitted by the worker. This value will match a key in the JSON object that specifies the answer.

**required**

A Boolean switch that, if present, requires the worker to provide input.
The following is an example of the syntax used to require a checkbox be selected.

```xml
<crowd-checkbox name="work_verified" required>Instructions were clear</crowd-checkbox>
```

**value**

A string used as the name for the checkbox state in the output. Defaults to "on" if not specified.

**Element Hierarchy**

This element has the following parent and child elements.

- **Parent elements**: `crowd-form` (p. 742)
- **Child elements**: none

**Output**

Provides a JSON object. The `name` string is the object name and the `value` string is the property name for a Boolean value based on the checkbox state; true if checked, false if not checked.

**Example : Sample Element Outputs**

**Using the same name value for multiple boxes.**

```xml
<!-- INPUT -->
<div><crowd-checkbox name="image_attributes" value="blurry"> Blurry </crowd-checkbox></div>
<div><crowd-checkbox name="image_attributes" value="dim"> Too Dim </crowd-checkbox></div>
<div><crowd-checkbox name="image_attributes" value="exposed"> Too Bright </crowd-checkbox></div>
```

//Output with "blurry" and "dim" checked

```json
[
  {
    "image_attributes": {
      "blurry": true,
      "dim": true,
      "exposed": false
    }
  }
]
```

Note that all three color values are properties of a single object.

**Using different name values for each box.**

```xml
<!-- INPUT -->
<div><crowd-checkbox name="Stop" value="Red"> Red </crowd-checkbox></div>
<div><crowd-checkbox name="Slow" value="Yellow"> Yellow </crowd-checkbox></div>
<div><crowd-checkbox name="Go" value="Green"> Green </crowd-checkbox></div>
```

//Output with "Red" checked

```json
[
  {
    "Go": {
      "Green": false
    }
  }
]```
"Slow": {
  "Yellow": false
},
"Stop": {
  "Red": true
}
]}

See Also

For more information, see the following.

- Use Amazon SageMaker Ground Truth to Label Data (p. 370)
- Crowd HTML Elements Reference (p. 720)

crowd-classifier

A widget for classifying non-image content, such as audio, video, or text.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of an HTML worker task template built using crowd-classifier. This example uses the Liquid template language to automate:

- Label categories in the categories parameter
- The objects that are being classified in the classification-target parameter.

Copy the following code and save it in a file with the extension .html. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <crowd-classifier
    name="category"
    categories="{{ task.input.labels | to_json | escape }}"
    header="What type of a document is this?"
  >
    <classification-target>
      <iframe style="width: 100%; height: 600px;" src="{{ task.input.taskObject | grant_read_access }}" type="application/pdf"></iframe>
    </classification-target>

    <full-instructions header="Document Classification Instructions">
      <p>Read the task carefully and inspect the document.</p>
      <p>Choose the appropriate label that best suits the document.</p>
    </full-instructions>

    <short-instructions>
      Please choose the correct category for the document
    </short-instructions>
  </crowd-classifier>
</crowd-form>
```

Attributes

The following attributes are supported by this element.
categories
A JSON formatted array of strings, each of which is a category that a worker can assign to the text. You should include "other" as a category, otherwise the worker may not be able to provide an answer.

header
The text to display above the image. This is typically a question or simple instruction for the worker.

name
The name of this widget. It is used as a key for the widget's input in the form output.

Element Hierarchy
This element has the following parent and child elements.
- **Parent elements**: crowd-form (p. 742)
- **Child elements**: classification-target (p. 735), full-instructions (p. 735), short-instructions (p. 735)

Regions
The following regions are supported by this element.

classification-target
The content to be classified by the worker. This can be plain text or HTML. Examples of how the HTML can be used include *but are not limited to* embedding a video or audio player, embedding a PDF, or performing a comparison of two or more images.

full-instructions
General instructions about how to do text classification.

short-instructions
Important task-specific instructions that are displayed in a prominent place.

Output
The output of this element is an object using the specified name value as a property name, and a string from the categories as the property's value.

**Example : Sample Element Outputs**
The following is a sample of output from this element.

```
[
  {
    "<name>": {
      "label": "<value>"
    }
  }
]
```

See Also
For more information, see the following.
- **Use Amazon SageMaker Ground Truth to Label Data (p. 370)**
Crowd HTML Elements Reference (p. 720)

crowd-classifier-multi-select

A widget for classifying various forms of content—such as audio, video, or text—into one or more categories. The content to classify is referred to as an object.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of an HTML worker task template built using this element. Copy the following code and save it in a file with the extension .html. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
  <crowd-classifier-multi-select
    name="category"
    categories="['Positive', 'Negative', 'Neutral']"
    header="Select the relevant categories"
    exclusion-category="{ text: 'None of the above' }"
  >
    <classification-target>
      {{ task.input.taskObject }}
    </classification-target>
  </crowd-classifier-multi-select>
</crowd-form>

Attributes

The following attributes are supported by the crowd-classifier-multi-select element. Each attribute accepts a string value or string values.

categories

Required. A JSON-formatted array of strings, each of which is a category that a worker can assign to the object.

header

Required. The text to display above the image. This is typically a question or simple instruction for workers.

name

Required. The name of this widget. In the form output, the name is used as a key for the widget's input.
**exclusion-category**

Optional. A JSON-formatted string with the following format: 
```
{  text: 'default-value' }
```
This attribute sets a default value that workers can choose if none of the labels applies to the object shown in the worker UI.

**Element Hierarchy**

This element has the following parent and child elements:

- **Parent elements**: crowd-form (p. 742)
- **Child elements**: classification-target (p. 735), full-instructions (p. 735), short-instructions (p. 735)

**Regions**

This element uses the following regions.

**classification-target**

The content to be classified by the worker. Content can be plain text or an object that you specify in the template using HTML. For example, you can use HTML elements to include a video or audio player, embedding a PDF file, or include a comparison of two or more images.

**full-instructions**

General instructions about how to classify text.

**short-instructions**

Important task-specific instructions. These instructions are displayed prominently.

**Output**

The output of this element is an object that uses the specified name value as a property name, and a string from categories as the property's value.

**Example : Sample Element Outputs**

The following is a sample of output from this element.

```
[
  {
    "<name>": {
      labels: ["label_a", "label_b"]
    }
  }
]
```

Amazon SageMaker Developer Guide
SageMaker Crowd HTML Elements

crowd-entity-annotation
A widget for labeling words, phrases, or character strings within a longer text. Workers select a label, and
highlight the text that the label applies to.

Important: Self-contained Widget

Do not use <crowd-entity-annotation> element with the <crowd-form> element. It
contains its own form submission logic and Submit button.
See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.
The following is an example of a template that uses the <crowd-entity-annotation> element. Copy
the following code and save it in a ﬁle with the extension .html. Open the ﬁle in any browser to preview
and interact with this template.
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-entity-annotation
name="crowd-entity-annotation"
header="Highlight parts of the text below"
labels="[{'label': 'person', 'shortDisplayName': 'per', 'fullDisplayName': 'Person'},
{'label': 'date', 'shortDisplayName': 'dat', 'fullDisplayName': 'Date'}, {'label':
'company', 'shortDisplayName': 'com', 'fullDisplayName': 'Company'}]"
text="Amazon SageMaker Ground Truth helps you build highly accurate training datasets for
machine learning quickly."
>
<full-instructions header="Named entity recognition instructions">
<ol>
<li><strong>Read</strong> the text carefully.</li>
<li><strong>Highlight</strong> words, phrases, or sections of the text.</li>
<li><strong>Choose</strong> the label that best matches what you have highlighted.</
li>
<li>To <strong>change</strong> a label, choose highlighted text and select a new
label.</li>
<li>To <strong>remove</strong> a label from highlighted text, choose the X next to
the abbreviated label name on the highlighted text.</li>
<li>You can select all of a previously highlighted text, but not a portion of it.</
li>
</ol>
</full-instructions>
<short-instructions>
Apply labels to words or phrases.
</short-instructions>
<div id="additionalQuestions" style="margin-top: 20px">
<h3>
What is the overall subject of this text?
</h3>
<crowd-radio-group>
<crowd-radio-button name="tech" value="tech">Technology</crowd-radio-button>
<crowd-radio-button name="politics" value="politics">Politics</crowd-radio-button>
</crowd-radio-group>
</div>
</crowd-entity-annotation>
<script>
document.addEventListener('all-crowd-elements-ready', () => {
document
.querySelector('crowd-entity-annotation')
.shadowRoot
.querySelector('crowd-form')
.form
.appendChild(additionalQuestions);

738


Attributes

The following attributes are supported by this element.

header

The text to display above the image. This is typically a question or simple instruction for the worker.

initial-value

A JSON formatted array of objects, each of which defines an annotation to apply to the text at initialization. Objects contain a label value that matches one in the labels attribute, an integer startOffset value for labeled span's starting unicode offset, and an integer endOffset value for the ending unicode offset.

Example

```json
[
  {
    label: 'person',
    startOffset: 0,
    endOffset: 16
  },
  ...
]
```

labels

A JSON formatted array of objects, each of which contains:

- **label** (required): The name used to identify entities.
- **fullDisplayName** (optional): Used for the label list in the task widget. Defaults to the label value if not specified.
- **shortDisplayName** (optional): An abbreviation of 3-4 letters to display above selected entities. Defaults to the label value if not specified.

  **shortDisplayName is highly recommended**

  Values displayed above the selections can overlap and create difficulty managing labeled entities in the workspace. Providing a 3-4 character shortDisplayName for each label is highly recommended to prevent overlap and keep the workspace manageable for your workers.

Example

```json
[
  {
    label: 'person',
    shortDisplayName: 'per',
    fullDisplayName: 'person'
  }
]
```

name

Serves as the widget's name in the DOM. It is also used as the label attribute name in form output and the output manifest.
text

The text to be annotated. The templating system escapes quotes and HTML strings by default. If your code is already escaped or partially escaped, see Variable filters (p. 514) for more ways to control escaping.

Element Hierarchy

This element has the following parent and child elements.

- **Child elements:** full-instructions (p. 740), short-instructions (p. 740)

Regions

The following regions are supported by this element.

**full-instructions**

General instructions about how to work with the widget.

**short-instructions**

Important task-specific instructions that are displayed in a prominent place.

Output

The following output is supported by this element.

**entities**

A JSON object that specifies the start, end, and label of an annotation. This object contains the following properties.

- **label** – The assigned label.
- **startOffset** – The Unicode offset of the beginning of the selected text.
- **endOffset** – The Unicode offset of the first character after the selection.

Example : Sample Element Outputs

The following is a sample of the output from this element.

```json
{
  "myAnnotatedResult": {
    "entities": [
      {
        "endOffset": 54,
        "label": "person",
        "startOffset": 47
      },
      {
        "endOffset": 97,
        "label": "event",
        "startOffset": 93
      },
      {
        "endOffset": 219,
        "label": "date",
        "startOffset": 212
      }
    ]
  }
}
```
Amazon SageMaker Developer Guide
SageMaker Crowd HTML Elements

}

}

]

}

"endOffset": 271,
"label": "location",
"startOffset": 260

button1,
].forEach(function(button) {
button.addEventListener('click', function() {
document.querySelector('crowd-form').submit();

741


Attributes

The following attributes are supported by this element.

disabled

A Boolean switch that, if present, displays the floating button as disabled and prevents clicks.

icon

A string that specifies the icon to be displayed in the center of the button. The string must be either the name of an icon from the open-source iron-icons set, which is pre-loaded, or the URL to a custom icon.

The following is an example of the syntax that you can use to add an iron-icon to a <crowd-fab> HTML element. Replace icon-name with the name of the icon you’d like to use from this Icons set.

```html
<crowd-fab "id="button1" icon="icon-name" title="Issue"/>
```

label

A string consisting of a single character that can be used instead of an icon. Emojis or multiple characters may result in the button displaying an ellipsis instead.

title

A string that will display as a tool tip when the mouse hovers over the button.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 742)
- **Child elements**: none

See Also

For more information, see the following.

- Use Amazon SageMaker Ground Truth to Label Data (p. 370)
- Crowd HTML Elements Reference (p. 720)

crowd-form

The form wrapper for all custom tasks. Sets and implements important actions for the proper submission of your form data.

If a crowd-button (p. 724) of type "submit" is not included inside the <crowd-form> element, it will automatically be appended within the <crowd-form> element.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of an image classification template that uses the <crowd-form> element. Copy the following code and save it in a file with the extension .html. Open the file in any browser to preview and interact with this template.
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
    <crowd-image-classifier
        src="${image_url}"
        categories="['Cat', 'Dog', 'Bird', 'None of the Above']"
        header="Choose the correct category for the image"
        name="category"

    <full-instructions header="Classification Instructions">
        <p>Read the task carefully and inspect the image.</p>
        <p>Choose the appropriate label that best suits the image. Use the <b>None of the Above</b> option if none of the other labels suit the image.</p>
    </full-instructions>

</crowd-image-classifier>
</crowd-form>

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: none
- **Child elements**: Any of the [UI Template](p. 720) elements

Element Events

The `crowd-form` element extends the standard HTML `form` element and inherits its events, such as `onclick` and `onsubmit`.

See Also

For more information, see the following.

- Use Amazon SageMaker Ground Truth to Label Data (p. 370)
- Crowd HTML Elements Reference (p. 720)

crowd-icon-button

A button with an image placed in the center. When the user touches the button, a ripple effect emanates from the center of the button.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template designed for image classification that uses the `<crowd-icon-button>` element. This template uses JavaScript to enable workers to report issues with the worker UI. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
Attributes

The following attributes are supported by this element.

**disabled**
A Boolean switch that, if present, displays the button as disabled and prevents clicks.

**icon**
A string that specifies the icon to be displayed in the center of the button. The string must be either the name of an icon from the open-source *iron-icons* set, which is pre-loaded, or the URL to a custom icon.

The following is an example of the syntax that you can use to add an iron-icon to a `<crowd-icon-button>` HTML element. Replace *icon-name* with the name of the icon you'd like to use from this *Icons* set.

```
<crowd-icon-button id="button1" icon="icon-name" title="Issue"/>
```

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 742)
• **Child elements**: none

**See Also**

For more information, see the following.

- Use Amazon SageMaker Ground Truth to Label Data (p. 370)
- Crowd HTML Elements Reference (p. 720)

**crowd-image-classifier**

A widget for classifying an image. Use one of the following supported image formats: APNG, BMP, GIF, ICO, JPEG, PNG, SVG. Images do not have a size limit.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of an image classification template that uses the `<crowd-image-classifier>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
  <crowd-image-classifier
    src="${image_url}"
    categories="['Cat', 'Dog', 'Bird', 'None of the Above']"
    header="Choose the correct category for the image"
    name="category">
    <short-instructions>
      <p>Read the task carefully and inspect the image.</p>
      <p>Choose the appropriate label that best suits the image.</p>
    </short-instructions>
    <full-instructions header="Classification Instructions">
      <p>Read the task carefully and inspect the image.</p>
      <p>Choose the appropriate label that best suits the image. Use the &lt;b&gt;None of the Above&lt;/b&gt; option if none of the other labels suit the image.</p>
    </full-instructions>
  </crowd-image-classifier>
</crowd-form>
```

**Attributes**

The following attributes are required by this element.

**categories**

A JSON formatted array of strings, each of which is a category that a worker can assign to the image. You should include "other" as a category, so that the worker can provide an answer. You can specify up to 10 categories.

**header**

The text to display above the image. This is typically a question or simple instruction for the worker.
name

The name of this widget. It is used as a key for the widget's input in the form output.

overlay

Information to be overlaid on the source image. This is for verification workflows of bounding-box, semantic-segmentation, and instance-segmentation tasks.

It is a JSON object containing an object with the name of the task-type in camelCase as the key. That key's value is an object that contains the labels and other necessary information from the previous task.

An example of a `crowd-image-classifier` element with attributes for verifying a bounding-box task follows:

```xml
<crowd-image-classifier
    name="boundingBoxClassification"
    header="Rate the quality of the annotations based on the background section in the instructions on the left hand side."
    src="https://i.imgur.com/CIPKVJo.jpg"
    categories="['good', 'bad', 'okay']"
    overlay='{"boundingBox": {
        "labels": ["bird", "cat"],
        "value": [
            {
                height: 284,
                label: "bird",
                left: 230,
                top: 974,
                width: 223
            },
            {
                height: 69,
                label: "bird",
                left: 79,
                top: 889,
                width: 247
            }
        ]
    },
    "overlay": {
        "semanticSegmentation": {
            "labels": ["Cat", "Dog", "Bird", "Cow"],
            "labelMappings": {
                "Bird": {
                    "color": "#ff7f0e"
                },
                "Cat": {
                    "color": "#2ca02c"
                },
                "Cow": {
                    "color": "#d62728"
                }
            }
        }
    }
}> ... </crowd-image-classifier>
```

A semantic segmentation verification task would use the overlay value as follows:

```xml
<crowd-image-classifier
    name='crowd-image-classifier'
    categories='["good", "bad"]'
    src='URL of image to be classified'
    header='Please classify'
    overlay='{"semanticSegmentation": {
        "labels": ["Cat", "Dog", "Bird", "Cow"],
        "labelMappings": {
            "Bird": {
                "color": "#ff7f0e"
            },
            "Cat": {
                "color": "#2ca02c"
            },
            "Cow": {
                "color": "#d62728"
            }
        }
    }
}> ... </crowd-image-classifier>
```
An instance-segmentation task would use the overlay value as follows:

```html
crowd-image-classifier
  name='crowd-image-classifier'
  categories='["good", "bad"]'
  src='URL of image to be classified'
  header='Please classify instances of each category'
  overlay={
    "instanceSegmentation": {
      "labels": ["Cat", "Dog", "Bird", "Cow"],
      "instances": [{
        "color": "#2ca02c",
        "label": "Cat"
      },
      {
        "color": "#1f77b4",
        "label": "Cat"
      },
      {
        "color": "#d62728",
        "label": "Dog"
      }],
    "src": "URL of overlay image",
  }
}...
```

**src**

The URL of the image to be classified.

### Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 742)
- **Child elements**: full-instructions (p. 747), short-instructions (p. 747), worker-comment (p. 748)

### Regions

The following regions are used by this element.

- **full-instructions**
  General instructions for the worker on how to classify an image.
- **short-instructions**
  Important task-specific instructions that are displayed in a prominent place.
worker-comment

Use this in verification workflows when you need workers to explain why they made the choice they did. Use the text between the opening and closing tags to provide instructions for workers on what information should be included in the comment.

It uses the following attributes:

header

A phrase with a call to action for leaving a comment. Used as the title text for a modal window where the comment is added.

Optional. Defaults to "Add a comment."

link-text

This text appears below the categories in the widget. When clicked, it opens a modal window where the worker may add a comment.

Optional. Defaults to "Add a comment."

placeholder

An example text in the comment text area that is overwritten when worker begins to type. This does not appear in output if the worker leaves the field blank.

Optional. Defaults to blank.

Output

The output of this element is a string that specifies one of the values defined in the categories attribute of the <crowd-image-classifier> element.

Example: Sample Element Outputs

The following is a sample of output from this element.

```
[
  {
"<name>": {
  "label": "<value>"
  "workerComment": "Comment - if no comment is provided, this field will not be present"
  }
  }
]
```

See Also

- Use Amazon SageMaker Ground Truth to Label Data (p. 370)
- Crowd HTML Elements Reference (p. 720)

crowd-image-classifier-multi-select

A widget for classifying an image into one or more categories. Use one of the following supported image formats: APNG, BMP, GIF, ICO, JPEG, PNG, SVG. Images do not have a size limit.
Amazon SageMaker Developer Guide
SageMaker Crowd HTML Elements

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.
The following is an example of an HTML worker task template built using this crowd element. Copy the
following code and save it in a ﬁle with the extension .html. Open the ﬁle in any browser to preview
and interact with this template.
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
<crowd-image-classifier-multi-select
name="animals"
categories="['Cat', 'Dog', 'Horse', 'Pig', 'Bird']"
src="https://images.unsplash.com/photo-1509205477838-a534e43a849f?
ixlib=rb-1.2.1&ixid=eyJhcHBfaWQiOjEyMDd9&auto=format&fit=crop&w=1998&q=80"
header="Please identify the animals in this image"
exclusion-category="{ text: 'None of the above' }"
>
<full-instructions header="Classification Instructions">
<p>If more than one label applies to the image, select multiple labels.</p>
<p>If no labels apply, select <b>None of the above</b></p>
</full-instructions>
<short-instructions>
<p>Read the task carefully and inspect the image.</p>
<p>Choose the appropriate label(s) that best suit the image.</p>
</short-instructions>
</crowd-image-classifier-multi-select>
</crowd-form>

Attributes
The following attributes are supported by the crowd-image-classifier-multi-select element.
Each attribute accepts a string value or string values.

categories
Required. A JSON-formatted array of strings, each of which is a category that a worker can assign to the
image. A worker must choose at least one category and can choose all categories.

header
Required. The text to display above the image. This is typically a question or simple instruction for
workers.

name
Required. The name of this widget. In the form output, the name is used as a key for the widget's input.

src
Required. The URL of the image to be classiﬁed.

exclusion-category
Optional. A JSON-formatted string with the following format: "{ text: 'default-value' }". This
attribute sets a default value that workers can choose if none of the labels applies to the image shown in
the worker UI.

Element Hierarchy
This element has the following parent and child elements:

749


• **Parent elements**: crowd-form (p. 742)
• **Child elements**: full-instructions (p. 747), short-instructions (p. 747), worker-comment (p. 748)

**Regions**

This element uses the following regions

**full-instructions**

General instructions for the worker on how to classify an image.

**short-instructions**

Important task-specific instructions. These instructions are displayed prominently.

**Output**

The output of this element is a string that specifies one or more of the values defined in the categories attribute of the `<crowd-image-classifier-multi-select>` element.

**Example : Sample Element Outputs**

The following is a sample of output from this element.

```json
[
  {
    "<name>": {
      "labels": ["label_a", "label_b"]
    }
  }
]
```

**See Also**

For more information, see the following:

• Image Classification (Multi-label) (p. 391)
• Use Amazon SageMaker Ground Truth to Label Data (p. 370)
• Crowd HTML Elements Reference (p. 720)

**crowd-input**

A box that accepts input data.

**Cannot be self-closing**

Unlike the `input` element in the HTML standard, this element cannot be self-closed by putting a slash before the ending bracket, e.g. `<crowd-input ... />`. It must be followed with a `</crowd-input>` to close the element.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that uses the `<crowd-input>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
```
<crowd-form>
  <img style="max-width: 35vw; max-height: 50vh" src="{{ task.input.taskObject | grant_read_access }}">
  <crowd-input name="tag1" label="Word/phrase 1" required></crowd-input>
  <crowd-input name="tag2" label="Word/phrase 2" required></crowd-input>
  <crowd-input name="tag3" label="Word/phrase 3" required></crowd-input>
  
  <short-instructions>
    Your custom quick instructions and examples
  </short-instructions>
  
  <full-instructions>
    Your custom detailed instructions and more examples
  </full-instructions>
</crowd-form>

Attributes

The following attributes are supported by this element.

**allowed-pattern**

A regular expression that is used with the *auto-validate* attribute to ignore non-matching characters as the worker types.

**auto-focus**

When the value is set to true, the browser places focus inside the input area after loading. This way, the worker can start typing without having to select it first.

**auto-validate**

A Boolean switch that, if present, turns on input validation. The behavior of the validator can be modified by the *error-message* and *allowed-pattern* attributes.

**disabled**

A Boolean switch that, if present, displays the input area as disabled.

**error-message**

The text to be displayed below the input field, on the left side, if validation fails.

**label**

A string that is displayed inside a text field.

This text shrinks and rises up above a text field when the worker starts typing in the field or when the *value* attribute is set.

**max-length**

A maximum number of characters the input will accept. Input beyond this limit is ignored.

**min-length**

A minimum length for the input in the field

**name**

Sets the name of the input to be used in the DOM and the output of the form.
placeholder

A string value that is used as placeholder text, displayed until the worker starts entering data into the input. It is not used as a default value.

required

A Boolean switch that, if present, requires the worker to provide input.

type

Takes a string to set the HTML5 input-type behavior for the input. Examples include file and date.

value

A preset that becomes the default if the worker does not provide input. The preset appears in a text field.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 742)
- **Child elements**: none

Output

Provides a name string as the property name, and the text that was entered in the field as its value.

Example: Sample JSON Output

The values for multiple elements are output in the same object, with their name attribute value as their property name. Elements with no input do not appear in the output. For example, let's use three inputs:

```
<crowd-input name="tag1" label="Word/phrase 1"></crowd-input>
<crowd-input name="tag2" label="Word/phrase 2"></crowd-input>
<crowd-input name="tag3" label="Word/phrase 3"></crowd-input>
```

This is the output if only two have input:

```
[
  { 
    "tag1": "blue",
    "tag2": "red"
  }
]
```

This means any code built to parse these results should be able to handle the presence or absence of each input in the answers.

See Also

For more information, see the following.

- Use Amazon SageMaker Ground Truth to Label Data (p. 370)
- Crowd HTML Elements Reference (p. 720)
**crowd-instance-segmentation**

A widget for identifying individual instances of specific objects within an image and creating a colored overlay for each labeled instance.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that uses the `<crowd-instance-segmentation>`.

Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```html
<iframe src="https://example.com/interactive-example" width="100%" height="400"></iframe>
```

Use a template similar to the following to allow workers to add their own categories (labels).

```html
<iframe src="https://example.com/custom-label-template" width="100%" height="400"></iframe>
```
<full-instructions>
Describe your task in more detail here.
</full-instructions>
</crowd-instance-segmentation>
</crowd-form>

<script>
  document.addEventListener('all-crowd-elements-ready', function(event) {
    document.querySelector('crowd-instance-segmentation').labels = [];
  });

  function populateLabelsSection() {
    labelsSection.innerHTML = '
    annotator.labels.forEach(function(label) {
      const labelContainer = document.createElement('div');
      labelContainer.innerHTML = label + ' <a href="javascript:void(0)">(Delete)</a>';
      labelContainer.onclick = function() {
        annotator.labels = annotator.labels.filter(function(l) {
          return l !== label;
        });
        populateLabelsSection();
      };
      labelsSection.appendChild(labelContainer);
    });
  }

  addLabel.onclick = function() {
    annotator.labels = annotator.labels.concat([customLabel.value]);
    customLabel.value = null;
    populateLabelsSection();
  };
</script>

**Attributes**

The following attributes are supported by this element.

**header**

The text to display above the image. This is typically a question or simple instruction for the worker.

**labels**

A JSON formatted array of strings, each of which is a label that a worker can assign to an instance of an object in the image. Workers can generate different overlay colors for each relevant instance by selecting "add instance" under the label in the tool.

**name**

The name of this widget. It is used as a key for the labeling data in the form output.

**src**

The URL of the image that is to be labeled.

**initial-value**

A JSON object containing the color mappings of a prior instance segmentation job and a link to the overlay image output by the prior job. Include this when you want a human worker to verify the results of a prior labeling job and adjust it if necessary.

The attribute will appear as follows:
Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 742)
- **Child elements**: full-instructions (p. 755), short-instructions (p. 755)

Regions

The following regions are supported by this element.

- **full-instructions**
  General instructions about how to do image segmentation.

- **short-instructions**
  Important task-specific instructions that are displayed in a prominent place.

Output

The following output is supported by this element.

- **labeledImage**
  A JSON Object containing a Base64 encoded PNG of the labels.

- **instances**
  A JSON Array containing objects with the instance labels and colors.
  - **color** – The hexadecimal value of the label's RGB color in the labeledImage PNG.
  - **label** – The label given to overlay(s) using that color. This value may repeat, because the different instances of the label are identified by their unique color.

- **inputImageProperties**
  A JSON object that specifies the dimensions of the image that is being annotated by the worker. This object contains the following properties.
  - **height** – The height, in pixels, of the image.
- **width** – The width, in pixels, of the image.

**Example : Sample Element Outputs**

The following is an example of output from this element.

```json
[
    {
        "annotatedResult": {
            "inputImageProperties": {
                "height": 533,
                "width": 800
            },
            "instances": [
                {
                    "color": "#1f77b4",
                    "label": "<Label 1>"
                },
                {
                    "color": "#2ca02c",
                    "label": "<Label 1>"
                },
                {
                    "color": "#ff7f0e",
                    "label": "<Label 3>"
                }
            ],
            "labeledImage": {
                "pngImageData": "<Base-64 Encoded Data>"
            }
        }
    }
]
```

**See Also**

For more information, see the following.

- Use Amazon SageMaker Ground Truth to Label Data (p. 370)
- Crowd HTML Elements Reference (p. 720)

**crowd-instructions**

An element that displays instructions on three tabbed pages, **Summary**, **Detailed Instructions**, and **Examples**, when the worker clicks on a link or button.

See an interactive example of an HTML template that uses this Crowd HTML Element in [CodePen](https://codepen.io).

The following is an example of a Liquid template that used the `<crowd-instructions>` element. Copy the following code and save it in a file with the extension .html. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
    <crowd-instructions link-text="View instructions" link-type="button">
        <short-summary>
            <p>Given an image, write three words or short phrases that summarize its contents.</p>
        </short-summary>
    </crowd-instructions>
</crowd-form>
```
Imagine that you are describing an image to a friend or tagging it for a news website. Provide three specific words or short phrases that describe it.

These are not specific enough:

- Trees
- Outside
- Daytime

Attributes

The following attributes are supported by this element.

**link-text**

The text to display for opening the instructions. The default is *Click for instructions*.

**link-type**

A string that specifies the type of trigger for the instructions. The possible values are "link" (default) and "button".

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 742)
- **Child elements**: none

Regions

The following regions are supported by this element.
detailed-instructions
Content that provides specific instructions for a task. This appears on the page of the "Detailed Instructions" tab.

negative-example
Content that provides examples of inadequate task completion. This appears on the page of the "Examples" tab. More than one example may be provided within this element.

positive-example
Content that provides examples of proper task completion. This appears on the page of the "Examples" tab.

short-summary
A brief statement that summarizes the task to be completed. This appears on the page of the "Summary" tab. More than one example may be provided within this element.

See Also
For more information, see the following.
- Use Amazon SageMaker Ground Truth to Label Data (p. 370)
- Crowd HTML Elements Reference (p. 720)

crowd-keypoint
Generates a tool to select and annotate key points on an image.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of an Liquid template that uses the <crowd-keypoint> element. Copy the following code and save it in a file with the extension .html. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
  <div id="errorBox"></div>
  <crowd-keypoint
    src="{{ task.input.taskObject | grant_read_access }}"
    labels="['Item A', 'Item B', 'Item C']"
    header="Please locate the centers of each item."
    name="annotatedResult">
    <short-instructions>
      Describe your task briefly here and give examples
    </short-instructions>
    <full-instructions>
      Give additional instructions and good/bad examples here
    </full-instructions>
  </crowd-keypoint>
</crowd-form>
<script>
  var num_obj = 1;
  document.querySelector('crowd-form').onsubmit = function(e) {
    //...
  }
```
const keypoints = document.querySelector('crowd-keypoint').value.keypoints || document.querySelector('crowd-keypoint')._submittableValue.keypoints;
const labels = keypoints.map(function(p) {
  return p.label;
});

// 1. Make sure total number of keypoints is correct.
var original_num_labels = document.getElementsByTagName("crowd-keypoint")
[0].getAttribute("labels");
original_num_labels = original_num_labels.substring(2, original_num_labels.length - 2).split("","");
var goalNumKeypoints = num_obj*original_num_labels.length;
if (keypoints.length != goalNumKeypoints) {
  e.preventDefault();
  errorBox.innerHTML = '<crowd-alert type="error" dismissible>You must add all keypoint
   annotations and use each label only once.</crowd-alert>'';
  errorBox.scrollIntoView();
  return;
}

// 2. Make sure all labels are unique.
labelCounts = {};
for (var i = 0; i < labels.length; i++) {
  if (!labelCounts[labels[i]]) {
    labelCounts[labels[i]] = 0;
  }
  labelCounts[labels[i]]++;
}
const goalNumSingleLabel = num_obj;
const numLabels = Object.keys(labelCounts).length;
Object.entries(labelCounts).forEach(entry => {
  if (entry[1] != goalNumSingleLabel) {
    e.preventDefault();
    errorBox.innerHTML = '<crowd-alert type="error" dismissible>You must use each label
     only once.</crowd-alert>'';
    errorBox.scrollIntoView();
  }
});
</script>

**Attributes**

The following attributes are supported by this element.

**header**

The text to display above the image. This is typically a question or simple instruction for the worker.

**initial-value**

An array, in JSON format, of keypoints to be applied to the image on start. For example:

    initial-value="[
      { 'label': 'Left Eye',
        'x': 1022,
        'y': 429
      },
      { 'label': 'Beak',

{'x': 941,
'y': 403
}

**Note**

Please note that label values used in this attribute must have a matching value in the `labels` attribute or the point will not be rendered.

**labels**

An array, in JSON format, of strings to be used as keypoint annotation labels.

**name**

A string used to identify the answer submitted by the worker. This value will match a key in the JSON object that specifies the answer.

**src**

The source URI of the image to be annotated.

**Element Hierarchy**

This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 742)
- **Child elements**: full-instructions (p. 760), short-instructions (p. 760)

**Regions**

The following regions are required by this element.

**full-instructions**

General instructions about how to annotate the image.

**short-instructions**

Important task-specific instructions that are displayed in a prominent place.

**Output**

The following output is supported by this element.

**inputImageProperties**

A JSON object that specifies the dimensions of the image that is being annotated by the worker. This object contains the following properties.

- **height** – The height, in pixels, of the image.
- **width** – The width, in pixels, of the image.

**keypoints**

An array of JSON objects containing the coordinates and label of a keypoint. Each object contains the following properties.
• **label** – The assigned label for the keypoint.
• **x** – The X coordinate, in pixels, of the keypoint on the image.
• **y** – The Y coordinate, in pixels, of the keypoint on the image.

**Note**
X and Y coordinates are based on 0,0 being the top left corner of the image.

**Example : Sample Element Outputs**

The following is a sample output from using this element.

```
[
  {
    "crowdKeypoint": {
      "inputImageProperties": {
        "height": 1314,
        "width": 962
      },
      "keypoints": [
        {
          "label": "dog",
          "x": 155,
          "y": 275
        },
        {
          "label": "cat",
          "x": 341,
          "y": 447
        },
        {
          "label": "cat",
          "x": 491,
          "y": 513
        },
        {
          "label": "dog",
          "x": 714,
          "y": 578
        },
        {
          "label": "cat",
          "x": 712,
          "y": 763
        },
        {
          "label": "cat",
          "x": 397,
          "y": 814
        }
      ]
    }
  }
]
```

You may have many labels available, but only the ones that are used appear in the output.

**See Also**

For more information, see the following.

• **Use Amazon SageMaker Ground Truth to Label Data (p. 370)**
• Crowd HTML Elements Reference (p. 720)

crowd-line

A widget for drawing lines on an image. Each line is associated with a label, and output data will report the starting and ending points of each line.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that uses the `<crowd-line>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template. For more examples, see this GitHub repository.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
  <crowd-line
    name="crowdLine"
    src="{{ task.input.taskObject | grant_read_access }}"
    header="Add header here to describe the task"
    labels="['car','pedestrian','street car']"
  >
    <short-instructions>
      <p>Read the task carefully and inspect the image.</p>
      <p>Choose the appropriate label that best suits the image.</p>
      <p>Draw a line on each objects that the label applies to.</p>
    </short-instructions>
    <full-instructions>
      <p>Read the task carefully and inspect the image.</p>
      <p>Choose the appropriate label that best suits the image.</p>
      <p>Draw a line along each object that the image applies to.</p>
      <p>Make sure that the line does not extend beyond the boundaries of the object.</p>
      <p>Each line is defined by a starting and ending point. Carefully place the starting and ending points on the boundaries of the object.</p>
    </full-instructions>
  </crowd-line>
</crowd-form>

Attributes

The following attributes are supported by this element.

header

Optional. The text to display above the image. This is typically a question or simple instruction for the worker.

initial-value

Optional. An array of JSON objects, each of which sets a line when the component is loaded. Each JSON object in the array contains the following properties:

- label – The text assigned to the line as part of the labeling task. This text must match one of the labels defined in the `labels` attribute of the `<crowd-line>` element.
- vertices – the x and y pixel coordinates of the start point and end point of the line, relative to the top-left corner of the image.
Lines set via the `initial-value` property can be adjusted. Whether or not a worker answer was adjusted is tracked via an `initialValueModified` boolean in the worker answer output.

**labels**

Required. A JSON formatted array of strings, each of which is a label that a worker can assign to the line.

**Limit:** 10 labels

**label-colors**

Optional. An array of strings. Each string is a hexadecimal (hex) code for a label.

**name**

Required. The name of this widget. It's used as a key for the widget's input in the form output.

**src**

Required. The URL of the image on which to draw lines.

**Regions**

The following regions are required by this element.

**full-instructions**

General instructions about how to draw lines.

**short-instructions**

Important task-specific instructions that are displayed in a prominent place.
Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 742)
- **Child elements**: short-instructions (p. 763), full-instructions (p. 763)

Output

**inputImageProperties**

A JSON object that specifies the dimensions of the image that is being annotated by the worker. This object contains the following properties.

- **height** – The height, in pixels, of the image.
- **width** – The width, in pixels, of the image.

**lines**

A JSON Array containing objects with the line labels and vertices.

- **label** – The label given to a line.
- **vertices** – the x and y pixel coordinates of the start point and end point of the line, relative to the top-left corner of the image.

**Example: Sample Element Outputs**

The following is an example of output from this element.

```json
{
    "crowdLine": { //This is the name you set for the crowd-line
        "inputImageProperties": {
            "height": 1254,
            "width": 2048
        },
        "lines": [
            {
                "label": "yardline",
                "vertices": [
                    {
                        "x": 58,
                        "y": 295
                    },
                    {
                        "x": 1342,
                        "y": 398
                    }
                ]
            },
            {
                "label": "sideline",
                "vertices": [
                    {
                        "x": 472,
                        "y": 910
                    },
                    {
                        "x": 1480,
                        "y": 764
                    }
                ]
            }
        ]
    }
}
```
crowd-modal

A small window that pops up on the display when it is opened.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of the syntax that you can use with the `<crowd-modal>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-modal
  link-text = "See Examples"
  link-type = "button">
  Example Modal Text</crowd-modal>
```

Attributes

The following attributes are supported by this element.

- **link-text**
  
  The text to display for opening the modal. The default is "Click to open modal".

- **link-type**
  
  A string that specifies the type of trigger for the modal. The possible values are "link" (default) and "button".

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 742)
- **Child elements**: none

See Also

For more information, see the following.
• Use Amazon SageMaker Ground Truth to Label Data (p. 370)
• Crowd HTML Elements Reference (p. 720)

**crowd-polygon**

A widget for drawing polygons on an image and assigning a label to the portion of the image that is enclosed in each polygon.

See an interactive example of an HTML template that uses this Crowd HTML Element in [CodePen](https://codepen.io).

The following is an example of a Liquid template that uses the `<crowd-polygon>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
  <crowd-polygon
      name="annotatedResult"
      src="{{ task.input.taskObject | grant_read_access }}"
      header="Draw a polygon around each of the requested target(s) of interest"
      labels="["Cat", "Dog", "Bird"]"
>
    <full-instructions header="Polygon instructions">
      <ul>
        <li>Make the polygon tight around the object</li>
        <li>You need to select a label before starting a polygon</li>
        <li>You will need to select a label again after completing a polygon</li>
        <li>To select a polygon, you can click on its borders</li>
        <li>You can start drawing a polygon from inside another polygon</li>
        <li>You can undo and redo while you're drawing a polygon to go back and forth between points you've placed</li>
        <li>You are prevented from drawing lines that overlap other lines from the same polygon</li>
      </ul>
    </full-instructions>

    <short-instructions>
      <p>Draw a polygon around each of the requested target(s) of interest</p>
      <p>Make the polygon tight around the object</p>
    </short-instructions>
  </crowd-polygon>
</crowd-form>
```

**Attributes**

The following attributes are supported by this element.

**header**

The text to display above the image. This is typically a question or simple instruction for the worker.

**labels**

A JSON formatted array of strings, each of which is a label that a worker can assign to the image portion enclosed by a polygon.

**name**

The name of this widget. It's used as a key for the widget's input in the form output.
src
The URL of the image on which to draw polygons.

initial-value
An array of JSON objects, each of which defines a polygon to be drawn when the component is loaded. Each JSON object in the array contains the following properties.

- **label** – The text assigned to the polygon as part of the labeling task. This text must match one of the labels defined in the `labels` attribute of the `<crowd-polygon>` element.
- **vertices** – An array of JSON objects. Each object contains an x and y coordinate value for a point in the polygon.

**Example**
An `initial-value` attribute might look something like this.

