3. Select one of the edge packaging jobs. Copy the Amazon S3 URI under **Model artifact** in the **Output configuration** section.
4. In the Amazon S3 console, navigate to the corresponding location, and check if you need to delete the model artifact. To delete the model artifact, select the Amazon S3 object and choose **Delete**.

---

**Optimize model performance using Neo**

Neo is a capability of Amazon SageMaker that enables machine learning models to train once and run anywhere in the cloud and at the edge.

If you are a first time user of SageMaker Neo, we recommend you check out the Getting Started with Edge Devices section to get step-by-step instructions on how to compile and deploy to an edge device.

**What is SageMaker Neo?**

Generally, optimizing machine learning models for inference on multiple platforms is difficult because you need to hand-tune models for the specific hardware and software configuration of each platform. If you want to get optimal performance for a given workload, you need to know the hardware architecture,
instruction set, memory access patterns, and input data shapes, among other factors. For traditional software development, tools such as compilers and profilers simplify the process. For machine learning, most tools are specific to the framework or to the hardware. This forces you into a manual trial-and-error process that is unreliable and unproductive.

Neo automatically optimizes Gluon, Keras, MXNet, PyTorch, TensorFlow, TensorFlow-Lite, and ONNX models for inference on Android, Linux, and Windows machines based on processors from Ambarella, ARM, Intel, Nvidia, NXP, Qualcomm, Texas Instruments, and Xilinx. Neo is tested with computer vision models available in the model zoos across the frameworks. SageMaker Neo supports compilation and deployment for two main platforms: cloud instances (including Inferentia) and edge devices.

For more information about supported frameworks and cloud instance types you can deploy to, see Supported Instance Types and Frameworks (p. 2709) for cloud instances.

For more information about supported frameworks, edge devices, operating systems, chip architectures, and common machine learning models tested by SageMaker Neo for edge devices, see Supported Frameworks, Devices, Systems, and Architectures (p. 2736) for edge devices.

How it Works

Neo consists of a compiler and a runtime. First, the Neo compilation API reads models exported from various frameworks. It converts the framework-specific functions and operations into a framework-agnostic intermediate representation. Next, it performs a series of optimizations. Then it generates binary code for the optimized operations, writes them to a shared object library, and saves the model definition and parameters into separate files. Neo also provides a runtime for each target platform that loads and executes the compiled model.

You can create a Neo compilation job from either the SageMaker console, the AWS Command Line Interface (AWS CLI), a Python notebook, or the SageMaker SDK. For information on how to compile a
model, see Use Neo to Compile a Model (p. 2695). With a few CLI commands, an API invocation, or a few clicks, you can convert a model for your chosen platform. You can deploy the model to a SageMaker endpoint or on an AWS IoT Greengrass device quickly.

Neo can optimize models with parameters either in FP32 or quantized to INT8 or FP16 bit-width.

Topics
- Use Neo to Compile a Model (p. 2695)
- Cloud Instances (p. 2709)
- Edge Devices (p. 2735)
- Troubleshoot Errors (p. 2753)

Use Neo to Compile a Model

This section shows how to create, describe, stop, and list compilation jobs. The following options are available in Amazon SageMaker Neo for managing the compilation jobs for machine learning models: the AWS Command Line Interface, the Amazon SageMaker console, or the Amazon SageMaker SDK.

Topics
- Prepare Model for Compilation (p. 2695)
- Compile a Model (AWS Command Line Interface) (p. 2701)
- Compile a Model (Amazon SageMaker Console) (p. 2704)
- Compile a Model (Amazon SageMaker SDK) (p. 2708)

Prepare Model for Compilation

SageMaker Neo requires machine learning models to satisfy specific input data shapes. The input shape required for compilation depends on the deep learning framework you use. Once your model input shape is correctly formatted, save your model according to the requirements below. Once you have a saved model, compress the model artifacts.

Topics
- What input data shapes does SageMaker Neo expect? (p. 2695)
- Saving Models for SageMaker Neo (p. 2697)

What input data shapes does SageMaker Neo expect?

Before you compile your model, make sure your model is formatted correctly. Neo expects the name and shape of the expected data inputs for your trained model with JSON format or list format. The expected inputs are framework specific.

Below are the input shapes SageMaker Neo expects:

Keras

Specify the name and shape (NCHW format) of the expected data inputs using a dictionary format for your trained model. Note that while Keras model artifacts should be uploaded in NHWC (channel-last) format, DataInputConfig should be specified in NCHW (channel-first) format. The dictionary formats required are as follows:

- For one input: `{'input_1':[1,3,224,224]}`
MXNet/ONNX

Specify the name and shape (NCHW format) of the expected data inputs using a dictionary format for your trained model. The dictionary formats required are as follows:

- For one input: `{ 'data': [1, 3, 1024, 1024] }`
- For two inputs: `{ 'var1': [1, 1, 28, 28], 'var2': [1, 1, 28, 28] }`

PyTorch

For a PyTorch model, you don't need to provide the name and shape of the expected data inputs if you meet both of the following conditions:

- You created your model definition file by using PyTorch 2.0 or later. For more information about how to create the definition file, see the PyTorch (p. 2699) section under Saving Models for SageMaker Neo.
- You are compiling your model for a cloud instance. For more information about the instance types that SageMaker Neo supports, see Supported Instance Types and Frameworks (p. 2709).

If you meet these conditions, SageMaker Neo gets the input configuration from the model definition file (.pt or .pth) that you create with PyTorch.

Otherwise, you must do the following:

Specify the name and shape (NCHW format) of the expected data inputs using a dictionary format for your trained model. Alternatively, you can specify the shape only using a list format. The dictionary formats required are as follows:

- For one input in dictionary format: `{ 'input0': [1, 3, 224, 224] }`
- For one input in list format: `[[1, 3, 224, 224]]`
- For two inputs in dictionary format: `{ 'input0': [1, 3, 224, 224], 'input1': [1, 3, 224, 224] }`
- For two inputs in list format: `[[1, 3, 224, 224], [1, 3, 224, 224]]`

TensorFlow

Specify the name and shape (NHWC format) of the expected data inputs using a dictionary format for your trained model. The dictionary formats required are as follows:

- For one input: `{ 'input': [1, 1024, 1024, 3] }`
- For two inputs: `{ 'data1': [1, 28, 28, 1], 'data2': [1, 28, 28, 1] }`

TFLite

Specify the name and shape (NHWC format) of the expected data inputs using a dictionary format for your trained model. The dictionary formats required are as follows:

- For one input: `{ 'input': [1, 224, 224, 3] }`

Note

SageMaker Neo only supports TensorFlow Lite for edge device targets. For a list of supported SageMaker Neo edge device targets, see the SageMaker Neo Devices (p. 2737) page. For a list of
supported SageMaker Neo cloud instance targets, see the SageMaker Neo Supported Instance Types and Frameworks (p. 2709) page.

**XGBoost**

An input data name and shape are not needed.

**Saving Models for SageMaker Neo**

The following code examples show how to save your model to make it compatible with Neo. Models must be packaged as compressed tar files (*.tar.gz).

**Keras**

Keras models require one model definition file (.h5).

There are two options for saving your Keras model in order to make it compatible for SageMaker Neo:

1. Export to .h5 format with `model.save("<model-name>", save_format="h5")`.
2. Freeze the SavedModel after exporting.

Below is an example of how to export a `tf.keras` model as a frozen graph (option two):

```python
import os
import tensorflow as tf
from tensorflow.keras.applications.resnet50 import ResNet50
from tensorflow.keras import backend

tf.keras.backend.set_learning_phase(0)
model = tf.keras.applications.ResNet50(weights='imagenet', include_top=False, input_shape=(224, 224, 3), pooling='avg')
model.summary()

# Save as a SavedModel
export_dir = 'saved_model/'
model.save(export_dir, save_format='tf')

# Freeze saved model
input_node_names = [inp.name.split(':')[0] for inp in model.inputs]
output_node_names = [output.name.split(':')[0] for output in model.outputs]
print("Input names: ", input_node_names)
with tf.Session() as sess:
    loaded = tf.saved_model.load(sess, export_dir=export_dir, tags=['serve'])
    frozen_graph = tf.graph_util.convert_variables_to_constants(sess, sess.graph.as_graph_def(), output_node_names)
    tf.io.write_graph(graph_or_graph_def=frozen_graph, logdir=".", name="frozen_graph.pb", as_text=False)

import tarfile
tar = tarfile.open("frozen_graph.tar.gz", "w:gz")
tar.add("frozen_graph.pb")
tar.close()
```

**Warning**

Do not export your model with the SavedModel class using `model.save(<path>, save_format='tf')`. This format is suitable for training, but it is not suitable for inference.

**MXNet**

MXNet models must be saved as a single symbol file *-symbol.json and a single parameter *-params files.
Gluon Models

Define the neural network using the HybridSequential Class. This will run the code in the style of symbolic programming (as opposed to imperative programming).

```python
from mxnet import nd, sym
from mxnet.gluon import nn

def get_net():
    net = nn.HybridSequential()  # Here we use the class HybridSequential.
    net.add(nn.Dense(256, activation='relu'),
            nn.Dense(128, activation='relu'),
            nn.Dense(2))
    net.initialize()
    return net

# Define an input to compute a forward calculation.
x = nd.random.normal(shape=(1, 512))
net = get_net()

# During the forward calculation, the neural network will automatically infer
# the shape of the weight parameters of all the layers based on the shape of
# the input.
net(x)

# hybridize model
net.hybridize()
net(x)

# export model
net.export('my_model')  # this will create model-symbol.json and model-0000.params

import tarfile

tar = tarfile.open('my_model.tar.gz', 'w:gz')
for name in ['my_model-0000.params', 'my_model-symbol.json']:
    tar.add(name)
tar.close()

For more information about hybridizing models, see the MXNet hybridize documentation.

Gluon Model Zoo (GluonCV)

GluonCV model zoo models come pre-hybridized. So you can just export them.

```python
import numpy as np
import mxnet as mx
import gluoncv as gcv
from gluoncv.utils import export_block
import tarfile

net = gcv.model_zoo.get_model('my_model', pretrained=True)  # For example, choose
# my_model as resnet18_v1
export_block('my_model', net, preprocess=True, layout='HWC')

tar = tarfile.open('my_model.tar.gz', 'w:gz')
for name in ['my_model-0000.params', 'my_model-symbol.json']:
    tar.add(name)
tar.close()
Non Gluon Models

All non-Gluon models when saved to disk use *-symbol and *.params files. They are therefore already in the correct format for Neo.

```python
# Pass the following 3 parameters: sym, args, aux
mx.model.save_checkpoint('<model_name>', 0, sym, args, aux)  # this will create
              '<model_name>-symbol.json and <model_name>-0000.params files

import tarfile
tar = tarfile.open("<model_name>.tar.gz", "w:gz")

for name in ["<model_name>-0000.params", "<model_name>-symbol.json"]:
    tar.add(name)
tar.close()
```

PyTorch

PyTorch models must be saved as a definition file (.pt or .pth) with input datatype of float32.

To save your model, use the `torch.jit.trace` method followed by the `torch.save` method. This process saves an object to a disk file and by default uses python pickle (pickle_module=pickle) to save the objects and some metadata. Next, convert the saved model to a compressed tar file.

```python
import torchvision
import torch

model = torchvision.models.resnet18(pretrained=True)
model.eval()
inp = torch.rand(1, 3, 224, 224)
model_trace = torch.jit.trace(model, inp)

# Save your model. The following code saves it with the .pth file extension
model_trace.save('model.pth')

# Save as a compressed tar file
import tarfile
with tarfile.open('model.tar.gz', 'w:gz') as f:
    f.add('model.pth')
f.close()
```

If you save your model with PyTorch 2.0 or later, SageMaker Neo derives the input configuration for the model (the name and shape for its input) from the definition file. In that case, you don't need to specify the data input configuration to SageMaker when you compile the model.

If you want to prevent SageMaker Neo from deriving the input configuration, you can set the `_store_inputs` parameter of `torch.jit.trace` to False. If you do this, you must specify the data input configuration to SageMaker when you compile the model.

For more information about the `torch.jit.trace` method, see `TORCH.JIT.TRACE` in the PyTorch documentation.

TensorFlow

TensorFlow requires one .pb or one .pbtxt file and a variables directory that contains variables. For frozen models, only one .pb or .pbtxt file is required.

The following code example shows how to use the `tar` Linux command to compress your model. Run the following in your terminal or in a Jupyter notebook (if you use a Jupyter notebook, insert the ! magic command at the beginning of the statement):
# Download SSD_Mobilenet trained model
!wget http://download.tensorflow.org/models/object_detection/ssd_mobilenet_v2_coco_2018_03_29.tar.gz

# unzip the compressed tar file
!tar xvf ssd_mobilenet_v2_coco_2018_03_29.tar.gz

# Compress the tar file and save it in a directory called 'model.tar.gz'
!tar czvf model.tar.gz ssd_mobilenet_v2_coco_2018_03_29/frozen_inference_graph.pb

The command flags used in this example accomplish the following:

- c: Create an archive
- z: Compress the archive with gzip
- v: Display archive progress
- f: Specify the filename of the archive

## Built-In Estimators

Built-in estimators are either made by framework-specific containers or algorithm-specific containers. Estimator objects for both the built-in algorithm and framework-specific estimator saves the model in the correct format for you when you train the model using the built-in `.fit` method.

For example, you can use a `sagemaker.TensorFlow` to define a TensorFlow estimator:

```python
from sagemaker.tensorflow import TensorFlow

estimator = TensorFlow(entry_point='mnist.py',
                       role=role,  # param role can be arn of a sagemaker execution role
                       framework_version='1.15.3',
                       py_version='py3',
                       training_steps=1000,
                       evaluation_steps=100,
                       instance_count=2,
                       instance_type='ml.c4.xlarge')
```

Then train the model with `.fit` built-in method:

```python
estimator.fit(inputs)
```

Before finally compiling model with the build in `compile_model` method:

```python
# Specify output path of the compiled model
output_path = '/'.join(estimator.output_path.split('/').split('/')[::-1])

# Compile model
optimized_estimator = estimator.compile_model(target_instance_family='ml_c5',
                                               input_shape={'data':[1, 784]},  # Batch size 1, 3 channels,
                                               output_path=output_path,
                                               framework='tensorflow', framework_version='1.15.3')
```

You can also use the `sagemaker.Estimator.Estimator` Class to initialize an estimator object for training and compiling a built-in algorithm with the `compile_model` method from the SageMaker Python SDK:

```python
import sagemaker
from sagemaker.image_uris import retrieve
```
sagemaker_session = sagemaker.Session()
aws_region = sagemaker_session.boto_region_name

# Specify built-in algorithm training image
training_image = retrieve(framework='image-classification',
    region=aws_region, image_scope='training')

training_image = retrieve(framework='image-classification', region=aws_region,
    image_scope='training')

# Create estimator object for training
estimator = sagemaker.estimator.Estimator(image_uri=training_image,
    role=role, # param role can be arn of a sagemaker execution role
    instance_count=1,
    instance_type='ml.p3.8xlarge',
    volume_size = 50,
    max_run = 360000,
    input_mode= 'File',
    output_path=s3_training_output_location,
    base_job_name='image-classification-training')

# Setup the input data_channels to be used later for training.
train_data = sagemaker.inputs.TrainingInput(s3_training_data_location,
    content_type='application/x-recordio',
    s3_data_type='S3Prefix')
validation_data = sagemaker.inputs.TrainingInput(s3_validation_data_location,
    content_type='application/x-recordio',
    s3_data_type='S3Prefix')
data_channels = {'train': train_data, 'validation': validation_data}

# Train model
estimator.fit(inputs=data_channels, logs=True)

# Compile model with Neo
optimized_estimator = estimator.compile_model(target_instance_family='ml_c5',
    input_shape={'data':[1, 3, 224, 224],
              'softmax_label':[1]},
    output_path=s3_compilation_output_location,
    framework='mxnet',
    framework_version='1.7')

For more information about compiling models with the SageMaker Python SDK, see Compile a Model (Amazon SageMaker SDK) (p. 2708).

Compile a Model (AWS Command Line Interface)

This section shows how to manage Amazon SageMaker Neo compilation jobs for machine learning models using AWS Command Line Interface (CLI). You can create, describe, stop, and list the compilation jobs.

1. Create a Compilation Job

   With the `CreateCompilationJob` API operation, you can specify the data input format, the S3 bucket in which to store your model, the S3 bucket to which to write the compiled model, and the target hardware device or platform.

   The following table demonstrates how to configure CreateCompilationJob API based on whether your target is a device or a platform.
Device Example

```
{
    "CompilationJobName": "neo-compilation-job-demo",
    "RoleArn": "arn:aws:iam::<your-account>:role/service-role/AmazonSageMaker-ExecutionRole-yyyymmddThhmmss",
    "InputConfig": {
        "S3Uri": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/train",
        "DataInputConfig": "{'data': [1,3,1024,1024]}",
        "Framework": "MXNET"
    },
    "OutputConfig": {
        "S3OutputLocation": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/compile",
        "TargetDevice": "ml_c5"
    },
    "StoppingCondition": {
        "MaxRuntimeInSeconds": 300
    }
}
```

You can optionally specify the framework version you used with the `FrameworkVersion` field if you used the PyTorch framework to train your model and your target device is a `ml_*` target.

```
{
    "CompilationJobName": "neo-compilation-job-demo",
    "RoleArn": "arn:aws:iam::<your-account>:role/service-role/AmazonSageMaker-ExecutionRole-yyyymmddThhmmss",
    "InputConfig": {
        "S3Uri": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/train",
        "DataInputConfig": "{'data': [1,3,1024,1024]}",
        "Framework": "PYTORCH",
        "FrameworkVersion": "1.6"
    },
    "OutputConfig": {
        "S3OutputLocation": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/compile",
        "TargetDevice": "ml_c5"
    },
    "StoppingCondition": {
        "MaxRuntimeInSeconds": 300
    }
}
```

Notes:

- If you saved your model by using PyTorch version 2.0 or later, the `DataInputConfig` field is optional. SageMaker Neo gets the input configuration from the model definition file that you create with PyTorch. For more information about how to create the definition file, see the PyTorch (p. 2699) section under Saving Models for SageMaker Neo.
• This API field is only supported for PyTorch.

Platform Example

```
{
    "CompilationJobName": "neo-test-compilation-job",
    "RoleArn": "arn:aws:iam::<your-account>:role/service-role/AmazonSageMaker-
                ExecutionRole-yyyymmddThhmmss",
    "InputConfig": {
        "S3Uri": "s3://<your-bucket>/sagemaker/neo- compilation-job-demo-data/
                train",
        "DataInputConfig": "{'data': [1,3,1024,1024]}",
        "Framework": "MXNET"
    },
    "OutputConfig": {
        "S3OutputLocation": "s3://<your-bucket>/sagemaker/neo- compilation-job-demo-
                    data/compile",
        # A target platform configuration example for a p3.2xlarge instance
        "TargetPlatform": {
            "Os": "LINUX",
            "Arch": "X86_64",
            "Accelerator": "NVIDIA"
        },
        "CompilerOptions": "{'cuda-ver': '10.0', 'trt-ver': '6.0.1', 'gpu-code':
            'sm_70'}"
    },
    "StoppingCondition": {
        "MaxRuntimeInSeconds": 300
    }
}
```

**Note**

For the OutputConfig API operation, the TargetDevice and TargetPlatform API operations are mutually exclusive. You have to choose one of the two options.

To find the JSON string examples of DataInputConfig depending on frameworks, see [What input data shapes Neo expects](#).

For more information about setting up the configurations, see the [InputConfig](#), [OutputConfig](#), and [TargetPlatform](#) API operations in the SageMaker API reference.

2. After you configure the JSON file, run the following command to create the compilation job:

```
aws sagemaker create-compilation-job \
--cli-input-json file://job.json \
--region us-west-2
```

   # You should get CompilationJobArn

3. Describe the compilation job by running the following command:

```
aws sagemaker describe-compilation-job \
--compilation-job-name $JOB_NM \
--region us-west-2
```

4. Stop the compilation job by running the following command:

```
aws sagemaker stop-compilation-job \
--compilation-job-name $JOB_NM \
--region us-west-2
```
5. List the compilation job by running the following command:

```bash
aws sagemaker list-compilation-jobs \
--region us-west-2
```

**Compile a Model (Amazon SageMaker Console)**

You can create an Amazon SageMaker Neo compilation job in the Amazon SageMaker console.

1. In the **Amazon SageMaker** console, choose **Compilation jobs**, and then choose **Create compilation job**.

2. On the **Create compilation job** page, under **Job name**, enter a name. Then select an **IAM role**.

3. If you don’t have an IAM role, choose **Create a new role**.
4. On the Create an IAM role page, choose Any S3 bucket, and choose Create role.

5. Non PyTorch Frameworks

Within the Input configuration section, enter the full path of the Amazon S3 bucket URI that contains your model artifacts in the Location of model artifacts input field. Your model artifacts must be in a compressed tarball file format (.tar.gz).

For the Data input configuration field, enter the JSON string that specifies the shape of the input data.

For Machine learning framework, choose the framework of your choice.
To find the JSON string examples of input data shapes depending on frameworks, see [What input data shapes Neo expects](#).

**PyTorch Framework**

Similar instructions apply for compiling PyTorch models. However, if you trained with PyTorch and are trying to compile the model for `ml_*` (except `ml_inf`) target, you can optionally specify the version of PyTorch you used.

To find the JSON string examples of input data shapes depending on frameworks, see [What input data shapes Neo expects](#).

**Notes**

- If you saved your model by using PyTorch version 2.0 or later, the Data input configuration field is optional. SageMaker Neo gets the input configuration from the model definition file that you create with PyTorch. For more information about how to create the definition file, see the [PyTorch](p. 2699) section under [Saving Models for SageMaker Neo](#).

- When compiling for `ml_*` instances using PyTorch framework, use Compiler options field in Output Configuration to provide the correct data type (dtype) of the model's input. The default is set to "float32".
Warning
If you specify a Amazon S3 bucket URI path that leads to .pth file, you will receive the following error after starting compilation: ClientError: InputConfiguration: Unable to untar input model. Please confirm the model is a tar.gz file.

6. Go to the Output configuration section. Choose where you want to deploy your model. You can deploy your model to a Target device or a Target platform. Target devices include cloud and edge devices. Target platforms refer to specific OS, architecture, and accelerators you want your model to run on.

For S3 Output location, enter the path to the S3 bucket where you want to store the model. You can optionally add compiler options in JSON format under the Compiler options section.
7. Check the status of the compilation job when started. This status of the job can be found at the top of the Compilation Job page, as shown in the following screenshot. You can also check the status of it in the Status column.

8. Check the status of the compilation job when completed. You can check the status in the Status column as shown in the following screenshot.

### Compile a Model (Amazon SageMaker SDK)

You can use the `compile_model` API in the Amazon SageMaker SDK for Python to compile a trained model and optimize it for specific target hardware. The API should be invoked on the estimator object used during model training.

**Note**

You must set MMS_DEFAULT_RESPONSE_TIMEOUT environment variable to 500 when compiling the model with MXNet or PyTorch. The environment variable is not needed for TensorFlow.

The following is an example of how you can compile a model using the `trained_model_estimator` object:

```python
# Replace the value of expected_trained_model_input below and
# specify the name & shape of the expected inputs for your trained model
# in json dictionary form
expected_trained_model_input = {'data':[1, 784]}

# Replace the example target_instance_family below to your preferred target_instance_family
compiled_model = trained_model_estimator.compile_model(target_instance_family='ml_c5',
    input_shape=expected_trained_model_input,
    output_path='insert s3 output path',
    env={'MMS_DEFAULT_RESPONSE_TIMEOUT': '500'})
```
The code compiles the model, saves the optimized model at output_path, and creates a SageMaker model that can be deployed to an endpoint. Sample notebooks of using the SDK for Python are provided in the Neo Model Compilation Sample Notebooks section.

Cloud Instances

Amazon SageMaker Neo provides compilation support for popular machine learning frameworks such as TensorFlow, PyTorch, MXNet, and more. You can deploy your compiled model to cloud instances and AWS Inferentia instances. For a full list of supported frameworks and instances types, see Supported Instances Types and Frameworks.

You can compile your model in one of three ways: through the AWS CLI, the SageMaker Console, or the SageMaker SDK for Python. See, Use Neo to Compile a Model for more information. Once compiled, your model artifacts are stored in the Amazon S3 bucket URI you specified during the compilation job. You can deploy your compiled model to cloud instances and AWS Inferentia instances using the SageMaker SDK for Python, AWS SDK for Python (Boto3), AWS CLI, or the AWS console.

If you deploy your model using AWS CLI, the console, or Boto3, you must select a Docker image Amazon ECR URI for your primary container. See Neo Inference Container Images for a list of Amazon ECR URIs.

Topics
- Supported Instance Types and Frameworks (p. 2709)
- Deploy a Model (p. 2712)
- Request Inferences from a Deployed Service (p. 2729)
- Inference Container Images (p. 2732)

Supported Instance Types and Frameworks

Amazon SageMaker Neo supports popular deep learning frameworks for both compilation and deployment. You can deploy your model to cloud instances, AWS Inferentia instance types, or Amazon Elastic Inference accelerators.

The following describes frameworks SageMaker Neo supports and the target cloud instances you can compile and deploy to. For information on how to deploy your compiled model to a cloud or Inferentia instance, see Deploy a Model with Cloud Instances. For information on how to deploy your compiled model with Elastic Inference accelerators, see Use EI on Amazon SageMaker Hosted Endpoints (p. 2773).

Cloud Instances

SageMaker Neo supports the following deep learning frameworks for CPU and GPU cloud instances:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>MXNet</td>
<td>1.8.0</td>
<td>Supports 1.8.0 or earlier</td>
<td>Image Classification, Object Detection, Semantic Segmentation, Pose Estimation, Activity Recognition</td>
<td>One symbol file (.json) and one parameter file (.params)</td>
<td>GluonCV v0.8.0</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------------</td>
<td>--------------</td>
<td>--------</td>
<td>--------------------------------------</td>
<td>----------</td>
</tr>
<tr>
<td>ONNX</td>
<td>1.7.0</td>
<td>Supports 1.7.0 or earlier</td>
<td>Image Classification, SVM</td>
<td>One model file (.onnx)</td>
<td></td>
</tr>
<tr>
<td>Keras</td>
<td>2.2.4</td>
<td>Supports 2.2.4 or earlier</td>
<td>Image Classification</td>
<td>One model definition file (.h5)</td>
<td></td>
</tr>
<tr>
<td>PyTorch</td>
<td>1.4, 1.5, 1.6, 1.7, 1.8, 1.12, 1.13, or 2.0</td>
<td>Supports 1.4, 1.5, 1.6, 1.7, 1.8, 1.12, 1.13, and 2.0</td>
<td>Image Classification Versions 1.13 and 2.0 support Object Detection, Vision Transformer, and HuggingFace</td>
<td>One model definition file (.pt or .pth) with input dtype of float32</td>
<td></td>
</tr>
<tr>
<td>TensorFlow</td>
<td>1.15.3 or 2.9</td>
<td>Supports 1.15.3 and 2.9</td>
<td>Image Classification</td>
<td>For saved models, one .pb or one .pbtxt file and a variables directory that contains variables For frozen models, only one .pb or .pbtxt file</td>
<td></td>
</tr>
<tr>
<td>XGBoost</td>
<td>1.3.3</td>
<td>Supports 1.3.3 or earlier</td>
<td>Decision Trees</td>
<td>One XGBoost model file (.model) where the number of nodes in a tree is less than $2^{31}$</td>
<td></td>
</tr>
</tbody>
</table>

**Note**

"Model Version" is the version of the framework used to train and export the model.

**Instance Types**

You can deploy your SageMaker compiled model to one of the cloud instances listed below:

<table>
<thead>
<tr>
<th>Instance</th>
<th>Compute Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ml_c4</td>
<td>Standard</td>
</tr>
<tr>
<td>Instance</td>
<td>Compute Type</td>
</tr>
<tr>
<td>----------</td>
<td>--------------</td>
</tr>
<tr>
<td>ml_c5</td>
<td>Standard</td>
</tr>
<tr>
<td>ml_m4</td>
<td>Standard</td>
</tr>
<tr>
<td>ml_m5</td>
<td>Standard</td>
</tr>
<tr>
<td>ml_p2</td>
<td>Accelerated computing</td>
</tr>
<tr>
<td>ml_p3</td>
<td>Accelerated computing</td>
</tr>
<tr>
<td>ml_g4dn</td>
<td>Accelerated computing</td>
</tr>
</tbody>
</table>

For information on the available vCPU, memory, and price per hour for each instance type, see [Amazon SageMaker Pricing](https://aws.amazon.com/sagemaker/pricing/).

**Note**

When compiling for ml_* instances using PyTorch framework, use **Compiler options** field in **Output Configuration** to provide the correct data type (**dtype**) of the model's input. The default is set to "**float32**".

**AWS Inferentia**

SageMaker Neo supports the following deep learning frameworks for Inf1:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>MXNet</td>
<td>1.5 or 1.8</td>
<td>Supports 1.8, 1.5 and earlier</td>
<td>Image Classification, Object Detection, Semantic Segmentation, Pose Estimation, Activity Recognition</td>
<td>One symbol file (.json) and one parameter file (.params)</td>
<td>GluonCV v0.8.0</td>
</tr>
<tr>
<td>PyTorch</td>
<td>1.7, 1.8 or 1.9</td>
<td>Supports 1.9 and earlier</td>
<td>Image Classification</td>
<td>One model definition file (.pt or .pth) with input dtype of float32</td>
<td></td>
</tr>
<tr>
<td>TensorFlow</td>
<td>1.15 or 2.5</td>
<td>Supports 2.5, 1.15 and earlier</td>
<td>Image Classification</td>
<td>For saved models, one .pb or one .pbtxt file and a variables directory</td>
<td></td>
</tr>
</tbody>
</table>
## Cloud Instances

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>TensorFlow</td>
<td>2.3.2</td>
<td>Supports 2.3</td>
<td>Image Classification, Object Detection, Semantic Segmentation, Pose Estimation, Activity Recognition</td>
<td>For saved models, one .pb or one .pbtxt file and a variables directory that contains variables.</td>
<td>For frozen models, only one .pb or .pbtxt file.</td>
</tr>
</tbody>
</table>

**Note**

“Model Version” is the version of the framework used to train and export the model.

You can deploy your SageMaker Neo-compiled model to AWS Inferentia-based Amazon EC2 Inf1 instances. AWS Inferentia is Amazon's first custom silicon chip designed to accelerate deep learning. Currently, you can use the ml1.inf1 instance to deploy your compiled models.

**AWS Inferentia2 and AWS Trainium**

Currently, you can deploy your SageMaker Neo-compiled model to AWS Inferentia2-based Amazon EC2 Inf2 instances (in US East (Ohio) Region), and to AWS Trainium-based Amazon EC2 Trn1 instances (in US East (N. Virginia) Region). For more information about supported models on these instances, see [Model Architecture Fit Guidelines](#) in the AWS Neuron documentation, and the examples in the [Neuron Github repository](#).

**Amazon Elastic Inference**

SageMaker Neo supports the following deep learning frameworks for Elastic Inference:

You can deploy your SageMaker Neo-compiled model to an Elastic Inference Accelerator. For more information, see [Use EI on Amazon SageMaker Hosted Endpoints](#) (p. 2773).

### Deploy a Model

To deploy an Amazon SageMaker Neo-compiled model to an HTTPS endpoint, you must configure and create the endpoint for the model using Amazon SageMaker hosting services. Currently, developers can use Amazon SageMaker APIs to deploy modules on to ml.c5, ml.c4, ml.m5, ml.m4, ml.p3, ml.p2, and ml.inf1 instances.
For **Inferentia** and **Trainium** instances, models need to be compiled specifically for those instances. Models compiled for other instance types are not guaranteed to work with Inferentia or Trainium instances.

For **Elastic Inference accelerators**, models need to be compiled specifically for ml_eia2 devices. For information on how to deploy your compiled model to an Elastic Inference accelerator, see **Use EI on Amazon SageMaker Hosted Endpoints** (p. 2773).

When you deploy a compiled model, you need to use the same instance for the target that you used for compilation. This creates a SageMaker endpoint that you can use to perform inferences. You can deploy a Neo-compiled model using any of the following: **Amazon SageMaker SDK for Python**, **SDK for Python (Boto3)**, **AWS Command Line Interface**, and the **SageMaker console**.

**Note**
For deploying a model using AWS CLI, the console, or Boto3, see **Neo Inference Container Images** to select the inference image URI for your primary container.

**Topics**
- Prerequisites (p. 2713)
- Deploy a Compiled Model Using SageMaker SDK (p. 2719)
- Deploy a Compiled Model Using Boto3 (p. 2721)
- Deploy a Compiled Model Using the AWS CLI (p. 2723)
- Deploy a Compiled Model Using the Console (p. 2725)

**Prerequisites**

**Note**
Follow the instructions in this section if you compiled your model using AWS SDK for Python (Boto3), AWS CLI, or the SageMaker console.

To create a SageMaker Neo-compiled model, you need the following:

1. A Docker image Amazon ECR URI. You can select one that meets your needs from [this list](#).
2. An entry point script file:
   a. **For PyTorch and MXNet models:**

   *If you trained your model using SageMaker*, the training script must implement the functions described below. The training script serves as the entry point script during inference. In the example detailed in **MNIST Training, Compilation and Deployment with MXNet Module and SageMaker Neo**, the training script (mnist.py) implements the required functions.

   *If you did not train your model using SageMaker*, you need to provide an entry point script (inference.py) file that can be used at the time of inference. Based on the framework—MXNet or PyTorch—the inference script location must conform to the SageMaker Python SDK Model Directory Structure for MXNet or Model Directory Structure for PyTorch.

   When using Neo Inference Optimized Container images with **PyTorch** and **MXNet** on CPU and GPU instance types, the inference script must implement the following functions:

   - `model_fn`: Loads the model. (Optional)
   - `input_fn`: Converts the incoming request payload into a numpy array.
   - `predict_fn`: Performs the prediction.
   - `output_fn`: Converts the prediction output into the response payload.
   - Alternatively, you can define `transform_fn` to combine `input_fn`, `predict_fn`, and `output_fn`.

2713
The following are examples of `inference.py` script within a directory named `code` (`code/inference.py`) for **PyTorch and MXNet (Gluon and Module)**. The examples first load the model and then serve it on image data on a GPU:

**MXNet Module**

```python
import numpy as np
import json
import mxnet as mx
import neomx  # noqa: F401
from collections import namedtuple

Batch = namedtuple('Batch', ['data'])

# Change the context to mx.cpu() if deploying to a CPU endpoint
cxt = mx.gpu()

def model_fn(model_dir):
    # The compiled model artifacts are saved with the prefix 'compiled'
sym, arg_params, aux_params = mx.model.load_checkpoint('compiled', 0)
mod = mx.mod.Module(symbol=sym, context=cxt, label_names=None)
exe = mod.bind(for_training=False,
data_shapes=[('data', (1,3,224,224))],
label_shapes=mod._label_shapes)
mod.set_params(arg_params, aux_params, allow_missing=True)
# Run warm-up inference on empty data during model load (required for GPU)
data = mx.nd.empty((1,3,224,224), ctx=cxt)
mod.forward(Batch([data]))
return mod

def transform_fn(mod, image, input_content_type, output_content_type):
    # pre-processing
    decoded = mx.image.imdecode(image)
    resized = mx.image.resize_short(decoded, 224)
cropped, crop_info = mx.image.center_crop(resized, (224, 224))
normalized = mx.image.color_normalize(cropped.astype(np.float32) / 255,
    mean=mx.nd.array([0.485, 0.456, 0.406]),
    std=mx.nd.array([0.229, 0.224, 0.225]))
transposed = normalized.transpose((2, 0, 1))
batchified = transposed.expand_dims(axis=0)
casted = batchified.astype(dtype='float32')
processed_input = casted.as_in_context(cxt)
# prediction/inference
mod.forward(Batch([processed_input]))
# post-processing
prob = mod.get_outputs()[0].asnumpy().tolist()
prob_json = json.dumps(prob)
return prob_json, output_content_type
```

**MXNet Gluon**

```python
import numpy as np
import json
import mxnet as mx
import neomx  # noqa: F401
# Change the context to mx.cpu() if deploying to a CPU endpoint
```
ctx = mx.gpu()

def model_fn(model_dir):
    # The compiled model artifacts are saved with the prefix 'compiled'
    block = mx.gluon.nn.SymbolBlock.imports('compiled-symbol.json', ['data'], 'compiled-0000.params', ctx=ctx)

    # Hybridize the model & pass required options for Neo: static_alloc=True &
    # static_shape=True
    block.hybridize(static_alloc=True, static_shape=True)

    # Run warm-up inference on empty data during model load (required for GPU)
    data = mx.nd.empty((1,3,224,224), ctx=ctx)
    warm_up = block(data)
    return block

def input_fn(image, input_content_type):
    # pre-processing
    decoded = mx.image.imdecode(image)
    resized = mx.image.resize_short(decoded, 224)
    cropped, crop_info = mx.image.center_crop(resized, (224, 224))
    normalized = mx.image.color_normalize(cropped.astype(np.float32) / 255,
    mean=mx.nd.array([0.485, 0.456, 0.406]),
    std=mx.nd.array([0.229, 0.224, 0.225]))
    transposed = normalized.transpose((2, 0, 1))
    batchified = transposed.expand_dims(axis=0)
    casted = batchified.astype(dtype='float32')
    processed_input = casted.as_in_context(ctx)
    return processed_input

def predict_fn(processed_input_data, block):
    # prediction/inference
    prediction = block(processed_input_data)
    return prediction

def output_fn(prediction, output_content_type):
    # post-processing
    prob = prediction.asnumpy().tolist()
    prob_json = json.dumps(prob)
    return prob_json, output_content_type

PyTorch 1.4 and Older

import os
import torch

         transforms.Normalize(
             mean=[0.485, 0.456, 0.406],
             std=[0.229, 0.224, 0.225]),
        ])

    normalized = preprocess(decoded)
    batchified = normalized.unsqueeze(0)

    # predict
    device = torch.device("cuda" if torch.cuda.is_available() else "cpu")
    batchified = batchified.to(device)
    output = model.forward(batchified)
    return json.dumps(output.cpu().numpy().tolist()), response_content_type

b. For inf1 instances or onnx, xgboost, keras container images

For all other Neo Inference-optimized container images, or inferentia instance types, the entry
point script must implement the following functions for Neo Deep Learning Runtime:

- neo_preprocess: Converts the incoming request payload into a numpy array.
• neo_postprocess: Converts the prediction output from Neo Deep Learning Runtime into
the response body.

Note
The preceding two functions do not use any of the functionalities of MXNet, PyTorch,
or TensorFlow.

For examples of how to use these functions, see Neo Model Compilation Sample Notebooks.

C. For TensorFlow models

If your model requires custom pre- and post-processing logic before data is sent to the model,
then you must specify an entry point script inference.py file that can be used at the time
of inference. The script should implement either a either a pair of input_handler and
output_handler functions or a single handler function.

Note
Note that if handler function is implemented, input_handler and output_handler
are ignored.

The following is a code example of inference.py script that you can put together with the
compile model to perform custom pre- and post-processing on an image classification model.
The SageMaker client sends the image file as an application/x-image content type to the
input_handler function, where it is converted to JSON. The converted image file is then sent
to the Tensorflow Model Server (TFX) using the REST API.

```python
import json
import numpy as np
import json
import io
from PIL import Image

def input_handler(data, context):
    """ Pre-process request input before it is sent to TensorFlow Serving REST API

    Args:
    data (obj): the request data, in format of dict or string
    context (Context): an object containing request and configuration details

    Returns:
    (dict): a JSON-serializable dict that contains request body and headers
    """
    f = data.read()
    f = io.BytesIO(f)
    image = Image.open(f).convert('RGB')
    batch_size = 1
    image = np.asarray(image.resize((512, 512)))
    image = np.concatenate([image[np.newaxis, :, :]] * batch_size)
    body = json.dumps({"signature_name": "serving_default", "instances":
                       image.tolist()})
    return body

def output_handler(data, context):
    """Post-process TensorFlow Serving output before it is returned to the client.

    Args:
    data (obj): the TensorFlow serving response
    context (Context): an object containing request and configuration details

    Returns:
    (bytes, string): data to return to client, response content type
    """
```
If data.status_code != 200:
    raise ValueError(data.content.decode('utf-8'))

response_content_type = context.accept_header
prediction = data.content
return prediction, response_content_type

If there is no custom pre- or post-processing, the SageMaker client converts the file image to JSON in a similar way before sending it over to the SageMaker endpoint.

For more information, see the Deploying to TensorFlow Serving Endpoints in the SageMaker Python SDK.

3. The Amazon S3 bucket URI that contains the compiled model artifacts.

Deploy a Compiled Model Using SageMaker SDK

You must satisfy the prerequisites section if the model was compiled using AWS SDK for Python (Boto3), AWS CLI, or the Amazon SageMaker console. Follow one of the following use cases to deploy a model compiled with SageMaker Neo based on how you compiled your model.

Topics
- If you compiled your model using the SageMaker SDK (p. 2719)
- If you compiled your model using MXNet or PyTorch (p. 2719)
- If you compiled your model using Boto3, SageMaker console, or the CLI for TensorFlow (p. 2721)

If you compiled your model using the SageMaker SDK

The sagemaker.Model object handle for the compiled model supplies the deploy() function, which enables you to create an endpoint to serve inference requests. The function lets you set the number and type of instances that are used for the endpoint. You must choose an instance for which you have compiled your model. For example, in the job compiled in Compile a Model (Amazon SageMaker SDK) section, this is ml_c5.

predictor = compiled_model.deploy(initial_instance_count = 1, instance_type = 'ml.c5.4xlarge')

# Print the name of newly created endpoint
print(predictor.endpoint_name)

If you compiled your model using MXNet or PyTorch

Create the SageMaker model and deploy it using the deploy() API under the framework-specific Model APIs. For MXNet, it is MXNetModel and for PyTorch, it is PyTorchModel. When you are creating and deploying an SageMaker model, you must set MMS_DEFAULT_RESPONSE_TIMEOUT environment variable to 500 and specify the entry_point parameter as the inference script (inference.py) and the source_dir parameter as the directory location (code) of the inference script. To prepare the inference script (inference.py) follow the Prerequisites step.

The following example shows how to use these functions to deploy a compiled model using the SageMaker SDK for Python:

MXNet

```python
from sagemaker.mxnet import MXNetModel

# Create SageMaker model and deploy an endpoint
```
sm_mxnet_compiled_model = MXNetModel(
    model_data='insert S3 path of compiled MXNet model archive',
    role='AmazonSageMaker-ExecutionRole',
    entry_point='inference.py',
    source_dir='code',
    framework_version='1.8.0',
    py_version='py3',
    image_uri='insert appropriate ECR Image URI for MXNet',
    env={'MMS_DEFAULT_RESPONSE_TIMEOUT': '500'},
)

# Replace the example instance_type below to your preferred instance_type
predictor = sm_mxnet_compiled_model.deploy(initial_instance_count = 1, instance_type = 'ml.p3.2xlarge')

# Print the name of newly created endpoint
print(predictor.endpoint_name)

PyTorch 1.4 and Older

from sagemaker.pytorch import PyTorchModel

# Create SageMaker model and deploy an endpoint
sm_pytorch_compiled_model = PyTorchModel(
    model_data='insert S3 path of compiled PyTorch model archive',
    role='AmazonSageMaker-ExecutionRole',
    entry_point='inference.py',
    source_dir='code',
    framework_version='1.4.0',
    py_version='py3',
    image_uri='insert appropriate ECR Image URI for PyTorch',
    env={'MMS_DEFAULT_RESPONSE_TIMEOUT': '500'},
)

# Replace the example instance_type below to your preferred instance_type
predictor = sm_pytorch_compiled_model.deploy(initial_instance_count = 1, instance_type = 'ml.p3.2xlarge')

# Print the name of newly created endpoint
print(predictor.endpoint_name)

PyTorch 1.5 and Newer

from sagemaker.pytorch import PyTorchModel

# Create SageMaker model and deploy an endpoint
sm_pytorch_compiled_model = PyTorchModel(
    model_data='insert S3 path of compiled PyTorch model archive',
    role='AmazonSageMaker-ExecutionRole',
    entry_point='inference.py',
    source_dir='code',
    framework_version='1.5',
    py_version='py3',
    image_uri='insert appropriate ECR Image URI for PyTorch',
)

# Replace the example instance_type below to your preferred instance_type
predictor = sm_pytorch_compiled_model.deploy(initial_instance_count = 1, instance_type = 'ml.p3.2xlarge')

# Print the name of newly created endpoint
print(predictor.endpoint_name)
Note
The AmazonSageMakerFullAccess and AmazonS3ReadOnlyAccess policies must be attached to the AmazonSageMaker-ExecutionRole IAM role.

If you compiled your model using Boto3, SageMaker console, or the CLI for TensorFlow
Construct a TensorFlowModel object, then call deploy:

```python
role='AmazonSageMaker-ExecutionRole'
model_path='S3 path for model file'
framework_image='inference container arn'
tf_model = TensorFlowModel(model_data=model_path,
                           framework_version='1.15.3',
                           role=role,
                           image_uri=framework_image)
instance_type='ml.c5.xlarge'
predictor = tf_model.deploy(instance_type=instance_type,
                           initial_instance_count=1)
```

See Deploying directly from model artifacts for more information.

You can select a Docker image Amazon ECR URI that meets your needs from this list.
For more information on how to construct a TensorFlowModel object, see the SageMaker SDK.

Note
Your first inference request might have high latency if you deploy your model on a GPU. This is because an optimized compute kernel is made on the first inference request. We recommend that you make a warm-up file of inference requests and store that alongside your model file before sending it off to a TFX. This is known as “warming up” the model.

The following code snippet demonstrates how to produce the warm-up file for image classification example in the prerequisites section:

```python
import tensorflow as tf
from tensorflow_serving.apis import classification_pb2
from tensorflow_serving.apis import inference_pb2
from tensorflow_serving.apis import model_pb2
from tensorflow_serving.apis import predict_pb2
from tensorflow_serving.apis import prediction_log_pb2
import numpy as np

with tf.python_io.TFRecordWriter("tf_serving_warmup_requests") as writer:
    img = np.random.uniform(0, 1, size=[224, 224, 3]).astype(np.float32)
    img = np.expand_dims(img, axis=0)
    test_data = np.repeat(img, 1, axis=0)
    request = predict_pb2.PredictRequest()
    request.model_spec.name = 'compiled_models'
    request.model_spec.signature_name = 'serving_default'
    request.inputs['Placeholder:0'].CopyFrom(tf.compat.v1.make_tensor_proto(test_data,
                                                              shape=test_data.shape, dtype=tf.float32))
    log = prediction_log_pb2.PredictionLog(
                              predict_log=prediction_log_pb2.PredictionLog(request=request))
    writer.write(log.SerializeToString())
```

For more information on how to “warm up” your model, see the TensorFlow TFX page.

Deploy a Compiled Model Using Boto3
You must satisfy the prerequisites section if the model was compiled using AWS SDK for Python (Boto3), AWS CLI, or the Amazon SageMaker console. Follow the steps below to create and deploy a SageMaker Neo-compiled model using Amazon Web Services SDK for Python (Boto3).
Deploy the Model

After you have satisfied the prerequisites, use the create_model, create_endpoint_config, and create_endpoint APIs.

The following example shows how to use these APIs to deploy a model compiled with Neo:

```python
import boto3
client = boto3.client('sagemaker')

# create sagemaker model
create_model_api_response = client.create_model(
    ModelName='my-sagemaker-model',
    PrimaryContainer={
        'Image': '<insert the ECR Image URI>',
        'ModelDataUrl': 's3://path/to/model/artifact/model.tar.gz',
        'Environment': {}
    },
    ExecutionRoleArn='ARN for AmazonSageMaker-ExecutionRole'
)
print("create_model API response", create_model_api_response)

# create sagemaker endpoint config
create_endpoint_config_api_response = client.create_endpoint_config(
    EndpointConfigName='sagemaker-neomxnet-endpoint-configuration',
    ProductionVariants=[
        {'VariantName': '<provide your variant name>',
         'ModelName': 'my-sagemaker-model',
         'InitialInstanceCount': 1,
         'InstanceType': '<provide your instance type here>'},
    ],
)
print("create_endpoint_config API response", create_endpoint_config_api_response)

# create sagemaker endpoint
create_endpoint_api_response = client.create_endpoint(
    EndpointName='provide your endpoint name',
    EndpointConfigName='sagemaker-neomxnet-endpoint-configuration',
)
print("create_endpoint API response", create_endpoint_api_response)
```

**Note**

The AmazonSageMakerFullAccess and AmazonS3ReadOnlyAccess policies must be attached to the AmazonSageMaker-ExecutionRole IAM role.

For full syntax of create_model, create_endpoint_config, and create_endpoint APIs, see create_model, create_endpoint_config, and create_endpoint, respectively.

If you did not train your model using SageMaker, specify the following environment variables:
MXNet and PyTorch

"Environment": {
  "SAGEMAKER_PROGRAM": "inference.py",
  "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code",
  "SAGEMAKER_CONTAINER_LOG_LEVEL": "20",
  "SAGEMAKER_REGION": "insert your region",
  "MMS_DEFAULT_RESPONSE_TIMEOUT": "500"
}

TensorFlow

"Environment": {
  "SAGEMAKER_PROGRAM": "inference.py",
  "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code",
  "SAGEMAKER_CONTAINER_LOG_LEVEL": "20",
  "SAGEMAKER_REGION": "insert your region"
}

If you trained your model using SageMaker, specify the environment variable SAGEMAKER_SUBMIT_DIRECTORY as the full Amazon S3 bucket URI that contains the training script.

Deploy a Compiled Model Using the AWS CLI

You must satisfy the prerequisites section if the model was compiled using AWS SDK for Python (Boto3), AWS CLI, or the Amazon SageMaker console. Follow the steps below to create and deploy a SageMaker Neo-compiled model using the AWS CLI.

Topics
- Deploy the Model (p. 2723)

Deploy the Model

After you have satisfied the prerequisites, use the create-model, create-enpoint-config, and create-endpoint AWS CLI commands. The following steps explain how to use these commands to deploy a model compiled with Neo:

Create a Model

From Neo Inference Container Images, select the inference image URI and then use create-model API to create a SageMaker model. You can do this with two steps:

1. Create a create_model.json file. Within the file, specify the name of the model, the image URI, the path to the model.tar.gz file in your Amazon S3 bucket, and your SageMaker execution role:

```
{
  "ModelName": "insert model name",
  "PrimaryContainer": {
    "Image": "insert the ECR Image URI",
    "ModelDataUrl": "insert S3 archive URL",
    "Environment": "See details below"
  },
  "ExecutionRoleArn": "ARN for AmazonSageMaker-ExecutionRole"
}
```

If you trained your model using SageMaker, specify the following environment variable:
"Environment": {
    "SAGEMAKER_SUBMIT_DIRECTORY" : "[Full S3 path for *.tar.gz file containing the training script]"
}

If you did not train your model using SageMaker, specify the following environment variables:

**MXNet and PyTorch**

"Environment": {
    "SAGEMAKER_PROGRAM": "inference.py",
    "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code",
    "SAGEMAKER_CONTAINER_LOG_LEVEL": "20",
    "SAGEMAKER_REGION": "insert your region",
    "MMS_DEFAULT_RESPONSE_TIMEOUT": "500"
}

**TensorFlow**

"Environment": {
    "SAGEMAKER_PROGRAM": "inference.py",
    "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code",
    "SAGEMAKER_CONTAINER_LOG_LEVEL": "20",
    "SAGEMAKER_REGION": "insert your region"
}

**Note**
The AmazonSageMakerFullAccess and AmazonS3ReadOnlyAccess policies must be attached to the AmazonSageMaker-ExecutionRole IAM role.

2. Run the following command:

```bash
aws sagemaker create-model --cli-input-json file://create_model.json
```

For the full syntax of the create-model API, see [create-model](https://docs.aws.amazon.com/sagemaker/latest/dg/API_CreateModel.html).

**Create an Endpoint Configuration**

After creating a SageMaker model, create the endpoint configuration using the create-endpoint-config API. To do this, create a JSON file with your endpoint configuration specifications. For example, you can use the following code template and save it as `create_config.json`:

```json
{
    "EndpointConfigName": "<provide your endpoint config name>",
    "ProductionVariants": [
        {
            "VariantName": "<provide your variant name>",
            "ModelName": "my-sagemaker-model",
            "InitialInstanceCount": 1,
            "InstanceType": "<provide your instance type here>",
            "InitialVariantWeight": 1.0
        }
    ]
}
```

Now run the following AWS CLI command to create your endpoint configuration:
aws sagemaker create-endpoint-config --cli-input-json file://create_config.json

For the full syntax of the create-endpoint-config API, see `create-endpoint-config`.

Create an Endpoint

After you have created your endpoint configuration, create an endpoint using the `create-endpoint` API:

aws sagemaker create-endpoint --endpoint-name '<provide your endpoint name>' --endpoint-config-name '<insert your endpoint config name>'

For the full syntax of the create-endpoint API, see `create-endpoint`.

Deploy a Compiled Model Using the Console

You must satisfy the prerequisites section if the model was compiled using AWS SDK for Python (Boto3), the AWS CLI, or the Amazon SageMaker console. Follow the steps below to create and deploy a SageMaker Neo-compiled model using the SageMaker console [https://console.aws.amazon.com/](https://console.aws.amazon.com/SageMaker).

Topics
• Deploy the Model (p. 2725)

Deploy the Model

After you have satisfied the prerequisites, use the following steps to deploy a model compiled with Neo:

1. Choose Models, and then choose Create models from the Inference group. On the Create model page, complete the Model name, IAM role, and VPC fields (optional), if needed.
2. To add information about the container used to deploy your model, choose **Add container** container, then choose **Next**. Complete the **Container input options**, **Location of inference code image**, and **Location of model artifacts**, and optionally, **Container host name**, and **Environmental variables** fields.

![Container definition 1](image)

3. To deploy Neo-compiled models, choose the following:

   - **Container input options**: Choose **Provide model artifacts and inference image**.
   - **Location of inference code image**: Choose the inference image URI from [Neo Inference Container Images](#), depending on the AWS Region and kind of application.
   - **Location of model artifact**: Enter the Amazon S3 bucket URI of the compiled model artifact generated by the Neo compilation API.
   - **Environment variables**:
     - Leave this field blank for **SageMaker XGBoost**.
     - If you trained your model using SageMaker, specify the environment variable `SAGEMAKER_SUBMIT_DIRECTORY` as the Amazon S3 bucket URI that contains the training script.
     - If you did not train your model using SageMaker, specify the following environment variables:

```
<table>
<thead>
<tr>
<th>Key</th>
<th>Values for MXNet and PyTorch</th>
<th>Values TensorFlow</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAGEMAKER_PROGRAM</td>
<td>inference.py</td>
<td>inference.py</td>
</tr>
</tbody>
</table>
```
### Key Values for MXNet and PyTorch | Values TensorFlow
--- | ---
SAGEMAKER_SUBMIT_DIRECTORY | /opt/ml/model/code | /opt/ml/model/code
SAGEMAKER_CONTAINER_LOG_LEVEL | 20 | 20
SAGEMAKER_REGION | <your region> | <your region>
MMS_DEFAULT_RESPONSE_TIMEOUT | Leave this field blank for TF | Leave this field blank for TF

4. Confirm that the information for the containers is accurate, and then choose **Create model**. On the **Create model landing page**, choose **Create endpoint**.

5. In **Create and configure endpoint** diagram, specify the **Endpoint name**. For **Attach endpoint configuration**, choose **Create a new endpoint configuration**.
6. In **New endpoint configuration** page, specify the **Endpoint configuration name**.

7. Choose **Edit** next to the name of the model and specify the correct **Instance type** on the **Edit Production Variant** page. It is imperative that the **Instance type** value match the one specified in your compilation job.
8. Choose **Save**.

9. On the **New endpoint configuration** page, choose **Create endpoint configuration**, and then choose **Create endpoint**.

**Request Inferences from a Deployed Service**

If you have followed instructions in **Deploy a Model (p. 2712)**, you should have a SageMaker endpoint set up and running. Regardless of how you deployed your Neo-compiled model, there are three ways you can submit inference requests:

**Topics**

- [Request Inferences from a Deployed Service (Amazon SageMaker SDK) (p. 2729)](#)
- [Request Inferences from a Deployed Service (Boto3) (p. 2731)](#)
- [Request Inferences from a Deployed Service (AWS CLI) (p. 2732)](#)

**Request Inferences from a Deployed Service (Amazon SageMaker SDK)**

Use the following the code examples to request inferences from your deployed service based on the framework you used to train your model. The code examples for the different frameworks are similar. The main difference is that TensorFlow requires `application/json` as the content type.
PyTorch and MXNet

If you are using PyTorch v1.4 or later or MXNet 1.7.0 or later and you have an Amazon SageMaker endpoint InService, you can make inference requests using the predictor package of the SageMaker SDK for Python.

**Note**
The API varies based on the SageMaker SDK for Python version:

- For version 1.x, use the `RealTimePredictor` and `Predict` API.
- For version 2.x, use the `Predictor` and the `Predict` API.

The following code example shows how to use these APIs to send an image for inference:

### SageMaker Python SDK v1.x

```python
from sagemaker.predictor import RealTimePredictor

endpoint = 'insert name of your endpoint here'

# Read image into memory
payload = None
with open("image.jpg", 'rb') as f:
    payload = f.read()

predictor = RealTimePredictor(endpoint=endpoint, content_type='application/x-image')
inference_response = predictor.predict(data=payload)
print (inference_response)
```

### SageMaker Python SDK v2.x

```python
from sagemaker.predictor import Predictor

endpoint = 'insert name of your endpoint here'

# Read image into memory
payload = None
with open("image.jpg", 'rb') as f:
    payload = f.read()

predictor = Predictor(endpoint)
inference_response = predictor.predict(data=payload)
print (inference_response)
```

### TensorFlow

The following code example shows how to use the SageMaker Python SDK API to send an image for inference:

```python
from sagemaker.predictor import Predictor
from PIL import Image
import numpy as np
import json

endpoint = 'insert the name of your endpoint here'

# Read image into memory
image = Image.open(input_file)
batch_size = 1
image = np.asarray(image.resize((224, 224)))
```
image = image / 128 - 1
image = np.concatenate([image[np.newaxis, :, :]] * batch_size)
body = json.dumps({'instances': image.tolist()})
predictor = Predictor(endpoint)
inference_response = predictor.predict(data=body)
print(inference_response)

Request Inferences from a Deployed Service (Boto3)

You can submit inference requests using SageMaker SDK for Python (Boto3) client and `invoke_endpoint()` API once you have an SageMaker endpoint InService. The following code example shows how to send an image for inference:

PyTorch and MXNet

```python
import boto3
import json

endpoint = 'insert name of your endpoint here'
runtime = boto3.Session().client('sagemaker-runtime')

# Read image into memory
with open(image, 'rb') as f:
    payload = f.read()

# Send image via InvokeEndpoint API
response = runtime.invoke_endpoint(EndpointName=endpoint, ContentType='application/x-image', Body=payload)

# Unpack response
result = json.loads(response['Body'].read().decode())
```

TensorFlow

For TensorFlow submit an input with `application/json` for the content type.

```python
from PIL import Image
import numpy as np
import json
import boto3

client = boto3.client('sagemaker-runtime')
input_file = 'path/to/image'
image = Image.open(input_file)
batch_size = 1
image = np.asarray(image.resize((224, 224)))
image = image / 128 - 1
image = np.concatenate([image[np.newaxis, :, :]] * batch_size)
body = json.dumps({'instances': image.tolist()})
ioc_predictor_endpoint_name = 'insert name of your endpoint here'
content_type = 'application/json'
ioc_response = client.invoke_endpoint(
    EndpointName=ioc_predictor_endpoint_name,
    Body=body,
    ContentType=content_type)
```

XGBoost

For an XGBoost application, you should submit a CSV text instead:
import boto3
import json

endpoint = 'insert your endpoint name here'
runtime = boto3.Session().client('sagemaker-runtime')

csv_text = '1,-1.0,1.0,1.5,2.6'
# Send CSV text via InvokeEndpoint API
response = runtime.invoke_endpoint(EndpointName=endpoint, ContentType='text/csv',
        Body=csv_text)
# Unpack response
result = json.loads(response['Body'].read().decode())

Note that BYOM allows for a custom content type. For more information, see
runtime_InvokeEndpoint.

**Request Inferences from a Deployed Service (AWS CLI)**

Inference requests can be made with the sagemaker-runtime invoke-endpoint once you have an
Amazon SageMaker endpoint InService. You can make inference requests with the AWS Command
Line Interface (AWS CLI). The following example shows how to send an image for inference:

```bash
aws sagemaker-runtime invoke-endpoint --endpoint-name 'insert name of your endpoint here'
        --body fileb://image.jpg --content-type=application/x-image output_file.txt
```

An output_file.txt with information about your inference requests is made if the inference was
successful.

For TensorFlow submit an input with application/json as the content type.

```bash
aws sagemaker-runtime invoke-endpoint --endpoint-name 'insert name of your endpoint here'
        --body fileb://input.json --content-type=application/json output_file.txt
```

**Inference Container Images**

SageMaker Neo now provides inference image URI information for ml_* targets. For more information
see DescribeCompilationJob.

Based on your use case, replace the highlighted portion in the inference image URI template provided
below with appropriate values.

**Amazon SageMaker XGBoost**

```bash
aws_account_id.dkr.ecr.aws_region.amazonaws.com/xgboost-neo:latest
```

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

**Keras**

```bash
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-neo-keras:fx_version-instance_type-py3
```

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.
Replace \textit{fx\_version} with 2.2.4.

Replace \textit{instance\_type} with either cpu or gpu.

**MXNet**

**CPU or GPU instance types**

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-inference-mxnet:fx_version-instance_type-py3
```

Replace \textit{aws\_account\_id} from the table at the end of this page based on the \textit{aws\_region} you used.

Replace \textit{fx\_version} with 1.8.0.

Replace \textit{instance\_type} with either cpu or gpu.

**Inferentia**

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-neo-mxnet:fx_version-instance_type-py3
```

Replace \textit{aws\_region} with either us-east-1 or us-west-2.

Replace \textit{aws\_account\_id} from the table at the end of this page based on the \textit{aws\_region} you used.

Replace \textit{fx\_version} with 1.5.1.

Replace \textit{instance\_type} with inf.

**ONNX**

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-neo-onnx:fx_version-instance_type-py3
```

Replace \textit{aws\_account\_id} from the table at the end of this page based on the \textit{aws\_region} you used.

Replace \textit{fx\_version} with 1.5.0.

Replace \textit{instance\_type} with either cpu or gpu.

**PyTorch**

**CPU or GPU instance types**

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-inference-pytorch:fx_version-instance_type-py3
```

Replace \textit{aws\_account\_id} from the table at the end of this page based on the \textit{aws\_region} you used.

Replace \textit{fx\_version} with 1.4, 1.5, 1.6, 1.7, 1.8, 1.12, 1.13, or 2.0.

Replace \textit{instance\_type} with either cpu or gpu.
Inferentia1

<table>
<thead>
<tr>
<th><strong>aws_account_id</strong>.dkr.ecr.<strong>aws_region</strong>.amazonsaws.com/sagemaker-neo-pytorch:<em>fx_version</em>-instance_type-py3</th>
</tr>
</thead>
</table>

Replace **aws_region** with either us-east-1 or us-west-2.

Replace **aws_account_id** from the table at the end of this page based on the **aws_region** you used.

Replace **fx_version** with 1.5.1.

Replace **instance_type** with inf.

Inferentia2 and Trainium1

|---|

Replace **aws_region** with us-east-2 for Inferentia2, and us-east-1 for Trainium1.

TensorFlow

CPU or GPU instance types

<table>
<thead>
<tr>
<th><strong>aws_account_id</strong>.dkr.ecr.<strong>aws_region</strong>.amazonsaws.com/sagemaker-inference-tensorflow:<em>fx_version</em>-instance_type-py3</th>
</tr>
</thead>
</table>

Replace **aws_account_id** from the table at the end of this page based on the **aws_region** you used.

Replace **fx_version** with 1.15.3 or 2.9.

Replace **instance_type** with either cpu or gpu.

Inferentia1

<table>
<thead>
<tr>
<th><strong>aws_account_id</strong>.dkr.ecr.<strong>aws_region</strong>.amazonsaws.com/sagemaker-neo-tensorflow:<em>fx_version</em>-instance_type-py3</th>
</tr>
</thead>
</table>

Replace **aws_account_id** from the table at the end of this page based on the **aws_region** you used. Note that for instance type inf only us-east-1 and us-west-2 are supported.

Replace **fx_version** with 1.15.0

Replace **instance_type** with inf.

Inferentia2 and Trainium1

<table>
<thead>
<tr>
<th>763104351884.dkr.ecr.<strong>aws_region</strong>.amazonaws.com/tensorflow-inference-neuronx:2.10.1-neuronx-py38-sdk2.10.0-ubuntu20.04</th>
</tr>
</thead>
</table>

Replace **aws_region** with us-east-2 for Inferentia2, and us-east-1 for Trainium1.

The following table maps **aws_account_id** with **aws_region**. Use this table to find the correct inference image URI you need for your application.
Edge Devices

Amazon SageMaker Neo provides compilation support for popular machine learning frameworks. You can deploy your Neo-compiled edge devices such as the Raspberry Pi 3, Texas Instruments' Sitara, Jetson TX1, and more. For a full list of supported frameworks and edge devices, see Supported Frameworks, Devices, Systems, and Architectures.

You must configure your edge device so that it can use AWS services. One way to do this is to install DLR and Boto3 to your device. To do this, you must set up the authentication credentials. See Boto3 AWS Configuration for more information. Once your model is compiled and your edge device is configured,
you can download the model from Amazon S3 to your edge device. From there, you can use the Deep Learning Runtime (DLR) to read the compiled model and make inferences.

For first-time users, we recommend you check out the Getting Started guide. This guide walks you through how to set up your credentials, compile a model, deploy your model to a Raspberry Pi 3, and make inferences on images.

Topics
- Supported Frameworks, Devices, Systems, and Architectures (p. 2736)
- Deploy Models (p. 2746)
- Getting Started with Neo on Edge Devices (p. 2746)

Supported Frameworks, Devices, Systems, and Architectures

Amazon SageMaker Neo supports common machine learning frameworks, edge devices, operating systems, and chip architectures. Find out if Neo supports your framework, edge device, OS, and chip architecture by selecting one of the topics below.

You can find a list of models that have been tested by the Amazon SageMaker Neo Team in the Tested Models (p. 2740) section.

Note
- Ambarella devices require additional files to be included within the compressed TAR file before it is sent for compilation. For more information, see Troubleshoot Ambarella Errors (p. 2757).
- TIM-VX (libtim-vx.so) is required for i.MX 8M Plus. For information on how to build TIM-VX, see the TIM-VX GitHub repository.

Topics
- Supported Frameworks (p. 2736)
- Supported Devices, Chip Architectures, and Systems (p. 2737)
- Tested Models (p. 2740)

Supported Frameworks

Amazon SageMaker Neo supports the following frameworks.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Tested Models

The following collapsible sections provide information about machine learning models that were tested by the Amazon SageMaker Neo team. Expand the collapsible section based on your framework to check if a model was tested.

**Note**
This is not a comprehensive list of models that can be compiled with Neo.

See [Supported Frameworks](#) and [SageMaker Neo Supported Operators](#) to find out if you can compile your model with SageMaker Neo.

**DarkNet**

<table>

Deploy Models

You can deploy the compute module to resource-constrained edge devices by: downloading the compiled model from Amazon S3 to your device and using **DLR**, or you can use **AWS IoT Greengrass**.

Before moving on, make sure your edge device must be supported by SageMaker Neo. See, [Supported Frameworks, Devices, Systems, and Architectures](#) to find out what edge devices are supported. Make sure that you specified your target edge device when you submitted the compilation job, see [Use Neo to Compile a Model](#).

Deploy a Compiled Model (DLR)

**DLR** is a compact, common runtime for deep learning models and decision tree models. DLR uses the [TVM runtime](#), [Treelite runtime](#), NVIDIA TensorRT™, and can include other hardware-specific runtimes. DLR provides unified Python/C++ APIs for loading and running compiled models on various devices.

You can install latest release of DLR package using the following pip command:

```
pip install dlr
```

For installation of DLR on GPU targets or non-x86 edge devices, please refer to [Releases](#) for prebuilt binaries, or [Installing DLR](#) for building DLR from source. For example, to install DLR for Raspberry Pi 3, you can use:

```
```

Deploy a Model (AWS IoT Greengrass)

**AWS IoT Greengrass** extends cloud capabilities to local devices. It enables devices to collect and analyze data closer to the source of information, react autonomously to local events, and communicate securely with each other on local networks. With AWS IoT Greengrass, you can perform machine learning inference at the edge on locally generated data using cloud-trained models. Currently, you can deploy models on to all AWS IoT Greengrass devices based on ARM Cortex-A, Intel Atom, and Nvidia Jetson series processors. For more information on deploying a Lambda inference application to perform machine learning inferences with AWS IoT Greengrass, see [How to configure optimized machine learning inference using the AWS Management Console](#).

Getting Started with Neo on Edge Devices

This guide to getting started with Amazon SageMaker Neo shows you how to compile a model, set up your device, and make inferences on your device. Most of the code examples use Boto3. We provide commands using AWS CLI where applicable, as well as instructions on how to satisfy prerequisites for Neo.

**Note**

You can run the following code snippets on your local machine, within a SageMaker notebook, within SageMaker Studio, or (depending on your edge device) on your edge device. The setup is similar; however, there are two main exceptions if you run this guide within a SageMaker notebook instance or SageMaker Studio session:

- You do not need to install Boto3.
- You do not need to add the ‘AmazonSageMakerFullAccess’ IAM policy

This guide assumes you are running the following instructions on your edge device.
Prerequisites

1. **Install Boto3**

   If you are running these commands on your edge device, you must install the AWS SDK for Python (Boto3). Within a Python environment (preferably a virtual environment), run the following locally on your edge device's terminal or within a Jupyter notebook instance:

   **Terminal**
   ```bash
   pip install boto3
   ```

   **Jupyter Notebook**
   ```bash
   !pip install boto3
   ```

2. **Set Up AWS Credentials**

   You need to set up Amazon Web Services credentials on your device in order to run SDK for Python (Boto3). By default, the AWS credentials should be stored in the file `~/.aws/credentials` on your edge device. Within the credentials file, you should see two environment variables: `aws_access_key_id` and `aws_secret_access_key`.

   In your terminal, run:

   ```bash
   $ more ~/.aws/credentials
   [default]
   aws_access_key_id = YOUR_ACCESS_KEY
   aws_secret_access_key = YOUR_SECRET_KEY
   ```

   The [AWS General Reference Guide](https://docs.aws.amazon.com/AmazonS3/latest/userguide/using-multipart-upload.html) has instructions on how to get the necessary `aws_access_key_id` and `aws_secret_access_key`. For more information on how to set up credentials on your device, see the Boto3 documentation.

3. **Set up an IAM Role and attach policies.**

   Neo needs access to your S3 bucket URI. Create an IAM role that can run SageMaker and has permission to access the S3 URI. You can create an IAM role either by using SDK for Python (Boto3), the console, or the AWS CLI. The following example illustrates how to create an IAM role using SDK for Python (Boto3):

   ```python
   import boto3
   AWS_REGION = 'aws-region'
   # Create an IAM client to interact with IAM
   iam_client = boto3.client('iam', region_name=AWS_REGION)
   role_name = 'role-name'
   ```

   For more information on how to create an IAM role with the console, AWS CLI, or through the AWS API, see [Creating an IAM user in your AWS account](https://docs.aws.amazon.com/IAM/latest/classic/creating-users.html).

   Create a dictionary describing the IAM policy you are attaching. This policy is used to create a new IAM role.

   ```python
   policy = {
       'Statement': [
   ```
Create a new IAM role using the policy you defined above:

```python
import json
new_role = iam_client.create_role(
    AssumeRolePolicyDocument=json.dumps(policy),
    Path='/',
    RoleName=role_name
)
```

You need to know what your Amazon Resource Name (ARN) is when you create a compilation job in a later step, so store it in a variable as well.

```python
role_arn = new_role['Role']['Arn']
```

Now that you have created a new role, attach the permissions it needs to interact with Amazon SageMaker and Amazon S3:

```python
iam_client.attach_role_policy(
    RoleName=role_name,
    PolicyArn='arn:aws:iam::aws:policy/AmazonSageMakerFullAccess'
)
iam_client.attach_role_policy(
    RoleName=role_name,
    PolicyArn='arn:aws:iam::aws:policy/AmazonS3FullAccess'
);
```

4. **Create an Amazon S3 bucket to store your model artifacts**

SageMaker Neo will access your model artifacts from Amazon S3

**Boto3**

```python
# Create an S3 client
s3_client = boto3.client('s3', region_name=AWS_REGION)

# Name buckets
bucket='name-of-your-bucket'

# Check if bucket exists
if s3_client.bucket(bucket) not in s3_client.buckets.all():
    s3_client.create_bucket(
        Bucket=bucket,
        CreateBucketConfiguration={
            'LocationConstraint': AWS_REGION
        }
    )
else:
    print(f'Bucket {bucket} already exists. No action needed.')
```
CLI

```bash
aws s3 mb s3://'name-of-your-bucket' --region specify-your-region

# Check your bucket exists
aws s3 ls s3://'name-of-your-bucket'/
```

5. **Train a machine learning model**

See [Train a Model with Amazon SageMaker](#) for more information on how to train a machine learning model using Amazon SageMaker. You can optionally upload your locally trained model directly into an Amazon S3 URI bucket.

**Note**

Make sure the model is correctly formatted depending on the framework you used. See [What input data shapes does SageMaker Neo expect?](#)

If you do not have a model yet, use the `curl` command to get a local copy of the `coco_ssd_mobilenet` model from TensorFlow's website. The model you just copied is an object detection model trained from the [COCO dataset](#). Type the following into your Jupyter notebook:

```python
model_zip_filename = './coco_ssd_mobilenet_v1_1.0.zip'
!curl http://storage.googleapis.com/download.tensorflow.org/models/tflite/coco_ssd_mobilenet_v1_1.0_quant_2018_06_29.zip --output {model_zip_filename}
```

Note that this particular example was packaged in a .zip file. Unzip this file and repackage it as a compressed tarfile (.tar.gz) before using it in later steps. Type the following into your Jupyter notebook:

```python
# Extract model from zip file
!unzip -u {model_zip_filename}
model_filename = 'detect.tflite'
model_name = model_filename.split('.')[0]

# Compress model into .tar.gz so SageMaker Neo can use it
model_tar = model_name + '.tar.gz'
!tar -czf {model_tar} {model_filename}
```

6. **Upload trained model to an S3 bucket**

Once you have trained your machine learning mode, store it in an S3 bucket.

**Boto3**

```python
# Upload model
s3_client.upload_file(Filename=model_filename, Bucket=bucket, Key=model_filename)
```

**CLI**

Replace `your-model-filename` and `your-S3-bucket` with the name of your S3 bucket.

```bash
aws s3 cp your-model-filename s3://your-S3-bucket
```
Step 1: Compile the Model

Once you have satisfied the Prerequisites, you can compile your model with Amazon SageMaker Neo. You can compile your model using the AWS CLI, the console or the Amazon Web Services SDK for Python (Boto3), see Use Neo to Compile a Model. In this example, you will compile your model with Boto3.

To compile a model, SageMaker Neo requires the following information:

1. **The Amazon S3 bucket URI where you stored the trained model.**

   If you followed the prerequisites, the name of your bucket is stored in a variable named bucket. The following code snippet shows how to list all of your buckets using the AWS CLI:

   ```bash
   aws s3 ls
   ```

   For example:

   ```bash
   $ aws s3 ls
   2020-11-02 17:08:50 bucket
   ```

2. **The Amazon S3 bucket URI where you want to save the compiled model.**

   The code snippet below concatenates your Amazon S3 bucket URI with the name of an output directory called output:

   ```python
   s3_output_location = f's3://{bucket}/output'
   ```

3. **The machine learning framework you used to train your model.**

   Define the framework you used to train your model.

   ```python
   framework = 'framework-name'
   ```

   For example, if you wanted to compile a model that was trained using TensorFlow, you could either use tflite or tensorflow. Use tflite if you want to use a lighter version of TensorFlow that uses less storage memory.

   ```python
   framework = 'tflite'
   ```

   For a complete list of Neo-supported frameworks, see Supported Frameworks, Devices, Systems, and Architectures.

4. **The shape of your model's input.**

   Neo requires the name and shape of your input tensor. The name and shape are passed in as key-value pairs. value is a list of the integer dimensions of an input tensor and key is the exact name of an input tensor in the model.

   ```python
   data_shape = '{"name": [tensor-shape]}'
   ```

   For example:

   ```python
   data_shape = '{"normalized_input_image_tensor": [1, 300, 300, 3]}'
   ```
Note
Make sure the model is correctly formatted depending on the framework you used. See What input data shapes does SageMaker Neo expect? The key in this dictionary must be changed to the new input tensor's name.

5. Either the name of the target device to compile for or the general details of the hardware platform

```python
target_device = 'target-device-name'
```

For example, if you want to deploy to a Raspberry Pi 3, use:

```python
target_device = 'rasp3b'
```

You can find the entire list of supported edge devices in Supported Frameworks, Devices, Systems, and Architectures.

Now that you have completed the previous steps, you can submit a compilation job to Neo.

```python
# Create a SageMaker client so you can submit a compilation job
sagemaker_client = boto3.client('sagemaker', region_name=AWS_REGION)

# Give your compilation job a name
compilation_job_name = 'getting-started-demo'
print(f'Compilation job for {compilation_job_name} started')

response = sagemaker_client.create_compilation_job(
    CompilationJobName=compilation_job_name,
    RoleArn=role_arn,
    InputConfig={
        'S3Uri': s3_input_location,
        'DataInputConfig': data_shape,
        'Framework': framework.upper()
    },
    OutputConfig={
        'S3OutputLocation': s3_output_location,
        'TargetDevice': target_device
    },
    StoppingCondition={
        'MaxRuntimeInSeconds': 900
    }
)

# Optional - Poll every 30 sec to check completion status
import time
while True:
    response = sagemaker_client.describe_compilation_job(CompilationJobName=compilation_job_name)
    if response['CompilationJobStatus'] == 'COMPLETED':
        break
    elif response['CompilationJobStatus'] == 'FAILED':
        raise RuntimeError('Compilation failed')
    print('Compiling ...')
    time.sleep(30)
    print('Done!')

If you want additional information for debugging, include the following print statement:
If the compilation job is successful, your compiled model is stored in the output Amazon S3 bucket you specified earlier (s3_output_location). Download your compiled model locally:

```python
object_path = f'output/{model}-{target_device}.tar.gz'
neo_compiled_model = f'compiled-{model}.tar.gz'
s3_client.download_file(bucket, object_path, neo_compiled_model)
```

### Step 2: Set Up Your Device

You will need to install packages on your edge device so that your device can make inferences. You will also need to either install AWS IoT Greengrass core or Deep Learning Runtime (DLR). In this example, you will install packages required to make inferences for the coco_ssd_mobilenet object detection algorithm and you will use DLR.

1. **Install additional packages**

   In addition to Boto3, you must install certain libraries on your edge device. What libraries you install depends on your use case.

   For example, for the coco_ssd_mobilenet object detection algorithm you downloaded earlier, you need to install NumPy for data manipulation and statistics, PIL to load images, and Matplotlib to generate plots. You also need a copy of TensorFlow if you want to gauge the impact of compiling with Neo versus a baseline.

   ```bash
   !pip3 install numpy pillow tensorflow matplotlib
   ```

2. **Install inference engine on your device**

   To run your Neo-compiled model, install the Deep Learning Runtime (DLR) on your device. DLR is a compact, common runtime for deep learning models and decision tree models. On x86_64 CPU targets running Linux, you can install the latest release of the DLR package using the following `pip` command:

   ```bash
   !pip install dlr
   ```

   For installation of DLR on GPU targets or non-x86 edge devices, refer to Releases for prebuilt binaries, or Installing DLR for building DLR from source. For example, to install DLR for Raspberry Pi 3, you can use:

   ```bash
   ```

### Step 3: Make Inferences on Your Device

In this example, you will use Boto3 to download the output of your compilation job onto your edge device. You will then import DLR, download an example images from the dataset, resize this image to match the model's original input, and then you will make a prediction.

1. **Download your compiled model from Amazon S3 to your device and extract it from the compressed tarfile.**

   ```bash
   # Download compiled model locally to edge device
   ```
object_path = f'output/{model_name}-{target_device}.tar.gz'
neo_compiled_model = f'compiled-{model_name}.tar.gz'
s3_client.download_file(bucket_name, object_path, neo_compiled_model)

# Extract model from .tar.gz so DLR can use it
!mkdir ./dlr_model # make a directory to store your model (optional)
!tar -xzvf ./compiled-detect.tar.gz --directory ./dlr_model

2. **Import DLR and an initialized DLRModel object.**

```python
import dlr
device = 'cpu'
model = dlr.DLRModel('./dlr_model', device)
```

3. **Download an image for inferencing and format it based on how your model was trained.**

For the coco_ssd_mobilenet example, you can download an image from the COCO dataset and then reform the image to 300x300:

```python
from PIL import Image

# Download an image for model to make a prediction
input_image_filename = './input_image.jpg'
!curl https://farm9.staticflickr.com/8325/8077197378_79efb4805e_z.jpg --output {input_image_filename}

# Format image so model can make predictions
resized_image = image.resize((300, 300))

# Model is quantized, so convert the image to uint8
x = np.array(resized_image).astype('uint8')
```

4. **Use DLR to make inferences.**

Finally, you can use DLR to make a prediction on the image you just downloaded:

```python
out = model.run(x)
```

For more examples using DLR to make inferences from a Neo-compiled model on an edge device, see the [neo-ai-dlr Github repository](https://github.com/awslabs/neo-ai-dlr).

**Troubleshoot Errors**

This section contains information about how to understand and prevent common errors, the error messages they generate, and guidance on how to resolve these errors. Before moving on, ask yourself the following questions:

**Did you encounter an error before you deployed your model?** If yes, see [Troubleshoot Neo Compilation Errors](https://docs.aws.amazon.com/sagemaker/latest/dg/troubleshooting-compilation.html).

**Did you encounter an error after you compiled your model?** If yes, see [Troubleshoot Neo Inference Errors](https://docs.aws.amazon.com/sagemaker/latest/dg/troubleshooting-inference.html).

**Did you encounter an error trying to compile your model for Ambarella devices?** If yes, see [Troubleshoot Ambarella Errors](p. 2757).
Error Classification Types

This list classifies the user errors you can receive from Neo. These include access and permission errors and load errors for each of the supported frameworks. All other errors are system errors.

Client permission error

Neo passes the errors for these straight through from the dependent service.

- *Access Denied* when calling sts:AssumeRole
- *Any 400 error* when calling Amazon S3 to download or upload a client model
- *PassRole error*

Load error

Assuming that the Neo compiler successfully loaded .tar.gz from Amazon S3, check whether the tarball contains the necessary files for compilation. The checking criteria is framework-specific:

- **TensorFlow**: Expects only protobuf file (*.pb or *.pbtxt). For saved models, expects one variables folder.
- **Pytorch**: Expect only one pytorch file (*.pth).
- **MXNET**: Expect only one symbol file (*.json) and one parameter file (*.params).
- **XGBoost**: Expect only one XGBoost model file (*.model). The input model has size limitation.

Compilation error

Assuming that the Neo compiler successfully loaded .tar.gz from Amazon S3, and that the tarball contains necessary files for compilation. The checking criteria is:

- **OperatorNotImplemented**: An operator has not been implemented.
- **OperatorAttributeNotImplemented**: The attribute in the specified operator has not been implemented.
- **OperatorAttributeRequired**: An attribute is required for an internal symbol graph, but it is not listed in the user input model graph.
- **OperatorAttributeValueNotValid**: The value of the attribute in the specific operator is not valid.

Topics

- Troubleshoot Neo Compilation Errors (p. 2754)
- Troubleshoot Neo Inference Errors (p. 2757)
- Troubleshoot Ambarella Errors (p. 2757)
How to Use This Page

Attempt to resolve your error by going through these sections in the following order:

1. Check that the input of your compilation job satisfies the input requirements. See [What input data shapes does SageMaker Neo expect?](p. 2695)
2. Check common framework-specific errors.
3. Check if your error is an infrastructure error.
4. Check your compilation log.

Framework-Related Errors

**Keras**

<table>
<thead>
<tr>
<th>Error</th>
<th>Solution</th>
</tr>
</thead>
</table>
| InputConfiguration: No h5 file provided in <model path> | Check your h5 file is in the Amazon S3 URI you specified.  
Or  
Check that the h5 file is correctly formatted. |
| InputConfiguration: Multiple h5 files provided, <model path>, when only one is allowed | Check you are only providing one h5 file. |
| ClientError: InputConfiguration: Unable to load provided Keras model. Error: 'sample_weight_mode' | Check the Keras version you specified is supported. See [supported frameworks for cloud instances and edge devices](index.html). |
| ClientError: InputConfiguration: Input input has wrong shape in Input Shape dictionary. Input shapes should be provided in NCHW format. | Check that your model input follows NCHW format. See [What input data shapes does SageMaker Neo expect?](index.html). |

**MXNet**

<table>

| InputConfiguration: We are unable to extract DataInputConfig from the model due to input_config_derivation_error. Please override by providing a DataInputConfig during compilation job creation. | Do either of the following:  
- Specify the name and shape of the expected inputs by providing a DataInputConfig definition in your compilation request.  
- Investigate the error in Amazon CloudWatch Logs. Check the /aws/sagemaker/CompilationJobs log group and look for a log stream named compilationJobName/model-info-extraction. |

### Infrastructure-Related Errors

<table>
<thead>
<tr>
<th>Error</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>ClientError: InputConfiguration: S3 object does not exist. Bucket: &lt;bucket&gt;, Key: &lt;bucket key&gt;</td>
<td>Check the Amazon S3 URI your provided.</td>
</tr>
<tr>
<td>ClientError: InputConfiguration: Bucket &lt;bucket name&gt; is in region &lt;region name&gt; which is different from AWS Sagemaker service region &lt;service region&gt;</td>
<td>Create an Amazon S3 bucket that is in the same region as the service.</td>
</tr>
<tr>
<td>ClientError: InputConfiguration: Unable to untar input model. Please confirm the model is a tar.gz file</td>
<td>Check that your model in Amazon S3 is compressed into a tar.gz file.</td>
</tr>
</tbody>
</table>

### Check your compilation log

2. Select the region you created the compilation job from the Region dropdown list in the top right.
3. In the navigation pane of the Amazon CloudWatch, choose Logs. Select Log groups.
4. Search for the log group called /aws/sagemaker/CompilationJobs. Select the log group.
5. Search for the logstream named after the compilation job name. Select the log stream.
Troubleshoot Neo Inference Errors

This section contains information about how to prevent and resolve some of the common errors you might encounter upon deploying and/or invoking the endpoint. This section applies to PyTorch 1.4.0 or later and MXNet v1.7.0 or later.

- Make sure the first inference (warm-up inference) on a valid input data is done in `model_fn()`, if you defined a `model_fn` in your inference script, otherwise the following error message may be seen on the terminal when `predict API` is called:

  An error occurred (ModelError) when calling the InvokeEndpoint operation: Received server error (0) from `<users-sagemaker-endpoint>` with message "Your invocation timed out while waiting for a response from container model. Review the latency metrics for each container in Amazon CloudWatch, resolve the issue, and try again."

- Make sure that the environment variables in the following table are set. If they are not set, the following error message might show up:

  **On the terminal:**

  An error occurred (ModelError) when calling the InvokeEndpoint operation: Received server error (503) from `<users-sagemaker-endpoint>` with message `{ "code": 503, "type": "InternalServerException", "message": "Prediction failed" } ".

  **In CloudWatch:**

  W-9001-model-stdout com.amazonaws.ml.mms.wlm.WorkerLifeCycle - AttributeError: 'NoneType' object has no attribute 'transform'

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAGEMAKER_PROGRAM</td>
<td>inference.py</td>
</tr>
<tr>
<td>SAGEMAKER_SUBMIT_DIRECTORY</td>
<td>/opt/ml/model/code</td>
</tr>
<tr>
<td>SAGEMAKER_CONTAINER_LOG_LEVEL</td>
<td>20</td>
</tr>
<tr>
<td>SAGEMAKER_REGION</td>
<td><code>&lt;your region&gt;</code></td>
</tr>
</tbody>
</table>

- Make sure that the `MMS_DEFAULT_RESPONSE_TIMEOUT` environment variable is set to 500 or a higher value while creating the Amazon SageMaker model; otherwise, the following error message may be seen on the terminal:

  An error occurred (ModelError) when calling the InvokeEndpoint operation: Received server error (0) from `<users-sagemaker-endpoint>` with message "Your invocation timed out while waiting for a response from container model. Review the latency metrics for each container in Amazon CloudWatch, resolve the issue, and try again."

Troubleshoot Ambarella Errors

SageMaker Neo requires models to be packaged in a compressed TAR file (*.tar.gz). Ambarella devices require additional files to be included within the compressed TAR file before it is sent for compilation. Include the following files within your compressed TAR file if you want to compile a model for Ambarella targets with SageMaker Neo:

- A trained model using a framework supported by SageMaker Neo
• A JSON configuration file
• Calibration images

For example, the contents of your compressed TAR file should look similar to the following example:

```bash
#amba_config.json
#calib_data
|    # data1
|    # data2
|    # .
|    # .
|    # .
|    # data500
#mobilenet_v1_1.0_0224_frozen.pb
```

The directory is configured as follows:

• `amba_config.json`: Configuration file
• `calib_data`: Folder containing calibration images
• `mobilenet_v1_1.0_0224_frozen.pb`: TensorFlow model saved as a frozen graph

For information about frameworks supported by SageMaker Neo, see [Supported Frameworks](#) (p. 2736).

**Setting up the Configuration File**

The configuration file provides information required by the Ambarella toolchain to compile the model. The configuration file must be saved as a JSON file and the name of the file must end with `config.json`. The following chart shows the contents of the configuration file.

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>inputs</td>
<td>Dictionary mapping input layers to attribute.</td>
<td><code>{inputs: {&quot;data&quot;: {...}, &quot;data1&quot;: {...}}}</code></td>
</tr>
<tr>
<td>&quot;data&quot;</td>
<td>Input layer name. Note: &quot;data&quot; is an example of the name you can use to label the input layer.</td>
<td>&quot;data&quot;</td>
</tr>
<tr>
<td>shape</td>
<td>Describes the shape of the input to the model. This follows the same conventions that SageMaker Neo uses.</td>
<td>&quot;shape&quot;: &quot;1,3,224,224&quot;</td>
</tr>
<tr>
<td>filepath</td>
<td>Relative path to the directory containing calibration images. These can be binary or image files like JPG or PNG.</td>
<td>&quot;filepath&quot;: &quot;calib_data/&quot;</td>
</tr>
<tr>
<td>colorformat</td>
<td>Color format that model expects. This will be used while converting images to binary. Supported values: [RGB, BGR]. Default is RGB.</td>
<td>&quot;colorformat&quot;: &quot;RGB&quot;</td>
</tr>
<tr>
<td>mean</td>
<td>Mean value to be subtracted from the input. Can be a single</td>
<td>&quot;mean&quot;: 128.0</td>
</tr>
<tr>
<td>Key</td>
<td>Description</td>
<td>Example</td>
</tr>
<tr>
<td>-----</td>
<td>-------------</td>
<td>---------</td>
</tr>
<tr>
<td></td>
<td>value or a list of values. When the mean is given as a list the number of entries must match the channel dimension of the input.</td>
<td></td>
</tr>
<tr>
<td>scale</td>
<td>Scale value to be used for normalizing the input. Can be a single value or a list of values. When the scale is given as a list, the number of entries must match the channel dimension of the input.</td>
<td>&quot;scale&quot;: 255.0</td>
</tr>
</tbody>
</table>

The following is a sample configuration file:

```json
{
  "inputs": {
    "data": {
      "shape": "1, 3, 224, 224",
      "filepath": "calib_data/",
      "colorformat": "RGB",
      "mean": [128, 128, 128],
      "scale": [128.0, 128.0, 128.0]
    }
  }
}
```

**Calibration Images**

Quantize your trained model by providing calibration images. Quantizing your model improves the performance of the CVFlow engine on an Ambarella System on a Chip (SoC). The Ambarella toolchain uses the calibration images to determine how each layer in the model should be quantized to achieve optimal performance and accuracy. Each layer is quantized independently to INT8 or INT16 formats. The final model has a mix of INT8 and INT16 layers after quantization.

**How many images should you use?**

It is recommended that you include between 100–200 images that are representative of the types of scenes the model is expected to handle. The model compilation time increases linearly to the number of calibration images in the input file.

**What are the recommended image formats?**

Calibration images can be in a raw binary format or image formats such as JPG and PNG.

Your calibration folder can contain a mixture of images and binary files. If the calibration folder contains both images and binary files, the toolchain first converts the images to binary files. Once the conversion is complete, it uses the newly generated binary files along with the binary files that were originally in the folder.

**Can I convert the images into binary format first?**

Yes. You can convert the images to the binary format with open-source packages such as [OpenCV](https://opencv.org) or [PIL](https://pillow.readthedocs.io). Crop and resize the images so they satisfy the input layer of your trained model.
Mean and Scale

You can specify mean and scaling pre-processing options to the Amberalla toolchain. These operations are embedded into the network and are applied during inference on each input. Do not provide processed data if you specify the mean or scale. More specifically, do not provide data you have subtracted the mean from or have applied scaling to.

Check your compilation log

For information on checking compilation log for Ambarella devices, see Check your compilation log (p. 2756).

Use Amazon SageMaker Elastic Inference (EI)

Starting April 15, 2023, AWS will not onboard new customers to Amazon Elastic Inference (EI), and will help current customers migrate their workloads to options that offer better price and performance. After April 15, 2023, new customers will not be able to launch instances with Amazon EI accelerators in Amazon SageMaker, Amazon ECS, or Amazon EC2. However, customers who have used Amazon EI at least once during the past 30-day period are considered current customers and will be able to continue using the service.

Machine learning (ML) on AWS helps you innovate faster with the most comprehensive set of ML services and infrastructure made available in a low-cost, pay-as-you-go usage model. AWS continuously delivers better performing and lower cost infrastructure for ML inference workloads. AWS launched Amazon Elastic Inference (EI) in 2018 to enable customers to attach low-cost GPU-powered acceleration to Amazon EC2, Amazon SageMaker instances, or Amazon Elastic Container Service (ECS) tasks to reduce the cost of running deep learning inference by up to 75% compared to standalone GPU based instances such as Amazon EC2 P4d and Amazon EC2 G5. In 2019, AWS launched AWS Inferentia, Amazon’s first custom silicon designed to accelerate deep learning workloads by providing high performance inference in the cloud. Amazon EC2 Inf1 instances based on AWS Inferentia chips deliver up 2.3x higher throughput and up to 70% lower cost per inference than comparable current generation GPU-based Amazon EC2 instances. With the availability of new accelerated compute options such as AWS Inferentia and Amazon EC2 G5 instances, the benefit of attaching a fractional GPU to a CPU host instance using Amazon EI has diminished. For example, customers hosting models on Amazon EI who move to ml.inf1.xlarge instances can get up to 56% in cost savings and 2x performance improvement.

Customers can use Amazon SageMaker Inference Recommender to help them choose the best alternative instances to Amazon EI for deploying their ML models.

Frequently asked questions

1. Why is Amazon encouraging customers to move workloads from Amazon Elastic Inference (EI) to newer hardware acceleration options such as AWS Inferentia?

   Customers get better performance at a much better price than Amazon EI with new hardware accelerator options such as AWS Inferentia for their inference workloads. AWS Inferentia is designed to provide high performance inference in the cloud, to drive down the total cost of inference, and to make it easy for developers to integrate machine learning into their business applications. To enable customers to benefit from such newer generation hardware accelerators, we will not onboard new customers to Amazon EI after April 15, 2023.

2. Which AWS services are impacted by the move to stop onboarding new customers to Amazon Elastic Inference (EI)?

   This announcement will affect Amazon EI accelerators attached to any Amazon EC2, Amazon SageMaker instances, or Amazon Elastic Container Service (ECS) tasks. In Amazon SageMaker, this applies to both endpoints and notebook kernels using Amazon EI accelerators.
3. Will I be able to create a new Amazon Elastic Inference (EI) accelerator after April 15, 2023?

No, if you are a new customer and have not used Amazon EI in the past 30 days, then you will not be able to create a new Amazon EI instance in your AWS account after April 15, 2023. However, if you have used an Amazon EI accelerator at least once in the past 30 days, you can attach a new Amazon EI accelerator to your instance.

4. We currently use Amazon Elastic Inference (EI) accelerators. Will we be able to continue using them after April 15, 2023?

Yes, you will be able to use Amazon EI accelerators. We recommend that you migrate your current ML Inference workloads running on Amazon EI to other hardware accelerator options at your earliest convenience.

5. How do I evaluate alternative instance options for my current Amazon SageMaker Inference Endpoints?

Amazon SageMaker Inference Recommender can help you identify cost-effective deployments to migrate existing workloads from Amazon Elastic Inference (EI) to an appropriate ML instance supported by SageMaker.

6. How do I change the instance type for my existing endpoint in Amazon SageMaker?

You can change the instance type for your existing endpoint by doing the following:

1. First, create a new EndpointConfig that uses the new instance type. If you have an autoscaling policy, delete the existing autoscaling policy.
2. Call UpdateEndpoint while specifying your newly created EndpointConfig.
3. Wait for your endpoint to change status to InService. This will take approximately 10-15 minutes.
4. Finally, if you need autoscaling for your new endpoint, create a new autoscaling policy for this new endpoint and ProductionVariant.

7. How do I change the instance type for my existing Amazon SageMaker Notebook Instance using Amazon Elastic Inference (EI)?

Choose Notebook instances in the SageMaker console, and then choose the Notebook Instance you want to update. Make sure the Notebook Instance has a Stopped status. Finally, you can choose Edit and change your instance type. Make sure that, when your Notebook Instance starts up, you select the right kernel for your new instance.

8. Is there a specific instance type which is a good alternative to Amazon Elastic Inference (EI)?

Every machine learning workload is unique. We recommend using Amazon SageMaker Inference Recommender to help you identify the right instance type for your ML workload, performance requirements, and budget. AWS Inferentia, specifically inf1.xlarge, is the best high performance and low-cost alternative for Amazon EI customers.

Migrate from Amazon Elastic Inference to other instances

The following information can help you migrate your SageMaker-hosted endpoints from instances that use Amazon Elastic Inference accelerators to other instances. The advice varies depending on your framework.

PyTorch

If you're migrating from PyTorch, use the following guidelines.
1. Choose the right instance type

Every machine learning workload is unique. We recommend using Amazon SageMaker Inference Recommender to help you identify the right instance type for your ML workload, performance requirements, and budget. AWS Inferentia, specifically inf1.xlarge, is the best high performance and low-cost alternative for Amazon Elastic Inference customers.

In our load testing with Inference Recommender, g4dn.xlarge instances performed better than m5.large instances with eia.2large attached. With Amazon Elastic Inference, you have to pay the additional cost of the ML instance to which the accelerator is attached. Amazon Elastic Inference also only supports PyTorch 1.5 and TensorFlow 2.3. If you migrate to ml.g4dn instances, you can use the latest versions of PyTorch 1.11 and TensorFlow 2.9. Additionally, ml.g4dn and AWS Inferentia are available in all AWS Regions, whereas Amazon Elastic Inference is only available in 6 Regions. Both AWS Inferentia and ml.g4dn offer better performance at lower price for most ML inference workloads.

2. Modify inference.py

Modify your inference.py file to remove any Elastic Inference-specific required changes and use default handlers. Based on different user cases, you might have different input and output handlers, but the main changes you must make are in the model loading handler functions model_fn and predict_fn. Remove the Elastic Inference-specific predict handler predict_fn and restore the model loading handler model_fn to the default format. The following example shows how to do this, with the parts you should remove from inference.py commented out:

```python
from __future__ import print_function
import os
import torch
import torch.nn as nn
import torch.nn.functional as F
import numpy as np

def model_fn(model_dir, context):
    # if torch.__version__ in VERSIONS_USE_NEW_API:
    #    import torchelia
    #    loaded_model = loaded_model.eval()
    #    loaded_model = torchelia.jit.attach_eia(loaded_model, 0)
    with open(os.path.join(model_dir, 'model.pth'), 'rb') as f:
        model.load_state_dict(torch.load(f))
    return model

# def predict_fn(input_data, model):
#    logger.info("Performing EIA inference with Torch JIT context with input of size {}").format(input_data.shape)
#    #
#    # device = torch.device("cuda" if torch.cuda.is_available() else "cpu")
#    input_data = input_data.to(device)
#    #
#    # if torch.__version__ in VERSIONS_USE_NEW_API:
#    #    import torchelia
#    #
#    # torch._C._jit_set_profiling_executor(False)
#    # with torch.jit.optimized_execution(True):
#    #    return model.forward(input_data)
#    #
#    # else:
#    #    with torch.jit.optimized_execution(True, {"target_device": "eia:0"}):  #
#        return model(input_data)
```
Migrate from Amazon Elastic Inference to other instances

```python
def predict_fn(input_data, model):
    return model(input_data)
```

3. Create a model

Create a new model that points to your modified `inference.py` file. You can keep the `inference.py` file locally and point to it by specifying `source_dir` and `entry_point` or tar the `inference.py` file into the model tarball. The following example shows the former case:

```python
from sagemaker.pytorch import PyTorchModel
pytorch = PyTorchModel(
    model_data=model_data_url,
    role=role,
    entry_point="inference.py",
    source_dir="code",
    framework_version="1.5.1",
    py_version="py3",
    sagemaker_session=sagemaker_session,
)
```

4. Deploy the model to the endpoint and invoke it

You can use one of the following options for deploying your model after making the preceding changes.

**Option 1: Deploy from scratch**

You can deploy the model to a new endpoint with a recommended instance from the **Accelerated Computing** category, such as G4.

```python
predictor = pytorch.deploy(
    ...  
    # instance_type = "ml.c5.xlarge",
    instance_type="ml.g4dn.2xlarge",
    ...  
    response = predictor.predict(payload)
```

**Option 2: Update the existing endpoint**

Complete the following steps to update your existing endpoint:

1. Call `CreateEndpointConfig` to create a new `EndpointConfig` that uses the new instance type. If you have an autoscaling policy, delete the existing autoscaling policy.

```python
endpoint_config_response = sagemaker_client.create_endpoint_config(
    EndpointConfigName=endpoint_config_name,
    ProductionVariants=[
        {
            "VariantName": "variant1",  # The name of the production variant.
            "ModelName": model_name,  # The name of new created model
            "InstanceType": instance_type,  # Specify the right-sized instance type.
            "InitialInstanceCount": 1  # Number of instances to launch initially.
        }
    ]
)
```

2. Call `UpdateEndpoint` and specify your newly created `EndpointConfig`.

```python
endpoint_config_response = sagemaker_client.update_endpoint(
```

2763
3. Wait for your endpoint to change status to InService. This takes approximately 10–15 minutes.
4. Finally, if you need autoscaling for your new endpoint, create a new autoscaling policy for your new endpoint and ProductionVariant.

**TensorFlow**

If you're migrating from TensorFlow, use the following guidelines.

1. **Choose the right instance type**

Refer to the [1. Choose the right instance type](#) guidance in the [PyTorch section](#) (p. 2761).

2. **Deploy the model to the endpoint and invoke it**

You can use one of the following options for deploying your model.

**Option 1: Deploy from scratch**

You can migrate from Elastic Inference by re-deploying the model to a new endpoint by removing the `accelerator_type` field and specifying a right-sized instance type from the [Accelerated Computing](#) category, such as G4. In the following example, the commented out line causes you to deploy without using an Elastic Inference accelerator.

```python
predictor = tensorflow_model.deploy(
    ...
    instance_type="ml.g4dn.2xlarge",
    # instance_type="ml.c5.xlarge",
    # accelerator_type="ml.eia1.medium",
    ...
)
```

**Option 2: Update the existing endpoint**

Refer to the [Option 2. Update the existing endpoint](#) guidance in Step 4 of the [PyTorch section](#) (p. 2761).

**MXNet**

If you're migrating from MXNet, use the following guidelines.

1. **Choose the right instance type**

Refer to the [1. Choose the right instance type](#) guidance in the [PyTorch section](#) (p. 2761).

2. **Deploy the model to the endpoint and invoke it**

You can use one of the following options for deploying your model.

**Option 1: Deploy from scratch**

You can migrate from Elastic Inference by re-deploying the model to a new endpoint by removing the `accelerator_type` field and specifying a right-sized instance type from the [Accelerated Computing](#) category, such as G4. In the following example, the commented out line causes you to deploy without using an Elastic Inference accelerator.
category, such as G4. In the following example, the commented out line causes you to deploy without using an Elastic Inference accelerator.

```python
predictor = mxnet_model.deploy(
    ...
    # instance_type="ml.c5.xlarge",
    instance_type="ml.g4dn.2xlarge"
    ...
)
```

**Option 2: Update the existing endpoint**

Refer to the *Option 2: Update the existing endpoint* guidance in Step 4 of the [PyTorch section (p. 2761)](p.2761).

**Topics**
- How EI Works (p. 2765)
- Choose an EI Accelerator Type (p. 2766)
- Use EI in a SageMaker Notebook Instance (p. 2766)
- Use EI on a Hosted Endpoint (p. 2766)

## How EI Works

Amazon Elastic Inference accelerators are network attached devices that work along with SageMaker instances in your endpoint to accelerate your inference calls. Elastic Inference accelerates inference by allowing you to attach fractional GPUs to any SageMaker instance. You can select the client instance to run your application and attach an Elastic Inference accelerator to use the right amount of GPU acceleration for your inference needs. Elastic Inference helps you lower your cost when not fully utilizing your GPU instance for inference. We recommend trying Elastic Inference with your model using different CPU instances and accelerator sizes.

The following EI accelerator types are available. You can configure your endpoints or notebook instances with any EI accelerator type.

In the table, the throughput in teraflops (TFLOPS) is listed for both single-precision floating-point (F32) and half-precision floating-point (F16) operations. The memory in GB is also listed.

<table>
<thead>
<tr>
<th>Accelerator Type</th>

</tr>
</tbody>
</table>
Choose an EI Accelerator Type

Consider the following factors when choosing an accelerator type for a hosted model:

- Models, input tensors and batch sizes influence the amount of accelerator memory you need. Start with an accelerator type that provides at least as much memory as the file size of your trained model. Factor in that a model might use significantly more memory than the file size at runtime.
- Demands on CPU compute resources, main system memory, and GPU-based acceleration and accelerator memory vary significantly between different kinds of deep learning models. The latency and throughput requirements of the application also determine the amount of compute and acceleration you need. Thoroughly test different configurations of instance types and EI accelerator sizes to make sure you choose the configuration that best fits the performance needs of your application.

For more information on selecting an EI accelerator, see:

- Amazon Elastic Inference Overview
- Choosing an Instance and Accelerator Type for Your Model
- Optimizing costs in Amazon Elastic Inference with TensorFlow

Use EI in a SageMaker Notebook Instance

Typically, you build and test machine learning models in a SageMaker notebook before you deploy them for production. You can attach EI to your notebook instance when you create the notebook instance. You can set up an endpoint that is hosted locally on the notebook instance by using the local mode supported by TensorFlow, MXNet, and PyTorch estimators and models in the Amazon SageMaker Python SDK to test inference performance. Elastic Inference enabled PyTorch is not currently supported on notebook instances. For instructions on how to attach EI to a notebook instance and set up a local endpoint for inference, see Attach EI to a Notebook Instance (p. 2771). There are also Elastic Inference-enabled SageMaker Notebook Jupyter kernels for Elastic Inference-enabled versions of TensorFlow and Apache MXNet. For information about using SageMaker notebook instances, see Use Amazon SageMaker Notebook Instances

Use EI on a Hosted Endpoint

When you are ready to deploy your model for production to provide inferences, you create a SageMaker hosted endpoint. You can attach EI to the instance where your endpoint is hosted to increase its performance at providing inferences. For instructions on how to attach EI to a hosted endpoint instance, see Use EI on Amazon SageMaker Hosted Endpoints (p. 2773).

Frameworks that Support EI

Amazon Elastic Inference is designed to be used with AWS enhanced versions of TensorFlow, Apache MXNet, or PyTorch machine learning frameworks. These enhanced versions of the frameworks are automatically built into containers when you use the Amazon SageMaker Python SDK, or you can download them as binary files and import them in your own Docker containers.
You can download the EI-enabled TensorFlow binary files from the public amazonei-tensorflow Amazon S3 bucket to the TensorFlow serving containers. For more information about building a container that uses the EI-enabled version of TensorFlow, see Amazon Elastic Inference with TensorFlow in SageMaker.

You can download the EI-enabled MXNet binary files from the public amazonei-apachemxnet Amazon S3 bucket to the MXNet serving containers. For more information about building a container that uses the EI-enabled version of MXNet, see Amazon Elastic Inference with MXNet in SageMaker.

You can download the Elastic Inference enabled binary for PyTorch. For more information about building a container that uses the EI-enabled version of PyTorch, see Amazon Elastic Inference with PyTorch in SageMaker.

To use Elastic Inference in a hosted endpoint, you can choose any of the following frameworks depending on your needs.

- SageMaker Python SDK - Deploy TensorFlow models
- SageMaker Python SDK - Deploy MXNet models
- SageMaker Python SDK - Deploy PyTorch models

If you need to create a custom container for deploying your model that is complex and requires extensions to a framework that the SageMaker pre-built containers do not support, use the low-level AWS SDK for Python (Boto 3).

Use EI with SageMaker Built-in Algorithms

Currently, the Image Classification - MXNet (p. 1754) and Object Detection - MXNet (p. 1778) built-in algorithms support EI. For an example that uses the Image Classification algorithm with EI, see End-to-End Multiclass Image Classification Example.

EI Sample Notebooks

The following Sample notebooks provide examples of using EI in SageMaker:

- Using Amazon Elastic Inference with MXNet on Amazon SageMaker
- Using Amazon Elastic Inference with MXNet on an Amazon SageMaker Notebook Instance
- Using Amazon Elastic Inference with Neo-compiled TensorFlow model on SageMaker
- Using Amazon Elastic Inference with a pre-trained TensorFlow Serving model on SageMaker

Set Up to Use EI

Use the instructions in this topic only if one of the following applies to you:

- You want to use a customized role or permission policy.
- You want to use a VPC for your hosted model or notebook instance.

Note

If you already have an execution role that has the AmazonSageMakerFullAccess managed policy attached (this is true for any IAM role that you create when you create a notebook instance, training job, or model in the console) and you are not connecting to an EI model or notebook instance in a VPC, you do not need to make any of these changes to use EI in Amazon SageMaker.
Set Up Required Permissions

To use EI in SageMaker, the role that you use to open a notebook instance or create a deployable model must have a policy with the required permissions attached. You can attach the AmazonSageMakerFullAccess managed policy, which contains the required permissions, to the role, or you can add a custom policy that has the required permissions. For information about creating an IAM role, see Creating a Role for an AWS Service (Console) in the AWS Identity and Access Management User Guide. For information about attaching a policy to a role, see Adding and Removing IAM Policies.

Add these permissions specifically for connecting EI in an IAM policy.

```json
{
  "Effect": "Allow",
  "Action": ["elastic-inference:Connect", "ec2:DescribeVpcEndpoints"],
  "Resource": "*"
}
```

The following IAM policy is the complete list of required permissions to use EI in SageMaker.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",

Use a Custom VPC to Connect to EI

To use EI with SageMaker in a VPC, you need to create and configure two security groups, and set up a PrivateLink VPC interface endpoint. EI uses VPC interface endpoint to communicate with SageMaker endpoints in your VPC. The security groups you create are used to connect to the VPC interface endpoint.

Set up Security Groups to Connect to EI

To use EI within a VPC, you need to create two security groups:

- A security group to control access to the VPC interface endpoint that you will set up for EI.
- A security group that allows SageMaker to call into the first security group.

To configure the two security groups

1. Create a security group with no outbound connections. You will attach this to the VPC endpoint interface you create in the next section.
2. Create a second security group with no inbound connections, but with an outbound connection to the first security group.
3. Edit the first security group to allow inbound connections only to the second security group an all outbound connections.

For more information about VPC security groups, see Security Groups for Your VPC in the Amazon Virtual Private Cloud User Guide.

Set up a VPC Interface Endpoint to Connect to EI

To use EI with SageMaker in a custom VPC, you need to set up a VPC interface endpoint (PrivateLink) for the EI service.

- Set up a VPC interface endpoint (PrivateLink) for the EI. Follow the instructions at Creating an Interface Endpoint. In the list of services, choose com.amazonaws.<region>.elastic-inference.runtime. For Security group, make sure you select the first security group you created in the previous section to the endpoint.
- When you set up the interface endpoint, choose all of the Availability Zones where EI is available. EI fails if you do not set up at least two Availability Zones. For information about VPC subnets, see VPCs and Subnets.
Attach EI to a Notebook Instance

To test and evaluate inference performance using EI, you can attach EI to a notebook instance when you create or update a notebook instance. You can then use EI in local mode to host a model at an endpoint hosted on the notebook instance. You should test various sizes of notebook instances and EI accelerators to evaluate the configuration that works best for your use case.

Set Up to Use EI

To use EI locally in a notebook instance, create a notebook instance with an EI instance.

To create a notebook instance with an EI instance

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose Notebook instances.
3. Choose Create notebook instance.
4. For Notebook instance name, provide a unique name for your notebook instance.
5. For notebook instance type, choose a CPU instance such as ml.t2.medium.
6. For Elastic Inference (EI), choose an instance from the list, such as ml.eia2.medium.
7. For IAM role, choose an IAM role that has the required permissions to use SageMaker and EI.
8. (Optional) For VPC - Optional, if you want the notebook instance to use a VPC, choose one from the available list. Otherwise, leave it as No VPC. If you use a VPC follow the instructions at Use a Custom VPC to Connect to EI (p. 2770).
9. (Optional) For Lifecycle configuration - optional, either leave it as No configuration or choose a lifecycle configuration. For more information, see Customize a Notebook Instance Using a Lifecycle Configuration Script (p. 323).
10. (Optional) For Encryption key - optional, (Optional) If you want SageMaker to use an AWS Key Management Service (AWS KMS) key to encrypt data in the ML storage volume attached to the notebook instance, specify the key.
11. (Optional) For Volume Size In GB - optional, leave the default value of 5.
12. (Optional) For Tags, add tags to the notebook instance. A tag is a label you assign to help manage your notebook instances. A tag consists of a key and a value, both of which you define.
13. Choose Create Notebook Instance.

After you create your notebook instance with EI attached, you can create a Jupyter notebook and set up an EI endpoint that is hosted locally on the notebook instance.

Topics

• Use EI in Local Mode in SageMaker (p. 2771)

Use EI in Local Mode in SageMaker

To use EI locally in an endpoint hosted on a notebook instance, use local mode with the Amazon SageMaker Python SDK versions of either the TensorFlow, MXNet, or PyTorch estimators or models. For more information about local mode support in the SageMaker Python SDK, see https://github.com/aws/sagemaker-python-sdk#sagemaker-python-sdk-overview.

Topics

• Use EI in Local Mode with SageMaker TensorFlow Estimators and Models (p. 2772)
• Use EI in Local Mode with SageMaker Apache MXNet Estimators and Models (p. 2772)
Use EI in Local Mode with SageMaker TensorFlow Estimators and Models

To use EI with TensorFlow in local mode, specify local for instance_type and local_sagemaker_notebook for accelerator_type when you call the deploy method of an estimator or a model object. For more information about Amazon SageMaker Python SDK TensorFlow estimators and models, see https://sagemaker.readthedocs.io/en/stable/frameworks/tensorflow/index.html.

The following code shows how to use local mode with an estimator object. To call the deploy method, you must have previously either:

- Trained the model by calling the fit method of an estimator.
- Pass a model artifact when you initialize the model object.

```python
# Deploys the model to a local endpoint
tf_predictor = tf_model.deploy(initial_instance_count=1,
                                instance_type='local',
                                accelerator_type='local_sagemaker_notebook')
```

Use EI in Local Mode with SageMaker Apache MXNet Estimators and Models

To use EI with MXNet in local mode, specify local for instance_type and local_sagemaker_notebook for accelerator_type when you call the deploy method of an estimator or a model object. For more information about Amazon SageMaker Python SDK MXNet estimators and models, see https://sagemaker.readthedocs.io/en/stable/frameworks/mxnet/index.html.

The following code shows how to use local mode with an estimator object. You must have previously called the fit method of the estimator to train the model.

```python
# Deploys the model to a local endpoint
mxnet_predictor = mxnet_estimator.deploy(initial_instance_count=1,
                                          instance_type='local',
                                          accelerator_type='local_sagemaker_notebook')
```

For a complete example of using EI in local mode with MXNet, see the sample notebook at https://sagemaker-examples.readthedocs.io/en/latest/sagemaker-python-sdk/mxnet_mnist/mxnet_mnist_elastic_inference_local.html.

Use EI in Local Mode with SageMaker PyTorch Estimators and Models

To use EI with PyTorch in local mode, when you call the deploy method of an estimator or a model object, specify local for instance_type and local_sagemaker_notebook for accelerator_type. For more information about Amazon SageMaker Python SDK PyTorch estimators and models, see SageMaker PyTorch Estimators and Models.

The following code shows how to use local mode with an estimator object. You must have previously called the fit method of the estimator to train the model.

```python
# Deploys the model to a local endpoint
pytorch_predictor = pytorch_estimator.deploy(initial_instance_count=1,
                                             instance_type='local',
                                             accelerator_type='local_sagemaker_notebook')
```
Use EI on Amazon SageMaker Hosted Endpoints

To use Elastic Inference (EI) in Amazon SageMaker with a hosted endpoint for real-time inference, specify an EI accelerator when you create the deployable model to be hosted at that endpoint. You can do this in one of the following ways:

- Use the Amazon SageMaker Python SDK versions of either the TensorFlow, MXNet, or PyTorch and the SageMaker pre-built containers for TensorFlow, MXNet, and PyTorch
- Build your own container, and use the low-level SageMaker API (Boto 3). You will need to import the EI-enabled version of either TensorFlow, MXNet, or PyTorch from the provided Amazon S3 locations into your container, and use one of those versions to write your training script.
- Use either the Image Classification - MXNet (p. 1754) or Object Detection - MXNet (p. 1778) built-in algorithms, and use the AWS SDK for Python (Boto3) to run your training job and create your deployable model and hosted endpoint.

Topics
- Use EI with a SageMaker TensorFlow Container (p. 2773)
- Use EI with a SageMaker MXNet Container (p. 2774)
- Use EI with a SageMaker PyTorch Container (p. 2774)
- Use EI with Your Own Container (p. 2775)

Use EI with a SageMaker TensorFlow Container

SageMaker provides default model training and inference code for your convenience. For custom file formats, you might need to implement custom model training and inference code.

Use an Estimator Object

To use an estimator object with EI, when you use the deploy method, include the accelerator_type input argument. The estimator returns a predictor object, which we call its deploy method, as shown in the example code.

```
# Deploy an estimator using EI (using the accelerator_type input argument)
predictor = estimator.deploy(initial_instance_count=1,
                          instance_type='ml.m4.xlarge',
                          accelerator_type='ml.eia2.medium')
```

Use a Model Object

To use a model object with EI, when you use the deploy method, include the accelerator_type input argument. The estimator returns a predictor object, which we call its deploy method, as shown in the example code.

```
# Deploy a model using EI (using the accelerator_type input argument)
predictor = model.deploy(initial_instance_count=1,
                        instance_type='ml.m4.xlarge',
                        accelerator_type='ml.eia2.medium')
```
Use El with a SageMaker MXNet Container

To use MXNet with El in SageMaker, you need to call the deploy method of either the Estimator or Model objects. You then specify an accelerator type using the accelerator_type input argument. For information about using MXNet in the Amazon SageMaker Python SDK, see https://sagemaker.readthedocs.io/en/stable/frameworks/mxnet/index.html

For your convenience, SageMaker provides default model training and inference code. For custom file formats, you might need to write custom model training and inference code.

Use an Estimator Object

To use an estimator object with El, when you use the deploy method, include the accelerator_type input argument. The estimator returns a predictor object, which we call its deploy method, as shown in the example code.

```python
# Deploy an estimator using El (using the accelerator_type input argument)
predictor = estimator.deploy(initial_instance_count=1,
                             instance_type='ml.m4.xlarge',
                             accelerator_type='ml.eia2.medium')
```

Use a Model Object

To use a model object with El, when you use the deploy method, include the accelerator_type input argument. The estimator returns a predictor object, which we call its deploy method, as shown in the example code.

```python
# Deploy a model using El (using the accelerator_type input argument)
predictor = model.deploy(initial_instance_count=1,
                         instance_type='ml.m4.xlarge',
                         accelerator_type='ml.eia2.medium')
```

For a complete example of using El with MXNet in SageMaker, see the sample notebook at https://github.com/awslabs/amazon-sagemaker-examples/blob/master/sagemaker-python-sdk/mxnet_mnist/mxnet_mnist_elastic_inference.ipynb

Use El with a SageMaker PyTorch Container

To use PyTorch with El in SageMaker, you need to call the deploy method of either the Estimator or Model objects. You then specify an accelerator type using the accelerator_type input argument. For information about using PyTorch in the Amazon SageMaker Python SDK, see SageMaker PyTorch Estimators and Models.

For your convenience, SageMaker provides default model training and inference code. For custom file formats, you might need to write custom model training and inference code.

Use an Estimator Object

To use an estimator object with El, when you use the deploy method, include the accelerator_type input argument. The estimator returns a predictor object, which we call its deploy method, as shown in this example code.

```python
# Deploy an estimator using El (using the accelerator_type input argument)
predictor = estimator.deploy(initial_instance_count=1,
                             instance_type='ml.m4.xlarge',
                             accelerator_type='ml.eia2.medium')
```
Use a Model Object

To use a model object with EI, when you use the deploy method, include the `accelerator_type` input argument. The model returns a predictor object, which we call its deploy method, as shown in this example code.

```python
# Deploy a model using EI (using the accelerator_type input argument)
predictor = model.deploy(initial_instance_count=1,
                         instance_type='ml.m4.xlarge',
                         accelerator_type='ml.eia2.medium')
```

Use EI with Your Own Container

To use EI with a model in a custom container that you build, use the low-level AWS SDK for Python (Boto 3). Download and import the AWS EI-enabled versions of TensorFlow, Apache MXNet, or PyTorch machine learning frameworks, and write your training script using those frameworks.

Import the EI Version of TensorFlow, MXNet, or PyTorch into Your Docker Container

To use EI with your own container, you need to import either the Amazon EI TensorFlow Serving library, the Amazon EI Apache MXNet library, or the Elastic Inference enabled PyTorch library into your container. The EI-enabled versions of TensorFlow and MXNet are currently available as binary files stored in Amazon S3 locations. You can download the EI-enabled binary for TensorFlow from the Amazon S3 bucket at `console.aws.amazon.com/s3/buckets/amazonei-tensorflow`. For information about building a container that uses the EI-enabled version of TensorFlow, see `https://github.com/aws/sagemaker-tensorflow-container#building-the-sagemaker-elastic-inference-tensorflow-serving-container`. You can download the EI-enabled binary for Apache MXNet from the public Amazon S3 bucket at `console.aws.amazon.com/s3/buckets/amazonei-apachemxnet`. For information about building a container that uses the EI-enabled version of MXNet, see `https://github.com/aws/sagemaker-mxnet-container#building-the-sagemaker-elastic-inference-mxnet-container`. You can download the Elastic Inference enabled binary for PyTorch. For information about building a container that uses the Elastic Inference enabled version of PyTorch, see `Building your image`.

Create an EI Endpoint with AWS SDK for Python (Boto 3)

To create an endpoint by using AWS SDK for Python (Boto 3), you first create an endpoint configuration. The endpoint configuration specifies one or more models (called production variants) that you want to host at the endpoint. To attach EI to one or more of the production variants hosted at the endpoint, you specify one of the EI instance types as the `AcceleratorType` field for that ProductionVariant. You then pass that endpoint configuration when you create the endpoint.

Create an Endpoint Configuration

To use EI, you need to specify an accelerator type in the endpoint configuration.

```python
# Create Endpoint Configuration
from time import gmtime, strftime

endpoint_config_name = 'ImageClassificationEndpointConfig-' + strftime("%Y-%m-%d-%H-%M-%S",
                                       gmtime())
print(endpoint_config_name)
create_endpoint_config_response = sagemaker.create_endpoint_config(
   EndpointConfigName = endpoint_config_name,
   ProductionVariants=[[
       'InstanceType':'ml.m4.xlarge',
       'InitialInstanceCount':1,
       'ModelName':model_name,
       'VariantName':'AllTraffic',
   ]])
```
Best practices for deploying models on SageMaker Hosting Services

When hosting models using SageMaker hosting services, consider the following:

- Typically, a client application sends requests to the SageMaker HTTPS endpoint to obtain inferences from a deployed model. You can also send requests to this endpoint from your Jupyter notebook during testing.

- You can deploy a model trained with SageMaker to your own deployment target. To do that, you need to know the algorithm-specific format of the model artifacts that were generated by model training. For more information about output formats, see the section corresponding to the algorithm you are using in Common Data Formats for Training (p. 1537).

- You can deploy multiple variants of a model to the same SageMaker HTTPS endpoint. This is useful for testing variations of a model in production. For example, suppose that you've deployed a model into production. You want to test a variation of the model by directing a small amount of traffic, say 5%, to the new model. To do this, create an endpoint configuration that describes both variants of the model. You specify the ProductionVariant in your request to the CreateEndPointConfig. For more information, see ProductionVariant.

- You can configure a ProductionVariant to use Application Auto Scaling. For information about configuring automatic scaling, see Automatically Scale Amazon SageMaker Models (p. 2447).
• You can modify an endpoint without taking models that are already deployed into production out of service. For example, you can add new model variants, update the ML Compute instance configurations of existing model variants, or change the distribution of traffic among model variants. To modify an endpoint, you provide a new endpoint configuration. SageMaker implements the changes without any downtime. For more information see, UpdateEndpoint and UpdateEndpointWeightsAndCapacities.

• Changing or deleting model artifacts or changing inference code after deploying a model produces unpredictable results. If you need to change or delete model artifacts or change inference code, modify the endpoint by providing a new endpoint configuration. Once you provide the new endpoint configuration, you can change or delete the model artifacts corresponding to the old endpoint configuration.

• If you want to get inferences on entire datasets, consider using batch transform as an alternative to hosting services. For information, see Use Batch Transform (p. 2545)

Deploy Multiple Instances Across Availability Zones

Create robust endpoints when hosting your model. SageMaker endpoints can help protect your application from Availability Zone outages and instance failures. If an outage occurs or an instance fails, SageMaker automatically attempts to distribute your instances across Availability Zones. For this reason, we strongly recommend that you deploy multiple instances for each production endpoint.

If you are using an Amazon Virtual Private Cloud (VPC), configure the VPC with at least two Subnets, each in a different Availability Zone. If an outage occurs or an instance fails, Amazon SageMaker automatically attempts to distribute your instances across Availability Zones.

In general, to achieve more reliable performance, use more small Instance Types in different Availability Zones to host your endpoints.

Monitor Security Best Practices

Low latency real-time inference with AWS PrivateLink

Amazon SageMaker provides low latency for real-time inferences while maintaining high availability and resiliency using multi-AZ deployment. The application latency is made up of two primary components: infrastructure or overhead latency and model inference latency. Reduction of overhead latency opens up new possibilities such as deploying more complex, deep, and accurate models or splitting monolithic applications into scalable and maintainable microservice modules. You can reduce the latency for real-time inferences with SageMaker using an AWS PrivateLink deployment. With AWS PrivateLink, you can privately access all SageMaker API operations from your Virtual Private Cloud (VPC) in a scalable manner by using interface VPC endpoints. An interface VPC endpoint is an elastic network interface in your subnet with private IP addresses that serves as an entry point for all SageMaker API calls.

By default, a SageMaker endpoint with 2 or more instances is deployed in at least 2 AWS Availability Zones (AZs) and instances in any AZ can process invocations. This results in one or more AZ “hops” that contribute to the overhead latency. An AWS PrivateLink deployment with the privateDNSEnabled option set as true alleviates this by achieving two objectives:

• It keeps all inference traffic within your VPC.
• It keeps invocation traffic in the same AZ as the client that originated it when using SageMaker Runtime. This avoids the “hops” between AZs reducing the overhead latency.
The following sections of this guide demonstrate how you can reduce the latency for real-time inferences with AWS PrivateLink deployment.

**Topics**

- [Deploy AWS PrivateLink](#)
- [Deploy SageMaker endpoint in a VPC](#)
- [Invoke the SageMaker endpoint](#)

**Deploy AWS PrivateLink**

To deploy AWS PrivateLink, first create an interface endpoint for the VPC from which you connect to the SageMaker endpoints. Please follow the steps in [Access an AWS service using an interface VPC endpoint](#) to create the interface endpoint. While creating the endpoint, select the following settings in the console interface:

- Select the **Enable DNS name** checkbox under **Additional Settings**
- Select the appropriate security groups and the subnets to be used with the SageMaker endpoints.

Also make sure that the VPC has DNS hostnames turned on. For more information on how to change DNS attributes for your VPC, see [View and update DNS attributes for your VPC](#).

**Deploy SageMaker endpoint in a VPC**

To achieve low overhead latency, create a SageMaker endpoint using the same subnets that you specified when deploying AWS PrivateLink. These subnets should match the AZs of your client application, as shown in the following code snippet.

```python
model_name = '<the-name-of-your-model>'
vpc = 'vpc-0123456789abcdef0'
subnet_a = 'subnet-0123456789abcdef0'
subnet_b = 'subnet-0123456789abcdef1'
security_group = 'sg-0123456789abcdef0'
create_model_response = sagemaker_client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = sagemaker_role,
    PrimaryContainer = {
        'Image': container,
        'ModelDataUrl': model_url
    },
    VpcConfig = {
        'SecurityGroupIds': [security_group],
        'Subnets': [subnet_a, subnet_b],
    },
)
```

The aforementioned code snippet assumes that you have followed the steps in [Before you begin](#).

**Invoke the SageMaker endpoint**

Finally, specify the SageMaker Runtime client and invoke the SageMaker endpoint as shown in the following code snippet.
endpoint_name = '<endpoint-name>'
runtime_client = boto3.client('sagemaker-runtime')
response = runtime_client.invoke_endpoint(EndpointName=endpoint_name,
    ContentType='text/csv',
    Body=payload)

For more information on endpoint configuration, see Create an Endpoint Configuration (p. 2393).

Migrate inference workload from x86 to AWS Graviton

AWS Graviton is a series of ARM-based processors designed by AWS. They are more energy efficient than x86-based processors and offer a compelling price-performance ratio. Amazon SageMaker offers Graviton-based instances so that you can take advantage of these advanced processors for your inference needs.

You can migrate your existing inference workloads from x86-based instances to Graviton-based instances, by using either ARM compatible container images or multi-architecture container images. This guide assumes that you are either using AWS Deep Learning container images, or your own ARM compatible container images. For more information on building your own images, check Building your image.

At a high level, migrating inference workload from x86-based instances to Graviton-based instances is a four-step process:

1. Push container images to Amazon Elastic Container Registry (Amazon ECR), an AWS managed container registry.
2. Create a SageMaker Model.
3. Create an endpoint configuration.
4. Create an endpoint.

This process is very similar to how you would deploy models to x86-based instances. Check Create your endpoint and deploy your model (p. 2389), and particularly Before you begin (p. 2390), for details on deploying to x86-based instances.

The following sections of this guide provide more details regarding the above steps. Replace the user placeholder text in the code examples with your own information.

Topics
- Push container images to Amazon ECR (p. 2779)
- Create a SageMaker Model (p. 2780)
- Create an endpoint configuration (p. 2781)
- Create an endpoint (p. 2781)

Push container images to Amazon ECR

You can push your container images to Amazon ECR with the AWS CLI. When using an ARM compatible image, verify that it supports ARM architecture:

docker inspect deep-learning-container-uri
The response "Architecture": "arm64" indicates that the image supports ARM architecture. You can push it to Amazon ECR with the docker push command. For more information, check Pushing a Docker image.

Multi-architecture container images are fundamentally a set of container images supporting different architectures or operating systems, that you can refer to by a common manifest name. If you are using multi-architecture container images, then in addition to pushing the images to Amazon ECR, you will also have to push a manifest list to Amazon ECR. A manifest list allows for the nested inclusion of other image manifests, where each included image is specified by architecture, operating system and other platform attributes. The following example creates a manifest list, and pushes it to Amazon ECR.

1. Create a manifest list.

```bash
docker manifest create aws-account-id.dkr.ecr.aws-region.amazonaws.com/my-repository \
    aws-account-id.dkr.ecr.aws-account-id.amazonaws.com/my-repository:amd64 \
    aws-account-id.dkr.ecr.aws-account-id.amazonaws.com/my-repository:arm64
```

2. Annotate the manifest list, so that it correctly identifies which image is for which architecture.

```bash
docker manifest annotate --arch arm64 aws-account-id.dkr.ecr.aws-region.amazonaws.com/my-repository \
    aws-account-id.dkr.ecr.aws-region.amazonaws.com/my-repository:arm64
```

3. Push the manifest.

```bash
docker manifest push aws-account-id.dkr.ecr.aws-region.amazonaws.com/my-repository
```

For more information on creating and pushing manifest lists to Amazon ECR, check Introducing multi-architecture container images for Amazon ECR, and Pushing a multi-architecture image.

Create a SageMaker Model

Create a SageMaker Model by calling the CreateModel API.

```python
import boto3
from sagemaker import get_execution_role

aws_region = "aws-region"
sagemaker_client = boto3.client("sagemaker", region_name=aws_region)

role = get_execution_role()
sagemaker_client.create_model(
    ModelName = "model-name",
    PrimaryContainer = {
        "Image": "deep-learning-container-uri",
        "ModelDataUrl": "model-s3-location",
        "Environment": {
        "SAGEMAKER_PROGRAM": "inference.py",
        "SAGEMAKER_SUBMIT_DIRECTORY": "inference-script-s3-location",
        "SAGEMAKER_CONTAINER_LOG_LEVEL": "20",
        "SAGEMAKER_REGION": aws_region,
    }
    )
```
Create an endpoint configuration

Create an endpoint configuration by calling the `CreateEndpointConfig` API. For a list of Graviton-based instances, check [Compute optimized instances](#).

```python
sagemaker_client.create_endpoint_config(
    EndpointConfigName = "endpoint-config-name",
    ProductionVariants = [
        {
            "VariantName": "variant-name",
            "ModelName": "model-name",
            "InitialInstanceCount": 1,
            "InstanceType": "ml.c7g.xlarge", # Graviton-based instance
        }
    ]
)
```

Create an endpoint

Create an endpoint by calling the `CreateEndpoint` API.

```python
sagemaker_client.create_endpoint(
    EndpointName = "endpoint-name",
    EndpointConfigName = "endpoint-config-name"
)
```

Troubleshoot Amazon SageMaker model deployments

If you encounter an issue when deploying machine learning models in Amazon SageMaker, see the following guidance.

Topics

- [Detection Errors in the Active CPU Count](#) (p. 2781)
- Issues with deploying a model.tar.gz file (p. 2782)
- Primary container did not pass ping health checks (p. 2783)

Detection Errors in the Active CPU Count

If you deploy a SageMaker model with a Linux Java Virtual Machine (JVM), you might encounter detection errors that prevent using available CPU resources. This issue affects some JVMs that support Java 8 and Java 9, and most that support Java 10 and Java 11. These JVMs implement a mechanism that detects and handles the CPU count and the maximum memory available when running a model in a Docker container, and, more generally, within Linux `taskset` commands or control groups (cgroups).
SageMaker deployments take advantage of some of the settings that the JVM uses for managing these resources. Currently, this causes the container to incorrectly detect the number of available CPUs.

SageMaker doesn't limit access to CPUs on an instance. However, the JVM might detect the CPU count as 1 when more CPUs are available for the container. As a result, the JVM adjusts all of its internal settings to run as if only 1 CPU core is available. These settings affect garbage collection, locks, compiler threads, and other JVM internals that negatively affect the concurrency, throughput, and latency of the container.

For an example of the misdetection, in a container configured for SageMaker that is deployed with a JVM that is based on Java8_191 and that has four available CPUs on the instance, run the following command to start your JVM:

```java
java -XX:+UnlockDiagnosticVMOptions -XX:+PrintActiveCpus -version
```

This generates the following output:

```
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: determined by OSContainer: 1
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: determined by OSContainer: 1
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: determined by OSContainer: 1
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: determined by OSContainer: 1
openjdk version "1.8.0_191"
OpenJDK Runtime Environment (build 1.8.0_191-8u191-b12-2ubuntu0.16.04.1-b12)
OpenJDK 64-Bit Server VM (build 25.191-b12, mixed mode)
```

Many of the JVMs affected by this issue have an option to disable this behavior and reestablish full access to all of the CPUs on the instance. Disable the unwanted behavior and establish full access to all instance CPUs by including the `-XX:-UseContainerSupport` parameter when starting Java applications. For example, run the `java` command to start your JVM as follows:

```java
java -XX:-UseContainerSupport -XX:+UnlockDiagnosticVMOptions -XX:+PrintActiveCpus -version
```

This generates the following output:

```
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: determined by OSContainer: 1
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: determined by OSContainer: 1
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: determined by OSContainer: 1
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: determined by OSContainer: 1
openjdk version "1.8.0_191"
OpenJDK Runtime Environment (build 1.8.0_191-8u191-b12-2ubuntu0.16.04.1-b12)
OpenJDK 64-Bit Server VM (build 25.191-b12, mixed mode)
```

Check whether the JVM used in your container supports the `-XX:-UseContainerSupport` parameter. If it does, always pass the parameter when you start your JVM. This provides access to all of the CPUs in your instances.

You might also encounter this issue when indirectly using a JVM in SageMaker containers. For example, when using a JVM to support SparkML Scala. The `-XX:-UseContainerSupport` parameter also affects the output returned by the `Java Runtime.getRuntime().availableProcessors()` API.

### Issues with deploying a model.tar.gz file

When you deploy a model using a `model.tar.gz` file, the model tarball should not include any symlinks. Symlinks cause the model creation to fail. Also, we recommend that you do not include any unnecessary files in the tarball.
Primary container did not pass ping health checks

If your primary container fails ping health checks with the following error message, it indicates that there is an issue with your container or script:

```
The primary container for production variant beta did not pass the ping health check. Please check CloudWatch Logs logs for this endpoint.
```

To troubleshoot this issue, you should check the CloudWatch Logs logs for the endpoint in question to see if there are any errors or issues that are preventing the container from responding to /ping or /invocations. The logs may provide an error message that could point to the issue. Once you have identified the error and failure reason you should resolve the error.

It is also good practice to test the model deployment locally before creating an endpoint.

- Use local mode in the SageMaker SDK to imitate the hosted environment by deploying the model to a local endpoint. For more information, see [Local Mode](#).
- Use vanilla docker commands to test the container responds to /ping and /invocations. For more information, see [local_test](#).

Inference cost optimization best practices

The following content provides techniques and considerations for optimizing the cost of endpoints. You can use these recommendations to optimize the cost for both new and existing endpoints.

### Best practices

To optimize your SageMaker Inference costs, follow these best practices.

**Pick the best inference option for the job.**

SageMaker offers 4 different inference options to provide the best inference option for the job. You may be able to save on costs by picking the inference option that best matches your workload.

- Use **real-time inference** for low latency workloads with predictable traffic patterns that need to have consistent latency characteristics and are always available. You pay for using the instance.
- Use **serverless inference** for synchronous workloads that have a spiky traffic pattern and can accept variations in the p99 latency. Serverless inference automatically scales to meet your workload traffic so you don’t pay for any idle resources. You only pay for the duration of the inference request. The same model and containers can be used with both real-time and serverless inference so you can switch between these two modes if your needs change.
- Use **asynchronous inference** for asynchronous workloads that process up to 1 GB of data (such as text corpus, image, video, and audio) that are latency insensitive and cost sensitive. With asynchronous inference, you can control costs by specifying a fixed number of instances for the optimal processing rate instead of provisioning for the peak. You can also scale down to zero to save additional costs.
- Use **batch inference** for workloads for which you need inference for a large set of data for processes that happen offline (that is, you don’t need a persistent endpoint). You pay for the instance for the duration of the batch inference job.

**Opt in to a SageMaker Savings Plan.**

- If you have a consistent usage level across all SageMaker services, you can opt in to a SageMaker Savings Plan to help reduce your costs by up to 64%.
Amazon SageMaker Savings Plans provide a flexible pricing model for Amazon SageMaker, in exchange for a commitment to a consistent amount of usage (measured in $/hour) for a one-year or three-year term. These plans automatically apply to eligible SageMaker ML instance usages including SageMaker Studio Notebook, SageMaker On-Demand Notebook, SageMaker Processing, SageMaker Data Wrangler, SageMaker Training, SageMaker Real-Time Inference, and SageMaker Batch Transform regardless of instance family, size, or Region. For example, you can change usage from a CPU ml.c5.xlarge instance running in US East (Ohio) to a ml.Inf1 instance in US West (Oregon) for inference workloads at any time and automatically continue to pay the Savings Plans price.

Optimize your model to run better.

- Unoptimized models can lead to longer run times and use more resources. You may choose to use more or bigger instances to improve performance; however, this leads to higher costs.
- By optimizing your models to be more performant, you may be able to lower costs by using fewer or smaller instances while keeping the same or better performance characteristics. You can use SageMaker Neo with SageMaker Inference to automatically optimize models. For more details and samples, see Optimize model performance using Neo (p. 2693).

Use the most optimal instance type and size for real-time inference.

- SageMaker Inference has over 70 instance types and sizes that can be used to deploy ML models including AWS Inferentia and Graviton chipsets that are optimized for ML. Choosing the right instance for your model helps ensure you have the most performant instance at the lowest cost for your models.
- By using Inference Recommender, you can quickly compare different instances to understand the performance of the model and the costs. With these results, you can choose the instance to deploy with the best return on investment.

Improve efficiency and costs by combining multiple endpoints into a single endpoint for real-time inference.

- Costs can quickly add up when you deploy multiple endpoints, especially if the endpoints don’t fully utilize the underlying instances. To understand if the instance is under-utilized, check the utilization metrics (CPU, GPU, etc) in Amazon CloudWatch for your instances. If you have more than one of these endpoints, you can combine the models or containers on these multiple endpoints into a single endpoint.
- Using Multi-model endpoints (MME) or Multi-container endpoints (MCE), you can deploy multiple ML models or containers in a single endpoint to share the instance across multiple models or containers and improve your return on investment. To learn more, see this Save on inference costs by using Amazon SageMaker multi-model endpoints or Deploy multiple serving containers on a single instance using Amazon SageMaker multi-container endpoints on the AWS Machine Learning blog.

Set up autoscaling to match your workload requirements for real-time and asynchronous inference.

- Without autoscaling, you need to provision for peak traffic or risk model unavailability. Unless the traffic to your model is steady throughout the day, there will be excess unused capacity. This leads to low utilization and wasted resources.
- Autoscaling is an out-of-the-box feature that monitors your workloads and dynamically adjusts the capacity to maintain steady and predictable performance at the possible lowest cost. When the workload increases, autoscaling brings more instances online. When the workload decreases, autoscaling removes unnecessary instances, helping you reduce your compute cost. To learn more,
Best practices to minimize interruptions during GPU driver upgrades

SageMaker Model Deployment upgrades GPU drivers on the ML instances for Real-time, Batch, and Asynchronous Inference options over time to provide customers access to improvements from the driver providers. Below you can see the GPU version supported for each Inference option. Different driver versions can change how your model interacts with the GPUs. Below are some strategies to help you understand how your application works with different driver versions.

Current versions and supported instance families

Amazon SageMaker Inference supports the following drivers and instance families:

<table>
<thead>
<tr>
<th>Service</th>
<th>GPU</th>
<th>Driver version</th>
<th>Instance types</th>
</tr>
</thead>
<tbody>
<tr>
<td>Real-time</td>
<td>NVIDIA</td>
<td>470.57.02</td>
<td>ml.p2.<em>, ml.p3.</em>, ml.p4d.<em>, ml.p4de.</em>, ml.g4dn.<em>, ml.g5.</em></td>
</tr>
<tr>
<td></td>
<td></td>
<td>535.54.03</td>
<td>ml.p5.*</td>
</tr>
<tr>
<td>Batch</td>
<td>NVIDIA</td>
<td>470.57.02</td>
<td>ml.p2.<em>, ml.p3.</em>, ml.p4d.<em>, ml.p4de.</em>, ml.g4dn.<em>, ml.g5</em></td>
</tr>
<tr>
<td>Asynchronous Inference</td>
<td>NVIDIA</td>
<td>470.57.02</td>
<td>ml.p2.<em>, ml.p3.</em>, ml.p4d.<em>, ml.p4de.</em>, ml.g4dn.<em>, ml.g5</em></td>
</tr>
<tr>
<td></td>

<td>535.54.03</td>
<td>ml.p5.*</td>
</tr>
</tbody>
</table>

Troubleshoot your model container with GPU capabilities

If you encounter an issue when running your GPU workload, see the following guidance:

**GPU card detection failure or NVIDIA initialization error**

Run the `nvidia-smi` (NVIDIA System Management Interface) command from within the Docker container. If the NVIDIA System Management Interface detects a GPU detection error or NVIDIA initialization error, it will return the following error message:

```
Failed to initialize NVML: Driver/library version mismatch
```

Based on your use case, follow these best practices to resolve the failure or error:

- Follow the best practice recommendation described in the [If you bring your own (BYO) model containers (p. 2786)](p. 2786) dropdown.
- Follow the best practice recommendation described in the [If you use a CUDA compatibility layer (p. 2786)](p. 2786) dropdown.

Refer to the [NVIDIA System Management Interface page](https://docs.nvidia.com/cuda/nvml/index.html) on the NVIDIA website for more information.
CannotStartContainerError

If your GPU instance uses NVIDIA driver versions that are not compatible with the CUDA version in the Docker container, then deploying an endpoint will fail with the following error message:

| Failure reason CannotStartContainerError. Please ensure the model container for variant <variant_name> starts correctly when invoked with 'docker run <image> serve' |

Based on your use case, follow these best practices to resolve the failure or error:

- Follow the best practice recommendation described in the The driver my container depends on is greater than the version on the ML GPU instances (p. 2786) dropdown.
- Follow the best practice recommendation described in the If you use a CUDA compatibility layer (p. 2786) dropdown.

Best practices for working with mismatched driver versions

The following provides information on how to update your GPU driver:

The driver my container depends on is lower than the version on the ML GPU instance

No action is required. NVIDIA provides backwards compatibility.

The driver my container depends on is greater than the version on the ML GPU instances

If it is a minor version difference, no action is required. NVIDIA provides minor version forward compatibility.

If it is a major version difference, the CUDA Compatibility Package will need to be installed. Please refer to CUDA Compatibility Package in the NVIDIA documentation.

Important

The CUDA Compatibility Package is not backwards compatible so it needs to be disabled if the driver version on the instance is greater than the CUDA Compatibility Package version.

If you bring your own (BYO) model containers

Ensure no NVIDIA driver packages are bundled in the image which could cause conflict with on host NVIDIA driver version.

If you use a CUDA compatibility layer

To verify if the platform Nvidia driver version supports the CUDA Compatibility Package version installed in the model container, see the CUDA documentation. If the platform Nvidia driver version does not support the CUDA Compatibility Package version, you can disable or remove the CUDA Compatibility Package from the model container image. If the CUDA compatibility libs version is supported by the latest Nvidia driver version, we suggest that you enable the CUDA Compatibility Package based on the detected Nvidia driver version for future compatibility by adding the code snippet below into the container start up shell script (at the ENTRYPOINT script).

The script demonstrates how to dynamically switch the use of the CUDA Compatibility Package based on the detected Nvidia driver version on the deployed host for your model container. When SageMaker releases a newer Nvidia driver version, the installed CUDA Compatibility Package can be turned off automatically if the CUDA application is supported natively on the new driver.

```bash
#!/bin/bash

verlte() {
    
    [ "$1" = "$2" ] && return 1 || [ "$2" = "\`echo -e "$1$2" | sort -V | head -n1\`" ]
}
```

Best practices for endpoint security and health with Amazon SageMaker

To address the latest security issues, Amazon SageMaker automatically patches endpoints to the latest and most secure software. However, if you incorrectly modify your endpoint dependencies, Amazon SageMaker can't automatically patch your endpoints or replace your unhealthy instances. To ensure your endpoints remain eligible for automatic updates, apply the following best practices.

Don’t delete resources while your endpoints use them

Avoid deleting any of the following resources if you have existing endpoints that use them:

- The model definition that you create with the `CreateModel` action in the Amazon SageMaker API.
- Any model artifacts that you specify for the `ModelDataUrl` parameter.
- The IAM role and permissions that you specify for the `ExecutionRoleArn` parameter.
  
  **Reminder**
  In the model definition that your endpoint uses, ensure that the IAM role that you specified has the correct permissions. For more information about the required permissions for Amazon SageMaker endpoints, see CreateModel API: Execution Role Permissions (p. 3404).

- The inference images that you specify for the `Image` parameter, if you use your own inference code.
  
  **Reminder**
  If you use the private registry feature, ensure that Amazon SageMaker can access the private registry as long as you’re using the endpoint.

- The Amazon VPC subnets and security groups that you specify for the `VpcConfig` parameter.
- The endpoint configuration that you create with the `CreateEndpointConfig` action in the Amazon SageMaker API.
- Any KMS keys or Amazon S3 buckets that you specify in the endpoint configuration.
  
  **Reminder**
  Ensure you don’t disable these KMS keys.

Follow these procedures to update your endpoints

When you update your Amazon SageMaker endpoints, use any of the following procedures that apply to your needs.
To update your model definition settings
1. Create a new model definition with your updated settings by using the CreateModel action in the Amazon SageMaker API.
2. Create a new endpoint configuration that uses the new model definition. To do this, use the CreateEndpointConfig action in the Amazon SageMaker API.
3. Update your endpoint with the new endpoint configuration so that your updated model definition settings take effect.
4. (Optional) Delete the old endpoint configuration if you're not using it with any other endpoints. You can also delete the resources that you specified in the model definition if you're not using them with any other endpoints. These resources include model artifacts in Amazon S3 and inference images.

To update your endpoint configuration
1. Create a new endpoint configuration with your updated settings.
2. Update your endpoint with the new configuration so that your updates take effect.
3. (Optional) Delete the old endpoint configuration if you're not using it with any other endpoints. You can also delete the resources that you specified in the model definition if you're not using them with any other endpoints. These resources include model artifacts in Amazon S3 and inference images.

Whenever you create a new model definition or endpoint configuration, we recommend that you use a unique name. If you want to update these resources and retain their original names, use the following procedures.

To update your model settings and retain the original model name
1. Delete the existing model definition. At this point, any endpoint that uses the model is broken, but you fix this in the following steps.
2. Create the model definition again with your updated settings, and use the same model name.
3. Create a new endpoint configuration that uses the updated model definition.
4. Update your endpoint with the new endpoint configuration so that your updates take effect.

To update your endpoint configuration and retain the original configuration name
1. Delete the existing endpoint configuration.
2. Create a new endpoint configuration with your updated settings, and use the original name.
3. Update your endpoint with the new configuration so that your updates take effect.

Supported features

Amazon SageMaker offers the following four options to deploy models for inference.

- Real-time inference for inference workloads with real-time, interactive, low latency requirements.
- Batch transform for offline inference with large datasets.
- Asynchronous inference for near-real-time inference with large inputs that require longer preprocessing times.
- Serverless inference for inference workloads that have idle periods between traffic spurs.
The following table summarizes the core platform features that are supported by each inference option. It does not show features that can be provided by frameworks, custom Docker containers, or through chaining different AWS services.

<table>

1 Availability of the Amazon EC2 instance types depends on the AWS Region. For availability of instances specific to AWS, see Amazon SageMaker Pricing.

2 To use any other framework or algorithm, use the SageMaker Inference toolkit to build a container that supports multi-model endpoints.

3 With SageMaker, you can deploy large models (up to 500 GB) for inference. You can configure the container health check and download timeout quotas, up to 60 minutes. This will allow you to have more time to download and load your model and associated resources. For more information, see SageMaker endpoint parameters for large model inference (p. 2557). You can use SageMaker compatible large model Inference containers. You can also use third-party model parallelization libraries, such as Triton with FasterTransformer and DeepSpeed. You have to ensure that they are compatible with SageMaker.

## Resources

Use the following resources for troubleshooting and reference, answerings FAQs, and learning more about Amazon SageMaker.

[Deploy ML models for inference at high performance and low cost](#)
Troubleshooting and reference

You can use the following resources and reference documentation to understand best practices when using SageMaker Inference and to troubleshoot issues with model deployments:

- For troubleshooting model deployments, see Troubleshoot Amazon SageMaker model deployments (p. 2781).
- For model deployment best practices, see Best practices.
- For reference information about the size of storage volumes provided for different sizes of hosting instances, see Host instance storage volumes (p. 2463).
- For reference information about SageMaker limits and quotas, see Amazon SageMaker endpoints and quotas.
- For frequently asked questions about SageMaker, see Model Hosting FAQs (p. 2795).

Model Hosting FAQs

Refer to the following FAQ items for answers to commonly asked questions about SageMaker Inference Hosting.

General Hosting

The following FAQ items answer common general questions for SageMaker Inference.

Q: What deployment options does Amazon SageMaker provide?

A: After you build and train models, Amazon SageMaker provides four options to deploy them so you can start making predictions. Real-Time Inference is suitable for workloads with millisecond latency requirements, payload sizes up to 6 MB, and processing times of up to 60 seconds. Batch Transform is ideal for offline predictions on large batches of data that are available up front. Asynchronous Inference is designed for workloads that do not have sub-second latency requirements, payload sizes up to 1 GB, and processing times of up to 15 minutes. With Serverless Inference, you can quickly deploy machine learning models for inference without having to configure or manage the underlying infrastructure, and you pay only for the compute capacity used to process inference requests, which is ideal for intermittent workloads.

Q: How do I choose a model deployment option in SageMaker?

A: The following diagram can help you choose a SageMaker Hosting model deployment option.
The preceding diagram walks you through the following decision process. If you want to process requests in batches, you might want to choose Batch Transform. Otherwise, if you want to receive inference for each request to your model, you might want to choose Asynchronous Inference, Serverless Inference, or Real-Time Inference. You can choose Asynchronous Inference if you have long processing times or large payloads and want to queue requests. You can choose Serverless Inference if your workload has unpredictable or intermittent traffic. You can choose Real-Time Inference if you have sustained traffic and need lower and consistent latency for your requests.

Q: I’ve heard SageMaker Inference is expensive. What’s the best way to optimize my cost when hosting models?

A: To optimize your costs with SageMaker Inference, you should choose the right hosting option for your use case. You can also use Inference features such as Amazon SageMaker Savings Plans, model optimization with SageMaker Neo, Multi-Model Endpoints and Multi-Container Endpoints, or autoscaling. For tips on how to optimize your Inference costs, see Inference cost optimization best practices (p. 2783).

Q: Why should I use Amazon SageMaker Inference Recommender?

A: You should use Amazon SageMaker Inference Recommender if you need recommendations for the right endpoint configuration to improve performance and reduce costs. Previously, data scientists who wanted to deploy their models had to run manual benchmarks to select the right endpoint configuration. First, they had to select the right machine learning instance type out of more than 70 available instance types based on the resource requirements of their models and sample payloads, and then optimize the model to account for differing hardware. Then, they had to conduct extensive load tests to validate that latency and throughput requirements were met and that the costs were low. Inference Recommender eliminates this complexity by helping you do the following:

- Get started in minutes with an instance recommendation.
- Conduct load tests across instance types to get recommendations on your endpoint configuration within hours.
- Automatically tune container and model server parameters as well as perform model optimizations for a given instance type.

Q: What is a model server?

A: SageMaker endpoints are HTTP REST endpoints that use a containerized web server, which includes a model server. These containers are responsible for loading up and serving requests for a machine
learning model. They implement a web server that responds to /invocations and /ping on port 8080.

Common model servers include TensorFlow Serving, TorchServe and Multi Model Server. SageMaker framework containers have these model servers built in.

Q: What is Bring Your Own Container with Amazon SageMaker?
A: Everything in SageMaker Inference is containerized. SageMaker provides managed containers for popular frameworks such as TensorFlow, SKlearn, and HuggingFace. For a comprehensive updated list of those images, see Available Images.

Sometimes there are custom frameworks for which you might need to build a container. This approach is known as Bring Your Own Container or BYOC. With the BYOC approach, you provide the Docker image to set up your framework or library. Then, you push the image to Amazon Elastic Container Registry (Amazon ECR) so that you can use the image with SageMaker. For an example of a BYOC approach, see Overview of Containers for Amazon SageMaker.

Alternatively, instead of building an image from scratch, you can extend a container. You can take one of the base images that SageMaker provides and add your dependencies on top of it in your Dockerfile.

Q: Do I need to train my models on SageMaker to host them on SageMaker endpoints?
A: SageMaker offers the capacity to bring your own trained framework model that you’ve trained outside of SageMaker and deploy it on any of the SageMaker hosting options.

SageMaker requires you to package the model in a model.tar.gz file and have a specific directory structure. Each framework has its own model structure (see the following question for example structures). For more information, see the SageMaker Python SDK documentation for TensorFlow, PyTorch, and MXNet.

While you can choose from prebuilt framework images such as TensorFlow, PyTorch, and MXNet to host your trained model, you can also build your own container to host your trained models on SageMaker endpoints. For a walkthrough, see the example Jupyter notebook Building your own algorithm container.

Q: How should I structure my model if I want to deploy on SageMaker but not train on SageMaker?
A: SageMaker requires your model artifacts to be compressed in a .tar.gz file, or a tarball. SageMaker automatically extracts this .tar.gz file into the /opt/ml/model/ directory in your container. The tarball shouldn’t contain any symlinks or unnecessary files. If you are making use of one of the framework containers, such as TensorFlow, PyTorch, or MXNet, the container expects your TAR structure to be as follows:

**TensorFlow**

model.tar.gz/
    |--[model_version_number]/
    |   |--variables
    |   |   |--saved_model.pb
    code/
    |   |--inference.py
    |   |--requirements.txt

**PyTorch**

model.tar.gz/
    |-  model.pth
    |-  code/
Q: When invoking a SageMaker endpoint, I can provide a ContentType and Accept MIME Type. Which one is used to identify the data type being sent and received?

A: ContentType is the MIME type of the input data in the request body (the MIME type of the data you are sending to your endpoint). The model server uses the ContentType to determine if it can handle the type provided or not.

Accept is the MIME type of the inference response (the MIME type of the data your endpoint returns). The model server uses the Accept type to determine if it can handle returning the type provided or not.

Common MIME types include text/csv, application/json, and application/jsonlines.

Q: What are the supported data formats for SageMaker Inference?

A: SageMaker passes any request onto the model container without modification. The container must contain the logic to deserialize the request. For information about the formats defined for built-in algorithms, see Common Data Formats for Inference. If you are building your own container or using a SageMaker Framework container, you can include the logic to accept a request format of your choice.

Similarly, SageMaker also returns the response without modification, and then the client must deserialize the response. In case of the built-in algorithms, they return responses in specific formats. If you are building your own container or using a SageMaker Framework container, you can include the logic to return a response in the format you choose.

Q: How do I invoke my endpoint with binary data such as videos or images?

Use the Invoke Endpoint API call to make inference against your endpoint.

When passing your input as a payload to the InvokeEndpoint API, you must provide the correct type of input data that your model expects. When passing a payload in the InvokeEndpoint API call, the request bytes are forwarded directly to the model container. For example, for an image, you may use application/jpeg for the ContentType, and make sure that your model can perform inference on this type of data. This applies for JSON, CSV, video, or any other type of input with which you may be dealing.

Another factor to consider is payload size limits. In terms of real-time and serverless endpoints, the payload limit is 6 MB. You can split your video into multiple frames and invoke the endpoint with each frame individually. Alternatively, if your use case permits, you can send the whole video in the payload using an asynchronous endpoint, which supports up to 1 GB payloads.

For an example that showcases how to run computer vision inference on large videos with Asynchronous Inference, see this blog post.

Real-Time Inference

The following FAQ items answer common questions for SageMaker Real-Time Inference.
Q: How do I create a SageMaker endpoint?

A: You can create a SageMaker endpoint through AWS-supported tooling such as the AWS SDKs, the SageMaker Python SDK, the AWS Management Console, AWS CloudFormation, and the AWS Cloud Development Kit (AWS CDK).

There are three key entities in endpoint creation: a SageMaker model, a SageMaker endpoint configuration, and a SageMaker endpoint. The SageMaker model points towards the model data and image you are using. The endpoint configuration defines your production variants, which might include the instance type and instance count. You can then use either the `create_endpoint` API call or the `.deploy()` call for SageMaker to create an endpoint using the metadata from your model and endpoint configuration.

Q: Do I need to use the SageMaker Python SDK to create/invoke endpoints?

A: No, you can use the various AWS SDKs (see `Invoke/Create` for available SDKs) or even call the corresponding web APIs directly.

Q: What is the difference between Multi-Model Endpoints (MME) and Multi Model Server (MMS)?

A: A Multi-Model Endpoint is a Real-Time Inference option that SageMaker provides. With Multi-Model Endpoints, you can host thousands of models behind one endpoint. Multi Model Server is an open-source framework for serving machine learning models. It provides the HTTP front-end and model management capabilities required by multi-model endpoints to host multiple models within a single container, load models into and unload models out of the container dynamically, and perform inference on a specified loaded model.

Q: What are the different model deployment architectures supported by Real-Time Inference?

A: SageMaker Real-Time Inference supports various model deployment architecture such as Multi-Model Endpoints, Multi-Container Endpoints, and Serial Inference Pipelines.

- **Multi-Model Endpoints (MME)** – MME allows customers to deploy 1000s of hyper-personalized models in a cost effective way. All the models are deployed on a shared-resource fleet. MME works best when the models are of similar size and latency and belong to the same ML framework. These endpoints are ideal for when you have don't need to call the same model at all times. You can dynamically load respective models onto the SageMaker endpoint to serve your request.

- **Multi-Container Endpoints (MCE)** – MCE allows customers to deploy 15 different containers with diverse ML frameworks and functionalities with no cold starts while only using one SageMaker endpoint. You can directly invoke these containers. MCE is best for when you want to keep all the models in memory.

- **Serial Inference Pipelines (SIP)** – You can use SIP to chain together 2-15 containers on a single endpoint. SIP is mostly suitable for combining preprocessing and model inference in one endpoint and for low latency operations.

**Serverless Inference**

The following FAQ items answer common questions for Amazon SageMaker Serverless Inference.

Q: What is Amazon SageMaker Serverless Inference?

A: Serverless Inference (p. 2496) is a purpose-built serverless model serving option that makes it easy to deploy and scale ML models. Serverless Inference endpoints automatically start compute resources and scale them in and out depending on traffic, eliminating the need for you to choose instance type, run provisioned capacity, or manage scaling. You can optionally specify the memory requirements for your serverless endpoint. You pay only for the duration of running the inference code and the amount of data processed, not for idle periods.
Q: Why should I use Serverless Inference?

A: Serverless Inference simplifies the developer experience by eliminating the need to provision capacity up front and manage scaling policies. Serverless Inference can scale instantly from tens to thousands of inferences within seconds based on the usage patterns, making it ideal for ML applications with intermittent or unpredictable traffic. For example, a chatbot service used by a payroll processing company experiences an increase in inquiries at the end of the month while traffic is intermittent for the rest of the month. Provisioning instances for the entire month in such scenarios is not cost-effective, as you end up paying for idle periods.

Serverless Inference helps address these types of use cases by providing you automatic and fast scaling out of the box without the need for you to forecast traffic up front or manage scaling policies. Additionally, you pay only for the compute time to run your inference code and for data processing, making it ideal for workloads with intermittent traffic.

Q: How do I choose the right memory size for my serverless endpoint?

A: Your serverless endpoint has a minimum RAM size of 1024 MB (1 GB), and the maximum RAM size you can choose is 6144 MB (6 GB). The memory sizes you can choose are 1024 MB, 2048 MB, 3072 MB, 4096 MB, 5120 MB, or 6144 MB. Serverless Inference auto-assigns compute resources proportional to the memory you select. If you choose a larger memory size, your container has access to more vCPUs.

Choose your endpoint's memory size according to your model size. Generally, the memory size should be at least as large as your model size. You may need to benchmark in order to choose the right memory selection for your model based on your latency SLAs. The memory size increments have different pricing; see the Amazon SageMaker pricing page for more information.

Batch Transform

The following FAQ items answer common questions for SageMaker Batch Transform.

Q: How does Batch Transform split my data?

A: For specific file formats such as CSV, RecordIO and TFRecord, SageMaker can split your data into single-record or multi-record mini batches and send this as a payload to your model container. When the value of BatchStrategy is MultiRecord, SageMaker sends the maximum number of records in each request, up to the MaxPayloadInMB limit. When the value of BatchStrategy is SingleRecord, SageMaker sends individual records in each request.

Q: What is the maximum timeout for Batch Transform and payload limit for a single record?

A: The maximum timeout for Batch Transform is 3600 seconds. The maximum payload size for a record (per mini batch) is 100 MB.

Q: How do I speed up a Batch Transform job?

A: If you are using the CreateTransformJob API, you can reduce the time it takes to complete batch transform jobs by using optimal values for parameters such as MaxPayloadInMB, MaxConcurrentTransforms, or BatchStrategy. The ideal value for MaxConcurrentTransforms is equal to the number of compute workers in the batch transform job. If you are using the SageMaker console, you can specify these optimal parameter values in the Additional configuration section of the Batch transform job configuration page. SageMaker automatically finds the optimal parameter settings for built-in algorithms. For custom algorithms, provide these values through an execution-parameters endpoint.

Q: What are the data formats natively supported in Batch Transform?

A: Batch Transform supports CSV and JSON.
Asynchronous Inference

The following FAQ items answer common general questions for SageMaker Asynchronous Inference.

Q: What is Amazon SageMaker Asynchronous Inference?

A: Asynchronous Inference queues incoming requests and processes them asynchronously. This option is ideal for requests with large payload sizes or long processing times that need to be processed as they arrive. Optionally, you can configure auto-scaling settings to scale down the instance count to zero when not actively processing requests.

Q: How do I scale my endpoints to 0 when there's no traffic?

A: Amazon SageMaker supports automatic scaling (autoscaling) your asynchronous endpoint. Autoscaling dynamically adjusts the number of instances provisioned for a model in response to changes in your workload. Unlike other hosted models SageMaker supports, with Asynchronous Inference you can also scale down your asynchronous endpoints instances to zero. Requests that are received when there are zero instances are queued for processing once the endpoint scales up. For more information, see Autoscale an asynchronous endpoint.

Amazon SageMaker Serverless Inference also automatically scales down to zero. You won't see this because SageMaker manages scaling your serverless endpoints, but if you are not experiencing any traffic, the same infrastructure applies.
Implement MLOps

Amazon SageMaker supports features to implement machine learning models in production environments with continuous integration and deployment. The following topics give information about how to set up MLOps infrastructure when using SageMaker.

Topics
- Why Should You Use MLOps? (p. 2802)
- SageMaker Experiments (p. 2804)
- SageMaker Workflows (p. 2804)
- Amazon SageMaker ML Lineage Tracking (p. 2973)
- Register and Deploy Models with Model Registry (p. 2989)
- Model Deployment in SageMaker (p. 3017)
- SageMaker Model Monitor (p. 3017)
- Automate MLOps with SageMaker Projects (p. 3017)
- Amazon SageMaker MLOps FAQ (p. 3045)

Why Should You Use MLOps?

As you move from running individual artificial intelligence and machine learning (AI/ML) projects to using AI/ML to transform your business at scale, the discipline of ML Operations (MLOps) can help. MLOps accounts for the unique aspects of AI/ML projects in project management, CI/CD, and quality assurance, helping you improve delivery time, reduce defects, and make data science more productive. MLOps refers to a methodology that is built on applying DevOps practices to machine learning workloads. For a discussion of DevOps principles, see the white paper Introduction to DevOps on AWS. To learn more about implementation using AWS services, see Practicing CI/CD on AWS and Infrastructure as Code.

Like DevOps, MLOps relies on a collaborative and streamlined approach to the machine learning development lifecycle where the intersection of people, process, and technology optimizes the end-to-end activities required to develop, build, and operate machine learning workloads.

MLOps focuses on the intersection of data science and data engineering in combination with existing DevOps practices to streamline model delivery across the machine learning development lifecycle. MLOps is the discipline of integrating ML workloads into release management, CI/CD, and operations. MLOps requires the integration of software development, operations, data engineering, and data science.

Challenges with MLOps

Although MLOps can provide valuable tools to help you scale your business, you might face certain issues as you integrate MLOps into your machine learning workloads.

Project management
- ML projects involve data scientists, a relatively new role, and one not often integrated into cross-functional teams. These new team members often speak a very different technical language than product owners and software engineers, compounding the usual problem of translating business requirements into technical requirements.

Communication and collaboration
Benefits of MLOps

- Building visibility on ML projects and enabling collaboration across different stakeholders such as data engineers, data scientists, ML engineers, and DevOps is becoming increasingly important to ensure successful outcomes.

Everything is code

- Use of production data in development activities, longer experimentation lifecycles, dependencies on data pipelines, retraining deployment pipelines, and unique metrics in evaluating the performance of a model.
- Models often have a lifecycle independent of the applications and systems integrating with those models.
- The entire end-to-end system is reproducible through versioned code and artifacts. DevOps projects use Infrastructure-as-Code (IaC) and Configuration-as-Code (CaC) to build environments, and Pipelines-as-Code (PaC) to ensure consistent CI/CD patterns. The pipelines have to integrate with Big Data and ML training workflows. That often means that the pipeline is a combination of a traditional CI/CD tool and another workflow engine. There are important policy concerns for many ML projects, so the pipeline may also need to enforce those policies. Biased input data produces biased results, an increasing concern for business stakeholders.

CI/CD

- In MLOps, the source data is a first-class input, along with source code. That’s why MLOps calls for versioning the source data and initiating pipeline runs when the source or inference data changes.
- Pipelines must also version the ML models, along with inputs and other outputs, in order to provide for traceability.
- Automated testing must include proper validation of the ML model during build phases and when the model is in production.
- Build phases may include model training and retraining, a time-consuming and resource-intensive process. Pipelines must be granular enough to only perform a full training cycle when the source data or ML code changes, not when related components change.
- Because machine learning code is typically a small part of an overall solution, a deployment pipeline may also incorporate the additional steps required to package a model for consumption as an API by other applications and systems.

Monitoring and logging

- The feature engineering and model training phases needed to capture model training metrics as well as model experiments. Tuning an ML model requires manipulating the form of the input data as well as algorithm hyperparameters, and systematically capture those experiments. Experiment tracking helps data scientists work more effectively and gives a reproducible snapshot of their work.
- Deployed ML models require monitoring of the data passed to the model for inference, along with the standard endpoint stability and performance metrics. The monitoring system must also capture the quality of model output, as evaluated by an appropriate ML metric.

Benefits of MLOps

Adopting MLOps practices gives you faster time-to-market for ML projects by delivering the following benefits.

- **Productivity**: Providing self-service environments with access to curated data sets lets data engineers and data scientists move faster and waste less time with missing or invalid data.
• **Repeatability**: Automating all the steps in the MLDC helps you ensure a repeatable process, including how the model is trained, evaluated, versioned, and deployed.

• **Reliability**: Incorporating CI/CD practices allows for the ability to not only deploy quickly but with increased quality and consistency.

• **Auditability**: Versioning all inputs and outputs, from data science experiments to source data to trained model, means that we can demonstrate exactly how the model was built and where it was deployed.

• **Data and model quality**: MLOps lets us enforce policies that guard against model bias and track changes to data statistical properties and model quality over time.

### SageMaker Experiments

SageMaker Experiments

ML model building requires many iterations of training as you tune the algorithm, model architecture, and parameters to achieve high prediction accuracy. You can track the inputs and outputs across these training iterations to improve repeatability of trials and collaboration within your team using Amazon SageMaker Experiments. You can also track parameters, metrics, datasets, and other artifacts related to your model training jobs. SageMaker Experiments offers a single interface where you can visualize your in-progress training jobs, share experiments within your team, and deploy models directly from an experiment.

To learn about SageMaker Experiments, see [Manage Machine Learning with Amazon SageMaker Experiments (p. 1838)](#).

### SageMaker Workflows

SageMaker Workflows

As you scale your machine learning (ML) operations, you can use Amazon SageMaker fully managed workflow services to implement continuous integration and deployment (CI/CD) practices for your ML lifecycle. With the SageMaker Pipelines SDK, you choose and integrate pipeline steps into a unified solution that automates the model-building process from data preparation to model deployment. For Kubernetes based architectures, you can install SageMaker Operators on your Kubernetes cluster to create SageMaker jobs natively using the Kubernetes API and command-line Kubernetes tools such as `kubectl`. With SageMaker components for Kubeflow pipelines, you can create and monitor native SageMaker jobs from your Kubeflow Pipelines. The job parameters, status, and outputs from SageMaker are accessible from the Kubeflow Pipelines UI. Lastly, if you want to schedule non-interactive batch runs of your Jupyter notebook, use the notebook-based workflows service to initiate standalone or regular runs on a schedule you define.

In summary, SageMaker offers the following workflow technologies:

- **Amazon SageMaker Model Building Pipelines (p. 2805)**: Tool for building and managing ML pipelines.
- **Kubernetes Orchestration (p. 2884)**: SageMaker custom operators for your Kubernetes cluster and components for Kubeflow Pipelines.
- **SageMaker Notebook Jobs (p. 2948)**: On demand or scheduled non-interactive batch runs of your Jupyter notebook.

You can also leverage other services that integrate with SageMaker to build your workflow. Options include the following services:

- **Airflow Workflows**: SageMaker APIs to export configurations for creating and managing Airflow workflows.
- **AWS Step Functions**: Multi-step ML workflows in Python that orchestrate SageMaker infrastructure without having to provision your resources separately.
For more information on managing SageMaker training and inference, see Amazon SageMaker Python SDK Workflows.

Topics
- Amazon SageMaker Model Building Pipelines (p. 2805)
- Kubernetes Orchestration (p. 2884)
- SageMaker Notebook Jobs (p. 2948)

Amazon SageMaker Model Building Pipelines

Amazon SageMaker Model Building Pipelines is a tool for building machine learning pipelines that take advantage of direct SageMaker integration. Because of this integration, you can create a pipeline and set up SageMaker Projects for orchestration using a tool that handles much of the step creation and management for you. You can build the pipeline using the SageMaker Python SDK, or you can author the pipeline using the SageMaker Pipeline Definition JSON Schema.

SageMaker Pipelines provides the following advantages over other AWS workflow offerings:

SageMaker Integration
SageMaker Pipelines is integrated directly with SageMaker, so you don't need to interact with any other AWS services. You also don't need to manage any resources because SageMaker Pipelines is a fully managed service, which means that it creates and manages resources for you.

SageMaker Python SDK Integration
Because SageMaker Pipelines is integrated with the SageMaker Python SDK, you can create your pipelines programmatically using a high-level Python interface that you might already be familiar with. To view the SageMaker Python SDK API reference, see Pipelines. For SageMaker Python SDK code examples, see Amazon SageMaker Model Building Pipelines.

SageMaker Studio Integration
SageMaker Studio offers an environment to manage the end-to-end SageMaker Pipelines experience. Using Studio, you can bypass the AWS console for your entire workflow management. For more information on managing SageMaker Pipelines from SageMaker Studio, see View, Track, and Execute SageMaker Pipelines in SageMaker Studio (p. 2876).

Data Lineage Tracking
With SageMaker Pipelines you can track the history of your data within the pipeline execution. Amazon SageMaker ML Lineage Tracking lets you analyze where the data came from, where it was used as an input, and the outputs that were generated from it. For example, you can view the models created from an individual dataset, and you can view the datasets that went into creating an individual model. For more information, see Amazon SageMaker ML Lineage Tracking (p. 2973).

Step Reuse
With SageMaker Pipelines, you can designate steps for caching. When a step is cached, it is indexed for reuse later if the same step is executed again. As a result, you can reuse the output from previous step executions of the same step in the same pipeline without having to run the step again. For more information on step caching, see Caching Pipeline Steps (p. 2836).

Topics
- SageMaker Pipelines Overview (p. 2806)
- Create and Manage SageMaker Pipelines (p. 2860)
SageMaker Pipelines Overview

An Amazon SageMaker Model Building Pipelines pipeline is a series of interconnected steps that are defined using the Pipelines SDK. You can also build your pipeline without the SDK using the pipeline definition JSON schema. This pipeline definition encodes a pipeline using a directed acyclic graph (DAG) that can be exported as a JSON definition. This DAG gives information on the requirements for and relationships between each step of your pipeline. The structure of a pipeline's DAG is determined by the data dependencies between steps. These data dependencies are created when the properties of a step's output are passed as the input to another step. The following image is an example of a pipeline DAG:

The following topics describe fundamental SageMaker Pipelines concepts. For a tutorial describing the implementation of these concepts, see Create and Manage SageMaker Pipelines (p. 2860).

Pipeline Structure and Execution

Topics

- Pipeline Structure (p. 2807)
- Pipeline Execution using Parallelism Configuration (p. 2807)

Pipeline Structure

An Amazon SageMaker Model Building Pipelines instance is composed of a name, parameters, and steps. Pipeline names must be unique within an (account, region) pair. All parameters used in step definitions must be defined in the pipeline. Pipeline steps listed automatically determine their order of execution by their data dependencies on one another. The SageMaker Pipelines service resolves the relationships between steps in the data dependency DAG to create a series of steps that the execution completes. The following is an example of a pipeline structure.

```python
from sagemaker.workflow.pipeline import Pipeline

pipeline_name = f"AbalonePipeline"
pipeline = Pipeline(
    name=pipeline_name,
    parameters=[
        processing_instance_type,
        processing_instance_count,
        training_instance_type,
        model_approval_status,
        input_data,
        batch_data,
    ],
    steps=[step_process, step_train, step_eval, step_cond],
)
```

Pipeline Execution using Parallelism Configuration

By default, a pipeline performs all steps that are available to run in parallel. You can control this behavior by using the ParallelismConfiguration property when creating or updating a pipeline, as well as when starting or retrying a pipeline execution.

Parallelism configurations are applied per execution. For example, if two executions are started they can each run a maximum of 50 steps concurrently, for a total of 100 concurrently running steps. Also, ParallelismConfiguration(s) specified when starting, retrying or updating an execution take precedence over parallelism configurations defined in the pipeline.

Example Creating a pipeline execution with ParallelismConfiguration

```python
pipeline = Pipeline(
    name="myPipeline",
    steps=[step_process, step_train]
)

pipeline.create(role, parallelism_config="MaxParallelExecutionSteps": 50))
```
IAM Access Management

The following sections describe the AWS Identity and Access Management (IAM) requirements for Amazon SageMaker Model Building Pipelines. For an example of how you can implement these permissions, see Prerequisites (p. 2861).

Topics
- Pipeline Role Permissions (p. 2808)
- Pipeline Step Permissions (p. 2808)
- Customize access management for SageMaker Pipelines jobs (p. 2809)
- Service Control Policies with Pipelines (p. 2811)

Pipeline Role Permissions

Your pipeline requires an IAM pipeline execution role that is passed to SageMaker Pipelines when you create a pipeline. The role for the SageMaker instance that is creating the pipeline must have the `iam:PassRole` permission for the pipeline execution role in order to pass it. For more information on IAM roles, see IAM Roles.

Your pipeline execution role requires the following permissions:

- To pass any role to a SageMaker job within a pipeline, the `iam:PassRole` permission for the role that is being passed.
- Create and Describe permissions for each of the job types in the pipeline.
- Amazon S3 permissions to use the `JsonGet` function. You control access to your Amazon S3 resources using resource-based policies and identity-based policies. A resource-based policy is applied to your Amazon S3 bucket and grants SageMaker Pipelines access to the bucket. An identity-based policy gives your pipeline the ability to make Amazon S3 calls from your account. For more information on resource-based policies and identity-based policies, see Identity-based policies and resource-based policies.

```
{
    "Action": [
        "s3:GetObject"
    ],
    "Resource": "arn:aws:s3::<your-bucket-name>/*",
    "Effect": "Allow"
}
```

Pipeline Step Permissions

SageMaker Pipelines include steps that run SageMaker jobs. In order for the pipeline steps to run these jobs, they require an IAM role in your account that provides access for the needed resource. This role is passed to the SageMaker service principal by your pipeline. For more information on IAM roles, see IAM Roles.

By default, each step takes on the pipeline execution role. You can optionally pass a different role to any of the steps in your pipeline. This ensures that the code in each step does not have the ability to impact resources used in other steps unless there is a direct relationship between the two steps specified in the pipeline definition. You pass these roles when defining the processor or estimator for your step. For examples of how to include these roles in these definitions, see the SageMaker Python SDK documentation.
Customize access management for SageMaker Pipelines jobs

You can further customize your IAM policies so selected members in your organization can run any or all pipeline steps. For example, you can give certain users permission to create training jobs, and another group of users permission to create processing jobs, and all of your users permission to run the remaining steps. To use this feature, you select a custom string which prefixes your job name. Your admin prepends the permitted ARNs with the prefix while your data scientist includes this prefix in pipeline instantiations. Because the IAM policy for permitted users contains a job ARN with the specified prefix, subsequent jobs of your pipeline step have necessary permissions to proceed. Job prefixing is off by default—you must toggle on this option in your Pipeline class to use it.

For jobs with prefixing turned off, the job name is formatted as shown and is a concatenation of fields described in the following table:

```plaintext
pipelines-<executionId>-<stepNamePrefix>-<entityToken>-<failureCount>
```

<table>
<thead>
<tr>
<th>Field</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>pipelines</td>
<td>A static string always prepended. This string identifies the pipeline orchestration service as the job's source.</td>
</tr>
<tr>
<td>executionId</td>
<td>A randomized buffer for the running instance of the pipeline.</td>
</tr>
<tr>
<td>stepNamePrefix</td>
<td>The user-specified step name (given in the name argument of the pipeline step), limited to the first 20 characters.</td>
</tr>
<tr>
<td>entityToken</td>
<td>A randomized token to ensure idempotency of the step entity.</td>
</tr>
<tr>
<td>failureCount</td>
<td>The current number of retries attempted to complete the job.</td>
</tr>
</tbody>
</table>

In this case, no custom prefix is prepended to the job name, and the corresponding IAM policy must match this string.

For users who turn on job prefixing, the underlying job name takes the following form, with the custom prefix specified as MyBaseJobName:

```plaintext
<MyBaseJobName>-<executionId>-<entityToken>-<failureCount>
```

The custom prefix replaces the static pipelines string to help you narrow the selection of users who can run the SageMaker job as a part of a pipeline.

**Prefix length restrictions**

The job names have internal length constraints specific to individual pipeline steps. This constraint also limits the length of the allowed prefix. The prefix length requirements are as follows:

<table>
<thead>
<tr>
<th>Pipeline step</th>
<th>Prefix length</th>
</tr>
</thead>
<tbody>
<tr>
<td>TrainingStep, ModelStep, TransformStep, ProcessingStep, ClarifyCheckStep, QualityCheckStep, RegisterModelStep</td>
<td>38</td>
</tr>
</tbody>
</table>
Apply job prefixes to an IAM policy

Your admin creates IAM policies allowing users of specific prefixes to create jobs. The following example policy permits data scientists to create training jobs if they use the MyBaseJobName prefix.

```json
{
    "Action": "sagemaker:CreateTrainingJob",
    "Effect": "Allow",
    "Resource": [
        "arn:aws:sagemaker:region:account-id:*/MyBaseJobName-*"
    ]
}
```

Apply job prefixes to pipeline instantiations

You specify your prefix with the *base_job_name argument of the job instance class.

**Note**
You pass your job prefix with the *base_job_name argument to the job instance before creating a pipeline step. This job instance contains the necessary information for the job to run as a step in a pipeline. This argument varies depending upon the job instance used. The following list shows which argument to use for each pipeline step type:

- `base_job_name` for the *Estimator (TrainingStep), Processor (ProcessingStep), and AutoML (AutoMLStep) classes*
- `tuning_base_job_name` for the *Tuner class (TuningStep)*
- `transform_base_job_name` for the *Transformer class (TransformStep)*
- `base_job_name` of *CheckJobConfig for the QualityCheckStep (Quality Check) and ClarifyCheckstep (Clarify Check) classes*
- **For the Model class, the argument used depends on if you run create or register on your model before passing the result to ModelStep**
  - If you call create, the custom prefix comes from the name argument when you construct your model (i.e., `Model(name=)`)
  - If you call register, the custom prefix comes from the model_package_name argument of your call to register (i.e., `my_model.register(model_package_name=)`)

The following example shows how to specify a prefix for a new training job instance.

```python
# Create a job instance
xgb_train = Estimator(
    image_uri=image_uri,
    instance_type="ml.m5.xlarge",
    instance_count=1,
    output_path=model_path,
    role=role,
    subnets=["subnet-0ab12c34567de89f0"],
    base_job_name="MyBaseJobName",
    security_group_ids=["sg-1a2bbcc3bd4444e55"],
    tags = [ ... ]
)
```

# Attach your job instance to a pipeline step
step_train = TrainingStep(
    name="TestTrainingJob",
    estimator=xgb_train,
    inputs={
        "train": TrainingInput(...),
        "validation": TrainingInput(...)  
    }
)

Job prefixing is off by default. To opt into this feature, use the use_custom_job_prefix option of PipelineDefinitionConfig as shown in the following snippet:

from sagemaker.workflow.pipeline_definition_config import PipelineDefinitionConfig

# Create a definition configuration and toggle on custom prefixing
definition_config = PipelineDefinitionConfig(use_custom_job_prefix=True);

# Create a pipeline with a custom prefix
pipeline = Pipeline(
    name="MyJobPrefixedPipeline",
    parameters=[]
    steps=[
        pipeline_definition_config=definition_config
    ]
)

Create and run your pipeline. The following example creates and runs a pipeline, and also demonstrates how you can turn off job prefixing and rerun your pipeline.

pipeline.create(role_arn=sagemaker.get_execution_role())

# Optionally, call definition() to confirm your prefixed job names are in the built JSON
pipeline.definition()

pipeline.start()

# To run a pipeline without custom-prefixes, toggle off use_custom_job_prefix, update the pipeline
# via upsert() or update(), and start a new run
definition_config = PipelineDefinitionConfig(use_custom_job_prefix=False)
pipeline.pipeline_definition_config = definition_config
pipeline.update()
execution = pipeline.start()

Similarly, you can toggle the feature on for existing pipelines and start a new run which uses job prefixes.

definition_config = PipelineDefinitionConfig(use_custom_job_prefix=True)
pipeline.pipeline_definition_config = definition_config
pipeline.update()
execution = pipeline.start()

Finally, you can view your custom-prefixed job by calling list_steps on the pipeline execution.

steps = execution.list_steps()

prefixed_training_job_name = steps['PipelineExecutionSteps'][0]['Metadata']['TrainingJob']['Arn']

Service Control Policies with Pipelines

Service control policies (SCPs) are a type of organization policy that you can use to manage permissions in your organization. SCPs offer central control over the maximum available permissions for all accounts.
in your organization. By using SageMaker Pipelines within your organization, you can ensure that data scientists manage your pipeline executions without having to interact with the AWS console.

If you’re using a VPC with your SCP that restricts access to Amazon S3, you need to take steps to allow your pipeline to access other Amazon S3 resources.

To allow SageMaker Pipelines to access Amazon S3 outside of your VPC with the `JsonGet` function, update your organization's SCP to ensure that the role using SageMaker Pipelines can access Amazon S3. To do this, create an exception for roles that are being used by the SageMaker Pipelines executor via the pipeline execution role using a principal tag and condition key.

**To allow SageMaker Pipelines to access Amazon S3 outside of your VPC**

1. Create a unique tag for your pipeline execution role following the steps in [Tagging IAM users and roles](#).
2. Grant an exception in your SCP using the `Aws:PrincipalTag` IAM condition key for the tag you created. For more information, see [Creating, updating, and deleting service control policies](#).

**Cross-Account Support for SageMaker Pipelines**

You can use cross-account support for Amazon SageMaker Model Building Pipelines to share pipeline entities across AWS accounts and access shared pipelines through direct API calls.

**Set up cross-account pipeline sharing**

SageMaker uses [AWS Resource Access Manager](https://aws.amazon.com/ram/) (AWS RAM) to help you securely share your pipeline entities across accounts.

**Create a resource share**

1. Select Create a resource share through the [AWS RAM console](https://console.aws.amazon.com/ram/).
2. When specifying resource share details, choose the SageMaker Pipelines resource type and select one or more pipelines that you want to share. When you share a pipeline with any other account, all of its executions are also shared implicitly.
3. Associate permissions with your resource share. Choose either the default read-only permission policy or the extended pipeline execution permission policy. For more detailed information, see [Permission policies for SageMaker Pipelines resources](#).

   **Note**
   
   If you select the extended pipeline execution policy, note that any start, stop, and retry commands called by shared accounts use resources in the AWS account that shared the pipeline.

4. Use AWS account IDs to specify the accounts to which you want to grant access to your shared resources.
5. Review your resource share configuration and select Create resource share. It may take a few minutes for the resource share and principal associations to complete.

**Get responses to your resource share invitation**

Once the resource share and principal associations are set, the specified AWS accounts receive an invitation to join the resource share. The AWS accounts must accept the invite to gain access to any shared resources.

Permission policies for SageMaker Pipelines resources

When creating your resource share, choose one of two supported permission policies to associate with the SageMaker pipeline resource type. Both policies grant access to any selected pipeline and all of its executions.

Default read-only permissions

The AWSRAMDefaultPermissionSageMakerPipeline policy allows the following read-only actions:

- "sagemaker:DescribePipeline"
- "sagemaker:DescribePipelineDefinitionForExecution"
- "sagemaker:DescribePipelineExecution"
- "sagemaker:ListPipelineExecutions"
- "sagemaker:ListPipelineExecutionSteps"
- "sagemaker:ListPipelineParametersForExecution"
- "sagemaker:Search"

Extended pipeline execution permissions

The AWSRAMPermissionSageMakerPipelineAllowExecution policy includes all of the read-only permissions from the default policy and also allows shared accounts to start, stop, and retry pipeline executions.

*Note*

Be mindful of AWS resource usage when using the extended pipeline execution permission policy. With this policy, shared accounts are allowed to start, stop, and retry pipeline executions. Any resources used for shared pipeline executions are consumed by the owner account.

The extended pipeline execution permission policy allows the following actions:

- "sagemaker:DescribePipeline"
- "sagemaker:DescribePipelineDefinitionForExecution"
- "sagemaker:DescribePipelineExecution"
- "sagemaker:ListPipelineExecutions"
- "sagemaker:ListPipelineExecutionSteps"
- "sagemaker:ListPipelineParametersForExecution"
- "sagemaker:StartPipelineExecution"
- "sagemaker:StopPipelineExecution"
- "sagemaker:RetryPipelineExecution"
- "sagemaker:Search"

Access shared pipeline entities through direct API calls

Once cross-account pipeline sharing is set up, you can call the following SageMaker API actions using a pipeline ARN:

*Note*

You can only call API commands if they are included in the permissions associated with your resource share. If you select the AWSRAMPermissionSageMakerPipelineAllowExecution policy, then the start, stop, and retry commands use resources in the AWS account that shared the pipeline.

- ListPipelineExecutions
- ListPipelineExecutionSteps
- ListPipelineParametersForExecution
Pipeline Parameters

You can introduce variables into your pipeline definition using parameters. You can reference parameters that you define throughout your pipeline definition. Parameters have a default value, which you can override by specifying parameter values when starting a pipeline execution. The default value must be an instance matching the parameter type. All parameters used in step definitions must be defined in your pipeline definition. Amazon SageMaker Model Building Pipelines supports the following parameter types:

- **ParameterString** – Representing a string parameter.
- **ParameterInteger** – Representing an integer parameter.
- **ParameterFloat** – Representing a float parameter.
- **ParameterBoolean** – Representing a Boolean Python type.

Parameters take the following format:

```python
<parameter> = <parameter_type>(
    name="<parameter_name>",
    default_value=<default_value>
)
```

The following example shows a sample parameter implementation.

```python
from sagemaker.workflow.parameters import (ParameterInteger,
                                            ParameterString,
                                            ParameterFloat,
                                            ParameterBoolean)

processing_instance_count = ParameterInteger(
    name="ProcessingInstanceCount",
    default_value=1)
```

You pass the parameter when creating your pipeline as shown in the following example.

```python
pipeline = Pipeline(
    name=pipeline_name,
    parameters=[
        processing_instance_count],
    steps=[step_process]
)
```

You can also pass a parameter value that differs from the default value to a pipeline execution, as shown in the following example.

```python
execution = pipeline.start(
    parameters=dict(
        ProcessingInstanceCount="2",
        ModelApprovalStatus="Approved"
    ))
```
You can manipulate parameters with SageMaker Python SDK functions like `sagemaker.workflow.functions.Join`. For more information on parameters, see [SageMaker Pipelines Parameters](#).

For known limitations of SageMaker Pipelines Parameters, see [Limitations - Parameterization](#) in the [Amazon SageMaker Python SDK](#).

## Pipeline Steps

SageMaker Pipelines are composed of steps. These steps define the actions that the pipeline takes and the relationships between steps using properties.

### Topics

- [Step Types](#)
- [Step Properties](#)

### Step Types

The following describes the requirements of each step type and provides an example implementation of the step. These are not functional implementations because they don't provide the resource and inputs needed. For a tutorial that implements these steps, see [Create and Manage SageMaker Pipelines](#).

Amazon SageMaker Model Building Pipelines support the following step types:

- [Processing](#)
- [Training](#)
- [Tuning](#)
- [AutoML](#)
- [Model](#)
- [CreateModel](#)
- [RegisterModel](#)
- [Transform](#)
- [Condition](#)
- [Callback](#)
- [Lambda](#)
- [ClarifyCheck](#)
- [QualityCheck](#)
- [EMR](#)
- [Fail](#)

### Processing Step

Use a processing step to create a processing job for data processing. For more information on processing jobs, see [Process Data and Evaluate Models](#).

- [QualityCheck](#)
- [EMR](#)
- [Fail](#)

### Processing Step

Use a processing step to create a processing job for data processing. For more information on processing jobs, see [Process Data and Evaluate Models](#).
A processing step requires a processor, a Python script that defines the processing code, outputs for processing, and job arguments. The following example shows how to create a ProcessingStep definition.

```python
from sagemaker.sklearn.processing import SKLearnProcessor
sklearn_processor = SKLearnProcessor(framework_version='1.0-1',
                              role=<role>,
                              instance_type='ml.m5.xlarge',
                              instance_count=1)
```

```python
from sagemaker.processing import ProcessingInput, ProcessingOutput
from sagemaker.workflow.steps import ProcessingStep
inputs = [
    ProcessingInput(source=<input_data>, destination="/opt/ml/processing/input"),
]
outputs = [
    ProcessingOutput(output_name="train", source="/opt/ml/processing/train"),
    ProcessingOutput(output_name="validation", source="/opt/ml/processing/validation"),
    ProcessingOutput(output_name="test", source="/opt/ml/processing/test")
]
step_process = ProcessingStep(
    name="AbaloneProcess",
    step_args = sklearn_processor.run(inputs=inputs, outputs=outputs,
                                       code="abalone/preprocessing.py")
)
```

**Pass runtime parameters**

The following example shows how to pass runtime parameters from a PySpark processor to a ProcessingStep.

```python
from sagemaker.workflow.pipeline_context import PipelineSession
from sagemaker.spark.processing import PySparkProcessor
from sagemaker.processing import ProcessingInput, ProcessingOutput
from sagemaker.workflow.steps import ProcessingStep
pipeline_session = PipelineSession()
pyspark_processor = PySparkProcessor(
    framework_version='2.4',
    role=<role>,
    instance_type='ml.m5.xlarge',
    instance_count=1,
    sagemaker_session=pipeline_session,
)
step_args = pyspark_processor.run(
    inputs=[ProcessingInput(source=<input_data>, destination="/opt/ml/processing/input"),],
    outputs=[
        ProcessingOutput(output_name="train", source="/opt/ml/processing/train"),
        ProcessingOutput(output_name="validation", source="/opt/ml/processing/validation"),
        ProcessingOutput(output_name="test", source="/opt/ml/processing/test")
    ],
    code="preprocess.py",
    arguments=None,
)```
For more information on processing step requirements, see the sagemaker.workflow.steps.ProcessingStep documentation. For an in-depth example, see Define a Processing Step for Feature Engineering in the Orchestrate Jobs to Train and Evaluate Models with Amazon SageMaker Pipelines example notebook.

Training Step

You use a training step to create a training job to train a model. For more information on training jobs, see Train a Model with Amazon SageMaker.

A training step requires an estimator, as well as training and validation data inputs. The following example shows how to create a TrainingStep definition. For more information on training step requirements, see the sagemaker.workflow.steps.TrainingStep documentation.

```python
from sagemaker.workflow.pipeline_context import PipelineSession
from sagemaker.inputs import TrainingInput
from sagemaker.workflow.steps import TrainingStep
from sagemaker.xgboost.estimator import XGBoost
pipeline_session = PipelineSession()
xgb_estimator = XGBoost(...) #, sagemaker_session=pipeline_session)
step_args = xgb_estimator.fit(
    inputs={
        "train": TrainingInput(
            s3_data=step_process.properties.ProcessingOutputConfig.Outputs["train"].S3Output.S3Uri,
            content_type="text/csv"
        ),
        "validation": TrainingInput(
            s3_data=step_process.properties.ProcessingOutputConfig.Outputs["validation"].S3Output.S3Uri,
            content_type="text/csv"
        )
    })
step_train = TrainingStep(
    name="TrainAbaloneModel",
    step_args=step_args,
)
```

Tuning Step

You use a tuning step to create a hyperparameter tuning job, also known as hyperparameter optimization (HPO). A hyperparameter tuning job runs multiple training jobs, each one producing a model version. For more information on hyperparameter tuning, see Perform Automatic Model Tuning with SageMaker (p. 1863).

The tuning job is associated with the SageMaker experiment for the pipeline, with the training jobs created as trials. For more information, see Experiments Integration (p. 2855).
A tuning step requires a **HyperparameterTuner** and training inputs. You can retrain previous tuning jobs by specifying the `warm_start_config` parameter of the `HyperparameterTuner`. For more information on hyperparameter tuning and warm start, see **Run a Warm Start Hyperparameter Tuning Job** (p. 1895).

You use the `get_top_model_s3_uri` method of the `sagemaker.workflow.steps.TuningStep` class to get the model artifact from one of the top-performing model versions. For a notebook that shows how to use a tuning step in a SageMaker pipeline, see **sagemaker-pipelines-tuning-step.ipynb**.

**Important**

Tuning steps were introduced in Amazon SageMaker Python SDK v2.48.0 and Amazon SageMaker Studio v3.8.0. You must update Studio before you use a tuning step or the pipeline DAG doesn’t display. To update Studio, see **Shut down and Update SageMaker Studio** (p. 292).

The following example shows how to create a `TuningStep` definition.

```python
from sagemaker.workflow.pipeline_context import PipelineSession
from sagemaker.tuner import HyperparameterTuner
from sagemaker.inputs import TrainingInput
from sagemaker.workflow.steps import TuningStep

tuner = HyperparameterTuner(..., sagemaker_session=PipelineSession())
step_tuning = TuningStep(
    name = "HPTuning",
    step_args = tuner.fit(inputs=TrainingInput(s3_data="s3://my-bucket/my-data"))
)
```

**Get the best model version**

The following example shows how to get the best model version from the tuning job using the `get_top_model_s3_uri` method. At most, the top 50 performing versions are available ranked according to `HyperParameterTuningJobObjective`. The top_k argument is an index into the versions, where top_k=0 is the best-performing version and top_k=49 is the worst-performing version.

```python
best_model = Model(
    image_uri=image_uri,
    model_data=step_tuning.get_top_model_s3_uri(
        top_k=0,
        s3_bucket=sagemaker_session.default_bucket()
    ),
    ...
)
```

For more information on tuning step requirements, see the **sagemaker.workflow.steps.TuningStep** documentation.

**AutoML Step**

Use the **AutoML** API to create an AutoML job to automatically train a model. For more information on AutoML jobs, see **Automate model development with Amazon SageMaker Autopilot**.

**Note**

Currently, the AutoML step supports only **ensembling training mode**.

The following example shows how to create a definition using `AutoMLStep`.

```python
from sagemaker.workflow.pipeline_context import PipelineSession
from sagemaker.workflow.autml_step import AutoMLStep
```
pipeline_session = PipelineSession()

auto_ml = AutoML(...,
    role="<role>",
    target_attribute_name="my_target_attribute_name",
    mode="ENSEMBLING",
    sagemaker_session=pipeline_session)

input_training = AutoMLInput(
    inputs="s3://my-bucket/my-training-data",
    target_attribute_name="my_target_attribute_name",
    channel_type="training",
)

input_validation = AutoMLInput(
    inputs="s3://my-bucket/my-validation-data",
    target_attribute_name="my_target_attribute_name",
    channel_type="validation",
)

step_args = auto_ml.fit(
    inputs=[input_training, input_validation]
)

step_automl = AutoMLStep(
    name="AutoMLStep",
    step_args=step_args,
)

Get the best model version

The AutoML step automatically trains several model candidates. You can get the model with the best objective metric from the AutoML job using the get_best_auto_ml_model method and an IAM role to access model artifacts as follows.

best_model = step_automl.get_best_auto_ml_model(role=<role>)

For more information, see the AutoML step in the SageMaker Python SDK.

Model Step

Use a ModelStep to create or register a SageMaker model. For more information on ModelStep requirements, see the sagemaker.workflow.model_step.ModelStep documentation.

Create a model

You can use a ModelStep to create a SageMaker model. A ModelStep requires model artifacts and information about the SageMaker instance type that you need to use to create the model. For more information on SageMaker models, see Train a Model with Amazon SageMaker.

The following example shows how to create a ModelStep definition.

from sagemaker.workflow.pipeline_context import PipelineSession
from sagemaker.model import Model
from sagemaker.workflow.model_step import ModelStep

step_train = TrainingStep(...)
model = Model(
    image_uri=pytorch_estimator.training_image_uri(),
    model_data=step_train.properties.ModelArtifacts.S3ModelArtifacts,
    sagemaker_session=PipelineSession(),
    role=role,
)
Register a model

You can use a ModelStep to register a sagemaker.model.Model or a sagemaker.pipeline.PipelineModel with the Amazon SageMaker model registry. A PipelineModel represents an inference pipeline, which is a model composed of a linear sequence of containers that process inference requests. For more information about how to register a model, see Register and Deploy Models with Model Registry (p. 2989).

The following example shows how to create a ModelStep that registers a PipelineModel.

```python
import time
from sagemaker.workflow.pipeline_context import PipelineSession
from sagemaker.sklearn import SKLearnModel
from sagemaker.xgboost import XGBoostModel
pipeline_session = PipelineSession()

code_location = 's3://{0}/{1}/code'.format(bucket_name, prefix)

sklearn_model = SKLearnModel(
    model_data=processing_step.properties.ProcessingOutputConfig.Outputs['model'].S3Output.S3Uri,
    entry_point='inference.py',
    source_dir='sklearn_source_dir/',
    code_location=code_location,
    framework_version='1.0-1',
    role=role,
    sagemaker_session=pipeline_session,
    py_version='py3'
)

xgboost_model = XGBoostModel(
    model_data=training_step.properties.ModelArtifacts.S3ModelArtifacts,
    entry_point='inference.py',
    source_dir='xgboost_source_dir/',
    code_location=code_location,
    framework_version='0.90-2',
    py_version='py3',
    role=role,
    sagemaker_session=pipeline_session,
)

from sagemaker.workflow.model_step import ModelStep
from sagemaker import PipelineModel
pipeline_model = PipelineModel(
    models=[sklearn_model, xgboost_model],
    role=role, sagemaker_session=pipeline_session,
)

register_model_step_args = pipeline_model.register(
    content_types=['application/json'],
    response_types=['application/json'],
    inference_instances=['ml.t2.medium', 'ml.m5.xlarge'],
    transform_instances=['ml.m5.xlarge'],
    model_package_group_name='sipgroup',
```
step_model_registration = ModelStep(
    name="AbaloneRegisterModel",
    step_args=register_model_step_args,
)

CreateModel Step

Important
We recommend using Model Step (p. 2819) to create models as of v2.90.0 of the SageMaker Python SDK. CreateModelStep will continue to work in previous versions of the SageMaker Python SDK, but is no longer actively supported.

You use a CreateModel step to create a SageMaker model. For more information on SageMaker models, see Train a Model with Amazon SageMaker.

A create model step requires model artifacts and information about the SageMaker instance type that you need to use to create the model. The following example shows how to create a CreateModel step definition. For more information on CreateModel step requirements, see the sagemaker.workflow.steps.CreateModelStep documentation.

from sagemaker.workflow.steps import CreateModelStep
step_create_model = CreateModelStep(
    name="AbaloneCreateModel",
    model=best_model,
    inputs=inputs
)

RegisterModel Step

Important
We recommend using Model Step (p. 2819) to register models as of v2.90.0 of the SageMaker Python SDK. RegisterModel will continue to work in previous versions of the SageMaker Python SDK, but is no longer actively supported.

You use a RegisterModel step to register a sagemaker.model.Model or a sagemaker.pipeline.PipelineModel with the Amazon SageMaker model registry. A PipelineModel represents an inference pipeline, which is a model composed of a linear sequence of containers that process inference requests.

For more information about how to register a model, see Register and Deploy Models with Model Registry (p. 2989). For more information on RegisterModel step requirements, see the sagemaker.workflow.step_collections.RegisterModel documentation.

The following example shows how to create a RegisterModel step that registers a PipelineModel.

import time
from sagemaker.sklearn import SKLearnModel
from sagemaker.xgboost import XGBoostModel
code_location = 's3://{0}/{1}/code'.format(bucket_name, prefix)
sklearn_model = SKLearnModel(model_data=processing_step.properties.ProcessingOutputConfig.Outputs[\'model\'].S3Output.S3Uri,
entry_point='inference.py',
source_dir='sklearn_source_dir/',
code_location=code_location,
framework_version='1.0-1',
role=role,
sagemaker_session=sagemaker_session,
py_version='py3')
from sagemaker.workflow.step_collections import RegisterModel
from sagemaker import PipelineModel
pipeline_model = PipelineModel(models=[sklearn_model, xgboost_model], role=role, sagemaker_session=sagemaker_session)

step_register = RegisterModel(
    name="AbaloneRegisterModel",
    model=pipeline_model,
    content_types=['application/json'],
    response_types=['application/json'],
    inference_instances=['ml.t2.medium', 'ml.m5.xlarge'],
    transform_instances=['ml.m5.xlarge'],
    model_package_group_name='sipgroup',
    approval_status=model_approval_status,
    model_metrics=model_metrics
)

If model isn’t provided, the register model step requires an estimator as shown in the following example.

from sagemaker.workflow.step_collections import RegisterModel

step_register = RegisterModel(
    name="AbaloneRegisterModel",
    estimator=xgb_train,
    model_data=step_train.properties.ModelArtifacts.S3ModelArtifacts,
    content_types=['text/csv'],
    response_types=['text/csv'],
    inference_instances=['ml.t2.medium', 'ml.m5.xlarge'],
    transform_instances=['ml.m5.xlarge'],
    model_package_group_name=model_package_group_name,
    approval_status=model_approval_status,
    model_metrics=model_metrics
)

Transform Step

You use a transform step for batch transformation to run inference on an entire dataset. For more information about batch transformation, see Run Batch Transforms with Inference Pipelines (p. 2439).

A transform step requires a transformer and the data on which to run batch transformation. The following example shows how to create a Transform step definition. For more information on Transform step requirements, see the sagemaker.workflow.steps.TransformStep documentation.

from sagemaker.workflow.pipeline_context import PipelineSession
from sagemaker.transformer import Transformer
from sagemaker.inputs import TransformInput
from sagemaker.workflow.steps import TransformStep

transformer = Transformer(..., sagemaker_session=PipelineSession())

step_transform = TransformStep(
    name="AbaloneTransform",
    step_args=transformer.transform(data="s3://my-bucket/my-data"),
)
Condition Step

You use a condition step to evaluate the condition of step properties to assess which action should be taken next in the pipeline.

A condition step requires a list of conditions, a list of steps to run if the condition evaluates to `true`, and a list of steps to run if the condition evaluates to `false`. The following example shows how to create a `ConditionStep` definition.

**Limitations**

- SageMaker Pipelines doesn't support the use of nested condition steps. You can't pass a condition step as the input for another condition step.
- A condition step can't use identical steps in both branches. If you need the same step functionality in both branches, duplicate the step and give it a different name.

```python
from sagemaker.workflow.conditions import ConditionLessThanOrEqualTo
from sagemaker.workflow.condition_step import (ConditionStep, JsonGet)

cond_lte = ConditionLessThanOrEqualTo(
    left=JsonGet(
        step_name=step_eval.name,
        property_file=evaluation_report,
        json_path="regression_metrics.mse.value"),
    right=6.0)

step_cond = ConditionStep(
    name="AbaloneMSECond",
    conditions=[cond_lte],
    if_steps=[step_register, step_create_model, step_transform],
    else_steps=[])
```

For more information on `ConditionStep` requirements, see the `sagemaker.workflow.condition_step.ConditionStep` API reference. For more information on supported conditions, see Amazon SageMaker Model Building Pipelines - Conditions in the SageMaker Python SDK documentation.

Callback Step

You use a Callback step to incorporate additional processes and AWS services into your workflow that aren't directly provided by Amazon SageMaker Model Building Pipelines. When a Callback step runs, the following procedure occurs:

- SageMaker Pipelines sends a message to a customer-specified Amazon Simple Queue Service (Amazon SQS) queue. The message contains a SageMaker Pipelines–generated token and a customer-supplied list of input parameters. After sending the message, SageMaker Pipelines waits for a response from the customer.
- The customer retrieves the message from the Amazon SQS queue and starts their custom process.
- When the process finishes, the customer calls one of the following APIs and submits the SageMaker Pipelines–generated token:
  - `SendPipelineExecutionStepSuccess`, along with a list of output parameters
• **SendPipelineExecutionStepFailure**, along with a failure reason
• The API call causes SageMaker Pipelines to either continue the pipeline process or fail the process.

For more information on Callback step requirements, see the `sagemaker.workflow.callback_step.CallbackStep` documentation. For a complete solution, see [Extend SageMaker Pipelines to include custom steps using callback steps](#).

**Important**
Callback steps were introduced in Amazon SageMaker Python SDK v2.45.0 and Amazon SageMaker Studio v3.6.2. You must update Studio before you use a Callback step or the pipeline DAG doesn't display. To update Studio, see [Shut down and Update SageMaker Studio](p. 292).

The following sample demonstrates an implementation of the preceding procedure.

```python
from sagemaker.workflow.callback_step import CallbackStep

step_callback = CallbackStep(
    name="MyCallbackStep",
    sqs_queue_url="https://sqs.us-east-2.amazonaws.com/012345678901/MyCallbackQueue",
    inputs={...},
    outputs=[...]
)

callback_handler_code = 'import boto3
import json
def handler(event, context):
    sagemaker_client=boto3.client("sagemaker")
    for record in event["Records"]:payload=json.loads(record["body"])
    token=payload["token"]

    # Custom processing
    
    # Call SageMaker to complete the step
    sagemaker_client.send_pipeline_execution_step_success(
        CallbackToken=token,
        OutputParameters={...}
    )
',
```

**Note**
Output parameters for CallbackStep should not be nested. For example, if you use a nested dictionary as your output parameter, then the dictionary is treated as a single string (ex. `{"output1": "{\"nested_output1\": "my-output\"\"}"}`). If you provide a nested value, then when you try to refer to a particular output parameter, a non-retryable client error is thrown.

**Stopping behavior**
A pipeline process doesn't stop while a Callback step is running.

When you call **StopPipelineExecution** on a pipeline process with a running Callback step, SageMaker Pipelines sends an additional Amazon SQS message to the specified SQS queue. The body of the SQS message contains a **Status** field, which is set to Stopping. The following shows an example SQS message body.

```json
{
```
You should add logic to your Amazon SQS message consumer to take any needed action (for example, resource cleanup) upon receipt of the message, followed by a call to SendPipelineExecutionStepSuccess or SendPipelineExecutionStepFailure. Only when SageMaker Pipelines receives one of these calls does it stop the pipeline process.

**Lambda Step**

You use a Lambda step to run an AWS Lambda function. You can run an existing Lambda function, or SageMaker can create and run a new Lambda function. For a notebook that shows how to use a Lambda step in a SageMaker pipeline, see sagemaker-pipelines-lambda-step.ipynb.

**Important**

Lambda steps were introduced in Amazon SageMaker Python SDK v2.51.0 and Amazon SageMaker Studio v3.9.1. You must update Studio before you use a Lambda step or the pipeline DAG doesn't display. To update Studio, see Shut down and Update SageMaker Studio (p. 292).

SageMaker provides the sagemaker.lambda_helper.Lambda class to create, update, invoke, and delete Lambda functions. Lambda has the following signature.

```
Lambda(
    function_arn,       # Only required argument to invoke an existing Lambda function
    function_name,
    execution_role_arn,
    zipped_code_dir,    # Specify either zipped_code_dir and s3_bucket, OR script
    s3_bucket,          # S3 bucket where zipped_code_dir is uploaded
    script,             # Path of Lambda function script
    handler,            # Lambda handler specified as "lambda_script.lambda_handler"
    timeout,            # Maximum time the Lambda function can run before the lambda step fails
    ...
)
```

The sagemaker.workflow.lambda_step.LambdaStep class has a lambda_func argument of type Lambda. To invoke an existing Lambda function, the only requirement is to supply the Amazon Resource Name (ARN) of the function to function_arn. If you don't supply a value for function_arn, you must specify handler and one of the following:

- **zipped_code_dir** – The path of the zipped Lambda function
- **s3_bucket** – Amazon S3 bucket where zipped_code_dir is to be uploaded
- **script** – The path of the Lambda function script file

The following example shows how to create a Lambda step definition that invokes an existing Lambda function.

```python
from sagemaker.workflow.lambda_step import LambdaStep
```
from sagemaker.lambda_helper import Lambda

step_lambda = LambdaStep(
    name="ProcessingLambda",
    lambda_func=Lambda(
        inputs={
            s3_bucket = s3_bucket,
            data_file = data_file
        },
        outputs=[
            "train_file", "test_file"
        ]
    ),
    inputs={
        s3_bucket = s3_bucket,
        data_file = data_file
    },
    outputs=[
    "train_file", "test_file"
    ]
)

The following example shows how to create a Lambda step definition that creates and invokes a Lambda function using a Lambda function script.

from sagemaker.workflow.lambda_step import LambdaStep
from sagemaker.lambda_helper import Lambda

step_lambda = LambdaStep(
    name="ProcessingLambda",
    lambda_func=Lambda(
        function_name="split-dataset-lambda",
        execution_role_arn=execution_role_arn,
        script="lambda_script.py",
        handler="lambda_script.lambda_handler",
        inputs={
            s3_bucket = s3_bucket,
            data_file = data_file
        },
        outputs=[
            "train_file", "test_file"
        ]
    ),
    inputs={
        s3_bucket = s3_bucket,
        data_file = data_file
    },
    outputs=[
    "train_file", "test_file"
    ]
)

Inputs and outputs

If your Lambda function has inputs or outputs, these must also be defined in your Lambda step.

**Note**

Input and output parameters should not be nested. For example, if you use a nested dictionary as your output parameter, then the dictionary is treated as a single string (ex. "{"output1": "{\"nested_output1\":\"my-output\"}"}"). If you provide a nested value and try to refer to it later, a non-retryable client error is thrown.

When defining the Lambda step, inputs must be a dictionary of key-value pairs. Each value of the inputs dictionary must be a primitive type (string, integer, or float). Nested objects are not supported. If left undefined, the inputs value defaults to None.

The outputs value must be a list of keys. These keys refer to a dictionary defined in the output of the Lambda function. Like inputs, these keys must be primitive types, and nested objects are not supported.

**Timeout and stopping behavior**

The Lambda class has a timeout argument that specifies the maximum time that the Lambda function can run. The default value is 120 seconds with a maximum value of 10 minutes. If the Lambda function is running when the timeout is met, the Lambda step fails; however, the Lambda function continues to run.
A pipeline process can't be stopped while a Lambda step is running because the Lambda function invoked by the Lambda step can't be stopped. If you attempt to stop the process while the Lambda function is running, the pipeline waits for the Lambda function to finish or until the timeout is hit, whichever occurs first, and then stops. If the Lambda function finishes, the pipeline process status is Stopped. If the timeout is hit the pipeline process status is Failed.

ClarifyCheck Step

You can use the ClarifyCheck step to conduct baseline drift checks against previous baselines for bias analysis and model explainability. You can then generate and register your baselines with the model.register() method and pass the output of that method to Model Step (p. 2819) using step_args. These baselines for drift check can be used by Amazon SageMaker Model Monitor for your model endpoints so that you don't need to do a baseline suggestion separately. The ClarifyCheck step can also pull baselines for drift check from the model registry. The ClarifyCheck step leverages the Amazon SageMaker Clarify prebuilt container that provides a range of model monitoring capabilities, including constraint suggestion and constraint validation against a given baseline. For more information, see Getting Started with a SageMaker Clarify Container.

Configuring the ClarifyCheck step

You can configure the ClarifyCheck step to conduct only one of the following check types each time it's used in a pipeline.

- Data bias check
- Model bias check
- Model explainability check

You do this by setting the clarify_check_config parameter with one of the following check type values:

- DataBiasCheckConfig
- ModelBiasCheckConfig
- ModelExplainabilityCheckConfig

The ClarifyCheck step launches a processing job that runs the SageMaker Clarify prebuilt container and requires dedicated configurations for the check and the processing job. ClarifyCheckConfig and CheckJobConfig are helper functions for these configurations that are aligned with how the SageMaker Clarify processing job computes for checking model bias, data bias, or model explainability. For more information, see Run SageMaker Clarify Processing Jobs for Bias Analysis and Explainability (p. 3185).

Controlling step behaviors for drift check

The ClarifyCheck step requires the following two boolean flags to control its behavior:

- skip_check: This parameter indicates if the drift check against the previous baseline is skipped or not. If it is set to False, the previous baseline of the configured check type must be available.
- register_new_baseline: This parameter indicates if a newly calculated baseline can be accessed through the BaselineUsedForDriftCheckConstraints property. If it is set to False, the previous baseline of the configured check type also must be available. This can be accessed through the BaselineUsedForDriftCheckConstraints property.

For more information, see Baseline calculation, drift detection and lifecycle with ClarifyCheck and QualityCheck steps in Amazon SageMaker Model Building Pipelines (p. 2848).
Working with baselines

You can optionally specify the model_package_group_name to locate the existing baseline and the ClarifyCheck step pulls the DriftCheckBaselines on the latest approved model package in the model package group. Or, you can provide a previous baseline through the supplied_baseline_constraints parameter. If you specify both the model_package_group_name and the supplied_baseline_constraints, the ClarifyCheck step uses the baseline specified by the supplied_baseline_constraints parameter.

For more information on using the ClarifyCheck step requirements, see the sagemaker.workflow.steps.ClarifyCheckStep in the Amazon SageMaker SageMaker SDK for Python. For an Amazon SageMaker Studio notebook that shows how to use ClarifyCheck step in SageMaker Pipelines, see sagemaker-pipeline-model-monitor-clarify-steps.ipynb.

Example Create a ClarifyCheck step for data bias check

```python
from sagemaker.workflow.check_job_config import CheckJobConfig
from sagemaker.workflow.clarify_check_step import DataBiasCheckConfig, ClarifyCheckStep
from sagemaker.workflow.execution_variables import ExecutionVariables

check_job_config = CheckJobConfig(
    role=role,
    instance_count=1,
    instance_type="ml.c5.xlarge",
    volume_size_in_gb=120,
    sagemaker_session=sagemaker_session,
)

data_bias_data_config = DataConfig(
    s3_data_input_path=step_process.properties.ProcessingOutputConfig.Outputs["train"].S3Output.S3Uri,
    s3_output_path=ExecutionVariables.PIPELINE_EXECUTION_ID, 'databiascheckstep',
    label=0,
    dataset_type="text/csv",
    s3_analysis_config_output_path=data_bias_analysis_cfg_output_path,
)

data_bias_config = BiasConfig(
    label_values_or_threshold=[15.0], facet_name=[8], facet_values_or_threshold=[[0.5]]
)

data_bias_check_config = DataBiasCheckConfig(
    data_config=data_bias_data_config,
    data_bias_config=data_bias_config,
)

data_bias_check_step = ClarifyCheckStep(
    name="DataBiasCheckStep",
    clarify_check_config=data_bias_check_config,
    check_job_config=check_job_config,
    skip_check=False,
    register_new_baseline=False,
    supplied_baseline_constraints="s3://sagemaker-us-west-2-111122223333/baseline/analysis.json",
    model_package_group_name="MyModelPackageGroup"
)
```

QualityCheck Step

You can use the QualityCheck step to conduct baseline suggestions and drift checks against a previous baseline for data quality or model quality in a pipeline. You can then generate and register
your baselines with the `model.register()` method and pass the output of that method to `ModelStep` using `step_args`. Model Monitor can use these baselines for drift check for your model endpoints so that you don't need to do a baseline suggestion separately. The QualityCheck step can also pull baselines for drift check from the model registry. The QualityCheck step leverages the Amazon SageMaker Model Monitor prebuilt container, which has a range of model monitoring capabilities including constraint suggestion, statistics generation, and constraint validation against a baseline. For more information, see Amazon SageMaker Model Monitor prebuilt container (p. 3100).

### Configuring the QualityCheck step

You can configure the QualityCheck step to conduct only one of the following check types each time it's used in a pipeline.

- Data quality check
- Model quality check

You do this by setting the `quality_check_config` parameter with one of the following check type values:

- `DataQualityCheckConfig`
- `ModelQualityCheckConfig`

The QualityCheck step launches a processing job that runs the Model Monitor prebuilt container and requires dedicated configurations for the check and the processing job. The `QualityCheckConfig` and `CheckJobConfig` are helper functions for these configurations that are aligned with how Model Monitor creates a baseline for the model quality or data quality monitoring. For more information on the Model Monitor baseline suggestions, see Create a Baseline (p. 3063) and Create a Model Quality Baseline (p. 3069).

### Controlling step behaviors for drift check

The QualityCheck step requires the following two Boolean flags to control its behavior:

- `skip_check`: This parameter indicates if the drift check against the previous baseline is skipped or not. If it is set to `False`, the previous baseline of the configured check type must be available.
- `register_new_baseline`: This parameter indicates if a newly calculated baseline can be accessed through step properties `BaselineUsedForDriftCheckConstraints` and `BaselineUsedForDriftCheckStatistics`. If it is set to `False`, the previous baseline of the configured check type must also be available. These can be accessed through the `BaselineUsedForDriftCheckConstraints` and `BaselineUsedForDriftCheckStatistics` properties.