```json
initial-value =
'[
  {
    "label": "dog",
    "vertices":
      [
        {
          "x": 570,
          "y": 239
        },
        ...
        {
          "x": 759,
          "y": 281
        }
      ]
  }
]'
```

Because this will be within an HTML element, the JSON array must be enclosed in single or double quotes. The example above uses single quotes to encapsulate the JSON and double quotes within the JSON itself. If you must mix single and double quotes inside your JSON, replace them with their HTML entity codes (`&quot;` for double quote, `&#39;` for single) to safely escape them.

**Element Hierarchy**
This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 742)
- **Child elements**: full-instructions (p. 767), short-instructions (p. 767)

**Regions**
The following regions are required.

**full-instructions**
General instructions about how to draw polygons.

**short-instructions**
Important task-specific instructions that are displayed in a prominent place.
Output

The following output is supported by this element.

polygons

An array of JSON objects, each of which describes a polygon that has been created by the worker. Each JSON object in the array contains the following properties.

- **label** – The text assigned to the polygon as part of the labeling task.
- **vertices** – An array of JSON objects. Each object contains an x and y coordinate value for a point in the polygon. The top left corner of the image is 0,0.

inputImageProperties

A JSON object that specifies the dimensions of the image that is being annotated by the worker. This object contains the following properties.

- **height** – The height, in pixels, of the image.
- **width** – The width, in pixels, of the image.

Example: Sample Element Outputs

The following are samples of outputs from common use scenarios for this element.

**Single Label, Single Polygon**

```json
{
    "annotatedResult": {
        "inputImageProperties": {
            "height": 853,
            "width": 1280
        },
        "polygons": [
            {
                "label": "dog",
                "vertices": [
                    {
                        "x": 570,
                        "y": 239
                    },
                    {
                        "x": 603,
                        "y": 513
                    },
                    {
                        "x": 823,
                        "y": 645
                    },
                    {
                        "x": 901,
                        "y": 417
                    },
                    {
                        "x": 759,
                        "y": 281
                    }
                ]
            }
        ]
    }
}
```
Single Label, Multiple Polygons

[
  {
    "annotatedResult": {
      "inputImageProperties": {
        "height": 853,
        "width": 1280
      },
      "polygons": [
        {
          "label": "dog",
          "vertices": [
            {
              "x": 570,
              "y": 239
            },
            {
              "x": 603,
              "y": 513
            },
            {
              "x": 823,
              "y": 645
            },
            {
              "x": 901,
              "y": 417
            },
            {
              "x": 759,
              "y": 281
            }
          ]
        },
        {
          "label": "dog",
          "vertices": [
            {
              "x": 870,
              "y": 278
            },
            {
              "x": 908,
              "y": 446
            },
            {
              "x": 1009,
              "y": 602
            },
            {
              "x": 1116,
              "y": 519
            },
            {
              "x": 1174,
              "y": 498
            }
          ]
        }
      ]
    }
  }
]
Multiple Labels, Multiple Polygons

[{
   "annotatedResult": {
      "inputImageProperties": {
         "height": 853,
         "width": 1280
      },
      "polygons": [
         {
            "label": "dog",
            "vertices": [
               {
                  "x": 570,
                  "y": 239
               },
               {
                  "x": 603,
                  "y": 513
               },
               {
                  "x": 823,
                  "y": 645
               },
               {
                  "x": 901,
                  "y": 417
               },
               {
                  "x": 759,
                  "y": 281
               }
            ]
         },
         {
            "label": "cat",
            "vertices": [
               {
                  "x": 870,
                  "y": 278
               },
               {
                  "x": 908,
                  "y": 446
               },
               {  
                  
               }  
            ]
         }
      ]
   }
}]}
You could have many labels available, but only the ones that are used appear in the output.

**See Also**

For more information, see the following.

- Use Amazon SageMaker Ground Truth to Label Data (p. 370)
- Crowd HTML Elements Reference (p. 720)

**crowd-polyline**

A widget for drawing polylines or lines on an image. Each polyline is associated with a label and can include two or more vertices. A polyline can intersect itself and its starting and ending points can be placed anywhere on the image.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that uses the `<crowd-polyline>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template. For more examples, see this GitHub repository.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <crowd-polyline
    name="crowdPolyline"
    src="{{ task.input.taskObject | grant_read_access }}"
    header="Add header here to describe the task"
    labels="['car','pedestrian','street car']">
    <full-instructions>
```

---

771
Attributes

The following attributes are supported by this element.

header

Optional. The text to display above the image. This is typically a question or simple instruction for the worker.

initial-value

Optional. An array of JSON objects, each of which sets a polyline when the component is loaded. Each JSON object in the array contains the following properties:

- label – The text assigned to the polyline as part of the labeling task. This text must match one of the labels defined in the labels attribute of the <crowd-polyline> element.
- vertices – the x and y pixel coordinates of the vertices of a polyline, relative to the top-left corner of the image.

```json
initial-value= "{
  polylines: [
    {
      label: 'sideline', // label of this line annotation
      vertices:[         // an array of vertices which decide the position of the line
        { x: 84,         // an array of vertices which decide the position of the line
          y: 110
        },
        { x: 60,         // an array of vertices which decide the position of the line
          y: 100
        }
      ]
    },
    {
      label: 'yardline',
      vertices:[
        
```
Polylines set via the initial-value property can be adjusted. Whether or not a worker answer was adjusted is tracked via an initialValueModified boolean in the worker answer output.

**labels**

Required. A JSON formatted array of strings, each of which is a label that a worker can assign to the line.

**Limit:** 10 labels

**label-colors**

Optional. An array of strings. Each string is a hexadecimal (hex) code for a label.

**name**

Required. The name of this widget. It's used as a key for the widget's input in the form output.

**src**

Required. The URL of the image on which to draw polylines.

**Regions**

The following regions are required by this element.

**full-instructions**

General instructions about how to draw polylines.

**short-instructions**

Important task-specific instructions that are displayed in a prominent place.

**Element Hierarchy**

This element has the following parent and child elements.

- **Parent elements:** crowd-form (p. 742)
- **Child elements:** short-instructions (p. 773), full-instructions (p. 773)

**Output**

**inputImageProperties**

A JSON object that specifies the dimensions of the image that is being annotated by the worker. This object contains the following properties.
• **height** – The height, in pixels, of the image.
• **width** – The width, in pixels, of the image.

**polylines**

A JSON Array containing objects with polylines' labels and vertices.

• **label** – The label given to a line.
• **vertices** – the x and y pixel coordinates of the vertices of a polyline, relative to the top-left corner of the image.

**Example : Sample Element Outputs**

The following is an example of output from this element.

```json
{
    "crowdPolyline": { //This is the name you set for the crowd-polyline
        "inputImageProperties": {
            "height": 1254,
            "width": 2048
        },
        "polylines": [
            {
                "label": "sideline",
                "vertices": [
                    {
                        "x": 651,
                        "y": 498
                    },
                    {
                        "x": 862,
                        "y": 869
                    },
                    {
                        "x": 1449,
                        "y": 611
                    }
                ]
            },
            {
                "label": "yardline",
                "vertices": [
                    {
                        "x": 1148,
                        "y": 322
                    },
                    {
                        "x": 1705,
                        "y": 474
                    },
                    {
                        "x": 1755,
                        "y": 474
                    }
                ]
            }
        ]
    }
}
```

- Use Amazon SageMaker Ground Truth to Label Data (p. 370)
- Crowd HTML Elements Reference (p. 720)

crowd-radio-button

A button that can be either checked or unchecked. When radio buttons are inside a radio group, exactly one radio button in the group can be checked at any time. The following is an example of how to configure a crowd-radio-button element inside of a crowd-radio-group element.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of the syntax that you can use with the <crowd-radio-button> element. Copy the following code and save it in a file with the extension .html. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
  <crowd-radio-group>
    <crowd-radio-button name="tech" value="tech">Technology</crowd-radio-button>
    <crowd-radio-button name="politics" value="politics">Politics</crowd-radio-button>
  </crowd-radio-group>
</crowd-form>
```

The previous example can be seen in a custom worker task template in this GitHub example: entity recognition labeling job custom template.

Crowd HTML Element radio buttons do not support the HTML tag, required. To make a radio button selection required, use <input type="radio"> elements to create radio buttons and add the required tag. The name attribute for all <input> elements that belong to the same group of radio buttons must be the same. For example, the following template requires the user to select a radio button in the animal-type group before submitting.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
  <p>Select an animal type:</p>
  <img src="https://images.unsplash.com/photo-1537151608828-ea2b11777ee8?ixlib=rb-1.2.1&ixid=eyJhcHBfaWQiOjEyMDd9&auto=format&fit=crop&w=1539&q=80" style="height: 500; width: 400;"/>

  <div>
    <input type="radio" id="cat" name="animal-type" value="cat" required>
    <label for="cat">Cat</label>
  </div>
  <div>
    <input type="radio" id="dog" name="animal-type" value="dog">
    <label for="dog">Dog</label>
  </div>
  <div>
    <input type="radio" id="unknown" name="animal-type" value="unknown">
    <label for="unknown">Unknown</label>
  </div>

  <full-instructions header="Classification Instructions">
    <p>Read the task carefully and inspect the image.</p>
    <p>Choose the appropriate label that best suits the image.</p>
  </full-instructions>
</crowd-form>
```
Attributes

The following attributes are supported by this element.

**checked**
A Boolean switch that, if present, displays the radio button as checked.

**disabled**
A Boolean switch that, if present, displays the button as disabled and prevents it from being checked.

**name**
A string that is used to identify the answer submitted by the worker. This value will match a key in the JSON object that specifies the answer.

**Note**
If you use the buttons outside of a crowd-radio-group (p. 777) element, but with the same name string and different value strings, the name object in the output will contain a Boolean value for each value string. To ensure that only one button in a group is selected, make them children of a crowd-radio-group (p. 777) element and use different name values.

**value**
A property name for the element's boolean value. If not specified, it uses "on" as the default, e.g. 

```json
{ "<name>": { "<value>": <true or false> } }
```

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements:** crowd-radio-group (p. 777)
- **Child elements:** none

Output

Outputs an object with the following pattern: 

```json
{ "<name>": { "<value>": <true or false> } }
```

If you use the buttons outside of a crowd-radio-group (p. 777) element, but with the same name string and different value strings, the name object will contain a Boolean value for each value string. To ensure that only one button in a group is selected, make them children of a crowd-radio-group (p. 777) element and use different name values.

Example Sample output of this element

```json
[
  {
    "btn1": {
      "yes": true
    },
    "btn2": {
      "no": false
    }
  }
]
```

**crowd-radio-group**

A group of radio buttons. Only one radio button within the group can be selected. Choosing one radio button clears any previously chosen radio button within the same group. For an example of a custom UI template that uses the `crowd-radio-group` element, see this [entity recognition labeling job custom template](#).

See an interactive example of an HTML template that uses this Crowd HTML Element in [CodePen](#).

The following is an example of the syntax that you can use with the `<crowd-radio-group>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<style>
body {
  padding-left: 20px;
  margin-bottom: 20px;
}
#outer-container {
  display: flex;
  justify-content: space-around;
  max-width: 900px;
  margin-left: 100px;
}
.left-container {
  margin-right: auto;
  padding-right: 50px;
}
.right-container {
  margin-left: auto;
  padding-left: 50px;
}
#vertical-separator {
  border: solid 1px #d5dbdb;
}
</style>

<crowd-form>
  <div>
    <h1>Instructions</h1>
    Lorem ipsum...
  </div>
  <div>
    <h2>Background</h2>
    Lorem ipsum dolor sit amet, consectetur adipiscing elit, sed do eiusmod tempor incididunt ut labore et dolore magna aliqua. Ut enim ad minim veniam, quis nostrud exercitation ullamco laboris nisi ut aliquip ex ea commodo consequat.
  </div>
</crowd-form>
```
**Attributes**

No special attributes are supported by this element.

**Element Hierarchy**

This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 742)
- **Child elements**: crowd-radio-button (p. 775)

**Output**

Outputs an array of objects representing the crowd-radio-button (p. 775) elements within it.

**Example Sample of Element Output**

```json
[
    {
        "btn1": {
            "yes": true
        },
        "btn2": {
            "no": false
        }
    }
]
```

**See Also**

For more information, see the following.

- Use Amazon SageMaker Ground Truth to Label Data (p. 370)
- Crowd HTML Elements Reference (p. 720)
crowd-semantic-segmentation

A widget for segmenting an image and assigning a label to each image segment.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that uses the `<crowd-semantic-segmentation>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <crowd-semantic-segmentation
    name="annotatedResult"
    src="{{ task.input.taskObject | grant_read_access }}"
    header="Please label each of the requested objects in this image"
    labels="['Cat', 'Dog', 'Bird']"
  >
    <full-instructions header="Segmentation Instructions">
      <ol>
        <li><strong>Read</strong> the task carefully and inspect the image.</li>
        <li><strong>Read</strong> the options and review the examples provided to understand more about the labels.</li>
        <li><strong>Choose</strong> the appropriate label that best suits the image.</li>
      </ol>
    </full-instructions>
    <short-instructions>
      <p>Use the tools to label the requested items in the image</p>
    </short-instructions>
  </crowd-semantic-segmentation>
</crowd-form>

Attributes

The following attributes are supported by this element.

**header**

The text to display above the image. This is typically a question or simple instruction for the worker.

**initial-value**

A JSON object containing the color mappings of a prior semantic segmentation job and a link to the overlay image output by the prior job. Include this when you want a human worker to verify the results of a prior labeling job and adjust it if necessary.

The attribute would appear as follows:

```json
initial-value='{
  "labelMappings": {
    "Bird": {
      "color": "#ff7f0e"
    },
    "Cat": {
      "color": "#2ca02c"
    },
    "Cow": {
      "color": "#62728"  
    }
}'}
```
When using Ground Truth built in task types with annotation consolidation (where more than one worker labels a single image), label mappings are included in individual worker output records, however the overall result is represented as the internal-color-map in the consolidated results.

You can convert the internal-color-map to label-mappings in a custom template using the Liquid templating language:

```liquid
initial-value="{
    'src': '{{ task.input.manifestLine.label-attribute-name-from-prior-job | grant_read_access }}',
    'labelMappings': {
        {% for box in task.input.manifestLine.label-attribute-name-from-prior-job-metadata.internal-color-map %}
            {% if box[1]['class-name'] != 'BACKGROUND' %}
                {{ box[1]['class-name'] | to_json }}: {
                    'color': {{ box[1]['hex-color'] | to_json }}
                },
            {% endif %}
        {% endfor %}
    }
}"
```

**labels**

A JSON formatted array of strings, each of which is a label that a worker can assign to a segment of the image.

**name**

The name of this widget. It is used as a key for the widget's input in the form output.

**src**

The URL of the image that is to be segmented.

**Element Hierarchy**

This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 742)
- **Child elements**: full-instructions (p. 780), short-instructions (p. 780)

**Regions**

The following regions are supported by this element.

- **full-instructions**
  General instructions about how to do image segmentation.

- **short-instructions**
  Important task-specific instructions that are displayed in a prominent place.
Output

The following output is supported by this element.

labeledImage

A JSON Object containing a Base64 encoded PNG of the labels.

labelMappings

A JSON Object containing objects with named with the segmentation labels.

- **color** – The hexadecimal value of the label's RGB color in the labeledImage PNG.

initialValueModified

A boolean representing whether the initial values have been modified. This is only included when the output is from an adjustment task.

inputImageProperties

A JSON object that specifies the dimensions of the image that is being annotated by the worker. This object contains the following properties.

- **height** – The height, in pixels, of the image.
- **width** – The width, in pixels, of the image.

Example: Sample Element Outputs

The following is a sample of output from this element.

```
[
  {
    "annotatedResult": {
      "inputImageProperties": {
        "height": 533,
        "width": 800
      },
      "labelMappings": {
        "<Label 2>": {
          "color": "#ff7f0e"
        },
        "<label 3>": {
          "color": "#2ca02c"
        },
        "<label 1>": {
          "color": "#1f77b4"
        }
      },
      "labeledImage": {
        "pngImageData": "<Base-64 Encoded Data>"
      }
    }
  }
]
```

crowd-slider
A bar with a sliding knob that allows a worker to select a value from a range of values by moving
the knob. The slider makes it a great choice for settings that reﬂect intensity levels, such as volume,
brightness, or color saturation.
See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.
The following is an example of a survey template that uses the <crowd-slider> element. Copy the
following code and save it in a ﬁle with the extension .html. Open the ﬁle in any browser to preview
and interact with this template.
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
<crowd-instructions link-text="View instructions" link-type="button">
<short-summary>
<p>Provide a brief instruction here</p>
</short-summary>
<detailed-instructions>
<h3>Provide more detailed instructions here</h3>
<p>Include additional information</p>
</detailed-instructions>
<positive-example>
<p>Provide an example of a good answer here</p>
<p>Explain why it's a good answer</p>
</positive-example>
<negative-example>
<p>Provide an example of a bad answer here</p>
<p>Explain why it's a bad answer</p>
</negative-example>
</crowd-instructions>
<div>
<p>What is your favorite color for a bird?</p>
<crowd-input name="favoriteColor" placeholder="example: pink" required></crowd-input>
</div>
<div>
<p>Check this box if you like birds</p>
<crowd-checkbox name="likeBirds" checked="true" required></crowd-checkbox>
</div>
<div>
<p>On a scale of 1-10, how much do you like birds?</p>
<crowd-slider name="howMuch" min="1" max="10" step="1" pin="true" required></crowdslider>
</div>
<div>
<p>Write a short essay describing your favorite bird</p>

</div>
</crowd-form>

782


Attributes

The following attributes are supported by this element.

**disabled**

A Boolean switch that, if present, displays the slider as disabled.

**editable**

A Boolean switch that, if present, displays an up/down button that can be chosen to select the value.

Selecting the value via the up/down button is an alternative to selecting the value by moving the knob on the slider. The knob on the slider will move synchronously with the up/down button choices.

**max**

A number that specifies the maximum value on the slider.

**min**

A number that specifies the minimum value on the slider.

**name**

A string that is used to identify the answer submitted by the worker. This value will match a key in the JSON object that specifies the answer.

**pin**

A Boolean switch that, if present, displays the current value above the knob as the knob is moved.

**required**

A Boolean switch that, if present, requires the worker to provide input.

**secondary-progress**

When used with a `crowd-slider-secondary-color` CSS attribute, the progress bar is colored to the point represented by the secondary-progress. For example, if this was representing the progress on a streaming video, the value would represent where the viewer was in the video timeline. The secondary-progress value would represent the point on the timeline to which the video had buffered.

**step**

A number that specifies the difference between selectable values on the slider.

**value**

A preset that becomes the default if the worker does not provide input.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 742)
- **Child elements**: none

    </crowd-tab>
  </crowd-tabs>
</crowd-form>
```
Attributes

This element has no attributes.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 742)
- **Child elements**: crowd-tab (p. 784)

See Also

For more information, see the following.

- Use Amazon SageMaker Ground Truth to Label Data (p. 370)
- Crowd HTML Elements Reference (p. 720)

crowd-text-area

A field for text input.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template designed to transcribe audio clips that uses the <crowd-text-area> element. Copy the following code and save it in a file with the extension .html. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
    <audio controls>
        <source src="{{ task.input.taskObject | grant_read_access }}" type="audio/mpeg">
        Your browser does not support the audio element.
    </audio>
    <h3>Instructions</h3>
    <p>Transcribe the audio</p>
    <p>Ignore "umms", "hmms", "uhs" and other non-textual phrases</p>
    <crowd-text-area name="transcription" rows="4"></crowd-text-area>
</crowd-form>
```
Attributes

The following attributes are supported by this element.

**allowed-pattern**

A regular expression that is used with the *auto-validate* attribute to ignore non-matching characters as the worker types.

**auto-focus**

A Boolean switch that, if present, puts the cursor in this element on-load so that users can immediately begin typing without having to click inside the element.

**auto-validate**

A Boolean switch that, if present, turns on input validation. The behavior of the validator can be modified by the *error-message* and *allowed-pattern* attributes.

**char-counter**

A Boolean switch that, if present, puts a small text field beneath the lower-right corner of the element, displaying the number of characters inside the element.

**disabled**

A Boolean switch that, if present, displays the input area as disabled.

**error-message**

The text to be displayed below the input field, on the left side, if validation fails.

**label**

A string that is displayed inside a text field.

This text shrinks and rises up above a text field when the worker starts typing in the field or when the *value* attribute is set.

**max-length**

An integer that specifies the maximum number of characters allowed by the element. Characters typed or pasted beyond the maximum are ignored.

**max-rows**

An integer that specifies the maximum number of rows of text that are allowed within a crowd-text-area. Normally the element expands to accommodate new rows. If this is set, after the number of rows exceeds it, content scrolls upward out of view and a scrollbar control appears.

**name**

A string used to represent the element's data in the output.

**placeholder**

A string presented to the user as placeholder text. It disappears after the user puts something in the input area.

**rows**

An integer that specifies the height of the element in rows of text.
value

A preset that becomes the default if the worker does not provide input. The preset appears in a text field.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 742)
- **Child elements**: none

Output

This element outputs the name as a property name and the element's text contents as the value. Carriage returns in the text are represented as `\n`.

Example Sample output for this element

```
[
  {
    "textInput1": "This is the text; the text that\nmakes the crowd go wild."
  }
]
```

See Also

For more information, see the following.

- Use Amazon SageMaker Ground Truth to Label Data (p. 370)
- Crowd HTML Elements Reference (p. 720)

crowd-toast

A subtle notification that temporarily appears on the display. Only one crowd-toast is visible.

See an interactive example of an HTML template that uses this Crowd HTML Element in [CodePen](https://codepen.io).

The following is an example of a Liquid template that uses the `<crowd-toast>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <p>Find the official website for: <strong>{{ task.input.company }}</strong></p>
  <p>Do not give Yelp pages, LinkedIn pages, etc.</p>
  <p>Include the http:// prefix from the website</p>
  <crowd-input name="website" placeholder="http://example.com"></crowd-input>

  <crowd-toast duration="10000" opened>
    This is a message that you want users to see when opening the template. This message will disappear in 10 seconds.
  </crowd-toast>
</crowd-form>
```
Attributes

The following attributes are supported by this element.

**duration**
A number that specifies the duration, in milliseconds, that the notification appears on the screen.

**text**
The text to display in the notification.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 742)
- **Child elements**: none

See Also

For more information, see the following.

- [Use Amazon SageMaker Ground Truth to Label Data](p. 370)
- [Crowd HTML Elements Reference](p. 720)

crowd-toggle-button

A button that acts as an ON/OFF switch, toggling a state.

See an interactive example of an HTML template that uses this Crowd HTML Element in [CodePen](https://codepen.io).

The following example shows different ways you can use to use the `<crowd-toggle-button>` HTML element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<!--Toggle button without value-->
<crowd-toggle-button name="toggleButtonWithoutValue"></crowd-toggle-button>

<!--Toggle button with value-->
<crowd-toggle-button name="toggleButtonWithValue" value="someValue"></crowd-toggle-button>

<!--Toggle button disabled-->
<crowd-toggle-button name="toggleButtonDisabled" disabled></crowd-toggle-button>

<!--Toggle button marked invalid-->
<crowd-toggle-button name="toggleButtonInvalid" invalid></crowd-toggle-button>

<!--Toggle button marked required-->
<crowd-toggle-button name="toggleButtonRequired" required></crowd-toggle-button>
</crowd-form>
```
Attributes

The following attributes are supported by this element.

checked
A Boolean switch that, if present, displays the button switched to the ON position.

disabled
A Boolean switch that, if present, displays the button as disabled and prevents toggling.

invalid
When in an off position, a button using this attribute, will display in an alert color. The standard is red, but may be changed in CSS. When toggled on, the button will display in the same color as other buttons in the on position.

name
A string that is used to identify the answer submitted by the worker. This value matches a key in the JSON object that specifies the answer.

required
A Boolean switch that, if present, requires the worker to provide input.

value
A value used in the output as the property name for the element's Boolean state. Defaults to "on" if not provided.

Element Hierarchy

This element has the following parent and child elements.

- Parent elements: crowd-form (p. 742)
- Child elements: none

Output

This element outputs the name as the name of an object, containing the value as a property name and the element's state as Boolean value for the property. If no value for the element is specified, the property name defaults to "on."

Example Sample output for this element

```json
[
   {
      "theToggler": {
         "on": true
      }
   }
]
```

Augmented AI Crowd HTML Elements

The following Crowd HTML Elements are only available for Amazon Augmented AI human workflow tasks.

Topics

• crowd-textract-analyze-document (p. 792)
• crowd-rekognition-detect-moderation-labels (p. 795)

crowd-textract-analyze-document

A widget to enable human review of an Amazon Textract document analysis result.

Attributes

The following attributes are supported by this element.

header

This is the text that is displayed as the header.

src

This is a link to the image to be analyzed by the worker.

initialValue

This sets initial values for attributes found in the worker UI.

The following is an example of an initialValue input:

```json
[
  {
    "blockType": "KEY_VALUE_SET",
    "confidence": 38.43309020996094,
    "geometry": {
      "boundingBox": {
        "width": 0.32613086700439453,
        "weight": 0.0942094624042511,
        "left": 0.483383575248718,
        "top": 0.5227988958558765
      },
      "polygon": [
        {
          "x": 0.123, "y": 0.345,
        }, ...]
    }
  },
  {
    "id": "8c97b240-0969-4678-834a-646c95da9cf4",
    "relationships": [
      {
        "type": "CHILD",
        "ids": [
          "7ee7b7da-ee1b-428d-a567-55a3e3affa56",
          "4d6da730-ba43-467c-a9a5-c6137ba0c472"
        ]
      }
    ]
  }
]
```
blockTypes

This determines the kind of analysis the workers can do. Only KEY_VALUE_SET is currently supported.

keys

This specifies new keys and the associated text value the worker can add. The input values for keys can include the following elements:

- importantFormKey accepts strings, and is used to specify a single key.
- importantFormKeyAliases can be used to specify aliases that are acceptable alternatives to the keys supplied. Use this element to identify alternative spellings or presentations of your keys. This parameter accepts a list of one or more strings.

The following is an example of an input for keys.

```
[  
  {  
    importantFormKey: 'Address',  
    importantFormKeyAliases: [  
      'address',  
      'Addr.',  
      'Add.',  
    ]  
  },  
  {  
    importantFormKey: 'Last name',  
    importantFormKeyAliases: ['Surname']  
  }  
]
```

no-key-edit

This prevents the workers from editing the keys of annotations passed through initialValu. This prevents workers from editing the keys that have been detected on your documents. This is required.

no-geometry-edit

This prevents workers from editing the polygons of annotations passed through initialValue. For example, this would prevent the worker from editing the bounding box around a given key. This is required.

Element Hierarchy

This element has the following parent and child elements.

- Parent elements – crowd-form
• Child elements – full-instructions (p. 794), short-instructions (p. 794)

Regions

The following regions are supported by this element. You can use custom HTML and CSS code within these regions to format your instructions to workers. For example, use the short-instructions section to provide good and bad examples of how to complete a task.

full-instructions

General instructions about how to work with the widget.

short-instructions

Important task-specific instructions that are displayed in a prominent place.

Example of a Worker Template Using the crowd Element

An example of a worker template using this crowd element would look like the following.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
{% capture s3_uri %}http://s3.amazonaws.com/{{ task.input.aiServiceRequest.document.s3Object.bucket }}/{{ task.input.aiServiceRequest.document.s3Object.name }}{% endcapture %}

<crowd-form>
  <crowd-textract-analyze-document
    src="{{ s3_uri | grant_read_access }}"
    initial-value="{{ task.input.selectedAiServiceResponse.blocks }}"
    header="Review the key-value pairs listed on the right and correct them if they don't match the following document."
    no-key-edit
    no-geometry-edit
    keys="{{ task.input.humanLoopContext.importantFormKeys }}"
    block-types="["KEY_VALUE_SET"]"
  >
  <short-instructions header="Instructions">
    <style>
      .instructions {
        white-space: pre-wrap;
      }
      .instructionsImage {
        display: inline-block;
        max-width: 100%;
      }
    </style>
    <p class='instructions'>Click on a key-value block to highlight the corresponding key-value pair in the document.

    If it is a valid key-value pair, review the content for the value. If the content is incorrect, correct it.

    The text of the value is incorrect, correct it.
    <img class='instructionsImage' src="https://assets.crowd.aws/images/a2i-console/correct-value-text.png"/>

    A wrong value is identified, correct it.
    <img class='instructionsImage' src="https://assets.crowd.aws/images/a2i-console/correct-value.png"/>

    If it is not a valid key-value relationship, choose No.
    <img class='instructionsImage' src="https://assets.crowd.aws/images/a2i-console/not-a-key-value-pair.png"/>
  </short-instructions>
</crowd-form>
```
Output

The following is a sample of the output from this element. You can find a detailed explanation of this output in the Amazon Textract `AnalyzeDocument` API documentation.

```
{
  "AWS/Textract/AnalyzeDocument/Forms/V1": {
    "blocks": [
      {
        "blockType": "KEY_VALUE_SET",
        "id": "8c97b240-0969-4678-834a-646c95da9cf4",
        "relationships": [
          {
            "type": "CHILD",
            "ids": ["7ee7b7da-ee1b-428d-a567-55a3e3affa56", "4d6da730-ba43-467c-a9a5-c6137ba0c472"]
          },
          {
            "type": "VALUE",
            "ids": ["6ee7b7da-ee1b-428d-a567-55a3e3affa54"]
          }
        ],
        "entityTypes": ["KEY"],
        "text": "Foo bar baz"
      }
    ]
  }
}
```

crowd-rekognition-detect-moderation-labels

A widget to enable human review of an Amazon Rekognition image moderation result.
Attributes

The following attributes are supported by this element.

**header**

This is the text that is displayed as the header.

**src**

This is a link to the image to be analyzed by the worker.

**categories**

This supports categories as an array of strings or an array of objects where each object has a name field.

If the categories come in as objects, the following applies:

- The displayed categories are the value of the name field.
- The returned answer contains the full objects of any selected categories.

If the categories come in as strings, the following applies:

- The returned answer is an array of all the strings that were selected.

**exclusion-category**

By setting this attribute you create a button underneath the categories in the UI.

- When a user chooses the button, all categories are deselected and disabled.
- Choosing the button again re-enables the categories so that users can choose them.
- If you submit after choosing the button, it returns an empty array.

Element Hierarchy

This element has the following parent and child elements.

- Parent elements – crowd-form
- Child elements – full-instructions (p. 796), short-instructions (p. 796)

AWS Regions

The following AWS Regions are supported by this element. You can use custom HTML and CSS code within these Regions to format your instructions to workers. For example, use the short-instructions section to provide good and bad examples of how to complete a task.

**full-instructions**

General instructions about how to work with the widget.

**short-instructions**

Important task-specific instructions that are displayed in a prominent place.
Example Worker Template with the crowd Element

An example of a worker template using the crowd element would look like the following.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
{% capture s3_uri %}http://s3.amazonaws.com/
{{ task.input.aiServiceRequest.image.s3Object.bucket }}/
{{ task.input.aiServiceRequest.image.s3Object.name }}{% endcapture %}

<crowd-form>
<crowd-rekognition-detect-moderation-labels
categories='[
    {% for label in task.input.selectedAiServiceResponse.moderationLabels %}
    {
        name: "{{ label.name }}",
        parentName: "{{ label.parentName }}",
    },
    {% endfor %}
]'
src="{{ s3_uri | grant_read_access }}"
header="Review the image and choose all applicable categories."
>
<short-instructions header="Instructions">
<style>
  .instructions {
    white-space: pre-wrap;
  }
</style>
<p class='instructions'>Review the image and choose all applicable categories. If no categories apply, choose None.

<b>Nudity</b>
Visuals depicting nude male or female person or persons

<b>Graphic Male Nudity</b>
Visuals depicting full frontal male nudity, often close ups

<b>Graphic Female Nudity</b>
Visuals depicting full frontal female nudity, often close ups

<b>Sexual Activity</b>
Visuals depicting various types of explicit sexual activities and pornography

<b>Illustrated Nudity or Sexual Activity</b>
Visuals depicting animated or drawn sexual activity, nudity or pornography

<b>Adult Toys</b>
Visuals depicting adult toys, often in a marketing context

<b>Female Swimwear or Underwear</b>
Visuals depicting female person wearing only swimwear or underwear

<b>Male Swimwear Or Underwear</b>
Visuals depicting male person wearing only swimwear or underwear

<b>Partial Nudity</b>
Visuals depicting covered up nudity, for example using hands or pose

<b>Revealing Clothes</b>
Visuals depicting revealing clothes and poses, such as deep cut dresses

<b>Graphic Violence or Gore</b>
Visuals depicting prominent blood or bloody injuries

<b>Physical Violence</b>
```
Visuals depicting violent physical assault, such as kicking or punching

<b>Weapon Violence</b>
Visuals depicting violence using weapons like firearms or blades, such as shooting

<b>Weapons</b>
Visuals depicting weapons like firearms and blades

<b>Self Injury</b>
Visuals depicting self-inflicted cutting on the body, typically in distinctive patterns using sharp objects

<b>Emaciated Bodies</b>
Visuals depicting extremely malnourished human bodies

<b>Corpses</b>
Visuals depicting human dead bodies

<b>Hanging</b>
Visuals depicting death by hanging

Output
The following is a sample of the output from this element. For details about this output, see Amazon Rekognition DetectModerationLabels API documentation.