For more information, see Baseline calculation, drift detection and lifecycle with ClarifyCheck and QualityCheck steps in Amazon SageMaker Model Building Pipelines (p. 2848).

### Working with baselines

You can specify a previous baseline directly through the `supplied_baseline_statistics` and `supplied_baseline_constraints` parameters, or you can simply specify the `model_package_group_name` and the QualityCheck step pulls the `DriftCheckBaselines` on the latest approved model package in the model package group. When you specify the `model_package_group_name`, `supplied_baseline_constraints`, and `supplied_baseline_statistics`, the QualityCheck step uses the baseline specified by `supplied_baseline_constraints` and `supplied_baseline_statistics` on the check type of the QualityCheck step you are running.
For more information on using the QualityCheck step requirements, see the `sagemaker.workflow.steps.QualityCheckStep` in the Amazon SageMaker SageMaker SDK for Python. For an Amazon SageMaker Studio notebook that shows how to use QualityCheck step in SageMaker Pipelines, see `sagemaker-pipeline-model-monitor-clarify-steps.ipynb`.

**Example Create a QualityCheck step for data quality check**

```python
from sagemaker.workflow.check_job_config import CheckJobConfig
from sagemaker.workflow.quality_check_step import DataQualityCheckConfig, QualityCheckStep
from sagemaker.workflow.execution_variables import ExecutionVariables

check_job_config = CheckJobConfig(
    role=role,
    instance_count=1,
    instance_type="ml.c5.xlarge",
    volume_size_in_gb=120,
    sagemaker_session=sagemaker_session,
)
data_quality_check_config = DataQualityCheckConfig(
    baseline_dataset=step_process.properties.ProcessingOutputConfig.Outputs["train"].S3Output.S3Uri,
    dataset_format=DatasetFormat.csv(header=False, output_columns_position="START"),
    output_s3_uri=Join(on='/', values=['s3:', your_bucket, base_job_prefix, ExecutionVariables.PIPELINE_EXECUTION_ID, 'dataqualitycheckstep'])
)
data_quality_check_step = QualityCheckStep(
    name="DataQualityCheckStep",
    skip_check=False,
    register_new_baseline=False,
    quality_check_config=data_quality_check_config,
    check_job_config=check_job_config,
    supplied_baseline_statistics="s3://sagemaker-us-west-2-555555555555/baseline/statistics.json",
    supplied_baseline_constraints="s3://sagemaker-us-west-2-555555555555/baseline/constraints.json",
    model_package_group_name="MyModelPackageGroup"
)
```

**EMR Step**

You can use the Amazon SageMaker Model Building Pipelines EMR step to process Amazon EMR steps on a running Amazon EMR cluster or have the pipeline create and manage an Amazon EMR cluster for you. For more information about Amazon EMR, see [Getting started with Amazon EMR](#).

The EMR step requires that EMRStepConfig include the location of the JAR file to be used by the Amazon EMR cluster and any arguments to be passed. You also provide the Amazon EMR cluster ID if you want to run the step on a running EMR cluster, or the cluster configuration if you want the EMR step to run on a cluster that it creates, manages, and terminates for you. The following sections include examples and links to sample notebooks demonstrating both methods.

**Note**

- EMR steps require that the role passed to your pipeline has additional permissions. You should attach the AWS managed policy: `AmazonSageMakerPipelinesIntegrations` to your pipeline role, or ensure that the role includes the permissions in that policy.
- EMR step is not supported on EMR serverless, nor on Amazon EMR on EKS.
- If you process an EMR step on a running cluster, you can only use a cluster that is in one of the following states: STARTING, BOOTSTRAPPING, RUNNING, or WAITING.
• If you process EMR steps on a running cluster, you can have at most 256 EMR steps in a PENDING state on an EMR cluster. EMR steps submitted beyond this limit result in pipeline execution failure. You may consider using Retry Policy for Pipeline Steps (p. 2842).
• You can specify either cluster ID or cluster configuration, but not both.
• The EMR step relies on Amazon EventBridge to monitor changes in the EMR step or cluster state. If you process your Amazon EMR job on a running cluster, the EMR step uses the SageMakerPipelineExecutionEMRStepStatusUpdateRule rule to monitor EMR step state. If you process your job on a cluster that the EMR step creates for you, the step uses the SageMakerPipelineExecutionEMRClusterStatusRule rule to monitor changes in cluster state. If you see either of these EventBridge rules in your AWS account, do not delete them or else your EMR step may not complete.

Launch a new job on a running Amazon EMR cluster

If you want to launch a new job on a running Amazon EMR cluster, you pass the cluster ID as a string to the cluster_id argument of EMRStep. The following example demonstrates this procedure.

```python
from sagemaker.workflow.emr_step import EMRStep, EMRStepConfig

emr_config = EMRStepConfig(
    jar="jar-location", # required, path to jar file used
    args=['--verbose', '--force'], # optional list of arguments to pass to the jar
    main_class="com.my.Main1", # optional main class, this can be omitted if jar above has
    properties=[ # optional list of Java properties that are set when the step runs
        {"key": "mapred.tasktracker.map.tasks.maximum", "value": "2"},
        {"key": "mapreduce.map.sort.spill.percent", "value": "0.90"},
        {"key": "mapreduce.tasktracker.reduce.tasks.maximum", "value": "5"}],
)

step_emr = EMRStep(
    name="EMRSampleStep", # required
    cluster_id="j-1ABCDEFG2HIJK", # include cluster_id to use a running cluster
    step_config=emr_config, # required
    display_name="My EMR Step",
    description="Pipeline step to execute EMR job"
)
```

For a sample notebook that guides you through a complete example, see SageMaker Pipelines EMR Step With Running EMR Cluster.

Launch a new job on a new Amazon EMR cluster

If you want to launch a new job on a new cluster that EMRStep creates for you, provide your cluster configuration as a dictionary with the same structure as a RunJobFlow request. However, do not include the following fields in your cluster configuration:

• [Name]
• [Steps]
• [AutoTerminationPolicy]
• [Instances][KeepJobFlowAliveWhenNoSteps]
• [Instances][TerminationProtected]

All other RunJobFlow arguments are available for use in your cluster configuration. For details about the request syntax, see RunJobFlow.

The following example passes a cluster configuration to an EMR step definition, which prompts the step to launch a new job on a new EMR cluster. The EMR cluster configuration in this example includes specifications for primary and core EMR cluster nodes. For more information about Amazon EMR node types, see Understand node types: primary, core, and task nodes.

```python
from sagemaker.workflow.emr_step import EMRStep, EMRStepConfig

emr_step_config = EMRStepConfig(
    jar="jar-location", # required, path to jar file used
    args=['--verbose', '--force'], # optional list of arguments to pass to the jar
    main_class="com.my.Main1", # optional main class, this can be omitted if jar above has
    properties=[ # optional list of Java properties that are set when the step runs
        "key": "mapred.tasktracker.map.tasks.maximum",
        "value": "2"
      ],
      "key": "mapreduce.map.sort.spill.percent",
      "value": "0.90"
    ],
    "key": "mapreduce.tasktracker.reduce.tasks.maximum",
    "value": "5"
)

# include your cluster configuration as a dictionary
emr_cluster_config = {
    "Applications": [
      { "Name": "Spark" },
    ],
    "Instances": {
      "InstanceGroups": [
        { "InstanceRole": "MASTER",
          "InstanceCount": 1,
          "InstanceType": "m5.2xlarge"
        },
        { "InstanceRole": "CORE",
          "InstanceCount": 2,
          "InstanceType": "m5.2xlarge"
        }
      ]
    },
    "BootstrapActions": [],
    "ReleaseLabel": "emr-6.6.0",
    "JobFlowRole": "job-flow-role",
    "ServiceRole": "service-role"
}

emr_step = EMRStep(
    name="emr-step",
    emr_step_config=emr_step_config,
    emr_cluster_config=emr_cluster_config,
)
```

2832
cluster_id=None,
display_name="emr_step",
description="MyEMRStepDescription",
step_config=emr_step_config,
cluster_config=emr_cluster_config
)

For a sample notebook that guides you through a complete example, see SageMaker Pipelines EMR Step With Cluster Lifecycle Management.

Fail Step

You use a FailStep to stop an Amazon SageMaker Model Building Pipelines execution when a desired condition or state is not achieved and to mark that pipeline's execution as failed. The FailStep also allows you to enter a custom error message, indicating the cause of the pipeline's execution failure.

Note

When a FailStep and other pipeline steps execute concurrently, the pipeline does not terminate until all concurrent steps are completed.

Limitations for using FailStep

- You cannot add a FailStep to the DependsOn list of other steps. For more information, see Custom Dependency Between Steps (p. 2834).
- Other steps cannot reference the FailStep. It is always the last step in a pipeline's execution.
- You cannot retry a pipeline execution ending with a FailStep.

You can create the FailStep ErrorMessage in the form of a static text string. Alternatively, you can also use Pipeline Parameters a Join operation, or other step properties to create a more informative error message.

Example

The following example code snippet uses a FailStep with an ErrorMessage configured with Pipeline Parameters and a Join operation.

```python
from sagemaker.workflow.fail_step import FailStep
from sagemaker.workflow.functions import Join
from sagemaker.workflow.parameters import ParameterInteger

mse_threshold_param = ParameterInteger(name="MseThreshold", default_value=5)
step_fail = FailStep(
    name="AbaloneMSEFail",
    error_message=Join(on=" ", values=["Execution failed due to MSE >", mse_threshold_param])
)
```

Step Properties

The properties attribute is used to add data dependencies between steps in the pipeline. These data dependencies are then used by SageMaker Pipelines to construct the DAG from the pipeline definition. These properties can be referenced as placeholder values and are resolved at runtime.

The properties attribute of a SageMaker Pipelines step matches the object returned by a Describe call for the corresponding SageMaker job type. For each job type, the Describe call returns the following response object:

- ProcessingStep - DescribeProcessingJob
• TrainingStep – DescribeTrainingJob
• TransformStep – DescribeTransformJob

To check which properties are referrable for each step type during data dependency creation, see Data Dependency - Property Reference in the Amazon SageMaker Python SDK.

Step Parallelism

When a step does not depend on any other step, it is run immediately upon pipeline execution. However, executing too many pipeline steps in parallel can quickly exhaust available resources. Control the number of concurrent steps for a pipeline execution with ParallelismConfiguration.

The following example uses ParallelismConfiguration to set the concurrent step limit to five.

```python
pipeline.create(
    parallelism_config=ParallelismConfiguration(5),
)
```

Data Dependency Between Steps

You define the structure of your DAG by specifying the data relationships between steps. To create data dependencies between steps, pass the properties of one step as the input to another step in the pipeline. The step receiving the input isn't started until after the step providing the input finishes running.

A data dependency uses JsonPath notation in the following format. This format traverses the JSON property file, which means you can append as many <property> instances as needed to reach the desired nested property in the file. For more information on JsonPath notation, see the JsonPath repo.

```json
<step_name>.properties.<property>.<property>
```

The following shows how to specify an Amazon S3 bucket using the ProcessingOutputConfig property of a processing step.

```python
step_process.properties.ProcessingOutputConfig.Outputs["train_data"].S3Output.S3Uri
```

To create the data dependency, pass the bucket to a training step as follows.

```python
from sagemaker.workflow.pipeline_context import PipelineSession
sklearn_train = SKLearn(..., sagemaker_session=PipelineSession())
step_train = TrainingStep(
    name="CensusTrain",
    step_args=sklearn_train.fit(inputs=TrainingInput(
        s3_data=step_process.properties.ProcessingOutputConfig.Outputs["train_data"].S3Output.S3Uri
    ))
)
```

To check which properties are referrable for each step type during data dependency creation, see Data Dependency - Property Reference in the Amazon SageMaker Python SDK.

Custom Dependency Between Steps

When you specify a data dependency, SageMaker Pipelines provides the data connection between the steps. Alternatively, one step can access the data from a previous step without directly using SageMaker.
Pipelines. In this case, you can create a custom dependency that tells SageMaker Pipelines not to start a step until after another step has finished running. You create a custom dependency by specifying a step's `DependsOn` attribute.

As an example, the following defines a step C that starts only after both step A and step B finish running.

```json
{
    'Steps': [
        {'Name': 'A', ...},
        {'Name': 'B', ...},
        {'Name': 'C', 'DependsOn': ['A', 'B']}
    ]
}
```

SageMaker Pipelines throws a validation exception if the dependency would create a cyclic dependency.

The following example creates a training step that starts after a processing step finishes running.

```python
processing_step = ProcessingStep(...)
training_step = TrainingStep(...)
training_step.add_depends_on([processing_step])
```

The following example creates a training step that doesn't start until two different processing steps finish running.

```python
processing_step_1 = ProcessingStep(...)
processing_step_2 = ProcessingStep(...)
training_step = TrainingStep(...)
training_step.add_depends_on([processing_step_1, processing_step_2])
```

The following provides an alternate way to create the custom dependency.

```python
training_step.add_depends_on([processing_step_1])
training_step.add_depends_on([processing_step_2])
```

The following example creates a training step that receives input from one processing step and waits for a different processing step to finish running.

```python
processing_step_1 = ProcessingStep(...)
processing_step_2 = ProcessingStep(...)
training_step = TrainingStep(...)
    ...,
    inputs=TrainingInput(
        s3_data=processing_step_1.properties.ProcessingOutputConfig.Outputs['train_data'].S3Output.S3Uri
    ),
training_step.add_depends_on([processing_step_2])
```

The following example shows how to retrieve a string list of the custom dependencies of a step.

```python
custom_dependencies = training_step.depends_on
```
Use a Custom Image in a Step

You can use any of the available SageMaker Deep Learning Container images when you create a step in your pipeline.

You can also use your own container with pipeline steps. Because you can't create an image from within Amazon SageMaker Studio, you must create your image using another method before using it with Amazon SageMaker Model Building Pipelines.

To use your own container when creating the steps for your pipeline, include the image URI in the estimator definition. For more information on using your own container with SageMaker, see Using Docker Containers with SageMaker.

Property Files and JsonGet

Use property files to store information from the output of a processing step. This is particularly useful when analyzing the results of a processing step to decide how a conditional step should be executed. The JsonGet function processes a property file and enables you to use JsonPath notation to query the property JSON file. For more information on JsonPath notation, see the JsonPath repo.

To store a property file for later use, you must first create a PropertyFile instance with the following format. The path parameter is the name of the JSON file to which the property file is saved. Any output_name must match the output_name of the ProcessingOutput that you define in your processing step. This enables the property file to capture the ProcessingOutput in the step.

```python
from sagemaker.workflow.properties import PropertyFile

@property_file_instance> = PropertyFile(  
    name='property_file_name',  
    output_name='processingoutput_output_name',  
    path='path_to_json_file'
)
```

When you create your ProcessingStep instance, add the property_files parameter to list all of the parameter files that the Amazon SageMaker Model Building Pipelines service must index. This saves the property file for later use.

```python
property_files=[@property_file_instance>]
```

To use your property file in a condition step, add the property_file to the condition that you pass to your condition step as shown in the following example to query the JSON file for your desired property using the json_path parameter.

```python
cond_lte = ConditionLessThanOrEqualTo(  
    left=JsonGet(  
        step_name=step_eval.name,  
        property_file=property_file_instance,  
        json_path="mse"  
    ),  
    right=6.0
)
```

For more in-depth examples, see Property File in the Amazon SageMaker Python SDK.

Caching Pipeline Steps

When you use step signature caching, SageMaker Pipelines tries to find a previous run of your current pipeline step with the same values for certain attributes. If found, SageMaker Pipelines propagates the
outputs from the previous run rather than recomputing the step. The attributes checked are specific to the step type, and are listed in Default cache key attributes by pipeline step type (p. 2840).

You must opt in to step caching — it is off by default. When you turn on step caching, you must also define a timeout. This timeout defines how old a previous run can be to remain a candidate for reuse.

Step caching only considers successful runs — it never reuses failed runs. When multiple successful runs exist within the timeout period, SageMaker Pipelines uses the result for the most recent successful run. If no successful runs match in the timeout period, SageMaker Pipelines reruns the step. If the executor finds a previous run that meets the criteria but is still in progress, both steps continue running and update the cache if they're successful.

Step caching is only scoped for individual pipelines, so you can't reuse a step from another pipeline even if there is a step signature match.

Step caching is available for the following step types:

- Processing (p. 2815)
- Training (p. 2817)
- Tuning (p. 2817)
- AutoML (p. 2818)
- Transform (p. 2822)
- ClarifyCheck (p. 2827)
- QualityCheck (p. 2828)
- EMR (p. 2830)

Topics

- Turn on step caching (p. 2837)
- Turn off step caching (p. 2839)
- Default cache key attributes by pipeline step type (p. 2840)
- Cached data access control (p. 2841)

Turn on step caching

To turn on step caching, you must add a CacheConfig property to the step definition.

CacheConfig properties use the following format in the pipeline definition file:

```json
{
  "CacheConfig": {
    "Enabled": false,
    "ExpireAfter": "<time>"
  }
}
```

The Enabled field indicates whether caching is turned on for the particular step. You can set the field to true, which tells SageMaker to try to find a previous run of the step with the same attributes. Or, you can set the field to false, which tells SageMaker to run the step every time the pipeline runs. ExpireAfter is a string in ISO 8601 duration format that defines the timeout period. The ExpireAfter duration can be a year, month, week, day, hour, or minute value. Each value consists of a number followed by a letter indicating the unit of duration. For example:

- "30d" = 30 days
- "5y" = 5 years
- "T16m" = 16 minutes
• "30dT5h" = 30 days and 5 hours.

The following discussion describes the procedure to turn on caching for new or pre-existing pipelines using the Amazon SageMaker Python SDK.

**Turn on caching for new pipelines**

For new pipelines, initialize a `CacheConfig` instance with `enable_caching=True` and provide it as an input to your pipeline step. The following example turns on caching with a 1-hour timeout period for a training step:

```python
from sagemaker.workflow.pipeline_context import PipelineSession
from sagemaker.workflow.steps import CacheConfig

cache_config = CacheConfig(enable_caching=True, expire_after="PT1H")
estimator = Estimator(..., sagemaker_session=PipelineSession())

step_train = TrainingStep(
    name="TrainAbaloneModel",
    step_args=estimator.fit(inputs=inputs),
    cache_config=cache_config
)
```

**Turn on caching for pre-existing pipelines**

To turn on caching for pre-existing, already-defined pipelines, turn on the `enable_caching` property for the step, and set `expire_after` to a timeout value. Lastly, update the pipeline with `pipeline.upsert()` or `pipeline.update()`. Once you run it again, the following code example turns on caching with a 1-hour timeout period for a training step:

```python
from sagemaker.workflow.pipeline_context import PipelineSession
from sagemaker.workflow.steps import CacheConfig
from sagemaker.workflow.pipeline import Pipeline

cache_config = CacheConfig(enable_caching=True, expire_after="PT1H")
estimator = Estimator(..., sagemaker_session=PipelineSession())

step_train = TrainingStep(
    name="TrainAbaloneModel",
    step_args=estimator.fit(inputs=inputs),
    cache_config=cache_config
)

# define pipeline
pipeline = Pipeline(
    steps=[step_train]
)

# additional step for existing pipelines
pipeline.update()
# or, call upsert() to update the pipeline
# pipeline.upsert()

Alternatively, update the cache config after you have already defined the (pre-existing) pipeline, allowing one continuous code run. The following code sample demonstrates this method:

```python
# turn on caching with timeout period of one hour
pipeline.steps[0].cache_config.enable_caching = True
pipeline.steps[0].cache_config.expire_after = "PT1H"

# additional step for existing pipelines
```
pipeline.update()
# or, call upsert() to update the pipeline
# pipeline.upsert()

For more detailed code examples and a discussion about how Python SDK parameters affect caching, see Caching Configuration in the Amazon SageMaker Python SDK documentation.

Turn off step caching

A pipeline step does not rerun if you change any attributes that are not listed in Default cache key attributes by pipeline step type (p. 2840) for its step type. However, you may decide that you want the pipeline step to rerun anyway. In this case, you need to turn off step caching.

To turn off step caching, set the Enabled attribute in the step definition's CacheConfig property in the step definition to false, as shown in the following code snippet:

```python
{
    "CacheConfig": {
        "Enabled": false,
        "ExpireAfter": "<time>"
    }
}
```

Note that the ExpireAfter attribute is ignored when Enabled is false.

To turn off caching for a pipeline step using the Amazon SageMaker Python SDK, define the pipeline of your pipeline step, turn off the enable_caching property, and update the pipeline.

Once you run it again, the following code example turns off caching for a training step:

```python
from sagemaker.workflow.pipeline_context import PipelineSession
from sagemaker.workflow.steps import CacheConfig
from sagemaker.workflow.pipeline import Pipeline

cache_config = CacheConfig(enable_caching=False, expire_after="PT1H")
estimator = Estimator(..., sagemaker_session=PipelineSession())
step_train = TrainingStep(
    name="TrainAbaloneModel",
    step_args=estimator.fit(inputs=inputs),
    cache_config=cache_config
)

# define pipeline
pipeline = Pipeline(
    steps=[step_train]
)

# update the pipeline
pipeline.update()
# or, call upsert() to update the pipeline
# pipeline.upsert()
```

Alternatively, turn off the enable_caching property after you have already defined the pipeline, allowing one continuous code run. The following code sample demonstrates this solution:

```python
# turn off caching for the training step
pipeline.steps[0].cache_config.enable_caching = False

# update the pipeline
pipeline.update()
```
For more detailed code examples and a discussion about how Python SDK parameters affect caching, see [Caching Configuration](#) in the Amazon SageMaker Python SDK documentation.

**Default cache key attributes by pipeline step type**

When deciding whether to reuse a previous pipeline step or rerun the step, SageMaker Pipelines checks to see if certain attributes have changed. If the set of attributes is different from all previous runs within the timeout period, the step runs again. These attributes include input artifacts, app or algorithm specification, and environment variables.

The following list shows each pipeline step type and the attributes that, if changed, initiate a rerun of the step. For more information about which Python SDK parameters are used to create the following attributes, see [Caching Configuration](#) in the Amazon SageMaker Python SDK documentation.

**Processing step**
- AppSpecification
- Environment
- ProcessingInputs. This attribute contains information about the preprocessing script.

**Training step**
- AlgorithmSpecification
- CheckpointConfig
- DebugHookConfig
- DebugRuleConfigurations
- Environment
- HyperParameters
- InputDataConfig. This attribute contains information about the training script.

**Tuning step**
- HyperParameterTuningJobConfig
- TrainingJobDefinition. This attribute is composed of multiple child attributes, not all of which cause the step to rerun. The child attributes that could incur a rerun (if changed) are:
  - AlgorithmSpecification
  - HyperParameterRanges
  - InputDataConfig
  - StaticHyperParameters
  - TuningObjective
  - TrainingJobDefinitions

**AutoML step**
- AutoMLJobConfig. This attribute is composed of multiple child attributes, not all of which cause the step to rerun. The child attributes that could incur a rerun (if changed) are:
  - CompletionCriteria
• CandidateGenerationConfig
• DataSplitConfig
• Mode
• AutoMLJobObjective
• InputDataConfig
• ProblemType

**Transform step**

• DataProcessing
• Environment
• ModelName
• TransformInput

**ClarifyCheck Step (p. 2827)**

• ClarifyCheckConfig
• CheckJobConfig
• SkipCheck
• RegisterNewBaseline
• ModelPackageGroupName
• SuppliedBaselineConstraints

**QualityCheck Step (p. 2828)**

• QualityCheckConfig
• CheckJobConfig
• SkipCheck
• RegisterNewBaseline
• ModelPackageGroupName
• SuppliedBaselineConstraints
• SuppliedBaselineStatistics

**EMR Step**

• ClusterId
• StepConfig

**Cached data access control**

When a SageMaker pipeline runs, it caches the parameters and metadata associated with the SageMaker jobs launched by the pipeline and saves them for reuse in subsequent runs. This metadata is accessible through a variety of sources in addition to cached pipeline steps, and includes the following types:

• Describe*Job requests
• CloudWatch Logs
• CloudWatch Events
• CloudWatch Metrics
• SageMaker Search

Note that access to each data source in the list is controlled by its own set of IAM permissions. Removing a particular role's access to one data source does not affect the level of access to the others. For example, an account admin might remove IAM permissions for Describe*Job requests from a caller's role. While the caller can no longer make Describe*Job requests, they can still retrieve the metadata from a pipeline run with cached steps as long as they have permission to run the pipeline. If an account admin wants to remove access to the metadata from a particular SageMaker job completely, they need to remove permissions for each of the relevant services that provide access to the data.

**Retry Policy for Pipeline Steps**

Retry policies help you automatically retry your SageMaker Pipelines steps after an error occurs. Any pipeline step can encounter exceptions, and exceptions happen for various reasons. In some cases, a retry can resolve these issues. With a retry policy for pipeline steps, you can choose whether to retry a particular pipeline step or not.

The retry policy only supports the following pipeline steps:

• [Processing Step](p. 2815)
• [Training Step](p. 2817)
• [Tuning Step](p. 2817)
• [AutoML Step](p. 2818)
• [CreateModel Step](p. 2821)
• [RegisterModel Step](p. 2821)
• [Transform Step](p. 2822)

**Note**

Jobs running inside both the tuning and AutoML steps conduct retries internally and will not retry the SageMaker.JOB_INTERNAL_ERROR exception type, even if a retry policy is configured. You can program your own [Retry Strategy](using the SageMaker API).

**Supported exception types for the retry policy**

The retry policy for pipeline steps supports the following exception types:

• Step.SERVICE_FAULT: These exceptions occur when an internal server error or transient error happens when calling downstream services. SageMaker Pipelines retries on this type of error automatically. With a retry policy, you can override the default retry operation for this exception type.
• Step.THROTTLING: Throttling exceptions can occur while calling the downstream services. SageMaker Pipelines retries on this type of error automatically. With a retry policy, you can override the default retry operation for this exception type.
• SageMaker.JOB_INTERNAL_ERROR: These exceptions occur when the SageMaker job returns InternalServerError. In this case, starting a new job may fix a transient issue.
• SageMaker.CAPACITY_ERROR: The SageMaker job may encounter Amazon EC2 InsufficientCapacityErrors, which leads to the SageMaker job's failure. You can retry by starting a new SageMaker job to avoid the issue.
• SageMaker.RESOURCE_LIMIT: You can exceed the resource limit quota when running a SageMaker job. You can wait and retry running the SageMaker job after a short period and see if resources are released.
The JSON schema for the retry policy

The retry policy for Pipelines has the following JSON schema:

```
"RetryPolicy": {
  "ExceptionType": [String]
  "IntervalSeconds": Integer
  "BackoffRate": Double
  "MaxAttempts": Integer
  "ExpireAfterMin": Integer
}
```

- **ExceptionType**: This field requires the following exception types in a string array format.
  - Step.SERVICE_FAULT
  - Step.THROTTLING
  - SageMaker.JOB_INTERNAL_ERROR
  - SageMaker.CAPACITY_ERROR
  - SageMaker.RESOURCE_LIMIT
- **IntervalSeconds** (optional): The number of seconds before the first retry attempt (1 by default). IntervalSeconds has a maximum value of 43200 seconds (12 hours).
- **BackoffRate** (optional): The multiplier by which the retry interval increases during each attempt (2.0 by default).
- **MaxAttempts** (optional): A positive integer that represents the maximum number of retry attempts (5 by default). If the error recurs more times than MaxAttempts specifies, retries cease and normal error handling resumes. A value of 0 specifies that errors are never retried. MaxAttempts has a maximum value of 20.
- **ExpireAfterMin** (optional): A positive integer that represents the maximum timespan of retry. If the error recurs after ExpireAfterMin minutes counting from the step gets executed, retries cease and normal error handling resumes. A value of 0 specifies that errors are never retried. ExpireAfterMin has a maximum value of 14,400 minutes (10 days).

**Note**
Only one of MaxAttempts or ExpireAfterMin can be given, but not both; if both are not specified, MaxAttempts becomes the default. If both properties are identified within one policy, then the retry policy generates a validation error.

Configuring a retry policy

The following is an example of a training step with a retry policy.

```
{
  "Steps": [
    {
      "Name": "MyTrainingStep",
      "Type": "Training",
      "RetryPolicies": [
        {
          "ExceptionType": [
            "SageMaker.JOB_INTERNAL_ERROR",
            "SageMaker.CAPACITY_ERROR"
          ],
          "IntervalSeconds": 1,
          "BackoffRate": 2,
          "MaxAttempts": 5
        }
      ]
    }
  ]
}
```
The following is an example of how to build a TrainingStep in SDK for Python (Boto3) with a retry policy.

```python
from sagemaker.workflow.retry import (StepRetryPolicy,
                                      StepExceptionTypeEnum,
                                      SageMakerJobExceptionTypeEnum,
                                      SageMakerJobStepRetryPolicy)
step_train = TrainingStep(
    name="MyTrainingStep",
    xxx,
    retry_policies=[
        // override the default
        StepRetryPolicy(
            exception_types=[
                StepExceptionTypeEnum.SERVICE_FAULT,
                StepExceptionTypeEnum.THROTTLING
            ],
            expire_after_mins=5,
            interval_seconds=10,
            backoff_rate=2.0
        ),
        // retry when resource limit quota gets exceeded
        SageMakerJobStepRetryPolicy(
            exception_types=[SageMakerJobExceptionTypeEnum.RESOURCE_LIMIT],
            expire_after_mins=120,
            interval_seconds=60,
            backoff_rate=2.0
        ),
        // retry when job failed due to transient error or EC2 ICE.
        SageMakerJobStepRetryPolicy(
            failure_reason_types=[
                SageMakerJobExceptionTypeEnum.INTERNAL_ERROR,
                SageMakerJobExceptionTypeEnum.CAPACITY_ERROR,
            ],
            max_attempts=10,
            interval_seconds=30,
            backoff_rate=2.0
        )
    ]
)
```

For more information on configuring retry behavior for certain step types, see Amazon SageMaker Model Building Pipelines - Retry Policy in the Amazon SageMaker Python SDK documentation.

**Selective execution of pipeline steps**

As you use SageMaker Pipelines to create workflows and orchestrate your ML training steps, you might need to undertake multiple experimentation phases. Instead of running the entire pipeline from start to finish, you might only want to iterate over particular steps. SageMaker Pipelines supports selective execution of pipeline steps to help you optimize your ML training. Selective execution is useful in the following scenarios:

- You want to restart a specific step with updated instance type, hyperparameters, or other variables while keeping the parameters from upstream steps.
Your pipeline fails an intermediate step. Previous steps in the execution, such as data preparation or feature extraction, are expensive to rerun. You might need to introduce a fix and rerun certain steps manually to complete the pipeline.

Using selective execution, you can choose to run any subset of steps as long as they are connected in the directed acyclic graph (DAG) of your pipeline. The following DAG shows an example pipeline workflow:

You can select steps AbaloneTrain and AbaloneEval in a selective execution, but you cannot select just AbaloneTrain and AbaloneMSECond steps to run a selective execution because these steps are not connected in the DAG. For non-selected steps in the workflow, the selective execution reuses the outputs from a reference pipeline execution rather than recomputing the steps. Also, non-selected steps that are downstream from the selected steps do not run in a selective execution.

If you choose to run a subset of intermediate steps in your pipeline, your steps may have dependencies on upstream steps. SageMaker needs a reference pipeline execution from which to resource these dependencies. For example, if you choose to run the steps AbaloneTrain and AbaloneEval, you need the output collaterals for the AbaloneProcess step from a reference pipeline execution. You can either provide a reference execution ARN or direct SageMaker to use the latest pipeline execution, which is the default behavior. If you have a reference execution, you can also build the runtime parameters from your reference run and supply them to your selective executive run with any overrides. For details, see Reuse runtime parameter values from a reference execution (p. 2847).

In detail, you specify a configuration for your selective execution pipeline run using SelectiveExecutionConfig. If you specify an ARN for a reference pipeline execution (with the source_pipeline_execution_arn argument), SageMaker uses the upstream step dependencies from the specified pipeline execution. If you do not specify an ARN and a latest pipeline execution exists, SageMaker uses the latest pipeline execution as a reference by default. If you do not specify an ARN and do not want SageMaker to use your latest pipeline execution, set reference_latest_execution to False. The pipeline execution which SageMaker ultimately uses as a reference, whether the latest or user-specified, must be in Success or Failed state.

The following table summarizes how SageMaker chooses a reference execution based on your arguments to SelectiveExecutionConfig.
The `source_pipeline_execution_arn` argument value | The `reference_latest_execution` argument value | The reference execution used
--- | --- | ---
A pipeline ARN | True or unspecified | The specified pipeline ARN
A pipeline ARN | False | The specified pipeline ARN
null or unspecified | True or unspecified | The latest pipeline execution
null or unspecified | False | None—in this case, select steps without upstream dependencies

For more information about selective execution configuration requirements, see the `sagemaker.workflow.selective_execution_config.SelectiveExecutionConfig` documentation.

The following discussion includes examples for the cases in which you want to specify a pipeline reference execution, use the latest pipeline execution as a reference, or run selective execution without a reference pipeline execution.

**Selective execution with a user-specified pipeline reference**

The following example demonstrates the use of selective execution to rerun `AbaloneTrain` and `AbaloneEval` in the same pipeline rerun using a reference pipeline execution.

```python
from sagemaker.workflow.selective_execution_config import SelectiveExecutionConfig

selective_execution_config = SelectiveExecutionConfig(
    selected_steps=["AbaloneTrain", "AbaloneEval"]
)

selective_execution = pipeline.start(
    execution_display_name=f"Sample-Selective-Execution-1",
    parameters={"MaxDepth":6, "NumRound":60},
    selective_execution_config=selective_execution_config,
)
```

**Selective execution with the latest pipeline execution as a reference**

The following example demonstrates the use of selective execution to rerun `AbaloneTrain` and `AbaloneEval` in the same pipeline rerun using the latest pipeline execution as a reference. Since SageMaker uses the latest pipeline execution by default, you can optionally set the `reference_latest_execution` argument to `True`.

```python
# Prepare a new selective execution. Select only the first step in the pipeline without providing source_pipeline_execution_arn.
selective_execution_config = SelectiveExecutionConfig(
    selected_steps=["AbaloneTrain", "AbaloneEval"],
    # optional
    reference_latest_execution=True
)

# Start pipeline execution without source_pipeline_execution_arn
pipeline.start(
    execution_display_name=f"Sample-Selective-Execution-1",
)
```
Selective execution without a reference pipeline

The following example demonstrates the use of selective execution to rerun AbaloneProcess and AbaloneTrain in the same pipeline rerun without providing a reference ARN and disallowing the use of the latest pipeline run as a reference. SageMaker allows this configuration since this subset of steps doesn't have upstream dependencies.

```python
# Prepare a new selective execution. Select only the first step in the pipeline without providing source_pipeline_execution_arn.
selective_execution_config = SelectiveExecutionConfig(
    selected_steps=['AbaloneProcess', 'AbaloneTrain'],
    reference_latest_execution=False
)
# Start pipeline execution without source_pipeline_execution_arn
pipeline.start(
    execution_display_name='Sample-Selective-Execution-1',
    parameters={'MaxDepth': 6, 'NumRound': 60},
    selective_execution_config=selective_execution_config,
)
```

Reuse runtime parameter values from a reference execution

You can build the parameters from your reference pipeline execution using `build_parameters_from_execution`, and supply the result to your selective execution pipeline. You can use the original parameters from the reference execution, or apply any overrides using the `parameter_value_overrides` argument.

The following example shows you how to build parameters from a reference execution and apply an override for the MseThreshold parameter.

```python
# Prepare a new selective execution.
selective_execution_config = SelectiveExecutionConfig(
    source_pipeline_execution_arn='arn:aws:sagemaker:us-west-2:123ab12cd3ef:pipeline/abalone/execution/123ab12cd3ef',
    selected_steps=['AbaloneTrain', 'AbaloneEval', 'AbaloneMSECond'],
)
# Define a new parameters list to test.
new_parameters_mse={
    "MseThreshold": 5,
}
# Build parameters from reference execution and override with new parameters to test.
new_parameters = pipeline.build_parameters_from_execution(  
    pipeline_execution_arn='arn:aws:sagemaker:us-west-2:123ab12cd3ef:pipeline/abalone/execution/123ab12cd3ef',
    parameter_value_overrides=new_parameters_mse
)
# Start pipeline execution with new parameters.
execution = pipeline.start(
    selective_execution_config=selective_execution_config,
    parameters=new_parameters
)```
Baseline calculation, drift detection and lifecycle with ClarifyCheck and QualityCheck steps in Amazon SageMaker Model Building Pipelines

The following topic discusses how baselines and model versions evolve in the Amazon SageMaker Model Building Pipelines when using the **ClarifyCheck** (p. 2827) and **QualityCheck** (p. 2828) steps.

For the ClarifyCheck step, a baseline is a single file that resides in the step properties with the suffix `constraints`. For the QualityCheck step, a baseline is a combination of two files that resides in the step properties: one with the suffix `statistics` and the other with the suffix `constraints`. In the following topics we discuss these properties with a prefix that describes how they are used, impacting baseline behavior and lifecycle in these two pipeline steps. For example, the ClarifyCheck step always calculates and assigns the new baselines in the `CalculatedBaselineConstraints` property and the QualityCheck step does the same in the `CalculatedBaselineConstraints` and `CalculatedBaselineStatistics` properties.

Baseline calculation and registration for ClarifyCheck and QualityCheck steps

Both the ClarifyCheck and QualityCheck steps always calculate new baselines based on step inputs through the underlying processing job run. These newly calculated baselines are accessed through the properties with the prefix `CalculatedBaseline`. You can record these properties as the `ModelMetrics` of your model package in the **Model Step** (p. 2819). This model package can be registered with 5 different baselines. You can register it with one for each check type: data bias, model bias, and model explainability from running the ClarifyCheck step and model quality, and data quality from running the QualityCheck step. The `register_new_baseline` parameter dictates the value set in the properties with the prefix `BaselineUsedForDriftCheck` after a step runs.

The following table of potential use cases shows different behaviors resulting from the step parameters you can set for the ClarifyCheck and QualityCheck steps:

<table>
<thead>
<tr>
<th>Possible use case that you may consider for selecting this configuration</th>
<th><code>skip_check</code> / <code>register_new_ba</code></th>
<th>Does step do a drift check?</th>
<th>Value of step property <code>CalculatedBaselineConstraints</code></th>
<th>Value of step property <code>BaselineUsedForDriftCheck</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>You are doing regular retraining with checks enabled to get a new model version, but you <strong>want to carry over the previous baselines</strong> as the DriftCheckBaselines in the model registry for your new model version.</td>
<td>False/ False</td>
<td>Drift check runs against existing baselines</td>
<td>New baselines calculated by running the step</td>
<td>Baseline from the latest approved model in Model Registry or the baseline supplied as step parameter</td>
</tr>
<tr>
<td>You are doing regular retraining with checks enabled to get a new model version, but you <strong>want to refresh the</strong></td>
<td>False/ True</td>
<td>Drift check runs against existing baselines</td>
<td>New baselines calculated by running the step</td>
<td>Newly calculated baseline by running the step (value of property <code>CalculatedBaseline</code>)</td>
</tr>
</tbody>
</table>
### Table: Possible Use Case for Selecting Configuration

<table>
<thead>
<tr>
<th>Possible use case that you may consider for selecting this configuration</th>
<th>skip_check / register_new_baseline</th>
<th>Does step do a drift check?</th>
<th>Value of step property</th>
<th>Value of step property</th>
</tr>
</thead>
<tbody>
<tr>
<td>DriftCheckBaselines in the model registry with the newly calculated baselines for your new model version.</td>
<td>skip_check / register_new_baseline</td>
<td>Does step do a drift check?</td>
<td>Value of step property</td>
<td>Value of step property</td>
</tr>
<tr>
<td>DriftCheckBaselines in the model registry with the newly calculated baselines for your new model version.</td>
<td>True/False</td>
<td>No drift check</td>
<td>New baselines calculated by running</td>
<td>Baseline from the latest approved model in the model registry or the baseline supplied as step parameter</td>
</tr>
</tbody>
</table>

You are initiating the pipeline to retrain a new model version because there is a violation detected by Amazon SageMaker Model Monitor on an endpoint for a particular type of check, and you want to **skip this type of check against the previous baseline, but carry over the previous baseline as DriftCheckBaselines in the model registry for your new model version.**
### Possible use case that you may consider for selecting this configuration

<table>
<thead>
<tr>
<th>skip_check / register_new_baseline</th>
<th>Does step do a drift check?</th>
<th>Value of step property</th>
<th>Value of step property</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>True/ True</strong></td>
<td>No drift check</td>
<td>New baselines calculated by running the step</td>
<td>Newly calculated baseline by running the step (value of property CalculatedBaseline)</td>
</tr>
</tbody>
</table>

This happens in the following cases:

- You are starting the initial run of the pipeline, building your first model version, and generating the initial baselines.
- You are initiating the pipeline to retrain a new model version because there is a violation detected by Model Monitor on the endpoint for a particular type of check. If you want to skip the check against the previous baseline and refresh the DriftCheckBaselines with the newly calculated baseline in the model registry directly.

**Note**

If you use scientific notation in your constraint, you need to convert to float. For a preprocessing script example of how to do this, see Create a Model Quality Baseline.

When you register a model with Model Step (p. 2819), you can register the BaselineUsedForDriftCheck property as DriftCheckBaselines. These baseline files can then be used by Model Monitor for model and data quality checks. In addition, these baselines can also be used in the ClarifyCheckStep and QualityCheck step to compare newly trained models against the existing models that are registered in the model registry for future pipeline runs.

**Drift Detection against Previous Baselines in SageMaker Pipelines**

In the case of the QualityCheck step, when you initiate the pipeline for regular retraining to get a new model version, you may not want to run the training step if the data quality and the data bias...
has Schema for Violations (constraint_violations json file) (p. 3067) on the baselines of your previous approved model version. You also may not want to register the newly trained model version if the model quality, model bias, or model explainability violates the registered baseline of your previous approved model version when running the ClarifyCheck step. In these cases, you can enable the checks you want by setting the skip_check property of the corresponding check step set to False, resulting in the ClarifyCheck and QualityCheck step failing if violation is detected against previous baselines. The pipeline process then does not proceed so that the model drifted from the baseline isn’t registered. ClarifyCheck and QualityCheck steps are able to get DriftCheckBaselines of the latest approved model version of a given model package group against which to compare. Previous baselines can also be supplied directly through supplied_baseline_constraints (in addition to supplied_baseline_statistics if it is a QualityCheck step) and are always prioritized over any baselines pulled from the model package group.

Baseline and model version lifecycle and evolution with SageMaker Pipelines

By setting register_new_baseline of your ClarifyCheck and QualityCheck step to False, your previous baseline is accessible through the step property prefix BaselineUsedForDriftCheck. You can then register these baselines as the DriftCheckBaselines BaselineUsedForDriftCheck in the new model version when you register a model with Model Step (p. 2819). Once you approve this new model version in the model registry, the DriftCheckBaseline in this model version becomes available for the ClarifyCheck and QualityCheck steps in the next pipeline process. If you want to refresh the baseline of a certain check type for future model versions, you can set register_new_baseline to True so that the properties with prefix BaselineUsedForDriftCheck become the newly calculated baseline. In these ways, you can preserve your preferred baselines for a model trained in the future, or refresh the baselines for drift checks when needed, managing your baseline evolution and lifecycle throughout your model training iterations.

The following diagram illustrates a model-version-centric view of the baseline evolution and lifecycle.
Pipeline Run 1:
initial run

Pipeline Run 2:
Scheduled retraining new model version
(Check Succeeded)

Pipeline Run 3:
Scheduled retraining new model version
(Check Succeeded)

Pipeline Run 4:
Drift detected on endpoint, suggest and register new baselines

Pipeline Run 5:
Scheduled retraining new model version
(Check Succeeded)
Amazon EventBridge Integration

You can schedule your Amazon SageMaker Model Building Pipelines executions using Amazon EventBridge. Amazon SageMaker Model Building Pipelines is supported as a target in Amazon EventBridge. This allows you to initiate the execution of your model building pipeline based on any event in your event bus. With EventBridge, you can automate your pipeline executions and respond automatically to events such as training job or endpoint status changes. Events include a new file being uploaded to your Amazon S3 bucket, a change in status of your Amazon SageMaker endpoint due to drift, and Amazon Simple Notification Service (SNS) topics.

The following SageMaker Pipelines actions can be automatically initiated:

- StartPipelineExecution

For more information on scheduling SageMaker jobs, see Automating SageMaker with Amazon EventBridge.

Schedule a Pipeline with Amazon EventBridge

To start a pipeline execution with Amazon CloudWatch Events, you must create an EventBridge rule. When you create a rule for events, you specify a target action to take when EventBridge receives an event that matches the rule. When an event matches the rule, EventBridge sends the event to the specified target and initiates the action defined in the rule.

The following tutorials show how to schedule a pipeline execution with EventBridge using the EventBridge console or the AWS CLI.

Prerequisites

- A role that EventBridge can assume with the SageMaker::StartPipelineExecution permission. This role can be created automatically if you create a rule from the EventBridge console; otherwise, you need to create this role yourself. For information on creating a SageMaker role, see SageMaker Roles.
- An Amazon SageMaker Pipeline to schedule. To create an Amazon SageMaker Pipeline, see Define a Pipeline.

Create an EventBridge rule using the EventBridge console

The following procedure shows how to create an EventBridge rule using the EventBridge console.

1. Navigate to the EventBridge console.
2. Select Rules on the left hand side.
3. Select Create Rule.
4. Enter a name and description for your rule.
5. Select how you want to initiate this rule. You have the following choices for your rule:

   - **Event pattern**: Your rule is initiated when an event matching the pattern occurs. You can choose a predefined pattern that matches a certain type of event, or you can create a custom pattern. If you select a predefined pattern, you can edit the pattern to customize it. For more information on Event patterns, see Event Patterns in CloudWatch Events.
   - **Schedule**: Your rule is initiated regularly on a specified schedule. You can use a fixed-rate schedule that initiates regularly for a specified number of minutes, hour, or weeks. You can also use a cron expression to create a more fine-grained schedule, such as “the first Monday of each month at 8am.” Schedule is not supported on a custom or partner event bus.
6. Select your desired Event bus.
7. Select the target(s) to invoke when an event matches your event pattern or when the schedule is initiated. You can add up to 5 targets per rule. Select SageMaker Pipeline in the target dropdown list.

8. Select the pipeline you want to initiate from the pipeline dropdown list.

9. Add parameters to pass to your pipeline execution using a name and value pair. Parameter values can be static or dynamic. For more information on Amazon SageMaker Pipeline parameters, see [AWS::Events::Rule SagemakerPipelineParameters](#). 

   • Static values are passed to the pipeline execution every time the pipeline is initiated. For example, if `{"Name": "Instance_type", "Value": "ml.4xlarge"}` is specified in the parameter list, then it is passed as a parameter in StartPipelineExecutionRequest every time EventBridge initiates the pipeline.

   • Dynamic values are specified using a JSON path. EventBridge parses the value from an event payload, then passes it to the pipeline execution. For example: `$\.detail\.param\.value`

10. Select the role to use for this rule. You can either use an existing role or create a new one.

11. (Optional) Add tags.

12. Select Create to finalize your rule.

Your rule is now in effect and ready to initiate your pipeline executions.

**Create an EventBridge rule using the AWS CLI**

The following procedure shows how to create an EventBridge rule using the AWS CLI.

1. Create a rule to be initiated. When creating an EventBridge rule using the AWS CLI, you have two options for how your rule is initiated, event pattern and schedule.

   • **Event pattern**: Your rule is initiated when an event matching the pattern occurs. You can choose a predefined pattern that matches a certain type of event, or you can create a custom pattern. If you select a predefined pattern, you can edit the pattern to customize it. You can create a rule with event pattern using the following command:

     ```
     aws events put-rule --name <RULE_NAME> ----event-pattern <YOUR_EVENT_PATTERN> --description <RULE_DESCRIPTION> --role-arn <ROLE_TO_EXECUTE_PIPELINE> --tags <TAGS>
     ```

   • **Schedule**: Your rule is initiated regularly on a specified schedule. You can use a fixed-rate schedule that initiates regularly for a specified number of minutes, hour, or weeks. You can also use a cron expression to create a more fine-grained schedule, such as "the first Monday of each month at 8am." Schedule is not supported on a custom or partner event bus. You can create a rule with schedule using the following command:

     ```
     aws events put-rule --name <RULE_NAME> --schedule-expression <YOUR_CRON_EXPRESSION> --description <RULE_DESCRIPTION> --role-arn <ROLE_TO_EXECUTE_PIPELINE> --tags <TAGS>
     ```

2. Add target(s) to invoke when an event matches your event pattern or when the schedule is initiated. You can add up to 5 targets per rule. For each target, you must specify:

   • ARN: The resource ARN of your pipeline.

   • Role ARN: The ARN of the role EventBridge should assume to execute the pipeline.

   • Parameters: Amazon SageMaker pipeline parameters to pass.

3. Run the following command to pass a Amazon SageMaker pipeline as a target to your rule using `put-targets`:

     ```
     aws events put-targets --rule <RULE_NAME> --event-bus-name <EVENT_BUS_NAME> --targets "["Id": <ID>, "Arn": <RESOURCE_ARN>, "RoleArn": <ROLE_ARN>,
     ```
Amazon SageMaker Experiments Integration

Amazon SageMaker Model Building Pipelines is closely integrated with Amazon SageMaker Experiments. By default, when SageMaker Pipelines creates and executes a pipeline, the following SageMaker Experiments entities are created if they don't exist:

- An experiment for the pipeline
- A run group for every execution of the pipeline
- A run that's added to the run group for each SageMaker job created in a pipeline execution step

You can compare metrics such as model training accuracy across multiple pipeline executions just as you can compare such metrics across multiple run groups of a SageMaker model training experiment.

The following sample shows the relevant parameters of the Pipeline class in the Amazon SageMaker Python SDK.

```python
Pipeline(
    name="MyPipeline",
    parameters=[...],
    pipeline_experiment_config=PipelineExperimentConfig(
        ExecutionVariables.PIPELINE_NAME,
        ExecutionVariables.PIPELINE_EXECUTION_ID
    ),
    steps=[...]
)
```

If you don't want an experiment and run group created for the pipeline, set pipeline_experiment_config to None.

**Note**

Experiments integration was introduced in the Amazon SageMaker Python SDK v2.41.0.

The following naming rules apply based on what you specify for the ExperimentName and TrialName parameters of pipeline_experiment_config:

- If you don't specify ExperimentName, the pipeline name is used for the experiment name.

  If you do specify ExperimentName, it's used for the experiment name. If an experiment with that name exists, the pipeline-created run groups are added to the existing experiment. If an experiment with that name doesn't exist, a new experiment is created.

- If you don't specify TrialName, the pipeline execution ID is used for the run group name.

  If you do specify TrialName, it's used for the run group name. If a run group with that name exists, the pipeline-created runs are added to the existing run group. If a run group with that name doesn't exist, a new run group is created.

**Note**

The experiment entities aren't deleted when the pipeline that created the entities is deleted. You can use the SageMaker Experiments API to delete the entities. For more information, see Clean Up Amazon SageMaker Experiment Resources (p. 1851).

For information about how to view the SageMaker Experiment entities associated with a pipeline, see View Experiment Entities Created by SageMaker Pipelines (p. 2880). For more information on SageMaker Experiments, see Manage Machine Learning with Amazon SageMaker Experiments (p. 1838).
The following sections show examples of the previous rules and how they are represented in the pipeline definition file. For more information on pipeline definition files, see SageMaker Pipelines Overview (p. 2806).

Topics
- Default Behavior (p. 2856)
- Disable Experiments Integration (p. 2856)
- Specify a Custom Experiment Name (p. 2857)
- Specify a Custom Run Group Name (p. 2857)

Default Behavior

Create a pipeline

The pipeline_experiment_config is omitted. ExperimentName defaults to the pipeline name. TrialName defaults to the execution ID.

```python
pipeline_name = f"MyPipeline"
pipeline = Pipeline(
    name=pipeline_name,
    parameters=[...],
    steps=[step_train]
)
```

Pipeline definition file

```json
{
    "Version": "2020-12-01",
    "Parameters": [
        {
            "Name": "InputDataSource"
        },
        {
            "Name": "InstanceCount",
            "Type": "Integer",
            "DefaultValue": 1
        }
    ],
    "PipelineExperimentConfig": {
        "ExperimentName": {"Get": "Execution.PipelineName"},
        "TrialName": {"Get": "Execution.PipelineExecutionId"}
    },
    "Steps": [...]
}
```

Disable Experiments Integration

Create a pipeline

The pipeline_experiment_config is set to None.

```python
pipeline_name = f"MyPipeline"
pipeline = Pipeline(
    name=pipeline_name,
    parameters=[...],
    pipeline_experiment_config=None,
    steps=[step_train]
)
```
Pipeline definition file

This is the same as the preceding default example, without the PipelineExperimentConfig.

Specify a Custom Experiment Name

A custom experiment name is used. The run group name is set to the execution ID, as with the default behavior.

Create a pipeline

```python
pipeline_name = f"MyPipeline"
pipeline = Pipeline(
    name=pipeline_name,
    parameters=[],
    pipeline_experiment_config=PipelineExperimentConfig(
        "CustomExperimentName",
        ExecutionVariables.PIPELINE_EXECUTION_ID
    ),
    steps=[step_train]
)
```

Pipeline definition file

```
{
    ...
    "PipelineExperimentConfig": {
        "ExperimentName": "CustomExperimentName",
        "TrialName": {"Get": "Execution.PipelineExecutionId"}
    },
    "Steps": [...]
}
```

Specify a Custom Run Group Name

A custom run group name is used and appended with the execution ID. The experiment name is set to the pipeline name, as with the default behavior.

Create a pipeline

```python
pipeline_name = f"MyPipeline"
pipeline = Pipeline(
    name=pipeline_name,
    parameters=[],
    pipeline_experiment_config=PipelineExperimentConfig(
        ExecutionVariables.PIPELINE_NAME,
        Join(on="-", values=["CustomTrialName", ExecutionVariables.PIPELINE_EXECUTION_ID])
    ),
    steps=[step_train]
)
```

Pipeline definition file

```
{
    ...
    "PipelineExperimentConfig": {
        "ExperimentName": {"Get": "Execution.PipelineName"},
        "TrialName": {
            "On": "-",
            "Values": [
```
Local Mode

SageMaker Pipelines local mode is an easy way to test your training, processing and inference scripts, as well as the runtime compatibility of pipeline parameters before you execute your pipeline on the managed SageMaker service. By using local mode, you can test your SageMaker pipeline locally using a smaller dataset. This allows quick and easy debugging of errors in user scripts and the pipeline definition itself without incurring the costs of using the managed service.

Pipelines local mode leverages SageMaker jobs local mode under the hood. This is a feature in the SageMaker Python SDK that allows you to run SageMaker built-in or custom images locally using Docker containers. Pipelines local mode is built on top of SageMaker jobs local mode. Therefore, you can expect to see the same results as if you were running those jobs separately. For example, local mode still uses Amazon S3 to upload model artifacts and processing outputs. If you want data generated by local jobs to reside on local disk, you can use the setup mentioned in Local Mode.

Pipeline local mode currently supports the following step types:

- **Training Step** (p. 2817)
- **Processing Step** (p. 2815)
- **Transform Step** (p. 2822)
- **Model Step** (with Create Model arguments only)
- **Condition Step** (p. 2823)
- **Fail Step** (p. 2833)

As opposed to the managed Pipelines service which allows multiple steps to execute in parallel using Parallelism Configuration, the local pipeline executor runs the steps sequentially. Therefore, overall execution performance of a local pipeline may be poorer than one that runs on the cloud - this mostly depends on the size of the dataset, algorithm, as well as the power of your local computer. Also note that Pipelines runs in local mode are not recorded in SageMaker Experiments.

**Note**

Pipelines local mode is not compatible with SageMaker algorithms such as XGBoost. If you want to use these algorithms, you must use them in script mode.

In order to execute a pipeline locally, the sagemaker_session fields associated with the pipeline steps and the pipeline itself need to be of type LocalPipelineSession. The following example shows how you can define a SageMaker pipeline to execute locally.

```python
from sagemaker.workflow.pipeline_context import LocalPipelineSession
from sagemaker.pytorch import PyTorch
from sagemaker.workflow.steps import TrainingStep
from sagemaker.workflow.pipeline import Pipeline

local_pipeline_session = LocalPipelineSession()

pytorch_estimator = PyTorch(
    sagemaker_session=local_pipeline_session,
    role=sagemaker.get_execution_role(),
    instance_type="ml.c5.xlarge",
)
```
instance_count=1,
        framework_version="1.8.0",
        py_version="py36",
        entry_point="./entry_point.py",
    )

step = TrainingStep(
    name="MyTrainingStep",
    step_args=pytorch_estimator.fit(
        inputs=TrainingInput(s3_data="s3://my-bucket/my-data/train"),
    )
)

pipeline = Pipeline(
    name="MyPipeline",
    steps=[step],
    sagemaker_session=local_pipeline_session
)

pipeline.create(
    role_arn=sagemaker.get_execution_role(),
    description="local pipeline example"
)

// pipeline will execute locally
execution = pipeline.start()
steps = execution.list_steps()

training_job_name = steps['PipelineExecutionSteps'][0]['Metadata']['TrainingJob']['Arn']
step_outputs = pipeline_session.sagemaker_client.describe_training_job(TrainingJobName =
    training_job_name)

Once you are ready to execute the pipeline on the managed SageMaker Pipelines service, you can do so by replacing LocalPipelineSession in the previous code snippet with PipelineSession (as shown in the following code sample) and rerunning the code.

```python
from sagemaker.workflow.pipeline_context import PipelineSession
pipeline_session = PipelineSession()
```

## Troubleshooting Amazon SageMaker Model Building Pipelines

When using Amazon SageMaker Model Building Pipelines, you might run into issues for various reasons. This topic provides information about common errors and how to resolve them.

### Pipeline Definition Issues

Your pipeline definition might not be formatted correctly. This can result in your execution failing or your job being inaccurate. These errors can be caught when the pipeline is created or when an execution occurs. If your definition doesn't validate, SageMaker Pipelines returns an error message identifying the character where the JSON file is malformed. To fix this problem, review the steps created using the SageMaker Python SDK for accuracy.

You can only include steps in a pipeline definition once. Because of this, steps cannot exist as part of a condition step *and* a pipeline in the same pipeline.

### Examining Pipeline Logs

You can view the status of your steps using the following command:
Each step includes the following information:

- The ARN of the entity launched by the pipeline, such as SageMaker job ARN, model ARN, or model package ARN.
- The failure reason includes a brief explanation of the step failure.
- If the step is a condition step, it includes whether the condition is evaluated to true or false.
- If the execution reuses a previous job execution, the CacheHit lists the source execution.

You can also view the error messages and logs in the Amazon SageMaker Studio interface. For information about how to see the logs in Studio, see View a Pipeline Execution (p. 2878).

**Missing Permissions**

Correct permissions are required for the role that creates the pipeline execution, and the steps that create each of the jobs in your pipeline execution. Without these permissions, you may not be able to submit your pipeline execution or run your SageMaker jobs as expected. To ensure that your permissions are properly set up, see IAM Access Management (p. 2808).

**Job Execution Errors**

You may run into issues when executing your steps because of issues in the scripts that define the functionality of your SageMaker jobs. Each job has a set of CloudWatch logs. To view these logs from Studio, see View a Pipeline Execution (p. 2878). For information about using CloudWatch logs with SageMaker, see Log Amazon SageMaker Events with Amazon CloudWatch (p. 3591).

**Property File Errors**

You may have issues when incorrectly implementing property files with your pipeline. To ensure that your implementation of property files works as expected, see Property Files and JsonGet (p. 2836).

**Create and Manage SageMaker Pipelines**

You can use Amazon SageMaker Model Building Pipelines to create end-to-end workflows that manage and deploy SageMaker jobs. SageMaker Pipelines comes with SageMaker Python SDK integration, so you can build each step of your pipeline using a Python-based interface.

After your pipeline is deployed, you can view the directed acyclic graph (DAG) for your pipeline and manage your executions using Amazon SageMaker Studio. Using SageMaker Studio, you can get information about your current and historical pipelines, compare executions, see the DAG for your executions, get metadata information, and more. To learn how to view pipelines from SageMaker Studio, see View, Track, and Execute SageMaker Pipelines in SageMaker Studio (p. 2876).

**Topics**

- Define a Pipeline (p. 2860)
- Run a pipeline (p. 2873)
- View, Track, and Execute SageMaker Pipelines in SageMaker Studio (p. 2876)

**Define a Pipeline**

To orchestrate your workflows with Amazon SageMaker Model Building Pipelines, you need to generate a directed acyclic graph (DAG) in the form of a JSON pipeline definition. The following image is a representation of the pipeline DAG that you create in this tutorial:
You can generate your JSON pipeline definition using the SageMaker Python SDK. The following tutorial shows how to generate a pipeline definition for a pipeline that solves a regression problem to determine the age of an abalone based on its physical measurements. For a Jupyter notebook that includes the content in this tutorial that you can run, see Orchestrating Jobs with Amazon SageMaker Model Building Pipelines.

Topics

- Prerequisites (p. 2861)
- Create a Pipeline (p. 2862)

Prerequisites

To run the following tutorial you must do the following:

- Set up your notebook instance as outlined in Create a notebook instance. This gives your role permissions to read and write to Amazon S3, and create training, batch transform, and processing jobs in SageMaker.
- Grant your notebook permissions to get and pass its own role as shown in Modifying a role permissions policy. Add the following JSON snippet to attach this policy to your role. Replace <your-role-arn> with the ARN used to create your notebook instance.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
        }
    ],
}
```
• Trust the SageMaker service principal by following the steps in Modifying a role trust policy. Add the following statement fragment to the trust relationship of your role:

```json
{
    "Sid": "",
    "Effect": "Allow",
    "Principal": {
        "Service": "sagemaker.amazonaws.com"
    },
    "Action": "sts:AssumeRole"
}
```

---

### Set Up Your Environment

Create a new SageMaker session using the following code block. This returns the role ARN for the session. This role ARN should be the execution role ARN that you set up as a prerequisite.

```python
import boto3
import sagemaker
import sagemaker.session

region = boto3.Session().region_name
sagemaker_session = sagemaker.session.Session()
role = sagemaker_session.get_execution_role()
default_bucket = sagemaker_session.default_bucket()
model_package_group_name = f"AbaloneModelPackageGroupName"
```

### Create a Pipeline

Run the following steps from your SageMaker notebook instance to create a pipeline including steps for preprocessing, training, evaluation, conditional evaluation, and model registration.

#### Step 1: Download the Dataset

This notebook uses the UCI Machine Learning Abalone Dataset. The dataset contains the following features:

- **length** – The longest shell measurement of the abalone.
- **diameter** – The diameter of the abalone perpendicular to its length.
- **height** – The height of the abalone with meat in the shell.
- **whole_weight** – The weight of the whole abalone.
- **shucked_weight** – The weight of the meat removed from the abalone.
- **viscera_weight** – The weight of the abalone viscera after bleeding.
- **shell_weight** – The weight of the abalone shell after meat removal and drying.
- **sex** – The sex of the abalone. One of 'M', 'F', or 'I', where 'I' is an infant abalone.
- **rings** – The number of rings in the abalone shell.
The number of rings in the abalone shell is a good approximation for its age using the formula 
\[ \text{age} = \text{rings} + 1.5 \]. However, obtaining this number is a time-consuming task. You must cut the shell 
through the cone, stain the section, and count the number of rings through a microscope. However, 
the other physical measurements are easier to determine. This notebook uses the dataset to build a 
predictive model of the variable \text{rings} using the other physical measurements.

**To download the dataset**

1. Download the dataset into your account's default Amazon S3 bucket.

   ```
   !mkdir -p data
   local_path = "data/abalone-dataset.csv"
   s3 = boto3.resource("s3")
   s3.Bucket(f"sagemaker-servicecatalog-seedcode-{region}").download_file( 
     "dataset/abalone-dataset.csv",
     local_path
   )
   base_uri = f"s3://{default_bucket}/abalone"
   input_data_uri = sagemaker.s3.S3Uploader.upload( 
     local_path=local_path,
     desired_s3_uri=base_uri,
   )
   print(input_data_uri)
   ```

2. Download a second dataset for batch transformation after your model is created.

   ```
   local_path = "data/abalone-dataset-batch.csv"
   s3 = boto3.resource("s3")
   s3.Bucket(f"sagemaker-servicecatalog-seedcode-{region}").download_file( 
     "dataset/abalone-dataset-batch",
     local_path
   )
   base_uri = f"s3://{default_bucket}/abalone"
   batch_data_uri = sagemaker.s3.S3Uploader.upload( 
     local_path=local_path,
     desired_s3_uri=base_uri,
   )
   print(batch_data_uri)
   ```

**Step 2: Define Pipeline Parameters**

This code block defines the following parameters for your pipeline:

- `processing_instance_count` – The instance count of the processing job.
- `input_data` – The Amazon S3 location of the input data.
- `batch_data` – The Amazon S3 location of the input data for batch transformation.
- `model_approval_status` – The approval status to register the trained model with for CI/CD. For 
  more information, see Automate MLOps with SageMaker Projects (p. 3017).

```python
from sagemaker.workflow.parameters import ( 
    ParameterInteger, 
    ParameterString,
)
```
Step 3: Define a Processing Step for Feature Engineering

This section shows how to create a processing step to prepare the data from the dataset for training.

To create a processing step

1. Create a directory for the processing script.

   ```
   !mkdir -p abalone
   ```

2. Create a file in the `/abalone` directory named `preprocessing.py` with the following content. This preprocessing script is passed in to the processing step for execution on the input data. The training step then uses the preprocessed training features and labels to train a model, and the evaluation step uses the trained model and preprocessed test features and labels to evaluate the model. The script uses scikit-learn to do the following:

   - Fill in missing `sex` categorical data and encode it so it's suitable for training.
   - Scale and normalize all numerical fields except for `rings` and `sex`.
   - Split the data into training, test, and validation datasets.

   ```
   %%writefile abalone/preprocessing.py
   import argparse
   import os
   import requests
   import tempfile
   import numpy as np
   import pandas as pd
   from sklearn.compose import ColumnTransformer
   from sklearn.impute import SimpleImputer
   from sklearn.pipeline import Pipeline
   from sklearn.preprocessing import StandardScaler, OneHotEncoder
   
   # Because this is a headerless CSV file, specify the column names here.
   feature_columns_names = [
   "sex",
   "length",
   "diameter",
   "height",
   "whole_weight",
   "shucked_weight",
   "viscera_weight",
   
   # Columns that should be handled by SimpleImputer
   columns_to_impute = [
   "length",
   "diameter",
   "height",
   "whole_weight",
   "shucked_weight",
   "viscera_weight",
   
   # Columns that should be handled by OneHotEncoder
   columns_to_onehot = [
   "sex",
   
   # Columns that should be handled by StandardScaler
   columns_to_scale = [
   "length",
   "diameter",
   "height",
   "whole_weight",
   "shucked_weight",
   "viscera_weight",
   ```

3. Write a script `preprocessing.py` inside the `/abalone` directory.

   ```
   import argparse
   import os
   import requests
   import tempfile
   import numpy as np
   import pandas as pd
   from sklearn.compose import ColumnTransformer
   from sklearn.impute import SimpleImputer
   from sklearn.pipeline import Pipeline
   from sklearn.preprocessing import StandardScaler, OneHotEncoder
   
   # Because this is a headerless CSV file, specify the column names here.
   feature_columns_names = [
   "sex",
   "length",
   "diameter",
   "height",
   "whole_weight",
   "shucked_weight",
   "viscera_weight",
   
   # Columns that should be handled by SimpleImputer
   columns_to_impute = [
   "length",
   "diameter",
   "height",
   "whole_weight",
   "shucked_weight",
   "viscera_weight",
   
   # Columns that should be handled by OneHotEncoder
   columns_to_onehot = [
   "sex",
   
   # Columns that should be handled by StandardScaler
   columns_to_scale = [
   "length",
   "diameter",
   "height",
   "whole_weight",
   "shucked_weight",
   "viscera_weight",
   ```

4. Modify the script to include the necessary data preprocessing steps.

5. Test the processing step with a test dataset to ensure the data is preprocessed correctly.

6. Deploy the trained model using the preprocessed data for evaluation.

This completes the feature engineering step, ready for model training and evaluation.
"shell_weight",
}
label_column = "rings"

feature_columns_dtype = {
    "sex": str,
    "length": np.float64,
    "diameter": np.float64,
    "height": np.float64,
    "whole_weight": np.float64,
    "shucked_weight": np.float64,
    "viscera_weight": np.float64,
    "shell_weight": np.float64
}
label_column_dtype = {"rings": np.float64}

def merge_two_dicts(x, y):
    z = x.copy()
    z.update(y)
    return z

if __name__ == "__main__":
    base_dir = "/opt/ml/processing"
    df = pd.read_csv(f"{base_dir}/input/abalone-dataset.csv",
             header=None,
             names=feature_columns_names + [label_column],
             dtype=merge_two_dicts(feature_columns_dtype, label_column_dtype)
         )
    numeric_features = list(feature_columns_names)
    numeric_features.remove("sex")
    numeric_transformer = Pipeline(
        steps=[
            ("imputer", SimpleImputer(strategy="median")),
            ("scaler", StandardScaler())
        ]
    )
    categorical_features = ["sex"]
    categorical_transformer = Pipeline(
        steps=[
            ("imputer", SimpleImputer(strategy="constant", fill_value="missing")),
            ("onehot", OneHotEncoder(handle_unknown="ignore"))
        ]
    )
    preprocess = ColumnTransformer(
        transformers=[
            ("num", numeric_transformer, numeric_features),
            ("cat", categorical_transformer, categorical_features)
        ]
    )
    y = df.pop("rings")
    X_pre = preprocess.fit_transform(df)
    y_pre = y.to_numpy().reshape(len(y), 1)
    X = np.concatenate((y_pre, X_pre), axis=1)
    np.random.shuffle(X)
    train, validation, test = np.split(X, [int(.7*len(X)), int(.85*len(X))])
pd.DataFrame(train).to_csv(f"{base_dir}/train/train.csv", header=False, index=False)

pd.DataFrame(validation).to_csv(f"{base_dir}/validation/validation.csv", header=False, index=False)

pd.DataFrame(test).to_csv(f"{base_dir}/test/test.csv", header=False, index=False)

3. Create an instance of an SKLearnProcessor to pass in to the processing step.

```python
from sagemaker.sklearn.processing import SKLearnProcessor

framework_version = "0.23-1"

sklearn_processor = SKLearnProcessor(
    framework_version=framework_version,
    instance_type="ml.m5.xlarge",
    instance_count=processing_instance_count,
    base_job_name="sklearn-abalone-process",
    role=role,
)
```

4. Create a processing step. This step takes in the SKLearnProcessor, the input and output channels, and the preprocessing.py script that you created. This is very similar to a processor instance's `run` method in the SageMaker Python SDK. The `input_data` parameter passed into `ProcessingStep` is the input data of the step itself. This input data is used by the processor instance when it runs.

Note the "train", "validation", and "test" named channels specified in the output configuration for the processing job. Step Properties such as these can be used in subsequent steps and resolve to their runtime values at execution.

```python
from sagemaker.processing import ProcessingInput, ProcessingOutput
from sagemaker.workflow.steps import ProcessingStep

step_process = ProcessingStep(
    name="AbaloneProcess",
    processor=sklearn_processor,
    inputs=[
        ProcessingInput(source=input_data, destination="/opt/ml/processing/input"),
    ],
    outputs=[
        ProcessingOutput(output_name="train", source="/opt/ml/processing/train"),
        ProcessingOutput(output_name="validation", source="/opt/ml/processing/validation"),
        ProcessingOutput(output_name="test", source="/opt/ml/processing/test")
    ],
    code="abalone/preprocessing.py",
)
```

**Step 4: Define a Training step**

This section shows how to use the SageMaker [XGBoost Algorithm](https://docs.aws.amazon.com/sagemaker/latest/dg/xgboost-algorithm.html) to train a model on the training data output from the processing steps.

**To define a training step**

1. Specify the model path where you want to save the models from training.

```python
model_path = f"s3://{default_bucket}/AbaloneTrain"
```
2. Configure an estimator for the XGBoost algorithm and the input dataset. The training instance type is passed into the estimator. A typical training script loads data from the input channels, configures training with hyperparameters, trains a model, and saves a model to `model_dir` so that it can be hosted later. SageMaker uploads the model to Amazon S3 in the form of a `model.tar.gz` at the end of the training job.

```python
from sagemaker.estimator import Estimator

image_uri = sagemaker.image_uris.retrieve(
    framework="xgboost",
    region=region,
    version="1.0-1",
    py_version="py3",
    instance_type="ml.m5.xlarge"
)
xgb_train = Estimator(
    image_uri=image_uri,
    instance_type="ml.m5.xlarge",
    instance_count=1,
    output_path=model_path,
    role=role,
)
xgb_train.set_hyperparameters(
    objective="reg:linear",
    num_round=50,
    max_depth=5,
    eta=0.2,
    gamma=4,
    min_child_weight=6,
    subsample=0.7,
    silent=0
)
```

3. Create a `TrainingStep` using the estimator instance and properties of the `ProcessingStep`. In particular, pass in the S3Uri of the "train" and "validation" output channel to the `TrainingStep`.

```python
from sagemaker.inputs import TrainingInput
from sagemaker.workflow.steps import TrainingStep

step_train = TrainingStep(
    name="AbaloneTrain",
    estimator=xgb_train,
    inputs={
        "train": TrainingInput(
            s3_data=step_process.properties.ProcessingOutputConfig.Outputs["train"].S3Output.S3Uri,
            content_type="text/csv"
        ),
        "validation": TrainingInput(
            s3_data=step_process.properties.ProcessingOutputConfig.Outputs["validation"].S3Output.S3Uri,
            content_type="text/csv"
        )
    },
)
```
Step 5: Define a Processing Step for Model Evaluation

This section shows how to create a processing step to evaluate the accuracy of the model. The result of this model evaluation is used in the condition step to determine which execute path to take.

To define a processing step for model evaluation

1. Create a file in the /abalone directory named evaluation.py. This script is used in a processing step to perform model evaluation. It takes a trained model and the test dataset as input, then produces a JSON file containing classification evaluation metrics.

```python
%%writefile abalone/evaluation.py
import json
import pathlib
import pickle
import tarfile
import joblib
import numpy as np
import pandas as pd
import xgboost

from sklearn.metrics import mean_squared_error

if __name__ == '__main__':
    model_path = f'/opt/ml/processing/model/model.tar.gz'
    with tarfile.open(model_path) as tar:
        tar.extractall(path='.')
    model = pickle.load(open("xgboost-model", "rb"))

    test_path = '/opt/ml/processing/test/test.csv'
    df = pd.read_csv(test_path, header=None)
    y_test = df.iloc[:, 0].to_numpy()
    df.drop(df.columns[0], axis=1, inplace=True)
    X_test = xgboost.DMatrix(df.values)
    predictions = model.predict(X_test)

    mse = mean_squared_error(y_test, predictions)
    std = np.std(y_test - predictions)
    report_dict = {
        "regression_metrics": {
            "mse": {
                "value": mse,
                "standard_deviation": std
            },
        }
    }

    output_dir = "/opt/ml/processing/evaluation"
    pathlib.Path(output_dir).mkdir(parents=True, exist_ok=True)
    evaluation_path = f"{output_dir}/evaluation.json"
    with open(evaluation_path, "w") as f:
        f.write(json.dumps(report_dict))
```

2. Create an instance of a ScriptProcessor that is used to create a ProcessingStep.

```python
from sagemaker.processing import ScriptProcessor
```
script_eval = ScriptProcessor(
    image_uri=image_uri,
    command=["python3"],
    instance_type="ml.m5.xlarge",
    instance_count=1,
    base_job_name="script-abalone-eval",
    role=role,
)

3. Create a ProcessingStep using the processor instance, the input and output channels, and the evaluation.py script. In particular, pass in the S3ModelArtifacts property from the step_train training step, as well as the S3Uri of the "test" output channel of the step_process processing step. This is very similar to a processor instance's run method in the SageMaker Python SDK.

```python
from sagemaker.workflow.properties import PropertyFile
evaluation_report = PropertyFile(
    name="EvaluationReport",
    output_name="evaluation",
    path="evaluation.json"
)
step_eval = ProcessingStep(
    name="AbaloneEval",
    processor=script_eval,
    inputs=[
        ProcessingInput(
            source=step_train.properties.ModelArtifacts.S3ModelArtifacts,
            destination="/opt/ml/processing/model"
        ),
        ProcessingInput(
            source=step_process.properties.ProcessingOutputConfig.Outputs["test"].S3Output.S3Uri,
            destination="/opt/ml/processing/test"
        )
    ],
    outputs=[
        ProcessingOutput(output_name="evaluation", source="/opt/ml/processing/evaluation"),
    ],
    code="abalone/evaluation.py",
    property_files=[evaluation_report],
)
```

Step 6: Define a CreateModelStep for Batch Transformation

**Important**

We recommend using Model Step (p. 2819) to create models as of v2.90.0 of the SageMaker Python SDK. CreateModelStep will continue to work in previous versions of the SageMaker Python SDK, but is no longer actively supported.

This section shows how to create a SageMaker model from the output of the training step. This model is used for batch transformation on a new dataset. This step is passed into the condition step and only executes if the condition step evaluates to true.

**To define a CreateModelStep for batch transformation**

from sagemaker.model import Model

model = Model(
    image_uri=image_uri,
    model_data=step_train.properties.ModelArtifacts.S3ModelArtifacts,
    sagemaker_session=sagemaker_session,
    role=role,
)

2. Define the model input for your SageMaker model.

from sagemaker.inputs import CreateModelInput

inputs = CreateModelInput(
    instance_type="ml.m5.large",
    accelerator_type="ml.eia1.medium",
)

3. Create your CreateModelStep using the CreateModelInput and SageMaker model instance you defined.

from sagemaker.workflow.steps import CreateModelStep

step_create_model = CreateModelStep(
    name="AbaloneCreateModel",
    model=model,
    inputs=inputs,
)

Step 7: Define a TransformStep to Perform Batch Transformation

This section shows how to create a TransformStep to perform batch transformation on a dataset after the model is trained. This step is passed into the condition step and only executes if the condition step evaluates to true.

To define a TransformStep to perform batch transformation

1. Create a transformer instance with the appropriate compute instance type, instance count, and desired output Amazon S3 bucket URI. Pass in the ModelName property from the step_create_model CreateModel step.

from sagemaker.transformer import Transformer

transformer = Transformer(
    model_name=step_create_model.properties.ModelName,
    instance_type="ml.m5.xlarge",
    instance_count=1,
    output_path=f"s3://{default_bucket}/AbaloneTransform"
)

2. Create a TransformStep using the transformer instance you defined and the batch_data pipeline parameter.

from sagemaker.inputs import TransformInput
Step 8: Define a RegisterModel Step to Create a Model Package

Important
We recommend using Model Step (p. 2819) to register models as of v2.90.0 of the SageMaker Python SDK. RegisterModel will continue to work in previous versions of the SageMaker Python SDK, but is no longer actively supported.

This section shows how to construct an instance of RegisterModel. The result of executing RegisterModel in a pipeline is a model package. A model package is a reusable model artifacts abstraction that packages all ingredients necessary for inference. It consists of an inference specification that defines the inference image to use along with an optional model weights location. A model package group is a collection of model packages. You can use a ModelPackageGroup for SageMaker Pipelines to add a new version and model package to the group for every pipeline execution. For more information about model registry, see Register and Deploy Models with Model Registry (p. 2989).

This step is passed into the condition step and only executes if the condition step evaluates to true.

To define a RegisterModel step to create a model package

- Construct a RegisterModel step using the estimator instance you used for the training step. Pass in the S3ModelArtifacts property from the step_train training step and specify a ModelPackageGroup. SageMaker Pipelines creates this ModelPackageGroup for you.
Step 9: Define a Condition Step to Verify Model Accuracy

A `ConditionStep` allows SageMaker Pipelines to support conditional execution in your pipeline DAG based on the condition of step properties. In this case, you only want to register a model package if the accuracy of that model, as determined by the model evaluation step, exceeds the required value. If the accuracy exceeds the required value, the pipeline also creates a SageMaker Model and runs batch transformation on a dataset. This section shows how to define the `Condition` step.

**To define a condition step to verify model accuracy**

1. Define a `ConditionLessThanOrEqualTo` condition using the accuracy value found in the output of the model evaluation processing step, `step_eval`. Get this output using the property file you indexed in the processing step and the respective JSONPath of the mean squared error value, "mse".

   ```python
   from sagemaker.workflow.conditions import ConditionLessThanOrEqualTo
   from sagemaker.workflow.condition_step import ConditionStep
   from sagemaker.workflow.functions import JsonGet

   cond_lte = ConditionLessThanOrEqualTo(
       left=JsonGet(
           step_name=step_eval.name,
           property_file=evaluation_report,
           json_path="regression_metrics.mse.value"),
       right=6.0)
   )
   ``

2. Construct a `ConditionStep`. Pass the `ConditionEquals` condition in, then set the model package registration and batch transformation steps as the next steps if the condition passes.

   ```python
   step_cond = ConditionStep(
       name="AbaloneMSECond",
       conditions=[cond_lte],
       if_steps=[step_register, step_create_model, step_transform],
       else_steps=[],
   )
   ```

Step 10: Create a pipeline

Now that you've created all of the steps, combine them into a pipeline.

**To create a pipeline**

1. Define the following for your pipeline: name, parameters, and steps. Names must be unique within an (account, region) pair.

   **Note**
   A step can only appear once in either the pipeline's step list or the if/else step lists of the condition step. It cannot appear in both.

   ```python
   from sagemaker.workflow.pipeline import Pipeline

   pipeline_name = f"AbalonePipeline"
   pipeline = Pipeline(
       name=pipeline_name,
       parameters=[
           processing_instance_count,
   ```
model_approval_status,
    input_data,
    batch_data,
],
    steps=[step_process, step_train, step_eval, step_cond],
)

2. (Optional) Examine the JSON pipeline definition to ensure that it's well-formed.

   ```python
   import json
   json.loads(pipeline.definition())
   ```

   This pipeline definition is ready to submit to SageMaker. In the next tutorial, you submit this pipeline to SageMaker and start an execution.

   **Next step:** Run a pipeline (p. 2873)

**Run a pipeline**

After you've created a pipeline definition using the SageMaker Python SDK, you can submit it to SageMaker to start your execution. The following tutorial shows how to submit a pipeline, start an execution, examine the results of that execution, and delete your pipeline.

**Topics**

- Prerequisites (p. 2873)
- Step 1: Start the Pipeline (p. 2873)
- Step 2: Examine a Pipeline Execution (p. 2874)
- Step 3: Override Default Parameters for a Pipeline Execution (p. 2875)
- Step 4: Stop and Delete a Pipeline Execution (p. 2876)

**Prerequisites**

This tutorial requires the following:

- A SageMaker notebook instance.
- A SageMaker Pipelines pipeline definition. This tutorial assumes you're using the pipeline definition created by completing the Define a Pipeline (p. 2860) tutorial.

**Step 1: Start the Pipeline**

First, you need to start the pipeline.

**To start the pipeline**

1. Examine the JSON pipeline definition to ensure that it's well-formed.

   ```python
   import json
   json.loads(pipeline.definition())
   ```

2. Submit the pipeline definition to the SageMaker Pipelines service to create a pipeline if it doesn't exist, or update the pipeline if it does. The role passed in is used by SageMaker Pipelines to create all of the jobs defined in the steps.
3. Start a pipeline execution.

```python
execution = pipeline.start()
```

### Step 2: Examine a Pipeline Execution

Next, you need to examine the pipeline execution.

**To examine a pipeline execution**

1. Describe the pipeline execution status to ensure that it has been created and started successfully.

```python
execution.describe()
```

2. Wait for the execution to finish.

```python
execution.wait()
```

3. List the execution steps and their status.

```python
execution.list_steps()
```

Your output should look like the following:

```json
 {'StepName': 'AbaloneMSECond', 'StartTime': datetime.datetime(2020, 11, 21, 2, 41, 25, 558000, tzinfo=tzlocal()), 'EndTime': datetime.datetime(2020, 11, 21, 2, 41, 26, 329000, tzinfo=tzlocal()), 'StepStatus': 'Succeeded', 'CacheHitResult': {'SourcePipelineExecutionArn': ''}, 'Metadata': {'Condition': {'Outcome': 'True'}}},
 {'StepName': 'AbaloneEval', 'StartTime': datetime.datetime(2020, 11, 21, 2, 37, 34, 767000, tzinfo=tzlocal()), 'EndTime': datetime.datetime(2020, 11, 21, 2, 41, 18, 80000, tzinfo=tzlocal()), 'StepStatus': 'Succeeded'}]```
4. After your pipeline execution is complete, download the resulting `evaluation.json` file from Amazon S3 to examine the report.

```python
evaluation_json = sagemaker.s3.S3Downloader.read_file("{}/evaluation.json".format(step_eval.arguments["ProcessingOutputConfig"]['Outputs'][0]['S3Output']['S3Uri']))
json.loads(evaluation_json)
```

Step 3: Override Default Parameters for a Pipeline Execution

You can run additional executions of the pipeline by specifying different pipeline parameters to override the defaults.

To override default parameters

1. Create the pipeline execution. This starts another pipeline execution with the model approval status override set to "Approved". This means that the model package version generated by the RegisterModel step is automatically ready for deployment through CI/CD pipelines, such as with SageMaker Projects. For more information, see Automate MLOps with SageMaker Projects (p. 3017).

```python
execution = pipeline.start(
    parameters=dict(
        ModelApprovalStatus="Approved",
    )
)
```

2. Wait for the execution to finish.

```python
execution.wait()
```

3. List the execution steps and their status.

```python
execution.list_steps()
```

4. After your pipeline execution is complete, download the resulting `evaluation.json` file from Amazon S3 to examine the report.

```python
evaluation_json = sagemaker.s3.S3Downloader.read_file("{}/evaluation.json".format(step_eval.arguments["ProcessingOutputConfig"]['Outputs'][0]['S3Output']['S3Uri']))
```
Step 4: Stop and Delete a Pipeline Execution

When you're finished with your pipeline, you can stop any ongoing executions and delete the pipeline.

To stop and delete a pipeline execution

1. Stop the pipeline execution.
   ```python
   execution.stop()
   ```

2. Delete the pipeline.
   ```python
   pipeline.delete()
   ```

View, Track, and Execute SageMaker Pipelines in SageMaker Studio

To view, track, and execute Amazon SageMaker Pipelines in Amazon SageMaker Studio, you must sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 10).

Topics

- View a Pipeline (p. 2876)
- View a Pipeline Execution (p. 2878)
- View Experiment Entities Created by SageMaker Pipelines (p. 2880)
- Execute a Pipeline (p. 2881)
- Track the Lineage of a SageMaker ML Pipeline (p. 2882)

View a Pipeline

This procedure shows you how to directly find a pipeline and view its details page. You can also find pipelines that are part of a project listed in the project's details page. For information on finding a pipeline that is part of a project, see Automate MLOps with SageMaker Projects (p. 3017).

To view a list of pipelines

1. In the Studio sidebar, choose the Home icon (🏠).
2. Select Pipelines from the menu.
3. Use search to narrow the list of pipelines by name.
4. Select a pipeline name to view details about the pipeline. The pipeline details tab opens and displays a list of pipeline executions. You can start an execution or choose one of the other tabs for more information about the pipeline. Use the Property Inspector icon (🔧) to choose which columns to display.
5. From the pipeline details page, choose one of the following tabs to view details about the pipeline:
   - Executions – Details about the executions. You can create an execution from this tab or the Graph tab.
   - Graph – The DAG for the pipeline.
• **Parameters** – Includes the model approval status.

![Pipeline Parameters](image1.png)

• **Settings** – The metadata associated with the pipeline. You can download the pipeline definition file and edit the pipeline name and description from this tab.

![Pipeline Settings](image2.png)
View a Pipeline Execution

This procedure shows you how to view a pipeline execution. For information on how to view a list of pipeline executions, and how to use SageMaker search to narrow the executions in the list, see View a Pipeline (p. 2876).

To view details of a pipeline execution

1. In the execution list, open an execution to view details about the execution. The execution details tab opens and displays a graph of the steps in the pipeline. You can choose one of the other tabs to view information about the pipeline execution, which is similar to that shown when viewing the pipeline details.

2. Use search to find a step in the graph. Type characters that match a step name. You can drag the graph around or use the resizing icons on the lower-right side of the graph. The inset on the lower-right side of the graph displays where you are in the graph.

3. Choose one of the steps in the graph to see details about the step. In the preceding screenshot, a training step is chosen and displays the following tabs:

   - **Input** – The training inputs. If an input source is from Amazon Simple Storage Service (Amazon S3), choose the link to view the file in the Amazon S3 console.
   - **Output** – The training outputs, such as metrics, charts, files, and evaluation outcome. The graphs were produced using the Tracker APIs.
- **Logs** – The Amazon CloudWatch logs produced by the step.

![View logs in CloudWatch console](image)

- **Info** – The parameters and metadata associated with the step.

![Info](image)

**View Experiment Entities Created by SageMaker Pipelines**

When you create a pipeline and specify `pipeline_experiment_config`, SageMaker Pipelines creates the following SageMaker Experiments entities by default if they don’t exist:

- An experiment for the pipeline
- A run group for every execution of the pipeline
- A run for each SageMaker job created in a pipeline step
For information on how experiments are integrated with pipelines, see Amazon SageMaker Experiments Integration (p. 2855). For more information on SageMaker Experiments, see Manage Machine Learning with Amazon SageMaker Experiments (p. 1838).

You can get to the list of runs associated with a pipeline from either the pipeline executions list or the experiments list.

**To view the runs list from the pipeline executions list**

1. To view the pipeline executions list, follow the first four steps in View a Pipeline (p. 2876).
2. On the top right of the screen, choose the Filter icon (🔍).
3. Select Experiment. If experiment integration wasn't deactivated when the pipeline was created, the experiment name is displayed in the executions list.

   **Note**
   Experiments integration was introduced in v2.41.0 of the Amazon SageMaker Python SDK. Pipelines created with an earlier version of the SDK aren't integrated with experiments by default.

4. Select the experiment of your choice to view run groups and runs related to that experiment.

**To view the runs list from the experiments list**

1. In the left sidebar of Studio, choose the Home icon (🏠).
2. Select Experiments from the menu.
3. Use search bar or Filter icon (🔍) to filter the list to experiments created by a pipeline.
4. Open an experiment name and view a list of runs created by the pipeline.

**Execute a Pipeline**

This procedure shows you how to execute a pipeline. For information on how to view a list of pipeline executions, see View a Pipeline (p. 2876).

**To start a pipeline execution**

1. From the Executions or Graph tab in the execution list, choose Create execution.
2. Enter or update the following required information:
   - **Name** – Must be unique to your account in the AWS Region.
   - **ProcessingInstanceCount** – The number of instances to use for processing.
   - **ModelApprovalStatus** – For your convenience.
   - **InputDataUrl** – The S3 URI of the input data.
3. Choose Start.

   - To see details of the execution or to stop the execution, choose View details on the status banner.
   - To stop the execution, choose Stop on the status banner.
   - To resume the execution from where it was stopped, choose Resume on the status banner.
Note
If your pipeline fails, the status banner will show Failed status. After troubleshooting the failed step, choose Retry on the status banner to resume running the pipeline from that step.

For a list of registered models, see Automate MLOps with SageMaker Projects (p. 3017).

Track the Lineage of a SageMaker ML Pipeline

In this tutorial, you use Amazon SageMaker Studio to track the lineage of an Amazon SageMaker ML Pipeline.

The pipeline was created by the Orchestrating Jobs with Amazon SageMaker Model Building Pipelines notebook in the Amazon SageMaker example GitHub repository. For detailed information on how the pipeline was created, see Define a Pipeline (p. 2860).

Lineage tracking in Studio is centered around a directed acyclic graph (DAG). The DAG represents the steps in a pipeline. From the DAG you can track the lineage from any step to any other step. The following diagram displays the steps in the pipeline. These steps appear as a DAG in Studio.

Prerequisites
- Access to Amazon SageMaker Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 10).
- Familiarity with the SageMaker Studio user interface. For more information, see Amazon SageMaker Studio UI Overview (p. 205).
- (Recommended) A completed run of the example notebook.

To track the lineage of a pipeline

1. Sign in to SageMaker Studio.
2. In the left sidebar of Studio, choose the Home icon ( ).
3. In the menu, select Pipelines.
4. Use the Search box to filter the pipelines list.
5. Double-click the AbalonePipeline pipeline to view the execution list and other details about the pipeline. Choose the Property Inspector icon ( ) in the right sidebar to open the TABLE PROPERTIES pane, where you can choose which properties to view.
6. Choose the Settings tab and then choose Download pipeline definition file. You can view the file to see how the pipeline graph was defined.
7. On the Execution tab, double-click the first row in the execution list to view its execution graph and other details about the execution. Note that the graph matches the diagram displayed at the beginning of the tutorial.

You can drag the graph around (select an area not on the graph itself) or use the resizing icons on the lower-right side of the graph. The inset on the lower-right side of the graph displays your location in the graph.
8. On the **Graph** tab, choose the **AbaloneProcess** step to view details about the step.

9. Find the Amazon S3 paths to the training, validation, and test datasets in the **Output** tab, under **Files**.

   **Note**
   To get the full paths, right-click the path and then choose **Copy cell contents**.

   ```
   s3://sagemaker-eu-west-1-acct-id/sklearn-abalone-process-2020-12-05-17-28-28-509/output/train
   ```
10. Choose the AbaloneTrain step.

![AbaloneTrain](image)

11. Find the Amazon S3 path to the model artifact in the **Output** tab, under **Files**:

```
s3://sagemaker-eu-west-1-acct-id/AbaloneTrain/pipelines-6locnsqz4bfu-AbaloneTrain-NtfEpI0Ahu/output/model.tar.gz
```

12. Choose the AbaloneRegisterModel step.

![AbaloneRegisterModel](image)

13. Find the ARN of the model package in the **Output** tab, under **Files**:

```
arn:aws:sagemaker:eu-west-1:acct-id:model-package/abalonemodelpackagename/2
```

## Kubernetes Orchestration

You can orchestrate your SageMaker training and inference jobs with SageMaker Operators for Kubernetes and SageMaker Components for Kubeflow Pipelines. SageMaker Operators for Kubernetes make it easier for developers and data scientists using Kubernetes to train, tune, and deploy machine learning (ML) models in SageMaker. SageMaker Components for Kubeflow Pipelines allow you to move your data processing and training jobs from the Kubernetes cluster to SageMaker's machine learning-optimized managed service.

### Contents

- [SageMaker Operators for Kubernetes](#) (p. 2885)
- [SageMaker Components for Kubeflow Pipelines](#) (p. 2931)
SageMaker Operators for Kubernetes

SageMaker Operators for Kubernetes make it easier for developers and data scientists using Kubernetes to train, tune, and deploy machine learning (ML) models in SageMaker. You can install these SageMaker Operators on your Kubernetes cluster in Amazon Elastic Kubernetes Service (Amazon EKS) to create SageMaker jobs natively using the Kubernetes API and command-line Kubernetes tools such as kubectl. This guide shows how to set up and use the operators to run model training, hyperparameter tuning, or inference (real-time and batch) on SageMaker from a Kubernetes cluster. The procedures and guidelines in this chapter assume that you are familiar with Kubernetes and its basic commands.

Important
We are stopping the development and technical support of the original version of SageMaker Operators for Kubernetes. If you are currently using version v1.2.2 or below of SageMaker Operators for Kubernetes, we recommend migrating your resources to theACK service controller for Amazon SageMaker. The ACK service controller is a new generation of SageMaker Operators for Kubernetes based on AWS Controllers for Kubernetes (ACK).

For information on the migration steps, see Migrate resources to the latest Operators (p. 2926).
For answers to frequently asked questions on the end of support of the original version of SageMaker Operators for Kubernetes, see Announcing the End of Support of the Original Version of SageMaker Operators for Kubernetes (p. 2929).

Note
There is no additional charge to use these operators. You do incur charges for any SageMaker resources that you use through these operators.

What is an operator?

A Kubernetes operator is an application controller managing applications on behalf of a Kubernetes user. Controllers of the control plane encompass various control loops listening to a central state manager (ETCD) to regulate the state of the application they control. Examples of such applications include theCloud-controller-manager and kube-controller-manager. Operators typically provide a higher-level abstraction than raw Kubernetes API, making it easier for users to deploy and manage applications. To add new capabilities to Kubernetes, developers can extend the Kubernetes API by creating a custom resource that contains their application-specific or domain-specific logic and components. Operators in Kubernetes allow users to natively invoke these custom resources and automate associated workflows.

How does AWS Controllers for Kubernetes (ACK) work?

The SageMaker Operators for Kubernetes allow you to manage jobs in SageMaker from your Kubernetes cluster. The latest version of SageMaker Operators for Kubernetes is based on AWS Controllers for Kubernetes (ACK). ACK includes a common controller runtime, a code generator, and a set of AWS service-specific controllers, one of which is the SageMaker controller.

The following diagram illustrates how ACK works.
In this diagram, a Kubernetes user wants to run model training on SageMaker from within the Kubernetes cluster using the Kubernetes API. The user issues a call to `kubectl apply`, passing in a file that describes a Kubernetes custom resource describing the SageMaker training job. `kubectl apply` passes this file, called a manifest, to the Kubernetes API server running in the Kubernetes controller node (Step 1 in the workflow diagram). The Kubernetes API server receives the manifest with the SageMaker training job specification and determines whether the user has permissions to create a custom resource of kind `sageMaker.services.k8s.aws/TrainingJob`, and whether the custom resource is properly formatted (Step 2). If the user is authorized and the custom resource is valid, the Kubernetes API server writes (Step 3) the custom resource to its etcd data store and then responds back (Step 4) to the user that the custom resource has been created. The SageMaker controller, which is running on a Kubernetes worker node within the context of a normal Kubernetes Pod, is notified (Step 5) that a new custom resource of kind `sageMaker.services.k8s.aws/TrainingJob` has been created. The SageMaker controller then communicates (Step 6) with the SageMaker API, calling the SageMaker `CreateTrainingJob` API to create the training job in AWS. After communicating with the SageMaker API, the SageMaker controller calls the Kubernetes API server to update (Step 7) the custom resource's status with information it received from SageMaker. The SageMaker controller therefore provides the same information to the developers that they would have received using the AWS SDK.

Permissions overview

The operators access SageMaker resources on your behalf. The IAM role that the operator assumes to interact with AWS resources differs from the credentials you use to access the Kubernetes cluster. The role also differs from the role that AWS assumes when running your machine learning jobs.

The following image explains the various authentication layers.
Amazon SageMaker Developer Guide
Kubernetes Orchestration

Latest SageMaker Operators for Kubernetes

This section is based on the latest version of SageMaker Operators for Kubernetes using AWS Controllers for Kubernetes (ACK).

Important
If you are currently using version v1.2.2 or below of SageMaker Operators for Kubernetes, we recommend migrating your resources to the ACK service controller for Amazon SageMaker. The ACK service controller is a new generation of SageMaker Operators for Kubernetes based on AWS Controllers for Kubernetes (ACK). For information on the migration steps, see Migrate resources to the latest Operators (p. 2926). For answers to frequently asked questions on the end of support of the original version of SageMaker Operators for Kubernetes, see Announcing the End of Support of the Original Version of SageMaker Operators for Kubernetes (p. 2929).

The latest version of SageMaker Operators for Kubernetes is based on AWS Controllers for Kubernetes (ACK), a framework for building Kubernetes custom controllers where each controller communicates with an AWS service API. These controllers allow Kubernetes users to provision AWS resources like databases or message queues using the Kubernetes API.
Use the following steps to install and use ACK to train, tune, and deploy machine learning models with Amazon SageMaker.

Contents
- Install SageMaker Operators for Kubernetes (p. 2888)
- Use SageMaker Operators for Kubernetes (p. 2888)
- Reference (p. 2888)

Install SageMaker Operators for Kubernetes

To set up the latest available version of SageMaker Operators for Kubernetes, see the Setup section in Machine Learning with the ACK SageMaker Controller.

Use SageMaker Operators for Kubernetes

For a tutorial on how to train a machine learning model with the ACK service controller for Amazon SageMaker using Amazon EKS, see Machine Learning with the ACK SageMaker Controller.

For an autoscaling example, see Scale SageMaker Workloads with Application Auto Scaling

Reference

See also the ACK service controller for Amazon SageMaker GitHub repository or read AWS Controllers for Kubernetes Documentation.

Old SageMaker Operators for Kubernetes

This section is based on the original version of SageMaker Operators for Kubernetes.

Important
We are stopping the development and technical support of the original version of SageMaker Operators for Kubernetes.

If you are currently using version v1.2.2 or below of SageMaker Operators for Kubernetes, we recommend migrating your resources to the ACK service controller for Amazon SageMaker. The ACK service controller is a new generation of SageMaker Operators for Kubernetes based on AWS Controllers for Kubernetes (ACK).

For information on the migration steps, see Migrate resources to the latest Operators (p. 2926).

For answers to frequently asked questions on the end of support of the original version of SageMaker Operators for Kubernetes, see Announcing the End of Support of the Original Version of SageMaker Operators for Kubernetes (p. 2929)

Contents
- Install SageMaker Operators for Kubernetes (p. 2888)
- Use Amazon SageMaker Jobs (p. 2901)
- Migrate resources to the latest Operators (p. 2926)
- Announcing the End of Support of the Original Version of SageMaker Operators for Kubernetes (p. 2929)

Install SageMaker Operators for Kubernetes

Use the following steps to install and use SageMaker Operators for Kubernetes to train, tune, and deploy machine learning models with Amazon SageMaker.

Contents
- IAM role-based setup and operator deployment (p. 2889)
IAM role-based setup and operator deployment

The following sections describe the steps to set up and deploy the original version of the operator.

Warning
Reminder: The following steps do not install the latest version of SageMaker Operators for Kubernetes. To install the new ACK-based SageMaker Operators for Kubernetes, see Latest SageMaker Operators for Kubernetes (p. 2887).

Prerequisites

This guide assumes that you have completed the following prerequisites:

- Install the following tools on the client machine used to access your Kubernetes cluster:
  - kubectl Version 1.13 or later. Use a kubectl version that is within one minor version of your Amazon EKS cluster control plane. For example, a 1.13 kubectl client works with Kubernetes 1.13 and 1.14 clusters. OpenID Connect (OIDC) is not supported in versions earlier than 1.13.
  - eksctl Version 0.7.0 or later
  - AWS CLI Version 1.16.232 or later
  - (optional) Helm Version 3.0 or later
  - aws-iam-authenticator
  - Have IAM permissions to create roles and attach policies to roles.
  - Created a Kubernetes cluster on which to run the operators. It should either be Kubernetes version 1.13 or 1.14. For automated cluster creation using eksctl, see Getting Started with eksctl. It takes 20–30 minutes to provision a cluster.

Cluster-scoped deployment

Before you can deploy your operator using an IAM role, associate an OpenID Connect (OIDC) Identity Provider (IdP) with your role to authenticate with the IAM service.

Create an OIDC provider for your cluster

The following instructions show how to create and associate an OIDC provider with your Amazon EKS cluster.

1. Set the local CLUSTER_NAME and AWS_REGION environment variables as follows:

   ```bash
   # Set the Region and cluster
   export CLUSTER_NAME="<your cluster name>"
   export AWS_REGION="<your region>"
   ```

2. Use the following command to associate the OIDC provider with your cluster. For more information, see Enabling IAM Roles for Service Accounts on your Cluster.

   ```bash
   eksctl utils associate-iam-oidc-provider --cluster ${CLUSTER_NAME} \
   --region ${AWS_REGION} --approve
   ```

   Your output should look like the following:

   ```bash
   [.] eksctl version 0.10.1
   ```
Now that the cluster has an OIDC identity provider, you can create a role and give a Kubernetes ServiceAccount permission to assume the role.

Get the OIDC ID

To set up the ServiceAccount, obtain the OIDC issuer URL using the following command:

```
aws eks describe-cluster --name ${CLUSTER_NAME} --region ${AWS_REGION} --query cluster.identity.oidc.issuer --output text
```

The command returns a URL like the following:

```
https://oidc.eks.${AWS_REGION}.amazonaws.com/id/D48675832CA65BD10A532F5970IDCID
```

In this URL, the value D48675832CA65BD10A532F5970IDCID is the OIDC ID. The OIDC ID for your cluster is different. You need this OIDC ID value to create a role.

If your output is None, it means that your client version is old. To work around this, run the following command:

```
aws eks describe-cluster --region ${AWS_REGION} --query cluster --name ${CLUSTER_NAME} --output text | grep OIDC
```

The OIDC URL is returned as follows:

```
OIDC https://oidc.eks.us-east-1.amazonaws.com/id/D48675832CA65BD10A532F5970IDCID
```

Create an IAM role

1. Create a file named trust.json and insert the following trust relationship code block into it. Be sure to replace all <OIDC ID>, <AWS account number>, and <EKS Cluster region> placeholders with values corresponding to your cluster.

   ```
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Principal": {
           "Federated": "arn:aws:iam::<AWS account number>:oidc-provider/oidc.eks.<EKS Cluster region>.amazonaws.com/id/<OIDC ID>"
         },
         "Action": "sts:AssumeRoleWithWebIdentity",
         "Condition": {}
       }
     }
   }
   ```
2. Run the following command to create a role with the trust relationship defined in `trust.json`. This role allows the Amazon EKS cluster to get and refresh credentials from IAM.

```bash
aws iam create-role --region ${AWS_REGION} --role-name <role name> --assume-role-policy-document file://trust.json --output=text
```

Your output should look like the following:

```
ASSUMEROLEPOLICYDOCUMENT        2012-10-17
STATEMENT       sts:AssumeRoleWithWebIdentity   Allow
PRINCIPAL       arn:aws:iam::123456789012:oidc-provider/oidc.eks.us-east-1.amazonaws.com/id/
```

Take note of ROLE ARN; you pass this value to your operator.

**Attach the AmazonSageMakerFullAccess policy to the role**

To give the role access to SageMaker, attach the `AmazonSageMakerFullAccess` policy. If you want to limit permissions to the operator, you can create your own custom policy and attach it.

To attach `AmazonSageMakerFullAccess`, run the following command:

```bash
aws iam attach-role-policy --role-name <role name> --policy-arn arn:aws:iam::aws:policy/AmazonSageMakerFullAccess
```

The Kubernetes ServiceAccount `sagemaker-k8s-operator-default` should have `AmazonSageMakerFullAccess` permissions. Confirm this when you install the operator.

**Deploy the operator**

When deploying your operator, you can use either a YAML file or Helm charts.

**Deploy the operator using YAML**

This is the simplest way to deploy your operators. The process is as follows:

1. Download the installer script using the following command:

```bash
```

2. Edit the `installer.yaml` file to replace `eks.amazonaws.com/role-arn`. Replace the ARN here with the Amazon Resource Name (ARN) for the OIDC-based role you've created.

3. Use the following command to deploy the cluster:

```bash
kubectl apply -f installer.yaml
```

**Deploy the operator using Helm Charts**

Use the provided Helm Chart to install the operator.
1. Clone the Helm installer directory using the following command:

   ```
git clone https://github.com/aws/amazon-sagemaker-operator-for-k8s.git
   ```

2. Navigate to the `amazon-sagemaker-operator-for-k8s/hack/charts/installer` folder. Edit the `rolebased/values.yaml` file, which includes high-level parameters for the chart. Replace the role ARN here with the Amazon Resource Name (ARN) for the OIDC-based role you've created.

3. Install the Helm Chart using the following command:

   ```
kubectl create namespace sagemaker-k8s-operator-system
helm install --namespace sagemaker-k8s-operator-system sagemaker-operator rolebased/
   ```

   If you decide to install the operator into a namespace other than the one specified, you need to adjust the namespace defined in the IAM role `trust.json` file to match.

4. After a moment, the chart is installed with a randomly generated name. Verify that the installation succeeded by running the following command:

   ```
helm ls
   ```

   Your output should look like the following:

<table>
<thead>
<tr>
<th>NAME</th>
<th>NAMESPACE</th>
<th>REVISION</th>
<th>UPDATED</th>
<th>STATUS</th>
<th>CHART</th>
<th>APP VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>sagemaker-operator</td>
<td>sagemaker-k8s-operator-system</td>
<td>1</td>
<td>2019-11-20T23:14:59</td>
<td>deployed</td>
<td>sagemaker-k8s-operator-0.1.0</td>
<td></td>
</tr>
</tbody>
</table>

**Verify the operator deployment**

1. You should be able to see the SageMaker Custom Resource Definitions (CRDs) for each operator deployed to your cluster by running the following command:

   ```
kubectl get crd | grep sagemaker
   ```

   Your output should look like the following:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>REVISION</th>
<th>UPDATED</th>
</tr>
</thead>
<tbody>
<tr>
<td>batchtransformjobs.sagemaker</td>
<td>active</td>
<td>2019-11-20T17:12</td>
<td>2019-11-20T17:12:34</td>
</tr>
<tr>
<td>endpointconfigs.sagemaker</td>
<td>active</td>
<td>2019-11-20T17:12</td>
<td>2019-11-20T17:12:34</td>
</tr>
<tr>
<td>hostingdeployments.sagemaker</td>
<td>active</td>
<td>2019-11-20T17:12</td>
<td>2019-11-20T17:12:34</td>
</tr>
<tr>
<td>hyperparametertuningjobs</td>
<td>active</td>
<td>2019-11-20T17:12</td>
<td>2019-11-20T17:12:34</td>
</tr>
<tr>
<td>models.sagemaker</td>
<td>active</td>
<td>2019-11-20T17:12</td>
<td>2019-11-20T17:12:34</td>
</tr>
<tr>
<td>trainingjobs.sagemaker</td>
<td>active</td>
<td>2019-11-20T17:12</td>
<td>2019-11-20T17:12:34</td>
</tr>
</tbody>
</table>

2. Ensure that the operator pod is running successfully. Use the following command to list all pods:

   ```
kubectl -n sagemaker-k8s-operator-system get pods
   ```

   You should see a pod named `sagemaker-k8s-operator-controller-manager-*****` in the namespace `sagemaker-k8s-operator-system` as follows:

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>sagemaker-k8s-operator-controller-manager-12345678-r8abc</td>
<td>2/2</td>
<td>Running</td>
<td>0</td>
</tr>
<tr>
<td>sagemaker-k8s-operator-controller-manager-12345678-r8abc-23s</td>
<td>2/2</td>
<td>Running</td>
<td>0</td>
</tr>
<tr>
<td>sagemaker-k8s-operator-controller-manager-12345678-r8abc-4567</td>
<td>2/2</td>
<td>Running</td>
<td>0</td>
</tr>
</tbody>
</table>
Namespace-scoped deployment

You have the option to install your operator within the scope of an individual Kubernetes namespace. In this mode, the controller only monitors and reconciles resources with SageMaker if the resources are created within that namespace. This allows for finer-grained control over which controller is managing which resources. This is useful for deploying to multiple AWS accounts or controlling which users have access to particular jobs.

This guide outlines how to install an operator into a particular, predefined namespace. To deploy a controller into a second namespace, follow the guide from beginning to end and change out the namespace in each step.

Create an OIDC provider for your Amazon EKS cluster

The following instructions show how to create and associate an OIDC provider with your Amazon EKS cluster.

1. Set the local CLUSTER_NAME and AWS_REGION environment variables as follows:

   ```
   # Set the Region and cluster
   export CLUSTER_NAME="<your cluster name>"
   export AWS_REGION="<your region>"
   ```

2. Use the following command to associate the OIDC provider with your cluster. For more information, see Enabling IAM Roles for Service Accounts on your Cluster.

   ```
   eksctl utils associate-iam-oidc-provider --cluster ${CLUSTER_NAME} \
   --region ${AWS_REGION} --approve
   ```

   Your output should look like the following:

   ```
   [ ] eksctl version 0.10.1
   [ ] using region us-east-1
   [ ] IAM OpenID Connect provider is associated with cluster "my-cluster" in "us-east-1"
   ```

Now that the cluster has an OIDC identity provider, create a role and give a Kubernetes ServiceAccount permission to assume the role.

Get your OIDC ID

To set up the ServiceAccount, first obtain the OpenID Connect issuer URL using the following command:

```
aws eks describe-cluster --name ${CLUSTER_NAME} --region ${AWS_REGION} \
--query cluster.identity.oidc.issuer --output text
```  

The command returns a URL like the following:

```
https://oidc.eks.${AWS_REGION}.amazonaws.com/id/D48675832CA65BD10A532F5970IDCID
```  

In this URL, the value D48675832CA65BD10A532F5970IDCID is the OIDC ID. The OIDC ID for your cluster is different. You need this OIDC ID value to create a role.

If your output is None, it means that your client version is old. To work around this, run the following command:
aws eks describe-cluster --region ${AWS_REGION} --query cluster --name ${CLUSTER_NAME} --output text | grep OIDC

The OIDC URL is returned as follows:

OIDC https://oidc.eks.us-east-1.amazonaws.com/id/D48675832CA65BD10A532F5970OIDCID

Create your IAM role

1. Create a file named `trust.json` and insert the following trust relationship code block into it. Be sure to replace all `<OIDC ID>`, `<AWS account number>`, `<EKS Cluster region>`, and `<Namespace>` placeholders with values corresponding to your cluster. For the purposes of this guide, `my-namespace` is used for the `<Namespace>` value.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Federated": "arn:aws:iam::<AWS account number>:oidc-provider/oidc.eks.<EKS Cluster region>.amazonaws.com/id/<OIDC ID>"
            },
            "Action": "sts:AssumeRoleWithWebIdentity",
            "Condition": {
                "StringEquals": {
                    "oidc.eks.<EKS Cluster region>.amazonaws.com/id/<OIDC ID>:aud": "sts.amazonaws.com",
                    "oidc.eks.<EKS Cluster region>.amazonaws.com/id/<OIDC ID>:sub": "system:serviceaccount:<Namespace>:sagemaker-k8s-operator-default"
                }
            }
        }
    ]
}
```

2. Run the following command to create a role with the trust relationship defined in `trust.json`. This role allows the Amazon EKS cluster to get and refresh credentials from IAM.

```bash
aws iam create-role --region ${AWS_REGION} --role-name <role name> --assume-role-policy-document file://trust.json --output=text
```

Your output should look like the following:

```
ABCFDESFODN7EXAMPLE    my-role 2012-10-17
ASSUMEROLEPOLICYDOCUMENT    2012-10-17
STATEMENT    sts:AssumeRoleWithWebIdentity    Allow
STRINGEQUALS    sts.amazonaws.com    system:serviceaccount:<Namespace>:sagemaker-k8s-operator-default
PRINCIPAL    arn:aws:iam::123456789012:oidc-provider/oidc.eks.us-east-1.amazonaws.com/id/
```

Take note of ROLE ARN. You pass this value to your operator.
Attach the AmazonSageMakerFullAccess policy to your role

To give the role access to SageMaker, attach the AmazonSageMakerFullAccess policy. If you want to limit permissions to the operator, you can create your own custom policy and attach it.

To attach AmazonSageMakerFullAccess, run the following command:

```
aws iam attach-role-policy --role-name <role name> --policy-arn arn:aws:iam::aws:policy/AmazonSageMakerFullAccess
```

The Kubernetes ServiceAccount sagemaker-k8s-operator-default should have AmazonSageMakerFullAccess permissions. Confirm this when you install the operator.

Deploy the operator to your namespace

When deploying your operator, you can use either a YAML file or Helm charts.

Deploy the operator to your namespace using YAML

There are two parts to deploying an operator within the scope of a namespace. The first is the set of CRDs that are installed at a cluster level. These resource definitions only need to be installed once per Kubernetes cluster. The second part is the operator permissions and deployment itself.

If you have not already installed the CRDs into the cluster, apply the CRD installer YAML using the following command:

```
kubectl apply -f https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/master/release/rolebased/namespaced/crd.yaml
```

To install the operator onto the cluster:

1. Download the operator installer YAML using the following command:

   ```
   ```

2. Update the installer YAML to place the resources into your specified namespace using the following command:

   ```
   sed -i -e 's/PLACEHOLDER-NAMESPACE/<YOUR NAMESPACE>/g' operator.yaml
   ```

3. Edit the operator.yaml file to place resources into your eks.amazonaws.com/role-arn. Replace the ARN here with the Amazon Resource Name (ARN) for the OIDC-based role you've created.

4. Use the following command to deploy the cluster:

   ```
   kubectl apply -f operator.yaml
   ```

Deploy the operator to your namespace using Helm Charts

There are two parts needed to deploy an operator within the scope of a namespace. The first is the set of CRDs that are installed at a cluster level. These resource definitions only need to be installed once per Kubernetes cluster. The second part is the operator permissions and deployment itself. When using Helm Charts you have to first create the namespace using kubectl.

1. Clone the Helm installer directory using the following command:
2. Navigate to the `amazon-sagemaker-operator-for-k8s/hack/charts/installer/namespaced` folder. Edit the `rolebased/values.yaml` file, which includes high-level parameters for the chart. Replace the role ARN here with the Amazon Resource Name (ARN) for the OIDC-based role you've created.

3. Install the Helm Chart using the following command:

   ```bash
git clone https://github.com/aws/amazon-sagemaker-operator-for-k8s.git
```

4. Create the required namespace and install the operator using the following command:

   ```bash
globally install kubectl create namespace <namespace>
helm install --namespace <namespace> op operator_chart/
```

5. After a moment, the chart is installed with the name `sagemaker-operator`. Verify that the installation succeeded by running the following command:

   ```bash
helm ls
```

Your output should look like the following:

<table>
<thead>
<tr>
<th>NAME</th>
<th>NAMESPACE</th>
<th>CHART</th>
<th>REVISION</th>
<th>UPDATED</th>
</tr>
</thead>
<tbody>
<tr>
<td>sagemaker-operator</td>
<td>my-namespace</td>
<td>sagemaker-k8s-operator-0.1.0</td>
<td>1</td>
<td>2019-11-20 23:14:59.6777082 +0000 UTC deployed</td>
</tr>
</tbody>
</table>

**Verify the operator deployment to your namespace**

1. You should be able to see the SageMaker Custom Resource Definitions (CRDs) for each operator deployed to your cluster by running the following command:

   ```bash
globally install kubectl get crd | grep sagemaker
```

Your output should look like the following:

<table>
<thead>
<tr>
<th>CRD</th>
<th>Created</th>
</tr>
</thead>
<tbody>
<tr>
<td>batchtransformjobs.sagemaker.aws.amazon.com</td>
<td>2019-11-20T17:12:34Z</td>
</tr>
<tr>
<td>endpointconfigs.sagemaker.aws.amazon.com</td>
<td>2019-11-20T17:12:34Z</td>
</tr>
<tr>
<td>hostingdeployments.sagemaker.aws.amazon.com</td>
<td>2019-11-20T17:12:34Z</td>
</tr>
<tr>
<td>hyperparametertuningjobs.sagemaker.aws.amazon.com</td>
<td>2019-11-20T17:12:34Z</td>
</tr>
<tr>
<td>models.sagemaker.aws.amazon.com</td>
<td>2019-11-20T17:12:34Z</td>
</tr>
<tr>
<td>trainingjobs.sagemaker.aws.amazon.com</td>
<td>2019-11-20T17:12:34Z</td>
</tr>
</tbody>
</table>

2. Ensure that the operator pod is running successfully. Use the following command to list all pods:

   ```bash
globally install kubectl -n my-namespace get pods
```

You should see a pod named `sagemaker-k8s-operator-controller-manager-*****` in the namespace `my-namespace` as follows:

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>sagemaker-k8s-operator-controller-manager-*****</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Install the SageMaker logs kubectl plugin

As part of the SageMaker Operators for Kubernetes, you can use the smlogs plugin for kubectl. This allows SageMaker CloudWatch logs to be streamed with kubectl. kubectl must be installed onto your PATH. The following commands place the binary in the sagemaker-k8s-bin directory in your home directory, and add that directory to your PATH.

```
export os="linux"
wget https://amazon-sagemaker-operator-for-k8s-us-east-1.s3.amazonaws.com/kubectl-smlogs-plugin/v1/${os}.amd64.tar.gz
tar xvzf ${os}.amd64.tar.gz

# Move binaries to a directory in your homedir.
mkdir ~/sagemaker-k8s-bin
cp ./kubectl-smlogs.${os}.amd64/kubectl-smlogs ~/sagemaker-k8s-bin/.

# This line adds the binaries to your PATH in your .bashrc.
echo 'export PATH=$PATH:~/sagemaker-k8s-bin' >> ~/.bashrc

# Source your .bashrc to update environment variables:
source ~/.bashrc
```

Use the following command to verify that the kubectl plugin is installed correctly:

```
kubectl smlogs
```

If the kubectl plugin is installed correctly, your output should look like the following:

```
View SageMaker logs via Kubernetes

Usage:
  smlogs [command]

Aliases:
  smlogs, SMLogs, Smlogs

Available Commands:

  BatchTransformJob       View BatchTransformJob logs via Kubernetes
  TrainingJob             View TrainingJob logs via Kubernetes
  help                    Help about any command

Flags:
  -h, --help  help for smlogs

Use "smlogs [command] --help" for more information about a command.
```

Clean up resources

To uninstall the operator from your cluster, you must first make sure to delete all SageMaker resources from the cluster. Failure to do so causes the operator delete operation to hang. Run the following commands to stop all jobs:

```
# Delete all SageMaker jobs from Kubernetes
kubectl delete --all --all-namespaces hyperparametertuningjob.sagemaker.aws.amazon.com
```
You should see output similar to the following:

$ kubectl delete --all --all-namespaces trainingjobs.sagemaker.aws.amazon.com
trainingjobs.sagemaker.aws.amazon.com "xgboost-mnist-from-for-s3" deleted

$ kubectl delete --all --all-namespaces hyperparametertuningjob.sagemaker.aws.amazon.com
hyperparametertuningjob.sagemaker.aws.amazon.com "xgboost-mnist-hpo" deleted

$ kubectl delete --all --all-namespaces batchtransformjob.sagemaker.aws.amazon.com
batchtransformjob.sagemaker.aws.amazon.com "xgboost-mnist" deleted

$ kubectl delete --all --all-namespaces hostingdeployment.sagemaker.aws.amazon.com
hostingdeployment.sagemaker.aws.amazon.com "host-xgboost" deleted

After you delete all SageMaker jobs, use kubectl to delete the operator from the cluster:

# Delete the operator and its resources
kubectl delete -f /installer.yaml

You should see output similar to the following:

$ kubectl delete -f raw-yaml/installer.yaml
namespace "sagemaker-k8s-operator-system" deleted
customresourcedefinition.apiextensions.k8s.io "batchtransformjobs.sagemaker.aws.amazon.com" deleted
customresourcedefinition.apiextensions.k8s.io "endpointconfigs.sagemaker.aws.amazon.com" deleted
customresourcedefinition.apiextensions.k8s.io "hostingdeployments.sagemaker.aws.amazon.com" deleted
customresourcedefinition.apiextensions.k8s.io "hyperparametertuningjobs.sagemaker.aws.amazon.com" deleted
customresourcedefinition.apiextensions.k8s.io "models.sagemaker.aws.amazon.com" deleted
customresourcedefinition.apiextensions.k8s.io "trainingjobs.sagemaker.aws.amazon.com" deleted
role.rbac.authorization.k8s.io "sagemaker-k8s-operator-leader-election-role" deleted
clusterrole.rbac.authorization.k8s.io "sagemaker-k8s-operator-manager-role" deleted
clusterrole.rbac.authorization.k8s.io "sagemaker-k8s-operator-proxy-role" deleted
rolebinding.rbac.authorization.k8s.io "sagemaker-k8s-operator-leader-election-rolebinding" deleted
clusterrolebinding.rbac.authorization.k8s.io "sagemaker-k8s-operator-manager-rolebinding" deleted

After you delete all SageMaker jobs, see Delete operators (p. 2898) to delete the operator from your cluster.

Delete operators

Delete cluster-based operators

Operators installed using YAML

To uninstall the operator from your cluster, make sure that all SageMaker resources have been deleted from the cluster. Failure to do so causes the operator delete operation to hang.

**Note**

Before deleting your cluster, be sure to delete all SageMaker resources from the cluster. See Clean up resources (p. 2897) for more information.

After you delete all SageMaker jobs, use kubectl to delete the operator from the cluster:

# Delete the operator and its resources
kubectl delete -f /installer.yaml

You should see output similar to the following:

$ kubectl delete -f raw-yaml/installer.yaml
namespace "sagemaker-k8s-operator-system" deleted
customresourcedefinition.apiextensions.k8s.io "batchtransformjobs.sagemaker.aws.amazon.com" deleted
customresourcedefinition.apiextensions.k8s.io "endpointconfigs.sagemaker.aws.amazon.com" deleted
customresourcedefinition.apiextensions.k8s.io "hostingdeployments.sagemaker.aws.amazon.com" deleted
customresourcedefinition.apiextensions.k8s.io "hyperparametertuningjobs.sagemaker.aws.amazon.com" deleted
customresourcedefinition.apiextensions.k8s.io "models.sagemaker.aws.amazon.com" deleted
customresourcedefinition.apiextensions.k8s.io "trainingjobs.sagemaker.aws.amazon.com" deleted
role.rbac.authorization.k8s.io "sagemaker-k8s-operator-leader-election-role" deleted
clusterrole.rbac.authorization.k8s.io "sagemaker-k8s-operator-manager-role" deleted
clusterrole.rbac.authorization.k8s.io "sagemaker-k8s-operator-proxy-role" deleted
rolebinding.rbac.authorization.k8s.io "sagemaker-k8s-operator-leader-election-rolebinding" deleted
clusterrolebinding.rbac.authorization.k8s.io "sagemaker-k8s-operator-manager-rolebinding" deleted

2898
Operators installed using Helm Charts

To delete the operator CRDs, first delete all the running jobs. Then delete the Helm Chart that was used to deploy the operators using the following commands:

```bash
# get the helm charts
helm ls

# delete the charts
helm delete <chart_name>
```

Delete namespace-based operators

Operators installed with YAML

To uninstall the operator from your cluster, first make sure that all SageMaker resources have been deleted from the cluster. Failure to do so causes the operator delete operation to hang.

**Note**
Before deleting your cluster, be sure to delete all SageMaker resources from the cluster. See [Clean up resources](p. 2897) for more information.

After you delete all SageMaker jobs, use `kubectl` to first delete the operator from the namespace and then the CRDs from the cluster. Run the following commands to delete the operator from the cluster:

```bash
# Delete the operator using the same yaml file that was used to install the operator
kubectl delete -f operator.yaml

# Now delete the CRDs using the CRD installer yaml

# Now you can delete the namespace if you want
kubectl delete namespace <namespace>
```

Operators installed with Helm Charts

To delete the operator CRDs, first delete all the running jobs. Then delete the Helm Chart that was used to deploy the operators using the following commands:

```bash
# Delete the operator
helm delete <chart_name>

# delete the crds
helm delete crds

# optionally delete the namespace
kubectl delete namespace <namespace>
```

Troubleshooting

Debugging a failed job

Use these steps to debug a failed job.
• Check the job status by running the following:

```bash
kubectl get <CRD Type> <job name>
```

• If the job was created in SageMaker, you can use the following command to see the STATUS and the SageMaker Job Name:

```bash
kubectl get crd <job name>
```

• You can use `smlogs` to find the cause of the issue using the following command:

```bash
kubectl smlogs <crd type> <job name>
```

• You can also use the `describe` command to get more details about the job using the following command. The output has an additional field that has more information about the status of the job.

```bash
kubectl describe <crd type> <job name>
```

• If the job was not created in SageMaker, then use the logs of the operator's pod to find the cause of the issue as follows:

```bash
$ kubectl get pods -A | grep sagemaker
# Output:
sagemaker-k8s-operator-system   sagemaker-k8s-operator-controller-manager-5cd7df4d74-wh22z   2/2     Running   0          3h33m
$ kubectl logs -p <pod name> -c manager -n sagemaker-k8s-operator-system
```

### Deleting an operator CRD

If deleting a job is not working, check if the operator is running. If the operator is not running, then you have to delete the finalizer using the following steps:

1. In a new terminal, open the job in an editor using `kubectl edit` as follows:

   ```bash
   kubectl edit <crd type> <job name>
   ```

2. Edit the job to delete the finalizer by removing the following two lines from the file. Save the file and the job is be deleted.

   ```yaml
   finalizers:
   - sagemaker-operator-finalizer
   ```

### Images and SMLogs in each Region

The following table lists the available operator images and SMLogs in each Region.

<table>
<thead>
<tr>
<th>Region</th>
<th>Controller Image</th>
<th>Linux SMLogs</th>
</tr>
</thead>
<tbody>
<tr>
<td>us-east-1</td>
<td>957583890962.dkr.ecr.us-east-1.amazonaws.com/amazon-sagemaker-operator-for-k8s:v1</td>
<td><a href="https://s3.us-east-1.amazonaws.com/amazon-sagemaker-operator-for-k8s-us-east-1/kubectl-smlogs-plugin/v1/linux.amd64.tar.gz">https://s3.us-east-1.amazonaws.com/amazon-sagemaker-operator-for-k8s-us-east-1/kubectl-smlogs-plugin/v1/linux.amd64.tar.gz</a></td>
</tr>
</tbody>
</table>
Use Amazon SageMaker Jobs

This section is based on the original version of SageMaker Operators for Kubernetes.

Important

We are stopping the development and technical support of the original version of SageMaker Operators for Kubernetes.

If you are currently using version v1.2.2 or below of SageMaker Operators for Kubernetes, we recommend migrating your resources to the ACK service controller for Amazon SageMaker. The ACK service controller is a new generation of SageMaker Operators for Kubernetes based on AWS Controllers for Kubernetes (ACK).

For information on the migration steps, see Migrate resources to the latest Operators (p. 2926).

For answers to frequently asked questions on the end of support of the original version of SageMaker Operators for Kubernetes, see Announcing the End of Support of the Original Version of SageMaker Operators for Kubernetes (p. 2929).

To run an Amazon SageMaker job using the Operators for Kubernetes, you can either apply a YAML file or use the supplied Helm Charts.

All sample operator jobs in the following tutorials use sample data taken from a public MNIST dataset. In order to run these samples, download the dataset into your Amazon S3 bucket. You can find the dataset in Download the MNIST Dataset.

Contents

- The TrainingJob operator (p. 2901)
- The HyperParameterTuningJob operator (p. 2906)
- The BatchTransformJob operator (p. 2911)
- The HostingDeployment operator (p. 2914)
- The ProcessingJob operator (p. 2919)
- HostingAutoscalingPolicy (HAP) Operator (p. 2923)

The TrainingJob operator

Training job operators reconcile your specified training job spec to SageMaker by launching it for you in SageMaker. You can learn more about SageMaker training jobs in the SageMaker CreateTrainingJob API documentation.

Topics

- Create a TrainingJob using a YAML file (p. 2902)
- Create a TrainingJob Using a Helm Chart (p. 2902)
- List TrainingJobs (p. 2903)
Create a TrainingJob using a YAML file

1. Download the sample YAML file for training using the following command:

   ```bash
   wget https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/master/samples/xgboost-mnist-trainingjob.yaml
   ```

2. Edit the `xgboost-mnist-trainingjob.yaml` file to replace the `roleArn` parameter with your `<sagemaker-execution-role>`, and `outputPath` with your Amazon S3 bucket to which the SageMaker execution role has write access. The `roleArn` must have permissions so that SageMaker can access Amazon S3, Amazon CloudWatch, and other services on your behalf. For more information on creating an SageMaker ExecutionRole, see [SageMaker Roles](#). Apply the YAML file using the following command:

   ```bash
   kubectl apply -f xgboost-mnist-trainingjob.yaml
   ```

Create a TrainingJob Using a Helm Chart

You can use Helm Charts to run TrainingJobs.

1. Clone the GitHub repository to get the source using the following command:

   ```bash
   git clone https://github.com/aws/amazon-sagemaker-operator-for-k8s.git
   ```

2. Navigate to the `amazon-sagemaker-operator-for-k8s/hack/charts/training-jobs/` folder and edit the `values.yaml` file to replace values like `rolearn` and `outputpath` with values that correspond to your account. The RoleARN must have permissions so that SageMaker can access Amazon S3, Amazon CloudWatch, and other services on your behalf. For more information on creating an SageMaker ExecutionRole, see [SageMaker Roles](#).

Create the TrainingJob

With the roles and Amazon S3 buckets replaced with appropriate values in `values.yaml`, you can create a training job using the following command:

```bash
helm install . --generate-name
```

Your output should look like the following:

```
NAME: chart-12345678
LAST DEPLOYED: Wed Nov 20 23:35:49 2019
NAMESPACE: default
STATUS: deployed
REVISION: 1
TEST SUITE: None
NOTES:
Thanks for installing the sagemaker-k8s-trainingjob.
```

Verify your training Helm Chart

To verify that the Helm Chart was created successfully, run:
helm ls

Your output should look like the following:

<table>
<thead>
<tr>
<th>NAME</th>
<th>NAMESPACE</th>
<th>REVISION</th>
<th>UPDATED APP VERSION</th>
<th>STATUS</th>
<th>CHART</th>
<th>APP VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>chart-12345678 deployed</td>
<td>default</td>
<td>1</td>
<td>2019-11-20 23:35:49.9136092 +0000 UTC</td>
<td>deployed</td>
<td>sagemaker-k8s-trainingjob-0.1.0</td>
<td></td>
</tr>
<tr>
<td>rolebased-12345678 deployed</td>
<td>default</td>
<td>1</td>
<td>2019-11-20 23:14:59.6777082 +0000 UTC</td>
<td>deployed</td>
<td>sagemaker-k8s-operator-0.1.0</td>
<td></td>
</tr>
</tbody>
</table>

helm install creates a TrainingJob Kubernetes resource. The operator launches the actual training job in SageMaker and updates the TrainingJob Kubernetes resource to reflect the status of the job in SageMaker. You incur charges for SageMaker resources used during the duration of your job. You do not incur any charges once your job completes or stops.

**Note**: SageMaker does not allow you to update a running training job. You cannot edit any parameter and re-apply the config file. Either change the metadata name or delete the existing job and create a new one. Similar to existing training job operators like TFJob in Kubeflow, update is not supported.

**List TrainingJobs**

Use the following command to list all jobs created using the Kubernetes operator:

```bash
cubectl get TrainingJob
```

The output listing all jobs should look like the following:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>SECONDARY-STATUS</th>
<th>CREATION-TIME</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAGEMAKER-JOB-NAME</td>
<td>InProgress</td>
<td>Starting</td>
<td>2019-11-20T23:42:35Z</td>
</tr>
</tbody>
</table>

A training job continues to be listed after the job has completed or failed. You can remove a TrainingJob job from the list by following the Delete TrainingJobs (p. 2905) steps. Jobs that have completed or stopped do not incur any charges for SageMaker resources.

**TrainingJob status values**

The STATUS field can be one of the following values:

- Completed
- InProgress
- Failed
- Stopped
- Stopping

These statuses come directly from the SageMaker official API documentation.

In addition to the official SageMaker status, it is possible for STATUS to be SynchronizingK8sJobWithSageMaker. This means that the operator has not yet processed the job.

**Secondary status values**

The secondary statuses come directly from the SageMaker official API documentation. They contain more granular information about the status of the job.
Describe a TrainingJob

You can get more details about the training job by using the `describe kubectl` command. This is typically used for debugging a problem or checking the parameters of a training job. To get information about your training job, use the following command:

```
kubectl describe trainingjob xgboost-mnist-from-for-s3
```

The output for your training job should look like the following:

```
Name:         xgboost-mnist-from-for-s3
Namespace:    default
Labels:       <none>
Annotations:  <none>

Delete TrainingJobs

Use the following command to stop a training job on Amazon SageMaker:

kubectldel trainingjob xgboost-mnist-from-for-s3

This command removes the SageMaker training job from Kubernetes. This command returns the
following output:

trainingjob.sagemaker.aws.amazon.com "xgboost-mnist-from-for-s3" deleted

If the job is still in progress on SageMaker, the job stops. You do not incur any charges for SageMaker
resources after your job stops or completes.
Note: SageMaker does not delete training jobs. Stopped jobs continue to show on the SageMaker console. The delete command takes about 2 minutes to clean up the resources from SageMaker.

The HyperParameterTuningJob operator

Hyperparameter tuning job operators reconcile your specified hyperparameter tuning job spec to SageMaker by launching it in SageMaker. You can learn more about SageMaker hyperparameter tuning jobs in the SageMaker CreateHyperParameterTuningJob API documentation.

Topics

• Create a HyperparameterTuningJob using a YAML file (p. 2906)
• Create a HyperparameterTuningJob using a Helm Chart (p. 2906)
• List HyperparameterTuningJobs (p. 2907)
• Describe a HyperparameterTuningJob (p. 2908)
• View logs from HyperparameterTuningJobs (p. 2911)
• Delete a HyperparameterTuningJob (p. 2911)

Create a HyperparameterTuningJob using a YAML file

1. Download the sample YAML file for the hyperparameter tuning job using the following command:

   wget https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/master/samples/xgboost-mnist-hpo.yaml

2. Edit the xgboost-mnist-hpo.yaml file to replace the roleArn parameter with your sagemaker-execution-role. For the hyperparameter tuning job to succeed, you must also change the s3InputPath and s3OutputPath to values that correspond to your account. Apply the updates YAML file using the following command:

   kubectl apply -f xgboost-mnist-hpo.yaml

Create a HyperparameterTuningJob using a Helm Chart

You can use Helm Charts to run hyperparameter tuning jobs.

1. Clone the GitHub repository to get the source using the following command:

   git clone https://github.com/aws/amazon-sagemaker-operator-for-k8s.git

2. Navigate to the amazon-sagemaker-operator-for-k8s/hack/charts/hyperparameter-tuning-jobs/ folder.

3. Edit the values.yaml file to replace the roleArn parameter with your sagemaker-execution-role. For the hyperparameter tuning job to succeed, you must also change the s3InputPath and s3OutputPath to values that correspond to your account.

Create the HyperparameterTuningJob

With the roles and Amazon S3 paths replaced with appropriate values in values.yaml, you can create a hyperparameter tuning job using the following command:

   helm install . --generate-name
Your output should look similar to the following:

<table>
<thead>
<tr>
<th>NAME</th>
<th>NAMESPACE</th>
<th>REVISION</th>
<th>UPDATED</th>
</tr>
</thead>
<tbody>
<tr>
<td>chart-1574292948</td>
<td>default</td>
<td>1</td>
<td>2019-11-20 23:35:49.9136092 +0000</td>
</tr>
<tr>
<td>rolebased-1574291698</td>
<td>default</td>
<td>1</td>
<td>2019-11-20 23:14:59.6777082 +0000</td>
</tr>
</tbody>
</table>

Verify chart installation

To verify that the Helm Chart was created successfully, run the following command:

```
helm ls
```

Your output should look like the following:

<table>
<thead>
<tr>
<th>NAME</th>
<th>NAMESPACE</th>
<th>REVISION</th>
<th>UPDATED</th>
</tr>
</thead>
<tbody>
<tr>
<td>chart-1474292948</td>
<td>default</td>
<td>1</td>
<td>2019-11-20 23:35:49.9136092 +0000</td>
</tr>
<tr>
<td>rolebased-1574291698</td>
<td>default</td>
<td>1</td>
<td>2019-11-20 23:14:59.6777082 +0000</td>
</tr>
</tbody>
</table>

Helm `install` creates a HyperParameterTuningJob Kubernetes resource. The operator launches the actual hyperparameter optimization job in SageMaker and updates the HyperParameterTuningJob Kubernetes resource to reflect the status of the job in SageMaker. You incur charges for SageMaker resources used during the duration of your job. You do not incur any charges once your job completes or stops.

Note: SageMaker does not allow you to update a running hyperparameter tuning job. You cannot edit any parameter and re-apply the config file. You must either change the metadata name or delete the existing job and create a new one. Similar to existing training job operators like TFJob in Kubeflow, update is not supported.

List HyperparameterTuningJobs

Use the following command to list all jobs created using the Kubernetes operator:

```
kubectl get hyperparametertuningjob
```

Your output should look like the following:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>CREATION-TIME</th>
<th>COMPLETED</th>
<th>INPROGRESS</th>
<th>ERRORS</th>
<th>STOPPED</th>
<th>SAGEMAKER-JOB-NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>BEST-TRAINING-JOB</td>
<td>Completed</td>
<td>2019-10-17T01:15:52Z</td>
<td>10</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>xgboost-mnist-hpo</td>
</tr>
<tr>
<td>xgboost-mnist-hpo</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>xgboost-mnist-hpo</td>
</tr>
</tbody>
</table>

A hyperparameter tuning job continues to be listed after the job has completed or failed. You can remove a hyperparametertuningjob from the list by following the steps in Delete a HyperparameterTuningJob (p. 2911). Jobs that have completed or stopped do not incur any charges for SageMaker resources.
Hyperparameter tuning job status values

The STATUS field can be one of the following values:

- Completed
- InProgress
- Failed
- Stopped
- Stopping

These statuses come directly from the SageMaker official API documentation.

In addition to the official SageMaker status, it is possible for STATUS to be SynchronizingK8sJobWithSageMaker. This means that the operator has not yet processed the job.

Status counters

The output has several counters, like COMPLETED and INPROGRESS. These represent how many training jobs have completed and are in progress, respectively. For more information about how these are determined, see TrainingJobStatusCounters in the SageMaker API documentation.

Best TrainingJob

This column contains the name of the TrainingJob that best optimized the selected metric.

To see a summary of the tuned hyperparameters, run:

```bash
tool describe hyperparametertuningjob xgboost-mnist-hpo
```

To see detailed information about the TrainingJob, run:

```bash
tool describe trainingjobs <job name>
```

Spawned TrainingJobs

You can also track all 10 training jobs in Kubernetes launched by HyperparameterTuningJob by running the following command:

```bash
tool get trainingjobs
```

Describe a HyperparameterTuningJob

You can obtain debugging details using the describe command.

```bash
tool describe hyperparametertuningjob xgboost-mnist-hpo
```

In addition to information about the tuning job, the SageMaker Operator for Kubernetes also exposes the best training job found by the hyperparameter tuning job in the describe output as follows:

<table>
<thead>
<tr>
<th>Name: xgboost-mnist-hpo</th>
</tr>
</thead>
<tbody>
<tr>
<td>Namespace: default</td>
</tr>
<tr>
<td>Labels: &lt;none&gt;</td>
</tr>
<tr>
<td>Annotations: kbuect1.kubernetes.io/last-applied-configuration:</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

View logs from HyperparameterTuningJobs

Hyperparameter tuning jobs do not have logs, but all training jobs launched by them do have logs. These logs can be accessed as if they were a normal training job. For more information, see View logs from TrainingJobs (p. 2905).

Delete a HyperparameterTuningJob

Use the following command to stop a hyperparameter job in SageMaker.

```
kubectl delete hyperparametertuningjob xgboost-mnist-hpo
```

This command removes the hyperparameter tuning job and associated training jobs from your Kubernetes cluster and stops them in SageMaker. Jobs that have stopped or completed do not incur any charges for SageMaker resources. SageMaker does not delete hyperparameter tuning jobs. Stopped jobs continue to show on the SageMaker console.

Your output should look like the following:

```
hyperparametertuningjob.sagemaker.aws.amazon.com "xgboost-mnist-hpo" deleted
```

**Note:** The delete command takes about 2 minutes to clean up the resources from SageMaker.

**The BatchTransformJob operator**

Batch transform job operators reconcile your specified batch transform job spec to SageMaker by launching it in SageMaker. You can learn more about SageMaker batch transform job in the SageMaker CreateTransformJob API documentation.

**Topics**

- Create a BatchTransformJob using a YAML File (p. 2911)
- Create a BatchTransformJob using a Helm Chart (p. 2912)
- List BatchTransformJobs (p. 2913)
- Describe a BatchTransformJob (p. 2913)
- View logs from BatchTransformJobs (p. 2914)
- Delete a BatchTransformJob (p. 2914)

Create a BatchTransformJob using a YAML File

1. Download the sample YAML file for the batch transform job using the following command:

   ```
   wget https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/master/samples/xgboost-mnist-batchtransform.yaml
   ```

2. Edit the file `xgboost-mnist-batchtransform.yaml` to change necessary parameters to replace the `inputdataconfig` with your input data and `s3outputPath` with your Amazon S3 buckets that the SageMaker execution role has write access to.

3. Apply the YAML file using the following command:

   ```
kubectl apply -f xgboost-mnist-batchtransform.yaml
   ```
Create a BatchTransformJob using a Helm Chart

You can use Helm Charts to run batch transform jobs.

Get the Helm installer directory

Clone the GitHub repository to get the source using the following command:

```bash
git clone https://github.com/aws/amazon-sagemaker-operator-for-k8s.git
```

Configure the Helm Chart

Navigate to the `amazon-sagemaker-operator-for-k8s/hack/charts/batch-transform-jobs/` folder.

Edit the `values.yaml` file to replace the `inputdataconfig` with your input data and `outputPath` with your S3 buckets to which the SageMaker execution role has write access.

Create a BatchTransformJob

1. Use the following command to create a batch transform job:

   ```bash
   helm install . --generate-name
   ```

   Your output should look like the following:

   ```text
   NAME: chart-1574292948
   LAST DEPLOYED: Wed Nov 20 23:35:49 2019
   NAMESPACE: default
   STATUS: deployed
   REVISION: 1
   TEST SUITE: None
   NOTES:
   Thanks for installing the sagemaker-k8s-batch-transform-job.
   ```

2. To verify that the Helm Chart was created successfully, run the following command:

   ```bash
   helm ls
   ```

   This command creates a BatchTransformJob Kubernetes resource. The operator launches the actual transform job in SageMaker and updates the BatchTransformJob Kubernetes resource to reflect the status of the job in SageMaker. You incur charges for SageMaker resources used during the duration of your job. You do not incur any charges once your job completes or stops.

   **Note:** SageMaker does not allow you to update a running batch transform job. You cannot edit any parameter and re-apply the config file. You must either change the metadata name or delete the existing job and create a new one. Similar to existing training job operators like TFJob in Kubeflow, update is not supported.
List BatchTransformJobs

Use the following command to list all jobs created using the Kubernetes operator:

```kubernetes
kubectl get batchtransformjob
```

Your output should look like the following:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>CREATION-TIME</th>
<th>SAGEMAKER-JOB-NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>xgboost-mnist-batch-transform</td>
<td>Completed</td>
<td>2019-11-18T03:44:00Z</td>
<td>xgboost-mnist-</td>
</tr>
<tr>
<td>a88fb19809b511eaac40a8a9gboost</td>
<td></td>
<td></td>
<td>a88fb19809b511eaac40a8a9gboost</td>
</tr>
</tbody>
</table>

A batch transform job continues to be listed after the job has completed or failed. You can remove a hyperparameter tuning job from the list by following the [Delete a BatchTransformJob](#) steps. Jobs that have completed or stopped do not incur any charges for SageMaker resources.

Batch transform status values

The STATUS field can be one of the following values:

- Completed
- InProgress
- Failed
- Stopped
- Stopping

These statuses come directly from the SageMaker official API documentation.

In addition to the official SageMaker status, it is possible for STATUS to be SynchronizingK8sJobWithSageMaker. This means that the operator has not yet processed the job.

Describe a BatchTransformJob

You can obtain debugging details using the describe `kubectl` command.

```kubernetes
kubectl describe batchtransformjob xgboost-mnist-batch-transform
```

Your output should look like the following:

<table>
<thead>
<tr>
<th>Name: xgboost-mnist-batch-transform</th>
</tr>
</thead>
<tbody>
<tr>
<td>Namespace: default</td>
</tr>
<tr>
<td>Labels:</td>
</tr>
<tr>

    Events: <none>

View logs from BatchTransformJobs

Use the following command to see the logs from the xgboost-mnist batch transform job:

```bash
kubectl smlogs batchtransformjob xgboost-mnist-batch-transform
```

Delete a BatchTransformJob

Use the following command to stop a batch transform job in SageMaker.

```bash
kubectl delete batchTransformJob xgboost-mnist-batch-transform
```

Your output should look like the following:

```
batchtransformjob.sagemaker.aws.amazon.com "xgboost-mnist" deleted
```

This command removes the batch transform job from your Kubernetes cluster, as well as stops them in SageMaker. Jobs that have stopped or completed do not incur any charges for SageMaker resources. Delete takes about 2 minutes to clean up the resources from SageMaker.

**Note:** SageMaker does not delete batch transform jobs. Stopped jobs continue to show on the SageMaker console.

The HostingDeployment operator

HostingDeployment operators support creating and deleting an endpoint, as well as updating an existing endpoint, for real-time inference. The hosting deployment operator reconciles your specified hosting deployment job spec to SageMaker by creating models, endpoint-configs and endpoints in SageMaker.

You can learn more about SageMaker inference in the SageMaker CreateEndpoint API documentation.

Topics
- Configure a HostingDeployment resource (p. 2915)
- Create a HostingDeployment (p. 2915)
- List HostingDeployments (p. 2915)
- Describe a HostingDeployment (p. 2916)
- Invoking the endpoint (p. 2917)
Configure a HostingDeployment resource

Download the sample YAML file for the hosting deployment job using the following command:

```
wget https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/master/samples/xgboost-mnist-hostingdeployment.yaml
```

The `xgboost-mnist-hostingdeployment.yaml` file has the following components that can be edited as required:

- **ProductionVariants.** A production variant is a set of instances serving a single model. SageMaker load-balances between all production variants according to set weights.
- **Models.** A model is the containers and execution role ARN necessary to serve a model. It requires at least a single container.
- **Containers.** A container specifies the dataset and serving image. If you are using your own custom algorithm instead of an algorithm provided by SageMaker, the inference code must meet SageMaker requirements. For more information, see [Using Your Own Algorithms with SageMaker](#).

Create a HostingDeployment

To create a HostingDeployment, use `kubectl` to apply the file `hosting.yaml` with the following command:

```
kubectl apply -f hosting.yaml
```

SageMaker creates an endpoint with the specified configuration. You incur charges for SageMaker resources used during the lifetime of your endpoint. You do not incur any charges once your endpoint is deleted.

The creation process takes approximately 10 minutes.

List HostingDeployments

To verify that the HostingDeployment was created, use the following command:

```
kubectl get hostingdeployments
```

Your output should look like the following:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>SAGEMAKER-ENDPOINT-NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>host-xgboost</td>
<td>Creating</td>
<td>host-xgboost-def0e83e0d5f11eaa450aSMLOGS</td>
</tr>
</tbody>
</table>

HostingDeployment status values

The status field can be one of several values:

- **SynchronizingK8sJobWithSageMaker:** The operator is preparing to create the endpoint.
- **ReconcilingEndpoint:** The operator is creating, updating, or deleting endpoint resources. If the HostingDeployment remains in this state, use `kubectl` `describe` to see the reason in the Additional field.
- **OutOfService:** The endpoint is not available to take incoming requests.
• Creating: **CreateEndpoint** is running.
• Updating: **UpdateEndpoint** or **UpdateEndpointWeightsAndCapacities** is running.
• SystemUpdating: The endpoint is undergoing maintenance and cannot be updated or deleted or re-scaled until it has completed. This maintenance operation does not change any customer-specified values such as VPC config, AWS KMS encryption, model, instance type, or instance count.
• RollingBack: The endpoint fails to scale up or down or change its variant weight and is in the process of rolling back to its previous configuration. Once the rollback completes, the endpoint returns to an InService status. This transitional status only applies to an endpoint that has autoscaling turned on and is undergoing variant weight or capacity changes as part of an **UpdateEndpointWeightsAndCapacities** call or when the **UpdateEndpointWeightsAndCapacities** operation is called explicitly.
• InService: The endpoint is available to process incoming requests.
• Deleting: **DeleteEndpoint** is running.
• Failed: The endpoint could not be created, updated, or re-scaled. Use **DescribeEndpoint:FailureReason** for information about the failure. **DeleteEndpoint** is the only operation that can be performed on a failed endpoint.

**Describe a HostingDeployment**

You can obtain debugging details using the describe kubectl command.

```
kubectl describe hostingdeployment
```

Your output should look like the following:

```
Name:         host-xgboost
Namespace:    default
Labels:       <none>
Annotations:  kubectl.kubernetes.io/last-applied-configuration:
  {"apiVersion":"sagemaker.aws.amazon.com/v1","kind":"HostingDeployment","metadata":{}
Kind:         HostingDeployment
Metadata:
  Creation Timestamp:  2019-11-22T19:40:00Z
  Finalizers:        sagemaker-operator-finalizer
  Generation:        1
  Resource Version:  4258134
  Self Link:         /apis/sagemaker.aws.amazon.com/v1/namespaces/default/hostingdeployments/host-xgboost
  UID:               def0e83e-0d5f-11ea-aa45-0a3507uiduid
Spec:
  Containers:
    Container Hostname:  xgboost
    Image:               123456789012.dkr.ecr.us-east-2.amazonaws.com/xgboost:latest
    Model Data URL:      s3://my-bucket/inference/xgboost-mnist/model.tar.gz
  Models:
    Containers:         xgboost
    Execution Role Arn:  arn:aws:iam::123456789012:role/service-role/AmazonSageMaker-ExecutionRole
    Name:               xgboost-model
    Primary Container:  xgboost
    Production Variants:
      Initial Instance Count:  1
      Instance Type:           ml.c5.large
      Model Name:              xgboost-model
      Variant Name:            all-traffic
```
The status field provides more information using the following fields:

- **Additional**: Additional information about the status of the hosting deployment. This field is optional and only gets populated in case of error.
- **Creation Time**: When the endpoint was created in SageMaker.
- **Endpoint ARN**: The SageMaker endpoint ARN.
- **Endpoint Config Name**: The SageMaker name of the endpoint configuration.
- **Endpoint Name**: The SageMaker name of the endpoint.
- **Endpoint Status**: The status of the endpoint.
- **Endpoint URL**: The HTTPS URL that can be used to access the endpoint. For more information, see [Deploy a Model on SageMaker Hosting Services](#).
- **FailureReason**: If a create, update, or delete command fails, the cause is shown here.
- **Last Check Time**: The last time the operator checked the status of the endpoint.
- **Last Modified Time**: The last time the endpoint was modified.
- **Model Names**: A key-value pair of HostingDeployment model names to SageMaker model names.

### Invoking the endpoint

Once the endpoint status is `InService`, you can invoke the endpoint in two ways: using the AWS CLI, which does authentication and URL request signing, or using an HTTP client like cURL. If you use your own client, you need to do AWS v4 URL signing and authentication on your own.

To invoke the endpoint using the AWS CLI, run the following command. Make sure to replace the Region and endpoint name with your endpoint's Region and SageMaker endpoint name. This information can be obtained from the output of `kubectl describe`.

```
# Invoke the endpoint with mock input data.
aws sagemaker-runtime invoke-endpoint
  --region us-east-2
  --endpoint-name <endpoint name>
  --body $(seq 784 | xargs echo | sed 's/ /,/g')
  >(cat)
  --content-type text/csv > /dev/null
```

For example, if your Region is `us-east-2` and your endpoint config name is `host-xgboost-f56b6b280d7511ea824b129926example`, then the following command would invoke the endpoint:

```
aws sagemaker-runtime invoke-endpoint
  --region us-east-2
  --endpoint-name host-xgboost-f56b6b280d7511ea824b129926example
  --body $(seq 784 | xargs echo | sed 's/ /,/g')
```
Here, 4.95847082138 is the prediction from the model for the mock data.

**Update HostingDeployment**

1. Once a HostingDeployment has a status of *InService*, it can be updated. It might take about 10 minutes for HostingDeployment to be in service. To verify that the status is *InService*, use the following command:

```bash
kubectl get hostingdeployments
```

2. The HostingDeployment can be updated before the status is *InService*. The operator waits until the SageMaker endpoint is *InService* before applying the update.

To apply an update, modify the *hosting.yaml* file. For example, change the `initialInstanceCount` field from 1 to 2 as follows:

```yaml
apiVersion: sagemaker.aws.amazon.com/v1
kind: HostingDeployment
metadata:
  name: host-xgboost
spec:
  region: us-east-2
  productionVariants:
    - variantName: all-traffic
      modelName: xgboost-model
      initialInstanceCount: 2
      instanceType: ml.c5.large
  models:
    - name: xgboost-model
      executionRoleArn: arn:aws:iam::123456789012:role/service-role/AmazonSageMaker-ExecutionRole
      primaryContainer: xgboost
      containers:
        - xgboost
        - containerHostname: xgboost
          modelDataUrl: s3://my-bucket/inference/xgboost-mnist/model.tar.gz
          image: 123456789012.dkr.ecr.us-east-2.amazonaws.com/xgboost:latest

3. Save the file, then use `kubectl` to apply your update as follows. You should see the status change from *InService* to *ReconcilingEndpoint*, then *Updating*.

```bash
$ kubectl apply -f hosting.yaml
hostingdeployment.sagemaker.aws.amazon.com/host-xgboost configured

$ kubectl get hostingdeployments
NAME           STATUS                SAGEMAKER-ENDPOINT-NAME
host-xgboost   ReconcilingEndpoint   host-xgboost-def0e85e0d5f11eaa450a350abcdef

$ kubectl get hostingdeployments
NAME           STATUS     SAGEMAKER-ENDPOINT-NAME
host-xgboost   Updating   host-xgboost-def0e85e0d5f11eaa450a350abcdef
```

SageMaker deploys a new set of instances with your models, switches traffic to use the new instances, and drains the old instances. As soon as this process begins, the status becomes *Updating*. After the update is complete, your endpoint becomes *InService*. This process takes approximately 10 minutes.
Delete the HostingDeployment

1. Use kubectl to delete a HostingDeployment with the following command:

   ```bash
   kubectl delete hostingdeployments host-xgboost
   ```

   Your output should look like the following:

   ```bash
   hostingdeployment.sagemaker.aws.amazon.com "host-xgboost" deleted
   ```

2. To verify that the hosting deployment has been deleted, use the following command:

   ```bash
   kubectl get hostingdeployments
   No resources found.
   ```

Endpoints that have been deleted do not incur any charges for SageMaker resources.

The ProcessingJob operator

ProcessingJob operators are used to launch Amazon SageMaker processing jobs. For more information on SageMaker processing jobs, see CreateProcessingJob.

Topics
- Create a ProcessingJob using a YAML file (p. 2919)
- List ProcessingJobs (p. 2920)
- Describe a ProcessingJob (p. 2921)
- Delete a ProcessingJob (p. 2922)

Create a ProcessingJob using a YAML file

Follow these steps to create an Amazon SageMaker processing job by using a YAML file:

1. Download the kmeans_preprocessing.py pre-processing script.

   ```bash
   wget https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/master/samples/kmeans_preprocessing.py
   ```

2. In one of your Amazon Simple Storage Service (Amazon S3) buckets, create a mnist_kmeans_example/processing_code folder and upload the script to the folder.

3. Download the kmeans-mnist-processingjob.yaml file.

   ```bash
   wget https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/master/samples/kmeans-mnist-processingjob.yaml
   ```

4. Edit the YAML file to specify your sagemaker-execution-role and replace all instances of my-bucket with your S3 bucket.

   ```yaml
   ...
   metadata:
     name: kmeans-mnist-processing
   ...
   roleArn: arn:aws:iam::<acct-id>:role/service-role/<sagemaker-execution-role>
   ...
   processingOutputConfig:
     outputs:
   ```
The sagemaker-execution-role must have permissions so that SageMaker can access your S3 bucket, Amazon CloudWatch, and other services on your behalf. For more information on creating an execution role, see SageMaker Roles.

5. Apply the YAML file using one of the following commands.

For cluster-scoped installation:

```bash
touch kmeans-mnist-processingjob.yaml
```

```bash
cr.sh apply -f kmeans-mnist-processingjob.yaml
```

For namespace-scoped installation:

```bash
touch kmeans-mnist-processingjob.yaml
```

```bash
cr.sh apply -f kmeans-mnist-processingjob.yaml -n <NAMESPACE>
```

**List ProcessingJobs**

Use one of the following commands to list all the jobs created using the ProcessingJob operator. SAGEMAKER-JOB-NAME comes from the metadata section of the YAML file.

For cluster-scoped installation:

```bash
cr.sh get ProcessingJob kmeans-mnist-processing
```

For namespace-scoped installation:

```bash
cr.sh get ProcessingJob -n <NAMESPACE> kmeans-mnist-processing
```

Your output should look similar to the following:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>CREATION-TIME</th>
<th>SAGEMAKER-JOB-NAME</th>
</tr>
</thead>
</table>

The output lists all jobs regardless of their status. To remove a job from the list, see Delete a Processing Job.

**ProcessingJob Status**

- **SynchronizingK8sJobWithSageMaker** – The job is first submitted to the cluster. The operator has received the request and is preparing to create the processing job.
- **Reconciling** – The operator is initializing or recovering from transient errors, along with others. If the processing job remains in this state, use the `kubectl describe` command to see the reason in the Additional field.
- **InProgress | Completed | Failed | Stopping | Stopped** – Status of the SageMaker processing job. For more information, see DescribeProcessingJob.
• **Error** – The operator cannot recover by reconciling.

Jobs that have completed, stopped, or failed do not incur further charges for SageMaker resources.

**Describe a ProcessingJob**

Use one of the following commands to get more details about a processing job. These commands are typically used for debugging a problem or checking the parameters of a processing job.

**For cluster-scoped installation:**

```
kubectl describe processingjob kmeans-mnist-processing
```

**For namespace-scoped installation:**

```
kubectl describe processingjob kmeans-mnist-processing -n <NAMESPACE>
```

The output for your processing job should look similar to the following.

```
$ kubectl describe ProcessingJob kmeans-mnist-processing
Name:         kmeans-mnist-processing
Namespace:    default
Labels:       <none>
Annotations:  kubectl.kubernetes.io/last-applied-configuration:
   {
      "apiVersion": "sagemaker.aws.amazon.com/v1",
      "kind": "ProcessingJob",
      "metadata": {
         "annotations": [],
         "name": "kmeans-mnist-processing",
         ...
   }
API Version:  sagemaker.aws.amazon.com/v1
Kind:         ProcessingJob
Metadata:
   Finalizers:        
   Generation:        2
   Resource Version:  21746658
   Self Link:         /apis/sagemaker.aws.amazon.com/v1/namespaces/default/processingjobs/kmeans-mnist-processing
   UID:               7410ed52-fd18-11ea-b19a-165ae9f9e385
Spec:
   App Specification:
      Container Entrypoint:   python
      Image Uri:              763104351884.dkr.ecr.us-west-2.amazonaws.com/pytorch-training:1.5.0-cpu-py36-ubuntu16.04
   Environment:
      Name:       MYVAR
      Value:      my_value
      Name:       MYVAR2
      Value:      my_value2
   Network Config:
      Processing Inputs:
      Input Name:  mnist_tar
      s3Input:
         Local Path:   /opt/ml/processing/input
         s3DataType:  S3Prefix
         s3InputMode:  File
         s3Uri:        s3://<s3bucket>-us-west-2/algorithms/kmeans/mnist/mnist.pkl.gz
      Input Name:  source_code
      s3Input:
         Local Path:   /opt/ml/processing/code
```
Delete a ProcessingJob

When you delete a processing job, the SageMaker processing job is removed from Kubernetes but the job isn't deleted from SageMaker. If the job status in SageMaker is InProgress the job is stopped. Processing jobs that are stopped do not incur any charges for SageMaker resources. Use one of the following commands to delete a processing job.

For cluster-scoped installation:

```
kubectl delete processingjob kmeans-mnist-processing
```

For namespace-scoped installation:

```
kubectl delete processingjob kmeans-mnist-processing -n <NAMESPACE>
```

The output for your processing job should look similar to the following.

```
processingjob.sagemaker.aws.amazon.com "kmeans-mnist-processing" deleted
```
Note
SageMaker does not delete the processing job. Stopped jobs continue to show in the SageMaker console. The delete command takes a few minutes to clean up the resources from SageMaker.

HostingAutoscalingPolicy (HAP) Operator

The HostingAutoscalingPolicy (HAP) operator takes a list of resource IDs as input and applies the same policy to each of them. Each resource ID is a combination of an endpoint name and a variant name. The HAP operator performs two steps: it registers the resource IDs and then applies the scaling policy to each resource ID. Delete undoes both actions. You can apply the HAP to an existing SageMaker endpoint or you can create a new SageMaker endpoint using the HostingDeployment operator. You can read more about SageMaker autoscaling in the Application Autoscaling Policy documentation.

Note
In your kubectl commands, you can use the short form, hap, in place of hostingautoscalingpolicy.

Topics
• Create a HostingAutoscalingPolicy using a YAML file (p. 2923)
• List HostingAutoscalingPolicies (p. 2925)
• Describe a HostingAutoscalingPolicy (p. 2926)
• Update a HostingAutoscalingPolicy (p. 2926)
• Delete a HostingAutoscalingPolicy (p. 2926)
• Update or delete an endpoint with a HostingAutoscalingPolicy (p. 2926)

Create a HostingAutoscalingPolicy using a YAML file

Use a YAML file to create a HostingAutoscalingPolicy (HAP) that applies a predefined or custom metric to one or multiple SageMaker endpoints.

Amazon SageMaker requires specific values in order to apply autoscaling to your variant. If these values are not specified in the YAML spec, the HAP operator applies the following default values.

```
# Do not change
Namespace                    = "sagemaker"
# Do not change
ScalableDimension            = "sagemaker:variant:DesiredInstanceCount"
# Only one supported
PolicyType                   = "TargetTrackingScaling"
# This is the default policy name but can be changed to apply a custom policy
DefaultAutoscalingPolicyName = "SageMakerEndpointInvocationScalingPolicy"
```

Use the following samples to create a HAP that applies a predefined or custom metric to one or multiple endpoints.

Sample 1: Apply a predefined metric to a single endpoint variant

1. Download the sample YAML file for a predefined metric using the following command:

   ```bash
   wget https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/master/samples/hap-predefined-metric.yaml
   ```

2. Edit the YAML file to specify your endpointName, variantName, and Region.
3. Use one of the following commands to apply a predefined metric to a single resource ID (endpoint name and variant name combination).

   For cluster-scoped installation:
kubectl apply -f hap-predefined-metric.yaml

For namespace-scoped installation:

```
kubectl apply -f hap-predefined-metric.yaml -n <NAMESPACE>
```

Sample 2: Apply a custom metric to a single endpoint variant

1. Download the sample YAML file for a custom metric using the following command:

```
wget https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/master/samples/hap-custom-metric.yaml
```

2. Edit the YAML file to specify your `endpointName`, `variantName`, and `Region`.

3. Use one of the following commands to apply a custom metric to a single resource ID (endpoint name and variant name combination) in place of the recommended `SageMakerVariantInvocationsPerInstance`.

**Note**
Amazon SageMaker does not check the validity of your YAML spec.

For cluster-scoped installation:

```
kubectl apply -f hap-custom-metric.yaml
```

For namespace-scoped installation:

```
kubectl apply -f hap-custom-metric.yaml -n <NAMESPACE>
```

Sample 3: Apply a scaling policy to multiple endpoints and variants

You can use the HAP operator to apply the same scaling policy to multiple resource IDs. A separate `scaling_policy` request is created for each resource ID (endpoint name and variant name combination).

1. Download the sample YAML file for a predefined metric using the following command:

```
wget https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/master/samples/hap-predefined-metric.yaml
```

2. Edit the YAML file to specify your `Region` and multiple `endpointName` and `variantName` values.

3. Use one of the following commands to apply a predefined metric to multiple resource IDs (endpoint name and variant name combinations).

For cluster-scoped installation:

```
kubectl apply -f hap-predefined-metric.yaml
```

For namespace-scoped installation:

```
kubectl apply -f hap-predefined-metric.yaml -n <NAMESPACE>
```
Considerations for HostingAutoscalingPolicies for multiple endpoints and variants

The following considerations apply when you use multiple resource IDs:

- If you apply a single policy across multiple resource IDs, one PolicyARN is created per resource ID. Five endpoints have five PolicyARNs. When you run the describe command on the policy, the responses show up as one job and include a single job status.
- If you apply a custom metric to multiple resource IDs, the same dimension or value is used for all the resource ID (variant) values. For example, if you apply a customer metric for instances 1-5, and the endpoint variant dimension is mapped to variant 1, when variant 1 exceeds the metrics, all endpoints are scaled up or down.
- The HAP operator supports updating the list of resource IDs. If you modify, add, or delete resource IDs to the spec, the autoscaling policy is removed from the previous list of variants and applied to the newly specified resource ID combinations. Use the describe command to list the resource IDs to which the policy is currently applied.

List HostingAutoscalingPolicies

Use one of the following commands to list all HostingAutoscalingPolicies (HAPs) created using the HAP operator.

For cluster-scoped installation:

```
kubectl get hap
```

For namespace-scoped installation:

```
kubectl get hap -n <NAMESPACE>
```

Your output should look similar to the following:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>CREATION-TIME</th>
</tr>
</thead>
<tbody>
<tr>
<td>hap-predefined</td>
<td>Created</td>
<td>2021-07-13T21:32:21Z</td>
</tr>
</tbody>
</table>

Use the following command to check the status of your HostingAutoscalingPolicy (HAP).

```
kubectl get hap <job-name>
```

One of the following values is returned:

- Reconciling – Certain types of errors show the status as Reconciling instead of Error. Some examples are server-side errors and endpoints in the Creating or Updating state. Check the Additional field in status or operator logs for more details.
- Created
- Error

To view the autoscaling endpoint to which you applied the policy

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the left side panel, expand Inference.
3. Choose Endpoints.
4. Select the name of the endpoint of interest.
5. Scroll to the **Endpoint runtime settings** section.

**Describe a HostingAutoscalingPolicy**

Use the following command to get more details about a HostingAutoscalingPolicy (HAP). These commands are typically used for debugging a problem or checking the resource IDs (endpoint name and variant name combinations) of a HAP.

```
kubectl describe hap <job-name>
```

**Update a HostingAutoscalingPolicy**

The HostingAutoscalingPolicy (HAP) operator supports updates. You can edit your YAML spec to change the values and then reapply the policy. The HAP operator deletes the existing policy and applies the new policy.

**Delete a HostingAutoscalingPolicy**

Use one of the following commands to delete a HostingAutoscalingPolicy (HAP) policy.

For cluster-scoped installation:

```
kubectl delete hap hap-predefined
```

For namespace-scoped installation:

```
kubectl delete hap hap-predefined -n <NAMESPACE>
```

This command deletes the scaling policy and deregisters the scaling target from Kubernetes. This command returns the following output:

```
hostingautoscalingpolicies.sagemaker.aws.amazon.com "hap-predefined" deleted
```

**Update or delete an endpoint with a HostingAutoscalingPolicy**

To update an endpoint that has a HostingAutoscalingPolicy (HAP), use the `kubectl delete` command to remove the HAP, update the endpoint, and then reapply the HAP.

To delete an endpoint that has a HAP, use the `kubectl delete` command to remove the HAP before you delete the endpoint.

**Migrate resources to the latest Operators**

We are stopping the development and technical support of the original version of [SageMaker Operators for Kubernetes](https://docs.aws.amazon.com/sagemaker/latest/dg/ops-operators.html).

If you are currently using version v1.2.2 or below of [SageMaker Operators for Kubernetes](https://docs.aws.amazon.com/sagemaker/latest/dg/ops-operators.html), we recommend migrating your resources to the [ACK service controller for Amazon SageMaker](https://docs.aws.amazon.com/sagemaker/latest/dg/ops-operators.html). The ACK service controller is a new generation of SageMaker Operators for Kubernetes based on [AWS Controllers for Kubernetes (ACK)](https://docs.aws.amazon.com/sagemaker/latest/dg/ops-operators.html).

For answers to frequently asked questions on the end of support of the original version of SageMaker Operators for Kubernetes, see [Announcing the End of Support of the Original Version of SageMaker Operators for Kubernetes](https://docs.aws.amazon.com/sagemaker/latest/dg/ops-operators.html).

Use the following steps to migrate your resources and use ACK to train, tune, and deploy machine learning models with Amazon SageMaker.
The latest SageMaker Operators for Kubernetes are not backwards compatible.

Contents

- Prerequisites (p. 2927)
- Adopt resources (p. 2927)
- Clean up old resources (p. 2928)
- Use the new SageMaker Operators for Kubernetes (p. 2929)

Prerequisites

To successfully migrate resources to the latest SageMaker Operators for Kubernetes, you must do the following:

2. If you are using HostingAutoscalingPolicy resources (p. 2928), install the new Application Auto Scaling Operators. See Setup in Scale SageMaker Workloads with Application Auto Scaling for step-by-step instructions. This step is optional if you are not using HostingAutoScalingPolicy resources.

If permissions are configured correctly, then the ACK SageMaker service controller can determine the specification and status of the AWS resource and reconcile the resource as if the ACK controller originally created it.

Adopt resources

The new SageMaker Operators for Kubernetes provide the ability to adopt resources that were not originally created by the ACK service controller. For more information, see Adopt Existing AWS Resources in the ACK documentation.

The following steps show how the new SageMaker Operators for Kubernetes can adopt an existing SageMaker endpoint. Save the following sample to a file named adopt-endpoint-sample.yaml.

```yaml
apiVersion: services.k8s.aws/v1alpha1
kind: AdoptedResource
metadata:
  name: adopt-endpoint-sample
spec:
  aws:
    # resource to adopt, not created by ACK
    nameOrID: xgboost-endpoint
  kubernetes:
    group: sagemaker.services.k8s.aws
    kind: Endpoint
    metadata:
      # target K8s CR name
      name: xgboost-endpoint
```

Submit the custom resource (CR) using kubectl apply:

```
kubectl apply -f adopt-endpoint-sample.yaml
```

Use kubectl describe to check the status conditions of your adopted resource.

```
kubectl describe adoptedresource adopt-endpoint-sample
```
Verify that the ACK.Adopted condition is True. The output should look similar to the following example:

```yaml
---
kind: AdoptedResource
metadata:
  annotations:
    kubectl.kubernetes.io/last-applied-configuration: |
      "apiVersion": "services.k8s.aws/v1alpha1",
      "kind": "AdoptedResource",
      "metadata": {
        "annotations": {},
        "name": "xgboost-endpoint",
        "namespace": "default",
        "spec": {
          "aws": {
            "nameOrID": "xgboost-endpoint",
            "kubernetes": {
              "group": "sagemaker.services.k8s.aws",
              "kind": "Endpoint",
              "metadata": {
                "name": "xgboost-endpoint"
              }
            }
          }
        }
      }
crea..." # Removed for brevity

---
```

Check that your resource exists in your cluster:

```
kubectl describe endpoints.sagemaker xgboost-endpoint
```

**HostingAutoscalingPolicy resources**

The HostingAutoscalingPolicy (HAP) resource consists of multiple Application Auto Scaling resources: ScalableTarget and ScalingPolicy. When adopting a HAP resource with ACK, first install the Application Auto Scaling controller. To adopt HAP resources, you need to adopt both ScalableTarget and ScalingPolicy resources. You can find the resource identifier for these resources in the status of the HostingAutoscalingPolicy resource (status.ResourceIDList).

**HostingDeployment resources**

The HostingDeployment resource consists of multiple SageMaker resources: Endpoint, EndpointConfig, and each Model. If you adopt a SageMaker endpoint in ACK, you need to adopt the Endpoint, EndpointConfig, and each Model separately. The Endpoint, EndpointConfig, and Model names can be found in status of the HostingDeployment resource (status.endpointName, status.endpointConfigName, and status.modelNames).

For a list of all supported SageMaker resources, refer to the [ACK API Reference](#).

**Clean up old resources**

After the new SageMaker Operators for Kubernetes adopt your resources, you can uninstall old operators and clean up old resources.
Step 1: Uninstall the old operator

To uninstall the old operator, see Delete operators (p. 2898).

**Warning**
Uninstall the old operator before deleting any old resources.

Step 2: Remove finalizers and delete old resources

**Warning**
Before deleting old resources, be sure that you have uninstalled the old operator.

After uninstalling the old operator, you must explicitly remove the finalizers to delete old operator resources. The following sample script shows how to delete all training jobs managed by the old operator in a given namespace. You can use a similar pattern to delete additional resources once they are adopted by the new operator.

**Note**
You must use full resource names to get resources. For example, use `kubectl get trainingjobs.sagemaker.aws.amazon.com` instead of `kubectl get trainingjob`.

```bash
namespace=\$\{sagemaker\_namespace\n
training\_jobs=\$(kubectl get trainingjobs.sagemaker.aws.amazon.com -n $namespace -ojson | jq -x ".items | .[] | .metadata.name")

for job in $training_jobs
do
  echo "Deleting $job resource in $namespace namespace"
  kubectl patch trainingjobs.sagemaker.aws.amazon.com $job -n $namespace -p '{"metadata": {"finalizers":null}}' --type=merge
  kubectl delete trainingjobs.sagemaker.aws.amazon.com $job -n $namespace
done
```

Use the new SageMaker Operators for Kubernetes

For in-depth guides on using the new SageMaker Operators for Kubernetes, see Use SageMaker Operators for Kubernetes (p. 2888)

Announcing the End of Support of the Original Version of SageMaker Operators for Kubernetes

This page announces the end of support for the original version of SageMaker Operators for Kubernetes and provides answers to frequently asked questions as well as migration information about the ACK service controller for Amazon SageMaker, a new generation of fully supported SageMaker Operators for Kubernetes. For general information about the new SageMaker Operators for Kubernetes, see Latest SageMaker Operators for Kubernetes (p. 2887).

End of Support Frequently Asked Questions

**Contents**

- Why are we ending support for the original version of SageMaker Operators for Kubernetes? (p. 2930)
- Where can I find more information about the new SageMaker Operators for Kubernetes and ACK? (p. 2930)
- What does end of support (EOS) mean? (p. 2930)
- How can I migrate my workload to the new SageMaker Operators for Kubernetes for training and inference? (p. 2930)
- Which version of ACK should I migrate to? (p. 2930)
• Are the initial SageMaker Operators for Kubernetes and the new Operators (ACK service controller for Amazon SageMaker) functionally equivalent? (p. 2930)

Why are we ending support for the original version of SageMaker Operators for Kubernetes?

Users can now take advantage of the ACK service controller for Amazon SageMaker. The ACK service controller is a new generation of SageMaker Operators for Kubernetes based on AWS Controllers for Kubernetes (ACK), a community-driven project optimized for production, standardizing the way to expose AWS services via a Kubernetes operator. We are therefore announcing the end of support (EOS) for the original version (not ACK-based) of SageMaker Operators for Kubernetes. The support ends on Feb 15, 2023 along with Amazon Elastic Kubernetes Service Kubernetes 1.21.

For more information on ACK, see ACK history and tenets.

Where can I find more information about the new SageMaker Operators for Kubernetes and ACK?

• For more information about the new SageMaker Operators for Kubernetes, see the ACK service controller for Amazon SageMaker GitHub repository or read AWS Controllers for Kubernetes Documentation.
• For a tutorial on how to train a machine learning model with the ACK service controller for Amazon SageMaker using Amazon EKS, see this SageMaker example.
  
  For an autoscaling example, see Scale SageMaker Workloads with Application Auto Scaling.
• For information on AWS Controller for Kubernetes (ACK), see the AWS Controllers for Kubernetes (ACK) documentation.
• For a list of supported SageMaker resources, see ACK API Reference.

What does end of support (EOS) mean?

While users can continue to use their current operators, we are no longer developing new features for the operators, nor will we release any patches or security updates for any issues found. v1.2.2 is the last release of SageMaker Operators for Kubernetes. Users should migrate their workloads to use the ACK service controller for Amazon SageMaker.

How can I migrate my workload to the new SageMaker Operators for Kubernetes for training and inference?

For information about migrating resources from the old to the new SageMaker Operators for Kubernetes, follow Migrate resources to the latest Operators (p. 2926).

Which version of ACK should I migrate to?

Users should migrate to the most recent released version of the ACK service controller for Amazon SageMaker.

Are the initial SageMaker Operators for Kubernetes and the new Operators (ACK service controller for Amazon SageMaker) functionally equivalent?

Yes, they are at feature parity.

A few highlights of the main notable differences between the two versions include:

• The Custom Resources Definitions (CRD) used by the ACK-based SageMaker Operators for Kubernetes follow the AWS API definition making it incompatible with the custom resources specifications from
the SageMaker Operators for Kubernetes in its original version. Refer to the CRDs in the new controller or use the migration guide to adopt the resources and use the new controller.

- The Hosting Autoscaling policy is no longer part of the new SageMaker Operators for Kubernetes and has been migrated to the Application autoscaling ACK controller. To learn how to use the application autoscaling controller to configure autoscaling on SageMaker Endpoints, follow this autoscaling example.
- The HostingDeployment resource was used to create Models, Endpoint Configurations, and Endpoints in one CRD. The new SageMaker Operators for Kubernetes has a separate CRD for each of these resources.

**SageMaker Components for Kubeflow Pipelines**

This document outlines how to use SageMaker Components for Kubeflow Pipelines. With these pipeline components, you can create and monitor native SageMaker training, tuning, endpoint deployment, and batch transform jobs from your Kubeflow Pipelines. By running Kubeflow Pipeline jobs on SageMaker, you move data processing and training jobs from the Kubernetes cluster to SageMaker's machine learning-optimized managed service. This document assumes prior knowledge of Kubernetes and Kubeflow.

Contents
- What are Kubeflow Pipelines? (p. 2931)
- What are Kubeflow Pipeline components? (p. 2931)
- Why use SageMaker Components for Kubeflow Pipelines? (p. 2932)
- SageMaker Components for Kubeflow Pipelines versions (p. 2932)
- List of SageMaker Components for Kubeflow Pipelines (p. 2933)
- IAM permissions (p. 2935)
- Converting pipelines to use SageMaker (p. 2936)
- Install Kubeflow Pipelines (p. 2936)
- Use SageMaker components (p. 2943)

**What are Kubeflow Pipelines?**

Kubeflow Pipelines (KFP) is a platform for building and deploying portable, scalable machine learning (ML) workflows based on Docker containers. The Kubeflow Pipelines platform consists of the following:

- A user interface (UI) for managing and tracking experiments, jobs, and runs.
- An engine (Argo) for scheduling multi-step ML workflows.
- An SDK for defining and manipulating pipelines and components.
- Notebooks for interacting with the system using the SDK.

A pipeline is a description of an ML workflow expressed as a directed acyclic graph. Every step in the workflow is expressed as a Kubeflow Pipeline component, which is a AWS SDK for Python (Boto3) module.

For more information on Kubeflow Pipelines, see the Kubeflow Pipelines documentation.

**What are Kubeflow Pipeline components?**

A Kubeflow Pipeline component is a set of code used to execute one step of a Kubeflow pipeline. Components are represented by a Python module built into a Docker image. When the pipeline runs, the component's container is instantiated on one of the worker nodes on the Kubernetes cluster.
running Kubeflow, and your logic is executed. Pipeline components can read outputs from the previous components and create outputs that the next component in the pipeline can consume. These components make it fast and easy to write pipelines for experimentation and production environments without having to interact with the underlying Kubernetes infrastructure.

You can use SageMaker Components in your Kubeflow pipeline. Rather than encapsulating your logic in a custom container, you simply load the components and describe your pipeline using the Kubeflow Pipelines SDK. When the pipeline runs, your instructions are translated into a SageMaker job or deployment. The workload then runs on the fully managed infrastructure of SageMaker.

**Why use SageMaker Components for Kubeflow Pipelines?**

SageMaker Components for Kubeflow Pipelines offer an alternative to launching your compute-intensive jobs from SageMaker. The components integrate SageMaker with the portability and orchestration of Kubeflow Pipelines. Using the SageMaker Components for Kubeflow Pipelines, you can create and monitor your SageMaker resources as part of a Kubeflow Pipelines workflow. Each of the jobs in your pipelines runs on SageMaker instead of the local Kubernetes cluster allowing you to take advantage of key SageMaker features such as data labeling, large-scale hyperparameter tuning and distributed training jobs, or one-click secure and scalable model deployment. The job parameters, status, logs, and outputs from SageMaker are still accessible from the Kubeflow Pipelines UI.

The SageMaker components integrate key SageMaker features into your ML workflows from preparing data, to building, training, and deploying ML models. You can create a Kubeflow Pipeline built entirely using these components, or integrate individual components into your workflow as needed. The components are available in one or two versions. Each version of a component leverages a different backend. For more information on those versions, see [SageMaker Components for Kubeflow Pipelines versions](p. 2932).

There is no additional charge for using SageMaker Components for Kubeflow Pipelines. You incur charges for any SageMaker resources you use through these components.

**SageMaker Components for Kubeflow Pipelines versions**

SageMaker Components for Kubeflow Pipelines come in two versions. Each version leverages a different backend to create and manage resources on SageMaker.

- The SageMaker Components for Kubeflow Pipelines version 1 (v1.x or below) use Boto3 (AWS SDK for Python (Boto3)) as backend.
- The version 2 (v2.0.0-alpha2 and above) of SageMaker Components for Kubeflow Pipelines use SageMaker Operator for Kubernetes (ACK).

AWS introduced ACK to facilitate a Kubernetes-native way of managing AWS Cloud resources. ACK includes a set of AWS service-specific controllers, one of which is the SageMaker controller. The SageMaker controller makes it easier for machine learning developers and data scientists using Kubernetes as their control plane to train, tune, and deploy machine learning (ML) models in SageMaker. For more information, see [SageMaker Operators for Kubernetes](p. 2932).

Both versions of the SageMaker Components for Kubeflow Pipelines are supported. However, the version 2 provides some additional advantages. In particular, it offers:

1. A consistent experience to manage your SageMaker resources from any application; whether you are using Kubeflow pipelines, or Kubernetes CLI (kubectl) or other Kubeflow applications such as Notebooks.
2. The flexibility to manage and monitor your SageMaker resources outside of the Kubeflow pipeline workflow.
3. Zero setup time to use the SageMaker components if you deployed the full [Kubeflow on AWS](p. 2932) release since the SageMaker Operator is part of its deployment.
List of SageMaker Components for Kubeflow Pipelines

The following is a list of all SageMaker Components for Kubeflow Pipelines and their available versions. Alternatively, you can find all SageMaker Components for Kubeflow Pipelines in GitHub.

Note
We encourage users to utilize Version 2 of a SageMaker component wherever it is available.

Ground Truth components

• Ground Truth

The Ground Truth component enables you to submit SageMaker Ground Truth labeling jobs directly from a Kubeflow Pipelines workflow.

<table>
<thead>
<tr>
<th>Version 1 of the component</th>
<th>Version 2 of the component</th>
</tr>
</thead>
<tbody>
<tr>
<td>SageMaker Ground Truth Kubeflow Pipelines component version 1</td>
<td>X</td>
</tr>
</tbody>
</table>

• Workteam

The Workteam component enables you to create SageMaker private workteam jobs directly from a Kubeflow Pipelines workflow.

<table>
<thead>
<tr>
<th>Version 1 of the component</th>
<th>Version 2 of the component</th>
</tr>
</thead>
<tbody>
<tr>
<td>SageMaker create private workteam Kubeflow Pipelines component version 1</td>
<td>X</td>
</tr>
</tbody>
</table>

Data processing components

• Processing

The Processing component enables you to submit processing jobs to SageMaker directly from a Kubeflow Pipelines workflow.

<table>
<thead>
<tr>
<th>Version 1 of the component</th>
<th>Version 2 of the component</th>
</tr>
</thead>
<tbody>
<tr>
<td>SageMaker Processing Kubeflow Pipeline component version 1</td>
<td>X</td>
</tr>
</tbody>
</table>

Training components

• Training

The Training component allows you to submit SageMaker Training jobs directly from a Kubeflow Pipelines workflow.

<table>
<thead>
<tr>
<th>Version 1 of the component</th>
<th>Version 2 of the component</th>
</tr>
</thead>
<tbody>
<tr>
<td>SageMaker Training Kubeflow Pipelines component version 1</td>
<td>SageMaker Training Kubeflow Pipelines component version 2</td>
</tr>
</tbody>
</table>

• Hyperparameter Optimization
The Hyperparameter Optimization component enables you to submit hyperparameter tuning jobs to SageMaker directly from a Kubeflow Pipelines workflow.

<table>
<thead>
<tr>
<th>Version 1 of the component</th>
<th>Version 2 of the component</th>
</tr>
</thead>
<tbody>
<tr>
<td>SageMaker hyperparameter optimization</td>
<td>X</td>
</tr>
<tr>
<td>Kubeflow Pipeline component version 1</td>
<td></td>
</tr>
</tbody>
</table>

Inference components

- **Hosting Deploy**

The Hosting components allow you to deploy a model using SageMaker hosting services from a Kubeflow Pipelines workflow.

<table>
<thead>
<tr>
<th>Version 1 of the component</th>
<th>Version 2 of the component</th>
</tr>
</thead>
<tbody>
<tr>
<td>SageMaker Hosting Services - Create Endpoint</td>
<td>Version 2 of the Hosting components consists of</td>

<tr>
<td></td>
<td>component version 2 responsible for creating</td>
</tr>
<tr>
<td></td>
<td>or updating the endpoint on SageMaker as</td>
</tr>
<tr>
<td></td>
<td>specified in the endpoint configuration.</td>
</tr>
</tbody>
</table>

- **Batch Transform**

The Batch Transform component allows you to run inference jobs for an entire dataset in SageMaker from a Kubeflow Pipelines workflow.

<table>
<thead>
<tr>
<th>Version 1 of the component</th>
<th>Version 2 of the component</th>
</tr>
</thead>
<tbody>
<tr>
<td>SageMaker Batch Transform Kubeflow Pipeline</td>
<td>X</td>
</tr>
<tr>
<td>component version 1</td>
<td></td>
</tr>
</tbody>
</table>

- **Model Monitor**

The Model Monitor components allow you to monitor the quality of SageMaker machine learning models in production from a Kubeflow Pipelines workflow.
The Model Monitor components consist of four sub-components for monitoring drift in a model.

- A SageMaker Data Quality Job Definition Kubeflow Pipelines component version 2 responsible for monitoring drift in data quality.
- A SageMaker Model Quality Job Definition Kubeflow Pipelines component version 2 responsible for monitoring drift in model quality metrics.
- A SageMaker Model Bias Job Definition Kubeflow Pipelines component version 2 responsible for monitoring bias in a model’s predictions.
- A SageMaker Model Explainability Job Definition Kubeflow Pipelines component version 2 responsible for monitoring drift in feature attribution.

Additionally, for on-schedule monitoring at a specified frequency, a fifth component, SageMaker Monitoring Schedule Kubeflow Pipelines component version 2, is responsible for monitoring the data collected from a real-time endpoint on a schedule.

For more information on Amazon SageMaker Model Monitor, see Monitor data and model quality (p. 3051).

### IAM permissions

Deploying Kubeflow Pipelines with SageMaker components requires the following three layers of authentication:

- An IAM role granting your gateway node (which can be your local machine or a remote instance) access to the Amazon Elastic Kubernetes Service (Amazon EKS) cluster.

The user accessing the gateway node assumes this role to:

- Create an Amazon EKS cluster and install KFP
- Create IAM roles
- Create Amazon S3 buckets for your sample input data

The role requires the following permissions:

- CloudWatchLogsFullAccess
- AWSCloudFormationFullAccess
- IAMFullAccess
- AmazonS3FullAccess
- AmazonEC2FullAccess
- AmazonEKSAdminPolicy (Create this policy using the schema from Amazon EKS Identity-Based Policy Examples)
A Kubernetes IAM execution role assumed by Kubernetes pipeline pods (kfp-example-pod-role) or the SageMaker Operator for Kubernetes controller pod to access SageMaker. This role is used to create and monitor SageMaker jobs from Kubernetes.

The role requires the following permission:
- AmazonSageMakerFullAccess

You can limit permissions to the KFP and controller pods by creating and attaching your own custom policy.

A SageMaker IAM execution role assumed by SageMaker jobs to access AWS resources such as Amazon S3 or Amazon ECR (kfp-example-sagemaker-execution-role).

SageMaker jobs use this role to:
- Access SageMaker resources
- Input Data from Amazon S3
- Store your output model to Amazon S3

The role requires the following permissions:
- AmazonSageMakerFullAccess
- AmazonS3FullAccess

Converting pipelines to use SageMaker

You can convert an existing pipeline to use SageMaker by porting your generic Python processing containers and training containers. If you are using SageMaker for inference, you also need to attach IAM permissions to your cluster and convert an artifact to a model.

Install Kubeflow Pipelines

Kubeflow Pipelines (KFP) is the pipeline orchestration component of Kubeflow.

You can deploy Kubeflow Pipelines (KFP) on an existing Amazon Elastic Kubernetes Service (Amazon EKS) or create a new Amazon EKS cluster. Use a gateway node to interact with your cluster. The gateway node can be your local machine or an Amazon EC2 instance.

The following section guides you through the steps to set up and configure these resources.

Topics
- Choose an installation option (p. 2936)
- Configure your pipeline permissions to access SageMaker (p. 2939)
- Access the KFP UI (Kubeflow Dashboard) (p. 2941)

Choose an installation option

Kubeflow Pipelines is available as a core component of the full distribution of Kubeflow on AWS or as a standalone installation.

Select the option that applies to your use case:

1. Full Kubeflow on AWS Deployment (p. 2937)
   To use other Kubeflow components in addition to Kubeflow Pipelines, choose the full AWS distribution of Kubeflow deployment.
2. Standalone Kubeflow Pipelines Deployment (p. 2937)
   To use the Kubeflow Pipelines without the other components of Kubeflow, install Kubeflow pipelines standalone.
Full Kubeflow on AWS Deployment

To install the full release of Kubeflow on AWS, choose the vanilla deployment option from [Kubeflow on AWS deployment guide](#) or any other deployment option supporting integrations with various AWS services (Amazon S3, Amazon RDS, Amazon Cognito).

Standalone Kubeflow Pipelines Deployment

This section assumes that your user has permissions to create roles and define policies for the role.

Set up a gateway node

You can use your local machine or an Amazon EC2 instance as your gateway node. A gateway node is used to create an Amazon EKS cluster and access the Kubeflow Pipelines UI.

Complete the following steps to set up your node.

1. **Create a gateway node.**
   
   You can use an existing Amazon EC2 instance or create a new instance with the latest Ubuntu 18.04 DLAMI version using the steps in [Launching and Configuring a DLAMI](#).

2. **Create an IAM role to grant your gateway node access to AWS resources.**
   
   Create an IAM role with permissions to the following resources: CloudWatch, AWS CloudFormation, IAM, Amazon EC2, Amazon S3, Amazon EKS.

   Attach the following policies to the IAM role:
   
   - CloudWatchLogsFullAccess
   - AWSCloudFormationFullAccess
   - IAMFullAccess
   - AmazonS3FullAccess
   - AmazonEC2FullAccess
   - AmazonEKSAdminPolicy (Create this policy using the schema from [Amazon EKS Identity-Based Policy Examples](#))

   For information on adding IAM permissions to an IAM role, see [Adding and removing IAM identity permissions](#).

3. **Install the following tools and clients**
   
   Install and configure the following tools and resources on your gateway node to access the Amazon EKS cluster and KFP User Interface (UI).

   - [AWS CLI](#): The command line tool for working with AWS services. For AWS CLI configuration information, see [Configuring the AWS CLI](#).
   - `aws-iam-authenticator` version 0.1.31 and above: A tool to use AWS IAM credentials to authenticate to a Kubernetes cluster.
   - `eksctl` version above 0.15: The command line tool for working with Amazon EKS clusters.
   - `kubectl`: The command line tool for working with Kubernetes clusters. The version needs to match your Kubernetes version within one minor version.
   - [AWS SDK for Python (Boto3)](#): 

   ```
   pip install boto3
   ```
Set up an Amazon EKS cluster

1. If you do not have an existing Amazon EKS cluster, run the following steps from the command line of your gateway node, skip this step otherwise.
   a. Run the following command to create an Amazon EKS cluster with version 1.17 or above. Replace `<clustername>` with any name for your cluster.

   ```
   eksctl create cluster --name <clustername> --region us-east-1 --auto-kubeconfig --timeout=50m --managed --nodes=1
   ```

   b. When the cluster creation is complete, ensure that you have access to your cluster by listing the cluster's nodes.

   ```
   kubectl get nodes
   ```

2. Ensure that the current `kubectl` context points to your cluster with the following command. The current context is marked with an asterisk (*) in the output.

   ```
   kubectl config get-contexts
   ```

   CURRENT NAME     CLUSTER
   *  <username>@<clustername>.us-east-1.eksctl.io  <clustername>.us-east-1.eksctl.io

3. If the desired cluster is not configured as your current default, update the default with the following command.

   ```
   aws eks update-kubeconfig --name <clustername> --region us-east-1
   ```

Install Kubeflow Pipelines

Run the following steps from the terminal of your gateway node to install Kubeflow Pipelines on your cluster.

1. Install all cert-manager components.

   ```
   kubectl apply -f https://github.com/cert-manager/cert-manager/releases/download/v1.9.1/cert-manager.yaml
   ```

2. Install the Kubeflow Pipelines.

   ```
   export PIPELINE_VERSION=2.0.0-alpha.5
   kubectl apply -k "github.com/kubeflow/pipelines/manifests/kustomize/env/cert-manager/cluster-scoped-resources?ref=$KFP_VERSION"
   kubectl wait --for condition=established --timeout=60s crd/applications.app.k8s.io
   kubectl apply -k "github.com/kubeflow/pipelines/manifests/kustomize/env/cert-manager/dev?ref=$KFP_VERSION"
   ```

3. Ensure that the Kubeflow Pipelines service and other related resources are running.

   ```
   kubectl -n kubeflow get all | grep pipeline
   ```

Your output should look like the following.

``` plain
pod/ml-pipeline-6b88c67994-kdtjv          1/1     Running     0
2d
```
Configure your pipeline permissions to access SageMaker

In this section, you create an IAM execution role granting Kubeflow Pipeline pods access to SageMaker services.

Configuration for SageMaker components version 2

To run SageMaker Components version 2 for Kubeflow Pipelines, you need to install SageMaker Operator for Kubernetes and configure Role-Based Access Control (RBAC) allowing the Kubeflow Pipelines pods to create SageMaker custom resources in your Kubernetes cluster.

Important

Follow this section if you are using Kubeflow pipelines standalone deployment. If you are using AWS distribution of Kubeflow version 1.6.0-aws-b1.0.0 or above, SageMaker components version 2 are already set up.

   Follow the Setup section of Machine Learning with ACK SageMaker Controller tutorial.

2. Configure RBAC permissions for the execution role (service account) used by Kubeflow Pipelines pods. In Kubeflow Pipelines standalone deployment, pipeline runs are executed in the namespace kubeflow using the pipeline-runner service account.

   a. Create a RoleBinding that gives the service account permission to manage SageMaker custom resources.

      ```
cat > manage_sagemaker_cr.yaml <<EOF
```
Configuration for SageMaker components version 1

To run SageMaker Components version 1 for Kubeflow Pipelines, the Kubeflow Pipeline pods need access to SageMaker.

**Important**
Follow this section whether you are using the full Kubeflow on AWS deployment or Kubeflow Pipelines standalone.

To create an IAM execution role granting Kubeflow pipeline pods access to SageMaker, follow those steps:

1. Export your cluster name (e.g., *my-cluster-name*) and cluster region (e.g., *us-east-1*).

```bash
export CLUSTER_NAME=your-cluster-name
export CLUSTER_REGION=us-east-1
```

2. Export the namespace and service account name according to your installation.
   • For the full Kubeflow on AWS installation, export your profile namespace (e.g., *kubeflow-user-example-com*) and *default-editor* as the service account.

```bash
export NAMESPACE=kubeflow-user-example-com
export KUBEFLOW_PIPELINE_POD_SERVICE_ACCOUNT=default-editor
```

   • For the standalone Pipelines deployment, export *kubeflow* as the namespace and *pipeline-runner* as the service account.

```bash
export NAMESPACE=kubeflow
export KUBEFLOW_PIPELINE_POD_SERVICE_ACCOUNT=pipeline-runner
```

3. Create an IAM OIDC provider for the Amazon EKS cluster with the following command.

```bash
eksctl utils associate-iam-oidc-provider --cluster ${CLUSTER_NAME} --region ${CLUSTER_REGION} --approve
```

4. Create an IAM execution role for the KFP pods to access AWS services (SageMaker, CloudWatch).
Once your pipeline permissions are configured to access SageMaker Components version 1, follow the SageMaker components for Kubeflow pipelines guide on the [Kubeflow on AWS documentation](https://docs.aws.amazon.com/kubeflow/user-guide/). Access the KFP UI (Kubeflow Dashboard)

The Kubeflow Pipelines UI is used for managing and tracking experiments, jobs, and runs on your cluster. For instructions on how to access the Kubeflow Pipelines UI from your gateway node, follow the steps that apply to your deployment option in this section.

**Full Kubeflow on AWS Deployment**

Follow the instructions on the [Kubeflow on AWS website](https://docs.aws.amazon.com/kubeflow/user-guide/) to connect to the Kubeflow dashboard and navigate to the pipelines tab.

**Standalone Kubeflow Pipelines Deployment**

Use port forwarding to access the Kubeflow Pipelines UI from your gateway node by following those steps.

**Set up port forwarding to the KFP UI service**

Run the following command from the command line of your gateway node.

```
1. Verify that the KFP UI service is running using the following command.

   kubectl -n kubeflow get service ml-pipeline-ui

   NAME      TYPE          CLUSTER-IP          EXTERNAL-IP     PORT(S)   AGE
   ml-pipeline-ui ClusterIP   10.100.38.71 <none>         80/TCP     2d22h

2. Run the following command to set up port forwarding to the KFP UI service. This forwards the KFP UI to port 8080 on your gateway node and allows you to access the KFP UI from your browser.

   kubectl port-forward -n kubeflow service/ml-pipeline-ui 8080:80

   The port forward from your remote machine drops if there is no activity. Run this command again if your dashboard is unable to get logs or updates. If the commands return an error, ensure that there is no process already running on the port you are trying to use.

   **Access the KFP UI service**

   Your method of accessing the KFP UI depends on your gateway node type.

   - Local machine as the gateway node:

     1. Access the dashboard in your browser as follows:
2. Choose **Pipelines** to access the pipelines UI.

- Amazon EC2 instance as the gateway node:

  1. You need to set up an SSH tunnel on your Amazon EC2 instance to access the Kubeflow dashboard from your local machine's browser.

     From a new terminal session in your local machine, run the following. Replace `<public-DNS-of-gateway-node>` with the IP address of your instance found on the Amazon EC2 console. You can also use the public DNS. Replace `<path_to_key>` with the path to the pem key used to access the gateway node.

     ```
     public_DNS_address=<public-DNS-of-gateway-node>
     key=<path_to_key>
     on Ubuntu:
     ssh -i ${key} -L 9000:localhost:8080 ubuntu@$public_DNS_address
     or on Amazon Linux:
     ssh -i ${key} -L 9000:localhost:8080 ec2-user@$public_DNS_address
     ```

     2. Access the dashboard in your browser.

     ```
     http://localhost:9000
     ```

     3. Choose **Pipelines** to access the KFP UI.

     *(Optional)* **Grant SageMaker notebook instances access to Amazon EKS, and run KFP pipelines from your notebook.**

     A SageMaker notebook instance is a fully managed Amazon EC2 compute instance that runs the Jupyter Notebook App. You can use a notebook instance to create and manage Jupyter notebooks then define, compile, deploy, and run your KFP pipelines using AWS SDK for Python (Boto3) or the KFP CLI.

     1. Follow the steps in [Create a SageMaker Notebook Instance](#) to create your notebook instance, then attach the S3FullAccess policy to its IAM execution role.

     2. From the command line of your gateway node, run the following command to retrieve the IAM role ARN of the notebook instance you created. Replace `<instance-name>` with the name of your instance.

        ```
        aws sagemaker describe-notebook-instance --notebook-instance-name <instance-name> --region <region> --output text --query 'RoleArn'
        ```

        This command outputs the IAM role ARN in the `arn:aws:iam::<account-id>::role/<role-name>` format. Take note of this ARN.

     3. Run this command to attach the following policies (AmazonSageMakerFullAccess, AmazonEKSWorkerNodePolicy, AmazonS3FullAccess) to this IAM role. Replace `<role-name>` with the `<role-name>` in your ARN.

        ```
        aws iam attach-role-policy --role-name <role-name> --policy-arn arn:aws:iam::aws:policy/AmazonSageMakerFullAccess
        aws iam attach-role-policy --role-name <role-name> --policy-arn arn:aws:iam::aws:policy/AmazonEKSWorkerNodePolicy
        ```
4. Amazon EKS clusters use IAM roles to control access to the cluster. The rules are implemented in a config map named aws-auth. `eksctl` provides commands to read and edit the aws-auth config map. Only the users that have access to the cluster can edit this config map.

   `system:masters` is one of the default user groups with super user permissions to the cluster. Add your user to this group or create a group with more restrictive permissions.

5. Bind the role to your cluster by running the following command. Replace `<IAM-Role-arn>` with the ARN of the IAM role. `<your_username>` can be any unique username.

   ```
   eksctl create iamidentitymapping \
   --cluster <cluster-name> \
   --arn <IAM-Role-arn> \
   --group system:masters \
   --username <your-username> \
   --region <region>
   ```

6. Open a Jupyter notebook on your SageMaker instance and run the following command to ensure that it has access to the cluster.

   ```
   aws eks --region <region> update-kubeconfig --name <cluster-name>
   kubectl -n kubeflow get all | grep pipeline
   ```

**Use SageMaker components**

In this tutorial, you run a pipeline using SageMaker Components for Kubeflow Pipelines to train a classification model using Kmeans with the MNIST dataset on SageMaker. The workflow uses Kubeflow Pipelines as the orchestrator and SageMaker to execute each step of the workflow. The example was taken from an existing SageMaker example and modified to work with SageMaker Components for Kubeflow Pipelines.

You can define your pipeline in Python using AWS SDK for Python (Boto3) then use the KFP dashboard, KFP CLI, or Boto3 to compile, deploy, and run your workflows. The full code for the MNIST classification pipeline example is available in the Kubeflow Github repository. To use it, clone the Python files to your gateway node.

You can find additional SageMaker Kubeflow Pipelines examples on GitHub. For information on the components used, see the Kubeflow Pipelines Github repository.

To run the classification pipeline example, create a SageMaker IAM execution role granting your training job the permission to access AWS resources, then continue with the steps that correspond to your deployment option.

**Create a SageMaker execution role**

The `kfp-example-sagemaker-execution-role` IAM role is a runtime role assumed by SageMaker jobs to access AWS resources. In the following command, you create an IAM execution role named `kfp-example-sagemaker-execution-role`, attach two managed policies (AmazonSageMakerFullAccess, AmazonS3FullAccess), and create a trust relationship with SageMaker to grant SageMaker jobs access to those AWS resources.

You provide this role as an input parameter when running the pipeline.

Run the following command to create the role. Note the ARN that is returned in your output.

```
SAGEMAKER_EXECUTION_ROLE_NAME=kfp-example-sagemaker-execution-role
```
aws iam create-role --role-name ${SAGEMAKER_EXECUTION_ROLE_NAME} --assume-role-policy-document "$TRUST"
aws iam attach-role-policy --role-name ${SAGEMAKER_EXECUTION_ROLE_NAME} --policy-arn arn:aws:iam::aws:policy/AmazonSageMakerFullAccess
aws iam attach-role-policy --role-name ${SAGEMAKER_EXECUTION_ROLE_NAME} --policy-arn arn:aws:iam::aws:policy/AmazonS3FullAccess
aws iam get-role --role-name ${SAGEMAKER_EXECUTION_ROLE_NAME} --output text --query 'Role.Arn'

Full Kubeflow on AWS Deployment

Follow the instructions of the SageMaker Training Pipeline tutorial for MNIST Classification with K-Means.

Standalone Kubeflow Pipelines Deployment

Prepare datasets

To run the pipelines, you need to upload the data extraction pre-processing script to an Amazon S3 bucket. This bucket and all resources for this example must be located in the us-east-1 region. For information on creating a bucket, see Creating a bucket.

From the mnist-kmeans-sagemaker folder of the Kubeflow repository you cloned on your gateway node, run the following command to upload the kmeans_preprocessing.py file to your Amazon S3 bucket. Change <bucket-name> to the name of your Amazon S3 bucket.

aws s3 cp mnist-kmeans-sagemaker/kmeans_preprocessing.py s3://<bucket-name>/mnist_kmeans_example/processing_code/kmeans_preprocessing.py

Compile and deploy your pipeline

After defining the pipeline, you must compile it to an intermediate representation before you submit it to the Kubeflow Pipelines service on your cluster. The intermediate representation is a workflow specification in the form of a YAML file compressed into a tar.gz file. You need the KFP SDK to compile your pipeline.

Install KFP SDK

Run the following from the command line of your gateway node:

1. Install the KFP SDK following the instructions in the Kubeflow pipelines documentation.
2. Verify that the KFP SDK is installed with the following command:

   pip show kfp

3. Verify that dsl-compile has been installed correctly as follows:

   which dsl-compile

Compile your pipeline

You have three options to interact with Kubeflow Pipelines: KFP UI, KFP CLI, or the KFP SDK. The following sections illustrate the workflow using the KFP UI and CLI.
Complete the following steps from your gateway node.

1. Modify your Python file with your Amazon S3 bucket name and IAM role ARN.
2. Use the `dsl-compile` command from the command line to compile your pipeline as follows.
   Replace `<path-to-python-file>` with the path to your pipeline and `<path-to-output>` with the location where you want your tar.gz file to be.

   ```bash
dsl-compile --py <path-to-python-file> --output <path-to-output>
   ```

Upload and run the pipeline using the KFP CLI

Complete the following steps from the command line of your gateway node. KFP organizes runs of your pipeline as experiments. You have the option to specify an experiment name. If you do not specify one, the run will be listed under **Default** experiment.

1. Upload your pipeline as follows:

   ```bash
kfp pipeline upload --pipeline-name <pipeline-name> <path-to-output-tar.gz>
   ```

   Your output should look like the following. Take note of the pipeline ID.

   ```text
   Pipeline 29c3ff21-49f5-4dfe-94f6-618c0e2420fe has been submitted
   Pipeline Details
   ------------------
   ID 29c3ff21-49f5-4dfe-94f6-618c0e2420fe
   Name sm-pipeline
   Description
   Uploaded at 2020-04-30T20:22:39+00:00
   ...
   ...
   ```

2. Create a run using the following command. The KFP CLI run command currently does not support specifying input parameters while creating the run. You need to update your parameters in the AWS SDK for Python (Boto3) pipeline file before compiling. Replace `<experiment-name>` and `<job-name>` with any names. Replace `<pipeline-id>` with the ID of your submitted pipeline. Replace `<your-role-arn>` with the ARN of kfp-example-pod-role. Replace `<your-bucket-name>` with the name of the Amazon S3 bucket you created.

   ```bash
   kfp run submit --experiment-name <experiment-name> --run-name <job-name> --pipeline-id <pipeline-id> role_arn="<your-role-arn>" bucket_name="<your-bucket-name>"
   ```

   You can also directly submit a run using the compiled pipeline package created as the output of the `dsl-compile` command.

   ```bash
   kfp run submit --experiment-name <experiment-name> --run-name <job-name> --package-file <path-to-output> role_arn="<your-role-arn>" bucket_name="<your-bucket-name>"
   ```

   Your output should look like the following:

   ```text
   Creating experiment aws.
   Run 95084a2c-f18d-4b77-a9da-eba00bf01e63 is submitted
   +--------------------------------------+--------+----------+---------------------------+------------------------+----------+----------+---------------------------+
   | run id | name | status | created at |
   |--------------------------------------+--------+----------+---------------------------+------------------------+----------+----------+---------------------------|
   ```
3. Navigate to the UI to check the progress of the job.

Upload and run the pipeline using the KFP UI

1. On the left panel, choose the **Pipelines** tab.
2. In the upper-right corner, choose **+UploadPipeline**.
3. Enter the pipeline name and description.
4. Choose **Upload a file** and enter the path to the tar.gz file you created using the CLI or with AWS SDK for Python (Boto3).
5. On the left panel, choose the **Pipelines** tab.
6. Find the pipeline you created.
7. Choose **+CreateRun**.
8. Enter your input parameters.
9. Choose **Run**.

Run predictions

Once your classification pipeline is deployed, you can run classification predictions against the endpoint that was created by the Deploy component. Use the KFP UI to check the output artifacts for sagemaker-deploy-model-endpoint_name. Download the .tgz file to extract the endpoint name or check the SageMaker console in the region you used.

Configure permissions to run predictions

If you want to run predictions from your gateway node, skip this section.

To use any other machine to run predictions, assign the **sagemaker:InvokeEndpoint** permission to the IAM role used by the client machine.

1. On your gateway node, run the following to create an IAM policy file:

   ```bash
   cat <<EoF > ./sagemaker-invoke.json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Action": [
           "sagemaker:InvokeEndpoint",
           "sagemaker:InvokeEndpoint"
         ],
         "Resource": "*"
       }
     ]
   }
   EoF
   
   2. Attach the policy to the IAM role of the client node.

      Run the following command. Replace `<your-instance-IAM-role>` with the name of the IAM role. Replace `<path-to-sagemaker-invoke-json>` with the path to the policy file you created.
Run predictions

1. Create a AWS SDK for Python (Boto3) file from your client machine named `mnist-predictions.py` with the following content. Replace the `ENDPOINT_NAME` variable. The script loads the MNIST dataset, creates a CSV from those digits, then sends the CSV to the endpoint for prediction and prints the results.

```python
import boto3
import gzip
import io
import json
import numpy
import pickle

ENDPOINT_NAME='<endpoint-name>'
region = boto3.Session().region_name

# S3 bucket where the original mnist data is downloaded and stored
downloaded_data_bucket = f'jumpstart-cache-prod-{region}'
download_data_prefix = 'ip-notebooks-datasets/mnist'

# Download the dataset
s3 = boto3.client("s3")
s3.download_file(downloaded_data_bucket, f'{download_data_prefix}/mnist.pkl.gz', 'mnist.pkl.gz')

# Load the dataset
with gzip.open('mnist.pkl.gz', 'rb') as f:
    train_set, valid_set, test_set = pickle.load(f, encoding='latin1')

# Simple function to create a csv from our numpy array
def np2csv(arr):
    csv = io.BytesIO()
    numpy.savetxt(csv, arr, delimiter=',', fmt='%.1f')
    return csv.getvalue().decode().rstrip()

runtime = boto3.Session(region).client('sagemaker-runtime')

payload = np2csv(train_set[0][30:31])
response = runtime.invoke_endpoint(EndpointName=ENDPOINT_NAME,
                                   ContentType='text/csv',
                                   Body=payload)
result = json.loads(response['Body'].read().decode())
print(result)
```

2. Run the AWS SDK for Python (Boto3) file as follows:

```
python mnist-predictions.py
```

View results and logs

When the pipeline is running, you can choose any component to check execution details, such as inputs and outputs. This lists the names of created resources.
If the KFP request is successfully processed and an SageMaker job is created, the component logs in the KFP UI provide a link to the job created in SageMaker. The CloudWatch logs are also provided if the job is successfully created.

If you run too many pipeline jobs on the same cluster, you may see an error message that indicates that you do not have enough pods available. To fix this, log in to your gateway node and delete the pods created by the pipelines you are not using:

```
kubectl get pods -n kubeflow
kubectl delete pods -n kubeflow <name-of-pipeline-pod>
```

**Cleanup**

When you're finished with your pipeline, you need to clean up your resources.

1. From the KFP dashboard, terminate your pipeline runs if they do not exit properly by choosing **Terminate**.
2. If the **Terminate** option doesn't work, log in to your gateway node and manually terminate all the pods created by your pipeline run as follows:

```
kubectl get pods -n kubeflow
kubectl delete pods -n kubeflow <name-of-pipeline-pod>
```

3. Using your AWS account, log in to the SageMaker service. Manually stop all training, batch transform, and HPO jobs. Delete models, data buckets, and endpoints to avoid incurring any additional costs. Terminating the pipeline runs does not stop the jobs in SageMaker.

**SageMaker Notebook Jobs**

You can use Amazon SageMaker to interactively build, train, and deploy machine learning models from your Jupyter notebook in any JupyterLab environment. However, there are various scenarios in which you might want to run your notebook as a noninteractive, scheduled job. For example, you might want to create regular audit reports that analyze all training jobs run over a certain time frame and analyze the business value of deploying those models into production. Or you might want to scale up a feature engineering job after testing the data transformation logic on a small subset of data. Other common use cases include:

- Scheduling jobs for model drift monitoring
- Exploring the parameter space for better models

In these scenarios, you can use SageMaker Notebook Jobs to create a noninteractive job to either run on demand or on a schedule. SageMaker Notebook Jobs provides an intuitive user interface so you can schedule your jobs right from JupyterLab by choosing the Notebook Jobs widget in your notebook. You can run multiple notebooks in parallel, and parameterize cells in your notebooks to customize the input parameters.

This feature leverages the Amazon EventBridge, SageMaker Training and SageMaker Pipelines services and is available for use in your Jupyter notebook in any of the following environments:

- SageMaker: Studio, Studio Lab, or Notebook Instances
- Local setup, such as your local machine, where you run JupyterLab

**Prerequisites**

To schedule a notebook job, make sure you meet the following criteria:
- Ensure your Jupyter notebook and any initialization or startup scripts are self-contained with respect to code and software packages. Otherwise, your noninteractive job may incur errors.

- Review [Constraints and considerations](p. 2972) to make sure you properly configured your Jupyter notebook, network settings, and container settings.

- Ensure your notebook can access needed external resources, such as Amazon EMR clusters.

- If you are setting up Notebook Jobs in a local Jupyter notebook, complete the installation. For instructions, see [Installation Guide](p. 2949).

- If you connect to an Amazon EMR cluster in your notebook and want to parameterize your Amazon EMR connection command, you must apply a workaround using environment variables to pass parameters. For details, see [Connect to an Amazon EMR cluster from your Studio notebook](p. 2967).

- If you connect to an Amazon EMR cluster using Kerberos, LDAP, or HTTP Basic Auth authentication, you must use the AWS Secrets Manager to pass your security credentials to your Amazon EMR connection command. For details, see [Connect to an Amazon EMR cluster from your Studio notebook](p. 2967).

- (optional) If you want the UI to preload a script to run upon notebook startup, your admin must install it with a Lifecycle Configuration (LCC). For information about how to use a LCC script, see [Customize a Notebook Instance Using a Lifecycle Configuration Script](p. 2967).

**Installation Guide**

The following discussion includes detailed instructions about additional installation you need to perform so you can use Notebook Jobs in your JupyterLab environment.

**For Amazon SageMaker Studio and Amazon SageMaker Studio Lab**

If your notebook is in Amazon SageMaker Studio or Amazon SageMaker Studio Lab, you don't need to perform additional installation—SageMaker Notebook Jobs is built into the platform. To set up required permissions for Studio, see [Install policies and permissions for Studio](p. 2950).

**For local Jupyter notebooks**

If you want to use SageMaker Notebook Jobs for your local JupyterLab environment, you need to perform additional installation.

To install SageMaker Notebook Jobs, complete the following steps:

1. Install Python 3. For details, see [Installing Python 3 and Python Packages](p. 2950).
2. Install JupyterLab version 3 or higher. For details, see [JupyterLab SDK documentation](p. 2950).
3. Install the AWS CLI. For details, see [Installing or updating the latest version of the AWS CLI](p. 2950).
4. Install two sets of permissions. The IAM user needs permissions to submit jobs to SageMaker, and once submitted, the notebook job itself assumes an IAM role that needs permissions to access resources depending on the job tasks.
   a. If you haven’t yet created an IAM user, see [Creating an IAM user in your AWS account](p. 2950).
   b. If you haven’t yet created your notebook job role, see [Creating a role to delegate permissions to an IAM user](p. 2950).
   c. Attach the necessary permissions and trust policy to attach to your user and role. For step-by-step instructions and permission details, see [Install policies and permissions for local Jupyter environments](p. 2954).
5. Generate AWS credentials for your newly-created IAM user and save them in the credentials file (~/.aws/credentials) of your JupyterLab environment. You can do this with the CLI command `aws configure`. For instructions, see section [Set and view configuration settings using commands](p. 2954) in [Configuration and credential file settings](p. 2954).
6. (optional) By default, the scheduler extension uses a pre-built SageMaker Docker image with Python 2.0. Any non-default kernel used in the notebook should be installed in the container. If you want to run your notebook in a container or Docker image, you need to create an Amazon Elastic Container...
Registry (Amazon ECR) image. For information about how to push a Docker image to an Amazon ECR, see `Pushing a Docker Image`.

7. Add the JupyterLab extension for SageMaker Notebook Jobs. You can add it to your JupyterLab environment with the command: `pip install amazon_sagemaker_jupyter_scheduler`. You may need to restart your Jupyter server with the command: `sudo systemctl restart jupyter-server`.

8. Start JupyterLab with the command: `jupyter lab`.

9. Verify that the Notebook Jobs widget (⌘) appears in your Jupyter notebook taskbar.

### Install policies and permissions for Studio

Before you schedule your first notebook run, make sure that you install the proper policies and permissions. The following instructions show you how to configure the following permissions:

- Job execution role trust relationships
- Additional IAM permissions attached to the job execution role
- (optional) The AWS KMS permission policy to use a custom KMS key

**Important**

If your AWS account belongs to an organization with service control policies (SCP) in place, your effective permissions are the logical intersection between what is allowed by the SCPs and what is allowed by your IAM role and user policies. For example, if your organization's SCP specifies that you can only access resources in `us-east-1` and `us-west-1`, and your policies only allow you to access resources in `us-west-1` and `us-west-2`, then ultimately you can only access resources in `us-west-1`. If you want to exercise all the permissions allowed in your role and user policies, your organization's SCPs should grant the same set of permissions as your own IAM user and role policies. For details about how to determine your allowed requests, see `Determining whether a request is allowed or denied within an account`.

### Trust relationships

To modify the trust relationships, complete the following steps:

1. Open the [IAM console](#).
2. Select **Roles** in the left panel.
3. Find the job execution role for your notebook job and choose the role name.
4. Choose the **Trust relationships** tab.
5. Choose **Edit trust policy**.
6. Copy and paste the following policy:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Principal": {
            "Service": "sagemaker.amazonaws.com"
         },
         "Action": "sts:AssumeRole"
      },
      {
         "Effect": "Allow",
         "Principal": {
            "Service": "events.amazonaws.com"
         },
         "Action": "sts:AssumeRole"
      }
   ]
}
```
Additional IAM permissions

You might need to include additional IAM permissions in the following situations:

- Your Studio execution and notebook job roles differ
- You need to access Amazon S3 resources through a S3 VPC endpoint
- You want to use a custom KMS key to encrypt your input and output Amazon S3 buckets

The following discussion provides the policies you need for each case.