```json
{
    "AWS/Rekognition/DetectModerationLabels/Image/V3": {
        "ModerationLabels": [
            { name: 'Gore', parentName: 'Violence' },
            { name: 'Corpses', parentName: 'Violence' }
        ]
    }
}
```
Prepare and Analyze Datasets

Import, prepare, transform, visualize and analyze data with Amazon SageMaker Data Wrangler. You can integrate Data Wrangler into your machine learning workflows to simplify and streamline data pre-processing and feature engineering using little to no coding. You can also add your own Python scripts and transformations to customize your data prep workflow.

Import data from Amazon S3, Amazon Redshift, Amazon Athena, and use Data Wrangler to create sophisticated machine learning data prep workflows with built-in and custom data transformations and analysis including feature target leakage and quick modeling.

After you have defined a data prep workflow, or data flow, you can integrate it with SageMaker Processing, SageMaker Pipelines, and SageMaker Feature Store, simplify the task of processing, sharing and storing ML training data. You can also export your data flow to a python script and create a custom ML data prep pipeline.

For more information, see Prepare ML Data with Amazon SageMaker Data Wrangler (p. 815).

Topics

- Detect Pretraining Data Bias (p. 799)
- Prepare ML Data with Amazon SageMaker Data Wrangler (p. 815)
- Prepare Data at Scale with Studio Notebooks (p. 983)

Detect Pretraining Data Bias

Algorithmic bias, discrimination, fairness, and related topics have been studied across disciplines such as law, policy, and computer science. A computer system might be considered biased if it discriminates against certain individuals or groups of individuals. The machine learning models powering these applications learn from data and this data could reflect disparities or other inherent biases. For example, the training data may not have sufficient representation of various demographic groups or may contain biased labels. The machine learning models trained on datasets that exhibit these biases could end up learning them and then reproduce or even exacerbate those biases in their predictions. The field of machine learning provides an opportunity to address biases by detecting them and measuring them at each stage of the ML lifecycle. You can use Amazon SageMaker Clarify to determine whether data used for training models encodes any bias.

Bias can be measured before training and after training, and monitored against baselines after deploying models to endpoints for inference. Pretraining bias metrics are designed to detect and measure bias in the raw data before it is used to train a model. The metrics used are model-agnostic because they do not depend on any model outputs. However, there are different concepts of fairness that require distinct measures of bias. Amazon SageMaker Clarify provides bias metrics to quantify various fairness criteria.

For additional information about bias metrics, see Learn How Amazon SageMaker Clarify Helps Detect Bias and Fairness Measures for Machine Learning in Finance.

Amazon SageMaker Clarify Terms for Bias and Fairness

SageMaker Clarify uses the following terminology to discuss bias and fairness.
Feature

An individual measurable property or characteristic of a phenomenon being observed, contained in a column for tabular data.

Label

Feature that is the target for training a machine learning model. Referred to as the observed label or observed outcome.

Predicted label

The label as predicted by the model. Also referred to as the predicted outcome.

Sample

An observed entity described by feature values and label value, contained in a row for tabular data.

Dataset

A collection of samples.

Bias

An imbalance in the training data or the prediction behavior of the model across different groups, such as age or income bracket. Biases can result from the data or algorithm used to train your model. For instance, if an ML model is trained primarily on data from middle-aged individuals, it may be less accurate when making predictions involving younger and older people.

Bias metric

A function that returns numerical values indicating the level of a potential bias.

Bias report

A collection of bias metrics for a given dataset, or a combination of a dataset and a model.

Positive label values

Label values that are favorable to a demographic group observed in a sample. In other words, designates a sample as having a positive result.

Negative label values

Label values that are unfavorable to a demographic group observed in a sample. In other words, designates a sample as having a negative result.

Group variable

Categorical column of the dataset that is used to form subgroups for the measurement of Conditional Demographic Disparity (CDD). Required only for this metric with regards to Simpson’s paradox.

Facet

A column or feature that contains the attributes with respect to which bias is measured.

Facet value

The feature values of attributes that bias might favor or disfavor.

Predicted probability

The probability, as predicted by the model, of a sample having a positive or negative outcome.

Sample Notebooks

Amazon SageMaker Clarify provides the following sample notebook for bias detection:
• **Explainability and bias detection with Amazon SageMaker Clarify** – Use SageMaker Clarify to create a processing job for the detecting bias and explaining model predictions with feature attributions.

This notebook has been verified to run in Amazon SageMaker Studio only. If you need instructions on how to open a notebook in Amazon SageMaker Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 133). If you’re prompted to choose a kernel, choose Python 3 (Data Science).

**Topics**
- Measure Pretraining Bias (p. 801)
- Generate Reports for Bias in Pretraining Data in SageMaker Studio (p. 810)

**Measure Pretraining Bias**

Measuring bias in ML models is a first step to mitigating bias. Each measure of bias corresponds to a different notion of fairness. Even considering simple concepts of fairness leads to many different measures applicable in various contexts. For example, consider fairness with respect to age, and, for simplicity, that middle-aged and rest of the age groups are the two relevant demographics, referred to as **facets**. In the case of an ML model for lending, we may want small business loans to be issued to equal numbers of both demographics. Or, when processing job applicants, we may want to see equal numbers of members of each demographic hired. However, this approach may assume that equal numbers of both age groups apply to these jobs, so we may want to condition on the number that apply. Further, we may want to consider not whether equal numbers apply, but whether we have equal numbers of qualified applicants. Or, we may consider fairness to be an equal acceptance rate of qualified applicants across both age demographics, or, an equal rejection rate of applicants, or both. You might use datasets with different proportions of data on the attributes of interest. This imbalance can conflate the bias measure you choose. The models might be more accurate in classifying one facet than in the other. Thus, you need to choose bias metrics that are conceptually appropriate for the application and the situation.

We use the following notation to discuss the bias metrics. The conceptual model described here is for binary classification, where events are labeled as having only two possible outcomes in their sample space, referred to as positive (with value 1) and negative (with value 0). This framework is usually extensible to multiclassification in a straightforward way or to cases involving continuous valued outcomes when needed. In the binary classification case, positive and negative labels are assigned to outcomes recorded in a raw dataset for a favored facet \( a \) and for a disfavored facet \( d \). These labels \( y \) are referred to as **observed labels** to distinguish them from the **predicted labels** \( y' \) that are assigned by a machine learning model during the training or inferences stages of the ML lifecycle. These labels are used to define probability distributions \( P_a(y) \) and \( P_d(y) \) for their respective facet outcomes.

- **labels:**
  - \( y \) represents the \( n \) observed labels for event outcomes in a training dataset.
  - \( y' \) represents the predicted labels for the \( n \) observed labels in the dataset by a trained model.

- **outcomes:**
  - A positive outcome (with value 1) for a sample, such as an application acceptance.
    - \( n^{(1)} \) is the number of observed labels for positive outcomes (acceptances).
    - \( n^{(1)} \) is the number of predicted labels for positive outcomes (acceptances).
  - A negative outcome (with value 0) for a sample, such as an application rejection.
    - \( n^{(0)} \) is the number of observed labels for negative outcomes (rejections).
    - \( n^{(0)} \) is the number of predicted labels for negative outcomes (rejections).

- **facet values:**
  - facet \( a \) – The feature value that defines a demographic that bias favors.
    - \( n_a \) is the number of observed labels for the favored facet value: \( n_a = n_a^{(1)} + n_a^{(0)} \) the sum of the positive and negative observed labels for the value facet \( a \).
Measure Pretraining Bias

- \( n'_a \) is the number of predicted labels for the favored facet value: \( n'_a = n'_a^{(1)} + n'_a^{(0)} \) the sum of the positive and negative predicted outcome labels for the facet value \( a \). Note that \( n'_a = n_a \).
- facet \( d \) – The feature value that defines a demographic that bias disfavors.
- \( n_d \) is the number of observed labels for the disfavored facet value: \( n_d = n_d^{(1)} + n_d^{(0)} \) the sum of the positive and negative observed labels for the facet value \( d \).
- \( n'_d \) is the number of predicted labels for the disfavored facet value: \( n'_d = n'_d^{(1)} + n'_d^{(0)} \) the sum of the positive and negative predicted labels for the facet value \( d \). Note that \( n'_d = n_d \).

- probability distributions for outcomes of the labeled facet data outcomes:
  - \( P_a(y) \) is the probability distribution of the observed labels for facet \( a \). For binary labeled data, this distribution is given by the ratio of the number of samples in facet \( a \) labeled with positive outcomes to the total number, \( P_a(y^{(1)}) = n_a^{(1)}/n_a \), and the ratio of the number of samples with negative outcomes to the total number, \( P_a(y^{(0)}) = n_a^{(0)}/n_a \).
  - \( P_d(y) \) is the probability distribution of the observed labels for facet \( d \). For binary labeled data, this distribution is given by the number of samples in facet \( d \) labeled with positive outcomes to the total number, \( P_d(y^{(1)}) = n_d^{(1)}/n_d \), and the ratio of the number of samples with negative outcomes to the total number, \( P_d(y^{(0)}) = n_d^{(0)}/n_d \).

Models trained on data biased by demographic disparities might learn and even exacerbate them. To identify bias in the data before expending resources to train models on it, SageMaker Clarify provides data bias metrics that you can compute on raw datasets before training. All of the pretraining metrics are model-agnostic because they do not depend on model outputs and so are valid for any model. The first bias metric examines facet imbalance, but not outcomes. It determines the extent to which the amount of training data is representative across different facets, as desired for the application. The remaining bias metrics compare the distribution of outcome labels in various ways for facets \( a \) and \( d \) in the data. The metrics that range over negative values can detect negative bias. The following table contains a cheat sheet for quick guidance and links to the pretraining bias metrics.

### Pretraining Bias Metrics

<table>
<thead>
<tr>
<th>Bias metric</th>
<th>Description</th>
<th>Example question</th>
<th>Interpreting metric values</th>
</tr>
</thead>
</table>
| Class Imbalance (CI) (p. 805) | Measures the imbalance in the number of members between different facet values. | Could there be age-based biases due to not having enough data for the demographic outside a middle-aged facet? | Normalized range: \([-1, +1]\)  
Interpretation:  
- Positive values indicate the facet \( a \) has more training samples in the dataset.  
- Values near zero indicate the facets are balanced in the number of training samples in the dataset.  
- Negative values indicate the facet \( d \) has more training samples in the dataset. |
<table>
<thead>
<tr>
<th>Bias metric</th>
<th>Description</th>
<th>Example question</th>
<th>Interpreting metric values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Difference in Proportions of Labels (DPL) (p. 806)</td>
<td>Measures the imbalance of positive outcomes between different facet values.</td>
<td>Could there be age-based biases in ML predictions due to biased labeling of facet values in the data?</td>
<td>Range for normalized binary &amp; multicategory facet labels: [-1,+1] Range for continuous labels: (-∞, +∞) Interpretation: • Positive values indicate facet a has a higher proportion of positive outcomes. • Values near zero indicate a more equal proportion of positive outcomes between facets. • Negative values indicate facet d has a higher proportion of positive outcomes.</td>
</tr>
<tr>
<td>Kullback-Leibler Divergence (KL) (p. 806)</td>
<td>Measures how much the outcome distributions of different facets diverge from each other entropically.</td>
<td>How different are the distributions for loan application outcomes for different demographic groups?</td>
<td>Range for binary, multicategory, continuous: [0, +∞) Interpretation: • Values near zero indicate the labels are similarly distributed. • Positive values indicate the label distributions diverge, the more positive the larger the divergence.</td>
</tr>
<tr>
<td>Jensen-Shannon Divergence (JS) (p. 807)</td>
<td>Measures how much the outcome distributions of different facets diverge from each other entropically.</td>
<td>How different are the distributions for loan application outcomes for different demographic groups?</td>
<td>Range for binary, multicategory, continuous: [0, +∞) Interpretation: • Values near zero indicate the labels are similarly distributed. • Positive values indicate the label distributions diverge, the more positive the larger the divergence.</td>
</tr>
</tbody>
</table>
### Measure Pretraining Bias

<table>
<thead>
<tr>
<th>Bias metric</th>
<th>Description</th>
<th>Example question</th>
<th>Interpreting metric values</th>
</tr>
</thead>
</table>
| **L_p-norm (LP) (p. 807)** | Measures a p-norm difference between distinct demographic distributions of the outcomes associated with different facets in a dataset. | How different are the distributions for loan application outcomes for different demographics? | Range for binary, multicategory, continuous: [0, +∞)  
Interpretation:  
• Values near zero indicate the labels are similarly distributed.  
• Positive values indicate the label distributions diverge, the more positive the larger the divergence. |
| **Total Variation Distance (TVD) (p. 808)** | Measures half of the L_1-norm difference between distinct demographic distributions of the outcomes associated with different facets in a dataset. | How different are the distributions for loan application outcomes for different demographics? | Range for binary, multicategory, and continuous outcomes: [0, +∞)  
Interpretation:  
• Values near zero indicate the labels are similarly distributed.  
• Positive values indicate the label distributions diverge, the more positive the larger the divergence. |
| **Kolmogorov-Smirnov (KS) (p. 808)** | Measures maximum divergence between outcomes in distributions for different facets in a dataset. | Which college application outcomes manifest the greatest disparities by demographic group? | Range of KS values for binary, multicategory, and continuous outcomes: [0,1]  
Interpretation:  
• Values near zero indicate the labels were evenly distributed between facets in all outcome categories.  
• Values near one indicate the labels for one category were all in one facet, so very imbalanced.  
• Intermittent values indicate relative degrees of maximum label imbalance. |
### Bias metric

<table>
<thead>
<tr>
<th>Bias metric</th>
<th>Description</th>
<th>Example question</th>
<th>Interpreting metric values</th>
</tr>
</thead>
</table>
| **Conditional Demographic Disparity (CDD) (p. 809)** | Measures the disparity of outcomes between different facets as a whole, but also by subgroups. | Do some groups have a larger proportion of rejections for college admission outcomes than their proportion of acceptances? | Range of CDD: [-1, +1]  
• Positive values indicate outcomes where facet \(d\) is rejected more than accepted.  
• Near zero indicates no demographic disparity on average.  
• Negative values indicate outcomes where facet \(a\) is rejected more than accepted. |

For additional information about bias metrics, see *Fairness Measures for Machine Learning in Finance*.

**Topics**

- Class Imbalance (CI) (p. 805)
- Difference in Proportions of Labels (DPL) (p. 806)
- Kullback-Leibler Divergence (KL) (p. 806)
- Jensen-Shannon Divergence (JS) (p. 807)
- Lp-norm (LP) (p. 807)
- Total Variation Distance (TVD) (p. 808)
- Kolmogorov-Smirnov (KS) (p. 808)
- Conditional Demographic Disparity (CDD) (p. 809)

### Class Imbalance (CI)

Class imbalance (CI) bias occurs when a facet value \(d\) has fewer training samples when compared with another facet \(a\) in the dataset. This is because models preferentially fit the larger facets at the expense of the smaller facets and so can result in a higher training error for facet \(d\). Models are also at higher risk of overfitting the smaller data sets, which can cause a larger test error for facet \(d\). Consider the example where a machine learning model is trained primarily on data from middle-aged individuals (facet \(a\)), it might be less accurate when making predictions involving younger and older people (facet \(d\)).

The formula for the (normalized) facet imbalance measure:

\[
CI = \frac{(n_a - n_d)}{(n_a + n_d)}
\]

Where \(n_a\) is the number of members of facet \(a\) and \(n_d\) the number for facet \(d\). Its values range over the interval \([-1, 1]\).

- Positive CI values indicate the facet \(a\) has more training samples in the dataset and a value of 1 indicates the data only contains members of the facet \(a\).
- Values of CI near zero indicate a more equal distribution of members between facets and a value of zero indicates a perfectly equal partition between facets and represents a balanced distribution of samples in the training data.
• Negative CI values indicate the facet \( d \) has more training samples in the dataset and a value of -1 indicates the data only contains members of the facet \( d \).

• CI values near either of the extremes values of -1 or 1 are very imbalanced and are at a substantial risk of making biased predictions.

If a significant facet imbalance is found to exist among the facets, you might want to rebalance the sample before proceeding to train models on it.

**Difference in Proportions of Labels (DPL)**

The difference in proportions of labels (DPL) compares the proportion of observed outcomes with positive labels for facet \( d \) with the proportion of observed outcomes with positive labels of facet \( a \) in a training dataset. For example, you could use it to compare the proportion of middle-aged individuals (facet \( a \)) and other age groups (facet \( d \)) approved for financial loans. Machine learning models try to mimic the training data decisions as closely as possible. So a machine learning model trained on a dataset with a high DPL is likely to reflect the same imbalance in its future predictions.

The formula for the difference in proportions of labels is as follows:

\[
DPL = (q_a - q_d)
\]

Where:

• \( q_a = \frac{n_a^{(1)}}{n_a} \) is the proportion of facet \( a \) who have an observed label value of 1. For example, the proportion of a middle-aged demographic who get approved for loans. Here \( n_a^{(1)} \) represents the number of members of facet \( a \) who get a positive outcome and \( n_a \) the is number of members of facet \( a \).

• \( q_d = \frac{n_d^{(1)}}{n_d} \) is the proportion of facet \( d \) who have an observed label value of 1. For example, the proportion of people outside the middle-aged demographic who get approved for loans. Here \( n_d^{(1)} \) represents the number of members of the facet \( d \) who get a positive outcome and \( n_d \) the is number of members of the facet \( d \).

If DPL is close enough to 0, then we say that **demographic parity** has been achieved.

For binary and multiclass facet labels, the DPL values range over the interval (-1, 1). For continuous labels, we set a threshold to collapse the labels to binary.

• Positive DPL values indicate that facet \( a \) is has a higher proportion of positive outcomes when compared with facet \( d \).

• Values of DPL near zero indicate a more equal proportion of positive outcomes between facets and a value of zero indicates perfect demographic parity.

• Negative DPL values indicate that facet \( d \) has a higher proportion of positive outcomes when compared with facet \( a \).

Whether or not a high magnitude of DPL is problematic varies from one situation to another. In a problematic case, a high-magnitude DPL might be a signal of underlying issues in the data. For example, a dataset with high DPL might reflect historical biases or prejudices against age-based demographic groups that would be undesirable for a model to learn.

**Kullback-Leibler Divergence (KL)**

The Kullback-Leibler divergence (KL) measures how much the observed label distribution of facet \( a \), \( P_a(y) \), diverges from distribution of facet \( d \), \( P_d(y) \). It is also known as the relative entropy of \( P_a(y) \) with respect to \( P_d(y) \) and quantifies the amount of information lost when moving from \( P_a(y) \) to \( P_d(y) \).

The formula for the Kullback-Leibler divergence is as follows:
KL(P_a \| P_d) = \sum_y P_a(y) \cdot \log[P_a(y)/P_d(y)]

It is the expectation of the logarithmic difference between the probabilities $P_a(y)$ and $P_d(y)$, where the expectation is weighted by the probabilities $P_a(y)$. This is not a true distance between the distributions as it is asymmetric and does not satisfy the triangle inequality. The implementation uses natural logarithms, giving KL in units of nats. Using different logarithmic bases gives proportional results but in different units. For example, using base 2 gives KL in units of bits.

For example, assume that a group of applicants for loans have a 30% approval rate (facet $d$) and that the approval rate for other applicants (facet $a$) is 80%. The Kullback-Leibler formula gives you the label distribution divergence of facet $a$ from facet $d$ as follows:

$$KL = 0.8 \cdot \ln(0.8/0.3) + 0.2 \cdot \ln(0.2/0.7) = 0.53$$

There are two terms in the formula here because labels are binary in this example. This measure can be applied to multiple labels in addition to binary ones. For example, in a college admissions scenario, assume an applicant may be assigned one of three category labels: $y_i = \{y_0, y_1, y_2\} = \{\text{rejected}, \text{waitlisted}, \text{accepted}\}$.

Range of values for the KL metric for binary, multicategory, and continuous outcomes is $[0, +\infty)$.

- Values near zero mean the outcomes are similarly distributed for the different facets.
- Positive values mean the label distributions diverge, the more positive the larger the divergence.

### Jensen-Shannon Divergence (JS)

The Jensen-Shannon divergence (JS) measures how much the label distributions of different facets diverge from each other entropically. It is based on the Kullback-Leibler divergence, but it is symmetric.

The formula for the Jensen-Shannon divergence is as follows:

$$JS = \frac{1}{2} \cdot [KL(P_a \| P) + KL(P_d \| P)]$$

Where $P = \frac{1}{2} (P_a + P_d)$, the average label distribution across facets $a$ and $d$.

The range of JS values for binary, multicategory, continuous outcomes is $[0, \ln(2))$.

- Values near zero mean the labels are similarly distributed.
- Positive values mean the label distributions diverge, the more positive the larger the divergence.

This metric indicates whether there is a big divergence in one of the labels across facets.

### L_p-norm (LP)

The L_p-norm (LP) measures the p-norm distance between the facet distributions of the observed labels in a training dataset. This metric is non-negative and so cannot detect reverse bias.

The formula for the L_p-norm is as follows:

$$L_p(P_a, P_d) = (\sum ||P_a - P_d||^p)^{1/p}$$

Where the p-norm distance between the points $x$ and $y$ is defined as follows:

$$L_p(x, y) = (|x_1-y_1|^p + |x_2-y_2|^p + \ldots + |x_n-y_n|^p)^{1/p}$$

The 2-norm is the Euclidean norm. Assume you have an outcome distribution with three categories, for example, $y_i = \{y_0, y_1, y_2\} = \{\text{accepted}, \text{waitlisted}, \text{rejected}\}$ in a college admissions multicategory scenario. You take the sum of the squares of the differences between the outcome counts for facets $a$ and $d$. The resulting Euclidean distance is calculated as follows:
\[ L_2(P_a, P_d) = \left[ (n_a^{(0)} - n_d^{(0)})^2 + (n_a^{(1)} - n_d^{(1)})^2 + (n_a^{(2)} - n_d^{(2)})^2 \right]^{1/2} \]

Where:

- \( n_a^{(i)} \) is number of the \( i \)th category outcomes in facet \( a \): for example \( n_a^{(0)} \) is number of facet \( a \) acceptances.
- \( n_d^{(i)} \) is number of the \( i \)th category outcomes in facet \( d \): for example \( n_d^{(2)} \) is number of facet \( d \) rejections.

The range of LP values for binary, multicategory, and continuous outcomes is \([0, \sqrt{2})\), where:

- Values near zero mean the labels are similarly distributed.
- Positive values mean the label distributions diverge, the more positive the larger the divergence.

### Total Variation Distance (TVD)

The total variation distance data bias metric (TVD) is half the \( L_1 \)-norm. The TVD is the largest possible difference between the probability distributions for label outcomes of facets \( a \) and \( d \). The \( L_1 \)-norm is the Hamming distance, a metric used compare two binary data strings by determining the minimum number of substitutions required to change one string into another. If the strings were to be copies of each other, it determines the number of errors that occurred when copying. In the bias detection context, TVD quantifies how many outcomes in facet \( a \) would have to be changed to match the outcomes in facet \( d \).

The formula for the Total variation distance is as follows:

\[ \text{TVD} = \frac{1}{2} \cdot L_1(P_a, P_d) \]

For example, assume you have an outcome distribution with three categories, \( y_i = \{y_0, y_1, y_2\} = \{\text{accepted, waitlisted, rejected}\} \), in a college admissions multicategory scenario. You take the differences between the counts of facets \( a \) and \( d \) for each outcome to calculate TVD. The result is as follows:

\[ L_1(P_a, P_d) = |n_a^{(0)} - n_d^{(0)}| + |n_a^{(1)} - n_d^{(1)}| + |n_a^{(2)} - n_d^{(2)}| \]

Where:

- \( n_a^{(i)} \) is number of the \( i \)th category outcomes in facet \( a \): for example \( n_a^{(0)} \) is number of facet \( a \) acceptances.
- \( n_d^{(i)} \) is number of the \( i \)th category outcomes in facet \( d \): for example \( n_d^{(2)} \) is number of facet \( d \) rejections.

The range of TVD values for binary, multicategory, and continuous outcomes is \([0, 1)\), where:

- Values near zero mean the labels are similarly distributed.
- Positive values mean the label distributions diverge, the more positive the larger the divergence.

### Kolmogorov-Smirnov (KS)

The Kolmogorov-Smirnov bias metric (KS) is equal to the maximum divergence between labels in the distributions for facets \( a \) and \( d \) of a dataset. The two-sample KS test implemented by SageMaker Clarify complements the other measures of label imbalance by finding the most imbalanced label.

The formula for the Kolmogorov-Smirnov metric is as follows:

\[ KS = \max(|P_a(y) - P_d(y)|) \]

For example, assume a group of applicants (facet \( a \)) to college are rejected, waitlisted, or accepted at 40%, 40%, 20% respectively and that these rates for other applicants (facet \( d \)) are 20%, 10%, 70%. Then the Kolmogorov-Smirnov bias metric value is as follows:
KS = max(|0.4-0.2|, |0.4-0.1|, |0.2-0.7|) = 0.5

This tells us the maximum divergence between facet distributions is 0.5 and occurs in the acceptance rates. There are three terms in the equation because labels are multiclass of cardinality three.

The range of LP values for binary, multicategory, and continuous outcomes is \([0, +1]\), where:

- Values near zero indicate the labels were evenly distributed between facets in all outcome categories. For example, both facets applying for a loan got 50% of the acceptances and 50% of the rejections.
- Values near one indicate the labels for one outcome were all in one facet. For example, facet \(a\) got 100% of the acceptances and facet \(d\) got none.
- Intermittent values indicate relative degrees of maximum label imbalance.

### Conditional Demographic Disparity (CDD)

The demographic disparity metric (DD) determines whether a facet has a larger proportion of the rejected outcomes in the dataset than of the accepted outcomes. In the binary case where there are two facets, men and women for example, that constitute the dataset, the disfavored one is labelled facet \(d\) and the favored one is labelled facet \(a\). For example, in the case of college admissions, if women applicants comprised 46% of the rejected applicants and comprised only 32% of the accepted applicants, we say that there is demographic disparity because the rate at which women were rejected exceeds the rate at which they are accepted. Women applicants are labelled facet \(d\) in this case. If men applicants comprised 54% of the rejected applicants and 68% of the accepted applicants, then there is not a demographic disparity for this facet as the rate of rejection is less that the rate of acceptance. Men applicants are labelled facet \(a\) in this case.

The formula for the demographic disparity for the less favored facet \(d\) is as follows:

$$DD_d = \frac{n_d^{(0)}}{n^{(0)}} - \frac{n_d^{(1)}}{n^{(1)}} = P_d^R(y^0) - P_d^A(y^1)$$

Where:

- \(n^{(0)} = n_a^{(0)} + n_d^{(0)}\) is the total number of rejected outcomes in the dataset for the favored facet \(a\) and disadvantaged facet \(d\).
- \(n^{(1)} = n_a^{(1)} + n_d^{(1)}\) is the total number of accepted outcomes in the dataset for the favored facet \(a\) and disadvantaged facet \(d\).
- \(P_d^R(y^0)\) is the proportion of rejected outcomes (with value 0) in facet \(d\).
- \(P_d^A(y^1)\) is the proportion of accepted outcomes (value 1) in facet \(d\).

For the college admission example, the demographic disparity for women is \(DD_d = 0.46 - 0.32 = 0.14\). For men \(DD_a = 0.54 - 0.68 = -0.14\).

A conditional demographic disparity (CDD) metric that conditions DD on attributes that define a strata of subgroups on the dataset is needed to rule out Simpson's paradox. The regrouping can provide insights into the cause of apparent demographic disparities for less favored facets. The classic case arose in the case of Berkeley admissions where men were accepted at a higher rate overall than women. The statistics for this case were used in the example calculations of DD. However, when departmental subgroups were examined, women were shown to have higher admission rates than men when conditioned by department. The explanation was that women had applied to departments with lower acceptance rates than men had. Examining the subgrouped acceptance rates revealed that women were actually accepted at a higher rate than men for the departments with lower acceptance rates.

The CDD metric gives a single measure for all of the disparities found in the subgroups defined by an attribute of a dataset by averaging them. It is defined as the weighted average of demographic disparities (DD) for each of the subgroups, with each subgroup disparity weighted in proportion to the number of observations in contains. The formula for the conditional demographic disparity is as follows:
CDD = (1/n)\(\sum n_i \cdot DD_i\)

Where:
- \(\sum n_i = n\) is the total number of observations and \(n_i\) is the number of observations for each subgroup.
- \(DD_i = n_i^{(0)}/n^{(0)} - n_i^{(1)}/n^{(1)} = P_i^R(y^0) - P_i^A(y^1)\) is the demographic disparity for the \(i\)th subgroup.

The demographic disparity for a subgroup \((DD_i)\) are the difference between the proportion of rejected outcomes and the proportion of accepted outcomes for each subgroup.

The range of \(DD\) values for binary outcomes for the full dataset \(DD_d\) or for its conditionalized subgroups \(DD_i\) is \([-1, +1]\).

- +1: when there are no rejections in facet \(a\) or subgroup and no acceptances in facet \(d\) or subgroup
- Positive values indicate there is a demographic disparity as facet \(d\) or subgroup has a greater proportion of the rejected outcomes in the dataset than of the accepted outcomes. The higher the value the less favored the facet and the greater the disparity.
- Negative values indicate there is not a demographic disparity as facet \(d\) or subgroup has a larger proportion of the accepted outcomes in the dataset than of the rejected outcomes. The lower the value the more favored the facet.
- -1: when there are no rejections in facet \(d\) or subgroup and no acceptances in facet \(a\) or subgroup

If you don’t condition on anything then CDD is zero if and only if DPL is zero.

This metric is useful for exploring the concepts of direct and indirect discrimination and of objective justification in EU and UK non-discrimination law and jurisprudence. For additional information, see Why Fairness Cannot Be Automated. This paper also contains the relevant data and analysis of the Berkeley admissions case that shows how conditionalizing on departmental admission rate subgroups illustrates Simpson’s paradox.

**Generate Reports for Bias in Pretraining Data in SageMaker Studio**

SageMaker Clarify is integrated with Amazon SageMaker Data Wrangler, which can help you identify bias during data preparation without having to write your own code. Data Wrangler provides an end-to-end solution to import, prepare, transform, featurize, and analyze data with Amazon SageMaker Studio. For an overview of the Data Wrangler data prep workflow, see Prepare ML Data with Amazon SageMaker Data Wrangler (p. 815). You specify attributes of interest, such as gender or age, and SageMaker Clarify runs a set of algorithms to detect the presence of bias in those attributes. After the algorithm runs, SageMaker Clarify provides a visual report with a description of the sources and severity of possible bias so that you can plan steps to mitigate. For example, in a financial dataset that contains few examples of business loans to one age group as compared to others, SageMaker flags the imbalance so that you can avoid a model that disfavors that age group.

**To analyze and report on data bias**

To get started with Data Wrangler, see Get Started with Data Wrangler (p. 817).

1. Open Amazon SageMaker Studio and choose Create Data Flow from the Import and prepare your data tile.
2. From the Import data tab, choose Amazon S3 and then specify your data source on the Data sources/S3 source page.

3. After you have imported your data, choose the plus sign on the Data flow page and then choose Add Analysis.
4. On the Create Analysis page, go to the Configure panel and then choose Bias Report from the Chart menu.

5. Configure the bias report by providing the Name, the column to predict and whether it is a value or threshold, the column to analyze for bias (the facet) and whether it is a value or threshold.
6. Continue configuring the bias report by choosing the bias metrics.
7. Choose **Check for bias** to generate and view the bias report. Scroll down to view all of the reports.

8. Choose the caret to the right of the bias metric description to see documentation that can help you interpret the significance of the metric values.

9. To view a table summary of the bias metric values, choose the table. You can save the report for export by choosing **Create** in the lower-right corner of the page.
10. On the page where your data bias reports are stored, choose the Export tab to download the reports.

Prepare ML Data with Amazon SageMaker Data Wrangler

Amazon SageMaker Data Wrangler (Data Wrangler) is a feature of Amazon SageMaker Studio that provides an end-to-end solution to import, prepare, transform, featurize, and analyze data. You can integrate a Data Wrangler data preparation flow into your machine learning (ML) workflows to simplify and streamline data pre-processing and feature engineering using little to no coding. You can also add your own Python scripts and transformations to customize workflows.
Data Wrangler provides the following core functionalities to help you analyze and prepare data for machine learning applications.

- **Import** – Connect to and import data from Amazon Simple Storage Service (Amazon S3), Amazon Athena (Athena), Amazon Redshift, Snowflake, and Databricks.
- **Data Flow** – Create a data flow to define a series of ML data prep steps. You can use a flow to combine datasets from different data sources, identify the number and types of transformations you want to apply to datasets, and define a data prep workflow that can be integrated into an ML pipeline.
- **Transform** – Clean and transform your dataset using standard transforms like string, vector, and numeric data formatting tools. Featurize your data using transforms like text and date/time embedding and categorical encoding.
- **Generate Data Insights** – Automatically verify data quality and detect abnormalities in your data with Data Wrangler Data Insights and Quality Report.
- **Analyze** – Analyze features in your dataset at any point in your flow. Data Wrangler includes built-in data visualization tools like scatter plots and histograms, as well as data analysis tools like target leakage analysis and quick modeling to understand feature correlation.
- **Export** – Export your data preparation workflow to a different location. The following are example locations:
  - Amazon Simple Storage Service (Amazon S3) bucket
  - Amazon SageMaker Model Building Pipelines – Use SageMaker Pipelines to automate model deployment. You can export the data that you’ve transformed directly to the pipelines.
  - Amazon SageMaker Feature Store – Store the features and their data in a centralized store.
  - Python script – Store the data and their transformations in a Python script for your custom workflows.

To start using Data Wrangler, see [Get Started with Data Wrangler](#) (p. 817).

**Important**
Data Wrangler no longer supports Jupyter Lab Version 1 (JL1). To access the latest features and updates, update to Jupyter Lab Version 3. For more information about upgrading, see [View and update the JupyterLab version of an app from the console](#) (p. 125).

Get Started with Data Wrangler

Amazon SageMaker Data Wrangler is a feature in Amazon SageMaker Studio. Use this section to learn how to access and get started using Data Wrangler. Do the following:

1. Complete each step in Prerequisites (p. 817).
2. Follow the procedure in Access Data Wrangler (p. 817) to start using Data Wrangler.

Prerequisites

To use Data Wrangler, you must complete the following prerequisites.

1. To use Data Wrangler, you need access to an Amazon Elastic Compute Cloud (Amazon EC2) instance. For more information about the Amazon EC2 instances that you can use, see Instances (p. 864). To learn how to view your quotas and, if necessary, request a quota increase, see AWS service quotas.
2. Configure the required permissions described in Security and Permissions (p. 966).

To use Data Wrangler, you need an active Studio instance. To learn how to launch a new instance, see Onboard to Amazon SageMaker Domain (p. 35). When your Studio instance is Ready, use the instructions in Access Data Wrangler (p. 817).

Access Data Wrangler

The following procedure assumes you have completed the Prerequisites (p. 817).

To access Data Wrangler in Studio:

1. Next to the user you want to use to launch Studio, select Open Studio.
2. When Studio opens, select the + sign on the New data flow card under ML tasks and components. This creates a new directory in Studio with a .flow file inside, which contains your data flow. The .flow file automatically opens in Studio.

You can also create a new flow by selecting File, then New, and choosing Data Wrangler Flow in the top navigation bar.
3. (Optional) Rename the new directory and the .flow file.

4. When you create a new .flow file in Studio, you might see a carousel that introduces you to Data Wrangler.

   This may take a few minutes.

   This messaging persists as long as the KernelGateway app on your User Details page is Pending. To see the status of this app, in the SageMaker console on the Amazon SageMaker Studio page, select the name of the user you are using to access Studio. On the User Details page, you see a KernelGateway app under Apps. Wait until this app status is Ready to start using Data Wrangler. This can take around 5 minutes the first time you launch Data Wrangler.
5. To get started, choose a data source and use it to import a dataset. See Import (p. 827) to learn more.

When you import a dataset, it appears in your data flow. To learn more, see Create and Use a Data Wrangler Flow (p. 864).

6. After you import a dataset, Data Wrangler automatically infers the type of data in each column. Choose + next to the Data types step and select Edit data types.

   **Important**
   After you add transforms to the Data types step, you cannot bulk-update column types using Update types.

7. Use the data flow to add transforms and analyses. To learn more see Transform Data (p. 889) and Analyze and Visualize (p. 930).

8. To export a complete data flow, choose Export and choose an export option. To learn more, see Export (p. 945).

9. Finally, choose the Components and registries icon, and select Data Wrangler from the dropdown list to see all the .flow files that you’ve created. You can use this menu to find and move between data flows.
After you have launched Data Wrangler, you can use the following section to walk through how you might use Data Wrangler to create an ML data prep flow.

**Update Data Wrangler**

We recommend that you periodically update the Data Wrangler Studio app to access the latest features and updates. The Data Wrangler app name starts with `sagemaker-data-wrang`. To learn how to update a Studio app, see [Shut down and Update Studio Apps](p. 180).

**Demo: Data Wrangler Titanic Dataset Walkthrough**

The following sections provide a walkthrough to help you get started using Data Wrangler. This walkthrough assumes that you have already followed the steps in [Access Data Wrangler](p. 817) and have a new data flow file open that you intend to use for the demo. You may want to rename this .flow file to something similar to `titanic-demo.flow`.

This walkthrough uses the Titanic dataset. It's a modified version of the Titanic dataset that you can import into your Data Wrangler flow more easily. This data set contains the survival status, age, gender, and class (which serves as a proxy for economic status) of passengers aboard the maiden voyage of the RMS Titanic in 1912.

In this tutorial, you perform the following steps.

1. Do one of the following:
   - Open your Data Wrangler flow and choose **Use Sample Dataset**.
   - Upload the Titanic dataset to Amazon Simple Storage Service (Amazon S3), and then import this dataset into Data Wrangler.
2. Analyze this dataset using Data Wrangler analyses.
3. Define a data flow using Data Wrangler data transforms.
4. Export your flow to a Jupyter Notebook that you can use to create a Data Wrangler job.
5. Process your data, and kick off a SageMaker training job to train a XGBoost Binary Classifier.

**Upload Dataset to S3 and Import**

To get started, you can use one of the following methods to import the Titanic dataset into Data Wrangler:

- Importing the dataset directly from the Data Wrangler flow
- Uploading the dataset to Amazon S3 and then importing it into Data Wrangler

To import the dataset directly into Data Wrangler, open the flow and choose **Use Sample Dataset**.

Uploading the dataset to Amazon S3 and importing it into Data Wrangler is closer to the experience you have importing your own data. The following information tells you how to upload your dataset and import it.

Before you start importing the data into Data Wrangler, download the Titanic dataset and upload it to an Amazon S3 (Amazon S3) bucket in the AWS Region in which you want to complete this demo.

If you are a new user of Amazon S3, you can do this using drag and drop in the Amazon S3 console. To learn how, see [Uploading Files and Folders by Using Drag and Drop](in the Amazon Simple Storage Service User Guide).

**Important**

Upload your dataset to an S3 bucket in the same AWS Region you want to use to complete this demo.
When your dataset has been successfully uploaded to Amazon S3, it you can import it into Data Wrangler.

**Import the Titanic dataset to Data Wrangler**

1. Select the **Import** tab in your Data Wrangler flow file.
2. Select **Amazon S3**.
3. Use the **Import a dataset from S3** table to find the bucket to which you added the Titanic dataset. Choose the Titanic dataset CSV file to open the **Details** pane.
4. Under **Details**, the **File type** should be CSV. Choose **Add header to table** to specify that the first row of the dataset is a header. You can also name the dataset something more friendly, such as **Titanic-train**.
5. Select **Import dataset**.

When your dataset is imported into Data Wrangler, it appears in your data flow. You can view your data flow at any time by selecting the **Data Flow** tab. You can double click on a node to enter the node detail view, which allows you to add transformations or analysis; otherwise, you can use the plus icon to navigate for a quick navigation. In the next section, you use this data flow to add analysis and transform steps.

**Data Flow**

In the data flow section, the only steps in the data flow are your recently imported dataset and a **Data type** step. After applying transformations, you can come back to this tab see what the data flow looks like. Now, add some basic transformations under the **Prepare** and **Analyze** tabs.

**Prepare and Visualize**

Data Wrangler has built-in transformations and visualizations that you can use to analyze, clean, and transform your data.

The **Data** tab of the node detail view lists all built-in transformations in the right panel, which also contains an area in which you can add custom transformations. The following use case showcases how to use these transformations.

To get information that might help you with data exploration and feature engineering, create a data quality and insights report. The information from the report can help you clean and process your data.
It gives you information such as the number of missing values and the number of outliers. If you have issues with your data, such as target leakage or imbalance, the insights report can bring those issues to your attention. For more information about creating a report, see Get Insights On Data and Data Quality (p. 875).

Data Exploration

First, create a table summary of the data using an analysis. Do the following:

1. Choose the + next to the Data type step in your data flow and select Add analysis.
2. In the Analysis area, select Table summary from the dropdown list.
3. Give the table summary a Name.
4. Select Preview to preview the table that will be created.
5. Choose Create to save it to your data flow. It appears under All Analyses.

Using the statistics you see, you can make observations similar to the following about this dataset:

• Fare average (mean) is around $33, while the max is over $500. This column likely has outliers.
• This dataset uses ? to indicate missing values. A number of columns have missing values: cabin, embarked, and home.dest
• The age category is missing over 250 values.

Choose Prepare to go back to the data flow. Next, clean your data using the insights gained from these stats.

Drop Unused Columns

Using the analysis from the previous section, clean up the dataset to prepare it for training. To add a new transform to your data flow, choose + next to the Data type step in your data flow and choose Add transform.

First, drop columns that you don't want to use for training. You can use pandas data analysis library to do this, or you can use one of the built-in transforms.

Use the following procedure to drop the unused columns.

To drop the unused columns, do the following.

1. Open the Data Wrangler flow.
2. There are two nodes in your Data Wrangler flow. For the node on the right, choose the +.
3. Choose Add transform.
4. Choose Manage columns.
5. Under Transform, make sure Drop column is selected.
6. Under Columns to drop, specify the following column names:

   • cabin
   • ticket
   • name
   • sibsp
   • parch
   • home.dest
   • boat
7. Choose **Preview**.
8. Choose **Add**.

To do this using pandas, follow these steps.

1. In the **Custom Transform** section, select **Python (Pandas)** from the dropdown list.
2. Enter the following in the code box.
   ```python
   cols = ['name', 'ticket', 'cabin', 'sibsp', 'parch', 'home.dest', 'boat', 'body']
   df = df.drop(cols, axis=1)
   ```
3. Choose **Preview** to preview the change and then choose **Add** to add the transformation.

To use the built-in transformations, do the following:

1. Choose **Manage columns** from the right panel.
2. For **Input column**, choose **cabin**, and choose **Preview**.
3. Verify that the **cabin** column has been dropped, then choose **Add**.
4. Repeat these steps for the following columns: **ticket**, **name**, **sibsp**, **parch**, **home.dest**, **boat**, and **body**.

**Clean up Missing Values**

Now, clean up missing values. You can do this with the **Handling missing values** transform group.

A number of columns have missing values. Of the remaining columns, **age** and **fare** contain missing values. Inspect this using the **Custom Transform**.

Using the **Python (Pandas)** option, use the following to quickly review the number of entries in each column:

```python
df.info()
```
To drop rows with missing values in the *age* category, do the following:

1. Choose **Handling missing values**.
2. Choose **Drop missing** for the **Transformer**.
3. Choose **Drop Rows** for the **Dimension**.
4. Choose **age** for the **Input column**.
5. Choose **Preview** to see the new data frame, and then choose **Add** to add the transform to your flow.
6. Repeat the same process for **fare**.

You can use `df.info()` in the **Custom transform** section to confirm that all rows now have 1,045 values.

---

**Custom Pandas: Encode**

Try flat encoding using Pandas. Encoding categorical data is the process of creating a numerical representation for categories. For example, if your categories are *Dog* and *Cat*, you may encode this information into two vectors: `[1, 0]` to represent *Dog*, and `[0, 1]` to represent *Cat*.

1. In the **Custom Transform** section, choose **Python (Pandas)** from the dropdown list.
2. Enter the following in the code box:
import pandas as pd

dummies = []
cols = ['pclass', 'sex', 'embarked']
for col in cols:
    dummies.append(pd.get_dummies(df[col]))

encoded = pd.concat(dummies, axis=1)
df = pd.concat((df, encoded), axis=1)

3. Choose Preview to preview the change. The encoded version of each column is added to the dataset.
4. Choose Add to add the transformation.

**Custom SQL: SELECT Columns**

Now, select the columns you want to keep using SQL. For this demo, select the columns listed in the following SELECT statement. Because survived is your target column for training, put that column first.

1. In the Custom Transform section, select SQL (PySpark SQL) from the dropdown list.
2. Enter the following in the code box.

   ```sql
   SELECT survived, age, fare, 1, 2, 3, female, male, C, Q, S FROM df;
   ```

3. Choose Preview to preview the change. The columns listed in your SELECT statement are the only remaining columns.
4. Choose Add to add the transformation.

**Export to a Data Wrangler Notebook**

When you've finished creating a data flow, you have a number of export options. The following section explains how to export to a Data Wrangler job notebook. A Data Wrangler job is used to process your data using the steps defined in your data flow. To learn more about all export options, see Export (p. 945).

**Export to Data Wrangler Job Notebook**

When you export your data flow using a Data Wrangler job, the process automatically creates a Jupyter Notebook. This notebook automatically opens in your Studio instance and is configured to run a SageMaker processing job to run your Data Wrangler data flow, which is referred to as a Data Wrangler job.

1. Save your data flow. Select File and then select Save Data Wrangler Flow.
2. Choose the Export tab.
3. Select the last step in your data flow.

   ![Image of data flow]

4. Choose Data Wrangler Job. This opens a Jupyter Notebook.
5. Choose any Python 3 (Data Science) kernel for the Kernel.
6. When the kernel starts, run the cells in the notebook book until Kick off SageMaker Training Job (Optional).
7. Optionally, you can run the cells in **Kick off SageMaker Training Job (Optional)** if you want to create a SageMaker training job to train an XGBoost classifier. You can find the cost to run an SageMaker training job in [Amazon SageMaker Pricing](https://aws.amazon.com/sagemaker/pricing/).

Alternatively, you can add the code blocks found in Training XGBoost Classifier (p. 826) to the notebook and run them to use the [XGBoost](https://xgboost.readthedocs.io/en/latest/) open source library to train an XGBoost classifier.

8. Uncomment and run the cell under **Cleanup** and run it to revert the SageMaker Python SDK to its original version.

You can monitor your Data Wrangler job status in the SageMaker console in the **Processing** tab. Additionally, you can monitor your Data Wrangler job using Amazon CloudWatch. For additional information, see [Monitor Amazon SageMaker Processing Jobs with CloudWatch Logs and Metrics](https://docs.aws.amazon.com/sagemaker/latest/dg/monitor-processing-jobs-log-metrics.html).

If you kicked off a training job, you can monitor its status using the SageMaker console under **Training jobs** in the Training section.

**Training XGBoost Classifier**

You can train an XGBoost Binary Classifier using either a Jupyter notebook or a Amazon SageMaker Autopilot. You can use Autopilot to automatically train and tune models on the data that you’ve transformed directly from your Data Wrangler flow. For information about Autopilot, see [Automatically Train Models on Your Data Flow](https://docs.aws.amazon.com/sagemaker/latest/dg/automate-data-flow.html) (p. 888).

In the same notebook that kicked off the Data Wrangler job, you can pull the data and train an XGBoost Binary Classifier using the prepared data with minimal data preparation.

1. First, upgrade necessary modules using `pip` and remove the `_SUCCESS` file (this last file is problematic when using `awswrangler`).

   ```bash
   ! pip install --upgrade awscli awswrangler boto sklearn
   ! aws s3 rm {output_path} --recursive --exclude "*" --include "*_SUCCESS*"
   ```

2. Read the data from Amazon S3. You can use `awswrangler` to recursively read all the CSV files in the S3 prefix. The data is then split into features and labels. The label is the first column of the dataframe.

   ```python
   import awswrangler as wr
   df = wr.s3.read_csv(path=output_path, dataset=True)
   X, y = df.iloc[:,:-1], df.iloc[:,-1]
   ```

   - Finally, create DMatrices (the XGBoost primitive structure for data) and do cross-validation using the XGBoost binary classification.

   ```python
   import xgboost as xgb
   dmatrix = xgb.DMatrix(data=X, label=y)
   params = {'objective':"binary:logistic",'learning_rate': 0.1, 'max_depth': 5, 'alpha': 10}
   xgb.cv(
       dtrain=dmatrix,
       params=params,
       nfold=3,
       num_boost_round=50,
       early_stopping_rounds=10,
       metrics="rmse",
       as_pandas=True,
   )
   ```
Shut down Data Wrangler

When you are finished using Data Wrangler, we recommend that you shut down the instance it runs on to avoid incurring additional charges. To learn how to shut down the Data Wrangler app and associated instance, see Shut Down Data Wrangler (p. 982).

Import

You can use Amazon SageMaker Data Wrangler to import data from the following data sources: Amazon Simple Storage Service (Amazon S3), Amazon Athena, Amazon Redshift, and Snowflake. The dataset that you import can include up to 1000 columns.

Topics

- Import data from Amazon S3 (p. 827)
- Import data from Athena (p. 832)
- Import data from Amazon Redshift (p. 835)
- Import data from Databricks (JDBC) (p. 839)
- Import data from Snowflake (p. 841)
- Imported Data Storage (p. 863)

Some data sources allow you to add multiple data connections:

- You can connect to multiple Amazon Redshift clusters. Each cluster becomes a data source.
- You can query any Athena database in your account to import data from that database.

When you import a dataset from a data source, it appears in your data flow. Data Wrangler automatically infers the data type of each column in your dataset. To modify these types, select the Data types step and select Edit data types.

When you import data from Athena or Amazon Redshift, the imported data is automatically stored in the default SageMaker S3 bucket for the AWS Region in which you are using Studio. Additionally, Athena stores data you preview in Data Wrangler in this bucket. To learn more, see Imported Data Storage (p. 863).

Important

The default Amazon S3 bucket may not have the least permissive security settings, such as bucket policy and server-side encryption (SSE). We strongly recommend that you Add a Bucket Policy To Restrict Access to Datasets Imported to Data Wrangler.

Important

In addition, if you use the managed policy for SageMaker, we strongly recommend that you scope it down to the most restrictive policy that allows you to perform your use case. For more information, see Grant an IAM Role Permission to Use Data Wrangler (p. 967).

Import data from Amazon S3

You can use Amazon Simple Storage Service (Amazon S3) to store and retrieve any amount of data, at any time, from anywhere on the web. You can accomplish these tasks using the AWS Management Console, which is a simple and intuitive web interface, and the Amazon S3 API. If you've stored your
dataset locally, we recommend that you add it to an S3 bucket for import into Data Wrangler. To learn how, see Uploading an object to a bucket in the Amazon Simple Storage Service User Guide.

Data Wrangler uses S3 Select to allow you to preview your Amazon S3 files in Data Wrangler. You incur standard charges for each file preview. To learn more about pricing, see the Requests & data retrievals tab on Amazon S3 pricing.

**Important**
If you plan to export a data flow and launch a Data Wrangler job, ingest data into a SageMaker feature store, or create a SageMaker pipeline, be aware that these integrations require Amazon S3 input data to be located in the same AWS region.

**Important**
If you're importing a CSV file, make sure it meets the following requirements:

- A record in your dataset can't be longer than one line.
- A backslash, \, is the only valid escape character.
- Your dataset must use one of the following delimiters:
  - Comma – ,
  - Colon – :
  - Semicolon – ;
  - Pipe – |  
  - Tab – [TAB]

To save space, you can import compressed CSV files.

Data Wrangler gives you the ability to either import the entire dataset or sample a portion of it. For Amazon S3, it provides the following sampling options:

- None – Import the entire dataset.
- First K – Sample the first K rows of the dataset, where K is an integer that you specify.
- Randomized – Takes a random sample of a size that you specify.
- Stratified – Takes a stratified random sample. A stratified sample preserves the ratio of values in a column.

After you've imported your data, you can also use the sampling transformer to take one or more samples from your entire dataset. For more information about the sampling transformer, see Sampling (p. 923).

You can import either a single file or multiple files as a dataset. You can use the multifile import operation when you have a dataset that is partitioned into separate files. It takes all of the files from an Amazon S3 directory and imports them as a single dataset. For information on the types of files that you can import and how to import them, see the following sections.

**Single File Import**

You can import single files in the following formats:

- Comma Separated Values (CSV)
- Parquet
- Javascript Object Notation (JSON)
- Optimized Row Columnar (ORC)

For files formatted in JSON, Data Wrangler supports both JSON lines (.jsonl) and JSON documents (.json). When you preview your data, it automatically shows the JSON in tabular format. For nested
JSON documents that are larger than 5 MB, Data Wrangler shows the schema for the structure and the arrays as values in the dataset. Use the Flatten structured and Explode array operators to display the nested values in tabular format. For more information, see Unnest JSON Data (p. 928) and Explode Array (p. 929).

When you choose a dataset, you can rename it, specify the file type, and identify the first row as a header.

You can import a dataset that you've partitioned into multiple files in an Amazon S3 bucket in a single import step.

To import a dataset into Data Wrangler from a single file that you've stored in Amazon S3:

1. If you are not currently on the Import tab, choose Import.
2. Under Data Preparation, choose Amazon S3 to see the Import S3 Data Source view.
3. From the table of available S3 buckets, select a bucket and navigate to the dataset you want to import.
4. Select the file that you want to import. If your dataset does not have a .csv or .parquet extension, select the data type from the File Type dropdown list.
5. If your CSV file has a header, select the checkbox next to Add header to table.
6. Use the Preview table to preview your dataset. This table shows up to 100 rows.
7. In the Details pane, verify or change the Name and File Type for your dataset. If you add a Name that contains spaces, these spaces are replaced with underscores when your dataset is imported.
8. Specify the sampling configuration that you'd like to use.
9. Choose Import dataset.
Multifile Import

The following are the requirements for importing multiple files:

- The files must be in the same folder of your Amazon S3 bucket.
- The files must either share the same header or have no header.

Each file must be in one of the following formats:

- CSV
- Parquet
- Optimized Row Columnar (ORC)
- JSON

Use the following procedure to import multiple files.

**To import a dataset into Data Wrangler from multiple files that you've stored in an Amazon S3 directory**

1. If you are not currently on the Import tab, choose Import.
2. Under Data Preparation, choose Amazon S3 to see the Import S3 Data Source view.
3. From the table of available S3 buckets, select the bucket containing the folder that you want to import.

4. Select the folder containing the files that you want to import. Each file must be in one of the supported formats. Your files must be the same data type.

5. If your folder contains CSV files with headers, select the checkbox next to **First row is header**.

6. If your files are nested within other folders, select the checkbox next to **Include nested directories**.

7. (Optional) Choose **Add filename column** add a column to the dataset that shows the filename for each observation.

8. (Optional) By default, Data Wrangler doesn't show you a preview of a folder. You can activate previewing by choosing the blue **Preview off** button. A preview shows the first 10 rows of the first 10 files in the folder. The following images show you how to activate a preview for a dataset created from nested directories.
9. In the Details pane, verify or change the Name and File Type for your dataset. If you add a Name that contains spaces, these spaces are replaced with underscores when your dataset is imported.

10. Specify the sampling configuration that you'd like to use.

11. Choose Import dataset.

Import data from Athena

Use Amazon Athena to import your data from Amazon Simple Storage Service (Amazon S3) into Data Wrangler. In Athena, you write standard SQL queries to select the data that you're importing from Amazon S3. For more information, see What is Amazon Athena?

You can use the AWS Management Console to set up Amazon Athena. You must create at least one database in Athena before you start running queries. For more information about getting started with Athena, see Getting started.

Athena is directly integrated with Data Wrangler. You can write Athena queries without having to leave the Data Wrangler UI.

In addition to writing simple Athena queries in Data Wrangler, you can also use:

- Athena workgroups for query result management. For more information about workgroups, see Managing query results (p. 834).
- Lifecycle configurations for setting data retention periods. For more information about data retention, see Setting data retention periods (p. 834).

Query Athena within Data Wrangler

Note
Data Wrangler does not support federated queries.
If you use AWS Lake Formation with Athena, make sure your Lake Formation IAM permissions do not override IAM permissions for the database sagemaker_data_wrangler.

Data Wrangler gives you the ability to either import the entire dataset or sample a portion of it. For Athena, it provides the following sampling options:

- None – Import the entire dataset.
- First K – Sample the first K rows of the dataset, where K is an integer that you specify.
- Randomized – Takes a random sample of a size that you specify.
- Stratified – Takes a stratified random sample. A stratified sample preserves the ratio of values in a column.

The following procedure shows how to import a dataset from Athena into Data Wrangler.

To import a dataset into Data Wrangler from Athena

1. On the Import data screen, choose Amazon Athena.
2. For Data Catalog, choose a data catalog.
3. Use the Database dropdown list to select the database that you want to query. When you select a database, you can preview all tables in your database using the Tables listed under Details.
4. (Optional) Choose Advanced configuration.
   a. Choose a Workgroup.
   b. If your workgroup hasn't enforced the Amazon S3 output location or if you don't use a workgroup, specify a value for Amazon S3 location of query results.
   c. (Optional) For Data retention period, select the checkbox to set a data retention period and specify the number of days to store the data before it's deleted.
   d. (Optional) By default, Data Wrangler saves the connection. You can choose to deselect the checkbox and not save the connection.
5. For Sampling, choose a sampling method. Choose None to turn off sampling.
6. Enter your query in the query editor and use the Run button to run the query. After a successful query, you can preview your result under the editor.

   Note
   Salesforce data uses the timestamptz type. If you're querying the timestamp column that you've imported to Athena from Salesforce, cast the data in the column to the timestamp type. The following query casts the timestamp column to the correct type.

   ```sql
   # cast column timestamptz_col as timestamp type, and name it as timestamp_col
   select cast(timestamptz_col as timestamp) as timestamp_col from table
   ```

7. To import the results of your query, select Import.

After you complete the preceding procedure, the dataset that you've queried and imported appears in the Data Wrangler flow.

By default, Data Wrangler saves the connection settings as a new connection. When you import your data, the query that you've already specified appears as a new connection. The saved connections store information about the Athena workgroups and Amazon S3 buckets that you're using. When you're connecting to the data source again, you can choose the saved connection.
Managing query results

Data Wrangler supports using Athena workgroups to manage the query results within an AWS account. You can specify an Amazon S3 output location for each workgroup. You can also specify whether the output of the query can go to different Amazon S3 locations. For more information, see Using Workgroups to Control Query Access and Costs.

Your workgroup might be configured to enforce the Amazon S3 query output location. You can't change the output location of the query results for those workgroups.

If you don't use a workgroup or specify an output location for your queries, Data Wrangler uses the default Amazon S3 bucket in the same AWS Region in which your Studio instance is located to store Athena query results. It creates temporary tables in this database to move the query output to this Amazon S3 bucket. It deletes these tables after data has been imported; however the database, sagemaker_data_wrangler, persists. To learn more, see Imported Data Storage (p. 863).

To use Athena workgroups, set up the IAM policy that gives access to workgroups. If you're using a SageMaker-Execution-Role, we recommend adding the policy to the role. For more information about IAM policies for workgroups, see IAM policies for accessing workgroups. For example workgroup policies, see Workgroup example policies.

Setting data retention periods

Data Wrangler automatically sets a data retention period for the query results. The results are deleted after the length of the retention period. For example, the default retention period is five days. The results of the query are deleted after five days. This configuration is designed to help you clean up data that you're no longer using. Cleaning up your data prevents unauthorized users from gaining access. It also helps control the costs of storing your data on Amazon S3.

If you don't set a retention period, the Amazon S3 lifecycle configuration determines the duration that the objects are stored. The data retention policy that you've specified for the lifecycle configuration removes any query results that are older than the Lifecycle configuration that you've specified. For more information, see Setting lifecycle configuration on a bucket.

Data Wrangler uses S3 lifecycle configurations to manage data retention and expiration. You must give your Amazon SageMaker Studio IAM execution role permissions to manage bucket lifecycle configurations. Use the following procedure to give permissions.

To give permissions to manage the lifecycle configuration do the following.

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. Choose Roles.
3. In the search bar, specify the Amazon SageMaker execution role that Amazon SageMaker Studio is using.
4. Choose the role.
5. Choose Add permissions.
6. Choose Create inline policy.
7. For Service, specify S3 and choose it.
8. Under the Read section, choose GetLifecycleConfiguration.
9. Under the Write section, choose PutLifecycleConfiguration.
10. For Resources, choose Specific.
11. For Actions, select the arrow icon next to Permissions management.
13. For Resources, choose Specific.
14. Choose the checkbox next to Any in this account.
15. Choose Review policy.
16. For Name, specify a name.
17. Choose Create policy.

Import data from Amazon Redshift

Amazon Redshift is a fully managed, petabyte-scale data warehouse service in the cloud. The first step to create a data warehouse is to launch a set of nodes, called an Amazon Redshift cluster. After you provision your cluster, you can upload your dataset and then perform data analysis queries.

You can connect to and query one or more Amazon Redshift clusters in Data Wrangler. To use this import option, you must create at least one cluster in Amazon Redshift. To learn how, see Getting started with Amazon Redshift.

You can output the results of your Amazon Redshift query in one of the following locations:

- The default Amazon S3 bucket
- An Amazon S3 output location that you specify

You can either import the entire dataset or sample a portion of it. For Amazon Redshift, it provides the following sampling options:

- None – Import the entire dataset.
- First K – Sample the first K rows of the dataset, where K is an integer that you specify.
- Randomized – Takes a random sample of a size that you specify.
- Stratified – Takes a stratified random sample. A stratified sample preserves the ratio of values in a column.

The default Amazon S3 bucket is in the same AWS Region in which your Studio instance is located to store Amazon Redshift query results. For more information, see Imported Data Storage (p. 863).

For either the default Amazon S3 bucket or the bucket that you specify, you have the following encryption options:

- The default AWS service-side encryption with an Amazon S3 managed key (SSE-S3)
- An AWS Key Management Service (AWS KMS) key that you specify

An AWS KMS key is an encryption key that you create and manage. For more information on KMS keys, see AWS Key Management Service.

You can specify an AWS KMS key using either the key ARN or the ARN of your AWS account.

If you use the IAM managed policy, AmazonSageMakerFullAccess, to grant a role permission to use Data Wrangler in Studio, your Database User name must have the prefix sagemaker_access.

Use the following procedures to learn how to add a new cluster.

**Note**

Data Wrangler uses the Amazon Redshift Data API with temporary credentials. To learn more about this API, refer to Using the Amazon Redshift Data API in the Amazon Redshift Management Guide.
To connect to a Amazon Redshift cluster

1. Choose **Import**.
2. Choose + under **Add data connection**.
3. Choose **Amazon Redshift**.
4. Choose **Temporary credentials (IAM)** for **Type**.
5. Enter a **Connection Name**. This is a name used by Data Wrangler to identify this connection.
6. Enter the **Cluster Identifier** to specify to which cluster you want to connect. Note: Enter only the cluster identifier and not the full endpoint of the Amazon Redshift cluster.
7. Enter the **Database Name** of the database to which you want to connect.
8. Enter a **Database User** to identify the user you want to use to connect to the database.
9. For **UNLOAD IAM Role**, enter the IAM role ARN of the role that the Amazon Redshift cluster should assume to move and write data to Amazon S3. For more information about this role, see Authorizing Amazon Redshift to access other AWS services on your behalf in the Amazon Redshift Management Guide.
10. Choose **Connect**.
11. (Optional) For **Amazon S3 output location**, specify the S3 URI to store the query results.
12. (Optional) For **KMS key ID**, specify the ARN of the AWS KMS key or alias. The following image shows you where you can find either key in the AWS Management Console.
The following image shows all the fields from the preceding procedure.

After your connection is successfully established, it appears as a data source under Data Import. Select this data source to query your database and import data.

To query and import data from Amazon Redshift

1. Select the connection that you want to query from Data Sources.
2. Select a Schema. To learn more about Amazon Redshift Schemas, see Schemas in the Amazon Redshift Database Developer Guide.
3. (Optional) Under Advanced configuration, specify the Sampling method that you'd like to use.
4. Enter your query in the query editor and choose Run to run the query. After a successful query, you can preview your result under the editor.
5. Select Import dataset to import the dataset that has been queried.
6. Enter a Dataset name. If you add a Dataset name that contains spaces, these spaces are replaced with underscores when your dataset is imported.
7. Choose Add.
Import data from Databricks (JDBC)

You can use Databricks as a data source for your Amazon SageMaker Data Wrangler flow. To import a dataset from Databricks, use the JDBC (Java Database Connectivity) import functionality to access to your Databricks database. After you access the database, specify a SQL query to get the data and import it.

We assume that you have a running Databricks cluster and that you've configured your JDBC driver to it. For more information, see the following Databricks documentation pages:

- JDBC driver
- JDBC configuration and connection parameters
- Authentication parameters

Data Wrangler stores your JDBC URL in AWS Secrets Manager. You must give your Amazon SageMaker Studio IAM execution role permissions to use Secrets Manager. Use the following procedure to give permissions.

To give permissions to Secrets Manager, do the following.

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. Choose Roles.
3. In the search bar, specify the Amazon SageMaker execution role that Amazon SageMaker Studio is using.
4. Choose the role.
5. Choose Add permissions.
6. Choose Create inline policy.
7. For Service, specify Secrets Manager and choose it.
8. For Actions, select the arrow icon next to Permissions management.
10. For Resources, choose Specific.
11. Choose the checkbox next to Any in this account.
13. For Name, specify a name.
14. Choose Create policy.

You can use partitions to import your data more quickly. Partitions give Data Wrangler the ability to process the data in parallel. By default, Data Wrangler uses 2 partitions. For most use cases, 2 partitions give you near-optimal data processing speeds.

If you choose to specify more than 2 partitions, you can also specify a column to partition the data. The type of the values in the column must be numeric or date.

We recommend using partitions only if you understand the structure of the data and how it's processed.

You can either import the entire dataset or sample a portion of it. For a Databricks database, it provides the following sampling options:

- None – Import the entire dataset.
- First K – Sample the first K rows of the dataset, where K is an integer that you specify.
- Randomized – Takes a random sample of a size that you specify.
Stratified – Takes a stratified random sample. A stratified sample preserves the ratio of values in a column.

Use the following procedure to import your data from a Databricks database.

To import data from Databricks, do the following.

1. Sign into Amazon SageMaker Console.
2. Choose Studio.
3. Choose Launch app.
4. From the dropdown list, select Studio.
5. From the Import data tab of your Data Wrangler flow, choose Add data source.

7. Specify the following fields:
   - **Dataset name** – A name that you want to use for the dataset in your Data Wrangler flow.
   - **Driver** – `com.simba.spark.jdbc.Driver`.
   - **JDBC URL** – The URL of the Databricks database. The URL formatting can vary between Databricks instances. For information about finding the URL and the specifying the parameters within it, see JDBC configuration and connection parameters. The following is an example of how a URL can be formatted: `jdbc:spark://aws-sagemaker-datawrangler.cloud.databricks.com:443/default;transportMode=http;httpPath=sql/protocolv1/o/3122619508517275/0909-200301-cut318;AuthMech=3;UID=token;PWD=personal-access-token`.
     
     **Note**
     You can specify a secret ARN that contains the JDBC URL instead of specifying the JDBC URL itself. The secret must contain a key-value pair with the following format: `jdbcURL: JDBC-URL`. For more information, see What is Secrets Manager?.

8. Specify a SQL SELECT statement.
   
   **Note**
   Data Wrangler doesn't support Common Table Expressions (CTE) or temporary tables within a query.
9. For **Sampling**, choose a sampling method.

10. Choose **Run**.

11. (Optional) For the **PREVIEW**, choose the gear to open the **Partition settings**.
    The gear for the additional settings is located to the far right of the **PREVIEW** title.
    - Specify the number of partitions. You can partition by column if you specify the number of partitions:
      - **Enter number of partitions** – Specify a value greater than 2.
      - (Optional) **Partition by column** – Specify the following fields. You can only partition by a column if you've specified a value for **Enter number of partitions**.
        - **Select column** – Select the column that you're using for the data partition. The data type of the column must be numeric or date.
        - **Upper bound** – From the values in the column that you've specified, the upper bound is the value that you're using in the partition. The value that you specify doesn't change the data that you're importing. It only affects the speed of the import. For the best performance, specify an upper bound that's close to the column's maximum.
        - **Lower bound** – From the values in the column that you've specified, the lower bound is the value that you're using in the partition. The value that you specify doesn't change the data that you're importing. It only affects the speed of the import. For the best performance, specify a lower bound that's close to the column's minimum.

12. Choose **Import**.

### Import data from Snowflake

You can use Snowflake as a data source in SageMaker Data Wrangler to prepare data in Snowflake for machine learning.

With Snowflake as a data source in Data Wrangler, you can quickly connect to Snowflake without writing a single line of code. Additionally, you can join your data in Snowflake with data stored in Amazon S3 and data queried through Amazon Athena and Amazon Redshift to prepare data for machine learning.

Once connected, you can interactively query data stored in Snowflake, transform data with more than 300 preconfigured data transformations, understand data and identify potential errors and extreme values with a set of robust preconfigured visualization templates, quickly identify inconsistencies in your data preparation workflow, and diagnose issues before models are deployed into production. Finally, you can export your data preparation workflow to Amazon S3 for use with other SageMaker features such as Amazon SageMaker Autopilot, Amazon SageMaker Feature Store and Amazon SageMaker Model Building Pipelines.

You can encrypt the output of your queries using an AWS Key Management Service key that you've created. For more information about AWS KMS, see [AWS Key Management Service](#).

### Administrator Guide

**Important**
To learn more about granular access control and best practices, see [Security Access Control](#).

This section is for Snowflake administrators who are setting up access to Snowflake from within SageMaker Data Wrangler.

**Important**
Your administrator is responsible for managing and monitoring the access control within Snowflake. This includes what data a user can access, what storage integration a user can use, and what queries a user can run. Data Wrangler does not add a layer of access control with respect to Snowflake.
Important
Note that granting monitor privileges can permit users to see details within an object, such as queries or usage within a warehouse.

Configure Snowflake with Data Wrangler

To import data from Snowflake, Snowflake admins must configure access from Data Wrangler using Amazon S3.

This feature is currently not available in the opt-in Regions.

To configure access, follow these steps.

1. Configure access permissions for the S3 bucket.

AWS Access Control Requirements

Snowflake requires the following permissions on an S3 bucket and directory to be able to access files in the directory.

- s3:GetObject
- s3:GetObjectVersion
- s3:ListBucket
- s3:ListObjects
- s3:GetBucketLocation

Create an IAM policy

The following steps describe how to configure access permissions for Snowflake in your AWS Management Console so you can use an S3 bucket to load and unload data:

- Log in to the AWS Management Console.
- From the home dashboard, choose IAM.
• Choose Policies.
• Choose Create Policy.
• Select the JSON tab.
• Add a policy document that allows Snowflake to access the S3 bucket and directory.

The following policy (in JSON format) provides Snowflake with the required permissions to load and unload data using a single bucket and directory path. Make sure to replace `bucket` and `prefix` with your actual bucket name and directory path prefix.

```json
# Example policy for S3 write access
# This needs to be updated
{
```

843
"Version": "2012-10-17",
"Statement": [
{
  "Effect": "Allow",
  "Action": [
    "s3:PutObject",
    "s3:GetObject",
    "s3:GetObjectVersion",
    "s3:DeleteObject",
    "s3:DeleteObjectVersion"
  ],
  "Resource": "arn:aws:s3:::bucket/prefix/*"
},
{
  "Effect": "Allow",
  "Action": [
    "s3:ListBucket"
  ],
  "Resource": "arn:aws:s3:::bucket/",
  "Condition": {
    "StringLike": {
      "s3:prefix": "["prefix/**"]
    }
  }
}
]

• Choose Next: Tags.
• Choose Next: Review.

Enter the policy name (such as snowflake_access) and an optional description. Choose Create policy.

2. Create the IAM Role in AWS.
3. Create a Cloud Storage Integration in Snowflake.
4. Retrieve the AWS IAM User for your Snowflake Account.
5. Grant the IAM User Permissions to Access Bucket.
6. Grant the data scientist's Snowflake role usage permission to the storage integration.
   • In the Snowflake console, run GRANT USAGE ON INTEGRATION integration_name TO snowflake_role;
• integration_name is the name of your storage integration.
• snowflake_role is the name of the default Snowflake role given to the data scientist user.

Provide information to the data scientist

Provide the data scientist with the information that they need to access Snowflake from Amazon SageMaker Data Wrangler.

1. To allow your data scientist to access Snowflake from SageMaker Data Wrangler, provide them with one of the following:
   • A Snowflake account name, user name, and password.
   • A secret created with AWS Secrets Manager and the ARN of the secret. Use the following procedure below to create the secret for Snowflake if you choose this option.

   **Important**
   If your data scientists use the Snowflake Credentials (User name and Password) option to connect to Snowflake, you can use Secrets Manager to store the credentials in a secret. Secrets Manager rotates secrets as part of a best practice security plan. The secret created in Secrets Manager is only accessible with the Studio role configured when you set up a Studio user profile. This requires you to add this permission, secretsmanager:PutResourcePolicy, to the policy that is attached to your Studio role.
   We strongly recommend that you scope the role policy to use different roles for different groups of Studio users. You can add additional resource-based permissions for the Secrets Manager secrets. See Manage Secret Policy for condition keys you can use.
   For information about creating a secret, see Create a secret. You're charged for the secrets that you create.

2. Provide the data scientist with the name of the storage integration you created in Step 3: Create a Cloud Storage Integration in Snowflake. This is the name of the new integration and is called integration_name in the CREATE INTEGRATION SQL command you ran, which is shown in the following snippet:

   ```sql
   CREATE STORAGE INTEGRATION integration_name
   TYPE = EXTERNAL_STAGE
   STORAGE_PROVIDER = S3
   ENABLED = 'true'
   STORAGE_AWS_ROLE_ARN = 'iam_role'
   [ STORAGE_AWS_OBJECT_ACL = 'bucket-owner-full-control' ]
   STORAGE_ALLOWED_LOCATIONS = ('s3://bucket/path/', 's3://bucket/path/')
   [ STORAGE_BLOCKED_LOCATIONS = ('s3://bucket/path/', 's3://bucket/path/') ]
   ```

Data Scientist Guide

This section outlines how to access your Snowflake data warehouse from within SageMaker Data Wrangler and how to use Data Wrangler features.

**Important**
Note: Your administrator needs to follow the Administer Guide set up in the preceding section before you can use Data Wrangler within Snowflake.

Use the following procedure to open Amazon SageMaker Studio and see which version you're running.

To open Studio and check its version, see the following procedure.
1. Use the steps in Prerequisites (p. 817) to access Data Wrangler through Amazon SageMaker Studio.
2. Next to the user you want to use to launch Studio, select Launch app.
3. Choose Studio.
4. After Studio loads, select File, then New, and then Terminal.

5. Once you have launched Studio, select File, then New, and then Terminal.

6. Enter `cat /opt/conda/share/jupyter/lab/staging/yarn.lock | grep -A 1 "@amzn/sagemaker-ui-data-prep-plugin@"` to print the version of your Studio instance. You must have Studio version 1.3.0 to use Snowflake.

Use the following procedure to check that you're running version 1.3.0 or greater.

To check the version of Studio, do the following.

1. If you do not have this version, then update your Studio version. To do this, close your Studio window and navigate to the SageMaker Studio Console.
2. Next, select the user you are using to access Studio and then select **Delete app**. After the deletion is complete, launch Studio again by selecting **Open Studio**.

3. Follow Step 3 again to verify that your Studio version is 1.3.0.

Use the following procedure to connect to Snowflake.

1. Create a new data flow from within Data Wrangler

   Once you have accessed Data Wrangler from within Studio and have version 1.3.0, select the + sign on the **New data flow** card under **ML tasks and components**. This creates a new directory in Studio with a .flow file inside, which contains your data flow. The .flow file automatically opens in Studio.

   Alternatively, you can also create a new flow by selecting **File**, then **New**, and then choosing **Flow**.
When you create a new .flow file in Studio, you may see a message at the top of the Data Wrangler interface that says:

**Connecting to engine**

**Establishing connection to engine...**

2. Connect to Snowflake.

There are two ways to connect to Snowflake from within Data Wrangler. You only need to choose one of the two ways.

1. Specify your Snowflake credentials (account name, user name, and password) in Data Wrangler.
2. Provide an Amazon Resource Name (ARN) of a secret.
Important
If you do not have your Snowflake credentials or ARN, reach out to your administrator. Your administrator can tell you which of the preceding methods to use to connect to Snowflake.

Start on the Import data screen and first select Add data source from the dropdown menu, and then select Snowflake. The following screenshot illustrates where to find the Snowflake option.

Choose an authentication method. For this step, as previously mentioned, you can use your Snowflake credentials or ARN name. One of the two is provided by your administrator.

Next, we explain both authentication methods and provide screenshots for each.

1. **Snowflake Credentials Option.**

   Select the Basic (user name and password) option from the Authentication method dropdown list. Then, enter your credentials in the following fields:
   
   - **Storage integration**: Provide the name of the storage integration. Your administrator provides this name.
   - **Snowflake account name**: The full name of your Snowflake account.
   - **User name**: Snowflake account user name.
   - **Password**: Snowflake account password.
   - **Connection name**: Choose a connection name for your choice.
   - (Optional) **KMS key ID**: Choose the AWS KMS key to encrypt the output of the Snowflake query. For more information about AWS Key Management Service, see https://docs.aws.amazon.com/kms/latest/developerguide/overview.html. If you don't specify a AWS KMS key, Data Wrangler uses the default SSE-KMS encryption method.

   Select Connect.

   The following screenshot shows how to complete these fields.
2. ARN Option

Select the ARN option from the Authentication method dropdown list. Then, provide your ARN name under Secrets Manager ARN and your Storage integration, which is provided by your administrator. If you've created a KMS key, you can specify its ID for KMS key ID. For more information about AWS Key Management Service, see https://docs.aws.amazon.com/kms/latest/developerguide/overview.html. Create a Connection name and select Connect, as shown in the following screenshot.
3. The workflow at this point is to connect your Snowflake account to Data Wrangler, then run some queries on your data and then finally use Data Wrangler for performing data transformations.

The following steps explain the import and querying step from within Data Wrangler.

After creating your Snowflake connection, you are taken to the Import data from Snowflake screen, as shown in the following screenshot.
From here, select your warehouse. You can also optionally select your database and schema, in which case the written query should specify them. If **Database** and **Schema** are provided in the dropdown list, the written query does not need to specify the database and schema names.

Your schemas and tables from your Snowflake account are listed in the left panel. You can select and unravel these entities. When you select a specific table, select the eye icon on the right side of each table name to preview the table.

**Important**

If you’re importing a dataset with columns of type `TIMESTAMP_TZ` or `TIMESTAMP_LTZ`, add `::string` to the column names of your query. For more information, see [How To: Unload TIMESTAMP_TZ and TIMESTAMP_LTZ data to a Parquet file](#).

The following screenshot shows the panel with your data warehouses, databases, and schemas, along with the eye icon with which you can preview your table. Once you select the **Preview Table** icon, the schema preview of that table is generated. You must select a warehouse before you can preview a table.

After selecting a data warehouse, database and schema, you can now write queries and run them. The output of your query shows under **Query results**, as shown in the following screenshot.
Once you have settled on the output of your query, you can then import the output of your query into a Data Wrangler flow to perform data transformations.

To do this, select **Import**, then specify a name and select **Go**, as shown in the following screenshot.
From here, transition to the **Data flow** screen to prepare your data transformation, as shown in the following screenshot.
Private Connectivity between Data Wrangler and Snowflake via AWS PrivateLink

This section explains how to use AWS PrivateLink to establish a private connection between Data Wrangler and Snowflake. The steps are explained in the following sections.

Create a VPC

If you do not have a VPC set up, then follow the Create a new VPC instructions to create one.

Once you have a chosen VPC you would like to use for establishing a private connection, provide the following credentials to your Snowflake Administrator to enable AWS PrivateLink:

- VPC ID
- AWS Account ID
- Your corresponding account URL you use to access Snowflake

Important
As described in Snowflake's documentation, enabling your Snowflake account can take up to two business days.

Set up Snowflake AWS PrivateLink Integration

After AWS PrivateLink is activated, retrieve the AWS PrivateLink configuration for your Region by running the following command in a Snowflake worksheet. Log into your Snowflake console and enter the following under Worksheets: select SYSTEM$GET_PRIVATELINK_CONFIG();

1. Retrieve the values for the following: privatelink-account-name, privatelink_ocsp-url, privatelink-account-url, and privatelink_ocsp-url from the resulting JSON object. Examples of each value are shown in the following snippet. Store these values for later use.

| privatelink-account-name: xxxxxxxx.region.privatelink |
| privatelink-vpce-id: com.amazonaws.vpce.region.vpce-svc-xxxxxxxxxxxxxxxxxx |
| privatelink-account-url: xxxxxxxx.region.privatelink.snowflakecomputing.com |
2. Switch to your AWS Console and navigate to the VPC menu.
3. From the left side panel, choose the Endpoints link to navigate to the VPC Endpoints setup.

Once there, choose Create Endpoint.
4. Select the radio button for Find service by name, as shown in the following screenshot.

5. In the Service Name field, paste in the value for privatelink-vpce-id that you retrieved in the preceding step and choose Verify.

If the connection is successful, a green alert saying Service name found appears on your screen and the VPC and Subnet options automatically expand, as shown in the following screenshot. Depending on your targeted Region, your resulting screen may show another AWS Region name.

6. Select the same VPC ID that you sent to Snowflake from the VPC dropdown list.
7. If you have not yet created a subnet, then perform the following set of instructions on creating a subnet.

8. Select Subnets from the VPC dropdown list. Then select Create subnet and follow the prompts to create a subnet in your VPC. Ensure you select the VPC ID you sent Snowflake.

10. Provide a name for the new security group (such as datawrangler-doc-snowflake-privatelink-connection) and a description. Be sure to select the VPC ID you have used in previous steps.
11 Add two rules to allow traffic from within your VPC to this VPC endpoint.

Navigate to your VPC under Your VPCs in a separate tab, and retrieve your CIDR block for your VPC. Then choose Add Rule in the Inbound Rules section. Select HTTPS for the type, leave the Source as Custom in the form, and paste in the value retrieved from the preceding describe-vpcs call (such as 10.0.0.0/16).

12 Choose Create Security Group. Retrieve the Security Group ID from the newly created security group (such as sg-xxxxxxxxxxxxxxxx).

13 In the VPC Endpoint configuration screen, remove the default security group. Paste in the security group ID in the search field and select the checkbox.

14 Select Create Endpoint.

15 If the endpoint creation is successful, you see a page that has a link to your VPC endpoint configuration, specified by the VPC ID. Select the link to view the configuration in full.

Retrieve the topmost record in the DNS names list. This can be differentiated from other DNS names because it only includes the Region name (such as us-west-2), and no Availability Zone letter notation (such as us-west-2a). Store this information for later use.

Configure DNS for Snowflake Endpoints in your VPC

This section explains how to configure DNS for Snowflake endpoints in your VPC. This allows your VPC to resolve requests to the Snowflake AWS PrivateLink endpoint.

1. Navigate to the Route 53 menu within your AWS console.
2. Select the Hosted Zones option (if necessary, expand the left-hand menu to find this option).
3. Choose Create Hosted Zone.
   a. In the Domain name field, reference the value that was stored for privatelink-account-url in the preceding steps. In this field, your Snowflake account ID is removed from the DNS name and only uses the value starting with the Region identifier. A Resource Record Set is also created later for the subdomain, such as, region.privatelink.snowflakecomputing.com.
   b. Select the radio button for Private Hosted Zone in the Type section. Your Region code may not be us-west-2. Reference the DNS name returned to you by Snowflake.
c. In the **VPCs to associate with the hosted zone** section, select the Region in which your VPC is located and the VPC ID used in previous steps.

d. Choose **Create hosted zone**.

4. Next, create two records, one for `privatelink-account-url` and one for `privatelink_ocsp-url`.
   - In the **Hosted Zone** menu, choose **Create Record Set**.
     a. Under **Record name**, enter your Snowflake Account ID only (the first 8 characters in `privatelink-account-url`).
     b. Under **Record type**, select **CNAME**.
     c. Under **Value**, enter the DNS name for the regional VPC endpoint you retrieved in the last step of the **Set up the Snowflake AWS PrivateLink Integration** section.
d. Choose Create records.

e. Repeat the preceding steps for the OCSP record we notated as privatelink-ocsp-url, starting with ocsp through the 8-character Snowflake ID for the record name (such as ocsp.xxxxxxxx).

Configure Route 53 Resolver Inbound Endpoint for your VPC

This section explains how to configure Route 53 resolvers inbound endpoints for your VPC.

1. Navigate to the Route 53 menu within your AWS console.
   - In the left hand panel in the Security section, select the Security Groups option.
   - Provide a name for your security group (such as datawranger-doc-route53-resolver-sg) and a description.
   - Select the VPC ID used in previous steps.
   - Create rules that allow for DNS over UDP and TCP from within the VPC CIDR block.
3. Navigate to the **Route 53 menu** within your AWS console.
   - In the **Resolver** section, select the **Inbound Endpoint** option.
4. Choose **Create Inbound Endpoint**.
   - Provide an endpoint name.
   - From the **VPC in the Region** dropdown list, select the VPC ID you have used in all previous steps.
   - In the **Security group for this endpoint** dropdown list, select the security group ID from Step 2 in this section.

   - In the **IP Address** section, select an Availability Zones, select a subnet, and leave the radio selector for **Use an IP address that is selected automatically** selected for each IP address.
5. Select the Inbound endpoint after it has been created.

6. Once the inbound endpoint is created, note the two IP addresses for the resolvers.

- Choose Submit.

SageMaker VPC Endpoints

This section explains how to create VPC endpoints for the following: Amazon SageMaker Studio, SageMaker Notebooks, the SageMaker API, SageMaker Runtime, and Amazon SageMaker Feature Store Runtime.

Create a security group that is applied to all endpoints.

1. Navigate to the EC2 menu in the AWS Console.
2. In the Network & Security section, select the Security groups option.
3. Choose **Create security group**.
4. Provide a security group name and description (such as `datawrangler-doc-sagemaker-vpce-sg`).
   A rule is added later to allow traffic over HTTPS from SageMaker to this group.

**Creating the endpoints**

1. Navigate to the **VPC menu** in the AWS console.
2. Select the **Endpoints** option.
3. Choose **Create Endpoint**.
4. Search for the service by entering its name in the **Search** field.
5. From the **VPC** dropdown list, select the VPC in which your Snowflake AWS PrivateLink connection exists.
6. In the **Subnets** section, select the subnets which have access to the Snowflake PrivateLink connection.
7. Leave the **Enable DNS Name** checkbox selected.
8. In the **Security Groups** section, select the security group you created in the preceding section.
9. Choose **Create Endpoint**.

**Configure Studio and Data Wrangler**

This section explains how to configure Studio and Data Wrangler.

1. Configure the security group.
   a. Navigate to the Amazon EC2 menu in the AWS Console.
   b. Select the **Security Groups** option in the **Network & Security** section.
   c. Choose **Create Security Group**.
   d. Provide a name and description for your security group (such as `datawrangler-doc-sagemaker-studio`).
   e. Create the following inbound rules.
      • The HTTPS connection to the security group you provisioned for the Snowflake PrivateLink connection you created in the **Set up the Snowflake PrivateLink Integration** step.
      • The HTTP connection to the security group you provisioned for the Snowflake PrivateLink connection you created in the **Set up the Snowflake PrivateLink Integration step**.
      • The UDP and TCP for DNS (port 53) to Route 53 Resolver Inbound Endpoint security group you create in step 2 of **Configure Route 53 Resolver Inbound Endpoint for your VPC**.
   f. Choose **Create Security Group** button in the lower right hand corner.
2. Configure Studio.
   • Navigate to the SageMaker menu in the AWS console.
   • From the left hand console, Select the **SageMaker Studio** option.
   • If you do not have any domains configured, the **Get Started** menu is present.
   • Select the **Standard Setup** option from the **Get Started** menu.
   • Under **Authentication method**, select **AWS Identity and Access Management (IAM)**.
   • From the **Permissions** menu, you can create a new role or use a pre-existing role, depending on your use case.
      • If you choose **Create a new role**, you are presented the option to provide an S3 bucket name, and a policy is generated for you.
      • If you already have a role created with permissions for the S3 buckets to which you require access, select the role from the dropdown list. This role should have the **AmazonSageMakerFullAccess** policy attached to it.
- Select the **Network and Storage** dropdown list to configure the VPC, security, and subnets SageMaker uses.
  - Under **VPC**, select the VPC in which your Snowflake PrivateLink connection exists.
  - Under **Subnet(s)**, select the subnets which have access to the Snowflake PrivateLink connection.
  - Under **Network Access for Studio**, select **VPC Only**.
  - Under **Security Group(s)**, select the security group you created in step 1.
  - Choose **Submit**.

3. Edit the SageMaker security group.
   - Create the following inbound rules:
     - Port 2049 to the inbound and outbound NFS Security Groups created automatically by SageMaker in step 2 (the security group names contain the Studio domain ID).
     - Access to all TCP ports to itself (required for SageMaker for VPC Only).

4. Edit the VPC Endpoint Security Groups:
   - Navigate to the Amazon EC2 menu in the AWS console.
   - Locate the security group you created in a preceding step.
   - Add an inbound rule allowing for HTTPS traffic from the security group created in step 1.

5. Create a user profile.
   - From the **SageMaker Studio Control Panel**, choose **Add User**.
   - Provide a user name.
   - For the **Execution Role**, choose to create a new role or to use a pre-existing role.
     - If you choose **Create a new role**, you are presented the option to provide an Amazon S3 bucket name, and a policy is generated for you.
     - If you already have a role created with permissions to the Amazon S3 buckets to which you require access, select the role from the dropdown list. This role should have the AmazonSageMakerFullAccess policy attached to it.
   - Choose **Submit**.

6. Create a data flow (follow the data scientist guide outlined in a preceding section).
   - When adding a Snowflake connection, enter the value of `privatelink-account-name` (from the **Set up Snowflake PrivateLink Integration** step) into the **Snowflake account name (alphanumeric)** field, instead of the plain Snowflake account name. Everything else is left unchanged.

## Imported Data Storage

### Important
We strongly recommend that you follow the best practices around protecting your Amazon S3 bucket by following **Security best practices**.

When you query data from Amazon Athena or Amazon Redshift, the queried dataset is automatically stored in Amazon S3. Data is stored in the default SageMaker S3 bucket for the AWS Region in which you are using Studio.

Default S3 buckets have the following naming convention: `sagemaker-region-account number`. For example, if your account number is 111122223333 and you are using Studio in `us-east-1`, your imported datasets are stored in `sagemaker-us-east-1-111122223333`.

Data Wrangler flows depend on this Amazon S3 dataset location, so you should not modify this dataset in Amazon S3 while you are using a dependent flow. If you do modify this S3 location, and you want to continue using your data flow, you must remove all objects in `trained_parameters` in your .flow file.

To do this, download the .flow file from Studio and for each instance of `trained_parameters`, delete all entries. When you are done, `trained_parameters` should be an empty JSON object.
When you export and use your data flow to process your data, the .flow file you export refers to this dataset in Amazon S3. Use the following sections to learn more.

**Amazon Redshift Import Storage**

Data Wrangler stores the datasets that result from your query in a Parquet file in your default SageMaker S3 bucket.

This file is stored under the following prefix (directory): redshift/uuid/data/, where uuid is a unique identifier that gets created for each query.

For example, if your default bucket is sagemaker-us-east-1-111122223333, a single dataset queried from Amazon Redshift is located in s3://sagemaker-us-east-1-111122223333/redshift/uuid/data/.

**Amazon Athena Import Storage**

When you query an Athena database and import a dataset, Data Wrangler stores the dataset, as well as a subset of that dataset, or preview files, in Amazon S3.

The dataset you import by selecting **Import dataset** is stored in Parquet format in Amazon S3.

Preview files are written in CSV format when you select **Run** on the Athena import screen, and contain up to 100 rows from your queried dataset.

The subset of the dataset that is stored to preview dataframes in Data Wrangler is stored under the prefix: athena/.

**Create and Use a Data Wrangler Flow**

Use an Amazon SageMaker Data Wrangler flow, or a **data flow**, to create and modify a data preparation pipeline. The data flow connects the datasets, transformations, and analyses, or steps, you create and can be used to define your pipeline.

**Instances**

When you create a Data Wrangler flow in Amazon SageMaker Studio, Data Wrangler uses an Amazon EC2 instance to run the analyses and transformations in your flow. By default, Data Wrangler uses the m5.4xlarge instance. m5 instances are general purpose instances that provide a balance between compute and memory. You can use m5 instances for a variety of compute workloads.

Data Wrangler also gives you the option of using r5 instances. r5 instances are designed to deliver fast performance that process large datasets in memory.

We recommend that you choose an instance that is best optimized around your workloads. For example, the r5.8xlarge might have a higher price than the m5.4xlarge, but the r5.8xlarge might be better optimized for your workloads. With better optimized instances, you can run your data flows in less time at lower cost.
The following table shows the instances that you can use to run your Data Wrangler flow.

<table>
<thead>
<tr>
<th>Standard Instances</th>
<th>vCPU</th>
<th>Memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>ml.m5.4xlarge</td>
<td>16</td>
<td>64 GiB</td>
</tr>
<tr>
<td>ml.m5.8xlarge</td>
<td>32</td>
<td>128 GiB</td>
</tr>
<tr>
<td>ml.m5.16xlarge</td>
<td>64</td>
<td>256 GiB</td>
</tr>
<tr>
<td>ml.m5.24xlarge</td>
<td>96</td>
<td>384 GiB</td>
</tr>
<tr>
<td>r5.4xlarge</td>
<td>16</td>
<td>128 GiB</td>
</tr>
<tr>
<td>r5.8xlarge</td>
<td>32</td>
<td>256 GiB</td>
</tr>
<tr>
<td>r5.24xlarge</td>
<td>96</td>
<td>768 GiB</td>
</tr>
</tbody>
</table>

For more information about r5 instances, see Amazon EC2 R5 Instances. For more information about m5 instances, see Amazon EC2 M5 Instances.

Each Data Wrangler flow has an Amazon EC2 instance associated with it. You might have multiple flows that are associated with a single instance.

For each flow file, you can seamlessly switch the instance type. If you switch the instance type, the instance that you used to run the flow continues to run.

To switch the instance type of your flow, do the following.

1. Navigate to the instance that you're currently using and choose it. The following image shows you where to choose the instance.

2. Choose the instance type that you want to use.
3. Choose **Save**.

You are charged for all running instances. To avoid incurring additional charges, shut down the instances that you aren't using manually. To shut down an instance that is running, use the following procedure.

To shut down a running instance.

1. Choose the instance icon on the left of the UI. The following image shows you where to select the **RUNNING INSTANCES** icon.

2. Choose **Shut down** next to the instance that you want to shut down.

   If you shut down an instance used to run a flow, you temporarily can't access the flow. If you get an error while attempting to open the flow running an instance you previously shut down, wait for five minutes and try opening it again.

   When you export your data flow to a location such as Amazon Simple Storage Service or Amazon SageMaker Feature Store, Data Wrangler runs an Amazon SageMaker processing job. You can use one of the following instances for the processing job. For more information on exporting your data, see **Export** (p. 945).
### Standard Instances

<table>
<thead>
<tr>
<th>Instance</th>

<td>16</td>
<td>64 GiB</td>
</tr>
<tr>
<td>ml.m5.12xlarge</td>
<td>48</td>
<td>192 GiB</td>
</tr>
<tr>
<td>ml.m5.24xlarge</td>
<td>96</td>
<td>384 GiB</td>
</tr>
</tbody>
</table>

For more information about the cost per hour for using the available instance types, see [SageMaker Pricing](#).

## The Data Flow UI

When you import a dataset, the original dataset appears on the data flow and is named **Source**. If you turned on sampling when you imported your data, this dataset is named **Source - sampled**. Data Wrangler automatically infers the types of each column in your dataset and creates a new dataframe named **Data types**. You can select this frame to update the inferred data types. You see results similar to those shown in the following image after you upload a single dataset:

![Data Flow UI](https://example.com/data-flow-ui.png)

Each time you add a transform step, you create a new dataframe. When multiple transform steps (other than **Join** or **Concatenate**) are added to the same dataset, they are stacked.

**Join** and **Concatenate** create standalone steps that contain the new joined or concatenated dataset.

The following diagram shows a data flow with a join between two datasets, as well as two stacks of steps. The first stack (**Steps (2)**) adds two transforms to the type inferred in the **Data types** dataset. The **downstream** stack, or the stack to the right, adds transforms to the dataset resulting from a join named **demo-join**.
The small, gray box in the bottom right corner of the data flow provides an overview of number of stacks and steps in the flow and the layout of the flow. The lighter box inside the gray box indicates the steps that are within the UI view. You can use this box to see sections of your data flow that fall outside of the UI view. Use the fit screen icon ( ) to fit all steps and datasets into your UI view.

The bottom left navigation bar includes icons that you can use to zoom in ( ) and out ( ) of your data flow and resize the data flow to fit the screen ( ). Use the lock icon ( ) to lock and unlock the location of each step on the screen.
Add a Step to Your Data Flow

Select + next to any dataset or previously added step and then select one of the following options:

- **Edit data types** (For a Data types step only): If you have not added any transforms to a Data types step, you can select **Edit data types** to update the data types Data Wrangler inferred when importing your dataset.

- **Add transform**: Adds a new transform step. See Transform Data (p. 889) to learn more about the data transformations you can add.

- **Add analysis**: Adds an analysis. You can use this option to analyze your data at any point in the data flow. When you add one or more analyses to a step, an analysis icon (●) appears on that step. See Analyze and Visualize (p. 930) to learn more about the analyses you can add.

- **Join**: Joins two datasets and adds the resulting dataset to the data flow. To learn more, see Join Datasets (p. 895).

- **Concatenate**: Concatenates two datasets and adds the resulting dataset to the data flow. To learn more, see Concatenate Datasets (p. 895).

Delete a Step from Your Data Flow

To delete a step, select the step and select **Delete**. If the node is a node that has a single input, you delete only the step that you select. Deleting a step that has a single input doesn't delete the steps that follow it. If you're deleting a step for a source, join, or concatenate node, all the steps that follow it are also deleted.

To delete a step from a stack of steps, select the stack and then select the step you want to delete.

You can use one of the following procedures to delete a step without deleting the downstream steps.

Delete a step in the Data Wrangler flow

You can delete an individual step for nodes in your data flow that have a single input. You can't delete individual steps for source, join, and concatenate nodes.

Use the following procedure to delete a step in the Data Wrangler flow.

1. Choose the group of steps that has the step that you're deleting.
2. Choose the icon next to the step.
3. Choose **Delete**.
Data flow
Choose the plus sign to add a step to the flow. Select a step to modify.
Source - sampled
S3: titanic-train.csv
Delete a step in the table view

Use the following procedure to delete a step in the table view.

You can delete an individual step for nodes in your data flow that have a single input. You can't delete individual steps for source, join, and concatenate nodes.

1. Choose the step and open the table view for the step.
2. Move your cursor over the step.
3. Choose the icon next to the step.
4. Choose Delete.
### Step 3. Standard deviation numeric outliers

Edit a Step in Your Data Wrangler Flow

You can edit each step that you've added in your Data Wrangler flow. Editing steps gives you the ability to change the transformations or the data types of the columns. You can edit the steps to make changes that give you the ability to perform better analyses.

There are many ways that you can edit a step. Some examples include changing the imputation method or changing the threshold for considering a value to be an outlier.

Use the following procedure to edit a step.

To edit a step, do the following.

1. Choose a step in the Data Wrangler flow to open the table view.
2. Choose a step in the data flow.
3. Edit the step.

The following is an example of editing a step.
Use the **Data Quality and Insights Report** to perform an analysis of the data that you've imported into Data Wrangler. We recommend that you create the report after you import your dataset. You can use the report to help you clean and process your data. It gives you information such as the number of missing values.

[Back to data flow]
values and the number of outliers. If you have issues with your data, such as target leakage or imbalance, the insights report can bring those issues to your attention.

**Note**
If you've sampled the data that you've imported, Data Wrangler creates the report from the sampled data. For information about turning off sampling, see Import (p. 827).

The following topics show the sections of the report:

**Topics**
- Summary (p. 876)
- Target column (p. 878)
- Quick model (p. 881)
- Feature summary (p. 883)
- Samples (p. 885)
- Definitions (p. 886)

You can either download the report or view it online. To download the report, choose the download button at the top right corner of the screen. The following image shows the button.

**Summary**

The insights report has a brief summary of the data that includes general information such as missing values, invalid values, feature types, outlier counts, and more. It can also include high severity warnings that point to probable issues with the data. We recommend that you investigate the warnings.

The following is an example of a report summary.
### SUMMARY

**High Priority Warnings**

2 high severity warnings were detected. See the list below.

- **Skewed target** **High**
  
The target column is skewed and contains outliers. Because the outliers induce lower prediction quality for the non-outlier samples. In case you are interested in prediction quality, there is no need for further action. However, if extreme values are not the point, this can be handled under **Handle outliers**.

- **Target leakage** **High**
  
The feature hoa_(BRL) predicts the target extremely well on its own. A feature that perfectly predicts the target column in the dataset can result in a high level of leakage. Alternatively, if the machine learning task is "easy", then a single feature can have only leaking anything further. However, if you think there's target leakage, we recommend...
Target column

When you create the data quality and insights report, Data Wrangler gives you the option to select a target column. A target column is a column that you're trying to predict. When you choose a target column, Data Wrangler automatically creates a target column analysis. It also ranks the features in the order of their predictive power. When you select a target column, you must specify whether you’re trying to solve a regression or a classification problem.

For classification, Data Wrangler shows a table and a histogram of the most common classes. A class is a category. It also presents observations, or rows, with a missing or invalid target value.

The following image shows an example target column analysis for a classification problem.
For regression, Data Wrangler shows a histogram of all the values in the target column. It also presents observations, or rows, with a missing, invalid, or outlier target value.

The following image shows an example target column analysis for a regression problem.

Quick model

The Quick model provides an estimate of the expected predicted quality of a model that you train on your data.

Data Wrangler splits your data into training and validation folds. It uses 80% of the samples for training and 20% of the values for validation. For classification, the sample is stratified split. For a stratified split, each data partition has the same ratio of labels. For classification problems, it's important to have the same ratio of labels between the training and classification folds. Data Wrangler trains the XGBoost model with the default hyperparameters. It applies early stopping on the validation data and performs minimal feature preprocessing.

For classification models, Data Wrangler returns both a model summary and a confusion matrix.

The following is an example of a classification model summary. To learn more about the information that it returns, see Definitions (p. 886).

<table>

</tbody>
</table>

The following is an example of a confusion matrix that the quick model returns.
A confusion matrix gives you the following information:

- The number of times the predicted label matches the true label.
- The number of times the predicted label doesn't match the true label.

The true label represents an actual observation in your data. For example, if you're using a model to detect fraudulent transactions, the true label represents a transaction that is actually fraudulent or non-fraudulent. The predicted label represents the label that your model assigns to the data.

You can use the confusion matrix to see how well the model predicts the presence or the absence of a condition. If you're predicting fraudulent transactions, you can use the confusion matrix to get a sense of both the sensitivity and the specificity of the model. The sensitivity refers to the model's ability to detect fraudulent transactions. The specificity refers to the model's ability to avoid detecting non-fraudulent transactions as fraudulent.

The following is an example of the quick model outputs for a regression problem.
Feature summary

When you specify a target column, Data Wrangler orders the features by their prediction power. Prediction power is measured on the data after it was split into 80% training and 20% validation folds. Data Wrangler fits a model for each feature separately on the training fold. It applies minimal feature preprocessing and measures prediction performance on the validation data.

It normalizes the scores to the range [0,1]. Higher prediction scores indicate columns that are more useful for predicting the target on their own. Lower scores point to columns that aren't predictive of the target column.

It's uncommon for a column that isn't predictive on its own to be predictive when it's used in tandem with other columns. You can confidently use the prediction scores to determine whether a feature in your dataset is predictive.

A low score usually indicates the feature is redundant. A score of 1 implies perfect predictive abilities, which often indicates target leakage. Target leakage usually happens when the dataset contains a column that isn't available at the prediction time. For example, it could be a duplicate of the target column.

The following are examples of the table and the histogram that show the prediction value of each feature.
<table>

</table>
Data Wrangler provides information about whether your samples are anomalous or if there are duplicates in your dataset.

Data Wrangler detects anomalous samples using the isolation forest algorithm. The isolation forest associates an anomaly score with each sample (row) of the dataset. Low anomaly scores indicate anomalous samples. High scores are associated with non-anomalous samples. Samples with a negative anomaly score are usually considered anomalous and samples with positive anomaly score are considered non-anomalous.

When you look at a sample that might be anomalous, we recommend that you pay attention to unusual values. For example, you might have anomalous values that result from errors in gathering and processing the data. The following is an example of the most anomalous samples according to the Data Wrangler’s implementation of the isolation forest algorithm. We recommend using domain knowledge and business logic when you examine the anomalous samples.

Data Wrangler detects duplicate rows and calculates the ratio of duplicate rows in your data. Some data sources could include valid duplicates. Other data sources could have duplicates that point to problems in data collection. Duplicate samples that result from faulty data collection could interfere with machine learning processes that rely on splitting the data into independent training and validation folds.

The following are elements of the insights report that can be impacted by duplicated samples:

- Quick model
Get Insights On Data and Data Quality

- Prediction power estimation
- Automatic hyperparameter tuning

You can remove duplicate samples from the dataset using the **Drop duplicates** transform under **Manage rows**. Data Wrangler shows you the most frequently duplicated rows.

**Definitions**

The following are definitions for the technical terms that are used in the data insights report.

**Feature types**

The following are the definitions for each of the feature types:

- **Numeric** – Numeric values can be either floats or integers, such as age or income. The machine learning models assume that numeric values are ordered and a distance is defined over them. For example, 3 is closer to 4 than to 10 and $3 < 4 < 10$.

- **Categorical** – The column entries belong to a set of unique values, which is usually much smaller than the number of entries in the column. For example, a column of length 100 could contain the unique values Dog, Cat, and Mouse. The values could be numeric, text, or a combination of both. Horse, House, 8, Love, and 3.1 would all be valid values and could be found in the same categorical column. The machine learning model does not assume order or distance on the values of categorical features, as opposed to numeric features, even when all the values are numbers.

- **Binary** – Binary features are a special categorical feature type in which the cardinality of the set of unique values is 2.

- **Text** – A text column contains many non-numeric unique values. In extreme cases, all the elements of the column are unique. In an extreme case, no two entries are the same.

- **Datetime** – A datetime column contains information about the date or time. It can have information about both the date and time.

**Feature statistics**

The following are definitions for each of the feature statistics:

- **Prediction power** – Prediction power measures how useful the column is in predicting the target.

- **Outliers** (in numeric columns) – Data Wrangler detects outliers using two statistics that are robust to outliers: median and robust standard deviation (RSTD). RSTD is derived by clipping the feature values to the range [5 percentile, 95 percentile] and calculating the standard deviation of the clipped vector. All values larger than median + 5 * RSTD or smaller than median - 5 * RSTD are considered to be outliers.

- **Skew** (in numeric columns) – Skew measures the symmetry of the distribution and is defined as the third moment of the distribution divided by the third power of the standard deviation. The skewness of the normal distribution or any other symmetric distribution is zero. Positive values imply that the right tail of the distribution is longer than the left tail. Negative values imply that the left tail of the distribution is longer than the right tail. As a rule of thumb, a distribution is considered skewed when the absolute value of the skew is larger than 3.

- **Kurtosis** (in numeric columns) – Pearson's kurtosis measures the heaviness of the tail of the distribution. It's defined as the fourth moment of the distribution divided by the square of the second moment. The kurtosis of the normal distribution is 3. Kurtosis values lower than 3 imply that the distribution is concentrated around the mean and the tails are lighter than the tails of the normal distribution. Kurtosis values higher than 3 imply heavier tails or outliers.

- **Missing values** – Null-like objects, empty strings and strings composed of only white spaces are considered missing.
• **Valid values for numeric features or regression target** – All values that you can cast to finite floats are valid. Missing values are not valid.

• **Valid values for categorical, binary, or text features, or for classification target** – All values that are not missing are valid.

• **Datetime features** – All values that you can cast to a datetime object are valid. Missing values are not valid.

• **Invalid values** – Values that are either missing or you can’t properly cast. For example, in a numeric column, you can’t cast the string "six" or a null value.

**Quick model metrics for regression**

The following are the definitions for the quick model metrics:

• **R2 or coefficient of determination** – R2 is the proportion of the variation in the target that is predicted by the model. R2 is in the range of [-infty, 1]. 1 is the score of the model that predicts the target perfectly and 0 is the score of the trivial model that always predicts the target mean.

• **MSE or mean squared error** – MSE is in the range [0, infty]. 0 is the score of the model that predicts the target perfectly.

• **MAE or mean absolute error** – MAE is in the range [0, infty] where 0 is the score of the model that predicts the target perfectly.

• **RMSE or root mean square error** – RMSE is in the range [0, infty] where 0 is the score of the model that predicts the target perfectly.

• **Max error** – The maximum absolute value of the error over the dataset. Max error is in the range [0, infty]. 0 is the score of the model that predicts the target perfectly.

• **Median absolute error** – Median absolute error is in the range [0, infty]. 0 is the score of the model that predicts the target perfectly.

**Quick model metrics for classification**

The following are the definitions for the quick model metrics:

• **Accuracy** – Accuracy is the ratio of samples that are predicted accurately. Accuracy is in the range [0, 1]. 0 is the score of the model that predicts all samples incorrectly and 1 is the score of the perfect model.

• **Balanced accuracy** – Balanced accuracy is the ratio of samples that are predicted accurately when the class weights are adjusted to balance the data. All classes are given the same importance, regardless of their frequency. Balanced accuracy is in the range [0, 1]. 0 is the score of the model that predicts all samples wrong. 1 is the score of the perfect model.

• **AUC (binary classification)** – This is the area under the receiver operating characteristic curve. AUC is in the range [0, 1] where a random model returns a score of 0.5 and the perfect model returns a score of 1.

• **AUC (OVR)** – For multiclass classification, this is the area under the receiver operating characteristic curve calculated separately for each label using one versus rest. Data Wrangler reports the average of the areas. AUC is in the range [0, 1] where a random model returns a score of 0.5 and the perfect model returns a score of 1.

• **Precision** – Precision is defined for a specific class. Precision is the fraction of true positives out of all the instances that the model classified as that class. Precision is in the range [0, 1]. 1 is the score of the model that has no false positives for the class. For binary classification, Data Wrangler reports the precision of the positive class.

• **Recall** – Recall is defined for a specific class. Recall is the fraction of the relevant class instances that are successfully retrieved. Recall is in the range [0, 1]. 1 is the score of the model that classifies all the instances of the class correctly. For binary classification, Data Wrangler reports the recall of the positive class.
• **F1** – F1 is defined for a specific class. It's the harmonic mean of the precision and recall. F1 is in the range \([0, 1]\). 1 is the score of the perfect model. For binary classification, Data Wrangler reports the F1 for classes with positive values.

**Textual patterns**

Patterns describe the textual format of a string using an easy to read format. The following are examples of textual patterns:

- "\{digits:4-7\}" describes a sequence of digits that have a length between 4 and 7.
- "\{alnum:5\}" describes an alpha-numeric string with a length of exactly 5.

Data Wrangler infers the patterns by looking at samples of non-empty strings from your data. It can describe many of the commonly used patterns. The confidence expressed as a percentage indicates how much of the data is estimated to match the pattern. Using the textual pattern, you can see which rows in your data you need to correct or drop.

The following describes the patterns that Data Wrangler can recognize:

<table>
<thead>
<tr>
<th>Pattern</th>
<th>Textual Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>{alnum}</td>
<td>Alphanumeric strings</td>
</tr>
<tr>
<td>{any}</td>
<td>Any string of word characters</td>
</tr>
<tr>
<td>{digits}</td>
<td>A sequence of digits</td>
</tr>
<tr>
<td>{lower}</td>
<td>A lowercase word</td>
</tr>
<tr>
<td>{mixed}</td>
<td>A mixed-case word</td>
</tr>
<tr>
<td>{name}</td>
<td>A word beginning with a capital letter</td>
</tr>
<tr>
<td>{upper}</td>
<td>An uppercase word</td>
</tr>
<tr>
<td>{whitespace}</td>
<td>whitespace characters</td>
</tr>
</tbody>
</table>

A word character is either an underscore or a character that might appear in a word in any language. For example, the strings 'Hello_word' and 'écoute' both consist of word characters. 'H' and 'é' are both examples of word characters.

**Automatically Train Models on Your Data Flow**

You can use Amazon SageMaker Autopilot to automatically train, tune, and deploy models on the data that you've transformed in your data flow. Amazon SageMaker Autopilot can go through several algorithms and use the one that works best with your data. For more information about Amazon SageMaker Autopilot, see [Automate model development with Amazon SageMaker Autopilot](#).

When you train and tune a model, Data Wrangler exports your data to an Amazon S3 location where Amazon SageMaker Autopilot can access it.

You can prepare and deploy a model by choosing a node in your Data Wrangler flow and choosing **Export and Train** in the data preview. You can use this method to view your dataset before you choose to train a model on it.

You can also train and deploy a model directly from your data flow.
Transform Data

The following procedure prepares and deploys a model from the data flow. For Data Wrangler flows with multi-row transforms, you can't use the transforms from the Data Wrangler flow when you're deploying the model. You can use the following procedure to process the data before you use it to perform inference.

To train and deploy a model directly from your data flow, do the following.

1. Choose the + next to the node containing the training data.
2. Choose Train model.
3. (Optional) Specify a AWS KMS key or ID. For more information about creating and controlling cryptographic keys to protect your data, see AWS Key Management Service.
4. Choose Export and train.
5. After Amazon SageMaker Autopilot trains the model on the data that Data Wrangler exported, specify a name for Experiment name.
6. Under Input data, choose Preview to verify that Data Wrangler properly exported your data to Amazon SageMaker Autopilot.
7. For Target, choose the target column.
8. (Optional) For S3 location under Output data, specify an Amazon S3 location other than the default location.
10. Choose a training method. For more information, see 
??? (p. 325).
11. (Optional) For Auto deploy endpoint, specify a name for the endpoint.
12. For Deployment option, choose a deployment method. You can choose to deploy with or without the transformations that you've made to your data.

Important
You can't deploy an Amazon SageMaker Autopilot model with the transformations that you've made in your Data Wrangler flow if you've used the following transformations:

- Join
- Concatenate
- Group by

You can export the dataset from a join to Amazon S3. You can create a new flow using the dataset that you've exported. You can use the dataset to train and deploy a model.

13. Choose Next: Review and create.
14. Choose Create experiment.

For more information about model training and deployment, see Create an Amazon SageMaker Autopilot experiment (p. 321). Autopilot shows you analyses about the best model's performance. For more information about model performance, see Autopilot Model Insights (p. 354).

Transform Data

Amazon SageMaker Data Wrangler provides numerous ML data transforms to streamline cleaning, transforming, and featurizing your data. When you add a transform, it adds a step to the data flow. Each transform you add modifies your dataset and produces a new dataframe. All subsequent transforms apply to the resulting dataframe.

Data Wrangler includes built-in transforms, which you can use to transform columns without any code. You can also add custom transformations using PySpark, Python (User-Defined Function), pandas,
and PySpark SQL. Some transforms operate in place, while others create a new output column in your dataset.

You can apply transforms to multiple columns at once. For example, you can delete multiple columns in a single step.

You can apply the **Process numeric** and **Handle missing** transforms only to a single column.

Use this page to learn more about these built-in and custom transforms.

**Transform UI**

Most of the built-in transforms are located in the **Prepare** tab of the Data Wrangler UI. You can access the join and concatenate transforms through the data flow view. Use the following table to preview these two views.

**Transform**

You can add a transform to any step in your data flow. Use the following procedure to add a transform to your data flow.

To add a step to your data flow, do the following.

1. Choose the + next to the step in the data flow.
2. Choose **Add transform**.
3. Choose **Add step**.
4. Choose a transform.

5. (Optional) You can search for the transform that you want to use. Data Wrangler highlights the query in the results.
Join View

To join two datasets, select the first dataset in your data flow and choose Join. When you choose Join, you see results similar to those shown in the following image. Your left and right datasets are displayed in the left panel. The main panel displays your data flow, with the newly joined dataset added.
When you choose Configure to configure your join, you see results similar to those shown in the following image. Your join configuration is displayed in the left panel. You can use this panel to choose the joined dataset name, join type, and columns to join. The main panel displays three tables. The top two tables display the left and right datasets on the left and right respectively. Under this table, you can preview the joined dataset.

See Join Datasets (p. 895) to learn more.

Concatenate View

To concatenate two datasets, you select the first dataset in your data flow and choose Concatenate. When you select Concatenate, you see results similar to those shown in the following image. Your
left and right datasets are displayed in the left panel. The main panel displays your data flow, with the newly concatenated dataset added.

When you choose Configure to configure your concatenation, you see results similar to those shown in the following image. Your concatenate configuration displays in the left panel. You can use this panel to choose the concatenated dataset's name, and choose to remove duplicates after concatenation and add columns to indicate the source dataframe. The main panel displays three tables. The top two tables display the left and right datasets on the left and right respectively. Under this table, you can preview the concatenated dataset.

See Concatenate Datasets (p. 895) to learn more.
Join Datasets

You join dataframes directly in your data flow. When you join two datasets, the resulting joined dataset appears in your flow. The following join types are supported by Data Wrangler.

- **Left Outer** – Include all rows from the left table. If the value for the column joined on a left table row does not match any right table row values, that row contains null values for all right table columns in the joined table.
- **Left Anti** – Include rows from the left table that do not contain values in the right table for the joined column.
- **Left semi** – Include a single row from the left table for all identical rows that satisfy the criteria in the join statement. This excludes duplicate rows from the left table that match the criteria of the join.
- **Right Outer** – Include all rows from the right table. If the value for the joined column in a right table row does not match any left table row values, that row contains null values for all left table columns in the joined table.
- **Inner** – Include rows from left and right tables that contain matching values in the joined column.
- **Full Outer** – Include all rows from the left and right tables. If the row value for the joined column in either table does not match, separate rows are created in the joined table. If a row doesn't contain a value for a column in the joined table, null is inserted for that column.
- **Cartesian Cross** – Include rows which combine each row from the first table with each row from the second table. This is a Cartesian product of rows from tables in the join. The result of this product is the size of the left table times the size of the right table. Therefore, we recommend caution in using this join between very large datasets.

Use the following procedure to join two dataframes.

1. Select + next to the left dataframe that you want to join. The first dataframe you select is always the left table in your join.
2. Choose Join.
3. Select the right dataframe. The second dataframe you select is always the right table in your join.
4. Choose Configure to configure your join.
5. Give your joined dataset a name using the Name field.
6. Select a Join type.
7. Select a column from the left and right tables to join.
8. Choose Apply to preview the joined dataset on the right.
9. To add the joined table to your data flow, choose Add.

Concatenate Datasets

**Concatenate two datasets:**

1. Choose + next to the left dataframe that you want to concatenate. The first dataframe you select is always the left table in your concatenate.
2. Choose Concatenate.
3. Select the right dataframe. The second dataframe you select is always the right table in your concatenate.
4. Choose Configure to configure your concatenate.
5. Give your concatenated dataset a name using the Name field.
6. (Optional) Select the checkbox next to **Remove duplicates after concatenation** to remove duplicate columns.

7. (Optional) Select the checkbox next to **Add column to indicate source dataframe** if, for each column in the new dataset, you want to add an indicator of the column's source.

8. Choose **Apply** to preview the new dataset.

9. Choose **Add** to add the new dataset to your data flow.

## Balance Data

You can balance the data for datasets with an underrepresented category. Balancing a dataset can help you create better models for binary classification.

**Note**

You can't balance datasets containing column vectors.

You can use the **Balance data** operation to balance your data using one of the following operators:

- **Random oversampling** – Randomly duplicates samples in the minority category. For example, if you're trying to detect fraud, you might only have cases of fraud in 10% of your data. For an equal proportion of fraudulent and non-fraudulent cases, this operator randomly duplicates fraud cases within the dataset 8 times.

- **Random undersampling** – Roughly equivalent to random oversampling. Randomly removes samples from the overrepresented category to get the proportion of samples that you desire.

- **Synthetic Minority Oversampling Technique (SMOTE)** – Uses samples from the underrepresented category to interpolate new synthetic minority samples. For more information about SMOTE, see the following description.

You can use all transforms for datasets containing both numeric and non-numeric features. SMOTE interpolates values by using neighboring samples. Data Wrangler uses the R-squared distance to determine the neighborhood to interpolate the additional samples. Data Wrangler only uses numeric features to calculate the distances between samples in the underrepresented group.

For two real samples in the underrepresented group, Data Wrangler interpolates the numeric features by using a weighted average. It randomly assigns weights to those samples in the range of [0, 1]. For numeric features, Data Wrangler interpolates samples using a weighted average of the samples. For samples A and B, Data Wrangler could randomly assign a weight of 0.7 to A and 0.3 to B. The interpolated sample has a value of 0.7A + 0.3B.

Data Wrangler interpolates non-numeric features by copying from either of the interpolated real samples. It copies the samples with a probability that it randomly assigns to each sample. For samples A and B, it can assign probabilities 0.8 to A and 0.2 to B. For the probabilities it assigned, it copies A 80% of the time.

## Custom Transforms

The **Custom Transforms** group allows you to use Python (User-Defined Function), PySpark, pandas, or PySpark (SQL) to define custom transformations. For all three options, you use the variable `df` to access the dataframe to which you want to apply the transform. If you're not using Python (User-Defined Function), you don't need to include a return statement. Choose **Preview** to preview the result of the custom transform. Choose **Add** to add the custom transform to your list of Previous steps.

You can import the popular libraries with an `import` statement in the custom transform code block, such as the following:

- NumPy version 1.19.0
Important

Custom transform doesn't support columns with spaces or special characters in the name. We recommend that you specify column names that only have alphanumeric characters and underscores. You can use the Rename column transform in the Manage columns transform group to remove spaces from a column's name. You can also add a Python (Pandas) Custom transform similar to the following to remove spaces from multiple columns in a single step. This example changes columns named A column and B column to A_column and B_column respectively.