Permissions needed if your Studio execution and notebook job roles differ

The following JSON snippet is an example policy that you should add to the Studio execution and notebook job roles if you don’t use the Studio execution role as the notebook job role. Review and modify this policy if you need to further restrict privileges.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":"iam:PassRole",
         "Resource":"arn:aws:iam::*:role/*",
         "Condition":{
            "StringLike":{
               "iam:PassedToService":[
                  "sagemaker.amazonaws.com",
                  "events.amazonaws.com"
               ]
            }
         }
      },
      {
         "Effect":"Allow",
         "Action":[
            "events:TagResource",
            "events:DeleteRule",
            "events:PutTargets",
            "events:DescribeRule",
            "events:PutRule",
            "events:RemoveTargets",
            "events:DisableRule",
            "events:EnableRule"
         ],
         "Resource":"
      },
      {
         "Effect":"Allow",
         "Action":[
            "s3:CreateBucket",
            "s3:PutBucketVersioning",
            "s3:GetObject"
         ],
         "Resource":"
      },
      {
         "Effect":"Allow",
         "Action":[
            "cloudwatch:PutMetricData",
            "cloudwatch:GetMetricData"
         ],
         "Resource":"
      }
   ]
}
```
"s3:PutEncryptionConfiguration"
],
"Resource": "arn:aws:s3:::sagemaker-automated-execution-*"
},
{
"Sid": "S3DriverAccess",
"Effect": "Allow",
"Action": [
"s3:ListBucket",
"s3:GetObject",
"s3:GetBucketLocation"
],

Permissions needed to access Amazon S3 resources through a S3 VPC endpoint

If you run SageMaker Studio in private VPC mode and access S3 through the S3 VPC endpoint, you can add permissions to the VPC endpoint policy to control which S3 resources are accessible through the VPC endpoint. Add the following permissions to your VPC endpoint policy. You can modify the policy if you need to further restrict permissions—for example, you can provide a more narrow specification for the Principal field.

```json
{  
    "Sid": "S3DriverAccess",  
    "Effect": "Allow",  
    "Principal": "*",  
    "Action": [  
        "s3:GetBucketLocation",  
        "s3:GetObject",  
        "s3:ListBucket"  
    ],  
    "Resource": "arn:aws:s3:::sagemakerheadlessexecution-*"
}
```

For details about how to set up a S3 VPC endpoint policy, see [Edit the VPC endpoint policy](#).

Permissions needed to use a custom KMS key (optional)

By default, the input and output Amazon S3 buckets are encrypted using server side encryption, but you can specify a custom KMS key to encrypt your data in the output Amazon S3 bucket and the storage volume attached to the notebook job.

If you want to use a custom KMS key, attach the following policy and supply your own KMS key ARN.

```json
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "kms:Encrypt",  
                "kms:Decrypt",  
                "kms:ReEncrypt\*",  
                "kms:GenerateDataKey\*",  
                "kms:DescribeKey",  
                "kms:CreateGrant"  
            ],  
            "Resource": "your_KMS_key_ARN"
        }
    ]
}
```
Install policies and permissions for local Jupyter environments

As previously stated, you install two sets of permissions—permissions for the IAM user and for the IAM role that the notebook job assumes. As shown in the following diagram, the IAM user needs to set up IAM permissions in order to submits jobs to SageMaker. Once the user submits the notebook job, the job itself assumes an IAM role that has permissions to access resources depending on the job tasks.

The following sections help you install necessary policies and permissions for both the IAM user and the job execution role.

IAM user permissions

Permissions to submit jobs to SageMaker

To add permissions to submit jobs, complete the following steps:

1. Open the IAM console.
2. Select Users in the left panel.
3. Find the IAM user for your notebook job and choose the user name.
4. Choose Add Permissions, and choose Create inline policy from the dropdown menu.
5. Choose the JSON tab.
6. Copy and paste the following policy:

```json
{
   "Version": "2012-10-17",
   "Statement": [
   {
```
"Sid": "EventBridgeSchedule",
"Effect": "Allow",
"Action": [
  "events:TagResource",
  "events:DeleteRule",
  "events:PutTargets",
  "events:DescribeRule",
  "events:EnableRule",
  "events:PutRule",
  "events:RemoveTargets",
  "events:DisableRule"
],
"Resource": "*",
"Condition": {
  "StringEquals": {
    "aws:ResourceTag/sagemaker:is-scheduling-notebook-job": "true"
  }
}
},
{
  "Sid": "IAMPassrole",
  "Effect": "Allow",
  "Action": "iam:PassRole",
  "Resource": "arn:aws:iam::*:role/*",
  "Condition": {
    "StringLike": {
      "iam:PassedToService": [
        "sagemaker.amazonaws.com",
        "events.amazonaws.com"
      ]
    }
  }
}
},
{
  "Sid": "IAMListRoles",
  "Effect": "Allow",
  "Action": "iam:ListRoles",
  "Resource": "*"
}
],
{
  "Sid": "S3ArtifactsAccess",
  "Effect": "Allow",
  "Action": [
    "s3:PutEncryptionConfiguration",
    "s3:CreateBucket",
    "s3:PutBucketVersioning",
    "s3:ListBucket",
    "s3:PutObject",
    "s3:GetObject",
    "s3:GetEncryptionConfiguration",
    "s3:DeleteObject",
    "s3:GetBucketLocation"
  ],
  "Resource": [
    "arn:aws:s3:::sagemaker-automated-execution-*"
  ]
}
},
{
  "Sid": "S3DriverAccess",
  "Effect": "Allow",
  "Action": [
    "s3:ListBucket",
    "s3:GetObject",
    "s3:GetBucketLocation"
  ],
  "Resource": [
    "arn:aws:s3:::sagemaker-automated-execution-*"
  ]
}
AWS KMS permission policy (optional)

By default, the input and output Amazon S3 buckets are encrypted using server side encryption, but you can specify a custom KMS key to encrypt your data in the output Amazon S3 bucket and the storage volume attached to the notebook job.

If you want to use a custom KMS key, repeat the previous instructions, attaching the following policy, and supply your own KMS key ARN.

```
{
  "Sid": "SagemakerJobs",
  "Effect": "Allow",
  "Action": [
    "sagemaker:DescribeTrainingJob",
    "sagemaker:StopTrainingJob",
    "sagemaker:DescribePipeline",
    "sagemaker:CreateTrainingJob",
    "sagemaker:DeletePipeline",
    "sagemaker:CreatePipeline"
  ],
  "Resource": "*",
  "Condition": {
    "StringEquals": {
      "aws:ResourceTag/sagemaker:is-scheduling-notebook-job": "true"
    }
  }
},
{
  "Sid": "AllowSearch",
  "Effect": "Allow",
  "Action": "sagemaker:Search",
  "Resource": "*"
},
{
  "Sid": "SagemakerTags",
  "Effect": "Allow",
  "Action": [
    "sagemaker:ListTags",
    "sagemaker:AddTags"
  ],
  "Resource": [
    "arn:aws:sagemaker:*:*:pipeline/*",
    "arn:aws:sagemaker:*:*:space/*",
    "arn:aws:sagemaker:*:*:training-job/*",
    "arn:aws:sagemaker:*:*:user-profile/*"
  ]
},
{
  "Sid": "ECRImage",
  "Effect": "Allow",
  "Action": [
    "ecr:GetAuthorizationToken",
    "ecr:BatchGetImage"
  ],
  "Resource": "*"
}
```
Job execution role permissions

Trust relationships

To modify the job execution role trust relationships, complete the following steps:

1. Open the IAM console.
2. Select Roles in the left panel.
3. Find the job execution role for your notebook job and choose the role name.
4. Choose the Trust relationships tab.
5. Choose Edit trust policy.
6. Copy and paste the following policy:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "kms:Encrypt",
            "kms:Decrypt",
            "kms:ReEncrypt*",
            "kms:GenerateDataKey*",
            "kms:DescribeKey",
            "kms:CreateGrant"
         ],
         "Resource": "your_KMS_key_ARN"
      }
   ]
}
```

Additional permissions

Once submitted, the notebook job needs permissions to access resources. The following instructions show you how to add a minimal set of permissions. If needed, add more permissions based on your notebook job needs. To add permissions to your job execution role, complete the following steps:

1. Open the IAM console.
2. Select Roles in the left panel.
3. Find the job execution role for your notebook job and choose the role name.
4. Choose Add Permissions, and choose Create inline policy from the dropdown menu.
5. Choose the JSON tab.
6. Copy and paste the following policy:
7. Add permissions to other resources your notebook job accesses.
8. Choose **Review policy**.
9. Enter a name for your policy.
10. Choose Create policy.

Create and manage your scheduled notebook jobs

SageMaker Notebook Jobs gives you the tools to create and manage your noninteractive notebook jobs. You can create jobs, view the jobs you created, and pause, stop, or resume existing jobs. You can also modify notebook schedules.

When you create your scheduled notebook job, the scheduler tries to infer a selection of default options and automatically populates the form to help you get started quickly. If you are using Studio, at minimum you can submit an on-demand job without setting any options. You can also submit a (scheduled) notebook job definition supplying just the time-specific schedule information. However, you can customize other fields if your scheduled job requires specialized settings. If you are running a local Jupyter notebook, the scheduler extension provides a feature for you to specify your own defaults (for a subset of options) so you don’t have to manually insert the same values every time. For details about how to schedule a notebook job, see Schedule a notebook job (p. 2959).

SageMaker Notebook Jobs dashboards help organize the job definitions that you schedule, and also keep track of the actual jobs that run from your job definitions. There are two important concepts to understand when scheduling notebook jobs: **job definitions** and **job runs**. Job definitions are schedules you set to run specific notebooks. For example, you can create a job definition that runs notebook XYZ.ipynb every Wednesday. This job definition launches the actual job runs which occur this coming Wednesday, next Wednesday, the Wednesday after that, and so on.

The interface provides two main tabs that help you track your existing job definitions and job runs:

- **Notebook Jobs** tab: This tab displays a list of all your job runs from your on-demand jobs and job definitions. From this tab, you can directly access the details for a single job run. For example, you can view a single job run that occurred two Wednesdays ago.

- **Notebook Job Definitions** tab: This tab displays a list of all your job definitions. From this tab, you can directly access the details for a single job definition. For example, you can view the schedule you created to run XYZ.ipynb every Wednesday.

For details about the **Notebook Jobs** tab, see View notebook jobs (p. 2969).

For details about the **Notebook Job Definitions** tab, see View notebook job definitions (p. 2970).

Schedule a notebook job

**Note**

The notebook scheduler is built from the Amazon EventBridge, SageMaker Training, and SageMaker Pipelines services. If your notebook jobs fail, you might see errors related to these services.

To schedule a notebook job, complete the following steps.

1. Open the **Create Job** form.

   In local JupyterLab environments, choose the Create a notebook job icon (⌘) in the taskbar. If you don’t see the icon, follow the instructions in Installation Guide (p. 2949) to install it.

   In Studio, open the form in one of two ways:

   - **Using the File Browser**

     1. In the **File Browser** in the left panel, right-click on the notebook you want to run as a scheduled job.
2. Choose **Create Notebook Job**.
   - Within the Studio notebook
     - Inside the Studio notebook you want to run as a scheduled job, choose the **Create a notebook job** icon ( fastball) in the Studio toolbar.

2. Complete the popup form. The form displays the following fields:
   - **Job name**: A descriptive name you specify for your job.
   - **Input file**: The name of the notebook which you are scheduling to run in noninteractive mode.
   - **Compute type**: The type of Amazon EC2 instance in which you want to run your notebook.
   - **Parameters**: Custom parameters you can optionally specify as inputs to your notebook. To use this feature, you must tag a specific cell in your Jupyter notebook with the **parameters** tag, or else your parameters may not have correct values in the notebook. For more details, see Parameterize your notebook (p. 2969).
   - **Additional Options**: You can specify additional customizations for your job. For example, you can specify an image or kernel, input and output folders, job retry and timeout options, encryption details, and custom initialization scripts. For the complete listing of customizations you can apply, see Additional options (p. 2960).

3. Schedule your job. You can run your notebook on demand or on a fixed schedule.
   - To run the notebook on demand, complete the following steps:
     - Select **Run Now**.
     - Choose **Create**.
     - The Notebook Jobs tab appears. Choose **Reload** to load your job into the dashboard.
   
   - To run the notebook on a fixed schedule, complete the following steps:
     - Choose **Run on a schedule**.
     - Choose the **Interval** dropdown list and select an interval. The intervals range from every minute to monthly. You can also select **Custom schedule**.
     - Based on the interval you choose, additional fields appear to help you further specify your desired run day and time. For example, if you select **Day** for a daily run, an additional field appears for you to specify the desired time. Note that any time you specify is in UTC format. Note also that if you choose a small interval, such as one minute, your jobs overlap if the previous job is not complete when the next job starts.

     If you select a custom schedule, you use cron syntax in the expression box to specify your exact run date and time. The cron syntax is a space-separated list of digits, each of which represent a unit of time from seconds to years. For help with cron syntax, you can choose **Get help with cron syntax** under the expression box.
     - Choose **Create**.
     - The Notebook Job Definitions tab appears. Choose **Reload** to load your job definition into the dashboard.

**Additional options**

Studio tries to infer details about your job's infrastructure settings so you can launch your jobs quickly without worrying about the backend details. However, if your job requires further customization, you can override the Studio provided defaults in the **Create Job** form.

If you choose the **Additional options** dropdown list in the **Create Job** form, you can customize the following options:
<table>
<thead>
<tr>
<th>Custom option</th>
<th>Description</th>
<th>Studio-specific guideline</th>
<th>Local Jupyter environment guideline</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Image</strong></td>
<td>The container image used to run the notebook noninteractively on the chosen compute type.</td>
<td>This field defaults to your notebook’s current image. Change this field from the default to a custom value if needed. If Studio cannot infer this value, the form displays a validation error requiring you to specify it. This image can be a custom, <strong>bring-your-own image</strong> or an available Amazon SageMaker image. For a list of available SageMaker images supported by the notebook scheduler, see [Available Amazon SageMaker Images](p. 244).</td>
<td>This field requires an ECR URI of a Docker image that can run the provided notebook on the selected compute type. By default, the scheduler extension uses a pre-built SageMaker Docker image—base Python 2.0. This is the official Python 3.8 image from DockerHub with boto3, AWS CLI, and the Python 3 kernel. You can also provide any ECR URI that meets the notebook custom image specification. For details, see [Custom SageMaker image specifications](p. 258). This image should have all the kernels and libraries needed for the notebook run.</td>
</tr>
<tr>
<td><strong>Kernel</strong></td>
<td>The Jupyter kernel used to run the notebook job.</td>
<td>This field defaults to your notebook’s current kernel. Change this field from the default to a custom value if needed. If Studio cannot infer this value, the form displays a validation error requiring you to specify it.</td>
<td>This kernel should be present in the image and follow the Jupyter kernel specs. This field defaults to the Python3 kernel found in the base Python 2.0 SageMaker image. Change this field to a custom value if needed.</td>
</tr>
<tr>
<td><strong>Role ARN</strong></td>
<td>The role’s Amazon Resource Name (ARN) used with the notebook job.</td>
<td>This field defaults to the Studio execution role. Change this field to a custom value if needed.</td>
<td>This field defaults to any role prefixed with SagemakerJupyterScheduler. If you have multiple roles with the prefix, the extension chooses one. Change this field to a custom value if needed. For this field, you can set your own user default that pre-populates whenever you create a new job definition. For details, see [Set up default options for local notebooks](p. 2966).</td>
</tr>
<tr>
<td><strong>Input folder</strong></td>
<td>The folder containing your inputs. The job inputs, including the input notebook and any optional start-up or initialization scripts, are put in this folder.</td>
<td>If you don’t provide a folder, the scheduler creates a default Amazon S3 bucket for your inputs.</td>
<td>Same as Studio. For this field, you can set your own user default that pre-populates whenever you create a new job definition. For details, see [Set up default options for local notebooks](p. 2966).</td>
</tr>
<tr>
<td><strong>Output folder</strong></td>
<td>The folder containing your outputs. The job</td>
<td>If you don’t specify a folder, the scheduler creates a default</td>
<td>Same as Studio. For this field, you can set your own user</td>
</tr>
<tr>
<td>Custom option</td>
<td>Description</td>
<td>Studio-specific guideline</td>
<td>Local Jupyter environment guideline</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------</td>
<td>--------------------------</td>
<td>-------------------------------------</td>
</tr>
<tr>
<td><strong>outputs</strong>, including the output notebook and logs, are put in this folder.</td>
<td>Amazon S3 bucket for your outputs.</td>
<td>default that pre-populates whenever you create a new job definition. For details, see [Set up default options for local notebooks](p. 2966).</td>
<td></td>
</tr>
<tr>
<td><strong>Environment variables</strong></td>
<td>Any existing environment variables that you want to override, or new environment variables that you want to introduce and use in your notebook.</td>
<td>N/A. Unavailable for local Jupyter notebooks.</td>
<td></td>
</tr>
<tr>
<td><strong>Start-up script</strong></td>
<td>A script preloaded in the notebook startup menu that you can choose to run before you run the notebook.</td>
<td>Select a Lifecycle Configuration (LCC) script that runs on the image at start-up. <strong>Note</strong> A start-up script runs in a shell outside of the Studio environment. Therefore, this script cannot depend on the Studio local storage, environment variables, or app metadata (in <code>/opt/ml/metadata</code>). Also, if you use a start-up script and an initialization script, the start-up script runs first.</td>
<td></td>
</tr>
<tr>
<td>Custom option</td>
<td>Description</td>
<td>Studio-specific guideline</td>
<td>Local Jupyter environment guideline</td>
</tr>
<tr>
<td>--------------------------</td>
<td>----------------------------------------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Initialization script</td>
<td>A path to a local script you can run when your notebook starts up.</td>
<td>Enter the EFS file path where a local script or a Lifecycle Configuration (LCC) script is located. If you use a start-up script and an initialization script, the start-up script runs first. Note An initialization script is sourced from the same shell as the notebook job. This is not the case for a start-up script described previously. Also, if you use a start-up script and an initialization script, the start-up script runs first.</td>
<td>Enter the local file path where a local script or a Lifecycle Configuration (LCC) script is located.</td>
</tr>
<tr>
<td>Max retry attempts</td>
<td>The number of times Studio tries to rerun a failed job run.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Max run time (in seconds)</td>
<td>The maximum length of time, in seconds, that a notebook job can run before it is stopped. If you configure both Max run time and Max retry attempts, the run time applies to each retry. If a job does not complete in this time, its status is set to Failed.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Configure job encryption</td>
<td>An indicator that you want to encrypt your notebook job outputs, job instance volume, or both.</td>
<td>Check this box to choose encryption. If left unchecked, the job outputs are encrypted with the account's default KMS key and the job instance volume is not encrypted.</td>
<td>Same as Studio.</td>
</tr>
<tr>
<td>Custom option</td>
<td>Description</td>
<td>Studio-specific guideline</td>
<td>Local Jupyter environment guideline</td>
</tr>
<tr>
<td>------------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Output encryption KMS key</td>
<td>A KMS key to use if you want to customize the encryption key used for your notebook job outputs. This field is only applicable if you checked Configure job encryption.</td>
<td>If you do not specify this field, your notebook job outputs are encrypted with SSE-KMS using the default Amazon S3 KMS key. Also, if you create the Amazon S3 bucket yourself and use encryption, your encryption method is preserved.</td>
<td>Same as Studio. For this field, you can set your own user default that pre-populates whenever you create a new job definition. For details, see Set up default options for local notebooks (p. 2966).</td>
</tr>
<tr>
<td>Job instance volume encryption KMS key</td>
<td>A KMS key to use if you want to encrypt your job instance volume. This field is only applicable if you checked Configure job encryption.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Custom option</td>
<td>Description</td>
<td>Studio-specific guideline</td>
<td>Local Jupyter environment guideline</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------</td>
<td>---------------------------</td>
<td>-------------------------------------</td>
</tr>
<tr>
<td>Use a Virtual Private Cloud to run this job (for VPC users)</td>
<td>An indicator that you want to run this job in a Virtual Private Cloud (VPC). For better security, it is recommend that you use a private VPC.</td>
<td>Check this box if you want to use a VPC. At minimum, create the following VPC endpoints to enable your notebook job to privately connect to those AWS resources:</td>
<td>Same as Studio.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <strong>SageMaker</strong>: For information on how to connect to SageMaker through a VPC interface endpoint, see [Connect to SageMaker Within your VPC](p. 3526).</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <strong>Amazon S3</strong>: For information on how to connect to Amazon S3 through a VPC interface endpoint, see [Gateway endpoints for Amazon S3](p. 3526).</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <strong>Amazon EC2</strong>: For information on how to connect to Amazon EC2 through a VPC interface endpoint, see [Access Amazon EC2 using an interface VPC endpoint](p. 3526).</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <strong>Amazon EventBridge</strong>: This endpoint is only needed when setting up a scheduled notebook. It is not needed when launching a job on demand. For information on how to connect to EventBridge through a VPC interface endpoint, see [Using Amazon EventBridge with interface VPC Endpoints](p. 3526).</td>
<td></td>
</tr>
</tbody>
</table>

If you choose to use a VPC, you need to specify at least one private subnet and at least one security group in the following options. If you don’t use any private subnets, you need to consider other configuration options. For details, see [Public VPC subnets not supported](p. 2972) in *Constraints and considerations*.

### Notebook Jobs

#### Custom option

<table>
<thead>
<tr>
<th><strong>Custom option</strong></th>
<th><strong>Description</strong></th>
<th><strong>Studio-specific guideline</strong></th>
<th><strong>Local Jupyter environment guideline</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Subnet(s) (for VPC users)</td>
<td>Your subnets. This field must contain at least one and at most five, and all the subnets you provide should be private. For details, see Public VPC subnets not supported in Constraints and considerations (p. 2972).</td>
<td>This field defaults to the subnets associated with the Studio domain, but you can change this field if needed.</td>
<td>The scheduler cannot detect your subnets, so you need to enter any subnets you configured for your VPC.</td>
</tr>
<tr>
<td>Security group(s) (for VPC users)</td>
<td>Your security groups. This field must contain at least one and at most 15. For details, see Public VPC subnets not supported in Constraints and considerations (p. 2972).</td>
<td>This field defaults to the security groups associated with the domain VPC, but you can change this field if needed.</td>
<td>The scheduler cannot detect your security groups, so you need to enter any security groups you configured for your VPC.</td>
</tr>
</tbody>
</table>

#### Set up default options for local notebooks

If you have to manually type (or paste in) custom values in the Create Job form, you can store new default values and the scheduler extension inserts your new values every time you create a new job definition. This feature is available for the following options:

- Role Arn
- S3 Input Folder
- S3 Output Folder
- KMS key ID (if you turn on Configure Job Encryption)

This feature saves you time if you insert different values than the provided defaults and continue to use those values for future job runs. Your chosen user settings are stored on the machine that runs your JupyterLab server and are retrieved with the help of native API. If you provide new default values for one or more but not all four options, the previous defaults are taken for the ones you don’t customize.

The following instructions show you how to set new default values, preview the existing default values, and reset your default values.

**To set new default values or preview existing default values, complete the following steps:**

1. From the Jupyter Lab top menu, choose **Settings**, then choose **Advanced Settings Editor**.
2. If you want to update or preview the user defaults, you can do so in the **Advanced Settings Editor** or in the **JSON settings editor**.

   - In the **Advanced Settings Editor**, preview or insert new values for Role ARN, S3 Input Folder, S3 Output Folder, or KMS key ID or ARN. If you change these values, you see your new defaults for these fields when you create your next notebook job.
   - (Optional) To update or preview the user defaults using the **JSON Settings Editor**, complete the following steps:
1. In the top right corner, choose **JSON Settings Editor**. You can see your current default values in the **System Defaults** panel.

2. To update your default values, copy and paste the JSON snippet from the **System Defaults** panel to the **User Preferences** panel, and update the fields.

3. If you updated the default values, choose the **Save user preferences** icon (.fname) in the top right corner. Closing the editor does not save the changes.

If you previously changed and now want to reset the user-defined default values, complete following steps:

1. From the Jupyter Lab top menu, choose **Settings**, then choose **Advanced Settings Editor**.
2. In the top right corner, choose **JSON Settings Editor**.
3. In the **Settings** left sidebar, choose **Amazon SageMaker Scheduler**.
4. Choose **Restore to Defaults**. Your defaults are restored to empty strings. You only see this option if you previously changed your default values.

Connect to an Amazon EMR cluster from your Studio notebook

If you connect to an Amazon EMR cluster from your Jupyter notebook in Studio, you might need to perform additional setup. In particular, the following discussion addresses two issues:

- **Passing parameters into your Amazon EMR connection command.** In SparkMagic kernels, parameters you pass to your Amazon EMR connection command may not work as expected due to differences in how Papermill passes parameters and how SparkMagic receives parameters. The workaround to address this limitation is to pass parameters as environment variables. For more details about the issue and workaround, see Pass parameters to your EMR connection command (p. 2967).

- **Passing user credentials to Kerberos, LDAP, or HTTP Basic Auth-authenticated Amazon EMR clusters.** In interactive mode, Studio asks for credentials in a popup form where you can enter your sign-in credentials. In your noninteractive scheduled notebook, you have to pass them through the AWS Secrets Manager. For more details about how to use the AWS Secrets Manager in your scheduled notebook jobs, see Pass user credentials to your Kerberos, LDAP, or HTTP Basic Auth-authenticated Amazon EMR cluster (p. 2968).

Pass parameters to your EMR connection command

If you are using images with the SparkMagic PySpark and Spark kernels and want to parameterize your EMR connection command, provide your parameters in the **Environment variables** field instead of the **Parameters** field in the Create Job form (in the **Additional Options** dropdown menu). Make sure your EMR connection command in the Jupyter notebook passes these parameters as environment variables. For example, suppose you pass `cluster-id` as an environment variable when you create your job. Your EMR connection command should look like the following:

```python
%%local
import os

%sm_analytics emr connect --cluster-id {os.getenv('cluster_id')} --auth-type None
```

You need this workaround to meet requirements by SparkMagic and Papermill. For background context, the SparkMagic kernel expects that the `%%local` magic command accompany any local variables you define. However, Papermill does not pass the `%%local` magic command with your overrides. In order to work around this Papermill limitation, you must supply your parameters as environment variables in the **Environment variables** field.
Pass user credentials to your Kerberos, LDAP, or HTTP Basic Auth-authenticated Amazon EMR cluster

To establish a secure connection to an Amazon EMR cluster that uses Kerberos, LDAP, or HTTP Basic Auth authentication, you use the AWS Secrets Manager to pass user credentials to your connection command. For information about how to create a Secrets Manager secret, see Create an AWS Secrets Manager secret. You pass the secret with the --secrets argument, as shown in the following example:

```
%sm_analytics emr connect --cluster-id j_abcde12345
   --auth Kerberos
   --secret aws_secret_id_123
```

Your administrator can set up a flexible access policy using an attribute-based-access-control (ABAC) method, which assigns access based on special tags. You can set up flexible access to create a single secret for all users in the account or a secret for each user. The following code samples demonstrate these scenarios:

**Create a single secret for all users in the account**

```
{
   "Version" : "2012-10-17",
   "Statement" : [
      {
         "Effect": "Allow",
         "Principal" : "arn:aws:iam::AWS_ACCOUNT_ID:role/service-role/AmazonSageMaker-ExecutionRole-20190101T012345",
         "Action" : "secretsmanager:GetSecretValue",
                         "arn:aws:secretsmanager:us-west-2:AWS_ACCOUNT_ID:secret:aes789-7g8h9i" ]
      }
   ]
}
```

**Create a different secret for each user**

You can create a different secret for each user using the PrincipalTag tag, as shown in the following example:

```
{
   "Version" : "2012-10-17",
   "Statement" : [
      {
         "Effect": "Allow",
         "Principal" : "arn:aws:iam::AWS_ACCOUNT_ID:role/service-role/AmazonSageMaker-ExecutionRole-20190101T012345",
         "Condition" : {
            "StringEquals" : {
               "aws:ResourceTag/user-identity": 
               "${aws:PrincipalTag/user-identity}"
            }
         },
         "Action" : "secretsmanager:GetSecretValue",
                         "arn:aws:secretsmanager:us-west-2:AWS_ACCOUNT_ID:secret:aes789-7g8h9i" ]
      }
   ]
}
```
Parameterize your notebook

To pass new parameters or parameter overrides to your scheduled notebook job, you must make some modifications to your notebook. When you pass a parameter, Studio uses the methodology enforced by Papermill. Studio searches for a Jupyter cell tagged with the `parameters` tag and applies the new parameters or parameter overrides immediately after this cell. If you don’t have any cells tagged with `parameters`, Studio applies the parameters at the beginning of the notebook. If you have more than one cell tagged with `parameters`, Studio applies the parameters after the first cell tagged with `parameters`.

To tag a cell in your notebook with the `parameters` tag, complete the following steps:

1. Select the cell to parameterize.
2. Choose the **Property Inspector** icon (🔧) in the right sidebar.
3. Type `parameters` in the **Add Tag** box.
4. Choose the + sign.
5. The `parameters` tag appears under **Cell Tags** with a check mark, which means the tag is applied to the cell.

View notebook jobs

The **Notebook Jobs** tab shows a history of your on-demand jobs and all the jobs that run from the job definitions you created. This tab opens after you create an on-demand job, or you can just view this tab yourself to see a history of past and current jobs. If you select the **Job name** for any job, you can view details for a single job in its **Job Detail** page. For more information about the **Job Detail** page, see the following section [View a single job (p. 2970)](#).

The **Notebook Jobs** tab includes the following information for each job:

- **Output files**: Displays the availability of output files. This column can contain one of the following:
  - A download icon (⬇️): The output notebook and log are available for download; choose this button to download them. Note that a failed job can still generate output files if the failure occurred after the files were created. In this case, it is helpful to view the output notebook to identify the failure point.
  - Links to the **Notebook** and **Output log**: The notebook and output log are downloaded. Choose the links to view their contents.
  - (blank): The job was stopped by the user, or a failure occurred in the job run before it could generate output files. For example, network failures could prevent the job from starting.

The output notebook is the result of running all cells in the notebook, and also incorporates any new or overriding parameters or environment variables you included. The output log captures the details of the job run to help you troubleshoot failed jobs.

- **Created at**: The time the on-demand job or scheduled job was created.
- **Status**: The current status of the job, which is one of the following values:
  - **In progress**: The job is running
  - **Failed**: The job failed from configuration or notebook logic errors
  - **Stopped**: The job was stopped by the user
  - **Completed**: The job completed
- **Actions**: This column provides shortcuts to help you stop or remove any job directly in the interface.
View a single job

From the Notebook Jobs tab, you can select a job name to view the Job Detail page for a specific job. The Job Detail page includes all the details you provided in the Create Job form. Use this page to confirm the settings you specified when you created the job definition.

In addition, you can access shortcuts to help you perform the following actions in the page itself:

- **Delete Job**: Remove the job from the Notebook Jobs tab.
- **Stop Job**: Stop your running job.

View notebook job definitions

When you create a job definition, you create a schedule for a job. The Notebook Job Definitions tab lists these schedules. For example, you might create a job definition that runs a specific notebook every minute. Once this job definition is active, you see a new job every minute in the Notebook Jobs tab.

The Notebook Job Definitions tab displays a dashboard with all your job definitions and includes the input notebook, the creation time, the schedule, and the status for each job definition. The value in the Status column is one of the following values:

- **Paused**: You paused the job definition. Studio does not initiate any jobs until you resume the definition.
- **Active**: The schedule is on and Studio can run the notebook according to the schedule you specified.

In addition, the Actions column provides shortcuts to help you perform the following tasks directly in the interface:

- **Pause**: Pauses the job definition. Studio won’t create any jobs until you resume the definition.
- **Delete**: Removes the job definition from the Notebook Job Definitions tab.
- **Resume**: Continues a paused job definition so that it can start jobs.

If you created a job definition but it doesn’t initiate jobs, see Job definition doesn’t create jobs (p. 2971) in the Troubleshooting guide (p. 2971).

View a single job definition

If you select a job definition name in the Notebook Job Definitions tab, you see the Job Definition page where you can view specific details for a job definition. Use this page to confirm the settings you specified when you created the job definition. If you don’t see any jobs created from your job definition, see Job definition doesn’t create jobs (p. 2971) in the Troubleshooting guide (p. 2971).

This page also contains a section listing the jobs that run from this job definition. Viewing your jobs in the Job Definition page may be a more productive way to help you organize your jobs instead of viewing jobs in the Notebook Jobs tab, which combines all jobs from all your job definitions.

In addition, this page provides shortcuts for the following actions:

- **Pause/Resume**: Pause your job definition, or resume a paused definition. Note that if a job is currently running for this definition, Studio does not stop it.
- **Run**: Run a single on-demand job from this job definition. This option also lets you specify different input parameters to your notebook before starting the job.
- **Edit Job Definition**: Change the schedule of your job definition. You can select a different time interval, or you can opt for a custom schedule using cron syntax.
• **Delete Job Definition:** Remove the job definition from the **Notebook Job Definitions** tab. Note that if a job is currently running for this definition, Studio does not stop it.

**Troubleshooting guide**

Refer to this troubleshooting guide to help you debug failures you might experience when your scheduled notebook job runs.

**Job definition doesn't create jobs**

If your job definition doesn't initiate any jobs, see the following possible causes:

**Missing permissions**

• The role assigned to the job definition does not have a trust relationship with Amazon EventBridge. That is, EventBridge cannot assume the role.
• The role assigned to the job definition does not have permission to call `SageMaker:StartPipelineExecution`.
• The role assigned to the job definition does not have permission to call `SageMaker:CreateTrainingJob`.

**EventBridge quota exceeded**

If you see a Put* error such as the following example, you exceeded an EventBridge quota. To resolve this, you can clean up unused EventBridge runs, or ask AWS Support to increase your quota.

```
LimitExceededException) when calling the PutRule operation:
The requested resource exceeds the maximum number allowed
```

For more information about EventBridge quotas, see [Amazon EventBridge quotas](https://aws.amazon.com/documentation/eventbridge/

**Pipeline quota limit exceeded**

If you see an error such as the following example, you exceeded the number of pipelines that you can run. To resolve this, you can clean up unused pipelines in your account, or ask AWS Support to increase your quota.

```
ResourceLimitExceeded: The account-level service limit
'Maximum number of pipelines allowed per account' is XXX Pipelines,
with current utilization of XXX Pipelines and a request delta of 1 Pipelines.
```

For more information about pipeline quotas, see [Amazon SageMaker endpoints and quotas](https://aws.amazon.com/documentation/sagemaker/

**Training job limit exceeded**

If you see an error such as the following example, you exceeded the number of training jobs that you can run. To resolve this, reduce the number of training jobs in your account, or ask AWS Support to increase your quota.

```
ResourceLimitExceeded: The account-level service limit
'ml.m5.2xlarge for training job usage' is 0 Instances, with current
utilization of 0 Instances and a request delta of 1 Instances.
Please contact AWS support to request an increase for this limit.
```

For more information about training job quotas, see [Amazon SageMaker endpoints and quotas](https://aws.amazon.com/documentation/sagemaker/
Constraints and considerations

Review the following constraints to ensure your notebook jobs complete successfully. Studio uses Papermill to run notebooks. You might need to update Jupyter notebooks to align to Papermill's requirements. There are also restrictions on the content of LCC scripts and important details to understand regarding VPC configuration.

JupyterLab version

JupyterLab versions 3.0 and above are supported.

Installation of packages that require kernel restart

Papermill does not support calling `pip install` to install packages that require a kernel restart. In this situation, use `pip install` in an initialization script. For a package installation that does not require kernel restart, you can still include `pip install` in the notebook.

Kernel and language names registered with Jupyter

Papermill registers a translator for specific kernels and languages. If you bring your own instance (BYOI), use a standard kernel name as shown in the following snippet:

```python
papermill_translators.register("python", PythonTranslator)
papermill_translators.register("R", RTranslator)
papermill_translators.register("scala", ScalaTranslator)
papermill_translators.register("julia", JuliaTranslator)
papermill_translators.register("matlab", MatlabTranslator)
papermill_translators.register(".net-csharp", CSharpTranslator)
papermill_translators.register(".net-fsharp", FSharpTranslator)
papermill_translators.register(".net-powershell", PowershellTranslator)
papermill_translators.register("pysparkkernel", PythonTranslator)
papermill_translators.register("sparkkernel", ScalaTranslator)
papermill_translators.register("sparkrkernel", RTranslator)
papermill_translators.register("bash", BashTranslator)
```

Parameters and environment variable limits

**Parameters and environment variable limits.** When you create your notebook job, it receives the parameters and environment variables you specify. You can pass up to 100 parameters. Each parameter name can be up to 256 characters long, and the associated value can be up to 2500 characters long. If you pass environment variables, you can pass up to 28 variables. The variable name and associated value can be up to 512 characters long. If you need more than 28 environment variables, use additional environment variables in an initialization script which has no limit on the number of environment variables you can use.

Image

**Image and kernel support.** The driver that launches your notebook job assumes the following:

- A base Python runtime environment is installed in the Studio or bring-your-own (BYO) images and is the default in the shell.
- The base Python runtime environment includes the Jupyter client with kernelspecs properly configured.
- The base Python runtime environment includes the `pip` function so the notebook job can install system dependencies.
- For images with multiple environments, your initialization script should switch to the proper kernel-specific environment before installing notebook-specific packages. You should switch back to the default Python runtime environment, if different from the kernel runtime environment, after configuring the kernel Python runtime environment.
The driver that launches your notebook job is a bash script, and Bash v4 must be available at /bin/bash.

**Root privileges on bring-your-own-images (BYOI).** You must have root privileges on your own Studio images, either as the root user or through sudo access. If you are not a root user but accessing root privileges through sudo, use `1000/100` as the UID/GID.

**VPC subnets used during job creation**

If you use a VPC, Studio uses your private subnets to create your job. Specify one to five private subnets (and 1–15 security groups).

If you use a VPC with private subnets, you must choose one of the following options to ensure the notebook job can connect to dependent services or resources:

- If the job needs access to an AWS service that supports interface VPC endpoints, create an endpoint to connect to the service. For a list of services that support interface endpoints, see [AWS services that integrate with AWS PrivateLink](#). For information about creating an interface VPC endpoint, see [Access an AWS service using an interface VPC endpoint](#). At minimum, an Amazon S3 VPC endpoint gateway must be provided.
- If a notebook job needs access to an AWS service that doesn't support interface VPC endpoints or to a resource outside of AWS, create a NAT gateway and configure your security groups to allow outbound connections. For information about setting up a NAT gateway for your VPC, see [VPC with public and private Subnets (NAT)](#) in the [Amazon Virtual Private Cloud User Guide](#).

**Service limits**

Since the notebook job scheduler is built from SageMaker Pipelines, SageMaker Training, and Amazon EventBridge services, your notebook jobs are subject to their service-specific quotas. If you exceed these quotas, you may see error messages related to these services. For example, there are limits for how many pipelines you can run at one time, and how many rules you can set up for a single event bus. For more information about SageMaker quotas, see [Amazon SageMaker Endpoints and Quotas](#). For more information about EventBridge quotas, see [Amazon EventBridge Quotas](#).

**Pricing for SageMaker Notebook Jobs**

When you schedule notebook jobs, your Jupyter notebooks run on SageMaker training instances. After you select an **Image** and **Kernel** in your **Create Job** form, the form provides a list of available compute types. You are charged for the compute type you choose, based on the combined duration of use for all notebook jobs that run from the job definition. If you don't specify a compute type, SageMaker assigns you a default Amazon EC2 instance type of `ml.m5.large`. For a breakdown of SageMaker pricing by compute type, see [Amazon SageMaker Pricing](#).

---

**Amazon SageMaker ML Lineage Tracking**

Amazon SageMaker ML Lineage Tracking creates and stores information about the steps of a machine learning (ML) workflow from data preparation to model deployment. With the tracking information, you can reproduce the workflow steps, track model and dataset lineage, and establish model governance and audit standards.

With SageMaker Lineage Tracking data scientists and model builders can do the following:

- Keep a running history of model discovery experiments.
- Establish model governance by tracking model lineage artifacts for auditing and compliance verification.
The following diagram shows an example lineage graph that Amazon SageMaker automatically creates in an end-to-end model training and deployment ML workflow.

### Topics
- [Lineage Tracking Entities](p. 2974)
- [Amazon SageMaker–Created Tracking Entities](p. 2976)
- [Manually Create Tracking Entities](p. 2978)
- [Querying Lineage Entities](p. 2981)
- [Cross-Account Lineage Tracking](p. 2987)

### Lineage Tracking Entities

Tracking entities maintain a representation of all the elements of your end-to-end machine learning workflow. You can use this representation to establish model governance, reproduce your workflow, and maintain a record of your work history.

Amazon SageMaker automatically creates tracking entities for trial components and their associated trials and experiments when you create SageMaker jobs such as processing jobs, training jobs, and batch transform jobs. In additional to auto tracking, you can also [Manually Create Tracking Entities](p. 2978) to model custom steps in your workflow. For more information, see [Manage Machine Learning with Amazon SageMaker Experiments](p. 1838).
SageMaker also automatically creates tracking entities for the other steps in a workflow so you can track the workflow from end to end. For more information, see Amazon SageMaker–Created Tracking Entities (p. 2976).

You can create additional entities to supplement those created by SageMaker. For more information, see Manually Create Tracking Entities (p. 2978).

SageMaker reuses any existing entities rather than creating new ones. For example, there can be only one artifact with a unique SourceUri.

Key concepts for querying lineage

- **Lineage** – Metadata that tracks the relationships between various entities in your ML workflows.
- **QueryLineage** – The action to inspect your lineage and discover relationships between entities.
- **Lineage entities** – The metadata elements of which your lineage is composed.
- **Cross-account lineage** – Your ML workflow may span more than one account. With cross-account lineage, you can configure multiple accounts to automatically create lineage associations between shared entity resources. QueryLineage then can return entities even from these shared accounts.

The following tracking entities are defined:

**Experiment entities**

- **Trial component** – A stage of a machine learning trial. Includes processing jobs, training jobs, and batch transform jobs.
- **Trial** – A combination of trial components that generally produces a model.
- **Experiment** – A grouping of trials generally focused on solving a specific use case.

**Lineage entities**

- **Trial Component** – Represents processing, training, and transform jobs in the lineage. Also part of experiment management.
- **Context** – Provides a logical grouping of other tracking or experiment entities. Conceptually, experiments and trials are contexts. Some examples are an endpoint and a model package.
- **Action** – Represents an action or activity. Generally, an action involves at least one input artifact or output artifact. Some examples are a workflow step and a model deployment.
- **Artifact** – Represents a URI addressable object or data. An artifact is generally either an input or an output to a trial component or action. Some examples include a dataset (S3 bucket URI), or an image (Amazon ECR registry path).
- **Association** – Links other tracking or experiment entities, such as an association between the location of training data and a training job.

An association has an optional AssociationType property. The following values are available along with the suggested use for each type. SageMaker places no restrictions on their use:

- **ContributedTo** – The source contributed to the destination or had a part in enabling the destination. For example, the training data contributed to the training job.
- **AssociatedWith** – The source is connected to the destination. For example, an approval workflow is associated with a model deployment.
- **DerivedFrom** – The destination is a modification of the source. For example, a digest output of a channel input for a processing job is derived from the original inputs.
- **Produced** – The source generated the destination. For example, a training job produced a model artifact.
- **SameAs** – When the same lineage entity used in different accounts.
Common properties

• **Type property**

The action, artifact, and context entities have a type property, ActionType, ArtifactType, and ContextType, respectively. This property is a custom string which can associate meaningful information with the entity and be used as a filter in the List APIs.

• **Source property**

The action, artifact, and context entities have a Source property. This property provides the underlying URI that the entity represents. Some examples are:

  - An UpdateEndpoint action where the source is the EndpointArn.
  - An image artifact for a processing job where the source is the ImageUri.
  - An Endpoint context where the source is the EndpointArn.

• **Metadata property**

The action and artifact entities have an optional Metadata property which can provide the following information:

  - ProjectId – For example, the ID of the SageMaker MLOps project to which a model belongs.
  - GeneratedBy – For example, the SageMaker pipeline execution that registered a model package version.
  - Repository – For example, the repository that contains an algorithm.
  - CommitId – For example, the commit ID of an algorithm version.

Amazon SageMaker–Created Tracking Entities

Amazon SageMaker automatically creates tracking entities for SageMaker jobs, models, model packages, and endpoints if the data is available. There is no limit to the number of lineage entities created by SageMaker.

For information on how you can manually create tracking entities, see [Manually Create Tracking Entities](p. 2978).

Topics

• Tracking Entities for SageMaker Jobs (p. 2976)
• Tracking Entities for Model Packages (p. 2977)
• Tracking Entities for Endpoints (p. 2977)

Tracking Entities for SageMaker Jobs

SageMaker creates a trial component for and associated with each SageMaker job. SageMaker creates artifacts to track the job metadata and associations between each artifact and the job.

Artifacts are created for the following job properties and associated with the Amazon Resource Name (ARN) of the SageMaker job. The artifact SourceUri is listed in parentheses.

**Training Job**

• The image that contains the training algorithm (TrainingImage).
• The data source of each input channel (S3Uri).
• The location for the model (S3OutputPath).
• The location for the managed spot checkpoint data (S3Uri).

Processing Job

• The container to be run by the processing job (ImageUri).
• The data location for each processing input and processing output (S3Uri).

Transform Job

• The input data source to be transformed (S3Uri).
• The results of the transform (S3OutputPath).

Note
Amazon Simple Storage Service (Amazon S3) artifacts are tracked based on the Amazon S3 URI values provided to the Create API, for example CreateTrainingJob, and not on the Amazon S3 key and hash or etag values from each file.

Tracking Entities for Model Packages

The following entities are created:

Model Packages

• A context for each model package group.
• An artifact for each model package.
• An association between each model package artifact and the context for each model package group to which the package belongs to.
• An action for the creation of a model package version.
• An association between the model package artifact and the creation action.
• An association between the model package artifact and each model package group context to which the package belongs to.
• Inference containers
  • An artifact for the image used in each container defined in the model package.
  • An artifact for the model used in each container.
  • An association between each artifact and the model package artifact.
• Algorithms
  • An artifact for each algorithm defined in the model package.
  • An artifact for the model created by each algorithm.
  • An association between each artifact and the model package artifact.

Tracking Entities for Endpoints

The following entities are created by Amazon SageMaker:

Endpoints

• A context for each endpoint
• An action for the model deployment that created each endpoint
• An artifact for each model deployed to the endpoint
• An artifact for the image used in the model
• An artifact for the model package for the model
• An artifact for each image deployed to the endpoint
• An association between each artifact and the model deployment action

Manually Create Tracking Entities

You can manually create tracking entities for any property. For information on the tracking entities that Amazon SageMaker automatically creates, see Amazon SageMaker–Created Tracking Entities (p. 2976).

You can add tags to all entities except associations. Tags are arbitrary key-value pairs that provide custom information. You can filter or sort a list or search query by tags. For more information, see Tagging AWS resources in the AWS General Reference.

For a sample notebook that demonstrates how to create lineage entities, see the Amazon SageMaker Lineage notebook in the Amazon SageMaker example GitHub repository.

Topics
• Manually Create Entities (p. 2978)
• Manually Track a Workflow (p. 2979)
• Limits (p. 2980)

Manually Create Entities

The following procedure shows you how to create and associate artifacts between a SageMaker training job and endpoint. You perform the following steps:

Import tracking entities and associations

1. Import the lineage tracking entities.

```python
import sys
!{sys.executable} -m pip install -q sagemaker
from sagemaker import get_execution_role
from sagemaker.session import Session
from sagemaker.lineage import context, artifact, association, action
import boto3
boto_session = boto3.Session(region_name=region)
sagemaker_client = boto_session.client("sagemaker")
```

2. Create the input and output artifacts.

```python
code_location_arn = artifact.Artifact.create(
    artifact_name='source-code-location',
    source_uri='s3:///...',
    artifact_type='code-location').artifact_arn
# Similar constructs for train_data_location_arn and test_data_location_arn

model_location_arn = artifact.Artifact.create(
    artifact_name='model-location',
    source_uri='s3:///...',
    artifact_type='model-location').artifact_arn
```
3. Train the model and get the `trial_component_arn` that represents the training job.

4. Associate the input artifacts and output artifacts with the training job (trial component).

```python
input_artifacts = [code_location_arn, train_data_location_arn, test_data_location_arn]
for artifact_arn in input_artifacts:
    try:
        association.Association.create(
            source_arn=artifact_arn,
            destination_arn=trial_component_arn,
            association_type='ContributedTo'
        )
    except:
        logging.info('association between {} and {} already exists', artifact_arn, trial_component_arn)

output_artifacts = [model_location_arn]
for artifact_arn in output_artifacts:
    try:
        association.Association.create(
            source_arn=trial_component_arn,
            destination_arn=artifact_arn,
            association_type='Produced'
        )
    except:
        logging.info('association between {} and {} already exists', artifact_arn, trial_component_arn)
```

5. Create the inference endpoint.

```python
predictor = mnist_estimator.deploy(initial_instance_count=1,
                                   instance_type='ml.m4.xlarge')
```

6. Create the endpoint context.

```python
from sagemaker.lineage import context

endpoint = sagemaker_client.describe_endpoint(EndpointName=predictor.endpoint_name)
endpoint_arn = endpoint['EndpointArn']

endpoint_context_arn = context.Context.create(
    context_name=predictor.endpoint_name,
    context_type='Endpoint',
    source_uri=endpoint_arn).
context_arn
```

7. Associate the training job (trial component) and endpoint context.

```python
association.Association.create(
    source_arn=trial_component_arn,
    destination_arn=endpoint_context_arn
)
```

---

**Manually Track a Workflow**

You can manually track the workflow created in the previous section.

Given the endpoint Amazon Resource Name (ARN) from the previous example, the following procedure shows you how to track the workflow back to the datasets used to train the model that was deployed to the endpoint. You perform the following steps:
To track a workflow from endpoint to training data source

1. Import the tracking entities.

   ```
   import sys
   !{sys.executable} -m pip install -q sagemaker
   from sagemaker import get_execution_role
   from sagemaker.session import Session
   from sagemaker.lineage import context, artifact, association, action
   import boto3
   boto_session = boto3.Session(region_name=region)
   sagemaker_client = boto_session.client("sagemaker")
   ```

2. Get the endpoint context from the endpoint ARN.

   ```
   endpoint_context_arn = sagemaker_client.list_contexts(
       SourceUri=endpoint_arn)['ContextSummaries'][0]['ContextArn']
   ```

3. Get the trial component from the association between the trial component and the endpoint context.

   ```
   trial_component_arn = sagemaker_client.list_associations(
       DestinationArn=endpoint_context_arn)['AssociationSummaries'][0]['SourceArn']
   ```

4. Get the training data location artifact from the association between the trial component and the endpoint context.

   ```
   train_data_location_artifact_arn = sagemaker_client.list_associations(
       DestinationArn=trial_component_arn, SourceType='Model')['AssociationSummaries'][0][
       'SourceArn']
   ```

5. Get the training data location from the training data location artifact.

   ```
   train_data_location = sagemaker_client.describe_artifact(
       ArtifactArn=train_data_location_artifact_arn)['Source']['SourceUri']
   print(train_data_location)
   ```

   Response:

   ```
   s3://sagemaker-sample-data-us-east-2/mxnet/mnist/train
   ```

**Limits**

You can create an association between any entities, experiment and lineage, except the following:

- You cannot create an association between two experiment entities. Experiment entities consist of experiments, trials, and trial components.
- You can create an association with another association.

An error occurs if you try to create an entity that already exists.

**Maximum number of manually created lineage entities**

- Actions: 3000
There is no limit to the number of lineage entities automatically created by Amazon SageMaker.

**Querying Lineage Entities**

Amazon SageMaker automatically generates graphs of lineage entities as you use them. You can query this data to answer a variety of questions. You can query your lineage entities to:

- Retrieve all data sets that went into the creation of a model.
- Retrieve all jobs that went into the creation of an endpoint.
- Retrieve all models that use a data set.
- Retrieve all endpoints that use a model.
- Retrieve which endpoints are derived from a certain data set.
- Retrieve the pipeline execution that created a training job.
- Retrieve the relationships between entities for investigation, governance, and reproducibility.
- Retrieve all downstream trials that use the artifact.
- Retrieve all upstream trials that use the artifact.
- Retrieve a list of artifacts that use the provided S3 uri.
- Retrieve upstream artifacts that use the dataset artifact.
- Retrieve downstream artifacts that use the dataset artifact.
- Retrieve datasets that use the image artifact.
- Retrieve actions that use the context.
- Retrieve processing jobs that use the endpoint.
- Retrieve transform jobs that use the endpoint.
- Retrieve trial components that use the endpoint.
- Retrieve the ARN for the pipeline execution associated with the model package group.
- Retrieve all artifacts that use the action.
- Retrieve all upstream datasets that use the model package approval action.
- Retrieve model package from model package approval action.
- Retrieve downstream endpoint contexts that use the endpoint.
- Retrieve the ARN for the pipeline execution associated with the trial component.
- Retrieve datasets that use the trial component.
- Retrieve models that use the trial component.
- Explore your lineage for visualization.

**Limitations**

- Lineage querying is not available in the following Regions:
  - Africa (Cape Town) – af-south
  - Asia Pacific (Jakarta) – ap-southeast-3
  - Asia Pacific (Osaka) – ap-northeast-3
  - Europe (Milan) – eu-south-1
  - Israel (Tel Aviv) – il-central-1
- The maximum depth of relationships to discover is currently limited to 10.
• Filtering is limited to the following properties: last modified date, created date, type, and lineage entity type.

Topics
• Getting Started with Querying Lineage Entities (p. 2982)

Getting Started with Querying Lineage Entities

The easiest way to get started is either via the:

• Amazon SageMaker SDK for Python which has defined many common use cases.
• For a notebook that demonstrates how to use SageMaker Lineage APIs to query relationships across the lineage graph, see sagemaker-lineage-multihop-queries.ipynb.

The following examples show how to use the LineageQuery and LineageFilter APIs to construct queries to answer questions about the Lineage Graph and extract entity relationships for a few use cases.

Example Using the LineageQuery API to find entity associations

```python
from sagemaker.lineage.context import Context, EndpointContext
from sagemaker.lineage.action import Action
from sagemaker.lineage.association import Association
from sagemaker.lineage.artifact import Artifact, ModelArtifact, DatasetArtifact
from sagemaker.lineage.query import (LineageQuery, LineageFilter, LineageSourceEnum, LineageEntityEnum, LineageQueryDirectionEnum,

# Find the endpoint context and model artifact that should be used for the lineage queries.
contexts = Context.list(source_uri=endpoint_arn)
context_name = list(contexts)[0].context_name
endpoint_context = EndpointContext.load(context_name=context_name)

Example Find all the datasets associated with an endpoint

# Define the LineageFilter to look for entities of type 'ARTIFACT' and the source of type 'DATASET'.
query_filter = LineageFilter(
    entities=[LineageEntityEnum.ARTIFACT], sources=[LineageSourceEnum.DATASET]
)

# Providing this 'LineageFilter' to the 'LineageQuery' constructs a query that traverses through the given context 'endpoint_context'
# and finds all datasets.
query_result = LineageQuery(sagemaker_session).query(start_arns=[endpoint_context.context_arn],
    query_filter=query_filter,
    direction=LineageQueryDirectionEnum.ASCENDANTS,
    include_edges=False,
)
```

2982
# Parse through the query results to get the lineage objects corresponding to the datasets
dataset_artifacts = []
for vertex in query_result.vertices:
    dataset_artifacts.append(vertex.to_lineage_object().source.source_uri)

pp.pprint(dataset_artifacts)

Example Find the models associated with an endpoint

# Define the LineageFilter to look for entities of type `ARTIFACT` and the source of type `MODEL`.
query_filter = LineageFilter(
    entities=[LineageEntityEnum.ARTIFACT], sources=[LineageSourceEnum.MODEL]
)

# Providing this `LineageFilter` to the `LineageQuery` constructs a query that traverses through the given context `endpoint_context` and find all datasets.
query_result = LineageQuery(sagemaker_session).query(
    start_arns=[endpoint_context.context_arn],
    query_filter=query_filter,
    direction=LineageQueryDirectionEnum.ASCENDANTS,
    include_edges=False,
)

# Parse through the query results to get the lineage objects corresponding to the model
model_artifacts = []
for vertex in query_result.vertices:
    model_artifacts.append(vertex.to_lineage_object().source.source_uri)

# The results of the `LineageQuery` API call return the ARN of the model deployed to the endpoint along with the S3 URI to the model.tar.gz file associated with the model
pp.pprint(model_artifacts)

Example Find the trial components associated with the endpoint

# Define the LineageFilter to look for entities of type `TRIAL_COMPONENT` and the source of type `TRAINING_JOB`.
query_filter = LineageFilter(
    entities=[LineageEntityEnum.TRIAL_COMPONENT],
    sources=[LineageSourceEnum.TRAINING_JOB],
)

# Providing this `LineageFilter` to the `LineageQuery` constructs a query that traverses through the given context `endpoint_context` and find all datasets.
query_result = LineageQuery(sagemaker_session).query(
    start_arns=[endpoint_context.context_arn],
    query_filter=query_filter,
    direction=LineageQueryDirectionEnum.ASCENDANTS,
    include_edges=False,
)

# Parse through the query results to get the ARNs of the training jobs associated with this Endpoint
trial_components = []
for vertex in query_result.vertices:
    trial_components.append(vertex.arn)
Example Changing the focal point of lineage

The LineageQuery can be modified to have different start_arns which changes the focal point of lineage. In addition, the LineageFilter can take multiple sources and entities to expand the scope of the query.

In the following we use the model as the lineage focal point and find the endpoints and datasets associated with it.

```
# Get the ModelArtifact
model_artifact_summary = list(Artifact.list(source_uri=model_package_arn))[0]
model_artifact = ModelArtifact.load(artifact_arn=model_artifact_summary.artifact_arn)
query_filter = LineageFilter(
    entities=[LineageEntityEnum.ARTIFACT],
    sources=[LineageSourceEnum.ENDPOINT, LineageSourceEnum.DATASET],
)
query_result = LineageQuery(sagemaker_session).query(
    start_arns=[model_artifact.artifact_arn],  # Model is the starting artifact
    query_filter=query_filter,
    # Find all the entities that descend from the model, i.e. the endpoint
    direction=LineageQueryDirectionEnum.DESCENDANTS,
    include_edges=False,
)
associations = []
for vertex in query_result.vertices:
    associations.append(vertex.to_lineage_object().source.source_uri)
query_result = LineageQuery(sagemaker_session).query(
    start_arns=[model_artifact.artifact_arn],  # Model is the starting artifact
    query_filter=query_filter,
    # Find all the entities that ascend from the model, i.e. the datasets
    direction=LineageQueryDirectionEnum.ASCENDANTS,
    include_edges=False,
)
for vertex in query_result.vertices:
    associations.append(vertex.to_lineage_object().source.source_uri)
pp.pprint(associations)
```

Example Using LineageQueryDirectionEnum.BOTH to find ascendent and descendent relationships

When the direction is set to BOTH, the query traverses the graph to find ascendent and descendant relationships. This traversal takes place not only from the starting node, but from each node that is visited. For example; if a training job is run twice and both models generated by the training job are deployed to endpoints, the result of the query with direction set to BOTH shows both endpoints. This is because the same image is used for training and deploying the model. Since the image is common to the model, the start_arn and both the endpoints, appear in the query result.

```
query_filter = LineageFilter(
    entities=[LineageEntityEnum.ARTIFACT],
    sources=[LineageSourceEnum.ENDPOINT, LineageSourceEnum.DATASET],
)
query_result = LineageQuery(sagemaker_session).query(
```
start_arns=[model_artifact.artifact_arn],  # Model is the starting artifact
query_filter=query_filter,
    # This specifies that the query should look for associations both ascending and
descending for the start
direction=LineageQueryDirectionEnum.BOTH,
include_edges=False,
}

associations = []
for vertex in query_result.vertices:
    associations.append(vertex.to_lineage_object().source.source_uri)
pp.pprint(associations)

Example Directions in LineageQuery - ASCENDANTS vs. DESCENDANTS

To understand the direction in the Lineage Graph, take the following entity relationship graph - Dataset -> Training Job -> Model -> Endpoint

The endpoint is a descendant of the model, and the model is a descendant of the dataset. Similarly, the model is an ascendant of the endpoint. The direction parameter can be used to specify whether the query should return entities that are descendants or ascendants of the entity in start_arns. If the start_arns contains a model and the direction is DESCENDANTS, the query returns the endpoint. If the direction is ASCENDANTS, the query returns the dataset.

# In this example, we'll look at the impact of specifying the direction as ASCENDANT or DESCENDANT in a 'LineageQuery'.
query_filter = LineageFilter(
    entities=[LineageEntityEnum.ARTIFACT],
    sources=[
        LineageSourceEnum.ENDPOINT,
        LineageSourceEnum.MODEL,
        LineageSourceEnum.DATASET,
        LineageSourceEnum.TRAINING_JOB,
    ],
)
query_result = LineageQuery(sagemaker_session).query(
    start_arns=[model_artifact.artifact_arn],
    query_filter=query_filter,
    direction=LineageQueryDirectionEnum.ASCENDANTS,
    include_edges=False,
)
ascendant_artifacts = []
# The lineage entity returned for the Training Job is a TrialComponent which can't be converted to a
# lineage object using the method 'to_lineage_object()' so we extract the TrialComponent ARN.
for vertex in query_result.vertices:
    try:
        ascendant_artifacts.append(vertex.to_lineage_object().source.source_uri)
    except:
        ascendant_artifacts.append(vertex.arn)
print("Ascendant artifacts : ")
pp.pprint(ascendant_artifacts)

query_result = LineageQuery(sagemaker_session).query(
    start_arns=[model_artifact.artifact_arn],
    query_filter=query_filter,
    direction=LineageQueryDirectionEnum.DESCENDANTS,

include_edges=False,
)
descendant_artifacts = []
for vertex in query_result.vertices:
    try:
        descendant_artifacts.append(vertex.to_lineage_object().source.source_uri)
    except:
        # Handling TrialComponents.
        descendant_artifacts.append(vertex.arn)
print("Descendant artifacts : ")
pp.pprint(descendant_artifacts)

Example SDK helper functions to make lineage queries easier

The classes EndpointContext, ModelArtifact, and DatasetArtifact have helper functions that are wrappers over the LineageQuery API to make certain lineage queries easier to leverage. The following example shows how to use these helper function.

# Find all the datasets associated with this endpoint
datasets = []
dataset_artifacts = endpoint_context.dataset_artifacts()
for dataset in dataset_artifacts:
    datasets.append(dataset.source.source_uri)
print("Datasets : ", datasets)

# Find the training jobs associated with the endpoint
training_job_artifacts = endpoint_context.training_job_arns()
training_jobs = []
for training_job in training_job_artifacts:
    training_jobs.append(training_job)
print("Training Jobs : ", training_jobs)

# Get the ARN for the pipeline execution associated with this endpoint (if any)
pipeline_executions = endpoint_context.pipeline_execution_arn()
if pipeline_executions:
    for pipeline in pipelines_executions:
        print(pipeline)

# Here we use the `ModelArtifact` class to find all the datasets and endpoints associated with the model

dataset_artifacts = model_artifact.dataset_artifacts()
endpoint_contexts = model_artifact.endpoint_contexts()
datasets = [dataset.source.source_uri for dataset in dataset_artifacts]
endpoints = [endpoint.source.source_uri for endpoint in endpoint_contexts]

print("Datasets associated with this model : ")
pp.pprint(datasets)

print("Endpoints associated with this model : ")
pp.pprint(endpoints)

# Here we use the `DatasetArtifact` class to find all the endpoints hosting models that were trained with a particular dataset
# Find the artifact associated with the dataset
dataset_artifact_arn = list(Artifact.list(source_uri=training_data))[0].artifact_arn
dataset_artifact = DatasetArtifact.load(artifact_arn=dataset_artifact_arn)

# Find the endpoints that used this training dataset
```python
dataset_artifact = sagemaker.dataset.Dataset(sagemaker_dataset.iloc[0][0])
endpoints = [endpoint.source.source_uri for endpoint in endpoint_contexts]
pp.print_endpoints = endpoints

print("Endpoints associated with the training dataset ".format(training_data))
pp.pprint(endpoints)
```

### Example Getting a Lineage graph visualization

A helper class `Visualizer` is provided in the sample notebook `visualizer.py` to help plot the lineage graph. When the query response is rendered, a graph with the lineage relationships from the `StartArns` is displayed. From the `StartArns` the visualization shows the relationships with the other lineage entities returned in the `query_lineage` API action.

```python
# Graph APIs
# Here we use the boto3 'query_lineage' API to generate the query response to plot.
from visualizer import Visualizer
query_response = sm_client.query_lineage(
    StartArns=[endpoint_context.context_arn], Direction="Ascendants", IncludeEdges=True
)

viz = Visualizer()
viz.render(query_response, "Endpoint")

query_response = sm_client.query_lineage(
    StartArns=[model_artifact.artifact_arn], Direction="Ascendants", IncludeEdges=True
)

viz.render(query_response, "Model")
```

### Cross-Account Lineage Tracking

Amazon SageMaker supports tracking lineage entities from a different AWS account. Other AWS accounts can share their lineage entities with you and you can access these lineage entities through direct API calls or SageMaker lineage queries.

SageMaker uses [AWS Resource Access Manager](https://docs.aws.amazon.com/IAM/latest/UserGuide/id委组织部inter-account-access.html) to help you securely share your lineage resources. You can share your resources through the [AWS RAM console](https://console.aws.amazon.com/basics/). You can share all lineage tracking entities in a lineage group or none.

**Note**
- After the resource share is created, it can take a few minutes for the resource and principal associations to complete. Once the association is set, the shared account receives an invitation to join the resource share. The shared account must accept the invite to gain access to shared resources. For more information on accepting a resource share invite in AWS RAM, see [Using shared AWS resources](https://docs.aws.amazon.com/IAM/latest/UserGuide/id委组织部inter-account-access.html) in the `AWS Resource Access Manager User Guide`.  

---

2987
Your cross-account lineage tracking resource policy

Amazon SageMaker supports only one type of resource policy. The SageMaker resource policy must allow all of the following operations:

"sagemaker:DescribeAction"
"sagemaker:DescribeArtifact"
"sagemaker:DescribeContext"
"sagemaker:DescribeTrialComponent"
"sagemaker:AddAssociation"
"sagemaker:DeleteAssociation"
"sagemaker:QueryLineage"

Example The following is a SageMaker resource policy created using AWS Resource Access Manager for creating a resource share for an accounts lineage group.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "FullLineageAccess",
            "Effect": "Allow",
            "Principal": {
                "AWS": "123456789012" #account-id
            },
            "Action": [
                "sagemaker:DescribeAction",
                "sagemaker:DescribeArtifact",
                "sagemaker:DescribeContext",
                "sagemaker:DescribeTrialComponent",
                "sagemaker:AddAssociation",
                "sagemaker:DeleteAssociation",
                "sagemaker:QueryLineage"
            ],
        }
    ]
}
```

Tracking Cross-Account Lineage Entities

With cross-account lineage tracking you can associate lineage entities in different accounts using the same AddAssociation API action. When you associate two lineage entities, SageMaker validates if you have permissions to perform the AddAssociation API action on both lineage entities. SageMaker then establishes the association. If you don't have the permissions, SageMaker does not create the association. Once the cross-account association is established, you can access either lineage entity from the other through the QueryLineage API action. For more information, see Querying Lineage Entities (p. 2981).

In addition to SageMaker automatically creating lineage entities, if you have cross-account access, SageMaker connects artifacts that reference the same object or data. If the data from one account is used in lineage tracking by different accounts, SageMaker creates an artifact in each account to track that data. With cross-account lineage, whenever SageMaker creates new artifacts, SageMaker checks if there are other artifacts created for the same data that are also shared with you. SageMaker then establishes associations between the newly created artifact and each of the artifacts shared with you with the AssociationType set to SameAs. You can then use the QueryLineage API action to traverse the lineage entities in your own account to lineage entities shared with you but owned by a different AWS account. For more information, see Querying Lineage Entities (p. 2981).
Topics

- Accessing lineage resources from a different accounts (p. 2989)
- Authorization for querying cross-account lineage entities (p. 2989)

Accessing lineage resources from a different accounts

Once the cross-account access for sharing lineage has been set up, you can call the following SageMaker API actions directly with the ARN to describe the shared lineage entities from another account:

- DescribeAction
- DescribeArtifact
- DescribeContext
- DescribeTrialComponent

You can also manage Associations for lineage entities owned by different accounts that are shared with you, using the following SageMaker API actions:

- AddAssociation
- DeleteAssociation

For a notebook that demonstrates how to use SageMaker Lineage APIs to query lineage across accounts, see sagemaker-lineage-cross-account-with-ram.ipynb.

Authorization for querying cross-account lineage entities

Amazon SageMaker must validate that you have permissions to perform the QueryLineage API action on the StartArns. This is enforced through the resource policy attached to the LineageGroup. The result from this action includes all the lineage entities to which you have access, whether they are owned by your account or shared by another account. For more information, see Querying Lineage Entities (p. 2981).

Register and Deploy Models with Model Registry

With the SageMaker Model Registry you can do the following:

- Catalog models for production.
- Manage model versions.
- Associate metadata, such as training metrics, with a model.
- Manage the approval status of a model.
- Deploy models to production.
- Automate model deployment with CI/CD.

Catalog models by creating SageMaker Model Registry Model (Package) Groups that contain different versions of a model. You can create a Model Group that tracks all of the models that you train to solve a particular problem. You can then register each model you train and the Model Registry adds it to the Model Group as a new model version. Lastly, you can create categories of Model Groups by further organizing them into SageMaker Model Registry Collections. A typical workflow might look like the following:

- Create a Model Group.
• Create an ML pipeline that trains a model. For information about SageMaker pipelines, see Create and Manage SageMaker Pipelines (p. 2860).
• For each run of the ML pipeline, create a model version that you register in the Model Group you created in the first step.
• Add your Model Group into one or more Model Registry Collections.

For details about how to create and work with models, model versions, and Model Groups, see Model Registry Models, Model Versions, and Model Groups (p. 2990). Optionally, if you want to further group your Model Groups into Collections, see Model Registry Collections (p. 3010).

Model Registry Models, Model Versions, and Model Groups

The SageMaker Model Registry is structured as several Model (Package) Groups with model packages in each group. These Model Groups can optionally be added to one or more Collections. Each model package in a Model Group corresponds to a trained model. The version of each model package is a numerical value that starts at 1 and is incremented with each new model package added to a Model Group. For example, if 5 model packages are added to a Model Group, the model package versions will be 1, 2, 3, 4, and 5.

There are two types of model packages in SageMaker. One type is used in the AWS Marketplace, and the other is used in the Model Registry. Model packages used in the AWS Marketplace are not versionable entities and are not associated with Model Groups in the Model Registry. For more information about model packages used in the AWS Marketplace, see Sell algorithms and packages in the AWS Marketplace (p. 3559).

The model packages used in the Model Registry are versioned, and must be associated with a Model Group. The ARN of this model package type has the structure: `arn:aws:sagemaker:region:account:model-group/version`.

The following topics show you how to create and work with models, model versions, and Model Groups in the Model Registry.

Topics
• Create a Model Group (p. 2990)
• Delete a Model Group (p. 2991)
• Register a Model Version (p. 2992)
• View Model Groups and Versions (p. 2999)
• View the Details of a Model Version (p. 2999)
• Compare Model Versions (p. 3001)
• Manage Model Group and Model Version Tags (p. 3002)
• Share Models with SageMaker Canvas Users (p. 3004)
• Delete a Model Version (p. 3004)
• Update the Approval Status of a Model (p. 3004)
• Deploy a Model from the Registry (p. 3006)
• View the Deployment History of a Model (p. 3009)

Create a Model Group

A Model Group contains a group of versioned models. Create a Model Group by using either the AWS SDK for Python (Boto3) or Amazon SageMaker Studio.
Create a Model Group (Boto3)

To create a Model Group by using Boto3, call the `create_model_package_group` method and specify a name and description as parameters. The following example shows how to create a Model Group. The response from the `create_model_package_group` call is the Amazon Resource Name (ARN) of the new Model Group.

First, import the required packages and set up the SageMaker Boto3 client.

```python
import time
import os
from sagemaker import get_execution_role, session
import boto3

region = boto3.Session().region_name
role = get_execution_role()
sm_client = boto3.client('sagemaker', region_name=region)
```

Now create the Model Group.

```python
model_package_group_name = "scikit-iris-detector-" + str(round(time.time()))
model_package_group_input_dict = {
    "ModelPackageName" : model_package_group_name,
    "ModelPackageGroupDescription" : "Sample model package group"
}

create_model_package_group_response = sm_client.create_model_package_group(**model_package_group_input_dict)
print('ModelPackageGroup Arn : {}'.format(create_model_package_group_response['ModelPackageGroupArn']))
```

Create a Model Group (Amazon SageMaker Studio)

To create a Model Group in Amazon SageMaker Studio, complete the following steps.

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 10).
2. In the left navigation pane, choose the Home icon (🏠).
3. Choose Models, and then Model registry.
4. Choose Actions, then choose Create model group.
5. In the Create model group dialog box, enter the following information:
   - Enter the name of the new Model Group in the Model group name field.
   - (Optional) Enter a description for the Model Group in the Description field.
   - (Optional) Enter any key-value pairs you want to associate with the Model Group in the Tags field. For information about using tags, see Tagging AWS resources in the AWS General Reference.
   - (Optional) Choose a project with which to associate the Model Group in the Project field. For information about projects, see Automate MLOps with SageMaker Projects (p. 3017).
6. Choose Create model group.

Delete a Model Group

This procedure demonstrates how to delete a Model Group in Amazon SageMaker Studio.
Delete a Model Group (Amazon SageMaker Studio)

**Important**
You can only delete an empty model group. Before you delete your model group, remove its model versions, if any.

To delete a Model Group in Amazon SageMaker Studio, complete the following steps.

1. Sign in to Amazon SageMaker Studio. For more information, see [Onboard to Amazon SageMaker Domain](#).
2. In the left navigation pane, choose the **Home** icon (🏠).
3. Choose **Models**, and then **Model registry**. A list of your Model Groups appears.
4. From the model groups list, select the name of the Model Group you want to delete.
5. In the top right corner, choose **Remove**.
6. In the confirmation dialog box, enter REMOVE.
7. Choose **Remove**.

Register a Model Version

You can register an Amazon SageMaker model by creating a model version that specifies the model group to which it belongs. A model version must include both the model artifacts (the trained weights of a model) and the inference code for the model.

An *inference pipeline* is a SageMaker model composed of a linear sequence of two to fifteen containers that process inference requests. You register an inference pipeline by specifying the containers and the associated environment variables. For more information on inference pipelines, see [Host models along with pre-processing logic as serial inference pipeline behind one endpoint](#).

You can register a model with an inference pipeline, by specifying the containers and the associated environment variables. To create a model version with an inference pipeline by using either the AWS SDK for Python (Boto3) or by creating a step in a SageMaker model building pipeline, use the following steps.

**Topics**

- [Register a Model Version (SageMaker Pipelines)](#)
- [Register a Model Version (Boto3)](#)
- [Register a Model Version (Amazon SageMaker Studio)](#)
- [Register a Model Version from a Different Account](#)

Register a Model Version (SageMaker Pipelines)

To register a model version by using a SageMaker model building pipeline, create a `RegisterModel` step in your pipeline. For information about creating a `RegisterModel` step as part of a pipeline, see [Step 8: Define a RegisterModel Step to Create a Model Package](#).

Register a Model Version (Boto3)

To register a model version by using Boto3, call the `create_model_package` method.

First, you set up the parameter dictionary to pass to the `create_model_package` method.

```python
# Specify the model source
model_url = "s3://your-bucket-name/model.tar.gz"
```
modelpackage_inference_specification = {
    "InferenceSpecification": {
        "Containers": [
            {
                "Image": '257758044811.dkr.ecr.us-east-2.amazonaws.com/sagemaker-xgboost:1.2-1',
                "ModelDataUrl": model_url
            }
        ],
        "SupportedContentTypes": [ "text/csv" ],
        "SupportedResponseMIMETypes": [ "text/csv" ]
    }
}

#create_model_package_input_dict = {
    "ModelPackageGroupName" : model_package_group_name,
    "ModelPackageDescription" : "Model to detect 3 different types of irises (Setosa, Versicolour, and Virginica)",
    "ModelApprovalStatus" : "PendingManualApproval"
}
create_model_package_input_dict.update(modelpackage_inference_specification)

Then you call the create_model_package method, passing in the parameter dictionary that you just set up.

create_model_package_response = sm_client.create_model_package(**create_model_package_input_dict)
model_package_arn = create_model_package_response["ModelPackageArn"]
print('ModelPackage Version ARN : {}'.format(model_package_arn))

Register a Model Version (Amazon SageMaker Studio)

To create a Model Version in Amazon SageMaker Studio, complete the following steps.

1. Sign in to Amazon SageMaker Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 10).
2. In the left navigation pane, choose the Home icon (🏠).
3. Choose Models, and then Model registry.
4. Open the Register Version form. You can do this in one of two ways:
   - Choose Actions, and then choose Create model version.
   - Select the name of the model group for which you want to create a model version, then choose Create model version.
5. In the Register model version form, enter the following information:
   - In the Model package group name dropdown, select the model group name.
   - (Optional) Enter a description for your model version.
   - In the Model Approval Status dropdown, select the version approval status.
   - (Optional) In the Custom metadata field, add custom tag(s) as key-value pairs.
6. Choose Next.
7. In the Inference Specification form, enter the following information:
   - Enter your inference image location.
8. Choose **Next**.
9. (Optional) Provide details to aid endpoint recommendations.
10. Choose **Next**.
11. (Optional) Choose model metrics you want to include.
12. Choose **Next**.
13. Ensure the displayed settings are correct, and choose **Register model version**. If you subsequently see a modal window with an error message, choose **View** (next to the message) to view the source of the error.
14. Confirm your new model version appears in the parent model group page.

**Register a Model Version from a Different Account**

To register model versions with a Model Group created by a different AWS account, you must add a cross-account AWS Identity and Access Management resource policy to enable that account. For example, one AWS account in your organization is responsible for training models, and a different account is responsible for managing, deploying, and updating models. You create IAM resource policies and apply the policies to the specific account resource to which you want to grant access for this case. For more information about cross-account resource policies in AWS, see [Cross-account policy evaluation logic](https://docs.aws.amazon.com/IAM/latest/userguide/cross-account-policy-eval-v2.html) in the [AWS Identity and Access Management User Guide](https://docs.aws.amazon.com/IAM/latest/userguide/).  

**Note**  
You must also use a KMS key to encrypt the **output data config** action during training for cross-account model deployment.

To enable cross-account model registry in SageMaker, you have to provide a cross-account resource policy for the Model Group that contains the model versions. The following is an example that creates cross-account policies for the Model Group and applies these policies to that specific resource.

The following configuration must be set in the source account which registers models cross-account in a Model Group. In this example, the source account is the model training account which will train and then register the model cross-account into the Model Registry account.

The example assumes that you previously defined the following variables:

- **sm_client** - A SageMaker Boto3 client.
- **model_package_group_name** - The Model Group to which you want to grant access.
- **model_package_group_arn** - The Model Group arn to which you want to grant cross-account access.
- **bucket** - The S3 bucket where the model training artifacts are stored.

To be able to deploy a model created in a different account, the user must have a role that has access to SageMaker actions, such as a role with the **AmazonSageMakerFullAccess** managed policy. For information about SageMaker managed policies, see [AWS Managed Policies for Amazon SageMaker](https://docs.aws.amazon.com/IAM/latest/userguide/).  

**Required IAM resource policies**

The following diagram captures the policies required to allow cross-account model registration. As shown, these policies need to be active during model training to properly register the model into the Model Registry account.
Amazon ECR, Amazon S3, and AWS KMS policies are demonstrated in the following code samples.

**Sample Amazon ECR policy**

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AddPerm",
            "Effect": "Allow",
```
Sample Amazon S3 policy

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "AddPerm",
         "Effect": "Allow",
         "Principal": {
            "AWS": "arn:aws:iam::{model_registry_account}:root"
         },
         "Action": [
            "s3:GetObject",
            "s3:GetBucketAcl",
            "s3:GetObjectAcl"
         ],
         "Resource": "arn:aws:s3:::{bucket}/*"
      }
   ]
}
```

Sample AWS KMS policy

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "AddPerm",
         "Effect": "Allow",
         "Principal": {
            "AWS": "arn:aws:iam::{model_registry_account}:root"
         },
         "Action": [
            "kms:Decrypt",
            "kms:GenerateDataKey"
         ],
         "Resource": "*"
      }
   ]
}
```

Apply resource policies to accounts

The following policy configuration applies the policies discussed in the previous section and must be put in the model training account.

```python
import json

# The Model Registry account id of the Model Group
model_registry_account = "111111111111"
```
The model training account id where training happens

```python
model_training_account = "222222222222"
```

1. Create a policy for access to the ECR repository

```python
ecr_repository_policy = {
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AddPerm",
            "Effect": "Allow",
            "Principal": {
                "AWS": f"arn:aws:iam::{model_registry_account}:root"
            },
            "Action": [
                "ecr:BatchGetImage",
                "ecr:Describe*"
            ]
        }
    ]
}
```

Convert the ECR policy from JSON dict to string

```python
ecrRepositoryPolicy = json.dumps(ecrRepositoryPolicy)
```

Set the new ECR policy

```python
ecr = boto3.client('ecr')
response = ecr.set_repository_policy(
    registryId = model_training_account,
    repositoryName = "decision-trees-sample",
    policyText = ecrRepositoryPolicy
)
```

2. Create a policy in the model training account for access to the S3 bucket

```python
bucket_policy = {
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AddPerm",
            "Effect": "Allow",
            "Principal": {
                "AWS": f"arn:aws:iam::{model_registry_account}:root"
            },
            "Action": [
                "s3:GetObject",
                "s3:GetBucketAcl",
                "s3:GetObjectAcl"
            ],
            "Resource": f"arn:aws:s3:::{bucket}/*"
        }
    ]
}
```

Convert the S3 policy from JSON dict to string

```python
bucketPolicy = json.dumps(bucketPolicy)
```

Set the new bucket policy

```python
s3 = boto3.client("s3")
response = s3.put_bucket_policy(
    Bucket = bucket,
    Policy = bucketPolicy)
```

3. Create the KMS grant for the key used during training for encryption

```python
client = boto3.client("kms")
response = client.create_grant(
    GranteePrincipal=model_registry_account,
    KeyId=kms_key_id,
    Operations=[
        "Decrypt",
        "GenerateDataKey"
    ],
```

```python
```

2997
The following configuration needs to be put in the Model Registry account where the Model Group exists.

```python
# The Model Registry account id of the Model Group
model_registry_account = "111111111111"

# 1. Create policy to allow the model training account to access the ModelPackageGroup
model_package_group_policy = {
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AddPermModelPackageVersion",
            "Effect": "Allow",
            "Principal": {
                "AWS": f"arn:aws:iam::{model_training_account}:root",
                "Action": ["sagemaker:CreateModelPackage"],
                "Resource": f"arn:aws:sagemaker:region:{model_registry_account}:model-package/{model_package_group_name}/**"
            }
        }
    ]
}

# Convert the policy from JSON dict to string
model_package_group_policy = json.dumps(model_package_group_policy)

# Set the new policy
response = sm_client.put_model_package_group_policy(
    ModelPackageGroupName = model_package_group_name,
    ResourcePolicy = model_package_group_policy)
```

Finally, use the `create_model_package` action from the model training account to register the model package in the cross-account.

```python
# Specify the model source
model_url = "s3://(bucket)/model.tar.gz"

# Set up the parameter dictionary to pass to the create_model_package method
modelpackage_inference_specification = {
    "InferenceSpecification": {
        "Containers": [
            {
                "Image": f"{model_training_account}.dkr.ecr.us-east-2.amazonaws.com/decision-trees-sample:latest",
                "ModelDataUrl": model_url
            }
        ],
        "SupportedContentTypes": [ "text/csv" ],
        "SupportedResponseMIMETypes": [ "text/csv" ],
    }
}

# Alternatively, you can specify the model source like this:
# modelpackage_inference_specification["InferenceSpecification"]["Containers"][0]["ModelDataUrl"]=model_url

create_model_package_input_dict = {
    "ModelPackageName": model_package_group_arn,
    "ModelPackageDescription": "Model to detect 3 different types of irises (Setosa, Versicolour, and Virginica)",
    "ModelApprovalStatus": "PendingManualApproval"
}
```

2998
View Model Groups and Versions

Model Groups and versions help you organize your models. You can view a list of the model versions in a Model Group.

View a List of Model Versions in a Group

You can view all of the model versions that are associated with a Model Group. If a Model Group represents all models that you train to address a specific ML problem, you can view all of those related models.

View a List of Model Versions in a Group (Boto3)

To view model versions associated with a Model Group by using Boto3, call the `list_model_packages` method, and pass the name of the Model Group as the value of the `ModelPackageGroupName` parameter. The following code lists the model versions associated with the Model Group you created in Create a Model Group (Boto3) (p. 2991).

```python
sm_client.list_model_packages(ModelPackageGroupName=model_package_group_name)
```

View a List of Model Versions in a Group (Amazon SageMaker Studio)

To view a list of the model versions in a Model Group, complete the following steps.

1. Sign in to Amazon SageMaker Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 10).
2. In the left navigation pane, choose the Home icon (🏠).
3. Choose Models, and then Model registry.
4. From the model groups list, select the name of the Model Group you want to view.
5. A new tab appears with a list of the model versions in the Model Group.

View the Details of a Model Version

You can view details of a specific model version by using either the AWS SDK for Python (Boto3) or by using Amazon SageMaker Studio.

View the Details of a Model Version (Boto3)

To view the details of a model version by using Boto3, complete the following steps.

1. Call the `list_model_packages` method to view the model versions in a Model Group.

```python
sm_client.list_model_packages(ModelPackageGroupName="ModelGroup1")
```

The response is a list of model package summaries. You can get the Amazon Resource Name (ARN) of the model versions from this list.
2. Call `describe_model_package` to see the details of the model version. You pass in the ARN of a model version that you got in the output of the call to `list_model_packages`.

```python
sm_client.describe_model_package(ModelPackageName="arn:aws:sagemaker:us-east-2:123456789012:model-package/ModelGroup1/1")
```

The output of this call is a JSON object with the model version details.

```json

```

View the Details of a Model Version (Amazon SageMaker Studio)

To view the details of a model version in Amazon SageMaker Studio, complete the following steps.

```python
```
1. Sign in to Amazon SageMaker Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 10).

2. In the left navigation pane, choose the Home icon (🏠).

3. Choose Models, and then Model registry.

4. From the model groups list, select the name of the Model Group you want to view.

5. A new tab appears with a list of the model versions in the Model Group.

6. In the list of model versions, select the name of the model version for which you want to view details.

7. On the model version tab that opens, choose one of the following to see details about the model version:
   - **Activity**: Shows events for the model version, such as approval status updates.
   - **Model quality**: Reports metrics related to your Model Monitor model quality checks, which compare model predictions to Ground Truth. For more information about Model Monitor model quality checks, see Monitor model quality (p. 3068).
   - **Explainability**: Reports metrics related to your Model Monitor feature attribution checks, which compare the relative rankings of your features in training data versus live data. For more information about Model Monitor explainability checks, see Monitor Feature Attribution Drift for Models in Production (p. 3086).
   - **Bias**: Reports metrics related to your Model Monitor bias drift checks, which compare the distribution of live data to training data. For more information about Model Monitor bias drift checks, see Monitor Bias Drift for Models in Production (p. 3077).
   - **Inference recommender**: Provides initial instance recommendations for optimal performance based on your model and sample payloads.
   - **Load test**: Runs load tests across your choice of instance types when you provide your specific production requirements, such as latency and throughput constraints.
   - **Inference specification**: Displays instance types for your real-time inference and transform jobs, and information about your Amazon ECR containers.
   - **Information**: Shows information such as the project with which the model version is associated, the pipeline that generated the model, the Model Group, and the model's location in Amazon S3.

---

**Compare Model Versions**

As you generate model versions, you might want to compare models versions by viewing relevant model quality metrics side-by-side. For example, you might want to track accuracy by comparing mean squared error (MSE) values, or you might decide to remove models that perform poorly on selected measures. The following procedure shows you how to set up model version comparison in Model Registry.

**Compare Model Versions (Amazon SageMaker Studio)**

To compare model versions within a model group, complete the following steps:

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 10).

2. In the left navigation pane, choose the Home icon (🏠).

3. Choose Models, and then Model registry.

4. From the model groups list, select the name of the Model Group you want to view. A new tab opens with a list of the model versions in the Model Group.

5. In the list of model versions, check the boxes next to the model versions you want to compare.

6. Choose the Actions dropdown menu, then choose Compare. A listing of model quality metrics appears for your selected models.
Manage Model Group and Model Version Tags

Model Registry helps you manage tags related to your model groups. You can use tags to categorize model groups by purpose, owner, environment, or other criteria. The following instructions show you how to add, delete, and edit your tags.

Manage model group tags

To add a model group tag, complete the following steps:

1. Sign in to Amazon SageMaker Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 10).
2. In the left navigation pane, choose the Home icon (🏠).
3. Choose Models, and then Model registry.
4. From the Model Groups list, select the name of the Model Group you want to edit.
5. Choose Information.
6. If you don't have any tags, choose Add tags.
7. If you have pre-existing tags, choose Manage tags in the Tags section. A list of the model group's tags appears as key-value pairs.
8. Above Add new tag, enter your new key in the blank Key field.
9. (Optional) Enter your new value in the blank Value field.
10. Choose Confirm changes.
11. Confirm your new tag appears in the Tags section of the Information page.

To delete a model group tag, complete the following steps:

1. Sign in to Amazon SageMaker Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 10).
2. In the left navigation pane, choose the Home icon (🏠).
3. Choose Models, and then Model registry.
4. From the Model Groups list, select the name of the Model Group you want to edit.
5. Choose Information.
6. In the Tags section, choose Manage tags. A list of the model group's tags appears as key-value pairs.
7. Choose the Trash icon to the right of the tag you want to remove.
8. Choose Confirm changes.

To edit a model group tag, complete the following steps:

1. Sign in to Amazon SageMaker Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 10).
2. In the left navigation pane, choose the Home icon (🏠).
3. Choose Models, and then Model registry.
4. From the Model Groups list, select the name of the Model Group you want to edit.
5. Choose Information.
6. In the **Tags** section, choose **Manage tags**. A list of the model group's tags appears as key-value pairs.
7. Edit any key or value.
8. Choose **Confirm changes**.
9. Confirm your tag contains your edits in the **Tags** section of the **Information** page.

**Manage model version tags**

**To add a model version tag, complete the following steps:**

1. Sign in to Amazon SageMaker Studio. For more information, see [Onboard to Amazon SageMaker Domain](p. 10).
2. In the left navigation pane, choose the **Home** icon (🏠).
3. Choose **Models**, and then **Model registry**.
4. From the model groups list, select the name of the Model Group you want to view. A new tab opens with a list of the model versions in the Model Group.
5. In the list of model versions, select the name of the model version you want to update.
6. Under the **Actions** dropdown menu, choose **Edit**.
7. (Optional) To add another custom metadata key-value pair, choose **Add New** and enter your new key-value pair in the blank **Name** and **Value** fields.
8. Choose **Save changes**.
9. Confirm your new tag appears in the **Tags** section of the **Information** page.

**To delete a model version tag, complete the following steps:**

1. Sign in to Amazon SageMaker Studio. For more information, see [Onboard to Amazon SageMaker Domain](p. 10).
2. In the left navigation pane, choose the **Home** icon (🏠).
3. Choose **Models**, and then **Model registry**.
4. From the model groups list, select the name of the Model Group you want to view. A new tab opens with a list of the model versions in the Model Group.
5. In the list of model versions, select the name of the model version you want to update.
6. Under the **Actions** dropdown menu, choose **Edit**.
7. Choose the **Trash** icon to the right of the tag you want to remove.
8. Choose **Confirm changes**.
9. Confirm your removed tag does not appear in the **Tags** section of the **Information** page.

**To edit a model version tag, complete the following steps:**

1. Sign in to Amazon SageMaker Studio. For more information, see [Onboard to Amazon SageMaker Domain](p. 10).
2. In the left navigation pane, choose the **Home** icon (🏠).
3. Choose **Models**, and then **Model registry**.
4. From the model groups list, select the name of the Model Group you want to view. A new tab opens with a list of the model versions in the Model Group.
5. In the list of model versions, select the name of the model version you want to update.
6. Under the **Actions** dropdown menu, choose **Edit**.
7. Edit any key or value.
8. Choose **Confirm changes**.
9. Confirm your tag contains your edits in the **Tags** section of the **Information** page.

### Share Models with SageMaker Canvas Users

You might have a model registered in your Model Registry that you want to share with a user in SageMaker Canvas. You can share a model that's been trained outside of SageMaker as long as it's registered in your Model Registry. With this functionality, SageMaker Canvas users can import models that you've trained and generate predictions with them. For more information about how to share a model with a SageMaker Canvas user, see [Bring your own model to SageMaker Canvas](p. 531).

### Delete a Model Version

This procedure demonstrates how to delete a model version in Amazon SageMaker Studio.

**Delete a Model Version (Amazon SageMaker Studio)**

To delete a model version in Amazon SageMaker Studio, complete the following steps.

1. Sign in to Amazon SageMaker Studio. For more information, see [Onboard to Amazon SageMaker Domain](p. 10).
2. In the left navigation pane, choose the **Home** icon (🏠).
3. Choose **Models**, and then **Model registry**. A list of your Model Groups appears.
4. From the model groups list, select the name of the Model Group of the model version you want to delete.
5. From the list of model versions, select the name of the model version you want to delete.
6. Choose the **Actions** dropdown menu, and choose **Remove**.
7. In the confirmation dialog box, enter **REMOVE**.
8. Choose **Remove**.
9. Confirm the model version you removed does not appear in the list of the model group's model versions.

### Update the Approval Status of a Model

After you create a model version, you typically want to evaluate its performance before you deploy it to a production endpoint. If it performs to your requirements, you can update the approval status of the model version to **Approved**. Setting the status to **Approved** can initiate CI/CD deployment for the model. If the model version does not perform to your requirements, you can update the approval status to **Rejected**.

You can manually update the approval status of a model version after you register it, or you can create a condition step to evaluate the model when you create a SageMaker pipeline. For information about creating a condition step in a SageMaker pipeline, see [Pipeline Steps](p. 2815).

When you use one of the SageMaker provided project templates and the approval status of a model version changes, the following action occurs. Only valid transitions are shown.
• PendingManualApproval to Approved – initiates CI/CD deployment for the approved model version
• PendingManualApproval to Rejected – No action
• Rejected to Approved – initiates CI/CD deployment for the approved model version
• Approved to Rejected – initiates CI/CD to deploy the latest model version with an Approved status

You can update the approval status of a model version by using the AWS SDK for Python (Boto3) or by using Amazon SageMaker Studio. You can also update the approval status of a model version as part of a condition step in a SageMaker pipeline. For information about using a model approval step in a SageMaker pipeline, see SageMaker Pipelines Overview (p. 2806).

Update the Approval Status of a Model (Boto3)

When you created the model version in Register a Model Version (p. 2992), you set the ModelApprovalStatus to PendingManualApproval. You update the approval status for the model by calling update_model_package. Note that you can automate this process by writing code that, for example, sets the approval status of a model depending on the result of an evaluation of some measure of the model’s performance. You can also create a step in a pipeline that automatically deploys a new model version when it is approved. The following code snippet shows how to manually change the approval status to Approved.

```python
model_package_update_input_dict = {
    "ModelPackageArn" : model_package_arn,
    "ModelApprovalStatus" : "Approved"
}
model_package_update_response = sm_client.update_model_package(**model_package_update_input_dict)
```

Update the Approval Status of a Model (Amazon SageMaker Studio)

The following procedure shows how to manually change the approval status from Approved to Rejected.

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 10).
2. In the left navigation pane, choose the Home icon ( ),
3. Choose Models, and then Model registry.
4. From the model groups list, select the name of the Model Group you want to view. A new tab opens with a list of the model versions in the Model Group.
5. In the list of model versions, select the name of the model version you want to update.
6. Under the Actions dropdown menu, you can choose one of two possible menu options to update the model version status.
   • Using the Update Status option
     1. Under the Actions dropdown menu, choose the Update Status dropdown menu, and choose the new model version status.
     2. (Optional) In the Comment field, add additional details.
     3. Choose Save and Update.
   • Using the Edit option
     1. Under the Actions dropdown menu, choose Edit.
     2. (Optional) In the Comment field, add additional details.
3. Choose Save changes.

7. Confirm the model version status is updated to the correct value in the model version page.

**Deploy a Model from the Registry**

After you register a model version and approve it for deployment, deploy it to a SageMaker endpoint for real-time inference.

When you create an MLOps project and choose an MLOps project template that includes model deployment, approved model versions in the Model Registry are automatically deployed to production. For information about using SageMaker MLOps projects, see [Automate MLOps with SageMaker Projects](p. 3017).

You can also enable an AWS account to deploy model versions that were created in a different account by adding a cross-account resource policy. For example, one team in your organization might be responsible for training models, and a different team is responsible for deploying and updating models.

**Topics**

- [Deploy a Model from the Registry (SageMaker SDK)](p. 3006)
- [Deploy a Model from the Registry (Boto3)](p. 3006)
- [Deploy a Model Version from a Different Account](p. 3007)

**Deploy a Model from the Registry (SageMaker SDK)**

To deploy a model version using the Amazon SageMaker Python SDK use the following code snippet:

```python
from sagemaker import ModelPackage
from time import gmtime, strftime

model_package_arn = 'arn:aws:sagemaker:us-east-2:12345678901:model-package/modeltest/1'
model = ModelPackage(role=role,
                      model_package_arn=model_package_arn,
                      sagemaker_session=sagemaker_session)
model.deploy(initial_instance_count=1, instance_type='ml.m5.xlarge')
```

**Deploy a Model from the Registry (Boto3)**

To deploy a model version using the AWS SDK for Python (Boto3), complete the following steps:

1. Create a model object from the model version by calling the `create_model` method. Pass the Amazon Resource Name (ARN) of the model version as part of the `Containers` for the model object.

   The following code snippet assumes you have already created the SageMaker Boto3 client `sm_client`, and that you have already created a model version with an ARN that you have stored in a variable named `model_version_arn`.

   ```python
   model_name = 'DEMO-modelregistry-model-' + strftime('%Y-%m-%d-%H-%M-%S', gmtime())
   print("Model name : {}".format(model_name))
   container_list = [[{'ModelPackageName': model_version_arn}]
   create_model_response = sm_client.create_model(
       ModelName = model_name,
       ExecutionRoleArn = role,
       Containers = container_list
   ```
2. Create an endpoint configuration by calling `create_endpoint_config`. The endpoint configuration specifies the number and type of Amazon EC2 instances to use for the endpoint.

```python
evaluation_logic

endpoint_config_name = 'DEMO-modelregistry-EndpointConfig-' + strftime("%Y-%m-%d-%H-%M-%S", gtime())
print(endpoint_config_name)
create_endpoint_config_response = sm_client.create_endpoint_config(
    EndpointConfigName = endpoint_config_name,
    ProductionVariants=[{
        'InstanceType':'ml.m4.xlarge',
        'InitialVariantWeight':1,
        'InitialInstanceCount':1,
        'ModelName':model_name,
        'VariantName':'AllTraffic'}])
```

3. Create the endpoint by calling `create_endpoint`.

```python
endpoint_name = 'DEMO-modelregistry-endpoint-' + strftime("%Y-%m-%d-%H-%M-%S", gtime())
print("EndpointName={}".format(endpoint_name))
create_endpoint_response = sm_client.create_endpoint(
    EndpointName=endpoint_name,
    EndpointConfigName=endpoint_config_name)
print(create_endpoint_response['EndpointArn'])
```

### Deploy a Model Version from a Different Account

You can permit an AWS account to deploy model versions that were created in a different account by adding a cross-account resource policy. For example, one team in your organization might be responsible for training models, and a different team is responsible for deploying and updating models. When you create these resource policies, you apply the policy to the specific resource to which you want to grant access. For more information about cross-account resource policies in AWS, see [Cross-account policy evaluation logic](https://docs.aws.amazon.com/IAM/latest/UserGuide/id atrav-security-context.html) in the AWS Identity and Access Management User Guide.

**Note**

You must use a KMS key to encrypt the `output data config` action during training for cross-account model deployment.

To enable cross-account model deployment in SageMaker, you have to provide a cross-account resource policy for the Model Group that contains the model versions you want to deploy, the Amazon ECR repository where the inference image for the Model Group resides, and the Amazon S3 bucket where the model versions are stored.

To be able to deploy a model that was created in a different account, you must have a role that has access to SageMaker actions, such as a role with the `AmazonSageMakerFullAccess` managed policy. For information about SageMaker managed policies, see [AWS Managed Policies for Amazon SageMaker](https://docs.aws.amazon.com/sagemaker/latest/dg/sagemaker-managed-policies.html).

The following example creates cross-account policies for all three of these resources, and applies the policies to the resources.

The example assumes that you previously defined the following variables:

- `bucket` - The Amazon S3 bucket where the model versions are stored.
- `kms_key_id` - The KMS key used to encrypt the training output.
import json

# The cross-account id to grant access to
cross_account_id = "123456789012"

# Create the policy for access to the ECR repository
ecr_repository_policy = {
    'Version': '2012-10-17',
    'Statement': [{
        'Sid': 'AddPerm',
        'Effect': 'Allow',
        'Principal': {
            'AWS': f'arn:aws:iam::{cross_account_id}:root'
        },
        'Action': ['ecr:*']
    }]
}

# Convert the ECR policy from JSON dict to string
ecr_repository_policy = json.dumps(ecr_repository_policy)

# Set the new ECR policy
ecr = boto3.client('ecr')
response = ecr.set_repository_policy(
    registryId = account,
    repositoryName = 'decision-trees-sample',
    policyText = ecr_repository_policy
)

# Create a policy for accessing the S3 bucket
bucket_policy = {
    'Version': '2012-10-17',
    'Statement': [{
        'Sid': 'AddPerm',
        'Effect': 'Allow',
        'Principal': {
            'AWS': f'arn:aws:iam::{cross_account_id}:root'
        },
        'Action': ['s3:*'],
        'Resource': f'arn:aws:s3:::{bucket}/'*
    }]
}

# Convert the policy from JSON dict to string
bucket_policy = json.dumps(bucket_policy)

# Set the new policy
s3 = boto3.client('s3')
response = s3.put_bucket_policy(
    Bucket = bucket,
    Policy = bucket_policy
)

# Create the KMS grant for encryption in the source account to the Model Registry account Model Group
client = boto3.client('kms')
response = client.create_grant(
    GranteePrincipal=cross_account_id,
KeyId=kms_key_id
Operations=['Decrypt',
            'GenerateDataKey'],
)

# 3. Create a policy for access to the Model Group.
model_package_group_policy = {
    'Version': '2012-10-17',
    'Statement': [{
        'Sid': 'AddPermModelPackageGroup',
        'Effect': 'Allow',
        'Principal': {
            'AWS': f'arn:aws:iam::{cross_account_id}:root'
        },
        'Action': ['sagemaker:DescribeModelPackageGroup'],
        'Resource': f'arn:aws:sagemaker:{region}:{account}:model-package-group/{model_package_group_name}''
    }],
    'Sid': 'AddPermModelPackageVersion',
    'Effect': 'Allow',
    'Principal': {
        'AWS': f'arn:aws:iam::{cross_account_id}:root'
    },
    'Action': ['sagemaker:DescribeModelPackage',
               'sagemaker:ListModelPackages',
               'sagemaker:UpdateModelPackage',
               'sagemaker:CreateModel'],
    'Resource': f'arn:aws:sagemaker:{region}:{account}:model-package/{model_package_group_name}/**'
}

# Convert the policy from JSON dict to string
model_package_group_policy = json.dumps(model_package_group_policy)

# Set the policy to the Model Group
response = sm_client.put_model_package_group_policy(
    ModelPackageName = model_package_group_name,
    ResourcePolicy = model_package_group_policy)

print('ModelPackageGroupArn : {}'.format(create_model_package_group_response['ModelPackageGroupArn']))
print("First Versioned ModelPackageArn: " + model_package_arn)
print("Second Versioned ModelPackageArn: " + model_package_arn2)
print("Success! You are all set to proceed for cross-account deployment.")

---

**View the Deployment History of a Model**

View the deployments for a model version Amazon SageMaker Studio by opening the tab for that model version.

**View the deployment history for a model version**

1. Sign in to Studio. For more information, see [Onboard to Amazon SageMaker Domain](#).
2. In the left navigation pane, choose the **Home** icon (🏠).
3. Choose **Models**, and then **Model registry**.
4. From the model groups list, select the name of the Model Group you want to view.
5. A new tab appears with a list of the model versions in the Model Group.
6. In the list of model versions, select the name of the model version for which you want to view details.
7. On the model version tab that opens, choose **Activity**. Deployments for the model version appear as events in the activity list with an **Event type** of **ModelDeployment**.

## Model Registry Collections

You can use Collections to group registered models that are related to each other and organize them in hierarchies to improve model discoverability at scale. With Collections, you can organize registered models that are associated with one another. For example, you could categorize your models based on the domain of the problem they solve as Collections titled **NLP-models**, **CV-models**, or **Speech-recognition-models**. To organize your registered models in a tree structure, you can nest Collections within each other. Any operations you perform on a Collection, such as create, read, update, or delete, will not alter your registered models. You can use the Amazon SageMaker Studio UI or the Python SDK to manage your Collections.

The **Collections** tab in the Model Registry displays a list of all the Collections in your account. The following sections describe how you can use options in the **Collections** tab to do the following:

- Create Collections
- Add Model Groups to a Collection
- Move Model Groups between Collections
- Remove Model Groups or Collections from other Collections

Any operation you perform on your Collections does not affect the integrity of the individual Model Groups they contain—the underlying Model Group artifacts in Amazon S3 and Amazon ECR are not modified.

While Collections provide greater flexibility in organizing your models, the internal representation imposes some constraints on the size of your hierarchy. For a summary of these constraints, see [Constraints](p. 3014).

The following topics show you how to create and work with Collections in the Model Registry.

### Topics

- [Prerequisites](p. 3010)
- [Create a Collection](p. 3011)
- [Add Model Groups to a Collection](p. 3012)
- [Remove Model Groups or Collections from a Collection](p. 3013)
- [Move a Model Group Between Collections](p. 3013)
- [View a Model Group's Parent Collection](p. 3014)
- [Constraints](p. 3014)

### Prerequisites

Create a custom policy which includes the following required Resource Groups actions:

- `resource-groups:CreateGroup`
- `resource-groups:DeleteGroup`
- `resource-groups:GetGroupQuery`
- `resource-groups:ListGroupResources`
- `resource-groups:Tag`
For instructions on how to add an inline policy, see Adding IAM identity permissions (console). When you choose the policy format, choose the JSON format and add the following policy:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "resource-groups:ListGroupResources"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "resource-groups:GetGroupQuery"
            ],
            "Resource": "arn:aws:resource-groups:*:*:group/*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "resource-groups:CreateGroup",
                "resource-groups:Tag"
            ],
            "Resource": "arn:aws:resource-groups:*:*:group/*",
            "Condition": {
                "ForAnyValue:StringEquals": {
                    "aws:TagKeys": "sagemaker:collection"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": "resource-groups:DeleteGroup",
            "Resource": "arn:aws:resource-groups:*:*:group/*",
            "Condition": {
                "StringEquals": {
                    "aws:ResourceTag/sagemaker:collection": "true"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": "tag:GetResources",
            "Resource": "*"
        }
    ]
}
```

## Create a Collection

To create a Collection, complete the following steps:

1. Sign in to Amazon SageMaker Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 10).
2. In the left navigation pane, choose the Home icon (Home).
3. Choose **Models**, and then **Model registry**.
4. Choose the **Collections** tab.
5. (Optional) If you want to create a Collection inside another Collection, navigate to the hierarchy where you want to add your Collection. Otherwise, your Collection is created at the root level.
6. In the **Actions** dropdown menu in the top right, choose **Create new collection**.
7. Enter a name for your Collection in the **Name** field of the dialog box.

   **Note**
   If you plan to create multiple hierarchies in this Collection, keep your Collection names short. The absolute path, which is a string representing the location of your Collections from the root level, must be 256 characters or less. For additional details, see [Collection and Model Group tagging](p. 3015).
8. (Optional) If you want to add Model Groups to your Collection, complete the following steps:
   a. Choose **Select model groups**.
   b. Select the Model Groups you want to add. You can select up to 10.
9. Choose **Create**.
10. Check to make sure your Collection was created in the current hierarchy. If you do not immediately see your new Collection, choose **Refresh**.

### Add Model Groups to a Collection

You can add Model Groups to a Collection from either the **Model Groups** or **Collections** tab.

To add one or more Model Groups to a Collection from the **Collections** tab, complete the following steps:

1. Sign in to Studio. For more information, see [Onboard to Amazon SageMaker Domain](p. 10).
2. In the left navigation pane, choose the **Home** icon ( ).
3. Choose **Models**, and then **Model registry**.
4. Choose the **Collections** tab.
5. Select the Collection to which you want to add Model Groups. If the desired Collection is not at root level, navigate to the hierarchy where you want to add your Model Groups.
6. In the **Actions** dropdown menu in the top right, choose **Add model groups**.
7. Select the Model Groups you want to add. You can select up to 10 Model Groups. If you select more than 10, the UI option to add your Model Groups to a Collection is inactive.
8. Choose **Add to collection**.
9. Check to make sure your Model Groups were added in the current hierarchy. If you do not immediately see your new Model Groups, choose **Refresh**.

To add one or more Model Groups to a Collection from the **Model Groups** tab, complete the following steps:

1. Sign in to Studio. For more information, see [Onboard to Amazon SageMaker Domain](p. 10).
2. In the left navigation pane, choose the **Home** icon ( ).
3. Choose **Models**, and then **Model registry**.
4. Choose the **Model Groups** tab.
5. Select the Model Groups you want to add. You can select up to 10. If you select more than 10, the UI option to add your Model Groups to a Collection is inactive.
6. In the **Actions** dropdown menu in the top right, choose **Add to collection**.
7. In the pop-up dialog, choose the root path location **Collections**. This link to the root location appears above the table.
8. Navigate to the hierarchy which contains your destination Collection, or where you want to create a new Collection to which you add your models.
9. (Optional) If you want to add your Model Groups to an existing Collection, complete the following steps:
   a. Select the destination Collection.
   b. Choose **Add to collection**.
10. (Optional) If you want to add your Model Groups to a new Collection, complete the following steps:
    a. Choose **New collection**.
    b. Enter a name for your new Collection.
    c. Choose **Create**.

### Remove Model Groups or Collections from a Collection

When you remove Model Groups or Collections from a Collection, you are removing them from a particular grouping and not from the Model Registry.

To remove one or more Model Groups or Collections from a Collection, complete the following steps:

1. Sign in to Studio. For more information, see [Onboard to Amazon SageMaker Domain](p. 10).
2. In the left navigation pane, choose the **Home** icon ( ).
3. Choose **Models**, and then **Model registry**.
4. Choose the **Collections** tab.
5. Navigate to the Collection which contains the Model Groups or Collections you want to remove.
6. Select the Model Groups or Collections you want to remove. You can select up to 10. If you select more than 10 Model Groups or Collections, the UI option to remove them is inactive.
   **Important**
   You cannot simultaneously select Model Groups and Collections for removal. If you want to remove both Model Groups and Collections, first remove Model Groups, and then remove Collections.
   **Important**
   You cannot remove non-empty Collections. If you want to remove a non-empty Collection, first remove its contents.
7. In the **Actions** dropdown menu in the top right, choose **Remove X items from collection** (where X is the number of Model Groups you selected).
8. Confirm that you want to remove the selected Model Groups.

### Move a Model Group Between Collections

To move one or more Model Groups from one Collection to another, complete the following steps:

1. Sign in to Studio. For more information, see [Onboard to Amazon SageMaker Domain](p. 10).
2. In the left navigation pane, choose the **Home** icon ( ).
3. Choose **Models**, and then **Model registry**.
4. Choose the Collections tab.
5. Navigate to the Collection which contains the Model Groups you want to move.
6. Select the Model Groups you want to move. You can select up to 10. If you select more than 10, the UI option to move your Model Groups is inactive.
7. In the Actions dropdown menu in the top right, choose Move to.
8. In the dialog box, choose the root path location Collections. This link to the root location appears above the table.
9. Navigate to the hierarchy which contains your destination Collection.
10. Select your destination Collection in the table.

View a Model Group's Parent Collection

To view the Collections which contain a particular Model Group, complete the following steps:

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 10).
2. In the left navigation pane, choose the Home icon (🏠).
3. Choose Models, and then Model registry.
4. Choose the Model Groups tab.
5. Find your Model Group in the table.
6. View the Collection column for your Model Group, which displays the name of the Collection which contains this Model Group. If multiple Collections contain this Model Group, choose the Collection column entry to display a pop-up listing the Collections which contain this Model Group.

Constraints

While using Collections, you may face issues related to tag length constraints or rate limits for Collection operations. Review the following list of caveats so you can avoid issues related to these limitations when you work with your Collections.

VPC constraints

- Collections are not supported in VPC mode.

Collection operation constraints

- You can add a maximum of 10 Model Groups to a Collection at a time.
- You can remove a maximum of 10 Model Groups from a Collection at a time.
- You can move a maximum of 10 Model Groups from one Collection to another at a time.
- You cannot delete a Collection unless it is empty.
- A Model Group can belong to multiple Collections, but a Collection can only belong to one Collection.

Tag-related constraints

- A Model Group can belong to a maximum of 48 Collections. For more details, see the following section Collection and Model Group tagging (p. 3015).
- A Collection's absolute path can be a maximum of 256 characters long. Since Collection names are user-specified, you can control the path length. For more details, see the following section Collection and Model Group tagging (p. 3015).
**Collection and Model Group tagging**

The SageMaker Model Registry uses tag rules and tags to internally represent your Collection groupings and hierarchy. You can access these tag elements in the AWS Resource Access Manager, the SageMaker SDK, and the AWS CLI, but it is important that you do not alter or delete them.

**Important**
- Do not delete or alter any tag rules or tags which belong to your Collections or Model Groups. Doing so prevents you from performing Collection operations!

A tag rule is a key-value pair that SageMaker uses to identify a Collection's location in the hierarchy. In short, the key is the key of the parent Collection, and the value is the path of the Collection within the hierarchy. SageMaker allows tag values to be 256 characters or less, so if you have multiple nested hierarchies you are advised to keep your Collection names short.

**Important**
- Keep your Collection names short. The absolute path to any Collection must be 256 characters long or less.

Model Groups, on the other hand, do not have tag rules but use tags. A Model Group's tags include the tag rules for all the Collections which contain the Model Group. For example, if four Collections contain `model-group-1`, `model-group-1` has four tags. SageMaker allows a single AWS resource to have a maximum of 50 tags. Since two are pre-allocated for general purposes, a Model Group can have a maximum of 48 tags. In conclusion, a Model Group can belong to a maximum of 48 Collections.

**Amazon SageMaker Model Registry FAQ**

Use the following FAQ items to find answers to commonly asked questions about SageMaker Model Registry.

**Q. How should I organize my models into Model Groups and model packages in the SageMaker Model Registry?**

A model package is the actual model that is registered into the Model Registry as a versioned entity. Please note there are two ways you can use model packages in SageMaker. One is with SageMaker Marketplace — these model packages are not versioned. The other is with the SageMaker Model Registry, in which the model package **must** be versioned. The Model Registry receives every new model that you retrain, gives it a version, and assigns it to a Model Group inside the Model Registry. The following image shows an example of a Model Group with 25 consecutively-versioned models.

Q. How does the SageMaker Model Registry differ from Amazon Elastic Container Registry (Amazon ECR)?

SageMaker's Model Registry is a metadata store for your machine learning models. Amazon Elastic Container Registry is a repository that stores all of your containers. Within the Model Registry, models are versioned and registered as model packages within Model Groups. Each model package contains an Amazon S3 URI to the model files associated with the trained model and an Amazon ECR URI that points to the container used while serving the model.

Q. How do I tag model packages in the SageMaker Model Registry?

Model packages in the SageMaker Model Registry do not support tags—these are versioned model packages. Instead, you can add key value pairs using CustomerMetadataProperties. Model package groups in the model registry support tagging.

Model Deployment in SageMaker

Once you train and approve a model for production, use SageMaker to deploy your model to an endpoint for real-time inference. SageMaker provides multiple inference options so that you can pick the option that best suits your workload. You also configure your endpoint by choosing the instance type and number of instances you need for optimal performance. For details about model deployment, see Deploy models for inference (p. 2335).

After you deploy your models to production, you might want to explore ways to further optimize model performance while maintaining availability of your current models. For example, you can set up a shadow test to try out a different model or model serving infrastructure before committing to the change. SageMaker deploys the new model, container, or instance in shadow mode and routes to it a copy of the inference requests in real time within the same endpoint. You can log the responses of the shadow variant for comparison. For details about shadow testing, see Shadow tests (p. 2610). If you decide to go ahead and change your model, deployment guardrails help you control the switch from the current model to a new one. You can select such methods as blue/green or canary testing of the traffic shifting process to maintain granular control during the update. For information about deployment guardrails, see Update models in production (p. 2586).

SageMaker Model Monitor

Once a model is in production, you can monitor its performance in real time with Amazon SageMaker Model Monitor. Model Monitor helps you maintain model quality by detecting violations of user-defined thresholds for data quality, model quality, bias drift and feature attribution drift. In addition, you can configure alerts so you can troubleshoot violations as they arise and promptly initiate retraining. Model Monitor is integrated with SageMaker Clarify to improve visibility into potential bias.

To learn about SageMaker Model Monitor, see Monitor data and model quality (p. 3051).

Automate MLOps with SageMaker Projects

Create end-to-end ML solutions with CI/CD by using SageMaker projects.

Use SageMaker projects to create an MLOps solution to orchestrate and manage:
Building custom images for processing, training, and inference
- Data preparation and feature engineering
- Training models
- Evaluating models
- Deploying models
- Monitoring and updating models

What is a SageMaker Project?

SageMaker Projects help organizations set up and standardize developer environments for data scientists and CI/CD systems for MLOps engineers. Projects also help organizations set up dependency management, code repository management, build reproducibility, and artifact sharing.

You can provision SageMaker Projects from the AWS Service Catalog using custom or SageMaker-provided templates. For information about the AWS Service Catalog, see What Is AWS Service Catalog. With SageMaker Projects, MLOps engineers and organization admins can define their own templates or use SageMaker-provided templates. The SageMaker-provided templates bootstrap the ML workflow with source version control, automated ML pipelines, and a set of code to quickly start iterating over ML use cases.

When Should You Use a SageMaker Project?

While notebooks are helpful for model building and experimentation, a team of data scientists and ML engineers sharing code needs a more scalable way to maintain code consistency and strict version control.

Every organization has its own set of standards and practices that provide security and governance for its AWS environment. SageMaker provides a set of first-party templates for organizations that want to quickly get started with ML workflows and CI/CD. The templates include projects that use AWS-native services for CI/CD, such as AWS CodeBuild, AWS CodePipeline, and AWS CodeCommit. The templates also offer the option to create projects that use third-party tools, such as Jenkins and GitHub. For a list of the project templates that SageMaker provides, see Use SageMaker-Provided Project Templates (p. 3023).

Organizations often need tight control over the MLOps resources that they provision and manage. Such responsibility assumes certain tasks, including configuring IAM roles and policies, enforcing resource tags, enforcing encryption, and decoupling resources across multiple accounts. SageMaker Projects can support all these tasks through custom template offerings where organizations use AWS CloudFormation.
templates to define the resources needed for an ML workflow. Data Scientists can choose a template to bootstrap and pre-configure their ML workflow. These custom templates are created as Service Catalog products and you can provision them in the Studio UI under **Organization Templates**. The Service Catalog is a service that helps organizations create and manage catalogs of products that are approved for use on AWS. For more information about creating custom templates, see [Build Custom SageMaker Project Templates – Best Practices](#).

SageMaker Projects can help you manage your Git repositories so that you can collaborate more efficiently across teams, ensure code consistency, and support CI/CD. SageMaker Projects can help you with the following tasks:

- Organize all entities of the ML lifecycle under one project.
- Establish a single-click approach to set up standard ML infrastructure for model training and deployment that incorporates best practices.
- Create and share templates for ML infrastructure to serve multiple use cases.
- Leverage SageMaker-provided pre-built templates to quickly start focusing on model building, or create custom templates with organization-specific resources and guidelines.
- Integrate with tools of your choice by extending the project templates. For an example, see [Create a SageMaker Project to integrate with GitLab and GitLab Pipelines](#).
- Organize all entities of the ML lifecycle under one project.

**What is in a SageMaker Project?**

Customers have the flexibility to set up their projects with the resources that best serve their use case. The example below showcases the MLOps setup for an ML workflow, including model training and deployment.

![SageMaker Project Diagram](#)

A typical project with a SageMaker-provided template might include the following:

- One or more repositories with sample code to build and deploy ML solutions. These are working examples that you can clone locally and modify for your needs. You own this code and can take advantage of the version-controlled repositories for your tasks.
- A SageMaker pipeline that defines steps for data preparation, training, model evaluation, and model deployment, as shown in the following diagram.
A CodePipeline or Jenkins pipeline that runs your SageMaker pipeline every time you check in a new version of the code. For information about CodePipeline, see What is AWS CodePipeline. For information about Jenkins, see Jenkins User Documentation.

A model group that contains model versions. Every time you approve the resulting model version from a SageMaker pipeline run, you can deploy it to a SageMaker endpoint.

Each SageMaker project has a unique name and ID that are applied as tags to all of the SageMaker and AWS resources created in the project. With the name and ID, you can view all of the entities associated with your project. These include:

- Pipelines
- Registered models
- Deployed models (endpoints)
- Datasets
- Service Catalog products
- CodePipeline and Jenkins pipelines
- CodeCommit and third-party Git repositories

Do I Need to Create a Project to Use SageMaker Pipelines?

No. SageMaker pipelines are standalone entities just like training jobs, processing jobs, and other SageMaker jobs. You can create, update, and run pipelines directly within a notebook by using the SageMaker Python SDK without using a SageMaker project.

Projects provide an additional layer to help you organize your code and adopt operational best practices that you need for a production-quality system.
SageMaker Studio Permissions Required to Use Projects

Users can view SageMaker provided project templates and create projects with those templates when you grant Projects permissions for users. You can grant these permissions when you onboard or update Amazon SageMaker Studio. There are two permissions to grant.

1. Grant Projects permissions for the Studio administrator to permit the Studio administrator to view the SageMaker-provided templates in the Service Catalog console. The administrator can see what other Studio users create if you grant them permission to use SageMaker projects. The administrator can also view the AWS CloudFormation template that the SageMaker-provided project templates define in the Service Catalog console. For information about using the Service Catalog console, see What Is Service Catalog in the Service Catalog User Guide.

2. Allow Studio users who are configured to use the same execution role as the domain to create projects. This grants Studio users permission to use the SageMaker-provided project templates to create a project from within Studio.

Important
Do not manually create your roles. Always create roles through Studio Settings using the steps described in the following procedure.

For users who use any role other than the domain's execution role to view and use SageMaker-provided project templates, you need to grant Projects permissions to the individual user profiles.

The following procedures show how to grant Projects permissions after you onboard to Studio. For more information about onboarding to Studio, see Onboard to Amazon SageMaker Domain (p. 10).

To grant Projects permissions for the administrator and domain execution role users

1. Open the SageMaker console.
2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. Choose Create domain.
5. If you choose Quick setup to set up your SageMaker Domain, you have permissions to use project templates by default.
6. If you choose Standard setup to set up your SageMaker Domain, make sure you turn on the following options when you configure Studio settings:
   - Enable Amazon SageMaker project templates and Amazon SageMaker JumpStart for this account
   - Enable Amazon SageMaker project templates and Amazon SageMaker JumpStart for Studio users
7. To confirm that your SageMaker Domain has active project template permissions:
   a. Open the SageMaker console.
   b. On the left navigation pane, choose Admin configurations.
   c. Under Admin configurations, choose Domains.
   d. Select your domain.
   e. Choose the Domain Settings tab.
   f. Under SageMaker Projects and JumpStart, make sure the following options are turned on:
      - Enable Amazon SageMaker project templates and Amazon SageMaker JumpStart for this account
Create an MLOps Project using Amazon SageMaker Studio

This procedure demonstrates how to create an MLOps project using Amazon SageMaker Studio.

Prerequisites

- An IAM account or IAM Identity Center to sign in to Studio. For information, see [Onboard to Amazon SageMaker Domain](p. 10).
- Permission to use SageMaker-provided project templates. For information, see [SageMaker Studio Permissions Required to Use Projects](p. 3021).
- Basic familiarity with the Studio user interface. For information, see [Amazon SageMaker Studio UI Overview](p. 205).

To create a project in Studio

1. Sign in to Studio. For more information, see [Onboard to Amazon SageMaker Domain](p. 10).
2. In the Studio sidebar, choose the Home icon (🏠).
3. Select Deployments from the menu, and then select Projects.
4. Choose Create project.

The Create project tab opens displaying a list of available templates.
5. If not selected already, choose SageMaker templates. For more information about project templates, see MLOps Project Templates (p. 3023).

6. Choose MLOps template for model building, training, and deployment.

7. Choose Select project template.

   The Create project tab changes to display Project details.

8. Enter the following information:
   
   • For Project details, enter a name and description for your project.
   • Optionally, add tags, which are key-value pairs that you can use to track your projects.

9. Choose Create project and wait for the project to appear in the Projects list.

MLOps Project Templates

An Amazon SageMaker project template automates the setup and implementation of MLOps for your projects. A SageMaker project template is an Service Catalog product that SageMaker makes available to Amazon SageMaker Studio users. These Service Catalog products are visible in your Service Catalog console after you enable permissions when you onboard or update Amazon SageMaker Studio. For information about enabling permissions to use SageMaker project templates, see SageMaker Studio Permissions Required to Use Projects (p. 3021). Use SageMaker project templates to create a project that is an end-to-end MLOps solution.

If you are an administrator, you can create custom project templates from scratch or modify one of the project templates provided by SageMaker. Studio users in your organization can use these custom project templates to create their projects.

Topics

• Use SageMaker-Provided Project Templates (p. 3023)
• Create Custom Project Templates (p. 3032)

Use SageMaker-Provided Project Templates

Amazon SageMaker provides project templates that create the infrastructure you need to create an MLOps solution for continuous integration and continuous deployment (CI/CD) of ML models. Use these templates to process data, extract features, train and test models, register the models in the SageMaker model registry, and deploy the models for inference. You can customize the seed code and the configuration files to suit your requirements.

Important

As of July 25, 2022, we require additional roles to use project templates. For a complete list of required roles and instructions on how to create them, see SageMaker Studio Permissions Required to Use Projects (p. 3021). If you do not have the new roles, you will get the error message CodePipeline is not authorized to perform AssumeRole on role arn:aws:iam::xxx:role/service-role/AmazonSagemakerServiceCatalogProductsCodePipelineRole when you try to create a new project and cannot proceed.

SageMaker project templates offer you the following choice of code repositories, workflow automation tools, and pipeline stages:

• Code repository: AWS CodeCommit or third-party Git repositories such as GitHub and Bitbucket
• CI/CD workflow automation: AWS CodePipeline or Jenkins
• Pipeline stages: Model building and training, model deployment, or both
The following discussion provides an overview of each template you can choose when you create your SageMaker project. You can also view the available templates in Studio by following Step 1: Create the Project of the Project walkthrough.

For step-by-step instructions on how to create a real project, you can follow one of the project walkthroughs:

- If you want to use the template MLOps template for model building, training, and deployment (p. 3024), see SageMaker MLOps Project Walkthrough (p. 3036).
- If you want to use the template MLOps template for model building, training, and deployment with third-party Git repositories using CodePipeline (p. 3027), see SageMaker MLOps Project Walkthrough Using Third-party Git Repos (p. 3041).
- If you want to use the template MLOps template for model building, training, and deployment with third-party Git repositories using Jenkins (p. 3028), see Create Amazon SageMaker projects using third-party source control and Jenkins.

Topics

- MLOps template for model building, training, and deployment (p. 3024)
- MLOps template for model building, training, deployment, and Amazon SageMaker Model Monitor (p. 3026)
- MLOps template for image building, model building, and model deployment (p. 3027)
- MLOps template for model building, training, and deployment with third-party Git repositories using CodePipeline (p. 3027)
- MLOps template for model building, training, and deployment with third-party Git repositories using Jenkins (p. 3028)
- Model deployment for Salesforce (p. 3029)
- Update SageMaker Projects to Use Third-Party Git Repositories (p. 3031)

MLOps template for model building, training, and deployment

This template is a combination of the following two templates, each of which can be used independently, and contains all of the resources provided in those templates.

- **Code repository**: AWS CodeCommit
- **CI/CD workflow automation**: AWS CodePipeline

MLOps template for model building and training

Use this template when you want an MLOps solution to process data, extract features, train and test models, and register the models in the SageMaker model registry.

This template provides the following resources:

- An AWS CodeCommit repository that contains sample code that creates an Amazon SageMaker pipeline in Python code and shows how to create and update the SageMaker pipeline. This repository also has a sample Python notebook that you can open and run in Studio.
- An AWS CodePipeline pipeline that has source and build steps. The source step points to the CodeCommit repository. The build step gets the code from that repository, creates and updates the SageMaker pipeline, starts a pipeline execution, and waits for the pipeline execution to complete.
- An Amazon S3 bucket to store artifacts, including CodePipeline and CodeBuild artifacts, and any artifacts generated from the SageMaker pipeline runs.
The following diagram illustrates the workflow and AWS resources used by this template to help you build and train your models.

**MLOps template for model deployment**

Use this template to automate the deployment of models in the SageMaker model registry to SageMaker endpoints for real-time inference. This template recognizes changes in the model registry. When a new model version is registered and approved, it automatically initiates a deployment.

The template provisions a CodeCommit repository with configuration files to specify the model deployment steps, AWS CloudFormation templates to define endpoints as infrastructure, and seed code for testing the endpoint.

This template provides the following resources:

- An AWS CodeCommit repository that contains sample code that deploys models to endpoints in staging and production environments.
- An AWS CodePipeline pipeline that has source, build, deploy-to-staging, and deploy-to-production steps. The source step points to the CodeCommit repository, and the build step gets the code from that repository and generates CloudFormation stacks to deploy. The deploy-to-staging and deploy-to-production steps deploy the CloudFormation stacks to their respective environments. There is a manual approval step between the staging and production build steps, so that a MLOps engineer must approve the model before it is deployed to production.

There is also a programmatic approval step with placeholder tests in the example code in the CodeCommit repository. You can add additional tests to replace the placeholders tests.

- An Amazon S3 bucket to store artifacts, including CodePipeline and CodeBuild artifacts, and any artifacts generated from the SageMaker pipeline runs.
- A CloudWatch event to initiate the pipeline when a model package version is approved or rejected.
The following diagram illustrates the workflow and AWS resources used by this template to help you deploy your models.

As previously mentioned, see Project Walkthrough for a demonstration that uses this template to create a real project.

**MLOps template for model building, training, deployment, and Amazon SageMaker Model Monitor**

This template is an extension of the MLOps template for model building, training, and deployment. It includes both the model building, training, and deployment components of the template, and an additional Amazon SageMaker Model Monitor template that provides the following types of monitoring:

- **Data Quality** – Monitor drift in data quality.
- **Model Quality** – Monitor drift in model quality metrics, such as accuracy.
- **Bias Drift for Models in Production** – Monitor bias in a model's predictions.

- **Code repository**: AWS CodeCommit
- **CI/CD workflow automation**: AWS CodePipeline

**MLOps template for Amazon SageMaker Model Monitor**

You can use this template for an MLOps solution to deploy one or more of the Amazon SageMaker data quality, model quality, model bias, and model explainability monitors to monitor a deployed model on a SageMaker inference endpoint.

This template provides the following resources:
• An AWS CodeCommit repository that contains sample Python code that gets the baselines used by the monitors from the SageMaker Model Registry, and updates the template's parameters for the staging and production environments. It also contains a AWS CloudFormation template to create the Amazon SageMaker Model Monitors.

• An AWS CodePipeline pipeline that has source, build, and deploy steps. The source step points to the CodePipeline repository. The build step gets the code from that repository, gets the baseline from the Model Registry, and updates template parameters for the staging and production environments. The deploy steps deploy the configured monitors into the staging and production environments. The manual approval step, within the DeployStaging stage, requires you to verify that the production SageMaker endpoint is InService before approving and moving to the DeployProd stage.

• The template uses the same S3 bucket created by the MLOps template for model building, training, and deployment to store the monitors' outputs.

• Two Amazon EventBridge events rules initiate the Amazon SageMaker Model Monitor AWS CodePipeline every time the staging SageMaker endpoint is updated, or a code change is committed to the CodePipeline repository.

MLOps template for image building, model building, and model deployment

This template is an extension of the MLOps template for model building, training, and deployment (p. 3024). It includes both the model building, training, and deployment components of that template and the following options:

• Include processing image–building pipeline
• Include training image–building pipeline
• Include inference image–building pipeline

For each of the components selected during project creation, the following are created by using the template:

• An Amazon ECR repository
• A SageMaker Image
• A CodeCommit repository containing a Dockerfile that you can customize
• A CodePipeline that is initiated by changes to the CodePipeline repository
• A CodeBuild project that builds a Docker image and registers it in the Amazon ECR repository
• An EventBridge rule that initiates the CodePipeline on a schedule

When the CodePipeline is initiated, it builds a new Docker container and registers it with an Amazon ECR repository. When a new container is registered with the Amazon ECR repository, a new ImageVersion is added to the SageMaker image. This initiates the model building pipeline, which in turn initiates the deployment pipeline.

The newly created image is used in the model building, training, and deployment portions of the workflow where applicable.

MLOps template for model building, training, and deployment with third-party Git repositories using CodePipeline

• Code repository: Third-party Git. Establish the AWS CodeStar connection from your AWS account to your GitHub user or organization. Add a tag with the key sagemaker and value true to this AWS CodeStar connection.

• CI/CD workflow automation: AWS CodePipeline
This template provides the following resources:

- Associations with one or more customer-specified Git repositories.
- An AWS CodePipeline pipeline that has source, build, deploy-to-staging, and deploy-to-production steps. The source step points to the third-party Git repository and the build step gets the code from that repository and generates CloudFormation stacks to deploy. The deploy-to-staging and deploy-to-production steps deploy the CloudFormation stacks to their respective environments. There is a manual approval step between the staging and production build steps, so that a MLOps engineer must approve the model before it is deployed to production.
- An AWS CodeBuild project to populate the Git repositories with the seed code information. This requires an AWS CodeStar connection from your AWS account to your account on the Git repository host.
- An Amazon S3 bucket to store artifacts, including CodePipeline and CodeBuild artifacts, and any artifacts generated from the SageMaker pipeline runs.

As previously mentioned, see Project Walkthrough Using Third-party Git Repos for a demonstration that uses this template to create a real project.

MLOps template for model building, training, and deployment with third-party Git repositories using Jenkins

- **Code repository**: Third-party Git. Establish the AWS CodeStar connection from your AWS account to your GitHub user or organization. Add a tag with the key `sagemaker` and value `true` to this AWS CodeStar connection.
- **CI/CD workflow automation**: Jenkins

This template provides the following resources:

- Associations with one or more customer-specified Git repositories.
- Seed code to generate Jenkins pipelines that have source, build, deploy-to-staging, and deploy-to-production steps. The source step points to the customer-specified Git repository. The build step gets the code from that repository and generates two CloudFormation stacks. The deploy steps deploy the CloudFormation stacks to their respective environments. There is an approval step between the staging step and the production step.
- An AWS CodeBuild project to populate the Git repositories with the seed code information. This requires an AWS CodeStar connection from your AWS account to your account on the Git repository host.
- An Amazon S3 bucket to store artifacts of the SageMaker project and SageMaker pipeline.

The template creates the association between your project and the source control repositories, but you need to perform additional manual steps to establish communication between your AWS account and Jenkins. For the detailed steps, see Create Amazon SageMaker projects using third-party source control and Jenkins.

The instructions help you build the architecture shown in the following diagram, with GitHub as the source control repository in this example. As shown, you are attaching your Git repository to the project to check in and manage code versions. Jenkins initiates the model build pipeline when it detects changes to the model build code in the Git repository. You are also connecting the project to Jenkins to orchestrate your model deployment steps, which start when you approve the model registered in the model registry, or when Jenkins detects changes to the model deployment code.
In summary, the steps guide you through the following tasks:

1. Establish the connection between your AWS and GitHub accounts.
2. Create the Jenkins account and import needed plugins.
3. Create the Jenkins IAM user and permissions policy.
4. Set the AWS credentials for the Jenkins IAM user on your Jenkins server.
5. Create an API token for communication with your Jenkins server.
6. Use a CloudFormation template to set up an EventBridge rule to monitor the model registry for newly-approved models.
7. Create the SageMaker project, which seeds your GitHub repositories with model build and deploy code.
8. Create your Jenkins model build pipeline with the model build seed code.
9. Create your Jenkins model deploy pipeline with the model deploy seed code.

Model deployment for Salesforce

- **Code repository**: AWS CodeCommit
- **CI/CD workflow automation**: AWS CodePipeline

This template provides the following resources:

- An AWS CodeCommit repository that contains sample code that creates an Amazon SageMaker pipeline in Python code and shows how to create and update the pipeline. This repository also has a Python Jupyter Notebook that you can open and run in Studio.
- An AWS CodePipeline pipeline that has source and build steps. The source step points to the CodeCommit repository. The build step gets the code from the repository, creates and updates the SageMaker pipeline, starts a pipeline run, and waits for the pipeline run to complete.
- An Amazon S3 bucket to store artifacts, including CodePipeline and CodeBuild artifacts, and any artifacts generated from the SageMaker pipeline runs.

Your admin may need to perform additional setup to enable data access from Salesforce Data Cloud to SageMaker Studio to build AI/ML models. See the solution overview in the blog post [Use the Amazon SageMaker and Salesforce Data Cloud integration to power your Salesforce apps with AI/ML](https://www.amazon.com) for detailed information and instructions.

The following diagram illustrates the high-level workflow used by this template to help you build and train your models. After you set up a connection between the Salesforce Data Cloud to Data Wrangler...
and preprocess your data, use the **Model deployment for Salesforce** project template to automate model training and deployment. The template provides customizable model deploy code and a sample notebook from AWS CodePipeline to train your model and register it into the SageMaker model registry. Once you approve the model, the endpoint is exposed to Salesforce as an API through API Gateway, and customers can start making predictions with the deployed model from within Salesforce.

**Note**
This template permits Transport Layer Security (TLS) policy versions 1.0 and 1.1 for API Gateway setup. You can make this configuration more secure with custom domain names. For details, see [Setting up custom domain names for REST APIs](#).

The blog post [Use the Amazon SageMaker and Salesforce Data Cloud integration to power your Salesforce apps with AI/ML](#) provides detailed instructions to guide you through the following steps:

1. Select the project template **Model deployment for Salesforce**, and provide the secret manager name.
2. Clone the repository to use the customizable SageMaker-provided sample notebook and model deploy code.
3. Preprocess your data with Data Wrangler.
   a. Create a connection to the Salesforce Data Cloud and import data into Data Wrangler.
   b. Use Data Wrangler to prepare the data with some example transformations.
   c. Initiate a processing job to process the data using your Data Wrangler configuration.
4. Train the model.
5. Register your model in the model registry.
6. Approve your model in model registry.
7. View your endpoint in the SageMaker console.
8. Invoke the API URL from Salesforce Einstein Studio to register and use the model inferences in Einstein Studio.

The following diagram shows in greater detail the workflow and AWS resources used by the SageMaker project template with Salesforce Data Cloud Integration.
Update SageMaker Projects to Use Third-Party Git Repositories

The managed policy attached to the AmazonSageMakerServiceCatalogProductsUseRole role was updated on July 27, 2021 for use with the third-party Git templates. Users who onboard to Amazon SageMaker Studio after this date and enable project templates use the new policy. Users who on boarded prior to this date must update the policy to use these templates. Use one of the following options to update the policy:

- Delete role and toggle Studio settings
Create Custom Project Templates

If the SageMaker-provided templates do not meet your needs (for example, you want to have more complex orchestration in the CodePipeline with multiple stages or custom approval steps), create your own templates.

We recommend starting by using SageMaker-provided templates to understand how to organize your code and resources and build on top of it. To do this, after you enable administrator access to the SageMaker templates, log in to the https://console.aws.amazon.com/servicecatalog/, choose Portfolios, then choose Imported. For information about Service Catalog, see Overview of Service Catalog in the Service Catalog User Guide.

Create your own project templates to customize your MLOps project. SageMaker project templates are Service Catalog–provisioned products to provision the resources for your MLOps project.

To create a custom project template, complete the following steps.

1. Create a portfolio. For information, see Step 3: Create an Service Catalog Portfolio.
2. Create a product. A product is a CloudFormation template. You can create multiple versions of the product. For information, see Step 4: Create an Service Catalog Product.

For the product to work with SageMaker projects, add the following parameters to your product template.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SageMakerProjectName</td>
<td>String</td>
<td>Name of the project</td>
</tr>
<tr>
<td>SageMakerProjectId</td>
<td>String</td>
<td></td>
</tr>
</tbody>
</table>
Important
We recommend that you wrap the CodeCommit repository into the SageMaker code repository for the project's repositories to be visible in VPC mode. The sample template and required addition are shown in the following code samples.
Original (sample) template:

```
ModelBuildCodecommitRepository:
  Type: AWS::CodeCommit::Repository
  Properties:
    RepositoryName: !Sub sagemaker-${SageMakerProjectName}-${SageMakerProjectId}-modelbuild # max: 10+33+15+10=68
    RepositoryDescription: !Sub SageMaker Model building workflow infrastructure as code for the Project ${SageMakerProjectName}
    Code:
      S3:
        Bucket: SEEDCODE_BUCKETNAME
        Key: toolchain/model-building-workflow-v1.0.zip
        BranchName: main
```

Additional content to add in VPC mode:

```
SageMakerRepository:
  Type: AWS::SageMaker::CodeRepository
  Properties:
    GitConfig:
      RepositoryUrl: !GetAtt ModelBuildCodeCommitRepository.CloneUrlHttp
      Branch: main
```

3. Add a launch constraint. A launch constraint designates an IAM role that Service Catalog assumes when a user launches a product. For information, see Step 6: Add a Launch Constraint to Assign an IAM Role.

4. Provision the product on https://console.aws.amazon.com/servicecatalog/ to test the template. If you are satisfied with your template, continue to the next step to make the template available in Studio.

5. Grant access to the Service Catalog portfolio that you created in step 1 to your Studio execution role. Use either the Studio domain execution role or a user role that has Studio access. For information about adding a role to the portfolio, see Step 7: Grant End Users Access to the Portfolio.

6. To make your project template available in your Organization templates list in Studio, create a tag with the following key and value to the Service Catalog product you created in step 2.
   - **key**: sagemaker:studio-visibility
   - **value**: true

After you complete these steps, Studio users in your organization can create a project with the template you created by following the steps in Create an MLOps Project using Amazon SageMaker Studio (p. 3022) and choosing Organization templates when you choose a template.

View Project Resources

After you create a project, view the resources associated with the project in Amazon SageMaker Studio.

To create a project in Studio

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 10).
2. In the Studio sidebar, choose the **Home** icon (🏠).
3. Select **Deployments** from the menu, and then select **Projects**.
4. Select the name of the project for which you want to view details.

A tab with the project details appears.

On the project details tab, you can view the following entities associated with the project.

- **Repositories**: Code repositories (repos) associated with this project. If you use a SageMaker-provided template when you create your project, it creates a AWS CodeCommit repo or a third-party Git repo. For more information about CodeCommit, see [What is AWS CodeCommit](https://aws.amazon.com/codecommit/).
- **Pipelines**: SageMaker ML pipelines that define steps to prepare data, train, and deploy models. For information about SageMaker ML pipelines, see [Create and Manage SageMaker Pipelines](https://docs.aws.amazon.com/sagemaker/latest/dg/CreateAndManageSageMakerPipelines.html).
- **Experiments**: One or more Amazon SageMaker Autopilot experiments associated with the project. For information about Autopilot, see [SageMaker Autopilot](https://docs.aws.amazon.com/sagemaker/latest/dg/AutoPilot.html).
- **Model groups**: Groups of model versions that were created by pipeline executions in the project. For information about model groups, see [Create a Model Group](https://docs.aws.amazon.com/sagemaker/latest/dg/CreateSageMakerModelGroup.html).
- **Endpoints**: SageMaker endpoints that host deployed models for real-time inference. When a model version is approved, it is deployed to an endpoint.
- **Settings**: Settings for the project. This includes the name and description of the project, information about the project template and **SourceModelPackageGroupName**, and metadata about the project.

## Update an MLOps Project in Amazon SageMaker Studio

This procedure demonstrates how to update an MLOps project in Amazon SageMaker Studio. You can update the **Description**, template version, and template parameters.

### Prerequisites

- An IAM account or IAM Identity Center to sign in to Studio. For information, see [Onboard to Amazon SageMaker Domain](https://docs.aws.amazon.com/sagemaker/latest/dg/OnboardToSageMakerDomain.html).
- Basic familiarity with the Studio user interface. For information, see [Amazon SageMaker Studio UI Overview](https://docs.aws.amazon.com/sagemaker/latest/dg/AmazonSageMakerStudioUIOverview.html).
- Add the following custom inline policies to the specified roles:

  User-created role having `AmazonSageMakerFullAccess`

  ```json
  {
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Action": [
          "servicecatalog:CreateProvisionedProductPlan",
          "servicecatalog:DescribeProvisionedProductPlan",
          "servicecatalog:DeleteProvisionedProductPlan"
        ],
        "Resource": "*"
      }
    ]
  }
  ```
Delete an MLOps Project using Amazon SageMaker Studio

This procedure demonstrates how to delete an MLOps project using Amazon SageMaker Studio.

**Prerequisites**

*Note*
You can only delete projects in Studio that you have created. This condition is part of the service catalog permission servicecatalog:TerminateProvisionedProduct in the AmazonSageMakerFullAccess policy. If needed, you can update this policy to remove this condition.
To delete a project in Amazon SageMaker Studio

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 10).
2. In the Studio sidebar, choose the Home icon (🏠).
3. Select Deployments from the menu, and then select Projects.
4. Select the target project from the dropdown list. If you don’t see your project, type the project name and apply the filter to find your project.
5. Once you’ve found your project, select the project name to view details.
6. Choose Delete from the Actions menu.
7. Confirm your choice by choosing Delete from the Delete Project window.

SageMaker MLOps Project Walkthrough

This walkthrough uses the template MLOps template for model building, training, and deployment (p. 3024) to demonstrate using MLOps projects to create a CI/CD system to build, train, and deploy models.

Prerequisites

To complete this walkthrough, you need:

- An IAM account or IAM Identity Center to sign in to Studio. For information, see Onboard to Amazon SageMaker Domain (p. 10).
- Permission to use SageMaker-provided project templates. For information, see SageMaker Studio Permissions Required to Use Projects (p. 3021).
- Basic familiarity with the Studio user interface. For information, see Amazon SageMaker Studio UI Overview (p. 205).

Topics

- Step 1: Create the Project (p. 3036)
- Step 2: Clone the Code Repository (p. 3037)
- Step 3: Make a Change in the Code (p. 3038)
- Step 4: Approve the Model (p. 3040)
- (Optional) Step 5: Deploy the Model Version to Production (p. 3040)
- Step 6: Clean Up Resources (p. 3040)

Step 1: Create the Project

In this step, you create a SageMaker MLOps project by using a SageMaker-provided project template to build, train, and deploy models.

To create the SageMaker MLOps project

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 10).
2. In the Studio sidebar, choose the Home icon ( ).
3. Select Deployments from the menu, and then select Projects.
4. Choose Create project.

The Create project tab appears.
5. If not selected already, choose SageMaker templates, then choose MLOps template for model building, training, and deployment.
6. For Project details, enter a name and description for your project.

When the project appears in the Projects list with a Status of Create completed, move on to the next step.

Important
As of July 25, 2022, we require additional roles to use project templates.
If you see the error message CodePipeline is not authorized to perform AssumeRole on role arn:aws:iam::xxx:role/service-role/AmazonSageMakerServiceCatalogProductsCodePipelineRole, see Steps 5-6 of SageMaker Studio Permissions Required to Use Projects (p. 3021) for a complete list of required roles and instructions on how to create them.

Step 2: Clone the Code Repository

After you create the project, two CodeCommit repositories are created in the project. One of the repositories contains code to build and train a model, and one contains code to deploy the model. In this step, you clone the repository to your local SageMaker project that contains the code to build and train the model to the local Studio environment so that you can work with the code.

To clone the code repository

1. In the Studio sidebar, choose the Home icon ( ).
2. Select Deployments from the menu, and then select Projects.
3. Select the project you created in the previous step to open the project tab for your project.
4. In the project tab, choose Repositories, and in the Local path column for the repository that ends with modelbuild, choose clone repo....
5. In the dialog box that appears, accept the defaults and choose Clone repository.
Step 3: Make a Change in the Code

Now make a change to the pipeline code that builds the model and check in the change to initiate a new pipeline run. The pipeline run registers a new model version.

To make a code change

1. In Studio, choose the file browser icon ( ), and navigate to the pipelines/abalone folder. Double-click pipeline.py to open the code file.
2. In the pipeline.py file, find the line that sets the training instance type.

```python
training_instance_type = ParameterString(
    name="TrainingInstanceType", default_value="ml.m5.xlarge"
)
```

Change `ml.m5.xlarge` to `ml.m5.large`, then type Ctrl+S to save the change.

3. Choose the Git icon ( ). Stage, commit, and push the change in pipeline.py. Also, enter a summary in the Summary field and an optional description in the Description field. For information about using Git in Studio, see Clone a Git Repository in SageMaker Studio (p. 287).
After pushing your code change, the MLOps system initiates a run of the pipeline that creates a new model version. In the next step, you approve the new model version to deploy it to production.

**Step 4: Approve the Model**

Now you approve the new model version that was created in the previous step to initiate a deployment of the model version to a SageMaker endpoint.

**To approve the model version**

1. In the Studio sidebar, choose the Home icon (🏠).
2. Select Deployments from the menu, and then select Projects.
3. Select the name of the project you created in the first step to open the project tab for your project.
4. In the project tab, choose Model groups, then double-click the name of the model group that appears.

   The model group tab appears.
5. In the model group tab, double-click Version 1. The Version 1 tab opens. Choose Update status.
6. In the model Update model version status dialog box, in the Status dropdown list, select Approve, then choose Update status.

   Approving the model version causes the MLOps system to deploy the model to staging. To view the endpoint, choose the Endpoints tab on the project tab.

**(Optional) Step 5: Deploy the Model Version to Production**

Now you can deploy the model version to the production environment.

**Note**

To complete this step, you need to be an administrator in your Studio domain. If you are not an administrator, skip this step.

**To deploy the model version to the production environment**

1. Log in to the CodePipeline console at [https://console.aws.amazon.com/codepipeline/](https://console.aws.amazon.com/codepipeline/)
2. Choose Pipelines, then choose the pipeline with the name sagemaker-projectname-projectid-modeldeploy, where projectname is the name of your project, and projectid is the ID of your project.
3. In the DeployStaging stage, choose Review.
4. In the Review dialog box, choose Approve.

   Approving the DeployStaging stage causes the MLOps system to deploy the model to production. To view the endpoint, choose the Endpoints tab on the project tab in Studio.

**Step 6: Clean Up Resources**

To stop incurring charges, clean up the resources that were created in this walkthrough. To do this, complete the following steps.

**Note**

To delete the AWS CloudFormation stack and the Amazon S3 bucket, you need to be an administrator in Studio. If you are not an administrator, ask your administrator to complete those steps.
1. In the Studio sidebar, choose the Home icon ( ).
2. Select Deployments from the menu, and then select Projects.
3. Select the target project from the dropdown list. If you don’t see your project, type the project name and apply the filter to find your project.
4. You can delete a Studio project in one of the following ways:
   a. You can delete the project from the projects list.
      Right-click the target project and choose Delete from the dropdown list.
      
      **Note**
      This functionality is supported in Studio version v3.17.1 or higher. For more information, see Shut down and Update SageMaker Studio (p. 292).
   b. You can delete a project from the Project details section.
      i. When you've found your project, double-click it to view its details in the main panel.
      ii. Choose Delete from the Actions menu.
5. Confirm your choice by choosing Delete from the Delete Project window.

This deletes the Service Catalog provisioned product that the project created. This includes the CodeCommit, CodePipeline, and CodeBuild resources created for the project.
6. Delete the AWS CloudFormation stacks that the project created. There are two stacks, one for staging and one for production. The names of the stacks are sagemaker-projectname-project-id-deploy-staging and sagemaker-projectname-project-id-deploy-prod, where projectname is the name of your project, and project-id is the ID of your project.

For information about how to delete a AWS CloudFormation stack, see Deleting a stack on the AWS CloudFormation console in the AWS CloudFormation User Guide.

7. Delete the Amazon S3 bucket that the project created. The name of the bucket is sagemaker-project-project-id, where project-id is the ID of your project.

**SageMaker MLOps Project Walkthrough Using Third-party Git Repos**

This walkthrough uses the template MLOps template for model building, training, and deployment with third-party Git repositories using CodePipeline (p. 3027) to demonstrate how to use MLOps projects to create a CI/CD system to build, train, and deploy models.

**Prerequisites**

To complete this walkthrough, you need:

- An IAM or IAM Identity Center account to sign in to Studio. For information, see Onboard to Amazon SageMaker Domain (p. 10).
- Permission to use SageMaker-provided project templates. For information, see SageMaker Studio Permissions Required to Use Projects (p. 3021).
- Basic familiarity with the Studio user interface. For information, see Amazon SageMaker Studio UI Overview (p. 205).
- Two GitHub repositories initialized with a README. You input these repositories into the project template, which will seed these repos with model build and deploy code.

**Topics**
Step 1: Set up the GitHub connection

In this step, you connect to your GitHub repositories using an AWS CodeStar connection. The SageMaker project uses this connection to access your source code repositories.

To set up the GitHub connection:

1. Log in to the CodePipeline console at https://console.aws.amazon.com/codepipeline/
2. Under Settings in the navigation pane, choose Connections.
3. Choose Create connection.
4. For Select a provider, select GitHub.
5. For Connection name, enter a name.
6. Choose Connect to GitHub.
7. If the AWS Connector GitHub app isn’t previously installed, choose Install new app.
   This displays a list of all the GitHub personal accounts and organizations to which you have access.
8. Choose the account where you want to establish connectivity for use with SageMaker projects and GitHub repositories.
9. Choose Configure.
10. You can optionally select your specific repositories or choose All repositories.
11. Choose Save. When the app is installed, you’re redirected to the Connect to GitHub page and the installation ID is automatically populated.
12. Choose Connect.
13. Add a tag with the key sagemaker and value true to this AWS CodeStar connection.
14. Copy the connection ARN to save for later. You use the ARN as a parameter in the project creation step.

Step 2: Create the Project

In this step, you create a SageMaker MLOps project by using a SageMaker-provided project template to build, train, and deploy models.

To create the SageMaker MLOps project

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 10).
2. In the Studio sidebar, choose the Home icon ( ).
3. Select Deployments from the menu, and then select Projects.
4. Choose Create project.
   The Create project tab appears.
5. For **SageMaker project templates**, choose **MLOps template for model building, training, and deployment with third-party Git repositories**.

6. Choose **Select project template**.

7. Under **ModelBuild CodeRepository Info**, provide the following parameters:

   - For **URL**, enter the URL of your Git repository for the model build code in `https://git-url.git` format.
   - For **Branch**, enter the branch to use from your Git repository for pipeline activities.
   - For **Full Repository Name**, enter the Git repository name in the format of `username/repository name` or `organization/repository name`.
   - For **Codestar Connection ARN**, enter the ARN of the AWS CodeStar connection you created in Step 1.
   - The **Sample Code** toggle switch lets you choose whether to populate the repository with model build seed code. We can leave it on for this demo.

8. Under **ModelDeploy CodeRepository Info**, provide the following parameters:

   - For **URL**, enter the URL of your Git repository for the model deploy code in `https://git-url.git` format.
   - For **Branch**, enter the branch to use from your Git repository for pipeline activities.
   - For **Full Repository Name**, enter the Git repository name in the format of `username/repository name` or `organization/repository name`.
   - For **Codestar Connection ARN**, enter the ARN of the AWS CodeStar connection you created in Step 1.
   - The **Sample Code** toggle switch lets you choose whether to populate the repository with model deployment seed code. We can leave it on for this demo.

9. Choose **Create Project**.

The project appears in the **Projects** list with a **Status of Created**.

**Step 3: Make a Change in the Code**

Now make a change to the pipeline code that builds the model and commit the change to initiate a new pipeline run. The pipeline run registers a new model version.

**To make a code change**

1. In your model build GitHub repo, navigate to the `pipelines/abalone` folder. Double-click `pipeline.py` to open the code file.

2. In the `pipeline.py` file, find the line that sets the training instance type.

   ```python
   training_instance_type = ParameterString(
       name="TrainingInstanceType", default_value="ml.m5.xlarge"
   )
   ```

   Open the file for editing, change `ml.m5.xlarge` to `ml.m5.large`, then commit.

After you commit your code change, the MLOps system initiates a run of the pipeline that creates a new model version. In the next step, you approve the new model version to deploy it to production.

**Step 4: Approve the Model**

Now you approve the new model version that was created in the previous step to initiate a deployment of the model version to a SageMaker endpoint.
To approve the model version

1. In the Studio sidebar, choose the Home icon ( ).
2. Select Deployments from the menu, and then select Projects.
3. Find the name of the project you created in the first step and double-click on it to open the project tab for your project.
4. In the project tab, choose Model groups, then double-click the name of the model group that appears.

   The model group tab appears.
5. In the model group tab, double-click Version 1. The Version 1 tab opens. Choose Update status.
6. In the model Update model version status dialog box, in the Status dropdown list, select Approve and then choose Update status.

   Approving the model version causes the MLOps system to deploy the model to staging. To view the endpoint, choose the Endpoints tab on the project tab.

(Optional) Step 5: Deploy the Model Version to Production

Now you can deploy the model version to the production environment.

Note
   To complete this step, you need to be an administrator in your Studio domain. If you are not an administrator, skip this step.

To deploy the model version to the production environment

1. Log in to the CodePipeline console at https://console.aws.amazon.com/codepipeline/
2. Choose Pipelines, then choose the pipeline with the name sagemaker-projectname-projectid-modeldeploy, where projectname is the name of your project, and projectid is the ID of your project.
3. In the DeployStaging stage, choose Review.
4. In the Review dialog box, choose Approve.

   Approving the DeployStaging stage causes the MLOps system to deploy the model to production. To view the endpoint, choose the Endpoints tab on the project tab in Studio.

Step 6: Clean Up Resources

To stop incurring charges, clean up the resources that were created in this walkthrough.

Note
   To delete the AWS CloudFormation stack and the Amazon S3 bucket, you need to be an administrator in Studio. If you are not an administrator, ask your administrator to complete those steps.

1. In the Studio sidebar, choose the Home icon ( ).
2. Select Deployments from the menu, and then select Projects.
3. Select the target project from the dropdown list. If you don’t see your project, type the project name and apply the filter to find your project.
4. Select your project to view its details in the main panel.
5. Choose Delete from the Actions menu.
6. Confirm your choice by choosing **Delete** from the **Delete Project** window.

   This deletes the Service Catalog provisioned product that the project created. This includes the CodeCommit, CodePipeline, and CodeBuild resources created for the project.

7. Delete the AWS CloudFormation stacks that the project created. There are two stacks, one for staging and one for production. The names of the stacks are `sagemaker-projectname-project-id-deploy-staging` and `sagemaker-projectname-project-id-deploy-prod`, where `projectname` is the name of your project, and `project-id` is the ID of your project.

   For information about how to delete a AWS CloudFormation stack, see [Deleting a stack on the AWS CloudFormation console](https://aws.amazon.com/documentation/cloudformation/#deleting-a-stack) in the **AWS CloudFormation User Guide**.

8. Delete the Amazon S3 bucket that the project created. The name of the bucket is `sagemaker-projectname-project-id`, where `project-id` is the ID of your project.

---

### Amazon SageMaker MLOps FAQ

Use the following FAQ items to find answers to commonly asked questions about MLOps in SageMaker.

**Q. Do I need to use the SageMaker Python SDK to create a SageMaker pipeline?**

No, the SageMaker Python SDK is not required to create a SageMaker pipeline. You can also use **boto3** or [AWS CloudFormation](https://aws.amazon.com/cloudformation). Creating a pipeline requires a pipeline definition, which is a JSON object that defines each step of the pipeline. The SageMaker SDK offers a simple way to construct the pipeline definition, which you can use with any of the APIs previously mentioned to create the pipeline itself. Without using the SDK, users have to write the raw JSON definition to create the pipeline without any of the error checks provided by the SageMaker Python SDK. To see the schema for the pipeline JSON definition, see [SageMaker Pipeline Definition JSON Schema](https://docs.aws.amazon.com/sagemaker/latest/dg/pipeline-definition.html). The following code sample shows an example of a SageMaker pipeline definition JSON object:

```json
{
    "Version": "2020-12-01",
    "Metadata": {},
    "Parameters": [
        {"Name": "ProcessingInstanceType", "Type": "String", "DefaultValue": "ml.m5.xlarge"},
        {"Name": "ProcessingInstanceCount", "Type": "Integer", "DefaultValue": 1},
        {"Name": "TrainingInstanceType", "Type": "String", "DefaultValue": "ml.m5.xlarge"},
        {"Name": "ModelApprovalStatus", "Type": "String", "DefaultValue": "PendingManualApproval"},
        {"Name": "ProcessedData", "Type": "String", "DefaultValue": "S3_URL"},
        {"Name": "InputDataUrl", "Type": "String", "DefaultValue": "S3_URL"},
        {"Name": "PipelineExperimentConfig": {"ExperimentName": {"Get": "Execution.PipelineName"}, "TrialName": {"Get": "Execution.PipelineExecutionId"}},
        {"Name": "ReadTrainDataFromFS", "Type": "Processing", "Arguments": {"ProcessingResources": {"ClusterConfig": {"InstanceType": "ml.m5.4xlarge", "InstanceCount": 2, "VolumeSizeInGB": 30}}, "AppSpecification": {"ImageUri": "IMAGE_URI", "ContainerArguments": [....]}, "RoleArn": "ROLE"},
```
Q. Why do I see a repack step in my SageMaker pipeline?

Model repacking happens when the pipeline needs to include a custom script in the compressed model file (model.tar.gz) to be uploaded to Amazon S3 and used to deploy a model to a SageMaker endpoint. When SageMaker pipeline trains a model and registers it to the model registry, it introduces a repack step if the trained model output from the training job needs to include a custom inference script. The repack step uncompresses the model, adds a new script, and recompresses the model. Running the pipeline adds the repack step as a training job.

Q. Can I use SageMaker Experiments with SageMaker Pipelines?

Yes. SageMaker Pipelines is natively integrated with SageMaker Experiments. You can use PipelineExperimentConfig when creating a pipeline and set your own SageMaker Experiment name. Each run of the pipeline creates a trial, and each step in the pipeline corresponds to a TrialComponent within the trial. If no trial name is specified in the experiment config, the pipeline execution ID is used as the trial name.

```
pipeline = Pipeline(
    name=pipeline_name,
    parameters=[...],
    steps=[...],
    sagemaker_session=sagemaker_session,
    pipeline_experiment_config=PipelineExperimentConfig(  # ExecutionVariables.PIPELINE_NAME
        ExecutionVariables.PIPELINE_EXECUTION_ID
    )
)
```

Q. SageMaker Project templates have a model deploy repository that uses CloudFormation (CFN) to create an endpoint. Are there ways to deploy the model without using CloudFormation?

You can customize the deploy repository in the project template to deploy the model from the model registry any way you like. The template uses CloudFormation to create a real-time endpoint, as an example. You can update the deployment to use the SageMaker SDK, boto3, or any other API that can create endpoints instead of CFN. If you need to update the CodeBuild steps as part of the deployment pipeline, you can create a custom template.

Q. How do we pass the model file Amazon S3 URL from the train step to the model register step in a SageMaker pipeline at run time?

You can reference the model location as a property of the training step, as shown in the end-to-end example CustomerChurn pipeline in Github.
Q. If I am extending a prebuilt container to train an estimator or for a ProcessingStep on SageMaker Pipelines, is it necessary to copy the script to the container in the Dockerfile?

No, you can either copy the script to the container or pass it via the entry_point argument (of your estimator entity) or code argument (of your processor entity), as demonstrated in the following code sample.

```python
step_process = ProcessingStep(
    name="PreprocessAbaloneData",
    processor=sklearn_processor,
    inputs=[
        ProcessingInput(
            input_name='dataset',
            source=...,
            destination="/opt/ml/processing/code",
        ),
    ],
    outputs=[
        ProcessingOutput(output_name="train", source="/opt/ml/processing/train",
            destination = processed_data_path),
        ProcessingOutput(output_name="validation", source="/opt/ml/processing/validation",
            destination = processed_data_path),
        ProcessingOutput(output_name="test", source="/opt/ml/processing/test", destination = processed_data_path),
    ],
    code=os.path.join(BASE_DIR, "process.py"), ## Code is passed through an argument
    cache_config = cache_config,
    job_arguments = ['--input', 'arg1']
)

sklearn_estimator = SKLearn(
    entry_point=os.path.join(BASE_DIR, "train.py"), ## Code is passed through the
    entry_point
    framework_version="0.23-1",
    instance_type=training_instance_type,
    role=role,
    output_path=model_path, # New
    sagemaker_session=sagemaker_session, # New
    instance_count=1, # New
    base_job_name=f"{base_job_prefix}/pilot-train",
    metric_definitions=[
        {'Name': 'train:accuracy', 'Regex': 'accuracy_train=(.*?);'},
        {'Name': 'validation:accuracy', 'Regex': 'accuracy_validation=(.*?);'}
    ],
)
```

Q. What's the recommended way to manage dependencies for different SageMaker Pipelines steps?

You can use a SageMaker Projects template to implement image-building CI/CD. With this template, you can automate the CI/CD of images that are built and pushed to Amazon ECR. Changes in the container files in your project's source control repositories initiate the ML pipeline and deploy the latest version for your container. For more information, see the blog [Create Amazon SageMaker projects with image building CI/CD pipelines](#).
Q. How do I provide SageMaker Project access to specific user profiles in Amazon SageMaker Studio?

Since SageMaker Projects is backed by Service Catalog, you must add each role that requires access to SageMaker Projects to the Amazon SageMaker Solutions and ML Ops products Portfolio in the service catalog. You can do this on the Groups, roles, and users tab, as shown in the following image. If each user profile in Studio has a different role, you should add each of those roles to the service catalog. You can also do this while creating a user profile in Studio.

Q. Where do I see the properties associated with each SageMaker pipeline step so that I can use them in subsequent steps?

Each step in the pipeline uses the underlying SageMaker APIs for the corresponding jobs. For example, TrainingStep invokes the CreateTrainingJob API and the step properties correspond to the response from DescribeTrainingJob API. The response output can be found in the API reference link for DescribeTrainingJob. You can follow the same procedure to get the properties for TransformStep, ProcessingStep, TuningStep, and CreateModelStep. For more information about pipeline steps, see Pipeline Steps.

Q. In SageMaker Pipelines, can I specify a unique output path for a pipeline step so that its output data will not be overridden by future runs?

Yes, you can use ExecutionVariables and the Join function to specify your output location. ExecutionVariables is resolved at runtime. For instance, ExecutionVariables.PIPELINE_EXECUTION_ID is resolved to the ID of the current execution, which can be used as a unique identifier across different runs.

```python
from sagemaker.workflow.execution_variables import ExecutionVariables

processor_run_args = sklearn_processor.run(
    outputs=[
        ProcessingOutput(
            output_name="train",
            source="/opt/ml/processing/train",
            destination=Join(
                on="/",
                values=[
                    "s3:/",
                    default_bucket,
            
```
Q. What’s the best way to reproduce my model in SageMaker?

SageMaker’s Lineage Tracking service works in the backend to track all the metadata associated with your model training and deployment workflows. This includes your training jobs, datasets used, pipelines, endpoints, and the actual models. You can query the lineage service at any point to find the exact artifacts used to train a model. Using those artifacts, you can recreate the same ML workflow to reproduce the model as long as you have access to the exact dataset that was used. A trial component tracks the training job. This trial component has all the parameters used as part of the training job. If you don’t need to rerun the entire workflow, you can reproduce the training job to derive the same model.

Q. If I try to delete a SageMaker project created from a SageMaker template and receive an error due to non-empty Amazon S3 buckets or Amazon ECR repositories, how can I delete the project?

If you try to delete your SageMaker project and get one of the following error messages:
The bucket you tried to delete is not empty

The repository with name 'repository-name' in registry
with id 'id' cannot be deleted because it still contains images

then you have non-empty Amazon S3 buckets or Amazon ECR repositories which you need to manually delete before you delete the SageMaker project. AWS CloudFormation does not automatically delete non-empty Amazon S3 buckets or Amazon ECR repositories for you.
Monitor data and model quality

Amazon SageMaker Model Monitor monitors the quality of Amazon SageMaker machine learning models in production. You can set up continuous monitoring with a real-time endpoint (or a batch transform job that runs regularly), or on-schedule monitoring for asynchronous batch transform jobs. With Model Monitor, you can set alerts that notify you when there are deviations in the model quality. Early and proactive detection of these deviations enables you to take corrective actions, such as retraining models, auditing upstream systems, or fixing quality issues without having to monitor models manually or build additional tooling. You can use Model Monitor prebuilt monitoring capabilities that do not require coding. You also have the flexibility to monitor models by coding to provide custom analysis.

Model Monitor provides the following types of monitoring:

- **Monitor data quality (p. 3062)** - Monitor drift in data quality.
- **Monitor model quality (p. 3068)** - Monitor drift in model quality metrics, such as accuracy.
- **Monitor Bias Drift for Models in Production (p. 3077)** - Monitor bias in your model's predictions.
- **Monitor Feature Attribution Drift for Models in Production (p. 3086)** - Monitor drift in feature attribution.

**Topics**

- Monitoring a Model in Production (p. 3051)
- How Model Monitor Works (p. 3052)
- Capture data (p. 3053)
- Monitor data quality (p. 3062)
- Monitor model quality (p. 3068)
- Monitor Bias Drift for Models in Production (p. 3077)
- Monitor Feature Attribution Drift for Models in Production (p. 3086)
- Schedule monitoring jobs (p. 3096)
- Amazon SageMaker Model Monitor prebuilt container (p. 3100)
- Interpret results (p. 3101)

**Monitoring a Model in Production**

After you deploy a model into your production environment, use Amazon SageMaker model monitor to continuously monitor the quality of your machine learning models in real time. Amazon SageMaker model monitor enables you to set up an automated alert triggering system when there are deviations in the model quality, such as data drift and anomalies. Amazon CloudWatch Logs collects log files of monitoring the model status and notifies when the quality of your model hits certain thresholds that you preset. CloudWatch stores the log files to an Amazon S3 bucket you specify. Early and pro-active detection of model deviations through AWS model monitor products enables you to take prompt actions to maintain and improve the quality of your deployed model.

For more information about SageMaker model monitoring products, see Monitor data and model quality (p. 3051).
To start your machine learning journey with SageMaker, sign up for an AWS account at [Set Up SageMaker](https://aws.amazon.com/sagemaker).

## How Model Monitor Works

Amazon SageMaker Model Monitor automatically monitors machine learning (ML) models in production and notifies you when quality issues arise. Model Monitor uses rules to detect drift in your models and alerts you when it happens. The following figure shows how this process works in the case that your model is deployed to a real-time endpoint.

You can also use Model Monitor to monitor a batch transform job instead of a real-time endpoint. In this case, instead of receiving requests to an endpoint and tracking the predictions, Model Monitor will monitor inference inputs and outputs. The following figure diagrams the process of monitoring a batch transform job.
To enable model monitoring, you take the following steps, which follow the path of the data through the various data collection, monitoring, and analysis processes:

- For a real-time endpoint, enable the endpoint to capture data from incoming requests to a trained ML model and the resulting model predictions.
- For a batch transform job, enable data capture of the batch transform inputs and outputs.
- Create a baseline from the dataset that was used to train the model. The baseline computes metrics and suggests constraints for the metrics. Real-time or batch predictions from your model are compared to the constraints, and are reported as violations if they are outside the constrained values.
- Create a monitoring schedule specifying what data to collect, how often to collect it, how to analyze it, and which reports to produce.
- Inspect the reports, which compare the latest data with the baseline, and watch for any violations reported and for metrics and notifications from Amazon CloudWatch.

### Notes

- Model Monitor computes model metrics and statistics on tabular data only. For example, an image classification model that takes images as input and outputs a label based on that image can still be monitored. Model Monitor would be able to calculate metrics and statistics for the output, not the input.
- Model Monitor currently supports only endpoints that host a single model and does not support monitoring multi-model endpoints. For information on using multi-model endpoints, see [Host multiple models in one container behind one endpoint](p. 2399).
- Model Monitor supports monitoring inference pipelines, but capturing and analyzing data is done for the entire pipeline, not for individual containers in the pipeline.
- To prevent impact to inference requests, Data Capture stops capturing requests at high levels of disk usage. It is recommended you keep your disk utilization below 75% in order to ensure data capture continues capturing requests.
- If you launch SageMaker Studio in a custom Amazon VPC, you need to create VPC endpoints to enable Model Monitor to communicate with Amazon S3 and CloudWatch. For information about VPC endpoints, see [VPC endpoints](p. 3522).

### Model Monitor Sample Notebooks

For a sample notebook that takes you through the full end-to-end workflow using Model Monitor with your real-time endpoint, see [Introduction to Amazon SageMaker Model Monitor](p. 298).

For a sample notebook that visualizes the statistics.json file for a selected execution in a monitoring schedule, see the [Model Monitor Visualization](p. 3522).

For instructions that show you how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see [Amazon SageMaker Notebook Instances](p. 298). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all the SageMaker samples. To open a notebook, choose the notebook's Use tab and choose Create copy.

### Capture data

To log the inputs to your endpoint and the inference outputs from your deployed model to Amazon S3, you can enable a feature called Data Capture. Data Capture is commonly used to record information that can be used for training, debugging, and monitoring. Amazon SageMaker Model Monitor automatically
Capture data from real-time endpoint

**Note**
To prevent impact to inference requests, Data Capture stops capturing requests at high levels of disk usage. It is recommended you keep your disk utilization below 75% in order to ensure data capture continues capturing requests.

To capture data for your real-time endpoint, you must deploy a model using SageMaker hosting services. This requires that you create a SageMaker model, define an endpoint configuration, and create an HTTPS endpoint.

The steps required to turn on data capture are similar whether you use the AWS SDK for Python (Boto) or the SageMaker Python SDK. If you use the AWS SDK, define the `DataCaptureConfig` dictionary, along with required fields, within the `CreateEndpointConfig` method to turn on data capture. If you use the SageMaker Python SDK, import the `DataCaptureConfig` Class and initialize an instance from this class. Then, pass this object to the `DataCaptureConfig` parameter in the `sagemaker.model.Model.deploy()` method.

To use the proceeding code snippets, replace the *italicized placeholder text* in the example code with your own information.

**How to enable data capture**

Specify a data capture configuration. You can capture the request payload, the response payload, or both with this configuration. The proceeding code snippet demonstrates how to enable data capture using the AWS SDK for Python (Boto) and the SageMaker Python SDK.

**Note**
You do not need to use Model Monitor to capture request or response payloads.

**AWS SDK for Python (Boto)**

Configure the data you want to capture with the `DataCaptureConfig` dictionary when you create an endpoint using the `CreateEndpointConfig` method. Set `EnableCapture` to the boolean value `True`. In addition, provide the following mandatory parameters:

- `EndpointConfigName`: the name of your endpoint configuration. You will use this name when you make a `CreateEndpoint` request.
- `ProductionVariants`: a list of models you want to host at this endpoint. Define a dictionary data type for each model.
- `DataCaptureConfig`: dictionary data type where you specify an integer value that corresponds to the initial percentage of data to sample (`InitialSamplingPercentage`), the Amazon S3 URI where you want captured data to be stored, and a capture options (`CaptureOptions`) list. Specify either `Input` or `Output` for `CaptureMode` within the `CaptureOptions` list.
You can optionally specify how SageMaker should encode captured data by passing key-value pair arguments to the CaptureContentTypeHeader dictionary.

```python
# Create an endpoint config name.
endpoint_config_name = '<endpoint-config-name>'

# The name of the production variant.
variant_name = '<name-of-production-variant>'

# The name of the model that you want to host.
# This is the name that you specified when creating the model.
model_name = '<The_name_of_your_model>'

instance_type = '<instance-type>'
#instance_type='ml.m5.xlarge' # Example

# Number of instances to launch initially.
initial_instance_count = <integer>

# Sampling percentage. Choose an integer value between 0 and 100
initial_sampling_percentage = <integer>

# The S3 URI containing the captured data
s3_capture_upload_path = 's3://<bucket-name>/<data_capture_s3_key>'

# Specify either Input, Output, or both
capture_modes = [ "Input", "Output" ]
#capture_mode = [ "Input"] # Example - If you want to capture input only

event_response = sagemaker_client.create_endpoint_config(
    EndpointConfigName=endpoint_config_name,
    ProductionVariants=[
        {
            "VariantName": variant_name,
            "ModelName": model_name,
            "InstanceType": instance_type, # Specify the compute instance type.
            "InitialInstanceCount": initial_instance_count # Number of instances to launch initially.
        }
    ],
    DataCaptureConfig={
        'EnableCapture': True, # Whether data should be captured or not.
        'InitialSamplingPercentage': initial_sampling_percentage,
        'DestinationS3Uri': s3_capture_upload_path,
        'CaptureOptions': [["CaptureMode" : capture_mode] for capture_mode in capture_modes] # Example - Use list comprehension to capture both Input and Output
    }
)
```

For more information about other endpoint configuration options, see the `CreateEndpointConfig` API in the Amazon SageMaker Service API Reference Guide.

SageMaker Python SDK

Import the DataCaptureConfig Class from `sagemaker.model_monitor` module. Enable data capture by setting EnableCapture to the boolean value True.

Optionally provide arguments for the following parameters:
• **SamplingPercentage**: an integer value that corresponds to percentage of data to sample. If you do not provide a sampling percentage, SageMaker will sample a default of 20 (20%) of your data.

• **DestinationS3Uri**: the Amazon S3 URI SageMaker will use to store captured data. If you do not provide one, SageMaker will store captured data in "s3://<default-session-bucket>/model-monitor/data-capture".

```python
from sagemaker.model_monitor import DataCaptureConfig

# Set to True to enable data capture
enable_capture = True

# Optional - Sampling percentage. Choose an integer value between 0 and 100
sampling_percentage = <int>
# sampling_percentage = 30 # Example 30%

# Optional - The S3 URI of stored captured-data location
s3_capture_upload_path = 's3://<bucket-name>/<data_capture_s3_key>'

# Specify either Input, Output or both.
capture_modes = ['REQUEST','RESPONSE'] # In this example, we specify both
# capture_mode = ['REQUEST'] # Example - If you want to only capture input.

data_capture_config = DataCaptureConfig(
enable_capture = enable_capture,
sampling_percentage = sampling_percentage, # Optional
destination_s3_uri = s3_capture_upload_path, # Optional
capture_options = ['REQUEST', 'RESPONSE'],
)
```

**Deploy your model**

Deploy your model and create an HTTPS endpoint with DataCapture enabled.

**AWS SDK for Python (Boto3)**

Provide the endpoint configuration to SageMaker. The service launches the ML compute instances and deploys the model or models as specified in the configuration.

Once you have your model and endpoint configuration, use the `CreateEndpoint` API to create your endpoint. The endpoint name must be unique within an AWS Region in your AWS account.

The following creates an endpoint using the endpoint configuration specified in the request. Amazon SageMaker uses the endpoint to provision resources and deploy models.

```python
# The name of the endpoint. The name must be unique within an AWS Region in your AWS account.
endpoint_name = '<endpoint-name>'

# The name of the endpoint configuration associated with this endpoint.
endpoint_config_name='<endpoint-config-name>'

create_endpoint_response = sagemaker_client.create_endpoint(  
    EndpointName=endpoint_name,  
    EndpointConfigName=endpoint_config_name)
```

For more information, see the `CreateEndpoint` API.
SageMaker Python SDK

Define a name for your endpoint. This step is optional. If you do not provide one, SageMaker will create a unique name for you:

```python
from datetime import datetime
endpoint_name = f"DEMO-{datetime.utcnow():%Y-%m-%d-%H%M}"
print("EndpointName = ", endpoint_name)
```

Deploy your model to a real-time, HTTPS endpoint with the Model object's built-in deploy() method. Provide the name of the Amazon EC2 instance type to deploy this model to in the instance_type field along with the initial number of instances to run the endpoint on for the initial_instance_count field:

```python
initial_instance_count=<integer>
# initial_instance_count=1 # Example
instance_type='<instance-type>'
# instance_type='ml.m4.xlarge' # Example

# Uncomment if you did not define this variable in the previous step
#data_capture_config = <name-of-data-capture-configuration>

model.deploy(
    initial_instance_count=initial_instance_count,
    instance_type=instance_type,
    endpoint_name=endpoint_name,
    data_capture_config=data_capture_config
)
```

**View Captured Data**

Create a predictor object from the SageMaker Python SDK Predictor Class. You will use the object returned by the Predictor Class to invoke your endpoint in a future step. Provide the name of your endpoint (defined earlier as endpoint_name), along with serializer and deserializer objects for the serializer and deserializer, respectively. For information about serializer types, see the Serializers Class in the SageMaker Python SDK.

```python
from sagemaker.predictor import Predictor
from sagemaker.serializers import <Serializer>
from sagemaker.deserializers import <Deserializers>

predictor = Predictor(endpoint_name=endpoint_name,
                       serializer = <Serializer_Class>,
                       deserializer = <Deserializer_Class>)

# Example
# from sagemaker.predictor import Predictor
# from sagemaker.serializers import CSVSerializer
# from sagemaker.deserializers import JSONDeserializer

#predictor = Predictor(endpoint_name=endpoint_name,
#                       serializer=CSVSerializer(),
#                       deserializer=JSONDeserializer())
```

In the proceeding code example scenario we invoke the endpoint with sample validation data that we have stored locally in a CSV file named validation_with_predictions. Our sample validation set contains labels for each input.
The first few lines of the with statement first opens the validation set CSV file, then splits each row within the file by the comma character ",", and then stores the two returned objects into a label and input_cols variables. For each row, the input (input_cols) is passed to the predictor variable's (predictor) objects built-in method Predictor.predict().

Suppose the model returns a probability. Probabilities range between integer values of 0 and 1.0. If the probability returned by the model is greater than 80% (0.8) we assign the prediction an integer value label of 1. Otherwise, we assign the prediction an integer value label of 0.

```python
def validate_dataset(dataset):
    cutoff = 0.8
    test_file = open(f"test_data/{dataset}", "w")
    test_file.write("probability,prediction,label
")
    for row in f:
        (label, input_cols) = row.split(",", 1)
        probability = float(predictor.predict(input_cols))
        prediction = "1" if probability > cutoff else "0"
        test_file.write(f"{probability},{prediction},{label}\n")
    print("Done!")
```

Because you enabled the data capture in the previous steps, the request and response payload, along with some additional meta data, is saved in the Amazon S3 location that you specified in DataCaptureConfig. The delivery of capture data to Amazon S3 can require a couple of minutes.

View captured data by listing the data capture files stored in Amazon S3. The format of the Amazon S3 path is: s3:///{endpoint-name}/{variant-name}/yyyy/mm/dd/hh/filename.jsonl.

Expect to see different files from different time periods, organized based on the hour when the invocation occurred. Run the following to print out the contents of a single capture file:

```
print("\n".join(capture_file[-3:-1]))
```

This will return a SageMaker specific JSON-line formatted file. The following is a response sample taken from a real-time endpoint that we invoked using csv/text data:

```json
{
"captureData":{"endpointInput":{"observedContentType":"text/csv","mode":"INPUT","data":"69,0,153.7,109,194.0,105,256.1,114,141,6,1,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,1,0,1,0,0,0,0,1,0,1,0,1,0\n","encoding":"CSV"},
"endpointOutput":{"observedContentType":"text/csv;charset=utf-8","mode":"OUTPUT","data":"0.0254181120544672","encoding":"CSV"},
"eventMetadata":{"eventId":"aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee","inferenceTime":"2022-02-14T17:25:49Z","eventVersion":"0"}
}
```
Amazon SageMaker Developer Guide
Capture data from batch transform job

In the proceeding example, the capture_file object is a list type. Index the ﬁrst element of the list to
view a single inference request.
# The capture_file object is a list. Index the first element to view a single inference
request
print(json.dumps(json.loads(capture_file[0]), indent=2))

This will return a response similar to the following. The values returned will diﬀer based on your
endpoint conﬁguration, SageMaker model, and captured data:
{

"captureData": {
"endpointInput": {
"observedContentType": "text/csv", # data MIME type
"mode": "INPUT",
"data":
"50,0,188.9,94,203.9,104,151.8,124,11.6,8,3,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,
"encoding": "CSV"
},
"endpointOutput": {
"observedContentType": "text/csv; charset=character-encoding",
"mode": "OUTPUT",
"data": "0.023190177977085114",
"encoding": "CSV"
}
},
"eventMetadata": {
"eventId": "aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee",
"inferenceTime": "2022-02-14T17:25:06Z"
},
"eventVersion": "0"

}

Capture data from batch transform job
The steps required to turn on data capture for your batch transform job are similar whether
you use the AWS SDK for Python (Boto) or the SageMaker Python SDK. If you use the
AWS SDK, deﬁne the DataCaptureConﬁg dictionary, along with required ﬁelds, within the
CreateTransformJob method to turn on data capture. If you use the SageMaker Python SDK, import
the BatchDataCaptureConfig class and initialize an instance from this class. Then, pass this object to
the batch_data_capture_config parameter of your transform job instance.
To use the following code snippets, replace the italicized placeholder text in the example code
with your own information.

How to enable data capture
Specify a data capture conﬁguration when you launch a transform job. Whether you use the AWS SDK
for Python (Boto3) or the SageMaker Python SDK, you must provide the DestinationS3Uri argument,
which is the directory where you want the transform job to log the captured data. Optionally, you can
also set the following parameters:
• KmsKeyId: The AWS KMS key used to encrypt the captured data.
• GenerateInferenceId: A Boolean ﬂag that, when capturing the data, indicates if you want the
transform job to append the inference ID and time to your output. This is useful for model quality
monitoring, where you need to ingest the Ground Truth data. The inference ID and time help to match
the captured data with your Ground Truth data.

3059


AWS SDK for Python (Boto3)

Configure the data you want to capture with the DataCaptureConfig dictionary when you create a transform job using the CreateTransformJob method.

```python
input_data_s3_uri = "s3://input_S3_uri"
output_data_s3_uri = "s3://output_S3_uri"
data_capture_destination = "s3://captured_data_S3_uri"

model_name = "model_name"

sm_client.create_transform_job(
    TransformJobName="transform_job_name",
    MaxConcurrentTransforms=2,
    ModelName=model_name,
    TransformInput={
        "DataSource": {
            "S3DataSource": {
                "S3DataType": "S3Prefix",
                "S3Uri": input_data_s3_uri,
            }
        },
        "ContentType": "text/csv",
        "CompressionType": "None",
        "SplitType": "Line",
    },
    TransformOutput={
        "S3OutputPath": output_data_s3_uri,
        "Accept": "text/csv",
        "AssembleWith": "Line",
    },
    TransformResources={
        "InstanceType": "ml.m4.xlarge",
        "InstanceCount": 1,
    },
    DataCaptureConfig={
        "DestinationS3Uri": data_capture_destination,
        "KmsKeyId": "kms_key",
        "GenerateInferenceId": True,
    }
)
```

SageMaker Python SDK

Import the BatchDataCaptureConfig class from the sagemaker.model_monitor.

```python
from sagemaker.transformer import Transformer
from sagemaker.inputs import BatchDataCaptureConfig

# Optional - The S3 URI of where to store captured data in S3
data_capture_destination = "s3://captured_data_S3_uri"

model_name = "model_name"

transformer = Transformer(model_name=model_name, ...)
transform_arg = transformer.transform(
    batch_data_capture_config=BatchDataCaptureConfig(
        destination_s3_uri=data_capture_destination,
        kms_key_id="kms_key",
        generate_inference_id=True,
    ),
    ...)
```
How to view data captured

Once the transform job completes, the captured data gets logged under the DestinationS3Uri you provided with the data capture configuration. There are two subdirectories under DestinationS3Uri, /input and /output. If DestinationS3Uri is s3://my-data-capture, then the transform job creates the following directories:

- s3://my-data-capture/input: The captured input data for the transform job.
- s3://my-data-capture/output: The captured output data for the transform job.

To avoid data duplication, the captured data under the preceding two directories are manifests. Each manifest is a JSONL file that contains the Amazon S3 locations of the source objects. A manifest file may look like the following example:

```json
# under "/input" directory
[{
"prefix":"s3://input_S3_uri/",
"dummy_0.csv",
"dummy_1.csv",
"dummy_2.csv",
...}
]

# under "/output" directory
[{
"prefix":"s3://output_S3_uri/",
"dummy_0.csv.out",
"dummy_1.csv.out",
"dummy_2.csv.out",
...}
]
```

The transform job organizes and labels these manifests with a yyyy/mm/dd/hh S3 prefix to indicate when they were captured. This helps the model monitor determine the appropriate portion of data to analyze. For example, if you start your transform job at 2022-8-26 13PM UTC, then the captured data is labeled with a 2022/08/26/13/ prefix string.

Inferenceld Generation

When you configure DataCaptureConfig for a transform job, you can turn on the Boolean flag GenerateInferenceId. This is particularly useful when you need to run model quality and model bias monitoring jobs, for which you need user-ingested Ground Truth data. Model monitor relies on an inference ID to match the captured data and the Ground Truth data. For additional details about Ground Truth ingestion, see Ingest Ground Truth Labels and Merge Them With Predictions (p. 3073). When GenerateInferenceId is on, the transform output appends an inference ID (a random UUID) as well as the transform job start time in UTC for each record. You need these two values to run model quality and model bias monitoring. When you construct the Ground Truth data, you need to provide the same inference ID to match the output data. Currently, this feature supports transform outputs in CSV, JSON, and JSONL formats.

If your transform output is in CSV format, the output file looks like the following example:

```
0, 1f1d57b1-2e6f-488c-8c30-db4e6d757861,2022-08-30T00:49:15Z
1, 22445434-0c67-45e9-bb4d-bd1bf26561e6,2022-08-30T00:49:15Z
...
```

The last two columns are inference ID and the transform job start time. Do not modify them. The remaining columns are your transform job outputs.
Monitor data quality

Data quality monitoring automatically monitors machine learning (ML) models in production and notifies you when data quality issues arise. ML models in production have to make predictions on real-life data that is not carefully curated like most training datasets. If the statistical nature of the data that your model receives while in production drifts away from the nature of the baseline data it was trained on, the model begins to lose accuracy in its predictions. Amazon SageMaker Model Monitor uses rules to detect data drift and alerts you when it happens. To monitor data quality, follow these steps:

1. Enable data capture. This captures inference input and output from a real-time inference endpoint or batch transform job and stores the data in Amazon S3. For more information, see [Capture data](p. 3053).
2. Create a baseline. In this step, you run a baseline job that analyzes an input dataset that you provide. The baseline computes baseline schema constraints and statistics for each feature using Deequ, an open source library built on Apache Spark, which is used to measure data quality in large datasets. For more information, see [Create a Baseline](p. 3063).
3. Define and schedule data quality monitoring jobs. For specific information and code samples of data quality monitoring jobs, see [Schedule data quality monitoring jobs](p. 3064). For general information about monitoring jobs, see [Schedule monitoring jobs](p. 3096).
4. Optionally use preprocessing and postprocessing scripts to transform the data coming out of your data quality analysis. For more information, see [Preprocessing and Postprocessing](p. 3109).
5. View data quality metrics. For more information, see [Schema for Statistics (statistics.json file)](p. 3065).
6. Integrate data quality monitoring with Amazon CloudWatch. For more information, see [CloudWatch Metrics](p. 3067).
7. Interpret the results of a monitoring job. For more information, see [Interpret results](p. 3101).
8. Use SageMaker Studio to enable data quality monitoring and visualize results if you are using a real-time endpoint. For more information, see [Visualize results for real-time endpoints in Amazon SageMaker Studio](p. 3103).

**Note**

Model Monitor computes model metrics and statistics on tabular data only. For example, an image classification model that takes images as input and outputs a label based on that image can still be monitored. Model Monitor would be able to calculate metrics and statistics for the output, not the input.

**Topics**

- [Create a Baseline](p. 3063)
Create a Baseline

The baseline calculations of statistics and constraints are needed as a standard against which data drift and other data quality issues can be detected. Model Monitor provides a built-in container that provides the ability to suggest the constraints automatically for CSV and flat JSON input. This `sagemaker-model-monitor-analyzer` container also provides you with a range of model monitoring capabilities, including constraint validation against a baseline, and emitting Amazon CloudWatch metrics. This container is based on Spark version 3.3.0 and is built with Deequ version 2.0.2. All column names in your baseline dataset must be compliant with Spark. For column names, use only lowercase characters, and _ as the only special character.

The training dataset that you used to train the model is usually a good baseline dataset. The training dataset data schema and the inference dataset schema should exactly match (the number and order of the features). Note that the prediction/output columns are assumed to be the first columns in the training dataset. From the training dataset, you can ask SageMaker to suggest a set of baseline constraints and generate descriptive statistics to explore the data. For this example, upload the training dataset that was used to train the pretrained model included in this example. If you already stored the training dataset in Amazon S3, you can point to it directly.

**To Create a baseline from a training dataset**

When you have your training data ready and stored in Amazon S3, start a baseline processing job with `DefaultModelMonitor.suggest_baseline(..)` using the Amazon SageMaker Python SDK. This uses an Amazon SageMaker Model Monitor prebuilt container (p. 3100) that generates baseline statistics and suggests baseline constraints for the dataset and writes them to the `output_s3_uri` location that you specify.

```python
from sagemaker.model_monitor import DefaultModelMonitor
from sagemaker.model_monitor.dataset_format import DatasetFormat

my_default_monitor = DefaultModelMonitor(
    role=role,
    instance_count=1,
    instance_type='ml.m5.xlarge',
    volume_size_in_gb=20,
    max_runtime_in_seconds=3600,
)

my_default_monitor.suggest_baseline(
    baseline_dataset=baseline_data_uri+'/training-dataset-with-header.csv',
    dataset_format=DatasetFormat.csv(header=True),
    output_s3_uri=baseline_results_uri,
    wait=True
)
```

**Note**

If you provide the feature/column names in the training dataset as the first row and set the `header=True` option as shown in the previous code sample, SageMaker uses the feature name in the constraints and statistics file.

The baseline statistics for the dataset are contained in the `statistics.json` file and the suggested baseline constraints are contained in the `constraints.json` file in the location you specify with `output_s3_uri`.  

---

3063
Output Files for Tabular Dataset Statistics and Constraints

<table>
<thead>
<tr>
<th>File Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>statistics.json</td>
<td>This file is expected to have columnar statistics for each feature in the dataset that is analyzed. For more information about the schema for this file, see Schema for Statistics (statistics.json file) (p. 3117).</td>
</tr>
<tr>
<td>constraints.json</td>
<td>This file is expected to have the constraints on the features observed. For more information about the schema for this file, see Schema for Constraints (constraints.json file) (p. 3118).</td>
</tr>
</tbody>
</table>

The Amazon SageMaker Python SDK provides convenience functions described to generate the baseline statistics and constraints. But if you want to call processing job directly for this purpose instead, you need to set the Environment map as shown in the following example:

```
"Environment": {
    "dataset_format": "\"csv\": { \"header\": true},
    "dataset_source": "/opt/ml/processing/sm_input",
    "output_path": "/opt/ml/processing/sm_output",
    "publish_cloudwatch_metrics": "Disabled",
}
```

Schedule data quality monitoring jobs

After you create your baseline, you can call the `create_monitoring_schedule()` method of your `DefaultModelMonitor` class instance to schedule an hourly data quality monitor. The following sections show you how to create a data quality monitor for a model deployed to a real-time endpoint as well as for a batch transform job.

**Important**
You can specify either a batch transform input or an endpoint input, but not both, when you create your monitoring schedule.

Data quality monitoring for models deployed to real-time endpoints

To schedule a data quality monitor for a real-time endpoint, pass your `EndpointInput` instance to the `endpoint_input` argument of your `DefaultModelMonitor` instance, as shown in the following code sample:

```python
from sagemaker.model_monitor import CronExpressionGenerator
data_quality_model_monitor = DefaultModelMonitor(
    role=sagemaker.get_execution_role(),
    ...
)
schedule = data_quality_model_monitor.create_monitoring_schedule(
    monitor_schedule_name=schedule_name,
    post_analytics_processor_script=s3_code_postprocessor_uri,
    output_s3_uri=s3_report_path,
    schedule_cron_expression=CronExpressionGenerator.hourly(),
)```
Data quality monitoring for batch transform jobs

To schedule a data quality monitor for a batch transform job, pass your BatchTransformInput instance to the batch_transform_input argument of your DefaultModelMonitor instance, as shown in the following code sample:

```python
from sagemaker.model_monitor import CronExpressionGenerator
data_quality_model_monitor = DefaultModelMonitor(
    role=sagemaker.get_execution_role(),
    ...
)
schedule = data_quality_model_monitor.create_monitoring_schedule(
    monitor_schedule_name=mon_schedule_name,
    batch_transform_input=BatchTransformInput(
        data_captured_destination_s3_uri=s3_capture_upload_path,
        destination="/opt/ml/processing/input",
        dataset_format=MonitoringDatasetFormat.csv(header=False),
    ),
    output_s3_uri=s3_report_path,
    statistics=statistics_path,
    constraints=constraints_path,
    schedule_cron_expression=CronExpressionGenerator.hourly(),
    enable_cloudwatch_metrics=True,
)
```

Schema for Statistics (statistics.json file)

Amazon SageMaker Model Monitor prebuilt container computes per column/feature statistics. The statistics are calculated for the baseline dataset and also for the current dataset that is being analyzed.

```json
{
    "version": 0,
    # dataset level stats
    "dataset": {
        "item_count": number
    },
    # feature level stats
    "features": [
        {
            "name": "feature-name",
            "inferred_type": "Fractional" | "Integral",
            "numerical_statistics": {
                "common": {
                    "num_present": number,
                    "num_missing": number
                },
                "mean": number,
                "sum": number,
            }
        }
    ]
}
```
"std_dev": number,
"min": number,
"max": number,
"distribution": {
  "kll": {
    "buckets": [
      {
        "lower_bound": number,
        "upper_bound": number,
        "count": number
      }
    ],
    "sketch": {
      "parameters": {
        "c": number,
        "k": number
      },
      "data": [
        [num, num, num, num],
        [num, num],
        [num, num]
      ]
    }
  }
}
}

Note the following:

- The prebuilt containers compute KLL sketch, which is a compact quantiles sketch.
CloudWatch Metrics

You can use the built-in Amazon SageMaker Model Monitor container for CloudWatch metrics. When the emit_metrics option is Enabled in the baseline constraints file, SageMaker emits these metrics for each feature/column observed in the dataset in the following namespace:

- For real-time endpoints: /aws/sagemaker/Endpoints/data-metric namespace with EndpointName and ScheduleName dimensions.
- For batch transform jobs: /aws/sagemaker/ModelMonitoring/data-metric namespace with MonitoringSchedule dimension.

For numerical fields, the built-in container emits the following CloudWatch metrics:

- Metric: Max → query for MetricName: feature_data_{feature_name}, Stat: Max
- Metric: Min → query for MetricName: feature_data_{feature_name}, Stat: Min
- Metric: Sum → query for MetricName: feature_data_{feature_name}, Stat: Sum
- Metric: SampleCount → query for MetricName: feature_data_{feature_name}, Stat: SampleCount
- Metric: Average → query for MetricName: feature_data_{feature_name}, Stat: Average

For both numerical and string fields, the built-in container emits the following CloudWatch metrics:

- Metric: Completeness → query for MetricName: feature_non_null_{feature_name}, Stat: Sum
- Metric: Baseline Drift → query for MetricName: feature_baseline_drift_{feature_name}, Stat: Sum

Schema for Violations (constraint_violations.json file)

The violations file is generated as the output of a MonitoringExecution, which lists the results of evaluating the constraints (specified in the constraints.json file) against the current dataset that was analyzed. The Amazon SageMaker Model Monitor prebuilt container provides the following violation checks.

```json
{
    "violations": [
      {
        "feature_name": "string",
        "constraint_check_type": "data_type_check",
        "completeness_check",
        "baseline_drift_check",
        "missing_column_check",
        "extra_column_check",
        "categorical_values_check",
        "description": "string"
      }
    ]
}
```
Types of Violations Monitored

<table>
<thead>
<tr>
<th>Violation Check Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data_type_check</td>
<td>If the data types in the current execution are not the same as in the baseline dataset, this violation is flagged.</td>
</tr>
<tr>
<td></td>
<td>During the baseline step, the generated constraints suggest the inferred data type for each column. The monitoring_config.datatype_check_threshold parameter can be tuned to adjust the threshold on when it is flagged as a violation.</td>
</tr>
<tr>
<td>completeness_check</td>
<td>If the completeness (% of non-null items) observed in the current execution exceeds the threshold specified in completeness threshold specified per feature, this violation is flagged.</td>
</tr>
<tr>
<td></td>
<td>During the baseline step, the generated constraints suggest a completeness value.</td>
</tr>
<tr>
<td>baseline_drift_check</td>
<td>If the calculated distribution distance between the current and the baseline datasets is more than the threshold specified in monitoring_config.comparison_threshold, this violation is flagged.</td>
</tr>
<tr>
<td>missing_column_check</td>
<td>If the number of columns in the current dataset is less than the number in the baseline dataset, this violation is flagged.</td>
</tr>
<tr>
<td>extra_column_check</td>
<td>If the number of columns in the current dataset is more than the number in the baseline, this violation is flagged.</td>
</tr>
<tr>
<td>categorical_values_check</td>
<td>If there are more unknown values in the current dataset than in the baseline dataset, this violation is flagged.</td>
</tr>
<tr>
<td></td>
<td>This value is dictated by the threshold in monitoring_config.domain_content_threshold.</td>
</tr>
</tbody>
</table>

Monitor model quality

Model quality monitoring jobs monitor the performance of a model by comparing the predictions that the model makes with the actual Ground Truth labels that the model attempts to predict. To do this, model quality monitoring merges data that is captured from real-time or batch inference with actual labels that you store in an Amazon S3 bucket, and then compares the predictions with the actual labels.

To measure model quality, model monitor uses metrics that depend on the ML problem type. For example, if your model is for a regression problem, one of the metrics evaluated is mean square error (mse). For information about all of the metrics used for the different ML problem types, see Model Quality Metrics (p. 3074).

Model quality monitoring follows the same steps as data quality monitoring, but adds the additional step of merging the actual labels from Amazon S3 with the predictions captured from the real-time inference endpoint or batch transform job. To monitor model quality, follow these steps:
Create a Model Quality Baseline

Create a baseline job that compares your model predictions with ground truth labels in a baseline dataset that you have stored in Amazon S3. Typically, you use a training dataset as the baseline dataset. The baseline job calculates metrics for the model and suggests constraints to use to monitor model quality drift.

To create a baseline job, you need to have a dataset that contains predictions from your model along with labels that represent the Ground Truth for your data.

To create a baseline job use the ModelQualityMonitor class provided by the SageMaker Python SDK, and complete the following steps.

To create a model quality baseline job

1. First, create an instance of the ModelQualityMonitor class. The following code snippet shows how to do this.

```python
from sagemaker import get_execution_role, session, Session
from sagemaker.model_monitor import ModelQualityMonitor

role = get_execution_role()
session = Session()

model_quality_monitor = ModelQualityMonitor(
    role=role,
    instance_count=1,
    instance_type='ml.m5.xlarge',
)
```
Now call the `suggest_baseline` method of the `ModelQualityMonitor` object to run a baseline job. The following code snippet assumes that you have a baseline dataset that contains both predictions and labels stored in Amazon S3.

```python
baseline_job_name = "MyBaseLineJob"
job = model_quality_monitor.suggest_baseline(
    job_name=baseline_job_name,
    baseline_dataset=baseline_dataset_uri, # The S3 location of the validation dataset.
    dataset_format=DatasetFormat.csv(header=True),
    output_s3_uri = baseline_results_uri, # The S3 location to store the results.
    problem_type='BinaryClassification',
    inference_attribute= "prediction", # The column in the dataset that contains predictions.
    probability_attribute= "probability", # The column in the dataset that contains probabilities.
    ground_truth_attribute= "label" # The column in the dataset that contains ground truth labels.
) 
job.wait(logs=False)
```

After the baseline job finishes, you can see the constraints that the job generated. First, get the results of the baseline job by calling the `latest_baselining_job` method of the `ModelQualityMonitor` object.

```python
baseline_job = model_quality_monitor.latest_baselining_job
```

The baseline job suggests constraints, which are thresholds for metrics that model monitor measures. If a metric goes beyond the suggested threshold, Model Monitor reports a violation. To view the constraints that the baseline job generated, call the `suggested_constraints` method of the baseline job. The following code snippet loads the constraints for a binary classification model into a Pandas dataframe.

```python
import pandas as pd
pd.DataFrame(baseline_job.suggested_constraints().body_dict["binary_classification_constraints"].T)
```

We recommend that you view the generated constraints and modify them as necessary before using them for monitoring. For example, if a constraint is too aggressive, you might get more alerts for violations than you want.

If your constraint contains numbers expressed in scientific notation, you will need to convert them to float. The following python preprocessing script example shows how to convert numbers in scientific notation to float.

```python
import csv

def fix_scientific_notation(col):
    try:
        return format(float(col), "f")
    except:
        return col

def preprocess_handler(csv_line):
    reader = csv.reader([csv_line])
    csv_record = next(reader)
    #skip baseline header, change HEADER_NAME to the first column's name
```
You can add your pre-processing script to a baseline or monitoring schedule as a record_preprocessor_script, as defined in the Model Monitor documentation.

5. When you are satisfied with the constraints, pass them as the constraints parameter when you create a monitoring schedule. For more information, see Schedule Model Quality Monitoring Jobs (p. 3071).

The suggested baseline constraints are contained in the constraints.json file in the location you specify with output_s3_uri. For information about the schema for this file in the Schema for Constraints (constraints.json file) (p. 3118).

Schedule Model Quality Monitoring Jobs

After you create your baseline, you can call the create_monitoring_schedule() method of your ModelQualityMonitor class instance to schedule an hourly model quality monitor. The following sections show you how to create a model quality monitor for a model deployed to a real-time endpoint as well as for a batch transform job.

**Important**
You can specify either a batch transform input or an endpoint input, but not both, when you create your monitoring schedule.

Unlike data quality monitoring, you need to supply Ground Truth labels if you want to monitor model quality. However, Ground Truth labels could be delayed. To address this, specify offsets when you create your monitoring schedule.

Model monitor offsets

Model quality jobs include StartTimeOffset and EndTimeOffset, which are fields of the ModelQualityJobInput parameter of the create_model_quality_job_definition method that work as follows:

- **StartTimeOffset** - If specified, jobs subtract this time from the start time.
- **EndTimeOffset** - If specified, jobs subtract this time from the end time.

The format of the offsets are, for example, -PT7H, where 7H is 7 hours. You can use -PT#H or -P#D, where H=hours, D=days, and M=minutes, and # is the number. In addition, the offset should be in ISO 8601 duration format.

For example, if your Ground Truth starts coming in after 1 day, but is not complete for a week, set StartTimeOffset to -P8D and EndTimeOffset to -P1D. Then, if you schedule a job to run at 2020-01-09T13:00, it analyzes data from between 2020-01-01T13:00 and 2020-01-08T13:00.

**Important**
The schedule cadence should be such that one execution finishes before the next execution starts, which allows the Ground Truth merge job and monitoring job from the execution to complete. The maximum runtime of an execution is divided between the two jobs, so for an hourly model quality monitoring job, the value of MaxRuntimeInSeconds specified as part of StoppingCondition should be no more than 1800.
Model quality monitoring for models deployed to real-time endpoints

To schedule a model quality monitor for a real-time endpoint, pass your EndpointInput instance to the endpoint_input argument of your ModelQualityMonitor instance, as shown in the following code sample:

```python
from sagemaker.model_monitor import CronExpressionGenerator

model_quality_model_monitor = ModelQualityMonitor(
    role=sagemaker.get_execution_role(),
    ...
)

schedule = model_quality_model_monitor.create_monitoring_schedule(
    monitor_schedule_name=schedule_name,
    endpoint_input=EndpointInput(
        endpoint_name=endpoint_name,
        destination="/opt/ml/processing/input/endpoint",
        start_time_offset="-PT2D",
        end_time_offset="-PT1D",
    ),
)
```

Model quality monitoring for batch transform jobs

To schedule a model quality monitor for a batch transform job, pass your BatchTransformInput instance to the batch_transform_input argument of your ModelQualityMonitor instance, as shown in the following code sample:

```python
from sagemaker.model_monitor import CronExpressionGenerator

model_quality_model_monitor = ModelQualityMonitor(
    role=sagemaker.get_execution_role(),
    ...
)

schedule = model_quality_model_monitor.create_monitoring_schedule(
    monitor_schedule_name=mon_schedule_name,
    batch_transform_input=BatchTransformInput(
        data_captured_destination_s3_uri=s3_capture_upload_path,
        destination="/opt/ml/processing/input/",
        dataset_format=MonitoringDatasetFormat.csv(header=False),
        probability_attribute="0",
        probability_threshold_attribute=0.5,
        start_time_offset="-PT06H",
        end_time_offset="-PT0H",
    ),
    ground_truth_input=gt_s3_uri,
)
```
Ingest Ground Truth Labels and Merge Them With Predictions

Model quality monitoring compares the predictions your model makes with ground truth labels to measure the quality of the model. For this to work, you periodically label data captured by your endpoint or batch transform job and upload it to Amazon S3.

To match Ground Truth labels with captured prediction data, there must be a unique identifier for each record in the dataset. The structure of each record for ground truth data is as follows:

```json
{
    "groundTruthData": {
        "data": "1",
        "encoding": "CSV" # only CSV supported at launch, we assume "data" only consists of label
    },
    "eventMetadata": {
        "eventId": "aaaa-bbbb-cccc"
    },
    "eventVersion": "0"
}
```

In the `groundTruthData` structure, `eventId` can be one of the following:

- `eventId` – This ID is automatically generated when a user invokes the endpoint.
- `inferenceId` – The caller supplies this ID when they invoke the endpoint.

If `inferenceId` is present in captured data records, Model Monitor uses it to merge captured data with Ground Truth records. You are responsible for making sure that the `inferenceId` in the Ground Truth records match the `inferenceId` in the captured records. If `inferenceId` is not present in captured data, model monitor uses `eventId` from the captured data records to match them with a Ground Truth record.

You must upload Ground Truth data to an Amazon S3 bucket that has the same path format as captured data, which is of the following form:

```
s3://bucket/prefix/yyyy/mm/dd/hh
```

The date in this path is the date when the Ground Truth label is collected, and does not have to match the date when the inference was generated.

After you create and upload the Ground Truth labels, include the location of the labels as a parameter when you create the monitoring job. If you are using AWS SDK for Python (Boto3), do this by specifying the location of Ground Truth labels as the `S3Uri` field of the `GroundTruthS3Input` parameter in a call to the `create_model_quality_job_definition` method. If you are using the SageMaker Python SDK, specify the location of the Ground Truth labels as the `ground_truth_input` parameter in the call to the `create_monitoring_schedule` of the `ModelQualityMonitor` object.
Model Quality Metrics

Model quality monitoring jobs compute different metrics depending on the ML problem type. The following sections list the metrics analyzed for each ML problem type.

**Note**
Standard deviation for metrics are provided only when at least 200 samples are available. Model Monitor computes standard deviation by randomly sampling 80% of the data 5 times, computing the metric, and taking the standard deviation for those results.

**Regression Metrics**

The following shows an example of the metrics that model quality monitor computes for a regression problem.

```
"regression_metrics" : {
    "mae" : {
        "value" : 0.3711832061068702,
        "standard_deviation" : 0.0037566388129940394
    },
    "mse" : {
        "value" : 0.3711832061068702,
        "standard_deviation" : 0.0037566388129940524
    },
    "rmse" : {
        "value" : 0.609248066149471,
        "standard_deviation" : 0.003079253267651125
    },
    "r2" : {
        "value" : -1.3766111872212665,
        "standard_deviation" : 0.022653980022771227
    }
}
```

**Binary Classification Metrics**

The following shows an example of the metrics that model quality monitor computes for a binary classification problem.

```
"binary_classification_metrics" : {
    "confusion_matrix" : {
        "0" : {
            "0" : 1,
            "1" : 2
        },
        "1" : {
            "0" : 0,
            "1" : 1
        }
    },
    "recall" : {
        "value" : 1.0,
        "standard_deviation" : "NaN"
    },
    "precision" : {
        "value" : 0.3333333333333333,
        "standard_deviation" : "NaN"
    },
    "accuracy" : {
        "value" : 0.5,
```

Model Quality Metrics

  },
  "weighted_f2_best_constant_classifier" : {
    "value" : 0.10570313141262414,
    "standard_deviation" : 0.003867109755267757
  }
}
```
Model Quality CloudWatch Metrics

If you set the value of the `enable_cloudwatch_metrics` to `True` when you create the monitoring schedule, model quality monitoring jobs send all metrics to Amazon CloudWatch.

Model quality metrics appear in the following namespace:

- For real-time endpoints: `aws/sagemaker/Endpoints/model-metrics`
- For batch transform jobs: `aws/sagemaker/ModelMonitoring/model-metrics`

For a list of the metrics that are emitted, see [Model Quality Metrics](p. 3074).

You can use CloudWatch metrics to create an alarm when a specific metric doesn't meet the threshold you specify. For instructions about how to create CloudWatch alarms, see [Create a CloudWatch Alarm Based on a Static Threshold](p. 3077) in the Amazon CloudWatch User Guide.

Monitor Bias Drift for Models in Production

Amazon SageMaker Clarify bias monitoring helps data scientists and ML engineers monitor predictions for bias on a regular basis. As the model is monitored, customers can view exportable reports and graphs detailing bias in SageMaker Studio and configure alerts in Amazon CloudWatch to receive notifications if bias beyond a certain threshold is detected. Bias can be introduced or exacerbated in deployed ML models when the training data differs from the data that the model sees during deployment (that is, the live data). These kinds of changes in the live data distribution might be temporary (for example, due to some short-lived, real-world events) or permanent. In either case, it might be important to detect these changes. For example, the outputs of a model for predicting home prices can become biased if the mortgage rates used to train the model differ from current, real-world mortgage rates. With bias detection capabilities in Model Monitor, when SageMaker detects bias beyond a certain threshold, it automatically generates metrics that you can view in SageMaker Studio and through Amazon CloudWatch alerts.

In general, measuring bias only during the train-and-deploy phase might not be sufficient. It is possible that after the model has been deployed, the distribution of the data that the deployed model sees (that is, the live data) is different from data distribution in the training dataset. This change might introduce bias in a model over time. The change in the live data distribution might be temporary (for example, due to some short-lived behavior like the holiday season) or permanent. In either case, it might be important to detect these changes and take steps to reduce the bias when appropriate.

To detect these changes, SageMaker Clarify provides functionality to monitor the bias metrics of a deployed model continuously and raise automated alerts if the metrics exceed a threshold. For example, consider the DPPL bias metric. Specify an allowed range of values $A=(a_{\text{min}}, a_{\text{max}})$, for instance an interval of $(-0.1, 0.1)$, that DPPL should belong to during deployment. Any deviation from this range should raise a bias detected alert. With SageMaker Clarify, you can perform these checks at regular intervals.

For example, you can set the frequency of the checks to 2 days. This means that SageMaker Clarify computes the DPPL metric on data collected during a 2-day window. In this example, $D_{\text{win}}$ is the data that the model processed during last 2-day window. An alert is issued if the DPPL value $b_{\text{win}}$ computed on $D_{\text{win}}$ falls outside of an allowed range $A$. This approach to checking if $b_{\text{win}}$ is outside of $A$ can be somewhat noisy. $D_{\text{win}}$ might consist of very few samples and might not be representative of the live data distribution. The small sample size means that the value of bias $b_{\text{win}}$ computed over $D_{\text{win}}$ might not be a very robust estimate. In fact, very high (or low) values of $b_{\text{win}}$ may be observed purely due to chance. To
Model Monitor Sample Notebook

Amazon SageMaker Clarify provides the following sample notebook that shows how to capture inference data for a real-time endpoint, create a baseline to monitor evolving bias against, and inspect the results:

- Monitoring bias drift and feature attribution drift Amazon SageMaker Clarify – Use Amazon SageMaker Model Monitor to monitor bias drift and feature attribution drift over time.

This notebook has been verified to run in Amazon SageMaker Studio only. If you need instructions on how to open a notebook in Amazon SageMaker Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 225). If you're prompted to choose a kernel, choose Python 3 (Data Science). The following topics contain the highlights from the last two steps, and they contain code examples from the example notebook.

Topics

- Create a Bias Drift Baseline (p. 3078)
- Bias Drift Violations (p. 3079)
- Configure Parameters to Monitor Bias Drift (p. 3080)
- Schedule Bias Drift Monitoring Jobs (p. 3083)
- Inspect Reports for Data Bias Drift (p. 3085)
- CloudWatch Metrics for Bias Drift Analysis (p. 3086)

Create a Bias Drift Baseline

After you have configured your application to capture real-time or batch transform inference data, the first task to monitor for bias drift is to create a baseline. This involves configuring the data inputs, which groups are sensitive, how the predictions are captured, and the model and its post-training bias metrics. Then you need to start the baselining job.

Model bias monitor can detect bias drift of ML models on a regular basis. Similar to the other monitoring types, the standard procedure of creating a model bias monitor is first baselining and then establishing a monitoring schedule.

```python
model_bias_monitor = ModelBiasMonitor(
    role=role,
    sagemaker_session=sagemaker_session,
    max_runtime_in_seconds=1800,
)
```

DataConfig stores information about the dataset to be analyzed (for example, the dataset file), its format (that is, CSV or JSON Lines), headers (if any) and label.

```python
model_bias_baselining_job_result_uri = f"{baseline_results_uri}/model_bias"
model_bias_data_config = DataConfig(
```
BiasConfig is the configuration of the sensitive groups in the dataset. Typically, bias is measured by computing a metric and comparing it across groups. The group of interest is called the facet. For post-training bias, you should also take the positive label into account.

```python
model_bias_config = BiasConfig(
    label_values_or_threshold=[1],
    facet_name="Account Length",
    facet_values_or_threshold=[100],
)
```

ModelPredictedLabelConfig specifies how to extract a predicted label from the model output. In this example, the 0.8 cutoff has been chosen in anticipation that customers will turn over frequently. For more complicated outputs, there are a few more options, like "label" is the index, name, or JMESPath to locate predicted label in endpoint response payload.

```python
model_predicted_label_config = ModelPredictedLabelConfig(
    probability_threshold=0.8,
)
```

ModelConfig is the configuration related to the model to be used for inferencing. In order to compute post-training bias metrics, the computation needs to get inferences for the model name provided. To accomplish this, the processing job uses the model to create an ephemeral endpoint (also known as shadow endpoint). The processing job deletes the shadow endpoint after the computations are completed. This configuration is also used by the explainability monitor.

```python
model_config = ModelConfig(
    model_name=model_name,
    instance_count=endpoint_instance_count,
    instance_type=endpoint_instance_type,
    content_type=dataset_type,
    accept_type=dataset_type,
)
```

Now you can start the baselining job.

```python
model_bias_monitor.suggest_baseline(
    model_config=model_config,
    data_config=model_bias_data_config,
    bias_config=model_bias_config,
    model_predicted_label_config=model_predicted_label_config,
)
print(f"ModelBiasMonitor baselining job: {model_bias_monitor.latest_baselining_job_name}"
)
```

The scheduled monitor automatically picks up baselining job name and waits for it before monitoring begins.

## Bias Drift Violations

Bias drift jobs evaluate the baseline constraints provided by the baseline configuration against the analysis results of current MonitoringExecution. If violations are detected, the job lists them to
the `constraint_violations.json` file in the execution output location, and marks the execution status as Interpret results (p. 3101).

Here is the schema of the bias drift violations file.

- **facet** – The name of the facet, provided by the monitoring job analysis configuration facet name_or_index.
- **facet_value** – The value of the facet, provided by the monitoring job analysis configuration facet value_or_threshold.
- **metric_name** – The short name of the bias metric. For example, "CI" for class imbalance. See Measure Pre-training Bias (p. 3209) for the short names of each of the pre-training bias metrics and Measure Post-training Data and Model Bias (p. 3220) for the short names of each of the post-training bias metrics.
- **constraint_check_type** – The type of violation monitored. Currently only bias_drift_check is supported.
- **description** – A descriptive message to explain the violation.

```json
{
   "version": "1.0",
   "violations": [
      {
         "facet": "string",
         "facet_value": "string",
         "metric_name": "string",
         "constraint_check_type": "string",
         "description": "string"
      }
   ]
}
```

A bias metric is used to measure the level of equality in a distribution. A value close to zero indicates that the distribution is more balanced. If the value of a bias metric in the job analysis results file (analysis.json) is worse than its corresponding value in the baseline constraints file, a violation is logged. As an example, if the baseline constraint for the DPPL bias metric is 0.2, and the analysis result is 0.1, no violation is logged because 0.1 is closer to 0 than 0.2. However, if the analysis result is -0.3, a violation is logged because it is farther from 0 than the baseline constraint of 0.2.