```python
df.rename(columns={"A column": "A_column", "B column": "B_column"})
```

If you include print statements in the code block, the result appears when you select Preview. You can resize the custom code transformer panel. Resizing the panel provides more space to write code. The following image shows the resizing of the panel.
Data flow

Choose the plus sign to add a step to the flow. Select a step to modify.

Source - sampled

S3: titanic.csv
The following sections provide additional context and examples for writing custom transform code.

**Python (User-Defined Function)**

The Python function gives you the ability to write custom transformations without needing to know Apache Spark or pandas. Data Wrangler is optimized to run your custom code quickly. You get similar performance using custom Python code and an Apache Spark plugin.

To use the Python (User-Defined Function) code block, you specify the following:

- **Input column** – The input column where you're applying the transform.
- **Mode** – The scripting mode, either pandas or Python.
- **Return type** – The data type of the value that you're returning.

Using the pandas mode gives better performance. The Python mode makes it easier for you to write transformations by using pure Python functions.

The following video shows an example of how to use custom code to create a transformation. It uses the Titanic dataset to create a column with the person's salutation.
Data flow

Choose the plus sign to add a step to the flow. Select a step to move...
**PySpark**

The following example extracts date and time from a timestamp.

```python
from pyspark.sql.functions import from_unixtime, to_date, date_format
df = df.withColumn('DATE_TIME', from_unixtime('TIMESTAMP'))
df = df.withColumn( 'EVENT_DATE', to_date('DATE_TIME')).withColumn('EVENT_TIME', date_format('DATE_TIME', 'HH:mm:ss'))
```

**pandas**

The following example provides an overview of the dataframe to which you are adding transforms.

```python
df.info()
```

**PySpark (SQL)**

The following example creates a new dataframe with four columns: `name`, `fare`, `pclass`, `survived`.

```sql
SELECT name, fare, pclass, survived FROM df
```

If you don’t know how to use PySpark, you can use custom code snippets to help you get started.

Data Wrangler has a searchable collection of code snippets. You can use code snippets to perform tasks such as dropping columns, grouping by columns, or modelling.

To use a code snippet, choose **Search example snippets** and specify a query in the search bar. The text you specify in the query doesn’t have to match the name of the code snippet exactly.

The following example shows a **Drop duplicate rows** code snippet that can delete rows with similar data in your dataset. You can find the code snippet by searching for one of the following:

- Duplicates
- Identical
- Remove

The following snippet has comments to help you understand the changes that you need to make. For most snippets, you must specify the column names of your dataset in the code.

```python
# Specify the subset of columns
# all rows having identical values in these columns will be dropped
subset = ["col1", "col2", "col3"]
df = df.dropDuplicates(subset)
# to drop the full-duplicate rows run
# df = df.dropDuplicates()
```

To use a snippet, copy and paste its content into the **Custom transform** field. You can copy and paste multiple code snippets into the custom transform field.

**Custom Formula**

Use **Custom formula** to define a new column using a Spark SQL expression to query data in the current dataframe. The query must use the conventions of Spark SQL expressions.
**Important**

**Custom formula** doesn't support columns with spaces or special characters in the name. We recommend that you specify column names that only have alphanumeric characters and underscores. You can use the **Rename column** transform in the **Manage columns** transform group to remove spaces from a column's name. You can also add a **Python (Pandas) Custom transform** similar to the following to remove spaces from multiple columns in a single step. This example changes columns named A_column and B_column to A_column and B_column respectively.

```python
df.rename(columns={"A column": "A_column", "B column": "B_column"})
```

You can use this transform to perform operations on columns, referencing the columns by name. For example, assuming the current dataframe contains columns named col_a and col_b, you can use the following operation to produce an **Output column** that is the product of these two columns with the following code:

```python
col_a * col_b
```

Other common operations include the following, assuming a dataframe contains col_a and col_b columns:

- Concatenate two columns: `concat(col_a, col_b)`
- Add two columns: `col_a + col_b`
- Subtract two columns: `col_a - col_b`
- Divide two columns: `col_a / col_b`
- Take the absolute value of a column: `abs(col_a)`

For more information, see the **Spark documentation** on selecting data.

### Reduce Dimensionality within a Dataset

Reduce the dimensionality in your data by using Principal Component Analysis (PCA). The dimensionality of your dataset corresponds to the number of features. When you use dimensionality reduction in Data Wrangler, you get a new set of features called components. Each component accounts for some variability in the data.

The first component accounts for the largest amount of variation in the data. The second component accounts for the second largest amount of variation in the data, and so on.

You can use dimensionality reduction to reduce the size of the data sets that you use to train models. Instead of using the features in your dataset, you can use the principal components instead.

To perform PCA, Data Wrangler creates axes for your data. An axis is an affine combination of columns in your dataset. The first principal component is the value on the axis that has the largest amount of variance. The second principal component is the value on the axis that has the second largest amount of variance. The nth principal component is the value on the axis that has the nth largest amount of variance.

You can configure the number of principal components that Data Wrangler returns. You can either specify the number of principal components directly or you can specify the variance threshold percentage. Each principal component explains an amount of variance in the data. For example, you might have a principal component with a value of 0.5. The component would explain 50% of the variation in the data. When you specify a variance threshold percentage, Data Wrangler returns the smallest number of components that meet the percentage that you specify.
The following are example principal components with the amount of variance that they explain in the data.

- Component 1 – 0.5
- Component 2 – 0.45
- Component 3 – 0.05

If you specify a variance threshold percentage of 94 or 95, Data Wrangler returns Component 1 and Component 2. If you specify a variance threshold percentage of 96, Data Wrangler returns all three principal components.

You can use the following procedure to run PCA on your dataset.

To run PCA on your dataset, do the following.

1. Open your Data Wrangler data flow.
2. Choose the +, and select Add transform.
3. Choose Add step.
4. Choose Dimensionality Reduction.
5. For Input Columns, choose the features that you’re reducing into the principal components.
6. (Optional) For Number of principal components, choose the number of principal components that Data Wrangler returns in your dataset. If specify a value for the field, you can’t specify a value for Variance threshold percentage.
7. (Optional) For Variance threshold percentage, specify the percentage of variation in the data that you want explained by the principal components. Data Wrangler uses the default value of 95 if you don’t specify a value for the variance threshold. You can’t specify a variance threshold percentage if you’ve specified a value for Number of principal components.
8. (Optional) Deselect Center to not use the mean of the columns as the center of the data. By default, Data Wrangler centers the data with the mean before scaling.
9. (Optional) Deselect Scale to not scale the data with the unit standard deviation.
10. (Optional) Choose Columns to output the components to separate columns. Choose Vector to output the components as a single vector.
11. (Optional) For Output column, specify a name for an output column. If you’re outputting the components to separate columns, the name that you specify is a prefix. If you’re outputting the components to a vector, the name that you specify is the name of the vector column.
12. (Optional) Select Keep input columns. We don’t recommend selecting this option if you plan on only using the principal components to train your model.

Encode Categorical

Categorical data is usually composed of a finite number of categories, where each category is represented with a string. For example, if you have a table of customer data, a column that indicates the country a person lives in is categorical. The categories would be Afghanistan, Albania, Algeria, and so on. Categorical data can be nominal or ordinal. Ordinal categories have an inherent order, and nominal categories do not. The highest degree obtained (High school, Bachelors, Masters, and so on) is an example of ordinal categories.

Encoding categorical data is the process of creating a numerical representation for categories. For example, if your categories are Dog and Cat, you may encode this information into two vectors, \([1, 0]\) to represent Dog, and \([0, 1]\) to represent Cat.
When you encode ordinal categories, you may need to translate the natural order of categories into your encoding. For example, you can represent the highest degree obtained with the following map: {"High school": 1, "Bachelors": 2, "Masters":3}.

Use categorical encoding to encode categorical data that is in string format into arrays of integers.

The Data Wrangler categorical encoders create encodings for all categories that exist in a column at the time the step is defined. If new categories have been added to a column when you start a Data Wrangler job to process your dataset at time $t$, and this column was the input for a Data Wrangler categorical encoding transform at time $t-1$, these new categories are considered missing in the Data Wrangler job.

The option you select for Invalid handling strategy is applied to these missing values. Examples of when this can occur are:

- When you use a .flow file to create a Data Wrangler job to process a dataset that was updated after the creation of the data flow. For example, you may use a data flow to regularly process sales data each month. If that sales data is updated weekly, new categories may be introduced into columns for which an encode categorical step is defined.
- When you select Sampling when you import your dataset, some categories may be left out of the sample.

In these situations, these new categories are considered missing values in the Data Wrangler job.

You can choose from and configure an ordinal and a one-hot encode. Use the following sections to learn more about these options.

Both transforms create a new column named Output column name. You specify the output format of this column with Output style:

- Select Vector to produce a single column with a sparse vector.
- Select Columns to create a column for every category with an indicator variable for whether the text in the original column contains a value that is equal to that category.

### Ordinal Encode

Select Ordinal encode to encode categories into an integer between 0 and the total number of categories in the Input column you select.

Invalid handling strategy: Select a method to handle invalid or missing values.

- Choose Skip if you want to omit the rows with missing values.
- Choose Keep to retain missing values as the last category.
- Choose Error if you want Data Wrangler to throw an error if missing values are encountered in the Input column.
- Choose Replace with NaN to replace missing with NaN. This option is recommended if your ML algorithm can handle missing values. Otherwise, the first three options in this list may produce better results.

### One-Hot Encode

Select One-hot encode for Transform to use one-hot encoding. Configure this transform using the following:

- Drop last category: If True, the last category does not have a corresponding index in the one-hot encoding. When missing values are possible, a missing category is always the last one and setting this to True means that a missing value results in an all zero vector.
• **Invalid handling strategy**: Select a method to handle invalid or missing values.
  • Choose **Skip** if you want to omit the rows with missing values.
  • Choose **Keep** to retain missing values as the last category.
  • Choose **Error** if you want Data Wrangler to throw an error if missing values are encountered in the Input column.

• **Is input ordinal encoded**: Select this option if the input vector contains ordinal encoded data. This option requires that input data contain non-negative integers. If **True**, input $i$ is encoded as a vector with a non-zero in the $i$th location.

**Similarity encode**

Use similarity encoding when you have the following:

• A large number of categorical variables
• Noisy data

The similarity encoder creates embeddings for columns with categorical data. An embedding is a mapping of discrete objects, such as words, to vectors of real numbers. It encodes similar strings to vectors containing similar values. For example, it creates very similar encodings for “California” and “Calfornia”.

Data Wrangler converts each category in your dataset into a set of tokens using a 3-gram tokenizer. It converts the tokens into an embedding using min-hash encoding.

The following example shows how the similarity encoder creates vectors from strings.
The similarity encodings that Data Wrangler creates:

- Have low dimensionality
- Are scalable to a large number of categories
- Are robust and resistant to noise

For the preceding reasons, similarity encoding is more versatile than one-hot encoding.

To add the similarity encoding transform to your dataset, use the following procedure.

To use similarity encoding, do the following.

1. Sign in to the Amazon SageMaker Console.
2. Choose Open Studio.
3. Choose Launch app.
4. Choose Studio.
5. Specify your data flow.
6. Choose a step with a transformation.
7. Choose Add step.
8. Choose Encode categorical.
9. Specify the following:
   
   - **Transform** – Similarity encode
   - **Input column** – The column containing the categorical data that you're encoding.
   - **Target dimension** – (Optional) The dimension of the categorical embedding vector. The default value is 30. We recommend using a larger target dimension if you have a large dataset with many categories.
   - **Output style** – Choose Vector for a single vector with all of the encoded values. Choose Column to have the encoded values in separate columns.
   - **Output column** – (Optional) The name of the output column for a vector encoded output. For a column-encoded output, this is the prefix of the column names followed by listed number.

**Featurize Text**

Use the **Featurize Text** transform group to inspect string-typed columns and use text embedding to featurize these columns.
This feature group contains two features, Character statistics and Vectorize. Use the following sections to learn more about these transforms. For both options, the input column must contain text data (string type).

Character Statistics

Use Character statistics to generate statistics for each row in a column containing text data.

This transform computes the following ratios and counts for each row, and creates a new column to report the result. The new column is named using the input column name as a prefix and a suffix that is specific to the ratio or count.

- **Number of words**: The total number of words in that row. The suffix for this output column is -stats_word_count.
- **Number of characters**: The total number of characters in that row. The suffix for this output column is -stats_char_count.
- **Ratio of upper**: The number of uppercase characters, from A to Z, divided by all characters in the column. The suffix for this output column is -stats_capital_ratio.
- **Ratio of lower**: The number of lowercase characters, from a to z, divided by all characters in the column. The suffix for this output column is -stats_lower_ratio.
- **Ratio of digits**: The ratio of digits in a single row over the sum of digits in the input column. The suffix for this output column is -stats_digit_ratio.
- **Special characters ratio**: The ratio of non-alphanumeric (characters like #$&%:@) characters to over the sum of all characters in the input column. The suffix for this output column is -stats_special_ratio.

Vectorize

Text embedding involves mapping words or phrases from a vocabulary to vectors of real numbers. Use the Data Wrangler text embedding transform to tokenize and vectorize text data into term frequency-inverse document frequency (TF-IDF) vectors.

When TF-IDF is calculated for a column of text data, each word in each sentence is converted to a real number that represents its semantic importance. Higher numbers are associated with less frequent words, which tend to be more meaningful.

When you define a Vectorize transform step, Data Wrangler uses the data in your dataset to define the count vectorizer and TF-IDF methods. Running a Data Wrangler job uses these same methods.

You configure this transform using the following:

- **Output column name**: This transform creates a new column with the text embedding. Use this field to specify a name for this output column.
- **Tokenizer**: A tokenizer converts the sentence into a list of words, or tokens.
  
  Choose **Standard** to use a tokenizer that splits by white space and converts each word to lowercase. For example, "Good dog" is tokenized to ["good", "dog"].
  
  Choose **Custom** to use a customized tokenizer. If you choose Custom, you can use the following fields to configure the tokenizer:
  
  - **Minimum token length**: The minimum length, in characters, for a token to be valid. Defaults to 1. For example, if you specify 3 for minimum token length, words like a, at, in are dropped from the tokenized sentence.
  - **Should regex split on gaps**: If selected, regex splits on gaps. Otherwise, it matches tokens. Defaults to True.
• **Regex pattern**: Regex pattern that defines the tokenization process. Defaults to `' \s+`.

• **To lowercase**: If chosen, Data Wrangler converts all characters to lowercase before tokenization. Defaults to `True`.

To learn more, see the Spark documentation on [Tokenizer](#).

• **Vectorizer**: The vectorizer converts the list of tokens into a sparse numeric vector. Each token corresponds to an index in the vector and a non-zero indicates the existence of the token in the input sentence. You can choose from two vectorizer options, `Count` and `Hashing`.

• **Count vectorize** allows customizations that filter infrequent or too common tokens. **Count vectorize parameters** include the following:
  
  • **Minimum term frequency**: In each row, terms (tokens) with smaller frequency are filtered. If you specify an integer, this is an absolute threshold (inclusive). If you specify a fraction between 0 (inclusive) and 1, the threshold is relative to the total term count. Defaults to 1.
  
  • **Minimum document frequency**: Minimum number of rows in which a term (token) must appear to be included. If you specify an integer, this is an absolute threshold (inclusive). If you specify a fraction between 0 (inclusive) and 1, the threshold is relative to the total term count. Defaults to 1.
  
  • **Maximum document frequency**: Maximum number of documents (rows) in which a term (token) can appear to be included. If you specify an integer, this is an absolute threshold (inclusive). If you specify a fraction between 0 (inclusive) and 1, the threshold is relative to the total term count. Defaults to 0.999.
  
  • **Maximum vocabulary size**: Maximum size of the vocabulary. The vocabulary is made up of all terms (tokens) in all rows of the column. Defaults to 262144.
  
  • **Binary outputs**: If selected, the vector outputs do not include the number of appearances of a term in a document, but rather are a binary indicator of its appearance. Defaults to `False`.

To learn more about this option, see the Spark documentation on [CountVectorizer](#).

• **Hashing** is computationally faster. **Hash vectorize parameters** includes the following:

  • **Number of features during hashing**: A hash vectorizer maps tokens to a vector index according to their hash value. This feature determines the number of possible hash values. Large values result in fewer collisions between hash values but a higher dimension output vector.

To learn more about this option, see the Spark documentation on [FeatureHasher](#).

• **IDF** applies an IDF transformation, which multiplies the term frequency with the standard inverse document frequency used for TF-IDF embedding. **IDF parameters** include the following:

  • **Minimum document frequency**: Minimum number of documents (rows) in which a term (token) must appear to be included. If `count_vectorize` is the chosen vectorizer, we recommend that you keep the default value and only modify the `min_doc_freq` field in **Count vectorize parameters**. Defaults to 5.

  • **Output format**: The output format of each row.

    • Select **Vector** to produce a single column with a sparse vector.

    • Select **Flattened** to create a column for every category with an indicator variable for whether the text in the original column contains a value that is equal to that category. You can only choose flattened when **Vectorizer** is set as **Count vectorizer**.

### Transform Time Series

In Data Wrangler, you can transform time series data. The values in a time series dataset are indexed to specific time. For example, a dataset that shows the number of customers in a store for each hour in a day is a time series dataset. The following table shows an example of a time series dataset.
Hourly number of customers in a store

<table>
<thead>
<tr>
<th>Number of customers</th>
<th>Time (hour)</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>09:00</td>
</tr>
<tr>
<td>10</td>
<td>10:00</td>
</tr>
<tr>
<td>14</td>
<td>11:00</td>
</tr>
<tr>
<td>25</td>
<td>12:00</td>
</tr>
<tr>
<td>20</td>
<td>13:00</td>
</tr>
<tr>
<td>18</td>
<td>14:00</td>
</tr>
</tbody>
</table>

For the preceding table, the Number of Customers column contains the time series data. The time series data is indexed on the hourly data in the Time (hour) column.

You might need to perform a series of transformations on your data to get it in a format that you can use for your analysis. Use the Time series transform group to transform your time series data. For more information about the transformations that you can perform, see the following sections.

Topics

- Group by a Time Series (p. 909)
- Resample Time Series Data (p. 910)
- Handle Missing Time Series Data (p. 912)
- Validate the Timestamp of Your Time Series Data (p. 913)
- Standardizing the Length of the Time Series (p. 914)
- Extract Features from Your Time Series Data (p. 915)
- Use Lagged Features from Your Time Series Data (p. 916)
- Create a Datetime Range In Your Time Series (p. 916)
- Use a Rolling Window In Your Time Series (p. 917)

Group by a Time Series

You can use the group by operation to group time series data for specific values in a column.

For example, you have the following table that tracks the average daily electricity usage in a household.

Average daily household electricity usage

<table>
<thead>
<tr>
<th>Household ID</th>
<th>Daily timestamp</th>
<th>Electricity usage (kWh)</th>
<th>Number of household occupants</th>
</tr>
</thead>
<tbody>
<tr>
<td>household_0</td>
<td>1/1/2020</td>
<td>30</td>
<td>2</td>
</tr>
<tr>
<td>household_0</td>
<td>1/2/2020</td>
<td>40</td>
<td>2</td>
</tr>
<tr>
<td>household_0</td>
<td>1/4/2020</td>
<td>35</td>
<td>3</td>
</tr>
<tr>
<td>household_1</td>
<td>1/2/2020</td>
<td>45</td>
<td>3</td>
</tr>
<tr>
<td>household_1</td>
<td>1/3/2020</td>
<td>55</td>
<td>4</td>
</tr>
</tbody>
</table>
If you choose to group by ID, you get the following table.

**Electricity usage grouped by household ID**

<table>
<thead>
<tr>
<th>Household ID</th>
<th>Electricity usage series (kWh)</th>
<th>Number of household occupants series</th>
</tr>
</thead>
<tbody>
<tr>
<td>household_0</td>
<td>[30, 40, 35]</td>
<td>[2, 2, 3]</td>
</tr>
<tr>
<td>household_1</td>
<td>[45, 55]</td>
<td>[3, 4]</td>
</tr>
</tbody>
</table>

Each entry in the time series sequence is ordered by the corresponding timestamp. The first element of the sequence corresponds to the first timestamp of the series. For household_0, 30 is the first value of the **Electricity Usage Series**. The value of 30 corresponds to the first timestamp of 1/1/2020.

You can include the starting timestamp and ending timestamp. The following table shows how that information appears.

**Electricity usage grouped by household ID**

<table>
<thead>
<tr>
<th>Household ID</th>
<th>Electricity usage series (kWh)</th>
<th>Number of household occupants series</th>
<th>Start_time</th>
<th>End_time</th>
</tr>
</thead>
<tbody>
<tr>
<td>household_0</td>
<td>[30, 40, 35]</td>
<td>[2, 2, 3]</td>
<td>1/1/2020</td>
<td>1/4/2020</td>
</tr>
<tr>
<td>household_1</td>
<td>[45, 55]</td>
<td>[3, 4]</td>
<td>1/2/2020</td>
<td>1/3/2020</td>
</tr>
</tbody>
</table>

You can use the following procedure to group by a time series column.

1. Open your Data Wrangler data flow.
2. If you haven't imported your dataset, import it under the Import data tab.
3. In your data flow, under Data types, choose the +, and select Add transform.
4. Choose **Add step**.
5. Choose **Time Series**.
6. Under Transform, choose **Group by**.
7. Specify a column in **Group by this column**.
8. For **Apply to columns**, specify a value.
9. Choose **Preview** to generate a preview of the transform.
10. Choose **Add** to add the transform to the Data Wrangler data flow.

**Resample Time Series Data**

Time series data usually has observations that aren't taken at regular intervals. For example, a dataset could have some observations that are recorded hourly and other observations that are recorded every two hours.

Many analyses, such as forecasting algorithms, require the observations to be taken at regular intervals. Resampling gives you the ability to establish regular intervals for the observations in your dataset.

You can either upsample or downsample a time series. Downsampling increases the interval between observations in the dataset. For example, if you downsample observations that are taken either every hour or every two hours, each observation in your dataset is taken every two hours. The hourly
observations are aggregated into a single value using an aggregation method such as the mean or median.

Upsampling reduces the interval between observations in the dataset. For example, if you upsample observations that are taken every two hours into hourly observations, you can use an interpolation method to infer hourly observations from the ones that have been taken every two hours. For information on interpolation methods, see pandas.DataFrame.interpolate.

You can resample both numeric and non-numeric data.

Use the Resample operation to resample your time series data. If you have multiple time series in your dataset, Data Wrangler standardizes the time interval for each time series.

The following table shows an example of downsampling time series data by using the mean as the aggregation method. The data is downsamped from every two hours to every hour.

### Hourly temperature readings over a day before downsampling

<table>
<thead>
<tr>
<th>Timestamp</th>
<th>Temperature (Celsius)</th>
</tr>
</thead>
<tbody>
<tr>
<td>12:00</td>
<td>30</td>
</tr>
<tr>
<td>1:00</td>
<td>32</td>
</tr>
<tr>
<td>2:00</td>
<td>35</td>
</tr>
<tr>
<td>3:00</td>
<td>32</td>
</tr>
<tr>
<td>4:00</td>
<td>30</td>
</tr>
</tbody>
</table>

### Temperature readings downsampled to every two hours

<table>
<thead>
<tr>
<th>Timestamp</th>
<th>Temperature (Celsius)</th>
</tr>
</thead>
<tbody>
<tr>
<td>12:00</td>
<td>30</td>
</tr>
<tr>
<td>2:00</td>
<td>33.5</td>
</tr>
<tr>
<td>2:00</td>
<td>35</td>
</tr>
<tr>
<td>4:00</td>
<td>32.5</td>
</tr>
</tbody>
</table>

You can use the following procedure to resample time series data.

1. Open your Data Wrangler data flow.
2. If you haven't imported your dataset, import it under the Import data tab.
3. In your data flow, under Data types, choose the +, and select Add transform.
5. Choose Resample.
6. For Timestamp, choose the timestamp column.
7. For Frequency unit, specify the frequency that you're resampling.
8. (Optional) Specify a value for Frequency quantity.
9. Configure the transform by specifying the remaining fields.
10. Choose Preview to generate a preview of the transform.
11. Choose Add to add the transform to the Data Wrangler data flow.
Handle Missing Time Series Data

If you have missing values in your dataset, you can do one of the following:

- For datasets that have multiple time series, drop the time series that have missing values that are greater than a threshold that you specify.
- Impute the missing values in a time series by using other values in the time series.

Imputing a missing value involves replacing the data by either specifying a value or by using an inferential method. The following are the methods that you can use for imputation:

- Constant value – Replace all the missing data in your dataset with a value that you specify.
- Most common value – Replace all the missing data with the value that has the highest frequency in the dataset.
- Forward fill – Use a forward fill to replace the missing values with the non-missing value that precedes the missing values. For the sequence: [2, 4, 7, NaN, NaN, NaN, 8], all of the missing values are replaced with 7. The sequence that results from using a forward fill is [2, 4, 7, 7, 7, 7, 8].
- Backward fill – Use a backward fill to replace the missing values with the non-missing value that follows the missing values. For the sequence: [2, 4, 7, NaN, NaN, NaN, 8], all of the missing values are replaced with 8. The sequence that results from using a backward fill is [2, 4, 7, 8, 8, 8, 8].
- Interpolate – Uses an interpolation function to impute the missing values. For more information on the functions that you can use for interpolation, see pandas.DataFrame.interpolate.

Some of the imputation methods might not be able to impute of all the missing value in your dataset. For example, a Forward fill can't impute a missing value that appears at the beginning of the time series. You can impute the values by using either a forward fill or a backward fill.

You can either impute missing values within a cell or within a column.

The following example shows how values are imputed within a cell.

**Electricity usage with missing values**

<table>
<thead>
<tr>
<th>Household ID</th>
<th>Electricity usage series (kWh)</th>
</tr>
</thead>
<tbody>
<tr>
<td>household_0</td>
<td>[30, 40, 35, NaN, NaN]</td>
</tr>
<tr>
<td>household_1</td>
<td>[45, NaN, 55]</td>
</tr>
</tbody>
</table>

**Electricity usage with values imputed using a forward fill**

<table>
<thead>
<tr>
<th>Household ID</th>
<th>Electricity usage series (kWh)</th>
</tr>
</thead>
<tbody>
<tr>
<td>household_0</td>
<td>[30, 40, 35, 35, 35]</td>
</tr>
<tr>
<td>household_1</td>
<td>[45, 45, 55]</td>
</tr>
</tbody>
</table>

The following example shows how values are imputed within a column.

**Average daily household electricity usage with missing values**

<table>
<thead>
<tr>
<th>Household ID</th>
<th>Electricity usage (kWh)</th>
</tr>
</thead>
<tbody>
<tr>
<td>household_0</td>
<td>30</td>
</tr>
</tbody>
</table>
Transform Data

### Average daily household electricity usage with values imputed using a forward fill

<table>
<thead>
<tr>
<th>Household ID</th>
<th>Electricity usage (kWh)</th>
</tr>
</thead>
<tbody>
<tr>
<td>household_0</td>
<td>30</td>
</tr>
<tr>
<td>household_0</td>
<td>40</td>
</tr>
<tr>
<td>household_0</td>
<td>40</td>
</tr>
<tr>
<td>household_1</td>
<td>40</td>
</tr>
<tr>
<td>household_1</td>
<td>40</td>
</tr>
</tbody>
</table>

You can use the following procedure to handle missing values.

1. Open your Data Wrangler data flow.
2. If you haven't imported your dataset, import it under the **Import data** tab.
3. In your data flow, under **Data types**, choose the +, and select **Add transform**.
4. Choose **Add step**.
5. Choose **Handle missing**.
6. For **Time series input type**, choose whether you want to handle missing values inside of a cell or along a column.
7. For **Impute missing values for this column**, specify the column that has the missing values.
8. For **Method for imputing values**, select a method.
9. Configure the transform by specifying the remaining fields.
10. Choose **Preview** to generate a preview of the transform.
11. If you have missing values, you can specify a method for imputing them under **Method for imputing values**.
12. Choose **Add** to add the transform to the Data Wrangler data flow.

### Validate the Timestamp of Your Time Series Data

You might have time stamp data that is invalid. You can use the **Validate time stamp** function to determine whether the timestamps in your dataset are valid. Your timestamp can be invalid for one or more of the following reasons:

- Your timestamp column has missing values.
- The values in your timestamp column are not formatted correctly.

If you have invalid timestamps in your dataset, you can't perform your analysis successfully. You can use Data Wrangler to identify invalid timestamps and understand where you need to clean your data.
The time series validation works in one of the two ways:

You can configure Data Wrangler to do one of the following if it encounters missing values in your dataset:

- Drop the rows that have the missing or invalid values.
- Identify the rows that have the missing or invalid values.
- Throw an error if it finds any missing or invalid values in your dataset.

You can validate the timestamps on columns that either have the timestamp type or the string type. If the column has the string type, Data Wrangler converts the type of the column to timestamp and performs the validation.

You can use the following procedure to validate the timestamps in your dataset.

1. Open your Data Wrangler data flow.
2. If you haven't imported your dataset, import it under the Import data tab.
3. In your data flow, under Data types, choose the +, and select Add transform.
5. Choose Validate timestamps.
6. For Timestamp Column, choose the timestamp column.
7. For Policy, choose whether you want to handle missing timestamps.
8. (Optional) For Output column, specify a name for the output column.
9. If the date time column is formatted for the string type, choose Cast to datetime.
10. Choose Preview to generate a preview of the transform.
11. Choose Add to add the transform to the Data Wrangler data flow.

Standardizing the Length of the Time Series

If you have time series data stored as arrays, you can standardize each time series to the same length. Standardizing the length of the time series array might make it easier for you to perform your analysis on the data.

You can standardize your time series for data transformations that require the length of your data to be fixed.

Many ML algorithms require you to flatten your time series data before you use them. Flattening time series data is separating each value of the time series into its own column in a dataset. The number of columns in a dataset can't change, so the lengths of the time series need to be standardized between you flatten each array into a set of features.

Each time series is set to the length that you specify as a quantile or percentile of the time series set. For example, you can have three sequences that have the following lengths:

- 3
- 4
- 5

You can set the length of all of the sequences as the length of the sequence that has the 50th percentile length.
Time series arrays that are shorter than the length you've specified have missing values added. The following is an example format of standardizing the time series to a longer length: [2, 4, 5, NaN, NaN, NaN].

You can use different approaches to handle the missing values. For information on those approaches, see Handle Missing Time Series Data (p. 912).

The time series arrays that are longer than the length that you specify are truncated.

You can use the following procedure to standardize the length of the time series.

1. Open your Data Wrangler data flow.
2. If you haven't imported your dataset, import it under the Import data tab.
3. In your data flow, under Data types, choose the +, and select Add transform.
5. Choose Standardize length.
6. For Standardize the time series length for the column, choose a column.
7. (Optional) For Output column, specify a name for the output column. If you don't specify a name, the transform is done in place.
8. If the datetime column is formatted for the string type, choose Cast to datetime.
9. Choose Cutoff quantile and specify a quantile to set the length of the sequence.
10. Choose Flatten the output to output the values of the time series into separate columns.
11. Choose Preview to generate a preview of the transform.
12. Choose Add to add the transform to the Data Wrangler data flow.

Extract Features from Your Time Series Data

If you're running a classification or a regression algorithm on your time series data, we recommend extracting features from the time series before running the algorithm. Extracting features might improve the performance of your algorithm.

Use the following options to choose how you want to extract features from your data:

- Use Minimal subset to specify extracting 8 features that you know are useful in downstream analyses. You can use a minimal subset when you need to perform computations quickly. You can also use it when your ML algorithm has a high risk of overfitting and you want to provide it with fewer features.
- Use Efficient subset to specify extracting the most features possible without extracting features that are computationally intensive in your analyses.
- Use All features to specify extracting all features from the time series.
- Use Manual subset to choose a list of features that you think explain the variation in your data well.

Use the following the procedure to extract features from your time series data.

1. Open your Data Wrangler data flow.
2. If you haven't imported your dataset, import it under the Import data tab.
3. In your data flow, under Data types, choose the +, and select Add transform.
5. Choose Extract features.
6. For Extract features for this column, choose a column.
7. (Optional) Select Flatten to output the features into separate columns.
8. For **Strategy**, choose a strategy to extract the features.
9. Choose **Preview** to generate a preview of the transform.
10. Choose **Add** to add the transform to the Data Wrangler data flow.

**Use Lagged Features from Your Time Series Data**

For many use cases, the best way to predict the future behavior of your time series is to use its most recent behavior.

The most common uses of lagged features are the following:

- Collecting a handful of past values. For example, for time, \( t + 1 \), you collect \( t, t - 1, t - 2, \) and \( t - 3 \).
- Collecting values that correspond to seasonal behavior in the data. For example, to predict the occupancy in a restaurant at 1:00 PM, you might want to use the features from 1:00 PM on the previous day. Using the features from 12:00 PM or 11:00 AM on the same day might not be as predictive as using the features from previous days.

1. Open your Data Wrangler data flow.
2. If you haven’t imported your dataset, import it under the **Import data** tab.
3. In your data flow, under **Data types**, choose the +, and select **Add transform**.
4. Choose **Add step**.
5. Choose **Lag features**.
6. For **Generate lag features for this column**, choose a column.
7. For **Timestamp Column**, choose the column containing the timestamps.
8. For **Lag**, specify the duration of the lag.
9. (Optional) Configure the output using one of the following options:
   - **Include the entire lag window**
   - **Flatten the output**
   - **Drop rows without history**
10. Choose **Preview** to generate a preview of the transform.
11. Choose **Add** to add the transform to the Data Wrangler data flow.

**Create a Datetime Range In Your Time Series**

You might have time series data that don’t have timestamps. If you know that the observations were taken at regular intervals, you can generate timestamps for the time series in a separate column. To generate timestamps, you specify the value for the start timestamp and the frequency of the timestamps.

For example, you might have the following time series data for the number of customers at a restaurant.

**Time series data on the number of customers at a restaurant**

<table>
<thead>
<tr>
<th>Number of customers</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
</tr>
<tr>
<td>14</td>
</tr>
<tr>
<td>24</td>
</tr>
</tbody>
</table>
If you know that the restaurant opened at 5:00 PM and that the observations are taken hourly, you can add a timestamp column that corresponds to the time series data. You can see the timestamp column in the following table.

<table>
<thead>
<tr>
<th>Number of customers</th>
<th>Timestamp</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>1:00 PM</td>
</tr>
<tr>
<td>14</td>
<td>2:00 PM</td>
</tr>
<tr>
<td>24</td>
<td>3:00 PM</td>
</tr>
<tr>
<td>40</td>
<td>4:00 PM</td>
</tr>
<tr>
<td>30</td>
<td>5:00 PM</td>
</tr>
<tr>
<td>20</td>
<td>6:00 PM</td>
</tr>
</tbody>
</table>

Use the following procedure to add a datetime range to your data.

1. Open your Data Wrangler data flow.
2. If you haven't imported your dataset, import it under the Import data tab.
3. In your data flow, under Data types, choose the +, and select Add transform.
5. Choose Datetime range.
6. For Frequency type, choose the unit used to measure the frequency of the timestamps.
7. For Starting timestamp, specify the start timestamp.
8. For Output column, specify a name for the output column.
9. (Optional) Configure the output using the remaining fields.
10. Choose Preview to generate a preview of the transform.
11. Choose Add to add the transform to the Data Wrangler data flow.

**Use a Rolling Window In Your Time Series**

You can extract features over a time period. For example, for time, $t$, and a time window length of 3, and for the row that indicates the $t$th timestamp, we append the features that are extracted from the time series at times $t - 3$, $t - 2$, and $t - 1$. For information on extracting features, see Extract Features from Your Time Series Data (p. 915).

You can use the following procedure to extract features over a time period.

1. Open your Data Wrangler data flow.
2. If you haven't imported your dataset, import it under the Import data tab.
3. In your data flow, under Data types, choose the +, and select Add transform.
5. Choose Rolling window features.
6. For Generate rolling window features for this column, choose a column.
7. For Timestamp Column, choose the column containing the timestamps.
8. (Optional) For Output Column, specify the name of the output column.
9. For Window size, specify the window size.
10. For Strategy, choose the extraction strategy.
11. Choose Preview to generate a preview of the transform.
12. Choose Add to add the transform to the Data Wrangler data flow.

Featurize Datetime

Use Featurize date/time to create a vector embedding representing a datetime field. To use this transform, your datetime data must be in one of the following formats:

- Strings describing datetime: For example, "January 1st, 2020, 12:44pm".
- A Unix timestamp: A Unix timestamp describes the number of seconds, milliseconds, microseconds, or nanoseconds from 1/1/1970.

You can choose to Infer datetime format and provide a Datetime format. If you provide a datetime format, you must use the codes described in the Python documentation. The options you select for these two configurations have implications for the speed of the operation and the final results.

- The most manual and computationally fastest option is to specify a Datetime format and select No for Infer datetime format.
- To reduce manual labor, you can choose Infer datetime format and not specify a datetime format. It is also a computationally fast operation; however, the first datetime format encountered in the input column is assumed to be the format for the entire column. If there are other formats in the column, these values are NaN in the final output. Inferring the datetime format can give you unparsed strings.
- If you don't specify a format and select No for Infer datetime format, you get the most robust results. All the valid datetime strings are parsed. However, this operation can be an order of magnitude slower than the first two options in this list.

When you use this transform, you specify an Input column which contains datetime data in one of the formats listed above. The transform creates an output column named Output column name. The format of the output column depends on your configuration using the following:

- Vector: Outputs a single column as a vector.
- Columns: Creates a new column for every feature. For example, if the output contains a year, month, and day, three separate columns are created for year, month, and day.

Additionally, you must choose an Embedding mode. For linear models and deep networks, we recommend choosing cyclic. For tree-based algorithms, we recommend choosing ordinal.

Format String

The Format string transforms contain standard string formatting operations. For example, you can use these operations to remove special characters, normalize string lengths, and update string casing.
This feature group contains the following transforms. All transforms return copies of the strings in the **Input column** and add the result to a new, output column.

<table>
<thead>
<tr>
<th>Name</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Left pad</td>
<td>Left-pad the string with a given Fill character to the given width. If the string is longer than width, the return value is shortened to width characters.</td>
</tr>
<tr>
<td>Right pad</td>
<td>Right-pad the string with a given Fill character to the given width. If the string is longer than width, the return value is shortened to width characters.</td>
</tr>
<tr>
<td>Center (pad on either side)</td>
<td>Center-pad the string (add padding on both sides of the string) with a given Fill character to the given width. If the string is longer than width, the return value is shortened to width characters.</td>
</tr>
<tr>
<td>Prepend zeros</td>
<td>Left-fill a numeric string with zeros, up to a given width. If the string is longer than width, the return value is shortened to width characters.</td>
</tr>
<tr>
<td>Strip left and right</td>
<td>Returns a copy of the string with the leading and trailing characters removed.</td>
</tr>
<tr>
<td>Strip characters from left</td>
<td>Returns a copy of the string with leading characters removed.</td>
</tr>
<tr>
<td>Strip characters from right</td>
<td>Returns a copy of the string with trailing characters removed.</td>
</tr>
<tr>
<td>Lower case</td>
<td>Convert all letters in text to lowercase.</td>
</tr>
<tr>
<td>Upper case</td>
<td>Convert all letters in text to uppercase.</td>
</tr>
<tr>
<td>Capitalize</td>
<td>Capitalize the first letter in each sentence.</td>
</tr>
<tr>
<td>Swap case</td>
<td>Converts all uppercase characters to lowercase and all lowercase characters to uppercase characters of the given string, and returns it.</td>
</tr>
<tr>
<td>Add prefix or suffix</td>
<td>Adds a prefix and a suffix the string column. You must specify at least one of Prefix and Suffix.</td>
</tr>
<tr>
<td>Remove symbols</td>
<td>Removes given symbols from a string. All listed characters are removed. Defaults to white space.</td>
</tr>
</tbody>
</table>

### Handle Outliers

Machine learning models are sensitive to the distribution and range of your feature values. Outliers, or rare values, can negatively impact model accuracy and lead to longer training times. Use this feature group to detect and update outliers in your dataset.

When you define a Handle outliers transform step, the statistics used to detect outliers are generated on the data available in Data Wrangler when defining this step. These same statistics are used when running a Data Wrangler job.

Use the following sections to learn more about the transforms this group contains. You specify an **Output name** and each of these transforms produces an output column with the resulting data.
Robust standard deviation numeric outliers

This transform detects and fixes outliers in numeric features using statistics that are robust to outliers.

You must define an Upper quantile and a Lower quantile for the statistics used to calculate outliers. You must also specify the number of Standard deviations from which a value must vary from the mean to be considered an outlier. For example, if you specify 3 for Standard deviations, a value must fall more than 3 standard deviations from the mean to be considered an outlier.

The Fix method is the method used to handle outliers when they are detected. You can choose from the following:

- **Clip**: Use this option to clip the outliers to the corresponding outlier detection bound.
- **Remove**: Use this option to remove rows with outliers from the dataframe.
- **Invalidate**: Use this option to replace outliers with invalid values.

Standard Deviation Numeric Outliers

This transform detects and fixes outliers in numeric features using the mean and standard deviation.

You specify the number of Standard deviations a value must vary from the mean to be considered an outlier. For example, if you specify 3 for Standard deviations, a value must fall more than 3 standard deviations from the mean to be considered an outlier.

The Fix method is the method used to handle outliers when they are detected. You can choose from the following:

- **Clip**: Use this option to clip the outliers to the corresponding outlier detection bound.
- **Remove**: Use this option to remove rows with outliers from the dataframe.
- **Invalidate**: Use this option to replace outliers with invalid values.

Quantile Numeric Outliers

Use this transform to detect and fix outliers in numeric features using quantiles. You can define an Upper quantile and a Lower quantile. All values that fall above the upper quantile or below the lower quantile are considered outliers.

The Fix method is the method used to handle outliers when they are detected. You can choose from the following:

- **Clip**: Use this option to clip the outliers to the corresponding outlier detection bound.
- **Remove**: Use this option to remove rows with outliers from the dataframe.
- **Invalidate**: Use this option to replace outliers with invalid values.

Min-Max Numeric Outliers

This transform detects and fixes outliers in numeric features using upper and lower thresholds. Use this method if you know threshold values that demark outliers.

You specify a Upper threshold and a Lower threshold, and if values fall above or below those thresholds respectively, they are considered outliers.

The Fix method is the method used to handle outliers when they are detected. You can choose from the following:
Transform Data

- **Clip**: Use this option to clip the outliers to the corresponding outlier detection bound.
- **Remove**: Use this option to remove rows with outliers from the dataframe.
- **Invalidate**: Use this option to replace outliers with invalid values.

**Replace Rare**

When you use the **Replace rare** transform, you specify a threshold and Data Wrangler finds all values that meet that threshold and replaces them with a string that you specify. For example, you may want to use this transform to categorize all outliers in a column into an "Others" category.

- **Replacement string**: The string with which to replace outliers.
- **Absolute threshold**: A category is rare if the number of instances is less than or equal to this absolute threshold.
- **Fraction threshold**: A category is rare if the number of instances is less than or equal to this fraction threshold multiplied by the number of rows.
- **Max common categories**: Maximum not-rare categories that remain after the operation. If the threshold does not filter enough categories, those with the top number of appearances are classified as not rare. If set to 0 (default), there is no hard limit to the number of categories.

**Handle Missing Values**

Missing values are a common occurrence in machine learning datasets. In some situations, it is appropriate to impute missing data with a calculated value, such as an average or categorically common value. You can process missing values using the **Handle missing values** transform group. This group contains the following transforms.

**Fill Missing**

Use the **Fill missing** transform to replace missing values with a **Fill value** you define.

**Impute Missing**

Use the **Impute missing** transform to create a new column that contains imputed values where missing values were found in input categorical and numerical data. The configuration depends on your data type.

For numeric data, choose an imputing strategy, the strategy used to determine the new value to impute. You can choose to impute the mean or the median over the values that are present in your dataset. Data Wrangler uses the value that it computes to impute the missing values.

For categorical data, Data Wrangler imputes missing values using the most frequent value in the column. To impute a custom string, use the **Fill missing** transform instead.

**Add Indicator for Missing**

Use the **Add indicator for missing** transform to create a new indicator column, which contains a Boolean "false" if a row contains a value, and "true" if a row contains a missing value.

**Drop Missing**

Use the **Drop missing** option to drop rows that contain missing values from the **Input column**.

**Manage Columns**

You can use the following transforms to quickly update and manage columns in your dataset:
Transform Data

<table>
<thead>
<tr>
<th>Name</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Drop Column</td>
<td>Delete a column.</td>
</tr>
<tr>
<td>Duplicate Column</td>
<td>Duplicate a column.</td>
</tr>
<tr>
<td>Rename Column</td>
<td>Rename a column.</td>
</tr>
<tr>
<td>Move Column</td>
<td>Move a column's location in the dataset. Choose to move your column to the start or end of the dataset, before or after a reference column, or to a specific index.</td>
</tr>
</tbody>
</table>

**Manage Rows**

Use this transform group to quickly perform sort and shuffle operations on rows. This group contains the following:

- **Sort**: Sort the entire dataframe by a given column. Select the check box next to *Ascending order* for this option; otherwise, deselect the check box and descending order is used for the sort.
- **Shuffle**: Randomly shuffle all rows in the dataset.

**Manage Vectors**

Use this transform group to combine or flatten vector columns. This group contains the following transforms.

- **Assemble**: Use this transform to combine Spark vectors and numeric data into a single column. For example, you can combine three columns: two containing numeric data and one containing vectors. Add all the columns you want to combine in *Input columns* and specify a *Output column name* for the combined data.
- **Flatten**: Use this transform to flatten a single column containing vector data. The input column must contain PySpark vectors or array-like objects. You can control the number of columns created by specifying a *Method to detect number of outputs*. For example, if you select *Length of first vector*, the number of elements in the first valid vector or array found in the column determines the number of output columns that are created. All other input vectors with too many items are truncated. Inputs with too few items are filled with NaNs.
  
  You also specify an *Output prefix*, which is used as the prefix for each output column.

**Process Numeric**

Use the **Process Numeric** feature group to process numeric data. Each scalar in this group is defined using the Spark library. The following scalars are supported:

- **Standard Scaler**: Standardize the input column by subtracting the mean from each value and scaling to unit variance. To learn more, see the Spark documentation for `StandardScaler`.
- **Robust Scaler**: Scale the input column using statistics that are robust to outliers. To learn more, see the Spark documentation for `RobustScaler`.
- **Min Max Scaler**: Transform the input column by scaling each feature to a given range. To learn more, see the Spark documentation for `MinMaxScaler`.
- **Max Absolute Scaler**: Scale the input column by dividing each value by the maximum absolute value. To learn more, see the Spark documentation for `MaxAbsScaler`.
Sampling

After you've imported your data, you can use the Sampling transformer to take one or more samples of it. When you use the sampling transformer, Data Wrangler samples your original dataset.

You can choose one of the following sample methods:

- **Limit**: Samples the dataset starting from the first row up to the limit that you specify.
- **Randomized**: Takes a random sample of a size that you specify.
- **Stratified**: Takes a stratified random sample.

You can stratify a randomized sample to make sure that it represents the original distribution of the dataset.

You might be performing data preparation for multiple use cases. For each use case, you can take a different sample and apply a different set of transformations.

The following procedure describes the process of creating a random sample.

To take a random sample from your data.

1. Choose the + to the right of the dataset that you've imported. The name of your dataset is located below the +.
2. Choose Add transform.
3. Choose Sampling.
4. For Sampling method, choose the sampling method.
5. For Approximate sample size, choose the approximate number of observations that you want in your sample.
6. (Optional) Specify an integer for Random seed to create a reproducible sample.

The following procedure describes the process of creating a stratified sample.

To take a stratified sample from your data.

1. Choose the + to the right of the dataset that you've imported. The name of your dataset is located below the +.
2. Choose Add transform.
3. Choose Sampling.
4. For Sampling method, choose the sampling method.
5. For Approximate sample size, choose the approximate number of observations that you want in your sample.
6. For Stratify column, specify the name of the column that you want to stratify on.
7. (Optional) Specify an integer for Random seed to create a reproducible sample.

Search and Edit

Use this section to search for and edit specific patterns within strings. For example, you can find and update strings within sentences or documents, split strings by delimiters, and find occurrences of specific strings.

The following transforms are supported under Search and edit. All transforms return copies of the strings in the Input column and add the result to a new output column.
<table>
<thead>
<tr>
<th>Name</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Find substring</td>
<td>Returns the index of the first occurrence of the <strong>Substring</strong> for which you searched <strong>Substring</strong> for which you searched. You can start and end the search at <strong>Start</strong> and <strong>End</strong> respectively.</td>
</tr>
<tr>
<td>Find substring (from right)</td>
<td>Returns the index of the last occurrence of the <strong>Substring</strong> for which you searched. You can start and end the search at <strong>Start</strong> and <strong>End</strong> respectively.</td>
</tr>
<tr>
<td>Matches prefix</td>
<td>Returns a Boolean value if the string contains a given <strong>Pattern</strong>. A pattern can be a character sequence or regular expression. Optionally, you can make the pattern case sensitive.</td>
</tr>
<tr>
<td>Find all occurrences</td>
<td>Returns an array with all occurrences of a given pattern. A pattern can be a character sequence or regular expression.</td>
</tr>
<tr>
<td>Extract using regex</td>
<td>Returns a string that matches a given Regex pattern.</td>
</tr>
<tr>
<td>Extract between delimiters</td>
<td>Returns a string with all characters found between <strong>Left delimiter</strong> and <strong>Right delimiter</strong>.</td>
</tr>
<tr>
<td>Extract from position</td>
<td>Returns a string, starting from <strong>Start position</strong> in the input string, that contains all characters up to the start position plus <strong>Length</strong>.</td>
</tr>
<tr>
<td>Find and replace substring</td>
<td>Returns a string with all matches of a given <strong>Pattern</strong> (regular expression) replaced by <strong>Replacement string</strong>.</td>
</tr>
<tr>
<td>Replace between delimiters</td>
<td>Returns a string with the substring found between the first appearance of a <strong>Left delimiter</strong> and the last appearance of a <strong>Right delimiter</strong> replaced by <strong>Replacement string</strong>. If no match is found, nothing is replaced.</td>
</tr>
<tr>
<td>Replace from position</td>
<td>Returns a string with the substring between <strong>Start position</strong> and <strong>Start position</strong> plus <strong>Length</strong> replaced by <strong>Replacement string</strong>. If <strong>Start position</strong> plus <strong>Length</strong> is greater than the length of the replacement string, the output contains <strong>....</strong>.</td>
</tr>
<tr>
<td>Convert regex to missing</td>
<td>Converts a string to None if invalid and returns the result. Validity is defined with a regular expression in <strong>Pattern</strong>.</td>
</tr>
<tr>
<td>Split string by delimiter</td>
<td>Returns an array of strings from the input string, split by <strong>Delimiter</strong>, with up to <strong>Max number of splits</strong> (optional). The delimiter defaults to white space.</td>
</tr>
</tbody>
</table>

**Split data**

Use the **Split data** transform to split your dataset into two or three datasets. For example, you can split your dataset into a dataset used to train your model and a dataset used to test it. You can determine the
proportion of the dataset that goes into each split. For example, if you’re splitting one dataset into two
datasets, the training dataset can have 80% of the data while the testing dataset has 20%.

Splitting your data into three datasets gives you the ability to create training, validation, and test
datasets. You can see how well the model performs on the test dataset by dropping the target column.

Your use case determines how much of the original dataset each of your datasets get and the method
you use to split the data. For example, you might want to use a stratified split to make sure that the
distribution of the observations in the target column are the same across datasets. You can use the
following split transforms:

- Randomized split — Each split is a random, non-overlapping sample of the original dataset. For larger
datasets, using a randomized split might be computationally expensive and take longer than an
ordered split.

- Ordered split – Splits the dataset based on the sequential order of the observations. For example, for
an 80/20 train-test split, the first observations that make up 80% of the dataset go to the training
data set. The last 20% of the observations go to the testing dataset. Ordered splits are effective in
keeping the existing order of the data between splits.

- Stratified split – Splits the dataset to make sure that the number of observations in the input column
have proportional representation. For an input column that has the observations 1, 1, 1, 1, 1, 2, 2, 2,
2, 2, 2, 2, 3, 3, 3, 3, 3, 3, 3, 3, 3, 3, 3, 3, an 80/20 split on the column would mean that approximately 80% of the
1s, 80% of the 2s, and 80% of the 3s go to the training set. About 20% of each type of observation go
to the testing set.

- Split by key – Avoids data with the same key occurring in more than one split. For example, if you have
a dataset with the column ‘customer_id’ and you’re using it as a key, no customer id is in more than
one split.

After you split the data, you can apply additional transformations to each dataset. For most use cases,
they aren’t necessary.

Data Wrangler calculates the proportions of the splits for performance. You can choose an error
threshold to set the accuracy of the splits. Lower error thresholds more accurately reflect the proportions
that you specify for the splits. If you set a higher error threshold, you get better performance, but lower
accuracy.

For perfectly split data, set the error threshold to 0. You can specify a threshold between 0 and 1 for
better performance. If you specify a value greater than 1, Data Wrangler interprets that value as 1.

If you have 10000 rows in your dataset and you specify an 80/20 split with an error of 0.001, you would
get observations approximating one of the following results:

- 8010 observations in the training set and 1990 in the testing set
- 7990 observations in the training set and 2010 in the testing set

The number of observations for the testing set in the preceding example is in the interval between 8010
and 7990.

By default, Data Wrangler uses a random seed to make the splits reproducible. You can specify a
different value for the seed to create a different reproducible split.

Randomized split

Use the following procedure to perform a randomized split on your dataset.

To split your dataset randomly, do the following

1. Choose the + next to the node containing the dataset that you’re splitting.
2. Choose **Add transform**.
3. Choose **Split data**.
4. (Optional) For **Splits**, specify the names and proportions of each split. The proportions must sum to 1.
5. (Optional) Choose the + to create an additional split.
   - Specify the names and proportions of all the splits. The proportions must sum to 1.
6. (Optional) Specify a value for **Error threshold** other than the default value.
7. (Optional) Specify a value for **Random seed**.
8. Choose **Preview**.
9. Choose **Add**.

**Ordered split**

Use the following procedure to perform an ordered split on your dataset.

To make an ordered split in your dataset, do the following.

1. Choose the + next to the node containing the dataset that you're splitting.
2. Choose **Add transform**.
3. For **Transform**, choose **Ordered split**.
4. Choose **Split data**.
5. (Optional) For **Splits**, specify the names and proportions of each split. The proportions must sum to 1.
6. (Optional) Choose the + to create an additional split.
   - Specify the names and proportions of all the splits. The proportions must sum to 1.
7. (Optional) Specify a value for **Error threshold** other than the default value.
8. (Optional) For **Input column**, specify a column with numeric values. Uses the values of the columns to infer which records are in each split. The smaller values are in one split with the larger values in the other splits.
9. (Optional) Select **Handle duplicates** to add noise to duplicate values and create a dataset of entirely unique values.
10. (Optional) Specify a value for **Random seed**.
11. Choose **Preview**.
12. Choose **Add**.

**Stratified split**

Use the following procedure to perform a stratified split on your dataset.

To make a stratified split in your dataset, do the following.

1. Choose the + next to the node containing the dataset that you're splitting.
2. Choose **Add transform**.
3. Choose **Split data**.
4. For **Transform**, choose **Stratified split**.
5. (Optional) For **Splits**, specify the names and proportions of each split. The proportions must sum to 1.
6. (Optional) Choose the + to create an additional split.
   - Specify the names and proportions of all the splits. The proportions must sum to 1.
7. For **Input column**, specify a column with up to 100 unique values. Data Wrangler can’t stratify a column with more than 100 unique values.
8. (Optional) Specify a value for **Error threshold** other than the default value.
9. (Optional) Specify a value for **Random seed** to specify a different seed.
10. Choose **Preview**.
11. Choose **Add**.

**Split by column keys**

Use the following procedure to split by the column keys in your dataset.

To split by the column keys in your dataset, do the following.

1. Choose the + next to the node containing the dataset that you're splitting.
2. Choose **Add transform**.
3. Choose **Split data**.
4. For **Transform**, choose **Split by key**.
5. (Optional) For **Splits**, specify the names and proportions of each split. The proportions must sum to 1.
6. (Optional) Choose the + to create an additional split.
   - Specify the names and proportions of all the splits. The proportions must sum to 1.
7. For **Key columns**, specify the columns with values that you don't want to appear in both datasets.
8. (Optional) Specify a value for **Error threshold** other than the default value.
9. Choose **Preview**.
10. Choose **Add**.

**Parse Value as Type**

Use this transform to cast a column to a new type. The supported Data Wrangler data types are:

- Long
- Float
- Boolean
- Date, in the format dd-MM-yyyy, representing day, month, and year respectively.
- String

**Validate String**

Use the **Validate string** transforms to create a new column that indicates that a row of text data meets a specified condition. For example, you can use a **Validate string** transform to verify that a string only contains lowercase characters. The following transforms are supported under **Validate string**.

The following transforms are included in this transform group. If a transform outputs a Boolean value, **True** is represented with a 1 and **False** is represented with a 0.
<table>
<thead>
<tr>
<th>Name</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>String length</td>
<td>Returns True if a string length equals specified length. Otherwise, returns False.</td>
</tr>
<tr>
<td>Starts with</td>
<td>Returns True if a string starts will a specified prefix. Otherwise, returns False.</td>
</tr>
<tr>
<td>Ends with</td>
<td>Returns True if a string length equals specified length. Otherwise, returns False.</td>
</tr>
<tr>
<td>Is alphanumeric</td>
<td>Returns True if a string only contains numbers and letters. Otherwise, returns False.</td>
</tr>
<tr>
<td>Is alpha (letters)</td>
<td>Returns True if a string only contains letters. Otherwise, returns False.</td>
</tr>
<tr>
<td>Is digit</td>
<td>Returns True if a string only contains digits. Otherwise, returns False.</td>
</tr>
<tr>
<td>Is space</td>
<td>Returns True if a string only contains numbers and letters. Otherwise, returns False.</td>
</tr>
<tr>
<td>Is title</td>
<td>Returns True if a string contains any white spaces. Otherwise, returns False.</td>
</tr>
<tr>
<td>Is lowercase</td>
<td>Returns True if a string only contains lower case letters. Otherwise, returns False.</td>
</tr>
<tr>
<td>Is uppercase</td>
<td>Returns True if a string only contains upper case letters. Otherwise, returns False.</td>
</tr>
<tr>
<td>Is numeric</td>
<td>Returns True if a string only contains numbers. Otherwise, returns False.</td>
</tr>
<tr>
<td>Is decimal</td>
<td>Returns True if a string only contains decimal numbers. Otherwise, returns False.</td>
</tr>
</tbody>
</table>

**Unnest JSON Data**

If you have a .csv file, you might have values in your dataset that are JSON strings. Similarly, you might have nested data in columns of either a Parquet file or a JSON document.

Use the **Flatten structured** operator to separate the first level keys into separate columns. A first level key is a key that isn't nested within a value.

For example, you might have a dataset that has a `person` column with demographic information on each person stored as JSON strings. A JSON string might look like the following.