```json
{
   "version": "1.0",
   "violations": [
      {
         "facet": "Age",
         "facet_value": "40",
         "metric_name": "CI",
         "constraint_check_type": "bias_drift_check",
         "description": "Value 0.0751544567666083 does not meet the constraint requirement"
      },
      {
         "facet": "Age",
         "facet_value": "40",
         "metric_name": "DPPL",
         "constraint_check_type": "bias_drift_check",
         "description": "Value -0.0791244970125596 does not meet the constraint requirement"
      }
   ]
}
```

**Configure Parameters to Monitor Bias Drift**

Amazon SageMaker Clarify bias monitoring reuses a subset of the parameters used in the analysis configuration of Configure the Analysis (p. 3144). After describing the configuration parameters, this
Configure Bias Drift Monitoring

The following parameters must be provided in a JSON file. The path to this JSON file must be provided in the `ConfigUri` parameter of the `ModelBiasJobInput` API.

- **"version"** – (Optional) Schema version of the configuration file. If not provided, the latest supported version is used.
- **"headers"** – (Optional) A list of column names in the dataset. If the dataset_type is "application/jsonlines" and "label" is specified, then the last header becomes the header of the label column.
- **"label"** – (Optional) Target attribute for the model to be used for bias metrics. Specified either as a column name, or an index (if dataset format is CSV), or as a JMESPath (if dataset format is JSON Lines).
- **"label_values_or_threshold"** – (Optional) List of label values or threshold. Indicates positive outcome used for bias metrics.
- **"facet"** – (Optional) A list of features that are sensitive attributes, referred to as facets. Facets are used for bias metrics in the form of pairs, and include the following:
  - **"name_or_index"** – Facet column name or index.
  - **"value_or_threshold"** – (Optional) List of values or threshold that the facet column can take. Indicates the sensitive group, such as the group that is used to measure bias against. If not provided, bias metrics are computed as one group for every unique value (rather than all values). If the facet column is numeric, this threshold value is applied as the lower bound to select the sensitive group.
- **"group_variable"** – (Optional) A column name or index to indicate the group variable to be used for the bias metric Conditional Demographic Disparity.

The other parameters should be provided in EndpointInput (for real-time endpoints) or BatchTransformInput (for batch transform jobs) of the `ModelBiasJobInput` API.

- **FeaturesAttribute** – This parameter is required if endpoint input data format is "application/jsonlines". It is the JMESPath used to locate the feature columns if the dataset format is JSON Lines.
- **InferenceAttribute** – Index or JMESPath location in the model output for the target attribute to be used for monitored for bias using bias metrics. If it is not provided in the CSV accept_type case, then it is assumed that the model output is a single numeric value corresponding to a score or probability.
- **ProbabilityAttribute** – Index or JMESPath location in the model output for probabilities. If the model output is JSON Lines with a list of labels and probabilities, for example, then the label that corresponds to the maximum probability is selected for bias computations.
- **ProbabilityThresholdAttribute** – (Optional) A float value to indicate the threshold to select the binary label, in the case of binary classification. The default value is 0.5.

### Example JSON Configuration Files for CSV and JSON Lines Datasets

Here are examples of the JSON files used to configure CSV and JSON Lines datasets to monitor them for bias drift.

**Topics**

- [CSV Datasets](p. 3082)
- [JSON Lines Datasets](p. 3082)
CSV Datasets

Consider a dataset that has four feature columns and one label column, where the first feature and the label are binary, as in the following example.

```
0, 0.5814568701544718, 0.6651538910132964, 0.3138080342665499, 0
1, 0.6711642728531724, 0.7466687034026017, 0.1215477472819713, 1
0, 0.0453256543003371, 0.6377430803264152, 0.3558625219713576, 1
1, 0.4785191813363956, 0.0265841045263860, 0.0376935084990697, 1
```

Assume that the model output has two columns, where the first one is the predicted label and the second one is the probability, as in the following example.

```
1, 0.5385257417814224
```

Then the following JSON configuration file shows an example of how this CSV dataset can be configured.

```
{
   "headers": [
      "feature_0",
      "feature_1",
      "feature_2",
      "feature_3",
      "target"
   ],
   "label": "target",
   "label_values_or_threshold": [1],
   "facet": [{
      "name_or_index": "feature_1",
      "value_or_threshold": [1]
   }]
}
```

The predicted label is selected by the "InferenceAttribute" parameter. Zero-based numbering is used, so 0 indicates the first column of the model output.

```
"EndpointInput": {
   ...
   "InferenceAttribute": 0
   ...
}
```

Alternatively, you can use different parameters to convert probability values to binary predicted labels. Zero-based numbering is used: 1 indicates the second column; the ProbabilityThresholdAttribute value of 0.6 indicates that a probability greater than 0.6 predicts the binary label as 1.

```
"EndpointInput": {
   ...
   "ProbabilityAttribute": 1,
   "ProbabilityThresholdAttribute": 0.6
   ...
}
```

JSON Lines Datasets

Consider a dataset that has four feature columns and one label column, where the first feature and the label are binary, as in the following example.
Amazon SageMaker Developer Guide
Schedule Bias Drift Monitoring Jobs

{"features":[0,
{"features":[1,
{"features":[0,
{"features":[1,

0.5814568701544718,
0.6711642728531724,
0.0453256543003371,
0.4785191813363956,

0.6651538910132964,
0.7466687034026017,
0.6377430803264152,
0.0265841045263860,

0.3138080342665499],
0.1215477472819713],
0.3558625219713576],
0.0376935084990697],

"label":0}
"label":1}
"label":1}
"label":1}

Assume that the model output has two columns, where the ﬁrst is a predicted label and the second is a
probability.
{"predicted_label":1, "probability":0.5385257417814224}

The following JSON conﬁguration ﬁle shows an example of how this JSON Lines dataset can be
conﬁgured.
{

}

"headers": [
"feature_0",
"feature_1",
"feature_2",
"feature_3",
"target"
],
"label": "label",
"label_values_or_threshold": [1],
"facet": [{
"name_or_index": "feature_1",
"value_or_threshold": [1]
}]

Then, the "features" parameter value in EndpointInput (for real-time endpoints) or
BatchTransformInput (for batch transform jobs) is used to locate the features in the dataset, and the
"predicted_label" parameter value selects the predicted label from the model output.
"EndpointInput": {
...
"FeaturesAttribute": "features",
"InferenceAttribute": "predicted_label"
...
}

Alternatively, you can convert probability values to predicted binary labels using the
ProbabilityThresholdAttribute parameter value. A value of 0.6, for example, indicates that a
probability greater than 0.6 predicts the binary label as 1.
"EndpointInput": {
...
"FeaturesAttribute": "features",
"ProbabilityAttribute": "probability",
"ProbabilityThresholdAttribute": 0.6
...
}

Schedule Bias Drift Monitoring Jobs
After you create your baseline, you can call the create_monitoring_schedule() method of your
ModelBiasModelMonitor class instance to schedule an hourly bias drift monitor. The following

3083


sections show you how to create bias drift monitor for a model deployed to a real-time endpoint as well as for a batch transform job.

**Important**
You can specify either a batch transform input or an endpoint input, but not both, when you create your monitoring schedule.

Unlike data quality monitoring, you need to supply Ground Truth labels if you want to monitor model quality. However, Ground Truth labels could be delayed. To address this, specify offsets when you create your monitoring schedule. For details about how to create time offsets, see [Model monitor offsets](p. 3071).

If you have submitted a baselining job, the monitor automatically picks up analysis configuration from the baselining job. If you skip the baselining step or the capture dataset has a different nature from the training dataset, you must provide the analysis configuration.

### Bias drift monitoring for models deployed to real-time endpoint

To schedule a bias drift monitor for a real-time endpoint, pass your `EndpointInput` instance to the `endpoint_input` argument of your `ModelBiasModelMonitor` instance, as shown in the following code sample:

```python
from sagemaker.model_monitor import CronExpressionGenerator

model_bias_monitor = ModelBiasModelMonitor(
    role=sagemaker.get_execution_role(),
    ...
)

model_bias_analysis_config = None
if not model_bias_monitor.latest_baselining_job:
    model_bias_analysis_config = BiasAnalysisConfig(
        model_bias_config,
        headers=all_headers,
        label=label_header,
    )

model_bias_monitor.create_monitoring_schedule(
    monitor_schedule_name=schedule_name,
    post_analytics_processor_script=s3_code_postprocessor_uri,
    output_s3_uri=s3_report_path,
    statistics=model_bias_monitor.baseline_statistics(),
    constraints=model_bias_monitor.suggested_constraints(),
    schedule_cron_expression=CronExpressionGenerator.hourly(),
    enable_cloudwatch_metrics=True,
    analysis_config=model_bias_analysis_config,
    endpoint_input=EndpointInput(
        endpoint_name=endpoint_name,
        destination="/opt/ml/processing/input/endpoint",
        start_time_offset="-PT1H",
        end_time_offset="-PT0H",
        probability_threshold_attribute=0.8,
    ),
)
```

### Bias drift monitoring for batch transform jobs

To schedule a bias drift monitor for a batch transform job, pass your `BatchTransformInput` instance to the `batch_transform_input` argument of your `ModelBiasModelMonitor` instance, as shown in the following code sample:
from sagemaker.model_monitor import CronExpressionGenerator

model_bias_monitor = ModelBiasModelMonitor(
    role=sagemaker.get_execution_role(),
    ...
)

model_bias_analysis_config = None
if not model_bias_monitor.latest_baselining_job:
    model_bias_analysis_config = BiasAnalysisConfig(
        model_bias_config,
        headers=all_headers,
        label=label_header,
    )

schedule = model_bias_monitor.create_monitoring_schedule(
    monitor_schedule_name=schedule_name,
    post_analytics_processor_script=s3_code_postprocessor_uri,
    output_s3_uri=s3_report_path,
    statistics=model_bias_monitor.baseline_statistics(),
    constraints=model_bias_monitor.suggested_constraints(),
    schedule_cron_expression=CronExpressionGenerator.hourly(),
    enable_cloudwatch_metrics=True,
    analysis_config=model_bias_analysis_config,
    batch_transform_input=BatchTransformInput(
        destination="opt/ml/processing/input",
        data_captured_destination_s3_uri=s3_capture_path,
        start_time_offset="-PT1H",
        end_time_offset="-PT0H",
        probability_threshold_attribute=0.8
    ),
)

Inspect Reports for Data Bias Drift

If you are not able to inspect the results of the monitoring in the generated reports in SageMaker Studio, you can print them out as follows:

schedule_desc = model_bias_monitor.describe_schedule()
execution_summary = schedule_desc.get("LastMonitoringExecutionSummary")
if execution_summary and execution_summary["MonitoringExecutionStatus"] in ["Completed", "CompletedWithViolations"]:
    last_model_bias_monitor_execution = model_bias_monitor.list_executions()[-1]
    last_model_bias_monitor_execution_report_uri = last_model_bias_monitor_execution.output.destination
    print("Report URI: {last_model_bias_monitor_execution.output_report_uri}")
    last_model_bias_monitor_execution_report_files = sorted(S3Downloader.list(last_model_bias_monitor_execution_report_uri))
    print("Found Report Files:")
    print("\n ".join(last_model_bias_monitor_execution_report_files))
else:
    last_model_bias_monitor_execution = None
    print("====STOP==== \n No completed executions to inspect further. Please wait till an execution completes or investigate previously reported failures.")

If there are violations compared to the baseline, they are listed here:

if last_model_bias_monitor_execution:
    model_bias_violations = last_model_bias_monitor_execution.constraint_violations()
    if model_bias_violations:
        print(model_bias_violations.body_dict)
If your model is deployed to a real-time endpoint, you can see visualizations in SageMaker Studio of the analysis results and CloudWatch metrics by choosing the **Endpoints** tab, and then double-clicking the endpoint.

### CloudWatch Metrics for Bias Drift Analysis

This guide shows CloudWatch metrics and their properties that you can use for bias drift analysis in SageMaker Clarify. Bias drift monitoring jobs compute both **pre-training bias metrics** and **post-training bias metrics**, and publish them to the following CloudWatch namespace:

- For real-time endpoints: `aws/sagemaker/Endpoints/bias-metrics`
- For batch transform jobs: `aws/sagemaker/ModelMonitoring/bias-metrics`

The CloudWatch metric name appends the metric's short name to `bias_metric`. For example, `bias_metric_CI` is the bias metric for class imbalance (CI).

**Note**

+-infinity is published as the floating point number +/- 2.348543e108, and errors including null values are not published.

Each metric has the following properties:

- **Endpoint**: The name of the monitored endpoint, if applicable.
- **MonitoringSchedule**: The name of the schedule for the monitoring job.
- **BiasStage**: The name of the stage of the bias drift monitoring job. Choose either Pre-training or Post-Training.
- **Label**: The name of the target feature, provided by the monitoring job analysis configuration label.
- **LabelValue**: The value of the target feature, provided by the monitoring job analysis configuration label_values_or_threshold.
- **Facet**: The name of the facet, provided by the monitoring job analysis configuration facet name_of_index.
- **FacetValue**: The value of the facet, provided by the monitoring job analysis configuration facet nvalue_or_threshold.

To stop the monitoring jobs from publishing metrics, set `publish_cloudwatch_metrics` to **Disabled** in the Environment map of **model bias job** definition.

### Monitor Feature Attribution Drift for Models in Production

A drift in the distribution of live data for models in production can result in a corresponding drift in the feature attribution values, just as it could cause a drift in bias when monitoring bias metrics. Amazon SageMaker Clarify feature attribution monitoring helps data scientists and ML engineers monitor predictions for feature attribution drift on a regular basis. As the model is monitored, customers can view exportable reports and graphs detailing feature attributions in SageMaker Studio and configure alerts in Amazon CloudWatch to receive notifications if it is detected that the attribution values drift beyond a certain threshold.

To illustrate this with a specific situation, consider a hypothetical scenario for college admissions. Assume that we observe the following (aggregated) feature attribution values in the training data and in the live data:
College Admission Hypothetical Scenario

<table>
<thead>
<tr>
<th>Feature</th>
<th>Attribution in training data</th>
<th>Attribution in live data</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAT score</td>
<td>0.70</td>
<td>0.10</td>
</tr>
<tr>
<td>GPA</td>
<td>0.50</td>
<td>0.20</td>
</tr>
<tr>
<td>Class rank</td>
<td>0.05</td>
<td>0.70</td>
</tr>
</tbody>
</table>

The change from training data to live data appears significant. The feature ranking has completely reversed. Similar to the bias drift, the feature attribution drifts might be caused by a change in the live data distribution and warrant a closer look into the model behavior on the live data. Again, the first step in these scenarios is to raise an alarm that a drift has happened.

We can detect the drift by comparing how the ranking of the individual features changed from training data to live data. In addition to being sensitive to changes in ranking order, we also want to be sensitive to the raw attribution score of the features. For instance, given two features that fall in the ranking by the same number of positions going from training to live data, we want to be more sensitive to the feature that had a higher attribution score in the training data. With these properties in mind, we use the Normalized Discounted Cumulative Gain (NDCG) score for comparing the feature attributions rankings of training and live data.

Specifically, assume we have the following:

- \( F = [f_1, ..., f_m] \) is the list of features sorted with respect to their attribution scores in the training data where \( m \) is the total number of features. For instance, in our case, \( F = [\text{SAT Score}, \text{GPA}, \text{Class Rank}] \).
- \( a(f) \) is a function that returns the feature attribution score on the training data given a feature \( f \). For example, \( a(\text{SAT Score}) = 0.70 \).
- \( F' = [f'_1, ..., f'_m] \) is the list of features sorted with respect to their attribution scores in the live data. For example, \( F' = [\text{Class Rank}, \text{GPA}, \text{SAT Score}] \).

Then, we can compute the NDCG as:

\[
\text{NDCG} = \frac{\text{DCG}}{\text{iDCG}}
\]

with

- \( \text{DCG} = \sum_{i=1}^{m} \frac{a(f'_i)}{\log_2(i+1)} \)
- \( \text{iDCG} = \sum_{i=1}^{m} \frac{a(f_i)}{\log_2(i+1)} \)

The quantity DCG measures whether features with high attribution in the training data are also ranked higher in the feature attribution computed on the live data. The quantity iDCG measures the ideal score and it's just a normalizing factor to ensure that the final quantity resides in the range \([0, 1]\), with 1 being the best possible value. A NDCG value of 1 means that the feature attribution ranking in the live data is the same as the one in the training data. In this particular example, because the ranking changed by quite a bit, the NDCG value is 0.69.

In SageMaker Clarify, if the NDCG value is below 0.90, we automatically raise an alert.

Model Monitor Example Notebook

SageMaker Clarify provides the following example notebook that shows how to capture inference data for a real-time endpoint, create a baseline to monitor evolving bias against, and inspect the results:
Create a SHAP Baseline

Explanations are typically contrastive, that is, they account for deviations from a baseline. For information on explainability baselines, see SHAP Baselines for Explainability (p. 3243).

In addition to providing explanations for per-instance inferences, SageMaker Clarify also supports global explanation for ML models that helps you understand the behavior of a model as a whole in terms of its features. SageMaker Clarify generates a global explanation of an ML model by aggregating the Shapley values over multiple instances. SageMaker Clarify supports the following different ways of aggregation, which you can use to define baselines:

- **mean_abs** – Mean of absolute SHAP values for all instances.
- **median** – Median of SHAP values for all instances.
- **mean_sq** – Mean of squared SHAP values for all instances.

After you have configured your application to capture real-time or batch transform inference data, the first task to monitor for drift in feature attribution is to create a baseline to compare against. This involves configuring the data inputs, which groups are sensitive, how the predictions are captured, and the model and its posttraining bias metrics. Then you need to start the baselining job. Model explainability monitor can explain the predictions of a deployed model that's producing inferences and detect feature attribution drift on a regular basis.

```python
model_explainability_monitor = ModelExplainabilityMonitor(
    role=role,
    sagemaker_session=sagemaker_session,
    max_runtime_in_seconds=1800,
)
```

In this example, the explainability baselining job shares the test dataset with the bias baselining job, so it uses the same DataConfig, and the only difference is the job output URI.

```python
model_explainability_baselining_job_result_uri = f"{baseline_results_uri}/model_explainability"
model_explainability_data_config = DataConfig(
    s3_data_input_path=validation_dataset,
    s3_output_path=model_explainability_baselining_job_result_uri,
)
Currently the SageMaker Clarify explainer offers a scalable and efficient implementation of SHAP, so the explainability config is SHAPConfig, including the following:

- **baseline** – A list of rows (at least one) or S3 object URI to be used as the baseline dataset in the Kernel SHAP algorithm. The format should be the same as the dataset format. Each row should contain only the feature columns/values and omit the label column/values.
- **num_samples** – Number of samples to be used in the Kernel SHAP algorithm. This number determines the size of the generated synthetic dataset to compute the SHAP values.
- **agg_method** – Aggregation method for global SHAP values. Following are valid values:
  - **mean_abs** – Mean of absolute SHAP values for all instances.
  - **median** – Median of SHAP values for all instances.
  - **mean_sq** – Mean of squared SHAP values for all instances.
  - **use_logit** – Indicator of whether the logit function is to be applied to the model predictions. Default is False. If use_logit is True, the SHAP values will have log-odds units.
- **save_local_shap_values** (bool) – Indicator of whether to save the local SHAP values in the output location. Default is False.

```python
# Here use the mean value of test dataset as SHAP baseline
test_dataframe = pd.read_csv(test_dataset, header=None)
shap_baseline = [list(test_dataframe.mean())]
shap_config = SHAPConfig(
    baseline=shap_baseline,
    num_samples=100,
    agg_method="mean_abs",
    save_local_shap_values=False,
)
```

Start a baselining job. The same `model_config` is required because the explainability baselining job needs to create a shadow endpoint to get predictions for the generated synthetic dataset.

```python
model_explainability_monitor.suggest_baseline(
    data_config=model_explainability_data_config,
    model_config=model_config,
    explainability_config=shap_config,
)
print(f"ModelExplainabilityMonitor baselining job: {model_explainability_monitor.latest_baselining_job_name}"
```

## Model Feature Attribution Drift Violations

Feature attribution drift jobs evaluate the baseline constraints provided by the baseline configuration against the analysis results of current MonitoringExecution. If violations are detected, the job lists them to the `constraintviolations.json` file in the execution output location, and marks the execution status as *Interpret results* (p. 3101).

Here is the schema of the feature attribution drift violations file.

- **label** – The name of the label, job analysis configuration `label_headers` or a placeholder such as "label0".
• **metric_name** – The name of the explainability analysis method. Currently only shap is supported.

• **constraint_check_type** – The type of violation monitored. Currently only feature_attribution_drift_check is supported.

• **description** – A descriptive message to explain the violation.

```json
{
    "version": "1.0",
    "violations": [
        {
            "label": "string",
            "metric_name": "string",
            "constraint_check_type": "string",
            "description": "string"
        }
    ]
}
```

For each label in the explanations section, the monitoring jobs calculate the nDCG score of its global SHAP values in the baseline constraints file and in the job analysis results file (analysis.json). If the score is less than 0.9, then a violation is logged. The combined global SHAP value is evaluated, so there are no “feature” fields in the violation entry. The following output provides an example of several logged violations.

```json
{
    "version": "1.0",
    "violations": [
        {
            "label": "label0",
            "metric_name": "shap",
            "constraint_check_type": "feature_attribution_drift_check",
            "description": "Feature attribution drift 0.7639720923277322 exceeds threshold 0.9"
        },
        {
            "label": "label1",
            "metric_name": "shap",
            "constraint_check_type": "feature_attribution_drift_check",
            "description": "Feature attribution drift 0.7323763972092327 exceeds threshold 0.9"
        }
    ]
}
```

### Configure Parameters to Monitor Attribution Drift

Amazon SageMaker Clarify explainability monitor reuses a subset of the parameters used in the analysis configuration of Configure the Analysis (p. 3144). The following parameters must be provided in a JSON file and the path must be provided in the ConfigUri parameter of ModelExplainabilityAppSpecification.

- **version** – (Optional) Schema version of the configuration file. If not provided, the latest supported version is used.

- **headers** – (Optional) A list of feature names in the dataset. Explainability analysis does not require labels.

- **methods** – A list of methods and their parameters for the analyses and reports. If any section is omitted, then it is not computed.

- **shap** – (Optional) Section on SHAP value computation.

- **baseline** – (Optional) A list of rows (at least one), or an Amazon Simple Storage Service Amazon S3 object URI. To be used as the baseline dataset (also known as a background dataset) in the Kernel SHAP algorithm. The format should be the same as the dataset format. Each row should contain only the feature columns (or values). Before you send each row to the model, omit any column that must be excluded.
• "num_samples" – Number of samples to be used in the Kernel SHAP algorithm. This number
determines the size of the generated synthetic dataset to compute the SHAP values. If not
provided, then a SageMaker Clarify job chooses the value based on a count of features.
• "agg_method" – Aggregation method for global SHAP values. Valid values are as follows:
  • "mean_abs" – Mean of absolute SHAP values for all instances.
  • "median" – Median of SHAP values for all instances.
  • "mean_sq" – Mean of squared SHAP values for all instances.
• "use_logit" – (Optional) Boolean value to indicate if the logit function is to be applied to the
  model predictions. If "use_logit" is true, then the SHAP values have log-odds units. The
default value is false.
• "save_local_shap_values" – (Optional) Boolean value to indicate if local SHAP values are to
  be saved in the output location. Use true to save them. Use false to not save them. The default
  is false.
• "predictor" – (Optional for real-time endpoint, required for batch transform) Section on model
  parameters, required if "shap" and "post_training_bias" sections are present.
  • "model_name" – Model name created by CreateModel API, with container mode as
    SingleModel.
  • "instance_type" – Instance type for the shadow endpoint.
  • "initial_instance_count" – Instance count for the shadow endpoint.
• "content_type" – (Optional) The model input format to be used for getting inferences with the
  shadow endpoint. Valid values are "text/csv" for CSV, "application/jsonlines" for JSON
  Lines, application/x-parquet for Apache Parquet, and application/x-image to enable
  Computer Vision explainability. The default value is the same as the dataset_type format.
• "accept_type" – (Optional) The model output format to be used for getting inferences with the
  shadow endpoint. Valid values are "text/csv" for CSV, "application/jsonlines" for JSON
  Lines. If omitted, SageMaker Clarify uses the response data type of the captured data.
• "content_template" – (Optional) A template string used to construct the model input from
  dataset instances. It is only used when "content_type" is "application/jsonlines". The
  template should have only one placeholder, $features, which is replaced by the features list at
  runtime. For example, given "content_template": "{"myfeatures":$features}", if an
  instance (no label) is 1, 2, 3, then model input becomes JSON Lines '{"myfeatures":[1,2,3]}'.
• "label_headers" – (Optional) A list of values that the "label" takes in the dataset. Associates
  the scores returned by the model endpoint or batch transform job with their corresponding label
  values. If it is provided, then the analysis report uses the headers instead of placeholders like
  "label0".

The other parameters should be provided in EndpointInput (for real-time endpoints) or
BatchTransformInput (for batch transform jobs) of the ModelExplainabilityJobInput API.

• FeaturesAttribute – This parameter is required if endpoint or batch job input data format is
  "application/jsonlines". It is the JMESPath used to locate the feature columns if the dataset
  format is JSON Lines.
• ProbabilityAttribute – Index or JMESPath location in the model output for probabilities. If the
  model output is JSON Lines with a list of labels and probabilities, for example, then the label that
  corresponds to the maximum probability is selected for bias computations.
Example JSON Configuration Files for CSV and JSON Lines Datasets

Here are examples of the JSON files used to configure CSV and JSON Lines datasets to monitor them for feature attribution drift.

Topics
- [CSV Datasets (p. 3092)]
- [JSON Lines Datasets (p. 3093)]

CSV Datasets

Consider a dataset that has three numerical feature columns, as in the following example.

| 0.5814568701544718, 0.6651538910132964, 0.3138080342665499 |
| 0.6711642728531724, 0.7466687034026017, 0.1215477472819713 |
| 0.0453256543003371, 0.6377430803264152, 0.3558625219713576 |
| 0.4785191813363956, 0.0265841045263860, 0.0376935084990697 |

Assume that the model output has two columns, where the first one is the predicted label and the second one is the probability, as in the following example.

| 1, 0.5385257417814224 |

The following example JSON configuration file shows how this CSV dataset can be configured.

```json
{
  "headers": [
    "feature_1",
    "feature_2",
    "feature_3"
  ],
  "methods": {
    "shap": {
      "baseline": [
        [0.4441164946610942, 0.5190374448171748, 0.20722795300473712]
      ],
      "num_samples": 100,
      "agg_method": "mean_abs"
    }
  },
  "predictor": {
    "model_name": "my_model",
    "instance_type": "ml.m5.xlarge",
    "initial_instance_count": 1
  }
}
```

The predicted label is selected by the "ProbabilityAttribute" parameter. Zero-based numbering is used, so 1 indicates the second column of the model output.

```json
"EndpointInput": {
  "\":
    "ProbabilityAttribute": 1
  ...}
```
JSON Lines Datasets

Consider a dataset that has four feature columns and one label column, where the first feature and the label are binary, as in the following example.

```json
[{
  "features": [0, 0.5814568701544718, 0.6651538910132964, 0.3138080342665499],
  "label": 0
},
{
  "features": [1, 0.6711642728531724, 0.7466687054026017, 0.1215477472819713],
  "label": 1
},
{
  "features": [0, 0.0453256543003371, 0.6377430803264152, 0.3558625219713576],
  "label": 1
},
{
  "features": [1, 0.4785191813363956, 0.0265841045263860, 0.0376935084990697],
  "label": 1
}]
```

The model input is the same as the dataset format, and the model output are JSON Lines, as in the following example.

```json
{"predicted_label": 1, "probability": 0.538527417814224}
```

In the following example, the JSON configuration file shows how this JSON Lines dataset can be configured.

```json
{
  "headers": [
    "feature_1",
    "feature_2",
    "feature_3"
  ],
  "methods": {
    "shap": {
      "baseline": [
        [0.4441164946610942, 0.5190374448171748, 0.20722795300473712]
      ],
      "num_samples": 100,
      "agg_method": "mean_abs"
    }
  },
  "predictor": {
    "model_name": "my_model",
    "instance_type": "ml.m5.xlarge",
    "initial_instance_count": 1,
    "content_template": "{"features":$features}"
  }
}
```

Then the "features" parameter value in EndpointInput (for real-time endpoints) or BatchTransformInput (for batch transform jobs) is used to locate the features in the dataset, and the "probability" parameter value selects the probability value from model output.

```
"EndpointInput": {
  ...
  "FeaturesAttribute": "features",
  "ProbabilityAttribute": "probability",
  ...
}
```

Schedule Feature Attribute Drift Monitoring Jobs

After you create your SHAP baseline, you can call the `create_monitoring_schedule()` method of your `ModelExplainabilityMonitor` class instance to schedule an hourly model explainability monitor. The following sections show you how to create a model explainability monitor for a model deployed to a real-time endpoint as well as for a batch transform job.
Important
You can specify either a batch transform input or an endpoint input, but not both, when you create your monitoring schedule.

If a baselining job has been submitted, the monitor automatically picks up analysis configuration from the baselining job. However, if you skip the baselining step or the capture dataset has a different nature from the training dataset, you have to provide the analysis configuration. ModelConfig is required by ExplainabilityAnalysisConfig for the same reason that it's required for the baselining job. Note that only features are required for computing feature attribution, so you should exclude Ground Truth labeling.

Feature attribution drift monitoring for models deployed to real-time endpoint
To schedule a model explainability monitor for a real-time endpoint, pass your EndpointInput instance to the endpoint_input argument of your ModelExplainabilityMonitor instance, as shown in the following code sample:

```python
from sagemaker.model_monitor import CronExpressionGenerator

model_exp_model_monitor = ModelExplainabilityMonitor(
    role=sagemaker.get_execution_role(),
    ...
)
schedule = model_exp_model_monitor.create_monitoring_schedule(
    monitor_schedule_name=schedule_name,
    post_analytics_processor_script=s3_code_postprocessor_uri,
    output_s3_uri=s3_report_path,
    statistics=model_exp_model_monitor.baseline_statistics(),
    constraints=model_exp_model_monitor.suggested_constraints(),
    schedule_cron_expression=CronExpressionGenerator.hourly(),
    enable_cloudwatch_metrics=True,
    endpoint_input=EndpointInput(
        endpoint_name=endpoint_name,
        destination="/opt/ml/processing/input/endpoint",
    ),
)
```

Feature attribution drift monitoring for batch transform jobs
To schedule a model explainability monitor for a batch transform job, pass your BatchTransformInput instance to the batch_transform_input argument of your ModelExplainabilityMonitor instance, as shown in the following code sample:

```python
from sagemaker.model_monitor import CronExpressionGenerator

model_exp_model_monitor = ModelExplainabilityMonitor(
    role=sagemaker.get_execution_role(),
    ...
)
schedule = model_exp_model_monitor.create_monitoring_schedule(
    monitor_schedule_name=schedule_name,
    post_analytics_processor_script=s3_code_postprocessor_uri,
    output_s3_uri=s3_report_path,
    statistics=model_exp_model_monitor.baseline_statistics(),
    constraints=model_exp_model_monitor.suggested_constraints(),
    schedule_cron_expression=CronExpressionGenerator.hourly(),
    enable_cloudwatch_metrics=True,
)```
Inspect Reports for Feature Attribute Drift in Production Models

After the schedule that you set up is started by default, you need to wait for its first execution to start, and then stop the schedule to avoid incurring charges.

To inspect the reports, use the following code:

```python
schedule_desc = model_explainability_monitor.describe_schedule()
execution_summary = schedule_desc.get("LastMonitoringExecutionSummary")
if execution_summary and execution_summary["MonitoringExecutionStatus"] in ["Completed", "CompletedWithViolations"]:
    last_model_explainability_monitor_execution = model_explainability_monitor.list_executions()[-1]
    last_model_explainability_monitor_execution_report_uri = last_model_explainability_monitor_execution.output.destination
    print(f"Report URI: {last_model_explainability_monitor_execution_report_uri}')
    last_model_explainability_monitor_execution_report_files = sorted(S3Downloader.list(last_model_explainability_monitor_execution_report_uri))
    print("Found Report Files:")
    print("\n ".join(last_model_explainability_monitor_execution_report_files))
else:
    last_model_explainability_monitor_execution = None
    print("====STOP==== 
  No completed executions to inspect further. Please wait till an execution completes or investigate previously reported failures.")
```

If there are any violations compared to the baseline, they are listed here:

```python
if last_model_explainability_monitor_execution:
    model_explainability_violations = last_model_explainability_monitor_execution.constraint_violations()
    if model_explainability_violations:
        print(model_explainability_violations.body_dict)
```

If your model is deployed to a real-time endpoint, you can see visualizations in SageMaker Studio of the analysis results and CloudWatch metrics by choosing the Endpoints tab, and then double-clicking the endpoint.

### CloudWatch Metrics for Feature Drift Analysis

This guide shows CloudWatch metrics and their properties that you can use for feature attribute drift analysis in SageMaker Clarify. Feature attribute drift monitoring jobs compute and publish two types of metrics:

- The global SHAP value of each feature.

  **Note**
  The name of this metric appends the feature name provided by the job analysis configuration to feature_. For example, feature_X is the global SHAP value for feature X.
• The ExpectedValue of the metric.

These metrics are published to the following CloudWatch namespace:
• For real-time endpoints: aws/sagemaker/Endpoints/explainability-metrics
• For batch transform jobs: aws/sagemaker/ModelMonitoring/explainability-metrics

Each metric has the following properties:
• Endpoint: The name of the monitored endpoint, if applicable.
• MonitoringSchedule: The name of the schedule for the monitoring job.
• ExplainabilityMethod: The method used to compute Shapley values. Choose KernelShap.
• Label: The name provided by job analysis configuration label_headers, or a placeholder like label0.
• ValueType: The type of the value returned by the metric. Choose either GlobalShapValues or ExpectedValue.

To stop the monitoring jobs from publishing metrics, set publish_cloudwatch_metrics to Disabled in the Environment map of model explainability job definition.

Schedule monitoring jobs

Amazon SageMaker Model Monitor provides you the ability to monitor the data collected from your real-time endpoints. You can monitor your data on a recurring schedule, or you can monitor it one time, immediately. You can create a monitoring schedule with the CreateMonitoringSchedule API.

With a monitoring schedule, SageMaker can start processing jobs to analyze the data collected during a given period. In the processing job, SageMaker compares the dataset for the current analysis with the baseline statistics and constraints that you provide. Then, SageMaker generate a violations report. In addition, CloudWatch metrics are emitted for each feature under analysis.

SageMaker provides a prebuilt container for performing analysis on tabular datasets. Alternatively, you could choose to bring your own container as outlined in the Bring Your Own Containers (p. 3114) topic.

You can create a model monitoring schedule for your real-time endpoint or batch transform job. Use the baseline resources (constraints and statistics) to compare against the real-time traffic or batch job inputs.

Example baseline assignments

In the following example, the training dataset used to train the model was uploaded to Amazon S3. If you already have it in Amazon S3, you can point to it directly.

```
# copy over the training dataset to Amazon S3 (if you already have it in Amazon S3, you could reuse it)
baseline_prefix = prefix + '/baselining'
baseline_data_prefix = baseline_prefix + '/data'
baseline_results_prefix = baseline_prefix + '/results'

baseline_data_uri = 's3://{}/{}'.format(bucket,baseline_data_prefix)
baseline_results_uri = 's3://{}/{}'.format(bucket, baseline_results_prefix)
print('Baseline data uri: {}'.format(baseline_data_uri))
print('Baseline results uri: {}'.format(baseline_results_uri))

training_data_file = open("test_data/training-dataset-with-header.csv", 'rb')
```
Schedule monitoring jobs

Example schedule for recurring analysis

If you are scheduling a model monitor for a real-time endpoint, use the baseline constraints and statistics to compare against real-time traffic. The following code snippet shows the general format you use to schedule a model monitor for a real-time endpoint. This example schedules the model monitor to run hourly.

```python
from sagemaker.model_monitor import CronExpressionGenerator
from time import gmtime, strftime

mon_schedule_name = 'my-model-monitor-schedule-' + strftime("%Y-%m-%d-%H-%M-%S", gmtime())
my_default_monitor.create_monitoring_schedule(
    monitor_schedule_name=mon_schedule_name,
    endpoint_input=EndpointInput(
        endpoint_name=endpoint_name,
        destination="/opt/ml/processing/input/endpoint"
    ),
    post_analytics_processor_script=s3_code_postprocessor_uri,
    output_s3_uri=s3_report_path,
    statistics=my_default_monitor.baseline_statistics(),
    constraints=my_default_monitor.suggested_constraints(),
    schedule_cron_expression=CronExpressionGenerator.hourly(),
    enable_cloudwatch_metrics=True,
)
```

Example schedule for one-time analysis

You can also schedule the analysis to run once without recurring by passing arguments like the following to the create_monitoring_schedule method:

```python
schedule_cron_expression=CronExpressionGenerator.now(),
data_analysis_start_time="-PT1H",
data_analysis_end_time="-PT0H",
```

In these arguments, the `schedule_cron_expression` parameter schedules the analysis to run once, immediately, with the value `CronExpressionGenerator.now()`. For any schedule with this setting, the `data_analysis_start_time` and `data_analysis_end_time` parameters are required. These parameters set the start time and end time of an analysis window. Define these times as offsets that are relative to the current time, and use ISO 8601 duration format. In this example, the times `-PT1H` and `-PT0H` define a window between one hour in the past and the current time. With this schedule, the analysis evaluates only the data that was collected during the specified window.

Example schedule for a batch transform job

The following code snippet shows the general format you use to schedule a model monitor for a batch transform job.

```python
from sagemaker.model_monitor import (  
    CronExpressionGenerator,
    BatchTransformInput,
    MonitoringDatasetFormat,
)
from time import gmtime, strftime

mon_schedule_name = 'my-model-monitor-schedule-' + strftime("%Y-%m-%d-%H-%M-%S", gmtime())
my_default_monitor.create_monitoring_schedule(
    monitor_schedule_name=mon_schedule_name,
)```
The cron expression for monitoring schedule

To provide details for the monitoring schedule, use `ScheduleConfig`, which is a `cron` expression that describes details about the monitoring schedule.

Amazon SageMaker Model Monitor supports the following `cron` expressions:

- **To set the job to start every hour**, use the following:
  
  Hourly: `cron(0 * ? * *)`

- **To run the job daily**, use the following:
  
  `cron(0 [00-23] ? * * *)`

- The run the job one time, immediately, use the following keyword:

  `NOW`

For example, the following are valid `cron` expressions:

- Daily at 12 PM UTC: `cron(0 12 ? * *)`
- Daily at 12 AM UTC: `cron(0 0 ? * *)`

To support running every 6, 12 hours, Model Monitor supports the following expression:

`cron(0 [00-23]/[01-24] ? * * *)`

For example, the following are valid `cron` expressions:

- Every 12 hours, starting at 5 PM UTC: `cron(0 17/12 ? * *)`
- Every two hours, starting at 12 AM UTC: `cron(0 0/2 ? * *)`

**Notes**

- Although the `cron` expression is set to start at 5 PM UTC, note that there could be a delay of 0-20 minutes from the actual requested time to run the execution.
- If you want to run on a daily schedule, don't provide this parameter. SageMaker picks a time to run every day.
- Currently, SageMaker only supports hourly integer rates between 1 hour and 24 hours.
Configuring service control policies for monitoring schedules

You have to specify the parameters of a monitoring job when you create or update a schedule for it with the CreateMonitoringSchedule API or the UpdateMonitoringSchedule API, respectively. Depending on your use case, you can do this in one of the following ways:

- You can specify the MonitoringJobDefinition field of MonitoringScheduleConfig, when you invoke CreateMonitoringSchedule or UpdateMonitoringSchedule. You can use this only to create or update a schedule for a data quality monitoring job.
- You can specify the name of a monitoring job definition, that you have already created, for the MonitoringJobDefinitionName field of MonitoringScheduleConfig, when you invoke CreateMonitoringSchedule or UpdateMonitoringSchedule. You can use this for any job definition that you create with one of the following APIs:
  - CreateDataQualityJobDefinition
  - CreateModelQualityJobDefinition
  - CreateModelBiasJobDefinition
  - CreateModelExplainabilityJobDefinition

If you want to use the SageMaker Python SDK to create or update schedules, then you have to use this process.

The aforementioned processes are mutually exclusive, that is, you can either specify the MonitoringJobDefinition field or the MonitoringJobDefinitionName field when creating or updating monitoring schedules.

When you create a monitoring job definition, or specify one in the MonitoringJobDefinition field, you can set security parameters, such as NetworkConfig and VolumeKmsKeyId. As an administrator, you might want that these parameters are always set to certain values, so that the monitoring jobs always run in a secure environment. To ensure this, set up appropriate Service control policies (SCPs). SCPs are a type of organization policy that you can use to manage permissions in your organization.

The following example shows a SCP that you can use to ensure that infrastructure parameters are properly set when creating or updating schedules for monitoring jobs.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Action": [
                "sagemaker:CreateDataQualityJobDefinition",
                "sagemaker:CreateModelBiasJobDefinition",
                "sagemaker:CreateModelExplainabilityJobDefinition",
                "sagemaker:CreateModelQualityJobDefinition"
            ],
            "Resource": "arn:*:sagemaker:*:*:*",
            "Condition": {
                "Null": {
                    "sagemaker:VolumeKmsKey": "true",
                    "sagemaker:VpcSubnets": "true",
                    "sagemaker:VpcSecurityGroupIds": "true"
                }
            }
        },
        {
            "Effect": "Deny",
```
The first two rules in the example, ensure that the security parameters are always set for monitoring job definitions. The final rule requires that anyone, in your organization, creating or updating a schedule, have to always specify the MonitoringJobDefinitionName field. This ensures that no one in your organization, can set insecure values for the security parameters by specifying the MonitoringJobDefinition field, when creating or updating schedules.

Amazon SageMaker Model Monitor prebuilt container

SageMaker provides a built-in image called sagemaker-model-monitor-analyzer that provides you with a range of model monitoring capabilities, including constraint suggestion, statistics generation, constraint validation against a baseline, and emitting Amazon CloudWatch metrics. This image is based on Spark version 3.3.0 and is built with Deequa version 2.0.2.

Note
You can not pull the built-in sagemaker-model-monitor-analyzer image directly. You can use the sagemaker-model-monitor-analyzer image when you submit a baseline processing or monitoring job using one of the AWS SDKs.

Use the SageMaker Python SDK (see image_uris.retrieve in the SageMaker Python SDK reference guide) to generate the ECR image URI for you, or specify the ECR image URI directly. The prebuilt image for SageMaker Model Monitor can be accessed as follows:

<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/sagemaker-model-monitor-analyzer

For example: 159807026194.dkr.ecr.us-west-2.amazonaws.com/sagemaker-model-monitor-analyzer
Interpret results

After you run a baseline processing job and obtained statistics and constraint for your dataset, you can execute monitoring jobs that calculate statistics and list any violations encountered relative to the baseline constraints. Amazon CloudWatch metrics are also reported in your account by default. For information on viewing the results of monitoring in Amazon SageMaker Studio, see Visualize results for real-time endpoints in Amazon SageMaker Studio (p. 3103).

List Executions

The schedule starts monitoring jobs at the specified intervals. The following code lists the latest five executions. If you are running this code after creating the hourly schedule, the executions might be empty, and you might have to wait until you cross the hour boundary (in UTC) to see the executions start. The following code includes the logic for waiting.

```python
mon_executions = my_default_monitor.list_executions()
print("We created a hourly schedule above and it will kick off executions ON the hour (plus 0 - 20 min buffer.\nWe will have to wait till we hit the hour...")

while len(mon_executions) == 0:
    print("Waiting for the 1st execution to happen...")
    time.sleep(60)
    mon_executions = my_default_monitor.list_executions()
```

Inspect a Specific Execution

In the previous step, you picked up the latest completed or failed scheduled execution. You can explore what went right or wrong. The terminal states are:

- **Completed** – The monitoring execution completed and no issues were found in the violations report.
- **CompletedWithViolations** – The execution completed, but constraint violations were detected.
- **Failed** – The monitoring execution failed, possibly due to client error (for example, a role issues) or infrastructure issues. To identify the cause, see the FailureReason and ExitMessage.

```python
latest_execution = mon_executions[-1] # latest execution's index is -1, previous is -2 and so on..
time.sleep(60)
latest_execution.wait(logs=False)
print("Latest execution status: {}".format(latest_execution.describe()['ProcessingJobStatus']))
print("Latest execution result: {}".format(latest_execution.describe()]['ExitMessage']))
```
latest_job = latest_execution.describe()
if (latest_job['ProcessingJobStatus'] != 'Completed'):
    print("====STOP==== \n No completed executions to inspect further. Please wait till an execution completes or investigate previously reported failures.")

report_uri=latest_execution.output.destination
print('Report Uri: {}'.format(report_uri))

List Generated Reports

List the generated reports. Use the following code to list the generated reports.

```python
from urllib.parse import urlparse
s3uri = urlparse(report_uri)
report_bucket = s3uri.netloc
report_key = s3uri.path.lstrip('/')
print('Report bucket: {}'.format(report_bucket))
print('Report key: {}'.format(report_key))
s3_client = boto3.Session().client('s3')
result = s3_client.list_objects(Bucket=report_bucket, Prefix=report_key)
report_files = [report_file.get("Key") for report_file in result.get('Contents')]
print("Found Report Files:")
print("\n".join(report_files))
```

Violations Report

If there are violations compared to the baseline, they are generated in the violations report. Use the following code to list the violations.

```python
violations = my_default_monitor.latest_monitoring_constraint_violations()
pd.set_option('display.max_colwidth', -1)
constraints_df = pd.io.json.json_normalize(violations.body_dict["violations"])
constraints_df.head(10)
```

This applies only to datasets that contain tabular data. The following schema files specify the statistics calculated and the violations monitored for.

Output Files for Tabular Datasets

<table>
<thead>
<tr>
<th>File Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>statistics.json</td>
<td>Contains columnar statistics for each feature in the dataset that is analyzed. See the schema of this file in the next topic.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> This file is created only for data quality monitoring.</td>
</tr>
<tr>
<td>constraint_violations.json</td>
<td>Contains a list of violations found in this current set of data as compared to the baseline statistics and constraints file specified in the baseline_constraints and baseline_statistics paths.</td>
</tr>
</tbody>
</table>
Visualize results for real-time endpoints in Amazon SageMaker Studio

If you are monitoring a real-time endpoint, you can also visualize the results in Amazon SageMaker Studio. You can view the details of any monitoring job run, and you can create charts that show the baseline and captured values for any metric that the monitoring job calculates.

To view the detailed results of a monitoring job

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 1).
2. In the left navigation pane, choose the Components and registries icon (🔍).
3. Choose Endpoints in the drop-down menu.
   
   ![Components and registries](image)

<table>
<thead>
<tr>
<th>Name</th>
<th>Endpoint status</th>
</tr>
</thead>
<tbody>
<tr>
<td>MyEndpoint1</td>
<td>InService</td>
</tr>
<tr>
<td>MyEndpoint2</td>
<td>InService</td>
</tr>
<tr>
<td>MyEndpoint3</td>
<td>InService</td>
</tr>
</tbody>
</table>

4. On the endpoint tab, choose the monitoring type for which you want to see job details.
5. Choose the name of the monitoring job run for which you want to view details from the list of monitoring jobs.

6. The **MONITORING JOB DETAILS** tab opens with a detailed report of the monitoring job.
You can create a chart that displays the baseline and captured metrics for a time period.

**To create a chart in SageMaker Studio to visualize monitoring results**

1. Sign in to Studio. For more information, see [Onboard to Amazon SageMaker Domain (p. 10)].
2. In the left navigation pane, choose the **Components and registries** icon (🔍).
3. Choose **Endpoints** in the drop-down menu.
4. On the **Endpoint** tab, choose the monitoring type you want to create a chart for. This example shows a chart for the **Model quality** monitoring type.

5. Choose **Add chart**.
6. On the **CHART PROPERTIES** tab, choose the time period, statistic, and metric that you want to chart. This example shows a chart for a **Timeline** of 1 week, the **Average Statistic** of, and the **F1 Metric**.
7. The chart that shows the baseline and current metric statistic you chose in the previous step shows up in the **Endpoint** tab.
Advanced topics

The following sections contain more advanced tasks that explain how to customize monitoring using preprocessing and postprocessing scripts, how to build your own container, and how to use AWS CloudFormation to create a monitoring schedule.

Topics
- Customize monitoring (p. 3109)
- Create a Monitoring Schedule for a Real-time Endpoint with an AWS CloudFormation Custom Resource (p. 3122)

Customize monitoring

In addition to using the built-in monitoring mechanisms, you can create your own custom monitoring schedules and procedures using preprocessing and postprocessing scripts or by using or building your own container.

Topics
- Preprocessing and Postprocessing (p. 3109)
- Bring Your Own Containers (p. 3114)

Preprocessing and Postprocessing

You can use custom preprocessing and postprocessing Python scripts to transform the input to your model monitor or extend the code after a successful monitoring run. Upload these scripts to Amazon S3 and reference them when creating your model monitor.

The following example shows how you can customize monitoring schedules with preprocessing and postprocessing scripts. Replace user placeholder text with your own information.

```python
import boto3, os
from sagemaker import get_execution_role, Session
```
from sagemaker.model_monitor import CronExpressionGenerator, DefaultModelMonitor

# Upload pre and postprocessor scripts
session = Session()
bucket = boto3.Session().resource("s3").Bucket(session.default_bucket())
prefix = "demo-sagemaker-model-monitor"
pre_processor_script = bucket.Object(os.path.join(prefix, "preprocessor.py")); upload_file("preprocessor.py")
post_processor_script = bucket.Object(os.path.join(prefix, "postprocessor.py")); upload_file("postprocessor.py")

# Get execution role
role = get_execution_role() # can be an empty string

# Instance type
instance_type = "instance-type"
# instance_type = "ml.m5.xlarge" # Example

# Create a monitoring schedule with pre and postprocessing
my_default_monitor = DefaultModelMonitor(
    role=role,
    instance_count=1,
    instance_type=instance_type,
    volume_size_in_gb=20,
    max_runtime_in_seconds=3600,
)
s3_report_path = "s3://{}/reports".format(bucket, "reports")
monitor_schedule_name = "monitor-schedule-name"
endpoint_name = "endpoint-name"
my_default_monitor.create_monitoring_schedule(
    post_analytics_processor_script=post_processor_script,
    record_preprocessor_script=pre_processor_script,
    monitor_schedule_name=monitor_schedule_name,
    # use endpoint_input for real-time endpoint
    endpoint_input=endpoint_name,
    # or use batch_transform_input for batch transform jobs
    # batch_transform_input=batch_transform_name,
    statistics=my_default_monitor.baseline_statistics(),
    constraints=my_default_monitor.suggested_constraints(),
    schedule_cron_expression=CronExpressionGenerator.hourly(),
    enable_cloudwatch_metrics=True,
)

Topics
- Preprocessing Script (p. 3110)
- Custom Sampling (p. 3113)
- Postprocessing Script (p. 3113)

Preprocessing Script

Use preprocessing scripts when you need to transform the inputs to your model monitor.

For example, suppose the output of your model is an array [1.0, 2.1]. The Amazon SageMaker Model Monitor container only works with tabular or flattened JSON structures, like {"prediction0": 1.0, "prediction1": 2.1}. You could use a preprocessing script like the following to transform the array into the correct JSON structure.

```python
def preprocess_handler(inference_record):
    # Transform the array into JSON structure
    return {'prediction0': 1.0, 'prediction1': 2.1}
```
input_data = inference_record.endpoint_input.data
data = output_data + "," + input_data
return { str(i).zfill(20) : d for i, d in enumerate(data.split(",")) }

In another example, suppose your model has optional features and you use -1 to denote that the optional feature has a missing value. If you have a data quality monitor, you may want to remove the -1 from the input value array so that it isn't included in the monitor's metric calculations. You could use a script like the following to remove those values.

def preprocess_handler(inference_record):
    input_data = inference_record.endpoint_input.data
    return {i : None if x == -1 else x for i, x in enumerate(input_data.split(","))}

Your preprocessing script receives an inference_record as its only input. The following code snippet shows an example of an inference_record.

```json
{
    "captureData": {
        "endpointInput": {
            "observedContentType": "text/csv",
            "mode": "INPUT",
            "data": "132.25,113.2,96,269.9,107,,0,0,0,0,0,0,1,0,1,0,0,1",
            "encoding": "CSV"
        },
        "endpointOutput": {
            "observedContentType": "text/csv; charset=utf-8",
            "mode": "OUTPUT",
            "data": "0.01076381653547287",
            "encoding": "CSV"
        }
    },
    "eventMetadata": {
        "eventId": "feca1ab1-8025-47e3-8f6a-99e3fdd7b8d9",
        "inferenceTime": "2019-11-20T23:33:12Z"
    },
    "eventVersion": "0"
}
```

The following code snippet shows the full class structure for an inference_record.

```python
KEY_EVENT_METADATA = "eventMetadata"
KEY_EVENT_METADATA_EVENT_ID = "eventId"
KEY_EVENT_METADATA_EVENT_TIME = "inferenceTime"
KEY_EVENT_METADATA_CUSTOM_ATTR = "customAttributes"

KEY_EVENTDATA_ENCODING = "encoding"
KEY_EVENTDATA_DATA = "data"

KEY_GROUND_TRUTH_DATA = "groundTruthData"

KEY_EVENTDATA = "captureData"
KEY_EVENTDATA_ENDPOINT_INPUT = "endpointInput"
KEY_EVENTDATA_ENDPOINT_OUTPUT = "endpointOutput"

KEY_EVENTDATA_BATCH_OUTPUT = "batchTransformOutput"
KEY_EVENTDATA_OBSERVED_CONTENT_TYPE = "observedContentType"
```
KEY_EVENT_VERSION = "eventVersion"

class EventConfig:
    def __init__(self, endpoint, variant, start_time, end_time):
        self.endpoint = endpoint
        self.variant = variant
        self.start_time = start_time
        self.end_time = end_time

class EventMetadata:
    def __init__(self, event_metadata_dict):
        self.event_id = event_metadata_dict.get(KEY_EVENT_METADATA_EVENT_ID, None)
        self.event_time = event_metadata_dict.get(KEY_EVENT_METADATA_EVENT_TIME, None)
        self.custom_attribute = event_metadata_dict.get(KEY_EVENT_METADATA_CUSTOM_ATTR, None)

class EventData:
    def __init__(self, data_dict):
        self.encoding = data_dict.get(KEY_EVENTDATA_ENCODING, None)
        self.data = data_dict.get(KEY_EVENTDATA_DATA, None)
        self.observedContentType = data_dict.get(KEY_EVENTDATA_OBSERVED_CONTENT_TYPE, None)
        self.mode = data_dict.get(KEY_EVENTDATA_MODE, None)

    def as_dict(self):
        ret = {
            KEY_EVENTDATA_ENCODING: self.encoding,
            KEY_EVENTDATA_DATA: self.data,
            KEY_EVENTDATA_OBSERVED_CONTENT_TYPE: self.observedContentType,
        }
        return ret

class CapturedData:
    def __init__(self, event_dict):
        self.event_metadata = None
        self.endpoint_input = None
        self.endpoint_output = None
        self.batch_transform_output = None
        self.ground_truth = None
        self.event_version = None
        self.event_dict = event_dict
        self._event_dict_postprocessed = False

        if KEY_EVENT_METADATA in event_dict:
            self.event_metadata = EventMetadata(event_dict[KEY_EVENT_METADATA])

        if KEY_EVENTDATA in event_dict:
            if KEY_EVENTDATA_ENDPOINT_INPUT in event_dict:
                self.endpoint_input = EventData(event_dict[KEY_EVENTDATA][KEY_EVENTDATA_ENDPOINT_INPUT])

            if KEY_EVENTDATA_ENDPOINT_OUTPUT in event_dict:
                self.endpoint_output = EventData(event_dict[KEY_EVENTDATA][KEY_EVENTDATA_ENDPOINT_OUTPUT])

            if KEY_EVENTDATA_BATCH_OUTPUT in event_dict:
                self.batch_transform_output = EventData(event_dict[KEY_EVENTDATA][KEY_EVENTDATA_BATCH_OUTPUT])

            if KEY_GROUND_TRUTH_DATA in event_dict:
                self.ground_truth = EventData(event_dict[KEY_GROUND_TRUTH_DATA])

        if KEY_EVENT_VERSION in event_dict:
            self.event_version = event_dict[KEY_EVENT_VERSION]

    def as_dict(self):
        if self._event_dict_postprocessed is True:
Customize monitoring

return self.event_dict
if KEY_EVENTDATA in self.event_dict:
    if KEY_EVENTDATA_ENDPOINT_INPUT in self.event_dict[KEY_EVENTDATA]:
        self.event_dict[KEY_EVENTDATA][KEY_EVENTDATA_ENDPOINT_INPUT] =
        self.endpoint_input.as_dict()
    if KEY_EVENTDATA_ENDPOINT_OUTPUT in self.event_dict[KEY_EVENTDATA]:
        self.event_dict[KEY_EVENTDATA][KEY_EVENTDATA_ENDPOINT_OUTPUT] =
        self.endpoint_output.as_dict()
    if KEY_EVENTDATA_BATCH_OUTPUT in self.event_dict[KEY_EVENTDATA]:
        self.event_dict[KEY_EVENTDATA][KEY_EVENTDATA_BATCH_OUTPUT] =
        self.batch_transform_output.as_dict()
self._event_dict_postprocessed = True
return self.event_dict

def __str__(self):
    return str(self.as_dict())

Custom Sampling

You can also apply a custom sampling strategy in your preprocessing script. To do this, configure Model Monitor's first-party, pre-built container to ignore a percentage of the records according to your specified sampling rate. In the following example, the handler samples 10 percent of the records by returning the record in 10 percent of handler calls and an empty list otherwise.

```python
import random
def preprocess_handler(inference_record):
    # we set up a sampling rate of 0.1
    if random.random() > 0.1:
        # return an empty list
        return []
    input_data = inference_record.endpoint_input.data
    return {i : None if x == -1 else x for i, x in enumerate(input_data.split(","))}
```

Custom logging for preprocessing script

If your preprocessing script returns an error, check the exception messages logged to CloudWatch to debug. You can access the logger on CloudWatch through the `preprocess_handler` interface. You can log any information you need from your script to CloudWatch. This can be useful when debug your preprocessing script. The following example shows how you can use the `preprocess_handler` interface to log to CloudWatch

```python
def preprocess_handler(inference_record, logger):
    logger.info(f"I'm a processing record: {inference_record}")
    logger.debug(f"I'm debugging a processing record: {inference_record}")
    logger.warning(f"I'm processing record with missing value: {inference_record}")
    logger.error(f"I'm a processing record with bad value: {inference_record}")
    return inference_record
```

Postprocessing Script

Use a postprocessing script when you want to extend the code following a successful monitoring run.

```python
def postprocess_handler():
    print("Hello from post-proc script!")
```
Bring Your Own Containers

Amazon SageMaker Model Monitor provides a prebuilt container with ability to analyze the data captured from endpoints or batch transform jobs for tabular datasets. If you would like to bring your own container, Model Monitor provides extension points which you can leverage.

Under the hood, when you create a MonitoringSchedule, Model Monitor ultimately kicks off processing jobs. Hence the container needs to be aware of the processing job contract documented in the Build Your Own Processing Container (Advanced Scenario) (p. 1408) topic. Note that Model Monitor kicks off the processing job on your behalf per the schedule. While invoking, Model Monitor sets up additional environment variables for you so that your container has enough context to process the data for that particular execution of the scheduled monitoring. For additional information on container inputs, see the Container Contract Inputs (p. 3114).

In the container, using the above environment variables/context, you can now analyze the dataset for the current period in your custom code. After this analysis is complete, you can chose to emit your reports to be uploaded to an S3 bucket. The reports that the prebuilt container generates are documented in Container Contract Outputs (p. 3116). If you would like the visualization of the reports to work in SageMaker Studio, you should follow the same format. You can also choose to emit completely custom reports.

You also emit CloudWatch metrics from the container by following the instructions in CloudWatch Metrics for Bring Your Own Containers (p. 3121).

Topics

- Container Contract Inputs (p. 3114)
- Container Contract Outputs (p. 3116)
- CloudWatch Metrics for Bring Your Own Containers (p. 3121)

Container Contract Inputs

The Amazon SageMaker Model Monitor platform invokes your container code according to a specified schedule. If you choose to write your own container code, the following environment variables are available. In this context, you can analyze the current dataset or evaluate the constraints if you choose and emit metrics, if applicable.

The available environment variables are the same for real-time endpoints and batch transform jobs, except for the dataset_format variable. If you are using a real-time endpoint, the dataset_format variable supports the following options:

```json
{"sagemakerCaptureJson": {"captureIndexNames": ["endpointInput","endpointOutput"]}}
```

If you are using a batch transform job, the dataset_format supports the following options:

```json
{"csv": {"header": ["true","false"]}}

{"json": {"line": ["true","false"]}}

{"parquet": {}}
```

The following code sample shows the complete set of environment variables available for your container code (and uses the dataset_format format for a real-time endpoint).

```json
"Environment": {
```
"dataset_format": "{"sagemakerCaptureJson": [{"captureIndexNames": ["endpointInput", "endpointOutput"]}]}, "dataset_source": "/opt/ml/processing/endpointdata", "end_time": "2019-12-01T16: 00Z", "output_path": "/opt/ml/processing/resultdata", "publish_cloudwatch_metrics": "Disabled", "sagemaker_endpoint_name": "endpoint-name", "sagemaker_monitoring_schedule_name": "schedule-name", "start_time": "2019-12-01T15: 00Z" }

## Parameters

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dataset_format</td>
<td>For a job started from a MonitoringSchedule backed by an Endpoint, this is sagemakerCaptureJson with the capture indices endpointInput, or endpointOutput, or both. For a batch transform job, this specifies the data format, whether CSV, JSON, or Parquet.</td>
</tr>
<tr>
<td>dataset_source</td>
<td>If you are using a real-time endpoint, the local path in which the data corresponding to the monitoring period, as specified by start_time and end_time, are available. At this path, the data is available in /{endpoint-name}/ {variant-name}/yyyy/mm/dd/hh. We sometimes download more than what is specified by the start and end times. It is up to the container code to parse the data as required.</td>
</tr>
<tr>
<td>output_path</td>
<td>The local path to write output reports and other files. You specify this parameter in the CreateMonitoringSchedule request as MonitoringOutputConfig.MonitoringOutput[0].LocalPath. It is uploaded to the S3Uri path specified in MonitoringOutputConfig.MonitoringOutput[0].S3Uri.</td>
</tr>
<tr>
<td>publish_cloudwatch_metrics</td>
<td>For a job launched by CreateMonitoringSchedule, this parameter is set to Enabled. The container can choose to write the Amazon CloudWatch output file at [filepath].</td>
</tr>
<tr>
<td>sagemaker_endpoint_name</td>
<td>If you are using a real-time endpoint, the name of the Endpoint that this scheduled job was launched for.</td>
</tr>
<tr>
<td>sagemaker_monitoring_schedule_name</td>
<td>The name of the MonitoringSchedule that launched this job.</td>
</tr>
<tr>
<td><em>sagemaker_endpoint_datacapture_prefix</em></td>
<td>If you are using a real-time endpoint, the prefix specified in the DataCaptureConfig parameter of the Endpoint. The container can use this if it needs to directly access more data than already downloaded by SageMaker at the dataset_source path.</td>
</tr>
</tbody>
</table>
### Parameter Name

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>start_time, end_time</td>
<td>The time window for this analysis run. For example, for a job scheduled to run at 05:00 UTC and a job that runs on 20/02/2020, start_time: is 2020-02-19T06:00:00Z and end_time: is 2020-02-20T05:00:00Z</td>
</tr>
<tr>
<td>baseline_constraints:</td>
<td>The local path of the baseline constraint file specified in BaselineConfig.ConstraintResource.S3Uri. This is available only if this parameter was specified in the CreateMonitoringSchedule request.</td>
</tr>
<tr>
<td>baseline_statistics</td>
<td>The local path to the baseline statistics file specified in BaselineConfig.StatisticsResource.S3Uri. This is available only if this parameter was specified in the CreateMonitoringSchedule request.</td>
</tr>
</tbody>
</table>

### Container Contract Outputs

The container can analyze the data available in the *dataset_source* path and write reports to the path in *output_path*. The container code can write any reports that suit your needs.

If you use the following structure and contract, certain output files are treated specially by SageMaker in the visualization and API. This applies only to tabular datasets.

### Output Files for Tabular Datasets

<table>
<thead>
<tr>
<th>File Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>statistics.json</td>
<td>This file is expected to have columnar statistics for each feature in the dataset that is analyzed. The schema for this file is available in the next section.</td>
</tr>
<tr>
<td>constraints.json</td>
<td>This file is expected to have the constraints on the features observed. The schema for this file is available in the next section.</td>
</tr>
<tr>
<td>constraints_violations.json</td>
<td>This file is expected to have the list of violations found in this current set of data as compared to the baseline statistics and constraints file specified in the baseline_constraints and baseline_statistics path.</td>
</tr>
</tbody>
</table>

In addition, if the publish_cloudwatch_metrics value is "Enabled" container code can emit Amazon CloudWatch metrics in this location: /opt/ml/output/metrics/cloudwatch. The schema for these files is described in the following sections.

**Topics**

- Schema for Statistics (statistics.json file) (p. 3117)
- Schema for Constraints (constraints.json file) (p. 3118)
Schema for Statistics (statistics.json file)

The schema defined in the statistics.json file specifies the statistical parameters to be calculated for the baseline and data that is captured. It also configures the bucket to be used by KLL, a very compact quantiles sketch with lazy compaction scheme.

```json
{
    "version": 0,
    # dataset level stats
    "dataset": {
        "item_count": number
    },
    # feature level stats
    "features": [
        {
            "name": "feature-name",
            "inferred_type": "Fractional" | "Integral",
            "numerical_statistics": {
                "common": {
                    "num_present": number,

Notes

- The specified metrics are recognized by SageMaker in later visualization changes. The container can emit more metrics if required.
- KLL sketch is the recognized sketch. Custom containers can write their own representation, but it won’t be recognized by SageMaker in visualizations.
- By default, the distribution is materialized in 10 buckets. You can’t change this.

Schema for Constraints (constraints.json file)

A constraints.json file is used to express the constraints that a dataset must satisfy. Amazon SageMaker Model Monitor containers can use the constraints.json file to evaluate datasets against. Prebuilt containers provide the ability to generate the constraints.json file automatically for a baseline dataset. If you bring your own container, you can provide it with similar abilities or you can create the constraints.json file in some other way. Here is the schema for the constraint file that the prebuilt container uses. Bring your own containers can adopt the same format or enhance it as required.

```json
{
    "version": 0,
    "features": [
        {
            "name": "string",
            "inferred_type": "Integral" | "Fractional" | "String" | "Unknown",
            "completeness": number,
            "num_constraints": {
                "is_non_negative": boolean
            },
            "string_constraints": {
                "domains": [
                    "list of", "observed values", "for small cardinality"
                ]
            },
            "monitoringConfigOverrides":
```
The monitoring_config object contains options for monitoring job for the feature. The following table describes each option.

**Monitoring Constraints**

<table>
<thead>
<tr>
<th>Constraint</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>evaluate_constraints</strong></td>
<td>When Enabled, evaluates whether the current dataset being analyzed satisfies the constraints specified in the constraints.json file taken as a baseline. Valid values: Enabled or Disabled Default: Enabled</td>
</tr>
<tr>
<td><strong>emit_metrics</strong></td>
<td>When Enabled, emits CloudWatch metrics for the data contained in the file. Valid values: Enabled or Disabled Default: Enabled</td>
</tr>
<tr>
<td><strong>datatype_check_threshold</strong></td>
<td>If the threshold is above the value of the specified datatype_check_threshold, this causes a failure that is treated as a violation in the violation report. If the data types in the current execution are not the same as in the baseline dataset, this threshold is used to evaluate if it needs to be flagged as a violation. During the baseline step, the generated constraints suggest the inferred data type for each column. The datatype_check_threshold parameter can be tuned to adjust the threshold on when it is flagged as a violation. Valid values: float Default: 0.1</td>
</tr>
<tr>
<td>Constraint</td>
<td>Description</td>

</table>
Customize monitoring

<table>
<thead>
<tr>
<th>Constraint</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>categorical_comparison_threshold</code></td>
<td>Optional. Sets a threshold for categorical features. If the value in the dataset exceeds the threshold that you set, a violation is recorded in the violation report. Valid values: float Default: The value assigned to the <code>comparison_threshold</code> parameter</td>
</tr>
<tr>
<td><code>categorical_drift_method</code></td>
<td>Optional. For categorical features, specifies the computation method used to detect distribution drift. If you don't set this parameter, the K-S (LInfinity) test is used. Valid Values: LInfinity or ChiSquared Default: LInfinity</td>
</tr>
</tbody>
</table>

CloudWatch Metrics for Bring Your Own Containers

If the `publish_cloudwatch_metrics` value is Enabled in the `Environment` map in the `/opt/ml/processing/processingjobconfig.json` file, the container code emits Amazon CloudWatch metrics in this location: `/opt/ml/output/metrics/cloudwatch`.

The schema for this file is closely based on the CloudWatch PutMetrics API. The namespace is not specified here. It defaults to the following:

- For real-time endpoints: `/aws/sagemaker/Endpoint/data-metrics`
- For batch transform jobs: `/aws/sagemaker/ModelMonitoring/data-metrics`

However, you can specify dimensions. We recommend you add the following dimensions at minimum:

- Endpoint and MonitoringSchedule for real-time endpoints
- MonitoringSchedule for batch transform jobs

The following JSON snippets show how to set your dimensions.

For a real-time endpoint, see the following JSON snippet which includes the Endpoint and MonitoringSchedule dimensions:

```json
{
  "MetricName": "", # Required
  "Timestamp": "2019-11-26T03:00:00Z", # Required
  "Dimensions": [
    {
      "Name": "Endpoint", "Value": "endpoint_0"
    },
    {
      "Name": "MonitoringSchedule", "Value": "schedule_0"
    }
  ],
  "Value": Float,
  # Either the Value or the StatisticValues field can be populated and not both.
  "StatisticValues": {
    "SampleCount": Float,
    "Sum": Float,
    "Count": Float
  }
}
```
For a batch transform job, see the following JSON snippet which includes the MonitoringSchedule dimension:

```json
{
  "MetricName": "",
  "Timestamp": "2019-11-26T03:00:00Z",
  "Dimensions": [{"Name":"MonitoringSchedule","Value":"schedule_0"}],
  "Value": Float,
  "StatisticValues": {
    "SampleCount": Float,
    "Sum": Float,
    "Minimum": Float,
    "Maximum": Float
  },
  "Unit": "Count", # Optional
}
```

Create a Monitoring Schedule for a Real-time Endpoint with an AWS CloudFormation Custom Resource

If you are using a real-time endpoint, you can use a AWS CloudFormation custom resource to create a monitoring schedule. The custom resource is in Python. To deploy it, see [Python Lambda deployment](#).

**Custom Resource**

Start by adding a custom resource to your AWS CloudFormation template. This points to a AWS Lambda function that you create in the next step.

This resource enables you to customize the parameters for the monitoring schedule. You can add or remove more parameters by modifying the AWS CloudFormation resource and the Lambda function in the following example resource.

```json
{
  "AWSTemplateFormatVersion": "2010-09-09",
  "Resources": {
    "MonitoringSchedule": {
      "Type": "Custom::MonitoringSchedule",
      "Version": "1.0",
      "Properties": {
        "ScheduleName": "YourScheduleName",
        "EndpointName": "YourEndpointName",
        "BaselineConstraintsUri": "s3://your-baseline-constraints/json",
        "BaselineStatisticsUri": "s3://your-baseline-stats/statistics.json",
        "PostAnalyticsProcessorSourceUri": "s3://your-post-processor/postprocessor.py",
        "RecordPreprocessorSourceUri": "s3://your-preprocessor/preprocessor.py",
        "InputLocalPath": "/opt/ml/processing/endpointdata",
        "OutputLocalPath": "/opt/ml/processing/localpath"
    }
  }
}
```
Lambda Custom Resource Code

This AWS CloudFormation custom resource uses the Custom Resource Helper AWS library, which you can install with pip using pip install crhelper.

This Lambda function is invoked by AWS CloudFormation during the creation and deletion of the stack. This Lambda function is responsible for creating and deleting the monitoring schedule and using the parameters defined in the custom resource described in the preceding section.

```python
import boto3
import botocore
import logging
from crhelper import CfnResource
from botocore.exceptions import ClientError

logger = logging.getLogger(__name__)
sm = boto3.client('sagemaker')

helper = CfnResource()

# CFN Handlers

def handler(event, context):
    helper(event, context)

@helper.create
def create_handler(event, context):
    ""
    Called when CloudFormation custom resource sends the create event
    ""
    create_monitoring_schedule(event)

@helper.delete
def delete_handler(event, context):
    ""
    Called when CloudFormation custom resource sends the delete event
    ""
    schedule_name = get_schedule_name(event)
    delete_monitoring_schedule(schedule_name)

@helper.poll_create
def poll_create(event, context):
    ""
    Return true if the resource has been created and false otherwise so CloudFormation polls again.
    ""
    schedule_name = get_schedule_name(event)
```
logger.info('Polling for creation of schedule: %s', schedule_name)
return is_schedule_ready(schedule_name)

@helper.update
def noop():
    
    Not currently implemented but crhelper will throw an error if it isn't added
    
    pass

# Helper Functions
def get_schedule_name(event):
    return event['ResourceProperties']['ScheduleName']

def create_monitoring_schedule(event):
    schedule_name = get_schedule_name(event)
    monitoring_schedule_config = create_monitoring_schedule_config(event)
    logger.info('Creating monitoring schedule with name: %s', schedule_name)
    sm.create_monitoring_schedule(
        MonitoringScheduleName=schedule_name,
        MonitoringScheduleConfig=monitoring_schedule_config)

def is_schedule_ready(schedule_name):
    is_ready = False
    schedule = sm.describe_monitoring_schedule(MonitoringScheduleName=schedule_name)
    status = schedule['MonitoringScheduleStatus']
    if status == 'Scheduled':
        logger.info('Monitoring schedule (%s) is ready', schedule_name)
        is_ready = True
    elif status == 'Pending':
        logger.info('Monitoring schedule (%s) still creating, waiting and polling again... ', schedule_name)
    else:
        raise Exception('Monitoring schedule ({}) has unexpected status: {}'.format(schedule_name, status))
    return is_ready

def create_monitoring_schedule_config(event):
    props = event['ResourceProperties']
    return {
        "ScheduleConfig": {
            "ScheduleExpression": props["ScheduleExpression"],
        },
        "MonitoringJobDefinition": {
            "BaselineConfig": {
                "ConstraintsResource": {
                    "S3Uri": props["BaselineConstraintsUri"],
                },
                "StatisticsResource": {
                    "S3Uri": props["BaselineStatisticsUri"],
                }
            },
            "MonitoringInputs": [
                {
                    "EndpointInput": {
                        "EndpointName": props["EndpointName"],
                        "LocalPath": props["InputLocalPath"],
                    }
                }
            ]
        }
    }
def delete_monitoring_schedule(schedule_name):
    logger.info('Deleting schedule: %s', schedule_name)
    try:
        sm.delete_monitoring_schedule(MonitoringScheduleName=schedule_name)
    except ClientError as e:
        if e.response['Error']['Code'] == 'ResourceNotFound':
            logger.info('Resource not found, nothing to delete')
        else:
            logger.error('Unexpected error while trying to delete monitoring schedule')
            raise e

Model Monitor FAQs

Refer to the following FAQs for more information about Amazon SageMaker Model Monitor.

**Q: How do Model Monitor and SageMaker Clarify help customers monitor model behavior?**

Customers can monitor model behavior along four dimensions - [Data quality](https://aws.amazon.com/sagemaker/model-monitor/), [Model quality](https://aws.amazon.com/sagemaker/model-monitor/), [Bias drift](https://aws.amazon.com/sagemaker/model-monitor/), and [Feature Attribution drift](https://aws.amazon.com/sagemaker/model-monitor/). **Model Monitor** continuously monitors the quality of Amazon SageMaker machine learning models in production. This includes monitoring drift in data quality and model quality metrics such as accuracy and RMSE. **SageMaker Clarify** bias monitoring helps data scientists and ML engineers monitor bias in model's prediction and feature attribution drift.

**Q: What happens in the background when Sagemaker Model monitor is enabled?**

Amazon SageMaker Model Monitor automates model monitoring alleviating the need to monitor the models manually or building any additional tooling. In order to automate the process, Model Monitor provides you with the ability to create a set of baseline statistics and constraints using the data with
which your model was trained, then set up a schedule to monitor the predictions made on your endpoint. Model Monitor uses rules to detect drift in your models and alerts you when it happens. The following steps describe what happens when you enable model monitoring:

- **Enable model monitoring**: For a real-time endpoint, you have to enable the endpoint to capture data from incoming requests to a deployed ML model and the resulting model predictions. For a batch transform job, enable data capture of the batch transform inputs and outputs.

- **Baseline processing job**: You then create a baseline from the dataset that was used to train the model. The baseline computes metrics and suggests constraints for the metrics. For example, the recall score for the model shouldn't regress and drop below 0.571, or the precision score shouldn't fall below 1.0. Real-time or batch predictions from your model are compared to the constraints and are reported as violations if they are outside the constrained values.

- **Monitoring job**: Then, you create a monitoring schedule specifying what data to collect, how often to collect it, how to analyze it, and which reports to produce.

- **Merge job**: This is only applicable if you are leveraging Amazon SageMaker Ground Truth. Model Monitor compares the predictions your model makes with Ground Truth labels to measure the quality of the model. For this to work, you periodically label data captured by your endpoint or batch transform job and upload it to Amazon S3.

After you create and upload the Ground Truth labels, include the location of the labels as a parameter when you create the monitoring job.

When you use Model Monitor to monitor a batch transform job instead of a real-time endpoint, instead of receiving requests to an endpoint and tracking the predictions, Model Monitor monitors inference inputs and outputs. In a Model Monitor schedule, the customer provides the count and type of instances that are to be used in the processing job. These resources remain reserved until the schedule is deleted irrespective of the status of current execution.

**Q: What is Data Capture, why is it required, and how can I enable it?**

In order to log the inputs to the model endpoint and the inference outputs from the deployed model to Amazon S3, you can enable a feature called Data Capture. For more details about how to enable it for a real-time endpoint and batch transform job, see [Capture data from real-time endpoint](#) and [Capture data from batch transform job](#).

**Q: Does enabling Data Capture impact the performance of a real-time endpoint?**

Data Capture happens asynchronously without impacting production traffic. After you have enabled the data capture, then the request and response payload, along with some additional meta data, is saved in the Amazon S3 location that you specified in the DataCaptureConfig. Note that there can be a delay in the propagation of the captured data to Amazon S3.

You can also view the captured data by listing the data capture files stored in Amazon S3. The format of the Amazon S3 path is: s3:///{endpoint-name}/{variant-name}/yyyy/mm/dd/hh/filename.jsonl. Amazon S3 Data Capture should be in the same region as the Model Monitor schedule. You should also ensure that the column names for the baseline dataset only have lowercase letters and an underscore (_) as the only separator.

**Q: Why is Ground Truth needed for model monitoring?**

Ground Truth labels are required by the following features of Model Monitor:

- **Model quality monitoring** compares the predictions your model makes with Ground Truth labels to measure the quality of the model.

- **Model bias monitoring** monitors predictions for bias. One way bias can be introduced in deployed ML models is when the data used in training differs from the data used to generate predictions. This is especially pronounced if the data used for training changes over time (such as fluctuating mortgage rates), and the model prediction is not as accurate unless the model is retrained with updated data.
For example, a model for predicting home prices can be biased if the mortgage rates used to train the model differ from the most current real-world mortgage rate.

Q: For customers leveraging Ground Truth for labeling, what are the steps I can take to monitor the quality of the model?

Model quality monitoring compares the predictions your model makes with Ground Truth labels to measure the quality of the model. For this to work, you periodically label data captured by your endpoint or batch transform job and upload it to Amazon S3. Besides captures, model bias monitoring execution also requires Ground Truth data. In real use cases, Ground Truth data should be regularly collected and uploaded to the designated Amazon S3 location. To match Ground Truth labels with captured prediction data, there must be a unique identifier for each record in the dataset. For the structure of each record for Ground Truth data, see Ingest Ground Truth Labels and Merge Them With Predictions.

The following code example can be used for generating artificial Ground Truth data for a tabular dataset.

```python
import random

def ground_truth_with_id(inference_id):
    random.seed(inference_id)  # to get consistent results
    rand = random.random()
    # format required by the merge container
    return {
        "groundTruthData": {
            "data": "1" if rand < 0.7 else "0",  # randomly generate positive labels 70% of the time
            "encoding": "CSV",
        },
        "eventMetadata": {
            "eventId": str(inference_id),
        },
        "eventVersion": "0",
    }

def upload_ground_truth(upload_time):
    records = [ground_truth_with_id(i) for i in range(test_dataset_size)]
    fake_records = [json.dumps(r) for r in records]
    data_to_upload = "\n".join(fake_records)
    target_s3_uri = f"{ground_truth_upload_path}/{upload_time:%Y/%m/%d/%H/%M%S}.jsonl"
    print(f"Uploading {len(fake_records)} records to {target_s3_uri}")
    S3Uploader.upload_string_as_file_body(data_to_upload, target_s3_uri)

# Generate data for the last hour
upload_ground_truth(datetime.utcnow() - timedelta(hours=1))
# Generate data once a hour
def generate_fake_ground_truth(terminate_event):
    upload_ground_truth(datetime.utcnow())
    for _ in range(0, 60):
        time.sleep(60)
        if terminate_event.is_set():
            break

ground_truth_thread = WorkerThread(do_run=generate_fake_ground_truth)
ground_truth_thread.start()
```

The following code example shows how to generate artificial traffic to send to the model endpoint. Notice the `inferenceId` attribute used above to invoke. If this is present, it is used to join with Ground Truth data (otherwise, the `eventId` is used).

```python
import threading
```
class WorkerThread(threading.Thread):
    def __init__(self, do_run, *args, **kwargs):
        super(WorkerThread, self).__init__(*args, **kwargs)
        self.__do_run = do_run
        self.__terminate_event = threading.Event()

    def terminate(self):
        self.__terminate_event.set()

    def run(self):
        while not self.__terminate_event.is_set():
            self.__do_run(self.__terminate_event)

    def invoke_endpoint(terminate_event):
        with open(test_dataset, "r") as f:
            i = 0
            for row in f:
                payload = row.rstrip("\n")
                response = sagemaker_runtime_client.invoke_endpoint(
                    EndpointName=endpoint_name,
                    ContentType="text/csv",
                    Body=payload,
                    InferenceId=str(i),  # unique ID per row
                )
                i += 1
                response["Body"].read()
                time.sleep(1)
                if terminate_event.is_set():
                    break

        # Keep invoking the endpoint with test data
        invoke_endpoint_thread = WorkerThread(do_run=invoke_endpoint)
        invoke_endpoint_thread.start()

You must upload Ground Truth data to an Amazon S3 bucket that has the same path format as captured data, which is in the following format: s3://<bucket>/<prefix>/yyyy/mm/dd/hh

    **Note**
    The date in this path is the date when the Ground Truth label is collected. It doesn't have to match the date when the inference was generated.

**Q: How can customers customize monitoring schedules?**

In addition to using the built-in monitoring mechanisms, you can create your own custom monitoring schedules and procedures using pre-processing and post-processing scripts, or by using or building your own container. It's important to note that pre-processing and post-processing scripts only work with data and model quality jobs.

Amazon SageMaker provides the capability for you to monitor and evaluate the data observed by the model endpoints. For this, you have to create a baseline with which you compare the real-time traffic. After a baseline is ready, set up a schedule to continuously evaluate and compare against the baseline. While creating a schedule, you can provide the pre-processing and post-processing script.

The following example shows how you can customize monitoring schedules with pre-processing and post-processing scripts.

```python
import boto3, os from sagemaker import get_execution_role, Session from sagemaker.model_monitor import CronExpressionGenerator, DefaultModelMonitor
# Upload pre and postprocessor scripts
session = Session()
bucket = boto3.Session().resource("s3").Bucket(session.default_bucket())
prefix = "demo-sagemaker-model-monitor"
```
Q: What are some of the scenarios or use cases where I can leverage a pre-processing script?

You can use pre-processing scripts when you need to transform the inputs to your model monitor. Consider the following example scenarios:

1. Pre-processing script for data transformation.

Suppose the output of your model is an array: [1.0, 2.1]. The Model Monitor container only works with tabular or flattened JSON structures, such as {"prediction0": 1.0, "prediction1": 2.1}. You could use a pre-processing script like the following example to transform the array into the correct JSON structure.

```python
def preprocess_handler(inference_record):
    input_data = inference_record.endpoint_input.data
    output_data = inference_record.endpoint_output.data.rstrip("\n")
    data = output_data + "," + input_data
    return { str(i).zfill(20) : d for i, d in enumerate(data.split(",")) }
```

2. Exclude certain records from Model Monitor's metric calculations.

Suppose your model has optional features and you use -1 to denote that the optional feature has a missing value. If you have a data quality monitor, you may want to remove the -1 from the input value array so that it isn't included in the monitor's metric calculations. You could use a script like the following to remove those values.

```python
def preprocess_handler(inference_record):
    input_data = inference_record.endpoint_input.data
    output_data = inference_record.endpoint_output.data
    data = output_data.replace("-1", "")
    return { str(i).zfill(20) : d for i, d in enumerate(data.split(",")) }
```
input_data = inference_record.endpoint_input.data
return {i : None if x == -1 else x for i, x in enumerate(input_data.split("",""))}

3. Apply a custom sampling strategy.

You can also apply a custom sampling strategy in your pre-processing script. To do this, configure Model Monitor's first-party, pre-built container to ignore a percentage of the records according to your specified sampling rate. In the following example, the handler samples 10% of the records by returning the record in 10% of handler calls and an empty list otherwise.

```python
import random
def preprocess_handler(inference_record):
    # we set up a sampling rate of 0.1
    if random.random() > 0.1:
        # return an empty list
        return []
    input_data = inference_record.endpoint_input.data
    return {i : None if x == -1 else x for i, x in enumerate(input_data.split("",""))}
```

4. Use custom logging.

You can log any information you need from your script to Amazon CloudWatch. This can be useful when debugging your pre-processing script in case of an error. The following example shows how you can use the `preprocess_handler` interface to log to CloudWatch.

```python
def preprocess_handler(inference_record, logger):
    logger.info(f"I'm a processing record: {inference_record}")
    logger.debug(f"I'm debugging a processing record: {inference_record}")
    logger.warning(f"I'm processing record with missing value: {inference_record}")
    logger.error(f"I'm a processing record with bad value: {inference_record}")
    return inference_record
```

**Note**
When the pre-processing script is run on batch transform data, the input type is not always the `CapturedData` object. For CSV data, the type is a string. For JSON data, the type is a Python dictionary.

**Q: When can I leverage a post-processing script?**

You can leverage a post-processing script as an extension following a successful monitoring run. The following is a simple example, but you can perform or call any business function that you need to perform after a successful monitoring run.

```python
def postprocess_handler():
    print("Hello from the post-processing script!")
```

**Q: When should I consider bringing my own container for model monitoring?**

SageMaker provides a pre-built container for analyzing data captured from endpoints or batch transform jobs for tabular datasets. However, there are scenarios where you might want to create your own container. Consider the following scenarios:

- You have regulatory and compliance requirements to only use the containers that are created and maintained internally in your organization.
- If you want to include a few third-party libraries, you can place a `requirements.txt` file in a local directory and reference it using the `source_dir` parameter in the SageMaker estimator, which
enables library installation at run-time. However, if you have lots of libraries or dependencies that increase the installation time while running the training job, you might want to leverage BYOC.

- Your environment forces no internet connectivity (or Silo), which prevents package download.
- You want to monitor data that's in data formats other than tabular, such as NLP or CV use cases.
- When you require additional monitoring metrics than the ones supported by Model Monitor.

Q: I have NLP and CV models. How do I monitor them for data drift?

Amazon SageMaker's prebuilt container supports tabular datasets. If you want to monitor NLP and CV models, you can bring your own container by leveraging the extension points provided by Model Monitor. For more details about the requirements, see Bring your own containers. Some of the following are more examples:

- For a detailed explanation of how to use Model Monitor for a computer vision use case, see Detecting and Analyzing incorrect predictions.
- For a scenario where Model Monitor can be leveraged for a NLP use case, see Detect NLP data drift using custom Amazon SageMaker Model Monitor.

Q: I want to delete the model endpoint for which Model Monitor was enabled, but I'm unable to do so since the monitoring schedule is still active. What should I do?

If you want to delete an inference endpoint hosted in SageMaker which has Model Monitor enabled, first you must delete the model monitoring schedule (with the DeleteMonitoringSchedule CLI or API). Then, delete the endpoint.

Q: Does SageMaker Model Monitor calculate metrics and statistics for input?

Model Monitor calculates metrics and statistics for output, not input.

Q: Does SageMaker Model Monitor support multi-model endpoints?

No, Model Monitor only supports endpoints that host a single model and doesn't support monitoring multi-model endpoints.

Q: Does SageMaker Model Monitor provide monitoring data about individual containers in an inference pipeline?

Model Monitor supports monitoring inference pipelines, but capturing and analyzing data is done for the entire pipeline, not for individual containers in the pipeline.

Q: What can I do to prevent impact to inference requests when data capture is set up?

To prevent impact to inference requests, Data Capture stops capturing requests at high levels of disk usage. It is recommended you keep your disk utilization below 75% in order to ensure data capture continues capturing requests.

Q: Can Amazon S3 Data Capture be in a different AWS region than the region in which the monitoring schedule was set up?

No, Amazon S3 Data Capture must be in the same region as the monitoring schedule.

Q: What is a baseline, and how do I create one? Can I create a custom baseline?

A baseline is used as a reference to compare real-time or batch predictions from the model. It computes statistics and metrics along with constraints on them. During monitoring, all of these are used in conjunction to identify violations.
To use the default solution of Amazon SageMaker Model Monitor, you can leverage the Amazon SageMaker Python SDK. Specifically, use the `suggest_baseline` method of the `ModelMonitor` or the `ModelQualityMonitor` class to trigger a processing job that computes the metrics and constraints for the baseline.

The result of a baseline job are two files: `statistics.json` and `constraints.json`. Schema for `statistics` and `schema for constraints` contain the schema of the respective files. You can review the generated constraints and modify them before using them for monitoring. Based on your understanding of the domain and business problem, you can make a constraint more aggressive, or relax it to control the number and nature of the violations.

**Q: What are the guidelines to create a baseline dataset?**

The primary requirement for any kind of monitoring is to have a baseline dataset that is used to compute metrics and constraints. Typically, this is the training dataset used by the model, but in some cases you might choose to use some other reference dataset.

The column names of the baseline dataset should be compatible with Spark. In order to maintain the maximum compatibility between Spark, CSV, JSON and parquet it is advisable to use only lowercase letters, and only use `_` as the separator. Special characters including “ ” can cause issues.

**Q: What are the `StartTimeOffset` and `EndTimeOffset` parameters, and when are they used?**

When Amazon SageMaker Ground Truth is required for monitoring jobs like model quality, you need to ensure that a monitoring job only uses data for which Ground Truth is available. The `start_time_offset` and `end_time_offset` parameters of `EndpointInput` can be used to select the data that the monitoring job uses. The monitoring job uses the data in the time window that is defined by `start_time_offset` and `end_time_offset`. These parameters need to be specified in the ISO 8601 duration format. The following are some examples:

- If your Ground Truth results arrive 3 days after the predictions have been made, set `start_time_offset="-P3D"` and `end_time_offset="-P1D"`, which is 3 days and 1 day respectively.
- If the Ground Truth results arrive 6 hours after the predictions and you have an hourly schedule, set `start_time_offset="-PT6H"` and `end_time_offset="-PT1H"`, which is 6 hours and 1 hour.

**Q: Can I run 'on demand' monitoring jobs?**

Yes, you can run 'on demand' monitoring jobs by running a SageMaker Processing job. For Batch Transform, SageMaker Pipelines has a `MonitorBatchTransformStep` that you can use to create a SageMaker pipeline that runs monitoring jobs on demand. The SageMaker examples repository has code samples for running data quality and model quality monitoring jobs on demand.

**Q: How do I set up Model Monitor?**

You can set up Model Monitor in the following ways:

- **Amazon SageMaker Python SDK** – There is a Model Monitor module which contains classes and functions that assist in suggesting baselines, creating monitoring schedules, and more. See the Amazon SageMaker Model Monitor notebook examples for detailed notebooks that leverage the SageMaker Python SDK for setting up Model Monitor.
- **SageMaker Pipelines** – SageMaker Pipelines are integrated with Model Monitor through the QualityCheck Step and ClarifyCheckStep APIs. You can create a SageMaker pipeline that contains these steps and that can be used to run monitoring jobs on demand whenever the pipeline is executed.
- **Amazon SageMaker Studio** – You can create a data or model quality monitoring schedule along with model bias and explainability schedules directly from the UI by selecting an endpoint from the list of deployed model endpoints. Schedules for other types of monitoring can be created by selecting the relevant tab in the UI.
• **SageMaker Model Dashboard** – You can enable monitoring on endpoints by selecting a model that has been deployed to an endpoint. In the following screenshot of the SageMaker console, a model named `group1` has been selected from the **Models** section of the **Model dashboard**. On this page, you can create a monitoring schedule, and you can edit, activate or deactivate existing monitoring schedules and alerts. For a step by step guide on how to view alerts and model monitor schedules, see [View Model Monitor schedules and alerts](#).

Q: **How does Model Monitor Integrate with SageMaker Model Dashboard**

*SageMaker Model Dashboard* gives you unified monitoring across all your models by providing automated alerts about deviations from expected behavior and troubleshooting to inspect models and analyze factors impacting model performance over time.
What is Fairness and Model Explainability?

Detect bias and understand explanations

Amazon SageMaker offers features to improve your machine learning (ML) models by detecting potential bias and helping explain the predictions that models make. It helps you identify various types of bias in pretraining data and in posttraining that can emerge during model training or when the model is in production.

The following topics give information about how to use bias detection with Amazon SageMaker.

Topics
- What Is Fairness and Model Explainability for Machine Learning Predictions? (p. 3134)
- Use Amazon SageMaker Clarify Bias Detection and Model Explainability (p. 3136)
- Use SageMaker Clarify Explainability with SageMaker Autopilot (p. 3243)

What Is Fairness and Model Explainability for Machine Learning Predictions?

Amazon SageMaker Clarify helps improve your machine learning (ML) models by detecting potential bias and helping explain the predictions that models make. It helps you identify various types of bias in pretraining data and in posttraining that can emerge during model training or when the model is in production. SageMaker Clarify helps explain how these models make predictions using a feature attribution approach. It also monitors inferences models make in production for bias or feature attribution drift. The fairness and explainability functionality provided by SageMaker Clarify provides components that help AWS customers build less biased and more understandable machine learning models. It also provides tools to help you generate model governance reports that you can use to inform risk and compliance teams, and external regulators.

Machine learning models and data-driven systems are being increasingly used to help make decisions across domains such as financial services, healthcare, education, and human resources. Machine learning applications provide benefits such as improved accuracy, increased productivity, and cost savings to help meet regulatory requirements, improve business decisions, and provide better insights into data science procedures.

- **Regulatory** – In many situations, it is important to understand why an ML model made a specific prediction and also whether the prediction it made was impacted by any bias, either during training or at inference. Recently, policymakers, regulators, and advocates have raised awareness about the ethical and policy challenges posed by ML and data-driven systems. In particular, they have expressed concerns about the potentially discriminatory impact of such systems (for example, inadvertently encoding of bias into automated decisions).
- **Business** – The adoption of AI systems in regulated domains requires trust, which can be built by providing reliable explanations of the behavior of trained models and how the deployed models make predictions. Model explainability may be particularly important to certain industries with reliability, safety, and compliance requirements, such as financial services, human resources, healthcare, and automated transportation. To take a common financial example, lending applications that incorporate the use of ML models might need to provide explanations about how those models made certain predictions to internal teams of loan officers, customer service representatives, and forecasters, in addition to end users/customers.
- **Data Science** – Data scientists and ML engineers need tools to generate the insights required to debug and improve ML models through better feature engineering, to determine whether a model is making
inferences based on noisy or irrelevant features, and to understand the limitations of their models and failure modes their models may encounter.

For a blog that shows how to architect and build a complete machine learning use case involving fraudulent automobile claims that integrates SageMaker Clarify into a SageMaker pipeline, see the Architect and build the full machine learning lifecycle with AWS: An end-to-end Amazon SageMaker demo. This blog discusses how to assess pre and post training bias, how to mitigate the bias, and how the data features impact the prediction. There are links to the relevant code for each task in the ML lifecycle, including the creation of an automated workflow that integrates the fairness and explainability functionality of SageMaker Clarify into a SageMaker Pipeline.

Best Practices for Evaluating Fairness and Explainability in the ML Lifecycle

**Fairness as a Process** – The notions of bias and fairness are highly dependent on the application. Further, the choice of the attributes for which bias is to be measured, as well as the choice of the bias metrics, may need to be guided by social, legal, and other non-technical considerations. Building consensus and achieving collaboration across key stakeholders (such as product, policy, legal, engineering, and AI/ML teams, as well as end users and communities) is a prerequisite for the successful adoption of fairness-aware ML approaches in practice.

**Fairness and Explainability by Design in the ML Lifecycle** – You should consider fairness and explainability during each stage of the ML lifecycle: problem formation, dataset construction, algorithm selection, model training process, testing process, deployment, and monitoring/feedback. It is important to have the right tools to do this analysis. To encourage engaging with these considerations, here are a few example questions we recommend you ask during each of these stages.

Sample Notebooks

Amazon SageMaker Clarify provides the following sample notebooks:

- **Explainability and bias detection with Amazon SageMaker Clarify** – Use SageMaker Clarify to create a processing job for the detecting bias and explaining model predictions with feature attributions.
- **Monitoring bias drift and feature attribution drift Amazon SageMaker Clarify** – Use Amazon SageMaker Model Monitor to monitor bias drift and feature attribution drift over time.
- **Fairness and Explainability with SageMaker Clarify (Bring Your Own Container)** – This sample notebook introduces key terms and concepts needed to understand SageMaker Clarify, and it walks you through
an end-to-end data science workflow demonstrating how to build your own model and container that can work seamlessly with your Clarify jobs, use the model and SageMaker Clarify to measure bias, explain the importance of the various input features on the model's decision and then access the reports through SageMaker Studio if you have an instance set up.

- **Fairness and Explainability with SageMaker Clarify - Spark Distributed Processing** – This sample notebook walks you through key terms and concepts needed to understand SageMaker Clarify, measures the pre-training bias of a dataset and post-training bias of a model, explains the importance of the various input features on the model's decision, and accesses the reports through SageMaker Studio if you have an instance set up.

- **Mitigate Bias, Train another unbiased Model and Put in the Model Registry** – This notebook describes how to detect bias using SageMaker Clarify, mitigate it with Synthetic Minority Over-sampling Technique (SMOTE), train another model, then put it in the Model Registry along with all the lineage of the artifacts created along the way: data, code and model metadata. This notebook forms part of a series that shows how to integrate SageMaker Clarify into a SageMaker Pipeline that is described in the [Architect and build the full machine learning lifecycle with AWS](#) blog.

These notebooks have been verified to run in Amazon SageMaker Studio only. If you need instructions on how to open a notebook in Amazon SageMaker Studio, see [Create or Open an Amazon SageMaker Studio Notebook](#). If you're prompted to choose a kernel, choose **Python 3 (Data Science)**.

# Guide to the SageMaker Clarify Documentation

Bias can occur and be measured in the data at each stage of the machine learning lifecycle: before training a model and after model training. SageMaker Clarify can provide feature attribution explanations of model predictions for trained models and for models deployed to production, where models can be monitored for any drift from their baseline explanatory attributions. Clarify calculates baselines when needed. The documentation for SageMaker Clarify is embedded throughout the larger SageMaker documentation set at the relevant ML stages as follows:

- For further information on detecting bias in preprocessing data before it's used to train a model, see [Detect Pre-training Data Bias](#).
- For further information on detecting posttraining data and model bias, see [Detect Post-training Data and Model Bias with Amazon SageMaker Clarify](#).
- For further information on the model-agnostic feature attribution approach to explain model predictions after training, see [Amazon SageMaker Clarify Model Explainability](#).
- For further information on monitoring for bias in production model inferences due to the drift of data away from the baseline used to train the model, see [Monitor Bias Drift for Models in Production](#).
- For further information on monitoring for the drift of features' contributions away from the baseline that was established during model training, see [Monitor Feature Attribution Drift for Models in Production](#).

# Use Amazon SageMaker Clarify Bias Detection and Model Explainability

This topic describes how to configure an Amazon SageMaker Clarify processing job that can compute bias metrics and feature attributions for explainability. SageMaker Clarify processing jobs are implemented using a specialized SageMaker Clarify container image. The following instructions show you how to configure, run, and troubleshoot a SageMaker Clarify processing job and how to configure an analysis.

**Topics**
How SageMaker Clarify Processing Jobs Work

You can use SageMaker Clarify to analyze your datasets and models for explainability and bias. A SageMaker Clarify processing job uses the SageMaker Clarify processing container to interact with an Amazon S3 bucket containing your input datasets. You can also use SageMaker Clarify to analyze a customer model that is deployed to a SageMaker inference endpoint.

The following graphic shows how a SageMaker Clarify processing job interacts with your input data and optionally, with a customer model. This interaction depends on the specific type of analysis being performed. The SageMaker Clarify processing container obtains the input dataset and configuration for analysis from an S3 bucket. For certain analysis types, including feature analysis, the SageMaker Clarify processing container must send requests to the model container. Then it retrieves the model predictions from the response that the model container sends. After that, the SageMaker Clarify processing container computes and saves analysis results to the S3 bucket.

You can run a SageMaker Clarify processing job at multiple stages in the lifecycle of the machine learning workflow. SageMaker Clarify can help you compute the following analysis types:

- **Pre-training bias metrics** can help you understand the bias in your data so that you can address it and train your model on a more fair dataset. To run a job to analyze pre-training bias metrics, you must provide the dataset and a JSON analysis configuration file to Configure the Analysis (p. 3144).
- **Post-training bias metrics** can help you understand any bias introduced by an algorithm, hyperparameter choices, or any bias that wasn't apparent earlier in the flow. SageMaker Clarify uses the model predictions in addition to the data and labels to identify bias. To run a job to analyze post-training bias metrics, you must provide the dataset and a JSON analysis configuration file. The configuration should include the model or endpoint name.
- **SHAP values for explainability** can help you understand what impact your feature has on what your model predicts. This feature requires a trained model.
- **Partial dependence plots (PDP)** can help you understand how much your predicted target variable would change if you varied the value of one feature. This feature requires a trained model.
SageMaker Clarify needs model predictions to compute post-training bias metrics and feature attributions. You can provide an endpoint or SageMaker Clarify will create an ephemeral endpoint using your model name, also known as a shadow endpoint. The SageMaker Clarify container deletes the shadow endpoint after the computations are completed. At a high level, the SageMaker Clarify container completes the following steps:

1. Validates inputs and parameters.
2. Creates the shadow endpoint (if a model name is provided).
3. Loads the input dataset into a data frame.
4. Obtains model predictions from the endpoint, if necessary.
5. Computes bias metrics and features attributions.
6. Deletes the shadow endpoint.
7. Generate the analysis results.

After the SageMaker Clarify processing job is complete, the analysis results will be saved in the output location that you specified in the processing output parameter of the job. These results include a JSON file with bias metrics and global feature attributions, a visual report, and additional files for local feature attributions. You can download the results from the output location and view them.

**Configure a SageMaker Clarify Processing Job**

To analyze your data and models for bias and explainability using SageMaker Clarify, you must configure a SageMaker Clarify processing job. This guide shows how to specify the input dataset name, analysis configuration file name, and output location for a processing job. To configure the processing container, job inputs, outputs, resources and other parameters, you have two options. You can either use the SageMaker CreateProcessingJob API, or use the SageMaker Python SDK API SageMaker ClarifyProcessor.

For information about parameters that are common to all processing jobs, see Amazon SageMaker API Reference.

**Configure a SageMaker Clarify processing job using the SageMaker API**

The following instructions show how to provide each portion of the SageMaker Clarify specific configuration using the CreateProcessingJob API.

1. Input the uniform research identifier (URI) of a SageMaker Clarify container image inside the AppSpecification parameter, as shown in the following code example.

```json
{
   "ImageUri": "the-clarify-container-image-uri"
}
```

**Note**
The URI must identify a pre-built SageMaker Clarify container image. ContainerEntrypoint and ContainerArguments are not supported.

2. Specify both the configuration for your analysis and parameters for your input dataset inside the ProcessingInputs parameter.

a. Specify the location of the JSON analysis configuration file, which includes the parameters for bias analysis and explainability analysis. The InputName parameter of the ProcessingInput object must be analysis_config as shown in the following code example.

```json
{
   "InputName": "analysis_config"
}
```
Configure a SageMaker Clarify Processing Job

b. Specify the location of the input dataset. The InputName parameter of the ProcessingInput object must be dataset. This parameter is optional if you have provided the "dataset_uri" in the analysis configuration file. The following values are required in the S3Input configuration.

i. S3Uri can be either an Amazon S3 object or an S3 prefix.
ii. S3InputMode must be of type File.
iii. S3CompressionType must be of type None (the default value).
iv. S3DataDistributionType must be of type FullyReplicated (the default value).
v. S3DataType can be either S3Prefix or ManifestFile. To use ManifestFile, the S3Uri parameter should specify the location of a manifest file that follows the schema from the SageMaker API Reference section S3Uri. This manifest file must list the S3 objects that contain the input data for the job.

The following code shows an example of an input configuration.

```json
{
  "InputName": "dataset",
  "S3Input": {
    "S3Uri": "s3://your-bucket/your-dataset.csv",
    "S3DataType": "S3Prefix",
    "S3InputMode": "File",
    "LocalPath": "/opt/ml/processing/input/data"
  }
}
```

3. Specify the configuration for the output of the processing job inside the ProcessingOutputConfig parameter. A single ProcessingOutput object is required in the Outputs configuration. The following are required of the output configuration:

a. OutputName must be analysis_result.
b. S3Uri must be an S3 prefix to the output location.
c. S3UploadMode must be set to EndOfJob.

The following code shows an example of an output configuration.

```json
{
  "Outputs": [
    {
      "OutputName": "analysis_result",
      "S3Output": {
        "S3Uri": "s3://your-bucket/result/",
        "S3UploadMode": "EndOfJob",
        "LocalPath": "/opt/ml/processing/output"
      }
    }
  ]
}
```

4. Specify the configuration ClusterConfig for the resources that you use in your processing job inside the ProcessingResources parameter. The following parameters are required inside the ClusterConfig object.
a. **InstanceCount** specifies the number of compute instances in the cluster that runs the processing job. Specify a value greater than 1 to activate distributed processing.

b. **InstanceType** refers to the resources that runs your processing job. Because SageMaker SHAP analysis is compute-intensive, using an instance type that is optimized for compute should improve runtime for analysis. The SageMaker Clarify processing job doesn't use GPUs.

The following code shows an example of resource configuration.

```json
{
   "ClusterConfig": {
      "InstanceCount": 1,
      "InstanceType": "ml.m5.xlarge",
      "VolumeSizeInGB": 20
   }
}
```

5. Specify the configuration of the network that you use in your processing job inside the `NetworkConfig` object. The following values are required in the configuration.

a. **EnableNetworkIsolation** must be set to `False` (default) so that SageMaker Clarify can invoke an endpoint, if necessary, for predictions.

b. If the model or endpoint that you provided to the SageMaker Clarify job is within an Amazon Virtual Private Cloud (Amazon VPC), then the SageMaker Clarify job must also be in the same VPC. Specify the VPC using `VpcConfig`. Additionally, the VPC must have endpoints to an Amazon S3 bucket, SageMaker service and SageMaker Runtime service.

   If distributed processing is activated, you must also allow communication between different instances in the same processing job. Configure a rule for your security group that allows inbound connections between members of the same security group. For more information, see [Give Amazon SageMaker SageMaker Clarify Jobs Access to Resources in Your Amazon VPC](#).

The following code gives an example of a network configuration.

```json
{
   "EnableNetworkIsolation": False,
   "VpcConfig": {
      ...
   }
}
```

6. Set the maximum time that the job will run using the `StoppingCondition` parameter. The longest that a SageMaker Clarify job can run is 7 days or 604800 seconds. If the job cannot be completed within this time limit, it will be stopped and no analysis results will be provided. As an example, the following configuration limits the maximum time that the job can run to 3600 seconds.

```json
{
   "MaxRuntimeInSeconds": 3600
}
```

7. Specify an IAM role for the `RoleArn` parameter. The role must have a trust relationship with Amazon SageMaker. It can be used to perform the SageMaker API operations listed in the following table. We recommend using the [Amazon SageMakerFullAccess](#) managed policy, which grants full access to SageMaker. If you have concerns about granting full access, the minimal permissions required depend on whether you provide a model or an endpoint name. Using an endpoint name allows for granting fewer permissions to SageMaker.

The following table contains API operations used by the SageMaker Clarify processing job. An X under **Model name** and **Endpoint name** notes the API operation that is required for each input.
API Operation | Model name | Endpoint name | What is it used for
--- | --- | --- | ---
ListTags | X | | Tags of the job are applied to the shadow endpoint.
CreateEndpointConfig | X | | Create endpoint config using the model name that you provided
CreateEndpoint | X | | Create shadow endpoint using the endpoint config.
DescribeEndpoint | X | X | Describe endpoint for its status, the endpoint must be InService to serve requests.
InvokeEndpoint | X | X | Invoke the endpoint for predictions.

For more information about required permissions, see [Amazon SageMaker API Permissions: Actions, Permissions, and Resources Reference](#).

For more information about passing roles to SageMaker, see [Passing Roles](#).

After you have the individual pieces of the processing job configuration, combine them to configure the job.

**Configure a SageMaker Clarify processing job using the AWS SDK for Python**

The following code example shows how to launch a SageMaker Clarify processing job using the [AWS SDK for Python](#).

```python
sagemaker_client.create_processing_job(
    ProcessingJobName="your-clarify-job-name",
    AppSpecification={
        "ImageUri": "the-clarify-container-image-uri",
    },
    ProcessingInputs=[{
        "InputName": "analysis_config",
        "S3Input": {
            "S3Uri": "s3://your-bucket/analysis_config.json",
            "S3DataType": "S3Prefix",
            "S3InputMode": "File",
            "LocalPath": "/opt/ml/processing/input/config",
        },
    }, {
        "InputName": "dataset",
        "S3Input": {
            "S3Uri": "s3://your-bucket/your-dataset.csv",
            "S3DataType": "S3Prefix",
            "S3InputMode": "File",
            "LocalPath": "/opt/ml/processing/input/data",
        },
    }],
)
```
Configure a SageMaker Clarify Processing Job

```python
ProcessingOutputConfig={
    "Outputs": [
        {
            "OutputName": "analysis_result",
            "S3Output": {
                "S3Uri": "s3://your-bucket/result/",
                "S3UploadMode": "EndOfJob",
                "LocalPath": "/opt/ml/processing/output",
            },
        },
    ],
},
ProcessingResources={
    "ClusterConfig": {
        "InstanceCount": 1,
        "InstanceType": "ml.m5.xlarge",
        "VolumeSizeInGB": 20,
    },
},
NetworkConfig={
    "EnableNetworkIsolation": False,
    "VpcConfig": {
        ...
    },
},
StoppingCondition={
    "MaxRuntimeInSeconds": 3600,
},

)
```

For an example notebook with instructions for running a SageMaker Clarify processing job using AWS SDK for Python, see Fairness and Explainability with SageMaker Clarify using AWS SDK for Python. Any S3 bucket used in the notebook must be in the same AWS Region as the notebook instance that accesses it.

**Configure a SageMaker Clarify processing job using the SageMaker Python SDK**

You can also configure a SageMaker Clarify processing job using the SageMaker ClarifyProcessor in the SageMaker Python SDK API. For more information, see Run SageMaker Clarify Processing Jobs for Bias Analysis and Explainability.

- Configure the Analysis (p. 3144)
- Data Format Compatibility Guide (p. 3166)

**Get Started with a SageMaker Clarify Container**

Amazon SageMaker provides prebuilt SageMaker Clarify container images that include the libraries and other dependencies needed to compute bias metrics and feature attributions for explainability. This image has been enabled to run SageMaker Process data (p. 1399) in your account.

The image URIs for the containers are in the following form:

```
<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/sagemaker-clarify-processing:1.0
```

For example:
The following table lists the addresses by AWS Region.

## Docker Images for SageMaker Clarify Processing Jobs

Configure the Analysis

To analyze your data and models for explainability and bias using SageMaker Clarify, you must configure a SageMaker Clarify processing job. Part of the configuration for this processing job includes the configuration of an analysis file. The analysis file specifies the parameters for bias analysis and explainability.