```
{"seq": 1,"name": {"first": "Nathaniel","last": "Ferguson"},"age": 59,"city": "Posbotno","state": "WV"}
```

The **Flatten structured** operator converts the following first level keys into additional columns in your dataset:

- `seq`
• name
• age
• city
• state

Data Wrangler puts the values of the keys as values under the columns. The following shows the column names and values of the JSON.

<table>
<thead>
<tr>
<th>seq</th>
<th>name</th>
<th>age</th>
<th>city</th>
<th>state</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>{&quot;first&quot;: &quot;Nathaniel&quot;,&quot;last&quot;: &quot;Ferguson&quot;}, 59, Posbotno, WV</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

For each value in your dataset containing JSON, the Flatten structured operator creates columns for the first-level keys. To create columns for nested keys, call the operator again. For the preceding example, calling the operator creates the columns:

• name_first
• name_last

The following example shows the dataset that results from calling the operation again.

<table>
<thead>
<tr>
<th>seq</th>
<th>name</th>
<th>age</th>
<th>city</th>
<th>state</th>
<th>name_first</th>
<th>name_last</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>{&quot;first&quot;: &quot;Nathaniel&quot;,&quot;last&quot;: &quot;Ferguson&quot;}, 59, Posbotno, WV, Nathaniel, Ferguson</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Choose Keys to flatten on to specify the first-level keys that want to extract as separate columns. If you don't specify any keys, Data Wrangler extracts all the keys by default.

**Explode Array**

Use Explode array to expand the values of the array into separate output rows. For example, the operation can take each value in the array, [[1, 2, 3], [4, 5, 6], [7, 8, 9]] and create a new column with the following rows:

[1, 2, 3]
[4, 5, 6]
[7, 8, 9]

Data Wrangler names the new column, input_column_name_flatten.

You can call the Explode array operation multiple times to get the nested values of the array into separate output columns. The following example shows the result of calling the operation multiple times on a dataset with a nested array.

**Putting the values of a nested array into separate columns**

<table>
<thead>
<tr>
<th>id</th>
<th>array</th>
<th>id</th>
<th>array_items</th>
<th>id</th>
<th>array_items_items</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>[[cat, dog], [bat, frog]]</td>
<td>1</td>
<td>[cat, dog]</td>
<td>1</td>
<td>cat</td>
</tr>
</tbody>
</table>
Analyze and Visualize

Amazon SageMaker Data Wrangler includes built-in analyses that help you generate visualizations and data analyses in a few clicks. You can also create custom analyses using your own code.

You add an analysis to a dataframe by selecting a step in your data flow, and then choosing Add analysis. To access an analysis you’ve created, select the step that contains the analysis, and select the analysis.

All analyses are generated using 100,000 rows of your dataset.

You can add the following analysis to a dataframe:

- Data visualizations, including histograms and scatter plots.
- A quick summary of your dataset, including number of entries, minimum and maximum values (for numeric data), and most and least frequent categories (for categorical data).
- A quick model of the dataset, which can be used to generate an importance score for each feature.
- A target leakage report, which you can use to determine if one or more features are strongly correlated with your target feature.
- A custom visualization using your own code.

Use the following sections to learn more about these options.

Histogram

Use histograms to see the counts of feature values for a specific feature. You can inspect the relationships between features using the Color by option. For example, the following histogram charts the distribution of user ratings of the best-selling books on Amazon from 2009–2019, colored by genre.
You can use the **Facet by** feature to create histograms of one column, for each value in another column. For example, the following diagram shows histograms of user reviews of best-selling books on Amazon if faceted by year.

### Scatter Plot

Use the **Scatter Plot** feature to inspect the relationship between features. To create a scatter plot, select a feature to plot on the **X axis** and the **Y axis**. Both of these columns must be numeric typed columns.

You can color scatter plots by an additional column. For example, the following example shows a scatter plot comparing the number of reviews against user ratings of top-selling books on Amazon between 2009 and 2019. The scatter plot is colored by book genre.
Additionally, you can facet scatter plots by features. For example, the following image shows an example of the same review versus user rating scatter plot, faceted by year.

Table Summary

Use the Table Summary analysis to quickly summarize your data.

For columns with numerical data, including log and float data, a table summary reports the number of entries (count), minimum (min), maximum (max), mean, and standard deviation (stddev) for each column.

For columns with non-numerical data, including columns with string, Boolean, or date/time data, a table summary reports the number of entries (count), least frequent value (min), and most frequent value (max).
Quick Model

Use the Quick Model visualization to quickly evaluate your data and produce importance scores for each feature. A feature importance score indicates how useful a feature is at predicting a target label. The feature importance score is between \([0, 1]\) and a higher number indicates that the feature is more important to the whole dataset. On the top of the quick model chart, there is a model score. A classification problem shows an F1 score. A regression problem has a mean squared error (MSE) score.

When you create a quick model chart, you select a dataset you want evaluated, and a target label against which you want feature importance to be compared. Data Wrangler does the following:

- Infers the data types for the target label and each feature in the dataset selected.
- Determines the problem type. Based on the number of distinct values in the label column, Data Wrangler determines if this is a regression or classification problem type. Data Wrangler sets a categorical threshold to 100. If there are more than 100 distinct values in the label column, Data Wrangler classifies it as a regression problem; otherwise, it is classified as a classification problem.
- Pre-processes features and label data for training. The algorithm used requires encoding features to vector type and encoding labels to double type.
- Trains a random forest algorithm with 70% of data. Spark’s RandomForestRegressor is used to train a model for regression problems. The RandomForestClassifier is used to train a model for classification problems.
- Evaluates a random forest model with the remaining 30% of data. Data Wrangler evaluates classification models using an F1 score and evaluates regression models using an MSE score.
- Calculates feature importance for each feature using the Gini importance method.

The following image shows the user interface for the quick model feature.

Target Leakage

Target leakage occurs when there is data in a machine learning training dataset that is strongly correlated with the target label, but is not available in real-world data. For example, you may have a column in your dataset that serves as a proxy for the column you want to predict with your model.

When you use the Target Leakage analysis, you specify the following:

- **Target**: This is the feature about which you want your ML model to be able to make predictions.
• **Problem type**: This is the ML problem type on which you are working. Problem type can either be *classification* or *regression*.

• *(Optional) Max features*: This is the maximum number of features to present in the visualization, which shows features ranked by their risk of being target leakage.

For classification, the target leakage analysis uses the area under the receiver operating characteristic, or AUC - ROC curve for each column, up to *Max features*. For regression, it uses a coefficient of determination, or R2 metric.

The AUC - ROC curve provides a predictive metric, computed individually for each column using cross-validation, on a sample of up to around 1000 rows. A score of 1 indicates perfect predictive abilities, which often indicates target leakage. A score of 0.5 or lower indicates that the information on the column could not provide, on its own, any useful information towards predicting the target. Although it can happen that a column is uninformative on its own but is useful in predicting the target when used in tandem with other features, a low score could indicate the feature is redundant.

For example, the following image shows a target leakage report for a diabetes classification problem, that is, predicting if a person has diabetes or not. An AUC - ROC curve is used to calculate the predictive ability of five features, and all are determined to be safe from target leakage.

**Multicollinearity**

Multicollinearity is a circumstance where two or more predictor variables are related to each other. The predictor variables are the features in your dataset that you’re using to predict a target variable. When you have multicollinearity, the predictor variables are not only predictive of the target variable, but also predictive of each other.

You can use the **Variance Inflation Factor (VIF)**, **Principal Component Analysis (PCA)**, or **Lasso feature selection** as measures for the multicollinearity in your data. For more information, see the following.

**Variance Inflation Factor (VIF)**

The Variance Inflation Factor (VIF) is a measure of collinearity among variable pairs. Data Wrangler returns a VIF score as a measure of how closely the variables are related to each other. A VIF score is a positive number that is greater than or equal to 1.

A score of 1 means that the variable is uncorrelated with the other variables. Scores greater than 1 indicate higher correlation.
Theoretically, you can have a VIF score with a value of infinity. Data Wrangler clips high scores to 50. If you have a VIF score greater than 50, Data Wrangler sets the score to 50.

You can use the following guidelines to interpret your VIF scores:

- A VIF score less than or equal to 5 indicates that the variables are moderately correlated with the other variables.
- A VIF score greater than or equal to 5 indicates that the variables are highly correlated with the other variables.

**Principle Component Analysis (PCA)**

Principal Component Analysis (PCA) measures the variance of the data along different directions in the feature space. The feature space consists of all the predictor variables that you use to predict the target variable in your dataset.

For example, if you're trying to predict who survived on the *RMS Titanic* after it hit an iceberg, your feature space can include the passengers' age, gender, and the fare that they paid.

From the feature space, PCA generates an ordered list of variances. These variances are also known as singular values. The values in the list of variances are greater than or equal to 0. We can use them to determine how much multicollinearity there is in our data.

When the numbers are roughly uniform, the data has very few instances of multicollinearity. When there is a lot of variability among the values, we have many instances of multicollinearity. Before it performs PCA, Data Wrangler normalizes each feature to have a mean of 0 and a standard deviation of 1.

*Note*

PCA in this circumstance can also be referred to as Singular Value Decomposition (SVD).

**Lasso feature selection**

Lasso feature selection uses the L1 regularization technique to only include the most predictive features in your dataset.

For both classification and regression, the regularization technique generates a coefficient for each feature. The absolute value of the coefficient provides an importance score for the feature. A higher importance score indicates that it is more predictive of the target variable. A common feature selection method is to use all the features that have a non-zero lasso coefficient.

**Detect Anomalies In Time Series Data**

You can use the anomaly detection visualization to see outliers in your time series data. To understand what determines an anomaly, you need to understand that we decompose the time series into a predicted term and an error term. We treat the seasonality and trend of the time series as the predicted term. We treat the residuals as the error term.

For the error term, you specify a threshold as the number of standard of deviations the residual can be away from the mean for it to be considered an anomaly. For example, you can specify a threshold as being 3 standard deviations. Any residual greater than 3 standard deviations away from the mean is an anomaly.

You can use the following procedure to perform an **Anomaly detection** analysis.

1. Open your Data Wrangler data flow.
2. In your data flow, under **Data types**, choose the +, and select **Add analysis**.
3. For **Analysis type**, choose **Time Series**.
4. For **Visualization**, choose **Anomaly detection**.
5. For **Anomaly threshold**, choose the threshold that a value is considered an anomaly.
6. Choose **Preview** to generate a preview of the analysis.
7. Choose **Add** to add the transform to the Data Wrangler data flow.

### Seasonal Trend Decomposition In Time Series Data

You can determine whether there's seasonality in your time series data by using the Seasonal Trend Decomposition visualization. We use the STL (Seasonal Trend decomposition using LOESS) method to perform the decomposition. We decompose the time series into its seasonal, trend, and residual components. The trend reflects the long term progression of the series. The seasonal component is a signal that recurs in a time period. After removing the trend and the seasonal components from the time series, you have the residual.

You can use the following procedure to perform a **Seasonal-Trend decomposition** analysis.

1. Open your Data Wrangler data flow.
2. In your data flow, under **Data types**, choose the +, and select **Add analysis**.
3. For **Analysis type**, choose **Time Series**.
4. For **Visualization**, choose **Seasonal-Trend decomposition**.
5. For **Anomaly threshold**, choose the threshold that a value is considered an anomaly.
6. Choose **Preview** to generate a preview of the analysis.
7. Choose **Add** to add the transform to the Data Wrangler data flow.

### Bias Report

You can use the bias report in Data Wrangler to uncover potential biases in your data. To generate a bias report, you must specify the target column, or **Label**, that you want to predict and a **Facet**, or the column that you want to inspect for biases.

**Label**: The feature about which you want a model to make predictions. For example, if you are predicting customer conversion, you may select a column containing data on whether or not a customer has placed an order. You must also specify whether this feature is a label or a threshold. If you specify a label, you must specify what a **positive outcome** looks like in your data. In the customer conversion example, a positive outcome may be a 1 in the orders column, representing the positive outcome of a customer placing an order within the last three months. If you specify a threshold, you must specify a lower bound defining a positive outcome. For example, if your customer orders columns contains the number of orders placed in the last year, you may want to specify 1.

**Facet**: The column that you want to inspect for biases. For example, if you are trying to predict customer conversion, your facet may be the age of the customer. You may choose this facet because you believe that your data is biased toward a certain age group. You must identify whether the facet is measured as a value or threshold. For example, if you wanted to inspect one or more specific ages, you select **Value** and specify those ages. If you want to look at an age group, you select **Threshold** and specify the threshold of ages you want to inspect.

After you select your feature and label, you select the types of bias metrics you want to calculate.

To learn more, see **Generate reports for bias in pre-training data**.

### Create Custom Visualizations

You can add an analysis to your Data Wrangler flow to create a custom visualization. Your dataset, with all the transformations you've applied, is available as a **Pandas DataFrame**. Data Wrangler uses the df variable to store the dataframe. You access the dataframe by calling the variable.
You must provide the output variable, chart, to store an Altair output chart. For example, you can use the following code block to create a custom histogram using the Titanic dataset.

```python
import altair as alt
df = df.iloc[:30]
df = df.rename(columns={"Age": "value"})
df = df.assign(count=df.groupby('value').value.transform('count'))
df = df["value", "count"]
base = alt.Chart(df)
bar = base.mark_bar().encode(x=alt.X('value', bin=True, axis=None), y=alt.Y('count'))
rule = base.mark_rule(color='red').encode(
    x='mean(value):Q',
    size=alt.value(5))
chart = bar + rule
```

To create a custom visualization:

1. Next to the node containing the transformation that you'd like to visualize, choose the +.
2. Choose Add analysis.
3. For Analysis type, choose Custom Visualization.
4. For Analysis name, specify a name.
5. Enter your code in the code box.
6. Choose Preview to preview your visualization.
7. Choose Save to add your visualization.

If you don’t know how to use the Altair visualization package in Python, you can use custom code snippets to help you get started.

Data Wrangler has a searchable collection of visualization snippets. To use a visualization snippet, choose Search example snippets and specify a query in the search bar.
The following example uses the Binned scatterplot code snippet. It plots a histogram for 2 dimensions. The snippets have comments to help you understand the changes that you need to make to the code. You usually need to specify the column names of your dataset in the code.

```python
import altair as alt

# Specify the number of top rows for plotting
rows_number = 1000
df = df.head(rows_number)
# You can also choose bottom rows or randomly sampled rows
# df = df.tail(rows_number)
# df = df.sample(rows_number)

chart = (alt.Chart(df)
    .mark_circle()
    .encode(
        # Specify the column names for binning and number of bins for X and Y axis
        x=alt.X("col1:Q", bin=alt.Bin(maxbins=20)),
        y=alt.Y("col2:Q", bin=alt.Bin(maxbins=20)),
        size="count()",
    )
)
```

Note: :Q specifies that label column has quantitative type.
For more details on Altair typing refer to https://altair-viz.github.io/user_guide/encoding.html#encoding-data-types

Reusing Data Flows for Different Datasets

For Amazon Simple Storage Service (Amazon S3) data sources, you can create and use parameters. A parameter is a variable that you've saved in your Data Wrangler flow. Its value can be any portion of the data source's Amazon S3 path. Use parameters to quickly change the data that you're importing into a Data Wrangler flow or exporting to a processing job.

After you created a Data Wrangler flow, you might have trained a model on the data that you've transformed. For datasets that have the same schema, you can use parameters to apply the same transformations on a different dataset and train a different model. You can use the new datasets to perform inference with your model or you could be using them to retrain your model.

In general, parameters have the following attributes:

- **Name** – The name you specify for the parameter
- **Type** – The type of value that the parameter represents
- **Default value** – The value of the parameter when you don't specify a new value

**Note**

Datet ime parameters have a time range attribute that they use as the default value.

Data Wrangler uses curly braces, {{}}, to indicate that a parameter is being used in the Amazon S3 path. For example, you can have a URL such as s3://{DOC-EXAMPLE-BUCKET1}{{example_parameter_name}}/example-dataset.csv.

You create a parameter when you're editing the Amazon S3 data source that you've imported. You can set any portion of the file path to a parameter value. You can set the parameter value to either a value or a pattern. The following are the available parameter value types in the Data Wrangler flow:
• Number
• String
• Pattern
• Datetime

**Note**
You can't create a pattern parameter or a datetime parameter for the name of the bucket in the Amazon S3 path.

You must set a number as the default value of a number parameter. You can change the value of the parameter to a different number when you're editing a parameter or when you're launching a processing job. For example, in the S3 path, `s3://DOC-EXAMPLE-BUCKET/example-prefix/example-file-1.csv`, you can create a number parameter named `number_parameter` in the place of `1`. Your S3 path now appears as `s3://DOC-EXAMPLE-BUCKET/example-prefix/example-file-{{number_parameter}}.csv`. The path continues to point to the example-file-1.csv dataset until you change the value of the parameter. If you change the value of `number_parameter` to 2, the path is now `s3://DOC-EXAMPLE-BUCKET/example-prefix/example-file-2.csv`. You can import `example-file-2.csv` into Data Wrangler if you've uploaded the file to that Amazon S3 location.

A string parameter stores a string as its default value. For example, in the S3 path, `s3://DOC-EXAMPLE-BUCKET/example-prefix/example-file-1.csv`, you can create a string parameter named `string_parameter` in the place of the filename, `example-file-1.csv`. The path now appears as `s3://DOC-EXAMPLE-BUCKET/example-prefix/{{string_parameter}}`. It continues to match `s3://DOC-EXAMPLE-BUCKET/example-prefix/example-file-1.csv`, until you change the value of the parameter.

Instead of specifying the filename as a string parameter, you can create a string parameter using the entire Amazon S3 path. You can specify a dataset from any Amazon S3 location in the string parameter.

A pattern parameter stores a regular expression (Python REGEX) string as its default value. You can use a pattern parameter to import multiple data files at the same time. To import more than one object at a time, specify a parameter value that matches the Amazon S3 objects that you're importing.

You can also create a pattern parameter for the following datasets:

- `s3://DOC-EXAMPLE-BUCKET1/example-prefix/example-file-1.csv`
- `s3://DOC-EXAMPLE-BUCKET1/example-prefix/example-file-2.csv`
- `s3://DOC-EXAMPLE-BUCKET1/example-prefix/example-file-10.csv`
- `s3://DOC-EXAMPLE-BUCKET/example-prefix/example-file-0123.csv`

For `s3://DOC-EXAMPLE-BUCKET1/example-prefix/example-file-1.csv`, you can create a pattern parameter in the place of `1`, and set the default value of the parameter to `\d+`. The `\d+` REGEX string matches any one or more decimal digits. If you create a pattern parameter named `pattern_parameter`, your S3 path appears as `s3://DOC-EXAMPLE-BUCKET1/example-prefix/example-file-{{pattern_parameter}}.csv`.

You can also use pattern parameters to match all CSV objects within your bucket. To match all objects in a bucket, create a pattern parameter with the default value of `.*` and set the path to `s3://DOC-EXAMPLE-BUCKET/{{pattern_parameter}}.csv`. The `.*` character matches any string character in the path.

The `s3://DOC-EXAMPLE-BUCKET/{{pattern_parameter}}.csv` path can match the following datasets:

- `example-file-1.csv`
A datetime parameter stores the format with the following information:

- A format for parsing strings inside an Amazon S3 path.
- A relative time range to limit the datetime values that match

For example, in the Amazon S3 file path, `s3://DOC-EXAMPLE-BUCKET/2020/01/01/example-dataset.csv`, 2020/01/01 represents a datetime in the format of `year/month/day`. You can set the parameter's time range to an interval such as 1 year or 24 hours. An interval of 1 year matches all S3 paths with datetimes that fall between the current time and the time exactly a year before the current time. The current time is the time when you start exporting the transformations that you've made to the data. For more information about exporting data, see Export (p. 945). If the current date is 2022/01/01 and the time range is 1 year, the S3 path matches datasets such as the following:

- `s3://DOC-EXAMPLE-BUCKET/2021/01/01/example-dataset.csv`
- `s3://DOC-EXAMPLE-BUCKET/2021/06/30/example-dataset.csv`
- `s3://DOC-EXAMPLE-BUCKET/2021/12/31/example-dataset.csv`

The datetime values within a relative time range change as time passes. The S3 paths that fall within the relative time range might also differ.

For the Amazon S3 file path, `s3://DOC-EXAMPLE-BUCKET/20200101/example-dataset.csv`, 20220101 is an example of a path that can become a datetime parameter.

To view a table of all parameters that you've created in Data Wrangler flow, choose the `{}` to the right of the text box containing the Amazon S3 path. If you no longer need a parameter that you've created, you can edit or delete. To edit or delete a parameter, choose icons to the right of the parameter.

**Important**
Before you delete a parameter, make sure that you haven't used it anywhere in your Data Wrangler flow. Deleted parameters that are still within the flow cause errors.

You can create parameters for any step of your Data Wrangler flow. You can edit or delete any parameter that you create. If the parameter has transformations that are no longer relevant to your use case, you can modify them.

The following sections provide additional examples and general guidance on using parameters. You can use the sections to understand the parameters that work best for you.

**Note**
The following sections contain procedures that use the Data Wrangler interface to override the parameters and create a processing job.
You can also override the parameters by using the following procedures.

To export your Data Wrangler flow and override the value of a parameter, do the following.

1. Choose the + next to the node that you want to export.
2. Choose Export to.
3. Choose the location where you're exporting the data.
4. Under parameter_overrides, specify different values for the parameters that you've created.
5. Run the Jupyter Notebook.
Applying a Data Wrangler flow to files using patterns

You can use parameters to apply transformations in your Data Wrangler flow to different files that match a pattern in the Amazon S3 URI path. This helps you specify the files in your S3 bucket that you want to transform with high specificity. For example, you might have a dataset with the path s3://DOC-EXAMPLE-BUCKET1/example-prefix-0/example-prefix-1/example-prefix-2/example-dataset.csv. Different datasets named example-dataset.csv are stored under many different example prefixes. The prefixes might also be numbered sequentially. You can create patterns for the numbers in the Amazon S3 URI. Pattern parameters use REGEX to select any number of files that match the pattern of the expression. The following are REGEX patterns that might be useful:

- .* – Matches zero or more of any character, except newline characters
- .+ – Matches one or more of any character, excluding newline characters
- \d+ – Matches one or more of any decimal digit
- \w+ – Matches one or more of any alphanumeric character
- [abc-\_]{2,4} – Matches a string two, three, or four characters composed of the set of characters provided within a set of brackets
- abc|def – Matches one string or another. For example, the operation matches either abc or def

You can replace each number in the following paths with a single parameter that has a value of \d+.

- s3://DOC-EXAMPLE-BUCKET1/example-prefix-3/example-prefix-4/example-prefix-5/example-dataset.csv
- s3://DOC-EXAMPLE-BUCKET1/example-prefix-8/example-prefix-12/example-prefix-13/example-dataset.csv
- s3://DOC-EXAMPLE-BUCKET1/example-prefix-4/example-prefix-9/example-prefix-137/example-dataset.csv

The following procedure creates a pattern parameter for a dataset with the path s3://DOC-EXAMPLE-BUCKET1/example-prefix-0/example-prefix-1/example-prefix-2/example-dataset.csv.

To create a pattern parameter, do the following.

1. Next to the dataset that you've imported, choose Edit dataset.
2. Highlight the 0 in example-prefix-0.
3. Specify values for the following fields:
   - Name – A name for parameter
   - Type – Pattern
   - Value – \d+ a regular expression that corresponds to one or more digits
4. Choose Create.
5. Replace the 1 and the 2 in S3 URI path with the parameter. The path should have the following format: s3://DOC-EXAMPLE-BUCKET1/example-prefix-{{example_parameter_name}}/example-prefix-{{example_parameter_name}}/example-prefix-{{example_parameter_name}}/example-dataset.csv

The following is a general procedure for creating a pattern parameter.

1. Navigate to your Data Wrangler flow.
2. Next to the dataset that you've imported, choose Edit dataset.
3. Highlight the portion of the URI that you're using as the value of the pattern parameter.
4. Choose Create custom parameter.
5. Specify values for the following fields:
   - **Name** – A name for parameter
   - **Type** – Pattern
   - **Value** – A regular expression containing the pattern that you'd like to store.
6. Choose Create.

### Applying a Data Wrangler flow to files using numeric values

You can use parameters to apply transformations in your Data Wrangler flow to different files that have similar paths. For example, you might have a dataset with the path `s3://DOC-EXAMPLE-BUCKET1/example-prefix-0/example-prefix-1/example-prefix-2/example-dataset.csv`.

You might have the transformations from your Data Wrangler flow that you've applied to datasets under `example-prefix-1`. You might want to apply the same transformations to `example-dataset.csv` that falls under `example-prefix-10` or `example-prefix-20`.

You can create a parameter that stores the value 1. If you want to apply the transformations to different datasets, you can create processing jobs that replace the value of the parameter with a different value. The parameter acts as a placeholder for you to change when you want to apply the transformations from your Data Wrangler flow to new data. You can override the value of the parameter when you create a Data Wrangler processing job to apply the transformations in your Data Wrangler flow to different datasets.

Use the following procedure to create numeric parameters for `s3://DOC-EXAMPLE-BUCKET1/example-prefix-0/example-prefix-1/example-prefix-2/example-dataset.csv`.

To create parameters for the preceding S3 URI path, do the following.

1. Navigate to your Data Wrangler flow.
2. Next to the dataset that you've imported, choose **Edit dataset**.
3. Highlight the number in an example prefix of **example-prefix-number**.
4. Choose **Create custom parameter**.
5. For **Name**, specify a name for the parameter.
6. For **Type**, choose **Integer**.
7. For **Value**, specify the number.
8. Create parameters for the remaining numbers by repeating the procedure.

After you've created the parameters, apply the transforms to your dataset and create a destination node for them. For more information about destination nodes, see Export (p. 945).

Use the following procedure to apply the transformations from your Data Wrangler flow to a different time range. It assumes that you've created a destination node for the transformations in your flow.

To change the value of a numeric parameter in a Data Wrangler processing job, do the following.

1. From your Data Wrangler flow, choose **Create job**.
2. Select only the destination node that contains the transformations to the dataset containing the datetime parameters.
3. Choose **Configure job**.
4. Choose **Parameters**.
5. Choose the name of a parameter that you've created.
6. Change the value of the parameter.
7. Repeat the procedure for the other parameters.
Applying a Data Wrangler flow to files using strings

You can use parameters to apply transformations in your Data Wrangler flow to different files that have similar paths. For example, you might have a dataset with the path `s3://DOC-EXAMPLE-BUCKET1/example-prefix/example-dataset.csv`.

You might have transformations from your Data Wrangler flow that you've applied to datasets under `example-prefix`. You might want to apply the same transformations to `example-dataset.csv` under another `example-prefix` or `example-prefix-20`.

You can create a parameter that stores the value `example-prefix`. If you want to apply the transformations to different datasets, you can create processing jobs that replace the value of the parameter with a different value. The parameter acts as a placeholder for you to change when you want to apply the transformations from your Data Wrangler flow to new data. You can override the value of the parameter when you create a Data Wrangler processing job to apply the transformations in your Data Wrangler flow to different datasets.

Use the following procedure to create a string parameter for `s3://DOC-EXAMPLE-BUCKET1/example-prefix/example-dataset.csv`.

To create a parameter for the preceding S3 URI path, do the following.

1. Navigate to your Data Wrangler flow.
2. Next to the dataset that you've imported, choose **Edit dataset**.
3. Highlight the example prefix, `example-prefix`.
4. Choose **Create custom parameter**.
5. For **Name**, specify a name for the parameter.
6. For **Type**, choose **String**.
7. For **Value**, specify the prefix.

After you've created the parameter, apply the transforms to your dataset and create a destination node for them. For more information about destination nodes, see Export (p. 945).

Use the following procedure to apply the transformations from your Data Wrangler flow to a different time range. It assumes that you've created a destination node for the transformations in your flow.

To change the value of a numeric parameter in a Data Wrangler processing job, do the following:

1. From your Data Wrangler flow, choose **Create job**
2. Select only the destination node that contains the transformations to the dataset containing the datetime parameters.
3. Choose **Configure job**.
4. Choose **Parameters**.
5. Choose the name of a parameter that you've created.
6. Change the value of the parameter.
7. Repeat the procedure for the other parameters.
8. Choose **Run**.

Applying a Data Wrangler flow to different datetime ranges

Use datetime parameters to apply transformations in your Data Wrangler flow to different time ranges. Highlight the portion of the Amazon S3 URI that has a timestamp and create a parameter for it.
When you create a parameter, you specify a time range from the current time to a time in the past. For example, you might have an Amazon S3 URI that looks like the following: s3://DOC-EXAMPLE-BUCKET1/example-prefix/2022/05/15/example-dataset.csv. You can save 2022/05/15 as a datetime parameter. If you specify a year as the time range, the time range includes the moment that you run the processing job containing the datetime parameter and the time exactly one year ago. If the moment you're running the processing job is September 6th, 2022 or 2022/09/06, the time ranges can include the following:

- s3://DOC-EXAMPLE-BUCKET1/example-prefix/2022/03/15/example-dataset.csv
- s3://DOC-EXAMPLE-BUCKET1/example-prefix/2022/01/08/example-dataset.csv
- s3://DOC-EXAMPLE-BUCKET1/example-prefix/2022/07/31/example-dataset.csv
- s3://DOC-EXAMPLE-BUCKET1/example-prefix/2021/09/07/example-dataset.csv

The transformations in the Data Wrangler flow apply to all of the preceding prefixes. Changing the value of the parameter in the processing job doesn't change the value of the parameter in the Data Wrangler flow. To apply the transformations to datasets within a different time range, do the following:

1. Create a destination node containing all the transformations that you'd like to use.
2. Create a Data Wrangler job.
3. Configure the job to use a different time range for the parameter. Changing the value of the parameter in the processing job doesn't change the value of the parameter in the Data Wrangler flow.

For more information about destination nodes and Data Wrangler jobs, see Export (p. 945).

The following procedure creates a datetime parameter for the Amazon S3 path: s3://DOC-EXAMPLE-BUCKET1/example-prefix/2022/05/15/example-dataset.csv.

To create a datetime parameter for the preceding S3 URI path, do the following.

1. Navigate to your Data Wrangler flow.
2. Next to the dataset that you've imported, choose Edit dataset.
3. Highlight the portion of the URI that you're using as the value of the datetime parameter.
4. Choose Create custom parameter.
5. For Name, specify a name for the parameter.
6. For Type, choose Datetime.

**Note**
By default, Data Wrangler selects Predefined, which provides a dropdown menu for you to select a date format. However, the timestamp format that you're using might not be available. Instead of using Predefined as the default option, you can choose Custom and specify the timestamp format manually.

7. For Date format, open the dropdown menu following Predefined and choose yyyy/MM/dd. The format, yyyy/MM/dd, corresponds to the year/month/day of the timestamp.
8. For Timezone, choose a time zone.

**Note**
The data that you're analyzing might have time stamps taken in a different time zone from your time zone. Make sure that the time zone that you select matches the time zone of the data.

9. For Time range, specify the time range for the parameter.
10. (Optional) Enter a description to describe how you're using the parameter.
11. Choose Create.
After you’ve created the datetime parameters, apply the transforms to your dataset and create a destination node for them. For more information about destination nodes, see Export (p. 945).

Use the following procedure to apply the transformations from your Data Wrangler flow to a different time range. It assumes that you’ve created a destination node for the transformations in your flow.

To change the value of a datetime parameter in a Data Wrangler processing job, do the following:

1. From your Data Wrangler flow, choose **Create job**
2. Select only the destination node that contains the transformations to the dataset containing the datetime parameters.
3. Choose **Configure job**.
4. Choose **Parameters**.
5. Choose the name of the datetime parameter that you’ve created.
6. For **Time range**, change the time range for the datasets.
7. Choose **Run**.

## Export

In your Data Wrangler flow, you can export some or all of the transformations that you’ve made to your data processing pipelines.

A **Data Wrangler flow** is the series of data preparation steps that you’ve performed on your data. In your data preparation, you perform one or more transformations to your data. Each transformation is done using a transform step. The flow has a series of nodes that represent the import of your data and the transformations that you’ve performed. For an example of nodes, see the following image.

The preceding image shows a Data Wrangler flow with two nodes. The **Source - sampled** node shows the data source from which you’ve imported your data. The **Data types** node indicates that Data Wrangler has performed a transformation to convert the dataset into a usable format.
Each transformation that you add to the Data Wrangler flow appears as an additional node. For information on the transforms that you can add, see Transform Data (p. 889). The following image shows a Data Wrangler flow that has a Rename-column node to change the name of a column in a dataset.

You can export your data transformations to the following:

- Amazon S3
- SageMaker Pipelines
- Amazon SageMaker Feature Store
- Python Code

**Important**

We recommend that you use the IAM AmazonSageMakerFullAccess managed policy to grant AWS permission to use Data Wrangler. If you don't use the managed policy, you can use an IAM policy that gives Data Wrangler access to an Amazon S3 bucket. For more information on the policy, see Security and Permissions (p. 966).

When you export your data flow, you're charged for the AWS resources that you use. You can use cost allocation tags to organize and manage the costs of those resources. You create these tags for your user-profile and Data Wrangler automatically applies them to the resources used to export the data flow. For more information, see Using Cost Allocation Tags.

**Export to Amazon S3**

Data Wrangler gives you the ability to export your data to a location within an Amazon S3 bucket. You can specify the location using one of the following methods:

- Destination node – Where Data Wrangler stores the data after it has processed it.
- Export to – Exports the data resulting from a transformation to Amazon S3.
- Export data – For small datasets, can quickly export the data that you've transformed.

Use the following sections to learn more about each of these methods.

**Destination Node**

If you want to output a series of data processing steps that you've performed to Amazon S3, you create a destination node. A destination node tells Data Wrangler where to store the data after you've processed it. After you create a destination node, you create a processing job to output the data. A processing job is an Amazon SageMaker processing job. When you're using a destination node, it runs the computational resources needed to output the data that you've transformed to Amazon S3.

You can use a destination node to export some of the transformations or all of the transformations that you've made in your Data Wrangler flow.

You can use multiple destination nodes to export different transformations or sets of transformations. The following example shows two destination nodes in a single Data Wrangler flow.
You can use the following procedure to create destination nodes and export them to an Amazon S3 bucket.

To export your data flow, you create destination nodes and a Data Wrangler job to export the data. Creating a Data Wrangler job starts a SageMaker processing job to export your flow. You can choose the destination nodes that you want to export after you've created them.

Use the following procedure to create destination nodes.

1. Choose the + next to the nodes that represent the transformations that you want to export.
2. Choose **Add destination**.
3. Choose Amazon S3.

4. Specify the fields shown in the following image.
5. Choose **Add destination**.

Use the following procedure to create a Data Wrangler job.

Create a job from the **Data flow** page and choose the destination nodes that you want to export.

1. Choose **Create job**. The following image shows the pane that appears after you select **Create job**.
2. For **Job name**, specify the name of the export job.
3. Choose the destination nodes that you want to export.
4. (Optional) Specify an AWS KMS key ARN. An AWS KMS key is a cryptographic key that you can use to protect your data. For more information about AWS KMS keys, see [AWS Key Management Service](#).
5. (Optional) Under **Trained parameters**, choose **Refit** if you’ve done the following:
   - Sampled your dataset
   - Applied a transform that uses your data to create a new column in the dataset

For more information about refitting the transformations you’ve made to an entire dataset, see [Refit Transforms to The Entire Dataset and Export Them](#) (p. 960).
6. Choose **Configure job**. The following image shows the **Configure job** page.

7. (Optional) Configure the Data Wrangler job.
8. Choose **Run**.
Export to

As an alternative to using a destination node, you can use the Export to option to export your Data Wrangler flow to Amazon S3 using a Jupyter Notebook. You can choose any data node in your Data Wrangler flow and export it. Exporting the data node exports the transformation that the node represents and the transformations that precede it.

Use the following procedure to generate a Jupyter Notebook and run it to export your Data Wrangler flow to Amazon S3.

1. Choose the + next to the node that you want to export.
2. Choose Export to.
3. Choose Amazon S3 (via Jupyter Notebook).
4. Run the Jupyter Notebook.

When you run the notebook, it exports your data flow (.flow file) in the same AWS Region as the Data Wrangler flow.

The notebook provides options that you can use to configure the processing job and the data that it outputs.

**Important**

We provide you with job configurations to configure the output of your data. For the partitioning and driver memory options, we strongly recommend that you don't specify a configuration unless you already have knowledge about them.

Under **Job Configurations**, you can configure the following:

- **output_content_type** – The content type of the output file. Uses CSV as the default format, but you can specify Parquet.
- **delimiter** – The character used to separate values in the dataset when writing to a CSV file.
- **compression** – If set, compresses the output file. Uses gzip as the default compression format.
- **num_partitions** – The number of partitions or files that Data Wrangler writes as the output.
- **partition_by** – The names of the columns that you use to partition the output.
To change the output file format from CSV to Parquet, change the value from "CSV" to "Parquet". For the rest of the preceding fields, uncomment the lines containing the fields that you want to specify.

Under **(Optional) Configure Spark Cluster Driver Memory** you can configure Spark properties for the job, such as the Spark driver memory, in the config dictionary.

The following shows the config dictionary.

```json
cfg = json.dumps({
    "Classification": "spark-defaults",
    "Properties": {
        "spark.driver.memory": f"{driver_memory_in_mb}m",
    }
})
```

To apply the configuration to the processing job, uncomment the following lines:

```python
# data_sources.append(ProcessingInput(
#     source=config_s3_uri,
#     destination="/opt/ml/processing/input/conf",
#     input_name="spark-config",
#     s3_data_type="S3Prefix",
#     s3_data_distribution_type="FullyReplicated"
# ))
```

Export data

If you have a transformation on a small dataset that you want to export quickly, you can use the Export data method. When you start choose Export data, Data Wrangler works synchronously to export the data that you've transformed to Amazon S3. You can't use Data Wrangler until either it finishes exporting your data or you cancel the operation.

For information on using the Export data method in your Data Wrangler flow, see the following procedure.

To use the Export data method.

1. Choose a node in your Data Wrangler flow by double-clicking on it.
2. Configure how you want to export the data.
3. Choose Export data.

When you export your data flow to an Amazon S3 bucket, Data Wrangler stores a copy of the flow file in the S3 bucket. It stores the flow file under the `data_wrangler_flows` prefix. If you use the default Amazon S3 bucket to store your flow files, they use the following naming convention: `sagemaker-region-account number`. For example, if your account number is 111122223333 and you are using Studio in us-east-1, your imported datasets are stored in `sagemaker-us-east-1-111122223333`. In this example, your .flow files created in us-east-1 are stored in `s3://sagemaker-region-account number/data_wrangler_flows/`.

Export to SageMaker Pipelines

When you want to build and deploy large-scale machine learning (ML) workflows, you can use SageMaker Pipelines to create end-to-end workflows that manage and deploy SageMaker jobs. SageMaker Pipelines gives you the ability to build workflows that manage your SageMaker data preparation, model training, and model deployment jobs. You can use the first-party algorithms that SageMaker offers by using SageMaker Pipelines. For more information on SageMaker Pipelines, see SageMaker Pipelines.

When you export one or more steps from your data flow to SageMaker Pipelines, Data Wrangler creates a Jupyter Notebook that you can use to define, instantiate, run, and manage a pipeline.

Use a Jupyter Notebook to Create a Pipeline

Use the following procedure to create a Jupyter Notebook to export your Data Wrangler flow to SageMaker Pipelines.

Use the following procedure to generate a Jupyter Notebook and run it to export your Data Wrangler flow to SageMaker Pipelines.

1. Choose the + next to the node that you want to export.
2. Choose Export to.
4. Run the Jupyter notebook.
The Jupyter Notebook that Data Wrangler produces can be used to define a pipeline. The pipeline includes the data processing steps that are defined by your Data Wrangler flow.

You can add additional steps to your pipeline by adding steps to the steps list in the following code in the notebook:

```python
pipeline = Pipeline(
    name=pipeline_name,
    parameters=[instance_type, instance_count],
    steps=[step_process],  # Add more steps to this list to run in your Pipeline
)
```

For more information on defining pipelines, see Define SageMaker Pipeline.

**Export to Python Code**

To export all steps in your data flow to a Python file that you can manually integrate into any data processing workflow, use the following procedure.

Use the following procedure to generate a Jupyter Notebook and run it to export your Data Wrangler flow to Python Code.

1. Choose the + next to the node that you want to export.
2. Choose Export to.
4. Run the Jupyter Notebook.
You might need to configure the Python script to make it run in your pipeline. For example, if you're running a Spark environment, make sure that you are running the script from an environment that has permission to access AWS resources.

### Export to Amazon SageMaker Feature Store

You can use Data Wrangler to export features you've created to Amazon SageMaker Feature Store. A feature is a column in your dataset. Feature Store is a centralized store for features and their associated metadata. You can use Feature Store to create, share, and manage curated data for machine learning (ML) development. Centralized stores make your data more discoverable and reusable. For more information about Feature Store, see [Amazon SageMaker Feature Store](#).

A core concept in Feature Store is a feature group. A feature group is a collection of features, their records (observations), and associated metadata. It's similar to a table in a database.

You can use Data Wrangler to do one of the following:

- Update an existing feature group with new records. A record is an observation in the dataset.
- Create a new feature group from a node in your Data Wrangler flow. Data Wrangler adds the observations from your datasets as records in your feature group.

If you're updating an existing feature group, your dataset's schema must match the schema of the feature group. All the records in the feature group are replaced with the observations in your dataset.

You can use either a Jupyter Notebook or a destination node to update your feature group with the observations in the dataset.

#### Destination Node

If you want to output a series of data processing steps that you've performed to a feature group, you can create a destination node. When you create and run a destination node, Data Wrangler updates a feature group with your data. You can also create a new feature group from the destination node UI. After you create a destination node, you create a processing job to output the data. A processing job is an Amazon SageMaker processing job. When you're using a destination node, it runs the computational resources needed to output the data that you've transformed to the feature group.
You can use a destination node to export some of the transformations or all of the transformations that you've made in your Data Wrangler flow.

Use the following procedure to create a destination node to update a feature group with the observations from your dataset.

To update a feature group using a destination node, do the following.
1. Choose the + symbol next to the node containing the dataset that you'd like to export.
2. Under **Add destination**, choose **SageMaker Feature Store**.
3. Double click on the feature group. Data Wrangler checks whether the schema of the feature group matches the schema of the data that you're using to update the feature group.
4. (Optional) Select **Export to offline store only** for feature groups that have both an online store and an offline store. This option only updates the offline store with observations from your dataset.
5. After Data Wrangler validates the schema of your dataset, choose **Add**.

Use the following procedure to create a new feature group with data from your dataset.

You can have the following options for how you want to store your feature group:

- **Online** – Low latency, high availability cache for a feature group that enables real-time lookup of records. The online store allows quick access to the latest value for a record in a feature group.
- **Offline** – Stores data for your feature group in an Amazon S3 bucket. You can store your data offline when you don't need low latency (sub-second) reads. You can use an offline store for features used in data exploration, model training, and batch inference.
- **Both online and offline** – Stores your data in both an online store and an offline store.

To create a feature group using a destination node, do the following.
1. Choose the + symbol next to the node containing the dataset that you'd like to export.
2. Under **Add destination**, choose **SageMaker Feature Store**.
3. Choose **Create Feature Group**.
4. In the following dialog box, if your dataset doesn't have an event time column, select **Create "EventTime" column**.
5. Choose **Next**.
6. Choose **Copy JSON Schema**. When you create a feature group, you paste the schema into the feature definitions.

7. Choose **Create**.

8. For **Feature group name**, specify a name for your feature group.

9. For **Description (optional)**, specify a description to make your feature group more discoverable.

10. To create a feature group for an online store, do the following.
   a. Select **Enable storage online**.
   b. For **Online store encryption key**, specify an AWS managed encryption key or an encryption key of your own.

11. To create a feature group for an offline store, do the following.
   a. Select **Enable storage offline**.
   b. Specify values for the following fields:
      - **S3 bucket name** – The name of the bucket storing the feature group.
      - **(Optional) Dataset directory name** – The Amazon S3 prefix that you're using to store the feature group.
      - **IAM Role ARN** – The IAM role that has access to feature store.
      - **Offline store encryption key** – By default, Feature Store uses an AWS managed key, but you can use the field to specify a key of your own.

12. Choose **Continue**.

13. Choose **JSON**.

14. Remove the placeholder brackets in the window.

15. Paste the JSON text from Step 6.

16. Choose **Continue**.

17. For **RECORD IDENTIFIER FEATURE NAME**, choose the column in your dataset that has unique identifiers for each record in your dataset.

18. For **EVENT TIME FEATURE NAME**, choose the column with the timestamp values.

19. Choose **Continue**.

20. (Optional) Add tags to make your feature group more discoverable.

21. Choose **Continue**.

22. Choose **Create feature group**.

23. Navigate back to your Data Wrangler flow and choose the refresh icon next to the **Feature Group** search bar.

**Note**
If you've already created a destination node for a feature group within a flow, you can't create another destination node for the same feature group. If you want to create another destination node for the same feature group, you must create another flow file.

Use the following procedure to create a Data Wrangler job.

Create a job from the **Data flow** page and choose the destination nodes that you want to export.

1. Choose **Create job**. The following image shows the pane that appears after you select **Create job**.

2. For **Job name**, specify the name of the export job.

3. Choose the destination nodes that you want to export.
4. (Optional) For **Output KMS Key**, specify an ARN, ID, or alias of an AWS KMS key. A KMS key is a cryptographic key. You can use the key to encrypt the output data from the job. For more information about AWS KMS keys, see *AWS Key Management Service*.

5. The following image shows the **Configure job** page with the **Job configuration** tab open.

![Configure job page](image_url)

(Optional) Under **Trained parameters**, choose **Refit** if you've done the following:

- Sampled your dataset
- Applied a transform that uses your data to create a new column in the dataset

For more information about refitting the transformations you've made to an entire dataset, see *Refit Transforms to The Entire Dataset and Export Them* (p. 960).

6. Choose **Configure job**. The following image shows the **Configure job** page.

7. (Optional) Configure the Data Wrangler job. The following are examples of optional configurations.

   a. For **Flow file S3 location**, specify the Amazon S3 location where you'd like to save the flow file.

   b. For **Flow file KMS key**, specify the AWS KMS key, ARN, or alias that you're using to encrypt the flow file.

Jupyter Notebook

Use the following procedure to a Jupyter Notebook to export to Amazon SageMaker Feature Store.

Use the following procedure to generate a Jupyter Notebook and run it to export your Data Wrangler flow to Feature Store.

1. Choose the + next to the node that you want to export.
2. Choose Export to.
4. Run the Jupyter Notebook.

Running a Jupyter Notebook runs a Data Wrangler job. Running a Data Wrangler job starts a SageMaker processing job. The processing job ingests the flow into an online and offline feature store.

**Important**

The IAM role you use to run this notebook must have the following AWS managed policies attached: AmazonSageMakerFullAccess and AmazonSageMakerFeatureStoreAccess.

You only need to enable one online or offline feature store when you create a feature group. You can also enable both. To disable online store creation, set `EnableOnlineStore` to `False`:

```python
# Online Store Configuration
online_store_config = {
    "EnableOnlineStore": False
}
```

The notebook uses the column names and types of the dataframe you export to create a feature group schema, which is used to create a feature group. A feature group is a group of features defined in the feature store to describe a record. The feature group defines the schema and features contained in the feature group. A feature group definition is composed of a list of features, a record
identifier feature name, an event time feature name, and configurations for its online store and offline store.

Each feature in a feature group can have one of the following types: String, Fractional, or Integral. If a column in your exported dataframe is not one of these types, it defaults to String.

The following is an example of a feature group schema.

```python
column_schema = [
    {
        "name": "Height",
        "type": "long"
    },
    {
        "name": "Input",
        "type": "string"
    },
    {
        "name": "Output",
        "type": "string"
    },
    {
        "name": "Sum",
        "type": "string"
    },
    {
        "name": "Time",
        "type": "string"
    }
]
```

Additionally, you must specify a record identifier name and event time feature name:

- The **record identifier name** is the name of the feature whose value uniquely identifies a record defined in the feature store. Only the latest record per identifier value is stored in the online store. The record identifier feature name must be one of feature definitions’ names.

- The **event time feature name** is the name of the feature that stores the EventTime of a record in a feature group. An EventTime is a point in time when a new event occurs that corresponds to the creation or update of a record in a feature. All records in the feature group must have a corresponding EventTime.

The notebook uses these configurations to create a feature group, process your data at scale, and then ingest the processed data into your online and offline feature stores. To learn more, see Data Sources and Ingestion.

The notebook uses these configurations to create a feature group, process your data at scale, and then ingest the processed data into your online and offline feature stores. To learn more, see Data Sources and Ingestion.

**Refit Transforms to The Entire Dataset and Export Them**

When you import data, Data Wrangler uses a sample of the data to apply the encodings. By default, Data Wrangler uses the first 50,000 rows as a sample, but you can import the entire dataset or use a different sampling method. For more information, see Import (p. 827).

The following transformations use your data to create a column in the dataset:

- **Encode Categorical (p. 903)**
• Featurize Text (p. 906)
• Handle Outliers (p. 919)
• Handle Missing Values (p. 921)

If you used sampling to import your data, the preceding transforms only use the data from the sample to create the column. The transform might not have used all of the relevant data. For example, if you use the **Encode Categorical** transform, there might have been a category in the entire dataset that wasn't present in the sample.

You can either use a destination node or a Jupyter notebook to refit the transformations to the entire dataset. When Data Wrangler exports the transformations in the flow, it creates a SageMaker processing job. When the processing job finishes, Data Wrangler saves the following files in either the default Amazon S3 location or an S3 location that you specify:

- The Data Wrangler flow file that specifies the transformations that are refit to the dataset
- The dataset with the refit transformations applied to it

You can open a Data Wrangler flow file within Data Wrangler and apply the transformations to a different dataset. For example, if you've applied the transformations to a training dataset, you can open and use the Data Wrangler flow file to apply the transformations to a dataset used for inference.

For a information about using destination nodes to refit transforms and export see the following pages:

- Export to Amazon S3 (p. 946)
- Export to Amazon SageMaker Feature Store (p. 955)

Use the following procedure to run a Jupyter notebook to refit the transformations and export the data.

To run a Jupyter Notebook and to refit the transformations and export your Data Wrangler flow, do the following.

1. Choose the + next to the node that you want to export.
2. Choose **Export to**.
3. Choose the location where you're exporting the data.
4. For the `refit_trained_params` object, set `refit` to `True`.
5. For the `output_flow` field, specify the name of the output flow file with the refit transformations.
6. Run the Jupyter Notebook.

**Create a Schedule to Automatically Process New Data**

If you're processing data periodically, you can create a schedule to run the processing job automatically. For example, you can create a schedule that runs a processing job automatically when you get new data. For more information about processing jobs, see Export to Amazon S3 (p. 946) and Export to Amazon SageMaker Feature Store (p. 955).

When you create a job you must specify an IAM role that has permissions to create the job. By default, the IAM role that you use to access Data Wrangler is the **SageMakerExecutionRole**.

The following permissions enable Data Wrangler to access EventBridge and allow EventBridge to run processing jobs:

- Add the following AWS Managed policy to the Amazon SageMaker Studio execution role that provides Data Wrangler with permissions to use EventBridge:
arn:aws:iam::aws:policy/AmazonEventBridgeFullAccess

For more information about the policy, see AWS managed policies for EventBridge.

- Add the following policy to the IAM role that you specify when you create a job in Data Wrangler:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "sagemaker:StartPipelineExecution",
        }
    ]
}
```

If you’re using the default IAM role, you add the preceding policy to the Amazon SageMaker Studio execution role.

Add the following trust policy to the role to allow EventBridge to assume it.

```
{
    "Effect": "Allow",
    "Principal": {
        "Service": "events.amazonaws.com"
    },
    "Action": "sts:AssumeRole"
}
```

**Important**
When you create a schedule, Data Wrangler creates an eventRule in EventBridge. You incur charges for both the event rules that you create and the instances used to run the processing job.

For information about EventBridge pricing, see Amazon EventBridge pricing. For information about processing job pricing, see Amazon SageMaker Pricing.

You can set a schedule using one of the following methods:

- **CRON expressions**
  
  **Note**
  Data Wrangler doesn't support the following expressions:
  
  - LW#
  - Abbreviations for days
  - Abbreviations for months

- **RATE expressions**
  
  Recurring – Set an hourly or daily interval to run the job.
  Specific time – Set specific days and times to run the job.
The following sections provide procedures on creating jobs.

CRON

Use the following procedure to create a schedule with a CRON expression.

To specify a schedule with a CRON expression, do the following.

1. Open your Data Wrangler flow.
2. Choose Create job.
3. (Optional) For Output KMS key, specify an AWS KMS key to configure the output of the job.
5. Select Associate Schedules.
6. Choose Create a new schedule.
7. For Schedule Name, specify the name of the schedule.
8. For Run Frequency, choose CRON.
9. Specify a valid CRON expression.
10. Choose Create.
11. (Optional) Choose Add another schedule to run the job on an additional schedule.

Note
You can associate a maximum of two schedules. The schedules are independent and don't affect each other unless the times overlap.

12. Choose one of the following:

- **Schedule and run now** – Data Wrangler the job runs immediately and subsequently runs on the schedules.
- **Schedule only** – Data Wrangler the job only runs on the schedules that you specify.

13. Choose Run

RATE

Use the following procedure to create a schedule with a RATE expression.

To specify a schedule with a RATE expression, do the following.

1. Open your Data Wrangler flow.
2. Choose Create job.
3. (Optional) For Output KMS key, specify an AWS KMS key to configure the output of the job.
5. Select Associate Schedules.
6. Choose Create a new schedule.
7. For Schedule Name, specify the name of the schedule.
8. For Run Frequency, choose Rate.
9. For Value, specify an integer.
10. For Unit, select one of the following:

- Minutes
- Hours
- Days

11. Choose Create.
12. (Optional) Choose Add another schedule to run the job on an additional schedule.

   Note
   You can associate a maximum of two schedules. The schedules are independent and
don't affect each other unless the times overlap.

13. Choose one of the following:
   • Schedule and run now – Data Wrangler the job runs immediately and subsequently runs on
     the schedules.
   • Schedule only – Data Wrangler the job only runs on the schedules that you specify.

14. Choose Run

Recurring

Use the following procedure to create a schedule that runs a job on a recurring basis.

To specify a schedule with a CRON expression, do the following.

1. Open your Data Wrangler flow.
2. Choose Create job.
3. (Optional) For Output KMS key, specify an AWS KMS key to configure the output of the job.
5. Select Associate Schedules.
6. Choose Create a new schedule.
7. For Schedule Name, specify the name of the schedule.
8. For Run Frequency, make sure Recurring is selected by default.
9. For Every x hours, specify the hourly frequency that the job runs during the day. Valid values are
   integers in the inclusive range of 1 and 23.
10. For On days, select one of the following options:
   • Every Day
   • Weekends
   • Weekdays
   • Select Days

   • (Optional) If you’ve selected Select Days, choose the days of the week to run the job.

   Note
   The schedule resets every day. If you schedule a job to run every five hours, it runs at
   the following times during the day:
   • 00:00
   • 05:00
   • 10:00
   • 15:00
   • 20:00

11. Choose Create.
12. (Optional) Choose Add another schedule to run the job on an additional schedule.

    Note
    You can associate a maximum of two schedules. The schedules are independent and
don't affect each other unless the times overlap.
13. Choose one of the following:
   - **Schedule and run now** – Data Wrangler the job runs immediately and subsequently runs on the schedules.
   - **Schedule only** – Data Wrangler the job only runs on the schedules that you specify.

14. Choose **Run**

**Specific time**

Use the following procedure to create a schedule that runs a job at specific times.

To specify a schedule with a CRON expression, do the following.

1. Open your Data Wrangler flow.
2. Choose **Create job**.
3. (Optional) For **Output KMS key**, specify an AWS KMS key to configure the output of the job.
4. Choose **Next, 2. Configure job**.
5. Select **Associate Schedules**.
6. Choose **Create a new schedule**.
7. For **Schedule Name**, specify the name of the schedule.
8. Choose **Create**.
9. (Optional) Choose **Add another schedule** to run the job on an additional schedule.

   **Note**
   You can associate a maximum of two schedules. The schedules are independent and don’t affect each other unless the times overlap.

10. Choose one of the following:
    - **Schedule and run now** – Data Wrangler the job runs immediately and subsequently runs on the schedules.
    - **Schedule only** – Data Wrangler the job only runs on the schedules that you specify.

11. Choose **Run**

You can use Amazon SageMaker Studio to view the jobs that are scheduled to run. Your processing jobs run within SageMaker Pipelines. Each processing job has its own pipeline. It runs as a processing step within the pipeline. You can view the schedules that you’ve created within a pipeline. For information about viewing a pipeline, see **View a Pipeline** (p. 3266).

Use the following procedure to view the jobs that you’ve scheduled.

To view the jobs you’ve scheduled, do the following.

1. Open Amazon SageMaker Studio.
2. Open SageMaker Pipelines
3. View the pipelines for the jobs that you’ve created.

   The pipeline running the job uses the job name as a prefix. For example, if you’ve created a job named housing-data-feature-engineering, the name of the pipeline is data-wrangler-housing-data-feature-engineering.
4. Choose the pipeline containing your job.
5. View the status of the pipelines. Pipelines with a **Status** of **Succeeded** have run the processing job successfully.
To stop the processing job from running, do the following:

To stop a processing job from running, delete the event rule that specifies the schedule. Deleting an event rule stops all the jobs associated with the schedule from running. For information about deleting a rule, see Disabling or deleting an Amazon EventBridge rule.

You can stop and delete the pipelines associated with the schedules as well. For information about stopping a pipeline, see StopPipelineExecution. For information about deleting a pipeline, see DeletePipeline.

Security and Permissions

When you query data from Athena or Amazon Redshift, the queried dataset is automatically stored in the default SageMaker S3 bucket for the AWS Region in which you are using Studio. Additionally, when you export a Jupyter Notebook from Amazon SageMaker Data Wrangler and run it, your data flows, or .flow files, are saved to the same default bucket, under the prefix data_wrangler_flows.

For high-level security needs, you can configure a bucket policy that restricts the AWS roles that have access to this default SageMaker S3 bucket. Use the following section to add this type of policy to an S3 bucket. To follow the instructions on this page, use the AWS Command Line Interface (AWS CLI). To learn how, see Configuring the AWS CLI in the IAM User Guide.

Additionally, you need to grant each IAM role that uses Data Wrangler permissions to access required resources. If you do not require granular permissions for the IAM role you use to access Data Wrangler, you can add the IAM managed policy, AmazonSageMakerFullAccess, to an IAM role that you use to create your Studio user. This policy grants you full permission to use Data Wrangler. If you require more granular permissions, refer to the section, Grant an IAM Role Permission to Use Data Wrangler (p. 967).

Add a Bucket Policy To Restrict Access to Datasets Imported to Data Wrangler

You can add a policy to the S3 bucket that contains your Data Wrangler resources using an Amazon S3 bucket policy. Resources that Data Wrangler uploads to your default SageMaker S3 bucket in the AWS Region you are using Studio in include the following:

- Queried Amazon Redshift results. These are stored under the redshift/ prefix.
- Queried Athena results. These are stored under the athena/ prefix.
- The .flow files uploaded to Amazon S3 when you run an exported Jupyter Notebook Data Wrangler produces. These are stored under the data_wrangler_flows/ prefix.

Use the following procedure to create an S3 bucket policy that you can add to restrict IAM role access to that bucket. To learn how to add a policy to an S3 bucket, see How do I add an S3 Bucket policy?.

To set up a bucket policy on the S3 bucket that stores your Data Wrangler resources:

1. Configure one or more IAM roles that you want to be able to access Data Wrangler.
2. Open a command prompt or shell. For each role that you create, replace role-name with the name of the role and run the following:

   $ aws iam get-role --role-name role-name

   In the response, you see a RoleId string which begins with AROA. Copy this string.
3. Add the following policy to the SageMaker default bucket in the AWS Region in which you are using Data Wrangler. Replace region with the AWS Region in which the bucket is located, and account-id with your AWS account ID. Replace userIds starting with AROAEXAMPLEID with the IDs of an AWS roles to which you want to grant permission to use Data Wrangler.
Grant an IAM Role Permission to Use Data Wrangler

You can grant an IAM role permission to use Data Wrangler with the general IAM managed policy, `AmazonSageMakerFullAccess`. This is a general policy that includes permissions required to use all SageMaker services. This policy grants an IAM role full access to Data Wrangler. You should be aware of the following when using `AmazonSageMakerFullAccess` to grant access to Data Wrangler:

- If you import data from Amazon Redshift, the **Database User** name must have the prefix `sagemaker_access`.
- This managed policy only grants permission to access buckets with one of the following in the name: SageMaker, SageMaker, sagemaker, or aws-glue. If want to use Data Wrangler to import from an S3 bucket without these phrases in the name, refer to the last section on this page to learn how to grant permission to an IAM entity to access your S3 buckets.

If you have high-security needs, you can attach the policies in this section to an IAM entity to grant permissions required to use Data Wrangler.

If you have datasets in Amazon Redshift or Athena that an IAM role needs to import from Data Wrangler, you must add a policy to that entity to access these resources. The following policies are the most restrictive policies you can use to give an IAM role permission to import data from Amazon Redshift and Athena.

To learn how to attach a custom policy to an IAM role, refer to Managing IAM policies in the IAM User Guide.

**Policy example to grant access to an Athena dataset import**

The following policy assumes that the IAM role has permission to access the underlying S3 bucket where data is stored through a separate IAM policy.
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "athena:ListDataCatalogs",
        "athena:ListDatabases",
        "athena:ListTableMetadata",
        "athena:GetQueryExecution",
        "athena:GetQueryResults",
        "athena:StartQueryExecution",
        "athena:StopQueryExecution"
      ],
      "Resource": [
        "*

        "arn:aws:glue::*:database/sagemaker_featurestore",
        "arn:aws:glue::*:database/sagemaker_processing",
        "arn:aws:glue::*:database/default",
        "arn:aws:glue::*:table/sagemaker_featurestore/**"
      ]
    }
  ]
}
Policy example to grant access to an Amazon Redshift dataset import

The following policy grants permission to set up an Amazon Redshift connection to Data Wrangler using database users that have the prefix `sagemaker_access` in the name. To grant permission to connect using additional database users, add additional entries under "Resources" in the following policy. The following policy assumes that the IAM role has permission to access the underlying S3 bucket where data is stored through a separate IAM policy, if applicable.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "redshift-data:ExecuteStatement",
                "redshift-data:DescribeStatement",
                "redshift-data:CancelStatement",
                "redshift-data:GetStatementResult",
                "redshift-data:ListSchemas",
                "redshift-data:ListTables"
            ],
            "Resource": ["*"]
        },
        {
            "Effect": "Allow",
            "Action": ["redshift:GetClusterCredentials"],
            "Resource": ["arn:aws:redshift:*:*:dbuser:*/sagemaker_access*", "arn:aws:redshift:*:*:dbname:*"]
        }
    ]
}
```

Policy to grant access to an S3 bucket

If your dataset is stored in Amazon S3, you can grant an IAM role permission to access this bucket with a policy similar to the following. This example grants programmatic read-write access to the bucket named `test`.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["s3:ListBucket"],
            "Resource": ["arn:aws:s3:::test"]
        },
        {
            "Effect": "Allow",
            "Action": ["s3:PutObject", "s3:GetObject"]
        }
    ]
}
```
To import data from Athena and Amazon Redshift, you must grant an IAM role permission to access the following prefixes under the default Amazon S3 bucket in the AWS Region Data Wrangler in which is being used: athena/, redshift/. If a default Amazon S3 bucket does not already exist in the AWS Region, you must also give the IAM role permission to create a bucket in this region.

Additionally, if you want the IAM role to be able to use the Amazon SageMaker Feature Store, SageMaker Pipelines, and Data Wrangler job export options, you must grant access to the prefix data_wrangler_flows/ in this bucket.

Data Wrangler uses the athena/ and redshift/ prefixes to store preview files and imported datasets. To learn more, see Imported Data Storage (p. 863).

Data Wrangler uses the data_wrangler_flows/ prefix to store .flow files when you run a Jupyter Notebook exported from Data Wrangler. To learn more, see Export (p. 945).

Use a policy similar to the following to grant the permissions described in the preceding paragraphs.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["s3:GetObject", "s3:PutObject"],
        },
        {
            "Effect": "Allow",
            "Action": ["s3:CreateBucket", "s3:ListBucket"],
            "Resource": "arn:aws:s3:::sagemaker-region-account-id"
        },
        {
            "Effect": "Allow",
            "Action": ["s3:ListAllMyBuckets", "s3:GetBucketLocation"],
            "Resource": "*"
        }
    ]
}
```

You can also access data in your Amazon S3 bucket from another AWS account by specifying the Amazon S3 bucket URI. To do this, the IAM policy that grants access to the Amazon S3 bucket in the other
account should use a policy similar to the following example, where BucketFolder is the specific directory in the user's bucket UserBucket. This policy should be added to the user granting access to their bucket for another user.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject",
                "s3:PutObject",
                "s3:PutObjectAcl"
            ],
            "Resource": "arn:aws:s3:::UserBucket/BucketFolder/*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:ListBucket"
            ],
            "Resource": "arn:aws:s3:::UserBucket",
            "Condition": {
                "StringLike": {
                    "s3:prefix": [
                        "BucketFolder/*"
                    ]
                }
            }
        }
    ]
}
```

The user that is accessing the bucket (not the bucket owner) must add a policy similar to the following example to their user. Note that AccountX and TestUser below refers to the bucket owner and their user respectively.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::AccountX:user/TestUser"
            },
            "Action": [
                "s3:GetObject",
                "s3:PutObject",
                "s3:PutObjectAcl"
            ],
            "Resource": ["arn:aws:s3:::UserBucket/BucketFolder/*"
        }
        ,
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::AccountX:user/TestUser"
            },
            "Action": [
                "s3:ListBucket"
            ],
            "Resource": ["arn:aws:s3:::UserBucket/BucketFolder/*"
        }
    ]
}
```

971
Policy example to grant access to use SageMaker Studio

Use a policy like the following to create an IAM execution role that can be used to set up a Studio instance.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "sagemaker:CreatePresignedDomainUrl",
        "sagemaker:DescribeDomain",
        "sagemaker:ListDomains",
        "sagemaker:DescribeUserProfile",
        "sagemaker:ListUserProfiles",
        "sagemaker:*App",
        "sagemaker:ListApps"
      ],
      "Resource": "*"
    }
  ]
}
```

Snowflake and Data Wrangler

All permissions for AWS resources are managed via your IAM role attached to your Studio instance. The Snowflake administrator manages Snowflake-specific permissions, as they can grant granular permissions and privileges to each Snowflake user. This includes databases, schemas, tables, warehouses, and storage integration objects. You must ensure that the correct permissions are set up outside of Data Wrangler.

Note that the Snowflake COPY INTO Amazon S3 command moves data from Snowflake to Amazon S3 over the public internet by default, but data in transit is secured using SSL. Data at rest in Amazon S3 is encrypted with SSE-KMS using the default AWS KMS key.

With respect to Snowflake credentials storage, Data Wrangler does not store customer credentials. Data Wrangler uses Secrets Manager to store the credentials in a secret and rotates secrets as part of a best practice security plan. The Snowflake or Studio administrator needs to ensure that the data scientist’s Studio execution role is granted permission to perform GetSecretValue on the secret storing the credentials. If already attached to the Studio execution role, the AmazonSageMakerFullAccess policy has the necessary permissions to read secrets created by Data Wrangler and secrets created by following the naming and tagging convention in the instructions above. Secrets that do not follow the conventions must be separately granted access. We recommend using Secrets Manager to prevent sharing credentials over unsecured channels; however, note that a logged-in user can retrieve the plain-text password by launching a terminal or Python notebook in Studio and then invoking API calls from the Secrets Manager API.

Data Encryption with AWS KMS

Within Data Wrangler, you can decrypt encrypted files and add them to your Data Wrangler flow. You can also encrypt the output of the transforms using either a default AWS KMS key or one that you provide.
You can import files if they have the following:

- server-side encryption
- SSE-KMS as the encryption type

To decrypt the file and import to a Data Wrangler flow, you must add the SageMaker Studio user that you’re using as a key user.

The following screenshot shows a Studio user role added as a key user. See IAM Roles to access users under the left panel to make this change.

![Key users](image)

**Amazon S3 customer managed key setup for Data Wrangler imported data storage**

By default, Data Wrangler uses Amazon S3 buckets that have the following naming convention: `sagemaker-region-account number`. For example, if your account number is `111122223333` and you are using Studio in us-east-1, your imported datasets are stored with the following naming convention: `sagemaker-us-east-1-111122223333`.

The following instructions explain how to set up a customer managed key for your default Amazon S3 bucket.

1. To enable server-side encryption and setup a customer managed key for your default S3 bucket, see Using KMS Encryption.
2. After following step 1, navigate to AWS KMS in your AWS Management Console. Find the customer managed key you selected in step 1 of the previous step and add the Studio role as the key user. To do this, follow the instructions in Allows key users to use a customer managed key.

**Encrypting the Data That You Export**

You can encrypt the data that you export using one of the following methods:

- Specifying that your Amazon S3 bucket has object use SSE-KMS encryption.
- Specifying an AWS KMS key to encrypt the data that you export from Data Wrangler.

On the Export data page, specify a value for the AWS KMS key ID or ARN.

For more information on using AWS KMS keys, see Protecting Data Using Server-Side Encryption with AWS KMS keys Stored in AWS Key Management Service (SSE-KMS).
Using Lifecycle Configurations in Data Wrangler

You might have an Amazon EC2 instance that is configured to run Kernel Gateway applications, but not the Data Wrangler application. Kernel Gateway applications provide access to the environment and the kernels that you use to run Studio notebooks and terminals. The Data Wrangler application is the UI application that runs Data Wrangler. Amazon EC2 instances that aren't Data Wrangler instances require a modification to their lifecycle configurations to run Data Wrangler. Lifecycle configurations are shell scripts that automate the customization of your Amazon SageMaker Studio environment.

For more information about lifecycle configurations, see Use Lifecycle Configurations with Amazon SageMaker Studio (p. 167).

The default lifecycle configuration for your instance doesn't support using Data Wrangler. You can make the following modifications to the default configuration to use Data Wrangler with your instance.

```bash
#!/bin/bash
set -eux
STATUS=$(python3 -c "import sagemaker_dataprep; echo $?"
if [ "$STATUS" -eq 0 ]; then
  echo 'Instance is of Type Data Wrangler'
else
  echo 'Instance is not of Type Data Wrangler'

# Replace this with the URL of your git repository
export REPOSITORY_URL="https://github.com/aws-samples/sagemaker-studio-lifecycle-config-examples.git"
git -C /root clone $REPOSITORY_URL
fi
```

You can save the script as lifecycle_configuration.sh.

You attach the lifecycle configuration to your Studio domain or user profile. For more information about creating and attaching a lifecycle configuration, see Creating and Associating a Lifecycle Configuration (p. 168).

The following instructions show you how to attach a lifecycle configuration to a Studio domain or user profile.

You might run into errors when you’re creating or attaching a lifecycle configuration. For information about debugging lifecycle configuration errors, KernelGateway App failure (p. 174).

Release Notes

Data Wrangler is regularly updated with new features and bug fixes. To upgrade the version of Data Wrangler you are using in Studio, follow the instructions in Shut down and Update Studio Apps (p. 180).

<table>
<thead>
<tr>
<th>Release Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>10/12/2022</td>
</tr>
</tbody>
</table>

New functionality:
**Release Notes**

You can now reuse data flows for different data sets. For more information, see [Reusing Data Flows for Different Datasets](p. 938).

**10/05/2022**

New functionality:

You can now use Principal Component Analysis (PCA) as a transform. For more information, see [Reduce Dimensionality within a Dataset](p. 902).

**10/05/2022**

New functionality:

You can now refit parameters in your Data Wrangler flow. For more information, see [Export](p. 945).

**10/03/2022**

New functionality:

You can now deploy models from your Data Wrangler flow. For more information, see [Automatically Train Models on Your Data Flow](p. 888).

**9/20/2022**

New functionality:

You can now set data retention periods in Athena. For more information, see [Import data from Athena](p. 832).

**6/9/2022**

New functionality:

You can now use Amazon SageMaker Autopilot to train a model directly from your Data Wrangler flow. For more information, see [Automatically Train Models on Your Data Flow](p. 888).

**5/6/2022**

New functionality:

You can now use additional m5 and r5 instances. For more information, see [Instances](p. 864).

**4/27/2022**

New functionalities:

- You can now get a data quality report. For more information, see [Get Insights On Data and Data Quality](p. 875)
- You can now perform random sampling and stratified sampling. For more information, see [Sampling](p. 923).

**4/1/2022**

New functionality:

You can now use Databricks as a data source. For more information, see [Import data from Databricks (JDBC)](p. 839).
### Release Notes

**2/2/2022**

New functionalities:

- You can now export using destination nodes. For more information, see [Export](#).
- You can import ORC and JSON files. For more information about file types, see [Import](#).
- Data Wrangler now supports using the SMOTE transform. For more information, see [Balance Data](#).
- Data Wrangler now supports similarity encoding for categorical data. For more information, see [Similarity encode](#).
- Data Wrangler now supports unnesting JSON data. For more information, see [Unnest JSON Data](#).
- Data Wrangler now supports expanding the values of an array into separate columns. For more information, see [Explode Array](#).
- Data Wrangler now supports reaching out to the service team when you're having issues. For more information, see [Troubleshoot](#).
- Data Wrangler now supports editing and deleting steps in your data flow. For more information, see [Delete a Step from Your Data Flow](#) and [Edit a Step in Your Data Wrangler Flow](#).
- You can now perform transformations on multiple columns. For more information, see [Transform Data](#).
- Data Wrangler now supports cost allocation tags. For more information, see [Using Cost Allocation Tags](#).

**10/16/2021**

New functionality:

Data Wrangler now supports Athena workgroups. For more information, see [Import data from Athena](#).

**10/6/2021**

New functionality:

Data Wrangler now supports transforming time series data. For more information, see [Transform Time Series](#).

**7/15/2021**

New functionalities:

- [Snowflake and Data Wrangler](#) is now supported. You can use Snowflake as a data source in Data Wrangler.
- Added support for custom field delimiter in CSV. Now comma, colon, semicolon, pipe (|) and Tab are supported.
- Now you can export results directly to Amazon S3.
- Added a few new multicollinearity analyzers: Variance Inflation Factors, Principal Component Analysis and Lasso feature selection.

Enhancements:

- The analyze charts can no longer be could be packed with overlapping labels.
## Release Notes

### Bug Fixes:
- One-hot encoder handles empty string gracefully.
- Fixed crashes that occurred when a dataframe column name contained dots.

### 4/26/2021

### Enhancements:
- Added support for distributed processing Jobs. You can use multiple instances when running a processing job.
- Data Wrangler Processing job now automatically coalesces small outputs when estimated result size is less than 1 gigabytes.
- Data Wrangler Processing jobs now use 1.x as the authoritative container tag for future releases.

### Bug Fixes:
- Fixed rendering issues for faceted histogram.
- Fixed **Export to Processing Job** to support vector type columns.
- Fixed **Extract using regex** operator to return the first captured group if one or more exists in the regular expression or regex.

### 2/8/2021

### New Functionalities:
- Data Wrangler Flows supports multiple instances.
- Updated Export to Data Wrangler Job Notebook to use SageMaker SDK 2.20.0.
- Updated Export to Pipeline Notebook to use SageMaker SDK 2.20.0.
- Updated Export to Pipeline Notebook to add XGBoost training example as an optional step.

### Enhancements:
- To improve performance, importing CSV files that contain multiple lines in a single field is no longer supported.

### Bug Fixes:
- Fixed type inference issue in Quick model.
- Fixed the bias metric bug in bias reports.
- Fixed the Featurize text transform to work with columns with missing values.
- Fixed Histogram and Scatter plot built-in visualizations to work with datasets that contain array-like columns.
- Athena query now re-runs if the query execution ID has expired.
Troubleshoot

If an issue arises when using Amazon SageMaker Data Wrangler, we recommend you do the following:

- If an error message is provided, read the message and resolve the issue it reports if possible.
- Make sure the IAM role of your Studio user has the required permissions to perform the action. For more information, see Security and Permissions (p. 966).
- If the issue occurs when you are trying to import from another AWS service, such as Amazon Redshift or Athena, make sure that you have configured the necessary permissions and resources to perform the data import. For more information, see Import (p. 827).
- If you're still having issues, choose Get help at the top right of your screen to reach out to the Data Wrangler team. For more information, see the following images.
As a last resort, you can try restarting the kernel on which Data Wrangler is running.

1. Save and exit the .flow file for which you want to restart the kernel.
2. Select the Running Terminals and Kernels icon, as shown in the following image.

3. Select the Stop icon to the right of the .flow file for which you want to terminate the kernel, as shown in the following image.
Increase Amazon EC2 Instance Limit

You might see the following error message when you're using Data Wrangler: The following instance type is not available: ml.m5.4xlarge. Try selecting a different instance below.

The message can indicate that you need to select a different instance type, but it can also indicate that you don’t have enough Amazon EC2 instances to successfully run Data Wrangler on your workflow. You can increase the number of instances by using the following procedure.

To increase the number of instances, do the following.

1. Open the AWS Management Console.
2. In the search bar, specify Services Quotas.
3. Choose Service Quotas.
Update Data Wrangler

To update Data Wrangler to the latest release, first shut down the corresponding KernelGateway app from the Amazon SageMaker Studio control panel. After the KernelGateway app is shut down, restart it by opening a new or existing Data Wrangler flow in Studio. When you open a new or existing Data Wrangler flow, the kernel that starts contains the latest version of Data Wrangler.

Update your Studio and Data Wrangler instance

1. Navigate to your SageMaker Console.
2. Choose SageMaker and then Studio.
3. Choose your user name.
4. Under Apps, in the row displaying the App name, choose Delete app for the app that starts with sagemaker-data-wrangler, and for the JupyterServer app.
5. Choose Yes, delete app.
6. Type delete in the confirmation box.
7. Choose Delete.
8. Reopen your Studio instance. When you begin to create a Data Wrangler flow, your instance now uses the latest version of Data Wrangler.

Alternatively, if you are using a Data Wrangler application version that is not the latest version, and you have an existing Data Wrangler flow open, you are prompted to update your Data Wrangler application version in the Studio UI. The following screenshot shows this prompt.

Important
This updates the Data Wrangler kernel gateway app only. You still need to shut down the JupyterServer app in your user account. To do this, follow the preceding steps.
You can also choose Remind me later, in which case an Update button appears in the top-right corner of the screen.

**Shut Down Data Wrangler**

When you are not using Data Wrangler, it is important to shut down the instance on which it runs to avoid incurring additional fees.

To avoid losing work, save your data flow before shutting Data Wrangler down. To save your data flow in Studio, choose File and then choose Save Data Wrangler Flow. Data Wrangler automatically saves your data flow every 60 seconds.
Prepare Data at Scale with Studio Notebooks

Amazon SageMaker Studio gives data scientists, machine learning (ML) engineers, and general practitioners tools to perform data analytics and data preparation at scale. Analyzing, transforming, and preparing large amounts of data is a foundational step of any data science and ML workflow. SageMaker Studio comes with built-in integration of Amazon EMR and AWS Glue Interactive Sessions to handle your large-scale interactive data preparation and machine learning workflows, all within your Studio notebook.

Amazon EMR is a managed big data platform with resources to help you run petabyte-scale distributed data processing jobs using open-source analytics frameworks on AWS such as Apache Spark, Apache Hive, Presto, HBase, Flink, and Hudi among others. Data engineers and data scientists use Amazon
EMR for a wide variety of use cases, including big data analytics, what-if analyses, real time analytics, and data preparation for machine learning. Studio integration with Amazon EMR allows you to easily create, browse, discover, and connect to EMR clusters without leaving your Studio notebook. You can even monitor and debug your Spark workloads with one-click access to the Spark UI from within the notebook. You should consider EMR for your data preparation workloads if you want maximum control over hardware and software versions, containers, and big data processing applications.

AWS Glue Interactive Sessions is a serverless service that you can enlist to collect, transform, cleanse, and prepare data for storage in your data lakes and data pipelines. Glue Interactive Sessions provides an on-demand, serverless Apache Spark runtime environment that you can initialize in seconds on a dedicated Data Processing Unit (DPU) without having to worry about provisioning and managing complex compute cluster infrastructure. After initialization, you can quickly browse the Glue data catalog, run large queries, access data governed by AWS Lake Formation, and interactively analyze and prepare data using Spark, right in your Studio notebook. You can then use the prepared data to build, train, tune and deploy models using the purpose-built ML tools within SageMaker Studio. You should consider Glue Interactive Sessions for your data preparation workloads when you want a serverless Spark service with moderate control of configurability and flexibility.

Prepare Data using Amazon EMR

Data scientists and data engineers use Apache Spark, Hive, and Presto on Amazon EMR for fast data preparation. Studio comes with built-in integration of Amazon EMR, enabling you to perform petabyte-scale interactive data preparation and machine learning right in your Studio notebook. Within your notebook, you can visually browse, discover, and connect to Amazon EMR. After you connect, you can interactively explore, visualize, and prepare petabyte-scale data for machine learning (ML) using Apache Spark, Hive, and Presto. Amazon EMR can handle your ETL jobs, run large-scale model training, perform analyses, and handle reporting, among many other capabilities.

For guided instructions about how to connect to an Amazon EMR cluster from SageMaker Studio, see Create and manage Amazon EMR Clusters from SageMaker Studio to run interactive Spark and ML workloads.

Prerequisites

• You will need access to SageMaker Studio that is set up to use Amazon Virtual Private Cloud (Amazon VPC) mode.
  • To connect to Amazon EMR, Studio must be configured as Amazon VPC only mode. For more information, see Connect SageMaker Studio Notebooks to Resources in a Amazon VPC. For more information on how to onboard, see Onboard to SageMaker Domain.
  • All subnets used by SageMaker Studio must be private subnets.
  • If you use the sm-analytics utility to configure the SparkMagic kernel, follow one of these two prerequisites:
    • Make sure that the Amazon VPC interface endpoint is attached to all of the subnets used by SageMaker Studio.
    • Ensure that all of the subnets used by SageMaker Studio are routed to use a NAT gateway. For more information, see NAT gateways.
  • If either one of the following points apply to you, you must have Spark and Livy installed when using Amazon EMR.
    • Your Amazon EMR cluster is in the same Amazon VPC as Studio.
    • Your cluster is in a Amazon VPC that's connected to the Amazon VPC in Studio.
    • The security groups for both Amazon SageMaker Studio and Amazon EMR must allow access to and from each other.
    • Your Amazon EMR security group must open port 8998, so that Amazon SageMaker Studio can communicate with the Spark cluster through Livy. For more information about setting up the security group, see Build SageMaker notebooks backed by Spark in Amazon EMR.
To connect to an Amazon EMR cluster from Studio, you must first access SageMaker Studio. If you have not set up SageMaker Studio, follow the Get Started guide.

If you created a new domain during Studio setup, then discovering an Amazon EMR cluster from Studio should be available to you.

If you are reusing an existing domain, you must update both Studio and Studio applications. For detailed instructions, see Update Studio and Update Studio applications.

SageMaker Studio comes with built-in support to connect to EMR clusters in the following images and kernels:

- **Images:** Data Science, Data Science 2.0, SparkMagic, SparkAnalytics 1.0, PyTorch 1.8, TensorFlow 2.6
- **Kernel:** PySpark and Spark kernels for the SparkMagic image, Python 3 (IPython) for the Data Science, Data Science 2.0, PyTorch 1.8, TensorFlow 2.6 images.

If you want to connect to EMR clusters using another built-in image or your own image, follow instructions in Bring your own image (p. 985).

### Bring your own image

If you want to bring your own image, first install the following dependencies to your kernel. The following list shows `pip` commands with the library name that you will install.

```
pip install sparkmagic
pip install sagemaker-studio-sparkmagic-lib
pip install sagemaker-studio-analytics-extension
```

You can update the libraries from the previous list manually, if they are not the latest version.

If you want to connect to Amazon EMR with Kerberos authentication, you must install the kinit client. Depending on your OS, the command to install the kinit client can vary. To bring an Ubuntu (Debian based) image, use the `apt-get install -y -qq krb5-user` command.

### Discover Amazon EMR Clusters from Studio

From within Studio, data scientists and data engineers can easily discover, connect to, and manage Amazon EMR clusters. Your Amazon EMR clusters may be in the same AWS account as SageMaker Studio or they may be in a different AWS account. This section explains how to discover an Amazon EMR cluster that exists in the same account as SageMaker Studio. For information about discovering Amazon EMR clusters in a different AWS account, see Discover Amazon EMR Clusters Across Accounts (p. 988).

Before you can activate discovering functionality, you must add a required policy to your Studio execution role. After you add this policy, you can connect to an Amazon EMR cluster in Studio.

#### To add the required policy to your Studio execution role

1. Open the IAM console.
2. Select Roles in the left-side panel.
3. Find the Studio execution role that you will be using and select it.
4. Under the Permissions tab, select Attach policies.
5. Select Create policy.
6. Select JSON.
7. Copy and paste in the following policy. For more information on required permissions, see Required Permissions (p. 1016).

```json
{
   "Statement": [
      {
         "Action": [
            "elasticmapreduce:DescribeCluster",
            "elasticmapreduce:ListInstanceGroups"
         ],
         "Effect": "Allow",
         "Resource": [
            "arn:aws:elasticmapreduce:*:*:cluster/**"
         ]
      },
      {
         "Action": [
            "elasticmapreduce:ListClusters"
         ],
         "Effect": "Allow",
         "Resource": "*"
      }
   ],
   "Version": "2012-10-17"
}
```

8. Select Next: Tags.
9. Select Next: Review.
10. Enter a Name, Description, and Select Create policy.
Now you can log in to Studio. If this is your first time logging in, follow the instructions in Log in to Studio.
Discover Amazon EMR Clusters Across Accounts

If you want to discover Amazon EMR clusters in a different AWS account than the SageMaker Studio is in, you must specify the IAM role ARN in the remote account. This IAM role ARN must be assumed to list and describe Amazon EMR clusters. Specify this remote role in a file that’s named emr-discovery-iam-role-arns-DO_NOT_DELETE.json, and in a directory named .cross-account-configuration-DO_NOT_DELETE. You will find this in your home directory, located in the Amazon EFS Storage volume used by SageMaker Studio. You can automate this process by using Lifecycle Configuration (LCC) scripts. You can attach the LCC to your Studio domain or user profile. You have the option to set your LCC script to run by default when your Jupyter server starts.

The LCC script that you use must be a JupyterServer configuration. For more information on how to create and use your LCC script and how to attach it at the Domain and UserProfile level, see Use Lifecycle Configurations with Studio. For more information on required permissions, see Required Permissions (p. 1016).

1. The following is an example LCC script that you can use. To modify the script, populate the script with the following details. Make sure that you replace ASSUMABLE-ROLE and 123456789012 with your role name and account ID, respectively. There is a limit of one role name and account ID combination.

```bash
#!/bin/bash
set -eux
FILE_DIRECTORY="/home/sagemaker-user/.cross-account-configuration-DO_NOT_DELETE"
FILE_NAME="emr-discovery-iam-role-arns-DO_NOT_DELETE.json"
FILE="$FILE_DIRECTORY/$FILE_NAME"
mkdir -p $FILE_DIRECTORY
cat > "$FILE" <<- "EOF"
{
  "123456789012": "arn:aws:iam::123456789012:role/ASSUMABLE-ROLE"
}
EOF
```

Connect to an Amazon EMR Cluster from Studio

This guide explains how you can connect to an Amazon EMR cluster from SageMaker Studio with the PySpark kernel selected.

To connect Amazon EMR cluster with PySpark kernel selected

1. After you connect to Studio, if you have an existing Studio notebook instance, open that. Otherwise, to create a new notebook instance, select File, and then select New.
2. After you have an open Studio notebook instance, choose a kernel and instance.

   Note
   Only a subset of kernels can connect to an Amazon EMR cluster. The supported images are Data Science and SparkMagic. The supported kernels are PySpark from the SparkMagic image and Python3 (IPython) from the Data Science image. Studio supports both PySpark and Scala kernels.
To switch your kernel, select in the top right of the UI the currently selected kernel where a pop-up window appears. Then select a kernel of your choice from the kernel drop-down menu. Lastly, select the **Select** button to make your changes.
3. After you have selected your kernel of choice, select **Cluster**.