This guide describes the schema and parameters for this analysis configuration file. This guide also includes examples of analysis configuration files for computing bias metrics for a tabular dataset, and generating explanations for natural language processing (NLP) and computer vision (CV) problems.

You can create the analysis configuration file or use the SageMaker Python SDK to generate one for you with the SageMaker ClarifyProcessor API. Viewing the file contents can be helpful for understanding the underlying configuration used by the SageMaker Clarify job.

Topics
- Schema for the analysis configuration file (p. 3144)
- Example analysis configuration files (p. 3154)

Schema for the analysis configuration file

The following section describes the schema for the analysis configuration file including requirements and descriptions of parameters.

Requirements for the analysis configuration file

The SageMaker Clarify processing job expects the analysis configuration file to be structured with the following requirements:

- The processing input name must be analysis_config.
- The analysis configuration file is in JSON format, and encoded in UTF-8.
- The analysis configuration file is an Amazon S3 object.
You can specify additional parameters in the analysis configuration file. The following section provides various options to tailor the SageMaker Clarify processing job for your use case and desired types of analysis.

**Parameters for analysis configuration files**

In the analysis configuration file, you can specify the following parameters.

- **version** – (Optional) The version string of the analysis configuration file schema. If a version is not provided, SageMaker Clarify uses the latest supported version. Currently, the only supported version is 1.0.
- **dataset_type** – The format of the dataset. The input dataset format can be any of the following values:
  - `text/csv` for CSV
  - `application/jsonlines` for SageMaker JSON Lines dense format
  - `application/json` for JSON
  - `application/x-parquet` for Apache Parquet
  - `application/x-image` to activate explainability for computer vision problems
- **dataset_uri** – (Optional) The uniform resource identifier (URI) of the main dataset. If you provide a S3 URI prefix, the SageMaker Clarify processing job recursively collects all S3 files located under the prefix. You can provide either a S3 URI prefix or a S3 URI to an image manifest file for computer vision problems. If dataset_uri is provided, it takes precedence over the dataset processing job input.
  - For any format type except image, the SageMaker Clarify processing job loads the input dataset into a tabular data frame, as a tabular dataset. This format allows SageMaker to easily manipulate and analyze the input dataset.
- **headers** – (Optional) An array of strings containing the column names of a tabular dataset. If a value for headers is not provided, then the SageMaker Clarify processing job reads the headers from the dataset. If the dataset doesn’t have headers, then the SageMaker Clarify processing job will automatically generate placeholder names based on zero-based column index. As an example, placeholder names for the first and second columns will be `column_0, column_1`.

  **Note**
  By convention, if dataset_type is application/jsonlines or application/json then headers should contain the following names in order: feature names, label name (if label is specified), and predicted label name (if predicted_label is specified). An example for headers for an application/jsonlines dataset type if label is specified is:
  ```javascript
  ["feature1","feature2","feature3","target_label"]
  ```
- **label** – (Optional) A string or a zero-based integer index. If provided, label is used to locate the ground truth label, also known as an observed label or target attribute in a tabular dataset. The ground truth label is used to compute bias metrics. The value for label is specified depending on the value of the dataset_type parameter as follows.
  - If dataset_type is `text/csv`, label can be specified as either of the following:
    - A valid column name
    - An index that lies within the range of dataset columns
  - If dataset_type is `application/parquet`, label must be a valid column name.
  - If dataset_type is `application/jsonlines`, label must be a JMESPath expression written to extract the ground truth label from the dataset. By convention, if headers is specified, then it should contain the label name.
  - If dataset_type is `application/json`, label must be a JMESPath expression written to extract the ground truth label for each record in the dataset. This JMESPath expression must produce a list of labels where the \(i^{th}\) label correlates to the \(i^{th}\) record.
- **predicted_label** – (Optional) A string or a zero-based integer index. If provided, predicted_label is used to locate the column containing the predicted label in a tabular dataset. The predicted label
is used to compute post-training **bias metrics**. The parameter `predicted_label` is optional if the dataset doesn’t include predicted label. If predicted labels are required for computation, then the SageMaker Clarify processing job will get predictions from the model.

The value for `predicted_label` is specified depending on the value of the `dataset_type` as follows:

- **If dataset_type is `text/csv`,** `predicted_label` can be specified as either of the following:
  - A valid column name. If `predicted_label_dataset_uri` is specified, but `predicted_label` is not provided, the default predicted label name is "predicted_label".
  - An index that lies within the range of dataset columns. If `predicted_label_dataset_uri` is specified, then the index is used to locate the predicted label column in the predicted label dataset.

- **If dataset_type is `application/x-parquet`,** `predicted_label` must be a valid column name.

- **If dataset_type is `application/jsonlines`,** `predicted_label` must be a valid JMESPath expression written to extract the predicted label from the dataset. By convention, if headers is specified, then it should contain the predicted label name.

- **If dataset_type is `application/json`,** `predicted_label` must be a JMESPath expression written to extract the predicted label for each record in the dataset. The JMESPath expression should produce a list of predicted labels where the $i^{th}$ predicted label is for the $i^{th}$ record.

- **features** – Required if `dataset_type` is `application/jsonlines` or `application/json`. A JMESPath string expression written to locate the features in the input dataset. For `application/jsonlines`, a JMESPath expression will be applied to each line to extract the features for that record. For `application/json`, a JMESPath expression will be applied to the whole input dataset. The JMESPath expression should extract a list of lists, or a 2D array/matrix of features where the $i^{th}$ row contains the features that correlate to the $i^{th}$ record. For a `dataset_type` of `text/csv` or `application/x-parquet`, all columns except for the ground truth label and predicted label columns are automatically assigned to be features.

- **predicted_label_dataset_uri** – Only applicable when `dataset_type` is `text/csv`. The S3 URI for a dataset containing predicted labels used to compute post-training **bias metrics**. The SageMaker Clarify processing job will load the predictions from the provided URI instead of getting predictions from the model. In this case, `predicted_label` is required to locate the predicted label column in the predicted label dataset. If the predicted label dataset or the main dataset is split across multiple files, an identifier column must be specified by `joinsource_name_or_index` to join the two datasets.

- **predicted_label_headers** – Only applicable when `predicted_label_dataset_uri` is specified. An array of strings containing the column names of the predicted label dataset. Besides the predicted label header, `predicted_label_headers` can also contain the header of the identifier column to join the predicted label dataset and the main dataset. For more information, see the following description for the parameter `joinsource_name_or_index`.

- **joinsource_name_or_index** – The name or zero-based index of the column in tabular datasets to be used as a identifier column while performing an inner join. This column is only used as an identifier. It isn't used for any other computations like bias analysis or feature attribution analysis. A value for `joinsource_name_or_index` is needed in the following cases:
  - There are multiple input datasets, and any one is split across multiple files.
  - Distributed processing is activated by setting the SageMaker Clarify processing job `InstanceCount` to a value greater than 1.

- **excluded_columns** – (Optional) An array of names or zero-based indices of columns to be excluded from being sent to the model as input for predictions. Ground truth label and predicted label are automatically excluded already.

- **probability_threshold** – (Optional) A floating point number above which, a label or object is selected. The default value is 0.5. The SageMaker Clarify processing job uses `probability_threshold` in the following cases:
  - In post-training bias analysis, `probability_threshold` converts a numeric model prediction (probability value or score) to a binary label, if the model is a binary classifier. A score greater than
the threshold is converted to 1. Whereas, a score less than or equal to the threshold is converted to 0.

- In computer vision explainability problems, if model_type is **OBJECT_DETECTION**, probability_threshold filters out objects detected with confidence scores lower than the threshold value.

- **label_values_or_threshold** – Required for bias analysis. An array of label values or a threshold number, which indicate positive outcome for ground truth and predicted labels for bias metrics. For more information, see positive label values in [Amazon SageMaker Clarify Terms for Bias and Fairness](https://docs.aws.amazon.com/sagemaker/latest/dg/clarify-bias-fairness-terms.html). If the label is numeric, the threshold is applied as the lower bound to select the positive outcome. To set label_values_or_threshold for different problem types, refer to the following examples:

  - For a binary classification problem, the label has two possible values, 0 and 1. If label value 1 is favorable to a demographic group observed in a sample, then label_values_or_threshold should be set to [1].
  
  - For a multiclass classification problem, the label has three possible values, **bird**, **cat**, and **dog**. If the latter two define a demographic group that bias favors, then label_values_or_threshold should be set to ["cat", "dog"].
  
  - For a regression problem, the label value is continuous, ranging from 0 to 1. If a value greater than 0.5 should designate a sample as having a positive result, then label_values_or_threshold should be set to 0.5.

- **facet** – Required for bias analysis. An array of facet objects, which are composed of sensitive attributes against which bias is measured. You can use facets to understand the bias characteristics of your dataset and model even if your model is trained without using sensitive attributes. For more information, see **Facet** in [Amazon SageMaker Clarify Terms for Bias and Fairness](https://docs.aws.amazon.com/sagemaker/latest/dg/clarify-bias-fairness-terms.html). Each facet object includes the following fields:

  - **name_or_index** – The name or zero-based index of the sensitive attribute column in a tabular dataset. If facet_dataset_uri is specified, then the index refers to the facet dataset instead of the main dataset.
  
  - **value_or_threshold** – Required if facet is numeric and label_values_or_threshold is applied as the lower bound to select the sensitive group). An array of facet values or a threshold number, that indicates the sensitive demographic group that bias favors. If facet data type is categorical and value_or_threshold is not provided, bias metrics are computed as one group for every unique value (rather than all values). To set value_or_threshold for different facet data types, refer to the following examples:

    - For a binary facet data type, the feature has two possible values, 0 and 1. If you want to compute the bias metrics for each value, then value_or_threshold can be either omitted or set to an empty array.

    - For a categorical facet data type, the feature has three possible values **bird**, **cat**, and **dog**. If the first two define a demographic group that bias favors, then value_or_threshold should be set to ["bird", "cat"]. In this example, the dataset samples are split into two demographic groups. The facet in the advantaged group has value **bird** or **cat**, while the facet in the disadvantaged group has value **dog**.

    - For a numeric facet data type, the feature value is continuous, ranging from 0 to 1. As an example, if a value greater than 0.5 should designate a sample as favored, then value_or_threshold should be set to 0.5. In this example, the dataset samples are split into two demographic groups. The facet in the advantaged group has value greater than 0.5, while the facet in the disadvantaged group has value less than or equal to 0.5.

- **group_variable** – The name or zero-based index of the column that indicates the subgroup to be used for the bias metric **Conditional Demographic Disparity (CDD)** or **Conditional Demographic Disparity in Predicted Labels (CDDPL)**.

- **facet_dataset_uri** – Only applicable when dataset_type is **text/csv**. The S3 URI for a dataset containing sensitive attributes for bias analysis. You can use facets to understand the bias characteristics of your dataset and model even if your model is trained without using sensitive attributes.
Note
If the facet dataset or the main dataset is split across multiple files, an identifier column must be specified by joinsource_name_or_index to join the two datasets. You must use the parameter facet to identify each facet in the facet dataset.

• facet_headers – (Only applicable when facet_dataset_uri is specified) An array of strings containing column names for the facet dataset, and optionally, the identifier column header to join the facet dataset and the main dataset, see joinsource_name_or_index.

• methods – An object containing one or more analysis methods and their parameters. If any method is omitted, it is neither used for analysis nor reported.

• pre_training_bias – Include this method if you want to compute pre-training bias metrics. The detailed description of the metrics can be found on Measure Pre-training Bias. The object has the following parameters:

  • methods – An array that contains any of the pre-training bias metrics from the following list that you want to compute. Set methods to all to compute all pre-training bias metrics. As an example, the array ['"CI", "DPL"] will compute Class Imbalance and Difference in Proportions of Labels.
  
  • CI for Class Imbalance
  • DPL for Difference in Proportions of Labels
  • KL for Kullback-Leibler Divergence
  • JS for Jensen-Shannon Divergence
  • LP for Lp-norm
  • TVD for Total Variation Distance
  • KS for Kolmogorov-Smirnov
  • CDDL for Conditional Demographic Disparity

• post_training_bias – Include this method if you want to compute post-training bias metrics. The detailed description of the metrics can be found on Measure Post-training Bias. The post_training_bias object has the following parameters.

  • methods – An array that contains any of the post-training bias metrics from the following list that you want to compute. Set methods to all to compute all post-training bias metrics. As an example, the array ['"DPPL", "DI"] computes the Difference in Positive Proportions in Predicted Labels and Disparate Impact. The available methods are as follows.

  • DPPL for Difference in Positive Proportions in Predicted Labels
  • DI for Disparate Impact
  • DCA for Difference in Conditional Acceptance
  • DCR for Difference in Conditional Rejection
  • SD for Specificity difference
  • RD for Recall Difference
  • DAR for Difference in Acceptance Rates
  • DRR for Difference in Rejection Rates
  • AD for Accuracy Difference
  • TE for Treatment Equality
  • CDDL for Conditional Demographic Disparity
  • FT for Counterfactual Fliptest
  • GE for Generalized entropy

• shap – Include this method if you want to compute SHAP values. The SageMaker Clarify processing job supports the Kernel SHAP algorithm. The shap object has the following parameters.

• baseline – (Optional) The SHAP baseline dataset, also known as the background dataset. Additional requirements for the baseline dataset in a tabular dataset or computer vision problem are as follows.
For a **tabular** dataset, baseline can be either the in-place baseline data or the S3 URI of a baseline file. If baseline is not provided, the SageMaker Clarify processing job computes a baseline by clustering the input dataset. The following are required of the baseline:

- The format must be the same as the dataset format specified by `dataset_type`.
- The baseline can only contain features that the model can accept as input.
- The baseline dataset can have one or more instances. The number of baseline instances directly affects the synthetic dataset size and job runtime.
- If `text_config` is specified, then the baseline value of a text column is a string used to replace the unit of text specified by `granularity`. For example, one common placeholder is `"[MASK]"`, which is used to represent a missing or unknown word or piece of text.

The following examples show how to set in-place baseline data for different `dataset_type` parameters:

- If `dataset_type` is either `text/csv` or `application/x-parquet`, the model accepts four numeric features, and the baseline has two instances. In this example, if one record has all zero feature values and the other record has all one feature values, then baseline should be set to `[[0, 0, 0, 0], [1, 1, 1, 1]]`, without any header.
- If `dataset_type` is `application/jsonlines`, and `features` is the key to a list of four numeric feature values. In addition, in this example, if the baseline has one record of all zero values, then `baseline` should be `[{"features": [0, 0, 0, 0]}]`.
- If `dataset_type` is `application/json`, the baseline dataset should have the same structure and format as the input dataset.

- For **computer vision** problems, baseline can be the S3 URI of an image that is used to mask out features (segments) from the input image. The SageMaker Clarify processing job loads the mask image and resizes it to the same resolution as the input image. If baseline is not provided, the SageMaker Clarify processing job generates a mask image of white noise at the same resolution as the input image.

- **features_to_explain** – (Optional) An array of strings or zero-based indices of feature columns to compute SHAP values for. If `features_to_explain` is not provided, SHAP values are computed for all feature columns. These feature columns cannot include the label column or predicted label column. The `features_to_explain` parameter is only supported for tabular datasets with numeric and categorical columns.

- **num_clusters** – (Optional) The number of clusters that the dataset is divided into to compute the baseline dataset. Each cluster is used to compute one baseline instance. If baseline is not specified, the SageMaker Clarify processing job attempts to compute the baseline dataset by dividing the tabular dataset into an optimal number of clusters between 1 and 12. The number of baseline instances directly affects the runtime of SHAP analysis.

- **num_samples** – (Optional) The number of samples to be used in the Kernel SHAP algorithm. If `num_samples` is not provided, the SageMaker Clarify processing job chooses the number for you. The number of samples directly affects both the synthetic dataset size and job runtime.

- **seed** – (Optional) An integer used to initialize the pseudo random number generator in the SHAP explainer to generate consistent SHAP values for the same job. If `seed` is not specified, then each time that the same job runs, the model may output slightly different SHAP values.

- **use_logit** – (Optional) A Boolean value that indicates that you want the logit function to be applied to the model predictions. Defaults to `false`. If `use_logit` is true, then the SHAP values are calculated using the logistic regression coefficients, which can be interpreted as log-odds ratios.

- **save_local_shap_values** – (Optional) A Boolean value that indicates that you want the local SHAP values of each record in the dataset to be included in the analysis result. Defaults to `false`.

If the main dataset is split across multiple files or distributed processing is activated, also specify an identifier column using the parameter `joinsource_name_or_index`. The identifier column
and the local SHAP values are saved in the analysis result. This way, you can map each record to its local SHAP values.

- **agg_method** – (Optional) The method used to aggregate the local SHAP values (the SHAP values for each instance) of all instances to the global SHAP values (the SHAP values for the entire dataset). Defaults to mean_abs. The following methods can be used to aggregate SHAP values.
  - mean_abs – The mean of absolute local SHAP values of all instances.
  - mean_sq – The mean of squared local SHAP values of all instances.
  - median – The median of local SHAP values of all instances.

- **text_config** – Required for natural language processing explainability. Include this configuration if you want to treat text columns as text and explanations should be provided for individual units of text.
  - **granularity** – The unit of granularity for the analysis of text columns. Valid values are sentence, paragraph, or character. Each unit of text is considered a feature, and local SHAP values are computed for each unit.
  - **language** – The language of the text columns. Valid values are afrikaans, arabic, basque, bengali, bulgarian, catalan, czech, da, danish, dutch, english, es, estonian, estonian, finnish, french, gujarati, hebrew, hindi, hungarian, icelandic, indonesian, irish, kazakh, kannada, kyrgyz, latvian, ligurian, lithuanian, lithuanian, malayalam, marathi, mongolian, nepali, persian, sanskrit, serbian, setswana, sinhala, slovak, slovenian, spanish, swahili, swedish, tagalog, tamil, tatar, telugu, thai, turkish, ukrainian, urdu, vietnamese, yoruba. Enter multi-language for a mix of multiple languages.
  - **max_top_tokens** – (Optional) The maximum number of top tokens, based on global SHAP values. Defaults to 50. It is possible for a token to appear multiple times in the dataset. The SageMaker Clarify processing job aggregates the SHAP values of each token, and then selects the top tokens based on their global SHAP values. The global SHAP values of the selected top tokens are included in the global_top_shap_text section of the analysis.json file.
  - The local SHAP value of aggregation.

- **image_config** – Required for computer vision explainability. Include this configuration if you have an input dataset consisting of images and you want to analyze them for explainability in a computer vision problem.
  - **model_type** – The type of the model. Valid values include:
    - IMAGE_CLASSIFICATION for an image classification model.
    - OBJECT_DETECTION for an object detection model.
  - **max_objects** – Applicable only when model_type is OBJECT_DETECTION. The max number of objects, ordered by confidence score, detected by the computer vision model. Any objects ranked lower than the top max_objects by confidence score are filtered out. Defaults to 3.
  - **context** – Applicable only when model_type is OBJECT_DETECTION. It indicates if the area around the bounding box of the detected object is masked by the baseline image or not. Valid values are 0 to mask everything, or 1 to mask nothing. Defaults to 1.
  - **iou_threshold** – Applicable only when model_type is OBJECT_DETECTION. The minimum intersection over union (IOU) metric for evaluating predictions against the original detection. A high IOU metric corresponds to a large overlap between the predicted and ground truth detection box. Defaults to 0.5.
  - **num_segments** – (Optional) An integer that determines the approximate number of segments to be labeled in the input image. Each segment of the image is considered a feature, and local SHAP values are computed for each segment. Defaults to 20.
  - **segment_compactness** – (Optional) An integer that determines the shape and size of the image segments generated by the scikit-image slic method. Defaults to 5.
  - **pdp** – Include this method to compute partial dependence plots (PDPs).
• **features** – Mandatory if the shap method is not requested. An array of feature names or indices to compute and plot PDP plots.

• **top_k_features** – (Optional) Specifies the number of top features used to generate PDP plots. If features is not provided, but the shap method is requested, then the SageMaker Clarify processing job chooses the top features based on their SHAP attributions. Defaults to 10.

• **grid_resolution** – The number of buckets to divide the range of numeric values into. This specifies the granularity of the grid for the PDP plots.

• **report** – (Optional) Use this object to customize the analysis report. There are three copies of the same report as part of the analysis result: Jupyter Notebook report, HTML report, and PDF report. The object has the following parameters:
  - **name** – File name of the report files. For example, if name is `MyReport`, then the report files are `MyReport.ipynb`, `MyReport.html`, and `MyReport.pdf`. Defaults to report.
  - **title** – (Optional) Title string for the report. Defaults to `SageMaker Analysis Report`.

• **predictor** – Required if the analysis requires predictions from the model. For example, when the shap, pdp, or post_training_bias method is requested, but predicted labels are not provided as part of the input dataset. The following are parameters to be used in conjunction with predictor:
  - **model_name** – The name of your SageMaker model created by the `CreateModel` API. If you specify `model_name` instead of `endpoint_name`, the SageMaker Clarify processing job creates an ephemeral endpoint with the model name, known as a **shadow endpoint**, and gets predictions from the endpoint. The job deletes the shadow endpoint after the computations are completed. If the model is multi-model then the `target_model` parameter must be specified.
  - **endpoint_name_prefix** – (Optional) A custom name prefix for the shadow endpoint. Applicable if you provide `model_name` instead of `endpoint_name`. For example, provide `endpoint_name_prefix` if you want to restrict access to the endpoint by endpoint name. The prefix must match the **EndpointName** pattern, and its maximum length is 23. Defaults to `sm-clarify`.
  - **initial_instance_count** – Specifies the number of instances for the shadow endpoint. Required if you provide `model_name` instead of `endpoint_name`. The value for `initial_instance_count` can be different from the `InstanceCount` of the job, but we recommend a 1:1 ratio.
  - **instance_type** – Specifies the instance type for the shadow endpoint. Required if you provide `model_name` instead of `endpoint_name`. As an example, `instance_type` can be set to "ml.m5.large". In some cases, the value specified for `instance_type` can help reduce model inference time. For example, to run efficiently, natural language processing models and computer vision models typically require a graphics processing unit (GPU) instance type.
  - **accelerator_type** – (Optional) Specifies the type of Elastic Inference (EI) accelerator to attach to the shadow endpoint. Applicable if you provide `model_name` instead of `endpoint_name` for `accelerator_type`. An example value for `accelerator_type` is `ml.eia2.large`. Defaults to not use an accelerator.
  - **endpoint_name** – The name of your SageMaker endpoint created by the `CreateEndpoint` API. If provided, `endpoint_name` takes precedence over the `model_name` parameter. Using an existing endpoint reduces the shadow endpoint bootstrap time, but it can also cause a significant increase in load for that endpoint. Additionally, some analysis methods (such as shap and pdp) generate synthetic datasets that are sent to the endpoint. This can cause the endpoint's metrics or captured data to be contaminated by synthetic data, which may not accurately reflect real-world usage. For these reasons, it's generally not recommended to use an existing production endpoint for SageMaker Clarify analysis.
  - **target_model** – The string value that is passed on to the TargetModel parameter of the SageMaker `InvokeEndpoint` API. Required if your model (specified by the `model_name` parameter) or endpoint (specified by the `endpoint_name` parameter) is multi-model.
  - **custom_attributes** – (Optional) A string that allows you to provide additional information about a request for an inference that is submitted to the endpoint. The string value is passed to the `CustomAttributes` parameter of the SageMaker `InvokeEndpoint` API.
• **content_type** – content_type – The model input format to be used for getting predictions from the endpoint. If provided, it is passed to the ContentType parameter of the SageMaker `InvokeEndpoint` API.

  • For computer vision explainability, the valid values are `image/jpeg`, `image/png` or `application/x-npy`. If `content_type` is not provided, the default value is `image/jpeg`.
  
  • For other types of explainability, the valid values are `text/csv`, `application/jsonlines`, and `application/json`. A value for `content_type` is required if the `dataset_type` is "application/x-parquet". Otherwise `content_type` defaults to the value of the `dataset_type` parameter.

• **accept_type** – The model output format to be used for getting predictions from the endpoint. The value for `accept_type` is passed to the `Accept` parameter of the SageMaker `InvokeEndpoint` API.

  • For computer vision explainability, if `model_type` is "OBJECT_DETECTION" then `accept_type` defaults to `application/json`.
  
  • For other types of explainability, the valid values are `text/csv`, `application/jsonlines`, and `application/json`. If a value for `accept_type` is not provided, `accept_type` defaults to the value of the `content_type` parameter.

• **content_template** – A template string used to construct the model input from dataset records. The parameter `content_template` is only used and required if the value of the `content_type` parameter is either `application/jsonlines` or `application/json`.

  When the `content_type` parameter is `application/jsonlines`, the template should have only one placeholder, `$features`, which is replaced by a features list at runtime. For example, if the template is "{"myfeatures":\$features}", and if a record has three numeric feature values: 1, 2 and 3, then the record will be sent to the model as JSON Line ("myfeatures":[1,2,3]).

  When the `content_type` is `application/json`, the template can have either placeholder `$record` or `$records`. If the placeholder is `$record`, a single record is replaced with a record that has the template in `record_template` applied to it. In this case, only a single record will be sent to the model at a time. If the placeholder is `$records`, the records are replaced by a list of records, each with a template supplied by `record_template`.

• **record_template** – A template string to be used to construct each record of the model input from dataset instances. It is only used and required when `content_type` is `application/json`. The template string may contain one of the following:

  • A placeholder `$features` parameter that is substituted by an array of feature values.
  
  • An additional optional placeholder can substitute feature column header names in `$feature_names`. This optional placeholder will be substituted by an array of feature names.
  
  • Exactly one placeholder `$features_kvp` that is substituted by the key-value pairs, feature name and feature value.
  
  • A feature in the `headers` configuration. As an example, a feature name A, notated by the placeholder syntax "${A}" will be substituted by the feature value for A.

  The value for `record_template` is used with `content_template` to construct the model input. A configuration example showing how to construct a model input using a content and record template follows.

  In the following code example, the headers and features are defined as follows.

  • `headers`:["A", "B"]
  
  • `features`:[[0,1], [3,4]]

  The example model input is as follows.

  ```json
  {
    "instances": [[0, 1], [3, 4]],
    "feature_names": ["A", "B"]
  }
  ```
The example content_template and record_template parameter values to construct the previous example model input follows.

- content_template: "{"instances": $records, "feature_names": $feature_names}"
- record_template: "$features"

In the following code example, the headers and features are defined as follows.

```
[
    { "A": 0, "B": 1 },
    { "A": 3, "B": 4 },
]
```

The example content_template and record_template parameter values to construct the previous example model input follows.

- content_template: "$records"
- record_template: "$features_kvp"

An alternate code example to construct the previous example model input follows.

- content_template: "$records"
- record_template: "{"A": "$A", "B": "$B"}"

In the following code example, the headers and features are defined as follows.

```
{ "A": 0, "B": 1 }
```

The example content_template and record_template parameters values to construct above: the previous example model input follows.

- content_template: "$record"
- record_template: "$features_kvp"

- label – A zero-based integer index or JMESPath expression string used to extract predicted labels from the model output for bias analysis. If the model is multiclass and the label parameter extracts all of the predicted labels from the model output, then the following apply.
  - The probability parameter is required to get the corresponding probabilities (or scores) from the model output.
  - The predicted label of the highest score is chosen.

The value for label depends on the value of the accept_type parameter as follows.

- If accept_type is text/csv, then label is the index of any predicted labels in the model output.
- If accept_type is application/jsonlines or application/json, then label is a JMESPath expression that's applied to the model output to get the predicted labels.

- label_headers – An array of values that the label can take in the dataset. If bias analysis is requested, then the probability parameter is also required to get the corresponding probability values (scores) from model output, and the predicted label of the highest score is chosen. If explainability analysis is requested, the label headers are used to beautify the analysis report. A value for label_headers is required for computer vision explainability. For example, for a multiclass classification problem, if the label has three possible values, bird, cat, and dog, then label_headers should be set to ["bird", "cat", "dog"].
• **probability** – (Optional) A zero-based integer index or a JMESPath expression string used to extract probabilities (scores) for explainability analysis, or to choose the predicted label for bias analysis. The value of probability depends on the value of the accept_type parameter as follows.

  • If `accept_type` is **text/csv**, probability is the index of the probabilities (scores) in the model output. If probability is not provided, the entire model output is taken as the probabilities (scores).

  • If `accept_type` is JSON data (either `application/jsonlines` or `application/json`), `probability` should be a JMESPath expression that is used to extract the probabilities (scores) from the model output.

### Example analysis configuration files

The following sections contain example analysis configuration files for data in CSV format, JSON Lines format, and for both natural language processing (NLP) and computer vision explainability.

#### Analysis configuration for a CSV dataset

The following examples show how to configure bias and explainability analysis for a tabular dataset in CSV format. In these examples, the incoming dataset has four feature columns, and one binary label column, **Target**. The contents of the dataset are as follows. A label value of 1 indicates a positive outcome. The dataset is provided to the SageMaker Clarify job by the dataset processing input.

```
"Target","Age","Gender","Income","Occupation"
0,25,0,2850,2
1,36,0,6585,0
1,22,1,1759,1
0,48,0,3446,1
...
```

The following sections show how to compute pre-training and post-training bias metrics, SHAP values, and partial dependence plots (PDPs) showing feature importance for a dataset in CSV format.

#### Compute all of the pre-training bias metrics

This example configuration shows how to measure if the previous sample dataset is favorably biased towards samples with a **Gender** value of 0. The following analysis configuration instructs the SageMaker Clarify processing job to compute all the pre-training bias metrics for the dataset.

```json
{
  "dataset_type": "text/csv",
  "label": "Target",
  "label_values_or_threshold": [1],
  "facet": [
    {
      "name_or_index": "Gender",
      "value_or_threshold": [0]
    }
  ],
  "methods": {
    "pre_training_bias": {
      "methods": "all"
    }
  }
}
```
Compute all of the post-training bias metrics

You can compute pre-training bias metrics prior to training. However, you must have a trained model to compute post-training bias metrics. The following example output is from a binary classification model that outputs data in CSV format. In this example output, each row contains two columns. The first column contains the predicted label, and the second column contains the probability value for that label.

| 0 | 0.028986845165491 |
| 1 | 0.825382471084594 |
| ... |

The following configuration example instructs the SageMaker Clarify processing job to compute all possible bias metrics using the dataset and the predictions from the model output. In the example, the model is deployed to a SageMaker endpoint your_endpoint.

**Note**

In the following example code, the parameter content_type and accept_type are not set. Therefore, they automatically use the value of the parameter dataset_type, which is text/csv.

```json
{
    "dataset_type": "text/csv",
    "label": "Target",
    "label_values_or_threshold": [1],
    "facet": [
        {
            "name_or_index": "Gender",
            "value_or_threshold": [0]
        }
    ],
    "methods": {
        "pre_training_bias": {
            "methods": "all"
        },
        "post_training_bias": {
            "methods": "all"
        }
    },
    "predictor": {
        "endpoint_name": "your_endpoint",
        "label": 0
    }
}
```

Compute the SHAP values

The following example analysis configuration instructs the job to compute the SHAP values designating the Target column as labels and all other columns as features.

```json
{
    "dataset_type": "text/csv",
    "label": "Target",
    "methods": {
        "shap": {
            "num_clusters": 1
        }
    },
    "predictor": {
        "endpoint_name": "your_endpoint",
        "probability": 1
    }
}
```
In this example, the SHAP baseline parameter is omitted and the value of the `num_clusters` parameter is 1. This instructs the SageMaker Clarify processor to compute one SHAP baseline sample. In this example, probability is set to 1. This instructs the SageMaker Clarify processing job to extract the probability score from the second column of the model output (using zero-based indexing).

**Compute partial dependence plots (PDPs)**

The following example shows how to view the importance of the Income feature on the analysis report using PDPs. The report parameter instructs the SageMaker Clarify processing job to generate a report. After the job completes, the generated report is saved as `report.pdf` to the `analysis_result` location. The `grid_resolution` parameter divides the range of the feature values into 10 buckets. Together, the parameters specified in the following example instruct the SageMaker Clarify processing job to generate a report containing a PDP graph for Income with 10 segments on the x-axis. The y-axis will show the marginal impact of Income on the predictions.

```json
{
  "dataset_type": "text/csv",
  "label": "Target",
  "methods": {
    "pdp": {
      "features": ["Income"],
      "grid_resolution": 10
    },
    "report": {
      "name": "report"
    }
  },
  "predictor": {
    "endpoint_name": "your_endpoint",
    "probability": 1
  }
}
```

**Compute both bias metrics and feature importance**

You can combine all the methods from the previous configuration examples into a single analysis configuration file and compute them all by a single job. The following example shows an analysis configuration with all steps combined.

In this example, the probability parameter is set to 1 to indicate that probabilities are contained in the second column (using zero-based indexing). However, because bias analysis needs a predicted label, the `probability_threshold` parameter is set to 0.5 to convert the probability score into a binary label. In this example, the `top_k_features` parameter of the partials dependence plots `pdp` method is set to 2. This instructs the SageMaker Clarify processing job to compute partials dependence plots (PDPs) for the top 2 features with the largest global SHAP values.

```json
{
  "dataset_type": "text/csv",
  "label": "Target",
  "probability_threshold": 0.5,
  "label_values_or_threshold": [1],
  "facet": [
    "name_or_index": "Gender",
    "value_or_threshold": [0]
  ],
  "methods": {
    "pre_training_bias": {
      "methods": "all"
    },
    "post_training_bias": {
      "methods": "all"
    },
    "pdp": {
      "features": ["Income"],
      "grid_resolution": 10
    }
  }
}
```
Instead of deploying the model to an endpoint, you can provide the name of your SageMaker model to the SageMaker Clarify processing job using the `model_name` parameter. The following example shows how to specify a model named `your_model`. The SageMaker Clarify processing job will create a shadow endpoint using the configuration.

```json
{
  ...
  "predictor": {
    "model_name": "your_model",
    "initial_instance_count": 1,
    "instance_type": "ml.m5.large",
    "probability": 1
  }
}
```

### Analysis configuration for a JSON Lines dataset

The following examples show how to configure bias analysis and explainability analysis for a tabular dataset in JSON Lines format. In these examples, the incoming dataset has the same data as the previous section but they are in the SageMaker JSON Lines dense format. Each line is a valid JSON object. The key "Features" points to an array of feature values, and the key "Label" points to the ground truth label. The dataset is provided to the SageMaker Clarify job by the "dataset" processing input.

```json
["Features":[25,0,2850,2],"Label":0]
["Features":[36,0,6585,0],"Label":1]
["Features":[22,1,1759,1],"Label":1]
["Features":[48,0,3446,1],"Label":0]
...
```

The following sections show how to compute pre-training and post-training bias metrics, SHAP values, and partial dependence plots (PDPs) showing feature importance for a dataset in JSON Lines format.

### Compute pre-training bias metrics

Specify the label, features, format, and methods to measure pre-training bias metrics for a `Gender` value of 0. In the following example, the `headers` parameter provides the feature names first. The label name is provided last. By convention, the last header is the label header.

The `features` parameter is set to the JMESPath expression "Features" so that the SageMaker Clarify processing job can extract the array of features from each record. The `label` parameter is set to JMESPath expression "Label" so that the SageMaker Clarify processing job can extract the ground truth label from each record. Use a facet name to specify the sensitive attribute, as follows.

```json
"methods": "all"
"shap": {
"num_clusters": 1
},
"pdp": {
"top_k_features": 2,
"grid_resolution": 10
},
"report": {
"name": "report"
},
"predictor": {
"endpoint_name": "your_endpoint",
"probability": 1
}
Configure a SageMaker Clarify Processing Job

```json
{
  "dataset_type": "application/jsonlines",
  "headers": ["Age", "Gender", "Income", "Occupation", "Target"],
  "label": "Label",
  "features": "Features",
  "label_values_or_threshold": [1],
  "facet": [
    {
      "name_or_index": "Gender",
      "value_or_threshold": [0]
    }
  ],
  "methods": {
    "pre_training_bias": {
      "methods": "all"
    }
  }
}
```

**Compute all the bias metrics**

You must have a trained model to compute post-training bias metrics. The following example is from a binary classification model that outputs JSON Lines data in the example's format. Each row of the model output is a valid JSON object. The key `predicted_label` points to the predicted label, and the key `probability` points to the probability value.

```json
{"predicted_label":0,"probability":0.0289868451654911}
{"predicted_label":1,"probability":0.8253824710845941}
...
```

You can deploy the model to a SageMaker endpoint named `your_endpoint`. The following example analysis configuration instructs the SageMaker Clarify processing job to compute all possible bias metrics for both the dataset and the model. In this example, the parameter `content_type` and `accept_type` are not set. Therefore, they are automatically set to use the value of the parameter `dataset_type`, which is `application/jsonlines`. The SageMaker Clarify processing job uses the `content_template` parameter to compose the model input, by replacing the `$features` placeholder by an array of features.

```json
{
  "dataset_type": "application/jsonlines",
  "headers": ["Age", "Gender", "Income", "Occupation", "Target"],
  "label": "Label",
  "features": "Features",
  "label_values_or_threshold": [1],
  "facet": [
    {
      "name_or_index": "Gender",
      "value_or_threshold": [0]
    }
  ],
  "methods": {
    "pre_training_bias": {
      "methods": "all"
    },
    "post_training_bias": {
      "methods": "all"
    }
  },
  "predictor": {
    "endpoint_name": "your_endpoint",
    "content_template": "{{\"Features\":$features}}",
    "label": "predicted_label"
  }
}
```
Compute the SHAP values

Because SHAP analysis doesn't need a ground truth label, the label parameter is omitted. In this example, the headers parameter is also omitted. Therefore, the SageMaker Clarify processing job must generate placeholders using generic names like column_0 or column_1 for feature headers, and label0 for a label header. You can specify values for headers and for a label to improve the readability of the analysis result. Because the probability parameter is set to JMESPath expression probability, the probability value will be extracted from the model output. The following is an example to calculate SHAP values.

```json
{
    "dataset_type": "application/jsonlines",
    "features": "Features",
    "methods": {
        "shap": {
            "num_clusters": 1
        }
    },
    "predictor": {
        "endpoint_name": "your_endpoint",
        "content_template": "\"Features\":\$features",
        "probability": "probability"
    }
}
```

Compute partials dependence plots (PDPs)

The following example shows how to view the importance of "Income" on PDP. In this example, the feature headers are not provided. Therefore, the features parameter of the pdp method must use zero-based index to refer to location of the feature column. The grid_resolution parameter divides the range of the feature values into 10 buckets. Together, the parameters in the example instruct the SageMaker Clarify processing job to generate a report containing a PDP graph for Income with 10 segments on the x-axis. The y-axis will show the marginal impact of Income on the predictions.

```json
{
    "dataset_type": "application/jsonlines",
    "features": "Features",
    "methods": {
        "pdp": {
            "features": [2],
            "grid_resolution": 10
        },
        "report": {
            "name": "report"
        }
    },
    "predictor": {
        "endpoint_name": "your_endpoint",
        "content_template": "\"Features\":\$features",
        "probability": "probability"
    }
}
```

Compute both bias metrics and feature importance

You can combine all previous methods into a single analysis configuration file and compute them all by a single job. The following example shows an analysis configuration with all steps combined. In
Configure a SageMaker Clarify Processing Job

In this example, the probability parameter is set. But because bias analysis needs a predicted label, the probability_threshold parameter is set to 0.5 to convert the probability score into a binary label. In this example, the top_k_features parameter of the pdp method is set to 2. This instructs the SageMaker Clarify processing job to compute PDPs for the top 2 features with the largest global SHAP values.

```json
{
    "dataset_type": "application/jsonlines",
    "headers": ["Age", "Gender", "Income", "Occupation", "Target"],
    "label": "Label",
    "features": "Features",
    "probability_threshold": 0.5,
    "label_values_or_threshold": [1],
    "facet": [
        {
            "name_or_index": "Gender",
            "value_or_threshold": [0]
        }
    ],
    "methods": {
        "pre_training_bias": {
            "methods": "all"
        },
        "post_training_bias": {
            "methods": "all"
        },
        "shap": {
            "num_clusters": 1
        },
        "pdp": {
            "top_k_features": 2,
            "grid_resolution": 10
        },
        "report": {
            "name": "report"
        }
    },
    "predictor": {
        "endpoint_name": "your_endpoint",
        "content_template": "\"Features\":$features",
        "probability": "probability"
    }
}
```

**Analysis configuration for a JSON dataset**

The following examples show how to configure bias and explainability analysis for a tabular dataset in JSON format. In these examples, the incoming dataset has the same data as the previous section but they are in the SageMaker JSON dense format.

The whole input request is valid JSON where the outer structure is a list and each element is the data for a record. Within each record, the key Features points to an array of feature values, and the key Label points to the ground truth label. The dataset is provided to the SageMaker Clarify job by the dataset processing input.

```json
[{
    "Features": [25, 0, 2850, 2],
    "Label": 0
},
{
    "Features": [36, 0, 6585, 0],
    "Label": 1
},
{
    "Features": [22, 1, 1759, 1],
    "Label": 1
},
{
    "Features": [48, 0, 3446, 1],
    "Label": 0
},
...
]```
The following sections show how to compute pre-training and post-training bias metrics, SHAP values, and partial dependence plots (PDPs) that show feature importance for a dataset in JSON Lines format.

### Compute pre-training bias metrics

Specify the label, features, format, and methods to measure pre-training bias metrics for a `Gender` value of `0`. In the following example, the `headers` parameter provides the feature names first. The label name is provided last. For JSON datasets, the last header is the label header.

The `features` parameter is set to the JMESPath expression that extracts a 2D array or matrix. Each row in this matrix must contain the list of features for each record. The `label` parameter is set to a JMESPath expression that extracts a list of ground truth labels. Each element in this list must contain the label for a record.

Use a facet name to specify the sensitive attribute, as follows.

```json
{
  "dataset_type": "application/json",
  "headers": ["Age","Gender","Income","Occupation","Target"],
  "label": "[*].Label",
  "features": "[*].Features",
  "label_values_or_threshold": [1],
  "facet": {
    "name_or_index": "Gender",
    "value_or_threshold": [0]
  },
  "methods": {
    "pre_training_bias": {
      "methods": "all"
    }
  }
}
```

### Compute all the bias metrics

You must have a trained model to compute post-training bias metrics. The following code example is from a binary classification model that outputs JSON data in the example's format. In the example, each element under `predictions` is the prediction output for a record. The example code contains the key `predicted_label`, that points to the predicted label, and the key `probability` points to the probability value.

```json
[
  {"predicted_label":0,"probability":0.028986845165491},
  {"predicted_label":1,"probability":0.825382471084594},
  ...
]
```

You can deploy the model to a SageMaker endpoint named `your_endpoint`.

In the following example, the parameter `content_type` and `accept_type` are not set. Therefore, `content_type` and `accept_type` are automatically set to use the value of the parameter `dataset_type`, which is `application/json`. The SageMaker Clarify processing job then uses the `content_template` parameter to compose the model input.

In the following example, the model input is composed by replacing the `$records` placeholder by an array of records. Then, the `record_template` parameter composes each record's JSON structure and replaces the `$features` placeholder with each record's array of features.
The following example analysis configuration instructs the SageMaker Clarify processing job to compute all possible bias metrics for both the dataset and the model.

```json
{
  "dataset_type": "application/json",
  "headers": ["Age", "Gender", "Income", "Occupation", "Target"],
  "label": "[*].Label",
  "features": "[*].Features",
  "label_values_or_threshold": [1],
  "facet": [
    {
      "name_or_index": "Gender",
      "value_or_threshold": [0]
    }
  ],
  "methods": {
    "pre_training_bias": {
      "methods": "all"
    },
    "post_training_bias": {
      "methods": "all"
    }
  },
  "predictor": {
    "endpoint_name": "your_endpoint",
    "content_template": "$records",
    "record_template": "{"Features":$features}"
  },
  "label": "predictions[*].predicted_label"
}
```

### Compute the SHAP values

You don't need to specify a label for SHAP analysis. In the following example, the `headers` parameter is not specified. Therefore, the SageMaker Clarify processing job will generate placeholders using generic names like `column_0` or `column_1` for feature headers, and `label0` for a label header. You can specify values for `headers` and for a `label` to improve the readability of the analysis result.

In the following configuration example, the probability parameter is set to a JMESPath expression that extracts the probabilities from each prediction for each record. The following is an example to calculate SHAP values.

```json
{
  "dataset_type": "application/json",
  "features": "[*].Features",
  "methods": {
    "shap": {
      "num_clusters": 1
    }
  },
  "predictor": {
    "endpoint_name": "your_endpoint",
    "content_template": "$records",
    "record_template": "{"Features":$features}"
  },
  "probability": "predictions[*].probability"
}
```

### Compute partial dependence plots (PDPs)

The following example shows you how to view a feature importance in PDPs. In the example, the feature headers are not provided. Therefore, the `features` parameter of the `pdp` method must use zero-based
index to refer to location of the feature column. The grid_resolution parameter divides the range of the feature values into 10 buckets.

Together, the parameters in the following example instruct the SageMaker Clarify processing job to generate a report containing a PDP graph for Income with 10 segments on the x-axis. The y-axis shows the marginal impact of Income on the predictions.

The following configuration example shows how to view the importance of Income on PDPs.

```json
{
    "dataset_type": "application/json",
    "features": "[*].Features",
    "methods": {
        "pdp": {
            "features": [2],
            "grid_resolution": 10
        },
        "report": {
            "name": "report"
        }
    },
    "predictor": {
        "endpoint_name": "your_endpoint",
        "content_template": "$records",
        "record_template": "{"Features":$features}"
    }
}
```

**Compute both bias metrics and feature importance**

You can combine all previous configuration methods into a single analysis configuration file and compute them all with a single job. The following example shows an analysis configuration with all steps combined.

In this example, the probability parameter is set. Because bias analysis needs a predicted label, the probability_threshold parameter is set to 0.5, which is used to convert the probability score into a binary label. In this example, the top_k_features parameter of the pdp method is set to 2. This instructs the SageMaker Clarify processing job to compute PDPs for the top 2 features with the largest global SHAP values.

```json
{
    "dataset_type": "application/json",
    "headers": ["Age","Gender","Income","Occupation","Target"],
    "label": "[*].Label",
    "features": "[*].Features",
    "probability_threshold": 0.5,
    "label_values_or_threshold": [1],
    "facet": ["name_or_index": "Gender", "value_or_threshold": [0]]
},
"methods": {
    "pre_training_bias": {
        "methods": "all"
    },
    "post_training_bias": {
        "methods": "all"
    },
    "shap": {
        "methods": "all"
    }
}
```
Analysis configuration for natural language processing explainability

The following example shows an analysis configuration file for computing feature importance for natural language processing (NLP). In this example, the incoming dataset is a tabular dataset in CSV format, with one binary label column and two feature columns, as follows. The dataset is provided to the SageMaker Clarify job by the dataset processing input parameter.

```
0,2,"They taste gross"
1,3,"Flavor needs work"
1,5,"Taste is awful"
0,1,"The worst"
...
```

In this example, a binary classification model was trained on the previous dataset. The model accepts CSV data, and it outputs a single score between 0 and 1, as follows.

```
0.491656005382537
0.569582343101501
...
```

The model is used to create a SageMaker model named "your_model". The following analysis configuration shows how to run a token-wise explainability analysis using the model and dataset. The text_config parameter activates the NLP explainability analysis. The granularity parameter indicates that the analysis should parse tokens.

In English, each token is a word. The following example also shows how to provide an in-place SHAP "baseline" instance using an average "Rating" of 4. A special mask token "[MASK]" is used to replace a token (word) in "Comments". This example also uses a GPU endpoint instance type to speed up inferencing.

```
{  
  "dataset_type": "text/csv",
  "headers": ["Target","Rating","Comments"]
  "label": "Target",
  "methods": {  
    "shap": {  
      "text_config": {  
        "granularity": "token",
        "language": "english"
      }
      "baseline": [[4,"[MASK]"],
    },
  },
}
"predictor": {
  "model_name": "your_nlp_model",
  "initial_instance_count": 1,
  "instance_type": "ml.g4dn.xlarge"
}
}

Analysis configuration for computer vision explainability

The following example shows an analysis configuration file computing feature importance for computer vision. In this example, the input dataset consists of JPEG images. The dataset is provided to the SageMaker Clarify job by the dataset processing input parameter. The example shows how to configure an explainability analysis using a SageMaker image classification model. In the example, a model named your_cv_ic_model, has been trained to classify the animals on the input JPEG images.

```json
{
  "dataset_type": "application/x-image",
  "methods": {
    "shap": {
      "image_config": {
        "model_type": "IMAGE_CLASSIFICATION",
        "num_segments": 20,
        "segment_compactness": 10
      }
    },
    "report": {
      "name": "report"
    }
  },
  "predictor": {
    "model_name": "your_cv_ic_model",
    "initial_instance_count": 1,
    "instance_type": "ml.p2.xlarge",
    "label_headers": ["bird","cat","dog"]
  }
}
```

In this example, a SageMaker object detection model, your_cv_od_model is trained on the same JPEG images to identify the animals on them. The following example shows how to configure an explainability analysis for the object detection model.

```json
{
  "dataset_type": "application/x-image",
  "probability_threshold": 0.5,
  "methods": {
    "shap": {
      "image_config": {
        "model_type": "OBJECT_DETECTION",
        "max_objects": 3,
        "context": 1.0,
        "iou_threshold": 0.5,
        "num_segments": 20,
        "segment_compactness": 10
      }
    },
    "report": {
      "name": "report"
    }
  },
  "predictor": {
    "model_name": "your_cv_od_model",
    "initial_instance_count": 1,
    "initial_instance_count": 1
  }
}
```
"instance_type": "ml.p2.xlarge",
"label_headers": ["bird","cat","dog"]
}
}

Data Format Compatibility Guide

This guide describes the data format types that are compatible with SageMaker Clarify processing jobs. The supported data format types include the file extensions, data structure, and specific requirements or restrictions for tabular and image datasets. This guide also shows how to check if your dataset conforms to these requirements.

At a high level, the SageMaker Clarify processing job follows the input–process–output model to compute bias metrics and feature attributions. Refer to the following examples for details.

The input to the SageMaker Clarify processing job consists of the following:

- The dataset to be analyzed.
- The analysis configuration.

During the processing stage, SageMaker Clarify computes bias metrics and feature attributions. The SageMaker Clarify processing job completes the following steps in the backend:

- The SageMaker Clarify processing job parses your analysis configuration and loads your dataset.
- To compute post-training bias metrics and feature attributions, the job requires model predictions from your model. The SageMaker Clarify processing job serializes your data and sends it as a request to your model that is deployed on a SageMaker real-time inference endpoint. After that, the SageMaker Clarify processing job extracts predictions from the response.
- The SageMaker Clarify processing job performs the bias and explainability analysis, and then it outputs the results.

For more information, see How SageMaker Clarify Processing Jobs Work (p. 3137).

The parameter that you use to specify the format of the data depends on where the data is used in the processing flow as follows:

- For an input dataset, use the dataset_type parameter to specify the format or MIME type.
- For a request to an endpoint, use the content_type parameter to specify the format.
- For a response from an endpoint, use the accept_type parameter to specify the format.

The input dataset, request, and the response to and from the endpoint don't require the same format. For example, you can use a Parquet dataset with a CSV request payload and a JSON Lines response payload given the following conditions.

- Your analysis is configured correctly.
- Your model supports the request and response formats.

Note
If content_type or accept_type are not provided, then the SageMaker Clarify container infers the content_type and accept_type.

Topics
- Tabular data (p. 3167)
- Image data (p. 3182)
Tabular data

Tabular data refers to data that can be loaded into a two-dimensional data frame. In the frame, each row represents a record, and each record has one or more columns. The values within each data frame cell can be of numerical, categorical, or text data types.

Tabular dataset prerequisites

Prior to analysis, your dataset should have had any necessary pre-processing steps already applied. This includes data cleaning or feature engineering.

You can provide one or multiple datasets. If you provide multiple datasets, use the following to identify them to the SageMaker Clarify processing job.

- Use either a `ProcessingInput` named `dataset` or the analysis configuration `dataset_uri` to specify the main dataset. For more information about `dataset_uri`, see the parameters list in Configure the Analysis.
- Use the baseline parameter provided in the analysis configuration file. The baseline dataset is required for SHAP analysis. For more information about the analysis configuration file, including examples, see Configure the Analysis.

The following table lists supported data formats, their file extensions, and MIME types.

<table>
<thead>
<tr>
<th>Data format</th>
<th>File extension</th>
<th>MIME type</th>
</tr>
</thead>
<tbody>
<tr>
<td>CSV</td>
<td>csv</td>
<td>text/csv</td>
</tr>
<tr>
<td>JSON Lines</td>
<td>jsonl</td>
<td>application/jsonlines</td>
</tr>
<tr>
<td>JSON</td>
<td>json</td>
<td>application/json</td>
</tr>
<tr>
<td>Parquet</td>
<td>parquet</td>
<td>&quot;application/x-parquet&quot;</td>
</tr>
</tbody>
</table>

The following sections show example tabular datasets in CSV, JSON Lines, and Apache Parquet formats.

Tabular dataset prerequisites in CSV format

The SageMaker Clarify processing job is designed to load CSV data files in the `csv.excel` dialect. However, it's flexible enough to support other line terminators, including \n and \r.

For compatibility, all CSV data files provided to the SageMaker Clarify processing job must be encoded in UTF-8.

If your dataset does not contain a header row, do the following:

- Set the analysis configuration label to index 0. This means that the first column is the ground truth label.
- If the parameter `headers` is set, set `label` to the label column header to indicate the location of the label column. All other columns are designated as features.

The following is an example of a dataset that does not contain a header row.

```
1,5,2.8,2.538,This is a good product
0,1,0.79,0.475,Bad shopping experience
...```
If your data contains a header row, set the parameter label to index 0. To indicate the location of the label column, use the ground truth label header Label. All other columns are designated as features.

The following is an example of a dataset that contains a header row.

<table>
<thead>
<tr>
<th>Label, Rating, A12, A13, Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>1, 5, 2.8, 2.538, This is a good product</td>
</tr>
<tr>
<td>0, 1, 0.79, 0.475, Bad shopping experience</td>
</tr>
<tr>
<td>...</td>
</tr>
</tbody>
</table>

**Tabular dataset prerequisites in JSON format**

JSON is a flexible format for representing structured data that contains any level of complexity. The SageMaker Clarify support for JSON is not restricted to any specific format and thus allows for more flexible data formats in comparison to datasets in CSV or JSON Lines formats. This guide shows you how to set an analysis configuration for tabular data in JSON format.

**Note**
To ensure compatibility, all JSON data files provided to the SageMaker Clarify processing job must be encoded in UTF-8.

The following is example input data with records that contain a top-level key, a list of features, and a label.

```json
[
  {
    "features": [1, 5, 2.8, 2.538, "This is a good product"],
    "label": 1,
  },
  {
    "features": [0, 1, 0.79, 0.475, "Bad shopping experience"],
    "label": 0,
  },
  ...
]
```

An example configuration analysis for the previous input example dataset should set the following parameters:

- The label parameter should use the JMESPath expression `[*].label` to extract the ground truth label for each record in the dataset. The JMESPath expression should produce a list of labels where the ith label corresponds to the ith record.
- The features parameter should use the JMESPath expression `[*].features` to extract an array of features for each record in the dataset. The JMESPath expression should produce a 2D array or matrix where the ith row contains the feature values for corresponding to the ith record.

The following is example input data with records that contains a top-level key and a nested key that contains a list of features and labels for each record.

```json
{
  "data": [
    {
      "features": [1, 5, 2.8, 2.538, "This is a good product"],
      "label": 1,
    },
    {
      "features": [0, 1, 0.79, 0.475, "Bad shopping experience"],
      "label": 0,
    }
  ]
}
```

An example configuration analysis for the previous input example dataset should set the following parameters:

- The label parameter uses the JMESPath expression `data[*].label` to extract the ground truth label for each record in the dataset. The JMESPath expression should produce a list of labels where the ith label is for the ith record.
The features parameter uses the JMESPath expression `data[*].features` to extract the array of features, for each record in the dataset. The JMESPath expression should produce a 2D array or matrix where the ith row contains the feature values for the ith record.

Tabular dataset prerequisites in JSON Lines format

JSON Lines is a text format for representing structured data where each line is a valid JSON object. Currently SageMaker Clarify processing jobs only support SageMaker Dense Format JSON Lines. To conform to the required format, all of the features of a record should be listed in a single JSON array.

Note

All JSON Lines data files provided to the SageMaker Clarify processing job must be encoded in UTF-8 to ensure compatibility.

The following is an example of how to set an analysis configuration for a record that contains a top-level key and a list of elements.

```
{"features":[1,5,2.8,2.538,"This is a good product"],"label":1}
{"features":[0,1,0.79,0.475,"Bad shopping experience"],"label":0}
...
```

The configuration analysis for the previous dataset example should set the parameters as follows:

- To indicate the location of the ground truth label, the parameter label should be set to the JMESPath expression `label`.
- To indicate the location of the array of features, the parameter features should be set to the JMESPath expression `features`.

The following is an example of how to set an analysis configuration for a record that contains a top-level key and a nested key that contains a list of elements.

```
{"data":{"features":[1,5,2.8,2.538,"This is a good product"],"label":1}}
{"data":{"features":[0,1,0.79,0.475,"Bad shopping experience"],"label":0}}
...
```

The configuration analysis for the previous dataset example should set the parameters as follows:

- The parameter label should be set to the JMESPath expression `data.label` to indicate the location of the ground truth label.
- The parameter features should be set to the JMESPath expression `data.features` to indicate the location of the array of features.

Tabular dataset prerequisites in Parquet format

Parquet is a column-oriented binary data format. Currently, SageMaker Clarify processing jobs support loading Parquet data files only when the processing instance count is 1.

Because SageMaker Clarify processing jobs don't support endpoint request or endpoint response in Parquet format, you must specify the data format of the endpoint request by setting the analysis configuration parameter content_type to a supported format. For more information, see content_type in Configure the Analysis.

The Parquet data must have column names that are formatted as strings. Use the analysis configuration label parameter to set the label column name to indicate the location of the ground truth labels. All other columns are designated as features.
Endpoint requests for tabular data

To obtain model predictions for post-training bias analysis and feature importance analysis, SageMaker Clarify processing jobs serialize the tabular data into bytes and sends these to an inference endpoint as a request payload. This tabular data is either sourced from the input dataset, or it's generated. If it's synthetic data, it's generated by the explainer for SHAP analysis or PDP analysis.

The data format of the request payload should be specified by the analysis configuration content_type parameter. If the parameter is not provided, the SageMaker Clarify processing job will use the value of the dataset_type parameter as the content type. For more information about content_type or dataset_type, see Configure the Analysis.

The following sections show example endpoint requests in CSV and JSON Lines formats.

Endpoint request in CSV format

The SageMaker Clarify processing job can serialize data to CSV format (MIME type: text/csv). The following table shows examples of the serialized request payloads.

<table>
<thead>
<tr>
<th>Endpoint request payload (string representation)</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>'1,2,3,4'</td>
<td>Single record (four numerical features).</td>
</tr>
<tr>
<td>'1,2,3,4\n5,6,7,8'</td>
<td>Two records, separated by line break \n.</td>
</tr>
<tr>
<td>&quot;&quot;This is a good product&quot;,5'</td>
<td>Single record (a text feature and a numerical feature).</td>
</tr>
<tr>
<td>&quot;This is a good product&quot;,5\n&quot;Bad shopping experience&quot;,1'</td>
<td>Two records.</td>
</tr>
</tbody>
</table>

Endpoint request is in JSON Lines format

The SageMaker Clarify processing job can serialize data to SageMaker JSON Lines dense format (MIME type: application/jsonlines).

To transform tabular data into JSON data, provide a template string to the analysis configuration content_template parameter. For more information about content_template see Configure the Analysis. The following table shows examples of serialized JSON Lines request payloads.

<table>
<thead>
<tr>
<th>Endpoint request payload (string representation)</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>'{&quot;data&quot;:{&quot;features&quot;:[1,2,3,4]}}'</td>
<td>Single record. In this case, the template looks like '{&quot;data&quot;:{&quot;features&quot;:$features}}' and $features is replaced by the list of features [1,2,3,4].</td>
</tr>
<tr>
<td>'{&quot;data&quot;:{&quot;features&quot;:[1,2,3,4]}}\n{&quot;data&quot;:{&quot;features&quot;:[5,6,7,8]}}'</td>
<td>Two records.</td>
</tr>
<tr>
<td>'{&quot;features&quot;:[&quot;This is a good product&quot;,5]}'</td>
<td>Single record. In this case, the template looks like '{&quot;features&quot;:$features}' and $features is replaced by the list of features [&quot;This is a good product&quot;,5].</td>
</tr>
</tbody>
</table>
### Endpoint request payload (string representation) | Comments
--- | ---
'{"features":["This is a good product",5]},{"features":["Bad shopping experience",1]}' | Two records.

**Endpoint request is in JSON format**

A SageMaker Clarify processing job can serialize data to arbitrary JSON structures (MIME type: application/json). To do this, you must provide a template string to the analysis configuration content_template parameter. This is used by the SageMaker Clarify processing job to construct the outer JSON structure. You must also provide a template string for record_template, which is used to construct the JSON structure for each record. For more information about content_template and record_template, see Configure the Analysis (p. 3144).

**Note**
Because content_template and record_template are string parameters, any double quote characters ("') that are part of the JSON serialized structure should be noted as an escaped character in your configuration. For example, if you want to escape a double quote in Python, you could enter the following for content_template.

```
{"data":{"features":"$record"}}
```

The following table shows examples of serialized JSON request payloads and the corresponding content_template and record_template parameters that are required to construct them.

<table>
<thead>
<tr>
<th>Endpoint request payload (string representation)</th>
<th>Comments</th>
<th>content_template</th>
<th>record_template</th>
</tr>
</thead>
</table>

'{"data":{"features": [1,2,3,4]}}' | Single record at a time. | '{"data":{"features": $record"}}' | "$features"

'{"instances":[[0, 1], [3, 4]], "feature-names": ["A", "B"]}' | Multi-records with feature names. | '{"instances":$records, "feature-names": $feature_names} | "$features"

'{"A":0, "B":1}, {"A":3, "B":4}]' | Multi-records and key-value pairs. | "$records" | "$features_kvp"

'{"A":0, "B":1}'} | Single record at a time and key-value pairs. | "$record" | "$features_kvp"

'{"A":0, "nested":{"B":1]]}' | Alternatively, use the fully verbose record_template for arbitrary structures. | "$record" | '{"A": "${A}", "nested": {"B": "$B"}'}

**Endpoint response for tabular data**

After the SageMaker Clarify processing job receives an inference endpoint invocation's response, it deserializes the response payload and extracts predictions from it. Use the analysis configuration accept_type parameter to specify the data format of the response payload. If accept_type is not provided, the SageMaker Clarify processing job will use the value of the content_type parameter as the model output format. For more information about accept_type, see Configure the Analysis.
The predictions could either consist of predicted labels for bias analysis, or probability values (scores) for feature importance analysis. In the predictor analysis configuration, the following three parameters extract the predictions.

- The parameter `probability` is used to locate the probability values (scores) in the endpoint response.
- The parameter `label` is used to locate the predicted labels in the endpoint response.
- (Optional) The parameter `label_headers` provides the predicted labels for a multiclass model.

The following guidelines pertain to endpoint responses in CSV, JSON Lines, and JSON formats.

**Endpoint Response is in CSV format**

If the response payload is in CSV format (MIME type: `text/csv`), the SageMaker Clarify processing job deserializes each row. It then extracts the predictions from the deserialized data using the column indexes provided in the analysis configuration. The rows in the response payload must match the records in the request payload.

The following tables provide examples of response data in different formats and for different problem types. Your data can vary from these examples, as long as the predictions can be extracted according to the analysis configuration.

The following sections show example endpoint responses in CSV formats.

**Endpoint response is in CSV format and contains probability only**

The following table is an example endpoint response for regression and binary classification problems.

<table>
<thead>
<tr>
<th>Endpoint request payload</th>
<th>Endpoint response payload (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record.</td>
<td>'0.6'</td>
</tr>
<tr>
<td>Two records (results in one line, divided by comma).</td>
<td>'0.6,0.3'</td>
</tr>
<tr>
<td>Two records (results in two lines).</td>
<td>'0.6\n0.3'</td>
</tr>
</tbody>
</table>

For the previous example, the endpoint outputs a single probability value (score) of the predicted label. To extract probabilities using the index and use them for feature importance analysis, set the analysis configuration parameter `probability` to column index 0. These probabilities can also be used for bias analysis if they're converted to binary value by using the `probability_threshold` parameter. For more information about `probability_threshold`, see Configure the Analysis.

The following table is an example endpoint response for a multiclass problem.

<table>
<thead>
<tr>
<th>Endpoint request payload</th>
<th>Endpoint response payload (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record of a multiclass model (three classes).</td>
<td>'0.1,0.6,0.3'</td>
</tr>
<tr>
<td>Two records of a multiclass model (three classes).</td>
<td>'0.1,0.6,0.3\n0.2,0.5,0.3'</td>
</tr>
</tbody>
</table>

For the previous example, the endpoint outputs a list of probabilities (scores). If no index is provided, all values are extracted and used for feature importance analysis. If the analysis configuration parameter
`label_headers` is provided. Then the SageMaker Clarify processing job can select the label header of the max probability as the predicted label, which can be used for bias analysis. For more information about `label_headers`, see Configure the Analysis.

**Endpoint response is in CSV format and contains predicted label only**

The following table is an example endpoint response for regression and binary classification problems.

<table>
<thead>
<tr>
<th>Endpoint request payload</th>
<th>Endpoint response payload (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record</td>
<td>'1'</td>
</tr>
<tr>
<td>Two records (results in one line, divided by comma)</td>
<td>'1,0'</td>
</tr>
<tr>
<td>Two records (results in two lines)</td>
<td>'1\n0'</td>
</tr>
</tbody>
</table>

For the previous example, the endpoint outputs the predicted label instead of probability. Set the `label` parameter of the predictor configuration to column index 0 so that the predicted labels can be extracted using the index and used for bias analysis.

**Endpoint response is in CSV format and contains predicted label and probability**

The following table is an example endpoint response for regression and binary classification problems.

<table>
<thead>
<tr>
<th>Endpoint request payload</th>
<th>Endpoint response payload (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record</td>
<td>'1,0.6'</td>
</tr>
<tr>
<td>Two records</td>
<td>'1,0.6\n0,0.3'</td>
</tr>
</tbody>
</table>

For the previous example, the endpoint outputs the predicted label followed by its probability. Set the `label` parameter of the predictor configuration to column index 0, and set `probability` to column index 1 to extract both parameter values.

**Endpoint response is in CSV format and contains predicted labels and probabilities (multiclass)**

A multiclass model trained by Amazon SageMaker Autopilot can be configured to output the string representation of the list of predicted labels and probabilities (see Autopilot: Configure inference output in generated containers). The following example table shows an example endpoint response from a model that is configured to output `predicted_label`, `probability`, `labels`, and `probabilities`.

<table>
<thead>
<tr>
<th>Endpoint request payload</th>
<th>Endpoint response payload (string representation)</th>
</tr>
</thead>
</table>
| Single record            | ""dog"",0.6,\"[\"cat\", \"dog\", \"fish\"]\",[0.1, 0.6, 0.3]"
| Two records              | ""dog"",0.6,\"[\"cat\", \"dog\", \"fish\"]\",[0.1, 0.6, 0.3]\n""cat"",0.7,\"[\"cat\", \"dog\", \"fish\"]\",[0.7, 0.2, 0.1]"
For the previous example, the SageMaker Clarify processing job can be configured in the following ways to extract the predictions.

For bias analysis, the previous example can be configured as one of the following.

- Set the `label` parameter of the `predictor` configuration to 0 to extract the predicted label.
- Set the parameter to 2 to extract the predicted labels, and set `probability` to 3 to extract the corresponding probabilities. The SageMaker Clarify processing job can automatically determine the predicted label by identifying the label with the highest probability value. Referring to the previous example of a single record, the model predicts three labels: cat, dog, and fish, with corresponding probabilities of 0.1, 0.6, and 0.3. Based on these probabilities, the predicted label is dog, as it has the highest probability value of 0.6.
- Set `probability` to 3 to extract the probabilities. If `label_headers` is provided, then the SageMaker Clarify processing job can automatically determine the predicted label by identifying the label header with the highest probability value.

For feature importance analysis, the previous example can be configured as follows.

- Set `probability` to 3 extract the probabilities of all the predicted labels. Then, feature attributions will be computed for all the labels. If the customer doesn't specify `label_headers`, then the predicted labels will be used as label headers in the analysis report.

**Endpoint Response is in JSON Lines format**

If the response payload is in JSON Lines format (MIME type: `application/jsonlines`), the SageMaker Clarify processing job deserializes each line as JSON. It then extracts predictions from the deserialized data using JMESPath expressions provided in analysis configuration. The lines in the response payload must match the records in the request payload. The following tables shows examples of response data in different formats. Your data can vary from these examples, as long as the predictions can be extracted according to the analysis configuration.

The following sections show example endpoint responses in JSON Lines formats.

**Endpoint response is in JSON Lines format and contains probability only**

The following table is an example endpoint response that only outputs the probability value (score).

<table>
<thead>
<tr>
<th>Endpoint request payload</th>
<th>Endpoint response payload (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record</td>
<td>'{&quot;score&quot;:0.6}'</td>
</tr>
</tbody>
</table>
| Two records              | '{"score":0.6}
{"score":0.3}'                                |

For the previous example, set the analysis configuration parameter `probability` to JMESPath expression "score" to extract its value.

**Endpoint response is in JSON Lines format and contains predicted label only**

The following table is an example endpoint response that only outputs the predicted label.

<table>
<thead>
<tr>
<th>Endpoint request payload</th>
<th>Endpoint response payload (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record</td>
<td>'{&quot;prediction&quot;:1}'</td>
</tr>
</tbody>
</table>
Configure a SageMaker Clarify Processing Job

## Endpoint request payload

<table>
<thead>
<tr>
<th></th>
<th>Endpoint response payload (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Two records</td>
<td>&quot;{&quot;prediction&quot;:1}\n{&quot;prediction&quot;:0}&quot;</td>
</tr>
</tbody>
</table>

For the previous example, set the `label` parameter of the predictor configuration to JMESPath expression `prediction`. Then, the SageMaker Clarify processing job can extract the predicted labels for bias analysis. For more information, see [Configure the Analysis](#).

**Endpoint response is in JSON Lines format and contains predicted label and probability**

The following table is an example endpoint response that outputs the predicted label and its score.

<table>
<thead>
<tr>
<th></th>
<th>Endpoint response payload (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record</td>
<td>&quot;{&quot;prediction&quot;:1,&quot;score&quot;:0.6}&quot;</td>
</tr>
<tr>
<td>Two records</td>
<td>&quot;{&quot;prediction&quot;:1,&quot;score&quot;:0.6}\n{&quot;prediction&quot;:0,&quot;score&quot;:0.3}&quot;</td>
</tr>
</tbody>
</table>

For the previous example, set the `label` parameter of the predictor configuration to JMESPath expression "prediction" to extract the predicted labels. Set `probability` to JMESPath expression "score" to extract the probability. For more information, see [Configure the Analysis](#).

**Endpoint response is in JSON Lines format and contains predicted labels and probabilities (multiclass)**

The following table is an example endpoint response from a multiclass model that outputs the following:

- A list of predicted labels.
- Probabilities, and the selected predicted label and its probability.

<table>
<thead>
<tr>
<th></th>
<th>Endpoint response payload (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record</td>
<td>&quot;{&quot;predicted_label&quot;:&quot;dog&quot;,&quot;probability&quot;:0.6,&quot;predicted_labels&quot;: [&quot;cat&quot;,&quot;dog&quot;,&quot;fish&quot;],&quot;probabilities&quot;: [0.1,0.6,0.3]}&quot;</td>
</tr>
<tr>
<td>Two records</td>
<td>&quot;{&quot;predicted_label&quot;:&quot;dog&quot;,&quot;probability&quot;:0.6,&quot;predicted_labels&quot;: [&quot;cat&quot;,&quot;dog&quot;,&quot;fish&quot;],&quot;probabilities&quot;: [0.1,0.6,0.3]}\n{&quot;predicted_label&quot;:&quot;cat&quot;,&quot;probability&quot;:0.7,&quot;predicted_labels&quot;: [&quot;cat&quot;,&quot;dog&quot;,&quot;fish&quot;],&quot;probabilities&quot;: [0.7,0.2,0.1]}&quot;</td>
</tr>
</tbody>
</table>

For the previous example, the SageMaker Clarify processing job can be configured in several ways to extract the predictions.

For bias analysis, the previous example can be configured as one of the following.

- Set the `label` parameter of the predictor configuration to JMESPath expression "predicted_label" to extract the predicted label.
- Set the parameter to JMESPath expression "predicted_labels" to extract the predicted labels. Set `probability` to JMESPath expression "probabilities" to extract their probabilities. The SageMaker Clarify job automatically determine the predicted label by identifying the label with the highest probability value.
• Set probability to JMESPath expression "probabilities" to extract their probabilities. If label_headers is provided, then the SageMaker Clarify processing job can automatically determine the predicted label by identifying the label with the highest probability value.

For feature importance analysis, do the following.

• Set probability to the JMESPath expression "probabilities" to extract their probabilities of all the predicted labels. Then, feature attributions will be computed for all the labels.

**Endpoint Response is in JSON format**

If the response payload is in JSON format (MIME type: application/json), the SageMaker Clarify processing job deserializes the entire payload as JSON. It then extracts predictions from the deserialized data using JMESPath expressions provided in the analysis configuration. The records in the response payload must match the records in the request payload.

The following sections show example endpoint responses in JSON formats. The sections contain tables with examples of response data in different formats and for different problem types. Your data can vary from these examples, as long as the predictions can be extracted according to the analysis configuration.

**Endpoint response is in JSON format and contains probability only**

The following table is an example response from an endpoint that only outputs the probability value (score).

<table>
<thead>
<tr>
<th>Endpoint request payload</th>
<th>Endpoint response payload (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record</td>
<td>'0.6'</td>
</tr>
<tr>
<td>Two records</td>
<td>'0.6,0.3'</td>
</tr>
</tbody>
</table>

For the previous example, there is no line break in the response payload. Instead, a single JSON object contains a list of scores, one for each record in the request. Set the analysis configuration parameter probability to JMESPath expression "[*]" to extract the value.

**Endpoint response is in JSON format and contains predicted label only**

The following table is an example response from an endpoint that only outputs the predicted label.

<table>
<thead>
<tr>
<th>Endpoint request payload</th>
<th>Endpoint response payload (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record</td>
<td>'{&quot;predicted_labels&quot;:[1]}'</td>
</tr>
<tr>
<td>Two records</td>
<td>'{&quot;predicted_labels&quot;:[1,0]}'</td>
</tr>
</tbody>
</table>

Set the label parameter of the predictor configuration to JMESPath expression "predicted_labels", and then the SageMaker Clarify processing job can extract the predicted labels for bias analysis.

**Endpoint response is JSON format and contains predicted label and probability**

The following table is an example response from an endpoint that outputs the predicted label and its score.
Configure a SageMaker Clarify Processing Job

**Endpoint request payload** | **Endpoint response payload (string representation)**
---|---
Single record | ‘{"predictions":[{"label":1,"score":0.6}]}
Two records | ‘{"predictions":[{"label":1,"score":0.6},
{"label":0,"score":0.3}]}

For the previous example, set the `label` parameter of the `predictor` configuration to the JMESPath expression "predictions[].label" to extract the predicted labels. Set `probability` to JMESPath expression "predictions[].score" to extract the probability.

**Endpoint response is in JSON format and contains predicted labels and probabilities (multiclass)**

The following table is an example response from an endpoint that from a multiclass model that outputs the following:

- A list of predicted labels.
- Probabilities, and the selected predicted label and its probability.

---

**Endpoint request payload** | **Endpoint response payload (string representation)**
---|---
Single record | ‘[{"predicted_label":"dog","probability":0.6,"predicted_labels":["cat","dog","fish"],"probabilities":[0.1,0.6,0.3}]}
Two records | ‘[{"predicted_label":"dog","probability":0.6,"predicted_labels":["cat","dog","fish"],"probabilities":[0.1,0.6,0.3]},
{"predicted_label":"cat","probability":0.7,"predicted_labels":["cat","dog","fish"],"probabilities":[0.7,0.2,0.1}]}

The SageMaker Clarify processing job can be configured in several ways to extract the predictions.

For bias analysis, the previous example can be configured as one of the following.

- Set the `label` parameter of the `predictor` configuration to JMESPath expression "[].predicted_label" to extract the predicted label.
- Set the parameter to JMESPath expression "[].predicted_labels" to extract the predicted labels. Set `probability` to JMESPath expression "[].probabilities" to extract their probabilities. The SageMaker Clarify processing job can automatically determine the predicted label by identifying the label with the highest proximity value.
- Set `probability` to JMESPath expression "[].probabilities" to extract their probabilities. If `label_headers` is provided, then the SageMaker Clarify processing job can automatically determine the predicted label by identifying the label with the highest probability value.

For feature importance analysis, set `probability` to JMESPath expression "[].probabilities" to extract their probabilities of all the predicted labels. Then, feature attributions will be computed for all the labels.

**Pre-check endpoint request and response for tabular data**

We recommend that you deploy your model to a SageMaker real-time inference endpoint, and send requests to the endpoint. Manually examine the requests and responses to make sure that both are...
compliant with the requirements in the Endpoint requests for tabular data (p. 3170) section and the Endpoint response for tabular data (p. 3171) section. If your model container supports batch requests, you can start with a single record request, and then try two or more records.

The following commands show how to request a response using the AWS CLI. The AWS CLI is pre-installed in SageMaker Studio, and SageMaker Notebook instances. If you must to install the AWS CLI, follow this installation guide.

```
aws sagemaker-runtime invoke-endpoint \
--endpoint-name $ENDPOINT_NAME \
--content-type $CONTENT_TYPE \
--accept $ACCEPT_TYPE \
--body $REQUEST_DATA \
$CLI_BINARY_FORMAT \
/dev/stderr 1>/dev/null
```

The parameters are defined, as follows.

- `$ENDPOINT_NAME` – The name of the endpoint.
- `$CONTENT_TYPE` – The MIME type of the request (model container input).
- `$ACCEPT_TYPE` – The MIME type of the response (model container output).
- `$REQUEST_DATA` – The requested payload string.
- `$CLI_BINARY_FORMAT` – The format of the command line interface (CLI) parameter. For AWS CLI v1, this parameter should remain blank. For v2, this parameter should be set to `--cli-binary-format raw-in-base64-out`.

**Note**
AWS CLI v2 passes binary parameters as base64-encoded strings by default.

The following request and response examples to and from the endpoint use AWS CLI v1.

**Endpoint request and response in CSV format**

In the following code example, the request consists of a single record and the response is its probability value.

```
aws sagemaker-runtime invoke-endpoint \
--endpoint-name test-endpoint-sagemaker-xgboost-model \
--content-type text/csv \
--accept text/csv \
--body '1,2,3,4' \
/dev/stderr 1>/dev/null
```

From the previous code example, the response output follows.

```
0.6
```

In the following code example, the request consists of two records, and the response includes their probabilities, which are separated by a comma.

```
aws sagemaker-runtime invoke-endpoint \
--endpoint-name test-endpoint-sagemaker-xgboost-model \
--content-type text/csv \
--accept text/csv \
--body '1,2,3,4
5,6,7,8'
```
From the previous code example, the `$ `content` expression in the `--body` tells the command to interpret `\n` in the content as a line break. The response output follows.

```
0.6,0.3
```

In the following code example, the request consists of two records, the response includes their probabilities, separated with a line break.

```
aws sagemaker-runtime invoke-endpoint \
   --endpoint-name test-endpoint-csv-1 \
   --content-type text/csv \
   --accept text/csv \
   --body $'1,2,3,4\n5,6,7,8'$ \
   /dev/stderr 1>/dev/null
```

From the previous code example, the response output follows.

```
0.6
0.3
```

In the following code example, the request consists of a single record, and the response is probability values from a multiclass model containing three classes.

```
aws sagemaker-runtime invoke-endpoint \
   --endpoint-name test-endpoint-csv-1 \
   --content-type text/csv \
   --accept text/csv \
   --body '1,2,3,4' \
   /dev/stderr 1>/dev/null
```

From the previous code example, the response output follows.

```
0.1,0.6,0.3
```

In the following code example, the request consists of two records, and the response includes their probability values from a multiclass model containing three classes.

```
aws sagemaker-runtime invoke-endpoint \
   --endpoint-name test-endpoint-csv-1 \
   --content-type text/csv \
   --accept text/csv \
   --body $'1,2,3,4\n5,6,7,8'$ \
   /dev/stderr 1>/dev/null
```

From the previous code example, the response output follows.

```
0.1,0.6,0.3
0.2,0.5,0.3
```

In the following code example, the request consists of two records, and the response includes predicted label and probability.

```
aws sagemaker-runtime invoke-endpoint \
```
Configure a SageMaker Clarify Processing Job

```
--endpoint-name test-endpoint-csv-2 \
--content-type text/csv \
--accept text/csv \
--body $'1,2,3,4\n5,6,7,8' \
/dev/stderr 1>/dev/null
```

From the previous code example, the response output follows.

```
1,0.6
0,0.3
```

In the following code example, the request consists of two records and the response includes label headers and probabilities.

```
aws sagemaker-runtime invoke-endpoint \
--endpoint-name test-endpoint-csv-3 \
--content-type text/csv \
--accept text/csv \
--body $'1,2,3,4\n5,6,7,8' \
/dev/stderr 1>/dev/null
```

From the previous code example, the response output follows.

```
"['cat','dog','fish']","[0.1,0.6,0.3]"
"['cat','dog','fish']","[0.2,0.5,0.3]"
```

**Endpoint request and response in JSON Lines format**

In the following code example, the request consists of a single record and the response is its probability value.

```
aws sagemaker-runtime invoke-endpoint \
--endpoint-name test-endpoint-jsonlines \
--content-type application/jsonlines \
--accept application/jsonlines \
--body '{"features":["This is a good product",5]}' \
/dev/stderr 1>/dev/null
```

From the previous code example, the response output follows.

```
{"score":0.6}
```

In the following code example, the request contains two records, and the response includes predicted label and probability.

```
aws sagemaker-runtime invoke-endpoint \
--endpoint-name test-endpoint-jsonlines-2 \
--content-type application/jsonlines-2 \
--accept application/jsonlines \
--body $'{"features":[1,2,3,4]\\"features":[5,6,7,8]}' \
/dev/stderr 1>/dev/null
```

From the previous code example, the response output follows.

```
{"predicted_label":1,"probability":0.6}
```
In the following code example, the request contains two records, and the response includes label headers and probabilities.

```bash
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name test-endpoint-jsonlines-3 \
  --content-type application/jsonlines \
  --accept application/jsonlines \
  --body $'{"data":{"features":[1,2,3,4]}\n{"data":{"features":[5,6,7,8]}}}'' \
  /dev/stderr 1>/dev/null
```

From the previous code example, the response output follows.

```json
["predicted_labels":["cat","dog","fish"],"probabilities":[0.1,0.6,0.3]}] 
["predicted_labels":["cat","dog","fish"],"probabilities":[0.2,0.5,0.3]}
```

### Endpoint request and response in mixed formats

In the following code example, the request is in CSV format and the response is in JSON Lines format.

```bash
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name test-endpoint-csv-in-jsonlines-out \
  --content-type text/csv \
  --accept application/jsonlines \
  --body '$1,2,3,4\n5,6,7,8' \
  /dev/stderr 1>/dev/null
```

From the previous code example, the response output follows.

```json
{"probability":0.6} 
{"probability":0.3}
```

In the following code example, the request is in JSON Lines format and the response is in CSV format.

```bash
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name test-endpoint-jsonlines-in-csv-out \
  --content-type application/jsonlines \
  --accept text/csv \
  --body $'{"features":[1,2,3,4]}\n{"features":[5,6,7,8]}' \
  /dev/stderr 1>/dev/null
```

From the previous code example, the response output follows.

```
0.6 
0.3
```

In the following code example, the request is in CSV format and the response is in JSON format.

```bash
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name test-endpoint-csv-in-jsonlines-out \
  --content-type text/csv \
  --accept application/jsonlines \
  --body $'1,2,3,4\n5,6,7,8' \
```

From the previous code example, the response output follows.

```
0.6 
0.3
```

In the following code example, the request is in CSV format and the response is in JSON format.
Image data

A SageMaker Clarify processing job provides support for explaining images. This topic provides the data format requirements for image data. For more information, see [SageMaker Clarify Computer Vision](#).

Image dataset prerequisites

An image dataset contains one or more image files. To identify an input dataset to the SageMaker Clarify processing job, set either a `ProcessingInput` named dataset or the analysis configuration `dataset_uri` parameter to an Amazon S3 URI prefix of your image files.

The supported image file formats and file extensions are listed in the following table.

<table>
<thead>
<tr>
<th>Image format</th>
<th>File extension</th>
</tr>
</thead>
<tbody>
<tr>
<td>JPEG</td>
<td>jpg, jpeg</td>
</tr>
<tr>
<td>PNG</td>
<td>png</td>
</tr>
</tbody>
</table>

Set the analysis configuration `dataset_type` parameter to `application/x-image`. Because the type is not a specific image file format, the `content_type` will be used to decide the image file format and extension.

The SageMaker Clarify processing job loads each image file to a 3-dimensional NumPy array for further processing. The three dimensions include height, width, and RGB values of each pixel.

Endpoint request for image data

The SageMaker Clarify processing job converts the raw RGB data of an image into a compatible image format, such as JPEG. It does this before it sends the data to the endpoint for predictions. The supported image formats are as follows.

<table>
<thead>
<tr>
<th>Data Format</th>
<th>MIME type</th>
<th>File extension</th>
</tr>
</thead>
<tbody>
<tr>
<td>JPEG</td>
<td>image/jpeg</td>
<td>jpg, jpeg</td>
</tr>
<tr>
<td>PNG</td>
<td>image/png</td>
<td>png</td>
</tr>
<tr>
<td>NPY</td>
<td>application/x-npy</td>
<td>All above</td>
</tr>
</tbody>
</table>

Specify the data format of the request payload by using the analysis configuration parameter `content_type`. If the `content_type` is not provided, the data format defaults to `image/jpeg`.

Endpoint response for image data

Upon receiving the response of an inference endpoint invocation, the SageMaker Clarify processing job deserializes response payload and then extracts the predictions from it.
Image classification problem

The data format of the response payload should be specified by the analysis configuration parameter accept_type. If accept_type is not provided, the data format defaults to application/json. The supported formats are the same as those described in the Endpoint response for tabular data in the tabular data section.

As an example, the SageMaker built-in image classification algorithms accepts a single image and then returns an array of probability values (scores), each for a class.

As shown in the following table, when the content_type parameter is set to application/jsonlines, the response is a JSON object.

<table>
<thead>
<tr>
<th>Endpoint request payload</th>
<th>Endpoint response payload (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single image</td>
<td>'{&quot;prediction&quot;:[0.1,0.6,0.3]}'</td>
</tr>
</tbody>
</table>

In the previous example, set the probability parameter to JMESPath expression "prediction" to extract the scores.

When the content_type is set to application/json, the response is a JSON object, as shown in the following table.

<table>
<thead>
<tr>
<th>Endpoint request payload</th>
<th>Endpoint response payload (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single image</td>
<td>'[0.1,0.6,0.3]'</td>
</tr>
</tbody>
</table>

In the previous example, set probability to JMESPath expression "[]" to extract all the elements of the array. In the previous example, \([0.1, 0.6, 0.3]\) is extracted. Alternatively, if you skip setting the probability configuration parameter, then all the elements of the array are also extracted. This is because the entire payload is deserialized as the predictions.

Object detection problem

The analysis configuration accept_type defaults to application/json and the only supported format is the Object Detection Inference Format.

The following table is an example response from an endpoint that outputs an array. Each element of the array is an array of values containing the class index, the confidence score, and the bounding box coordinates of the detected object.

<table>
<thead>
<tr>
<th>Endpoint request payload</th>
<th>Endpoint response payload (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single image (one object)</td>
<td>'[[4.0, 0.86419455409049988, 0.308374733924866, 0.07030484080314636, 0.7110607028007507, 0.9345266819000244]]'</td>
</tr>
<tr>
<td>Single image (two objects)</td>
<td>'[[4.0, 0.86419455409049988, 0.308374733924866, 0.07030484080314636, 0.7110607028007507, 0.9345266819000244], [0.0, 0.73376623392105103]]'</td>
</tr>
</tbody>
</table>
The following table is an example response from an endpoint that outputs a JSON object with a key referring to the array. Set the analysis configuration probability to the key "prediction" to extract the values.

<table>
<thead>
<tr>
<th>Endpoint request payload</th>
<th>Endpoint response payload (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single image (one object)</td>
<td>'{&quot;prediction&quot;:[[4.0, 0.86419455409049988, 0.3088374733924866, 0.07030484080314636, 0.7110607028007507, 0.9345266819000244], [0.0, 0.73376623392105103, 0.5714187026023865, 0.40427327156066895, 0.827075183391571, 0.9712159633636475]]}'}</td>
</tr>
<tr>
<td>Single image (two objects)</td>
<td>'{&quot;prediction&quot;:[[4.0, 0.86419455409049988, 0.3088374733924866, 0.07030484080314636, 0.7110607028007507, 0.9345266819000244], [0.0, 0.73376623392105103, 0.5714187026023865, 0.40427327156066895, 0.827075183391571, 0.9712159633636475]]}'}</td>
</tr>
</tbody>
</table>

Pre-check endpoint request and response for image data

We recommend that you deploy your model to a SageMaker real-time inference endpoint, and send requests to the endpoint. Manually examine the requests and responses. Make sure that both are compliant with the requirements in the Endpoint request for image data section and Endpoint response for image data section.

The following are two code examples showing how to send requests and examine the responses for both image classification and object detection problems.

**Image classification problem**

The following example code instructs an endpoint to read a PNG file and then classifies it.

```
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name test-endpoint-sagemaker-image-classification \
  --content-type "image/png" \
  --accept "application/json" \
  --body fileb://./test.png \
  /dev/stderr 1>/dev/null
```

From the previous code example, the response output follows.

```
[0.1, 0.6, 0.3]
```

**Object detection problem**

The following example code instructs an endpoint to read a JPEG file and then detects the objects in it.

```
aws sagemaker-runtime invoke-endpoint \
```

3184
## Run SageMaker Clarify Processing Jobs for Bias Analysis and Explainability

To analyze your data and models for bias and explainability using SageMaker Clarify, you must configure a SageMaker Clarify processing job. This guide shows how to configure the job inputs, outputs, resources, and analysis configuration using the SageMaker Python SDK API `SageMakerClarifyProcessor`.

The API acts as a high-level wrapper of the SageMaker `CreateProcessingJob` API. It hides many of the details that are involved in setting up a SageMaker Clarify processing job. The details to set up a job include retrieving the SageMaker Clarify container image URI and generating the analysis configuration file. The following steps show you how to configure, initialize and launch a SageMaker Clarify processing job.

### Configure a SageMaker Clarify processing job using the API

1. Define the configuration objects for each portion of the job configuration. These portions can include the following:
   - The input dataset and output location: `DataConfig`.
   - The model or endpoint to be analyzed: `ModelConfig`.
   - Bias analysis parameters: `BiasConfig`.
   - SHapley Additive exPlanations (SHAP) analysis parameters: `SHAPConfig`.

   The configuration objects for a SageMaker Clarify processing job vary for different types of data formats and use cases. Configuration examples for tabular data in CSV (p. 3186) and JSON Lines (p. 3190) format, natural language processing (NLP (p. 3191)), and computer vision (p. 3193) problems are provided in the following sections.

2. Create a `SageMakerClarifyProcessor` object and initialize it with parameters that specify the job resources. These resources include parameters such as the number of compute instances to use.

   The following code example shows how to create a `SageMakerClarifyProcessor` object and instruct it to use one ml.c4.xlarge compute instance to do the analysis.

   ```python
   from sagemaker import clarify

   clarify_processor = clarify.SageMakerClarifyProcessor(
       role=role,
       instance_count=1,
       instance_type='ml.c4.xlarge',
   )
   ```

   From the previous code example, the response output follows.

```json
{"prediction":
[[4.0, 0.864194549540949988, 0.3088374733924866, 0.07030484080314636, 0.7110607028807507, 0.9345266819000244],[0.0, 0.73576625392105103, 0.57141870280314636, 0.40427327156066895, 0.827075183391571, 0.9712159633636475],[4.0, 0.32643985450267792, 0.3677481412887573, 0.034883320331573486, 0.6318609714508057, 0.5967587828636169],[8.0, 0.22552496790885925, 0.6152569651603699, 0.5722782611846924, 0.882301390171051, 0.8985623121261597],[3.0, 0.42260299175977707, 0.019305512309074402, 0.08386176824569702, 0.39093565940856934, 0.9574796557426453]]
```
3. Call the specific run method of the `SageMakerClarifyProcessor` object with the configuration objects for your use case to launch the job. These run methods include the following:

- `run_pre_training_bias`
- `run_post_training_bias`
- `run_bias`
- `run_explainability`
- `run_bias_and_explainability`

This `SageMakerClarifyProcessor` handles several tasks behind the scenes. These tasks include retrieving the SageMaker Clarify container image universal resource identifier (URI), composing an analysis configuration file based on the provided configuration objects, uploading the file to an Amazon S3 bucket, and configuring the SageMaker Clarify processing job.

The following expandable sections show how to compute **pre-training** and **post-training bias metrics**, **SHAP values**, and **partial dependence plots (PDPs)**. The sections show feature importance for these data types:

- Tabular datasets in CSV format or JSON Lines format
- Natural language processing (NLP) datasets
- Computer vision datasets

A guide to run parallel SageMaker Clarify processing jobs with distributed training using **Spark** follows the expandable sections.

**Analyze tabular data in CSV format**

The following examples show how to configure bias analysis and explainability analysis for a tabular dataset in CSV format. In these examples, the incoming dataset has four feature columns and one binary label column, `Target`. The contents of the dataset are as follows. A label value of 1 indicates a positive outcome.

```
Target, Age, Gender, Income, Occupation
0,25,0,2850,2
1,36,0,6585,0
1,22,1,1759,1
0,48,0,3446,1
...  
```

This `DataConfig` object specifies the input dataset and where to store the output. The `s3_data_input_path` parameter can either be a URI of a dataset file or an Amazon S3 URI prefix. If you provide a S3 URI prefix, the SageMaker Clarify processing job recursively collects all Amazon S3 files located under the prefix. The value for `s3_output_path` should be an S3 URI prefix to hold the analysis results. The following code example shows how to specify a data configuration for the previous sample input dataset.

```python
data_config = clarify.DataConfig(
    s3_data_input_path=dataset_s3_uri,
    dataset_type='text/csv',
    headers=['Target', 'Age', 'Gender', 'Income', 'Occupation'],
    label='Target',
    s3_output_path=clarify_job_output_s3_uri,
)```
How to compute all pre-training bias metrics for a CSV dataset

The following code sample shows how to configure a `BiasConfig` object to measure bias of the previous sample input towards samples with a `Gender` value of 0.

```python
bias_config = clarify.BiasConfig(
    label_values_or_threshold=[1],
    facet_name='Gender',
    facet_values_or_threshold=[0],
)
```

The following code example shows how to use a run statement to launch a SageMaker Clarify processing job that computes all pre-training bias metrics for an input dataset.

```python
clarify_processor.run_pre_training_bias(
    data_config=data_config,
    data_bias_config=bias_config,
    methods="all",
)
```

Alternatively, you can choose which metrics to compute by assigning a list of pre-training bias metrics to the methods parameter. For example, replacing `methods="all"` with `methods=['CI', 'DPL']` instructs the SageMaker Clarify Processor to compute only Class Imbalance and Difference in Proportions of Labels.

How to compute all post-training bias metrics for a CSV dataset

You can compute pre-training bias metrics prior to training. However, to compute post-training bias metrics, you must have a trained model. The following example output is from a binary classification model that outputs data in CSV format. In this example output, each row contains two columns. The first column contains the predicted label, and the second column contains the probability value for that label.

```
0,0.028986845165491
1,0.825382471084594
...
```

In the following example configuration, the `ModelConfig` object instructs the job to deploy the SageMaker model to an ephemeral endpoint. The endpoint uses one `ml.m4.xlarge` inference instance. Because the parameter `content_type` and `accept_type` are not set, they automatically use the value of the parameter `dataset_type`, which is `text/csv`.

```python
model_config = clarify.ModelConfig(
    model_name=your_model,
    instance_type='ml.m4.xlarge',
    instance_count=1,
)
```

The following configuration example uses a `ModelPredictedLabelConfig` object with a label index of 0. This instructs the SageMaker Clarify processing job to locate the predicted label in the first column of the model output. The Processing job uses zero-based indexing in this example.

```python
predicted_label_config = clarify.ModelPredictedLabelConfig(
    label=0,
)
```
Combined with the previous configuration example, the following code example launches a SageMaker Clarify processing job to compute all the post-training bias metrics.

```python
clarify_processor.run_post_training_bias(
    data_config=data_config,
    data_bias_config=bias_config,
    model_config=model_config,
    model_predicted_label_config=predicted_label_config,
    methods="all",
)
```

Similarly, you can choose which metrics to compute by assigning a list of post-training bias metrics to the methods parameter. For example, replace methods="all" with methods=["DPPL", "DI"] to compute only Difference in Positive Proportions in Predicted Labels and Disparate Impact.

### How to compute all bias metrics for a CSV dataset

The following configuration example shows how to run all pre-training and post-training bias metrics in one SageMaker Clarify processing job.

```python
clarify_processor.run_bias(
    data_config=data_config,
    bias_config=bias_config,
    model_config=model_config,
    model_predicted_label_config=predicted_label_config,
    pre_training_methods="all",
    post_training_methods="all",
)
```

For an example notebook with instructions on how to run a SageMaker Clarify processing job in SageMaker Studio to detect bias, see [Fairness and Explainability with SageMaker Clarify](#).

### How to compute SHAP values for a CSV dataset

SageMaker Clarify provides feature attributions using the [KernelSHAP algorithm](#). SHAP analysis requires the probability value or score instead of predicted label, so this `ModelPredictedLabelConfig` object has probability index 1. This instructs the SageMaker Clarify processing job to extract the probability score from the second column of the model output (using zero-based indexing).

```python
probability_config = clarify.ModelPredictedLabelConfig(
    probability=1,
)
```

The `SHAPConfig` object provides SHAP analysis parameters. In this example, the SHAP baseline parameter is omitted and the value of the `num_clusters` parameter is 1. This instructs the SageMaker Clarify Processor to compute one SHAP baseline sample based on clustering the input dataset. If you want to choose the baseline dataset, see [SHAP Baselines for Explainability](#).

```python
shap_config = clarify.SHAPConfig(
    num_clusters=1,
)
```

The following code example launches a SageMaker Clarify processing job to compute SHAP values.

```python
clarify_processor.run_explainability(
    data_config=data_config,
    model_config=model_config,
)
```
Run SageMaker Clarify Processing Jobs

```python
model_scores=probability_config,
explainability_config=shap_config,
)
```

For an example notebook with instructions on how to run a SageMaker Clarify processing job in SageMaker Studio to compute SHAP values, see Fairness and Explainability with SageMaker Clarify.

How to compute partial dependence plots (PDPs) for a CSV dataset

PDPs show the dependence of the predicted target response on one or more input features of interest while holding all other features constant. An upward sloping line, or curve in the PDP, indicates that the relationship between the target and input feature(s) is positive, and the steepness indicates the strength of the relationship. A downward sloping line or curve indicates that if an input feature decreases, the target variable increases. Intuitively, you can interpret the partial dependence as the response of the target variable to each input feature of interest.

The following configuration example is for using a `PDPConfig` object to instruct the SageMaker Clarify processing job to compute the importance of the `Income` feature.

```python
pdp_config = clarify.PDPConfig(
    features=['Income'],
    grid_resolution=10,
)
```

In the previous example, the `grid_resolution` parameter divides the range of the `Income` feature values into 10 buckets. The SageMaker Clarify processing job will generate PDPs for `Income` split into 10 segments on the x-axis. The y-axis will show the marginal impact of `Income` on the target variable.

The following code example launches a SageMaker Clarify processing job to compute PDPs.

```python
clarify_processor.run_explainability(
    data_config=data_config,
    model_config=model_config,
    model_scores=probability_config,
    explainability_config=pdp_config,
)
```

For an example notebook with instructions on how to run a SageMaker Clarify processing job in SageMaker Studio to compute PDPs, see Explainability with SageMaker Clarify - Partial Dependence Plots (PDP).

How to compute both SHAP values and PDPs for a CSV dataset

You can compute both SHAP values and PDPs in a single SageMaker Clarify processing job. In the following configuration example, the `top_k_features` parameter of a new `PDPConfig` object is set to 2. This instructs the SageMaker Clarify processing job to compute PDPs for the 2 features that have the largest global SHAP values.

```python
shap_pdp_config = clarify.PDPConfig(
    top_k_features=2,
    grid_resolution=10,
)
```

The following code example launches a SageMaker Clarify processing job to compute both SHAP values and PDPs.

```python
clarify_processor.run_explainability(
    data_config=data_config,
    model_config=model_config,
    model_scores=probability_config,
    explainability_config=shap_pdp_config,
)
```
Analyze tabular data in JSON Lines format

The following examples show how to configure bias analysis and explainability analysis for a tabular dataset in SageMaker JSON Lines dense format. See JSONLINES Request Format (p. 1544) for more information. In these examples, the incoming dataset has the same data as the previous section, but they're in the JSON Lines format. Each line is a valid JSON object. The key `Features` points to an array of feature values, and the key `Label` points to the ground truth label.

```json
["Features":[25,0,2850,2],"Label":0]
["Features":[36,0,6585,0],"Label":1]
["Features":[22,1,1759,1],"Label":1]
["Features":[48,0,3446,1],"Label":0]
...
```

In the following configuration example, the `DataConfig` object specifies the input dataset and where to store the output. The features parameter is set to the JMESPath expression `Features` so that the SageMaker Clarify processing job can extract the array of features from each record. The label parameter is set to JMESPath expression `Label` so that the SageMaker Clarify processing job can extract the ground truth label from each record.

```python
data_config = clarify.DataConfig(
    s3_data_input_path=jsonl_dataset_s3_uri,
    dataset_type='application/jsonlines',
    headers=['Age', 'Gender', 'Income', 'Occupation', 'Target'],
    label='Label',
    features='Features',
    s3_output_path=clarify_job_output_s3_uri,
)
```

You must have a trained model to compute post-training bias metrics or feature importance. The following example is from a binary classification model that outputs JSON Lines data in the example's format. Each row of the model output is a valid JSON object. The key `predicted_label` points to the predicted label, and the key `probability` points to the probability value.

```json
{"predicted_label":0,"probability":0.028986845165491}
{"predicted_label":1,"probability":0.825382471084594}
...
```

In the following configuration example, a `ModelConfig` object instructs the SageMaker Clarify processing job to deploy the SageMaker model to an ephemeral endpoint. The endpoint uses one `ml.m4.xlarge` inference instance.

```python
model_config = clarify.ModelConfig(
    model_name=your_model,
    instance_type='ml.m4.xlarge',
    instance_count=1,
    content_template='{"Features":$features}',
)
```

In previous configuration example, the parameter `content_type` and `accept_type` are not set. Therefore, they automatically use the value of the `dataset_type` parameter of the `DataConfig`
object, which is application/jsonlines. The SageMaker Clarify processing job uses the content_template parameter to compose the model input by replacing the $features placeholder by an array of features.

The following example configuration shows how to set the label parameter of the ModelPredictedLabelConfig object to the JMESPath expression predicted_label. This will extract the predicted label from the model output.

```python
predicted_label_config = clarify.ModelPredictedLabelConfig(
    label='predicted_label',
)
```

The following example configuration shows how to set the probability parameter of the ModelPredictedLabelConfig object to the JMESPath expression probability. This will extract the score from the model output.

```python
probability_config = clarify.ModelPredictedLabelConfig(
    probability='probability',
)
```

To compute bias metrics and feature importance for datasets in JSON Lines format, use the same run statements and configuration objects as the previous section for CSV datasets. You can run a SageMaker Clarify processing job in SageMaker Studio to detect bias and compute feature importance. For instructions and an example notebook, see Fairness and Explainability with SageMaker Clarify (JSON Lines Format).

### Analyze tabular data for NLP explainability

SageMaker Clarify supports explanations for natural language processing (NLP) models. These explanations help you understand which sections of text are the most important for your model predictions. You can explain either the model prediction for a single instance of the input dataset, or model predictions from the baseline dataset. To understand and visualize a model's behavior, you can specify multiple levels of granularity. To do this, define the length of the text segment, such as its tokens, sentences, paragraphs.

SageMaker Clarify NLP explainability is compatible with both classification and regression models. You can also use SageMaker Clarify to explain your model's behavior on multi-modal datasets that contain text, categorical, or numerical features. NLP explainability for multi-modal datasets can help you understand how important each feature is to the model's output. SageMaker Clarify supports 62 languages and can handle text which includes multiple languages.

The following example shows an analysis configuration file for computing feature importance for NLP. In this example, the incoming dataset is a tabular dataset in CSV format, with one binary label column and two feature columns.

```python
0,2,"Flavor needs work"
1,3,"They taste good"
1,5,"The best"
0,1,"Taste is awful"
...
```

The following configuration example shows how to specify an input dataset in CSV format and output data path using the DataConfig object.

```python
nlp_data_config = clarify.DataConfig(
    s3_data_input_path=nlp_dataset_s3_uri,
)
```python
dataset_type='text/csv',
headers=['Target', 'Rating', 'Comments'],
label='Target',
s3_output_path=clarify_job_output_s3_uri,
)
```

The following example output was created from a binary classification model trained on the previous input dataset. The classification model accepts CSV data, and it outputs a single score in between 0 and 1.

```
0.491656005382537
0.569582343101501
...
```

The following example shows how to configure the `ModelConfig` object to deploy a SageMaker model. In this example, an ephemeral endpoint deploys the model. This endpoint uses one `ml.g4dn.xlarge` inference instance equipped with a GPU, for accelerated inferencing.

```python
nlp_model_config = clarify.ModelConfig(
    model_name=your_nlp_model_name,
    instance_type='ml.g4dn.xlarge',
    instance_count=1,
)
```

The following example shows how to configure the `ModelPredictedLabelConfig` object to locate the probability (score) in the first column with an index of 0.

```python
probability_config = clarify.ModelPredictedLabelConfig(
    probability=0,
)
```

The following example SHAP configuration shows how to run a token-wise explainability analysis using a model and an input dataset in the English language.

```python
text_config = clarify.TextConfig(
    language='english',
    granularity='token',
)
nlp_shap_config = clarify.SHAPConfig(
    baseline=[[4, '[MASK]']],
    num_samples=100,
    text_config=text_config,
)
```

In the previous example, the `TextConfig` object activates the NLP explainability analysis. The `granularity` parameter indicates that the analysis should parse tokens. In English, each token is a word. For other languages, see the [spaCy documentation for tokenization](https://spacy.io/api/vocab#tokenize), which SageMaker Clarify uses for NLP processing. The previous example also shows how to use an average Rating of 4 to set an in-place SHAP baseline instance. A special mask token `[MASK]` is used to replace a token (word) in `Comments`.

In the previous example, if the instance is 2, "Flavor needs work", set the baseline to an average Rating of 4 with the following baseline.

```
4, '[MASK]'
```
In the previous example, the SageMaker Clarify explainer iterates through each token and replaces it with the mask, as follows.

<table>
<thead>
<tr>
<th>Line</th>
<th>Text</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>&quot;[MASK] needs work&quot;</td>
</tr>
<tr>
<td>4</td>
<td>&quot;Flavor [MASK] work&quot;</td>
</tr>
<tr>
<td>4</td>
<td>&quot;Flavor needs [MASK]&quot;</td>
</tr>
</tbody>
</table>

Then, the SageMaker Clarify explainer will send each line to your model for predictions. This is so that the explainer learns the predictions with and without the masked words. The SageMaker Clarify explainer then uses this information to compute the contribution of each token.

The following code example launches a SageMaker Clarify processing job to compute SHAP values.

```python
clarify_processor.run_explainability(
    data_config=nlp_data_config,
    model_config=nlp_model_config,
    model_scores=probability_config,
    explainability_config=nlp_shap_config,
)
```

For an example notebook with instructions on how to run a SageMaker Clarify processing job in SageMaker Studio for NLP explainability analysis, see [Explaining Text Sentiment Analysis Using SageMaker Clarify](#).

### Analyze image data for computer vision explainability

SageMaker Clarify generates heat maps that provide insights into how your computer vision models classify and detect objects in your images.

In the previous configuration example, the input dataset consists of JPEG images.

```python
cv_data_config = clarify.DataConfig(
    s3_data_input_path=cv_dataset_s3_uri,
    dataset_type="application/x-image",
    s3_output_path=clarify_job_output_s3_uri,
)
```

In the previous configuration example, the DataConfig object contains an `s3_data_input_path` set to an S3 URI prefix. The SageMaker Clarify processing job recursively collects all image files located under the prefix.

### How to explain an image classification model

The SageMaker Clarify processing job explains images using the KernelSHAP algorithm, which treats the image as a collection of super pixels. Given a dataset consisting of images, the processing job outputs a dataset of images where each image shows the heat map of the relevant super pixels.

The following configuration example shows how to configure an explainability analysis using a SageMaker image classification model. See [Image Classification - MXNet (p. 1754)](##) for more information.

```python
ic_model_config = clarify.ModelConfig(
    model_name=your_cv_ic_model,
    instance_type="ml.p2.xlarge",
    instance_count=1,
    content_type="image/jpeg",
)`
In the previous configuration example, a model named `your_cv_ic_model`, has been trained to classify the animals on input JPEG images. The `ModelConfig` object in the previous example instructs the SageMaker Clarify processing job to deploy the SageMaker model to an ephemeral endpoint. For accelerated inferencing, the endpoint uses one `ml.p2.xlarge` inference instance equipped with a GPU.

After a JPEG image is sent to an endpoint, the endpoint classifies it and returns a list of scores. Each score is for a category. The `ModelPredictedLabelConfig` object provides the name of each category, as follows.

```python
ic_prediction_config = clarify.ModelPredictedLabelConfig(
    label_headers=['bird', 'cat', 'dog'],
)
```

An example output for the previous input of `['bird','cat','dog']` could be `0.3,0.6,0.1`, where `0.3` represents the confidence score for classifying an image as a bird.

The following example SHAP configuration shows how to generate explanations for an image classification problem. It uses an `ImageConfig` object to activate the analysis.

```python
ic_image_config = clarify.ImageConfig(
    model_type="IMAGE_CLASSIFICATION",
    num_segments=20,
    segment_compactness=5,
)

ic_shap_config = clarify.SHAPConfig(
    num_samples=100,
    image_config=ic_image_config,
)
```

SageMaker Clarify extracts features using the Simple Linear Iterative Clustering (SLIC) method from scikit-learn library for image segmentation. The previous configuration example, the `model_type` parameter, indicates the type of image classification problem. The parameter `num_segments` estimates how many approximate number of segments will be labeled in the input image. The number of segments is then passed to the `slic.n_segments` parameter.

Each segment of the image is considered a super-pixel, and local SHAP values are computed for each segment. The parameter `segment_compactness` determines the shape and size of the image segments that are generated by the scikit-image slic method. The sizes and shapes of the image segments are then passed to the `slic.compactness` parameter.

The following code example launches a SageMaker Clarify processing job to generate heat maps for your images. Positive heat map values show that the feature increased the confidence score of detecting the object. Negative values indicate that the feature decreased the confidence score.

```python
clarify_processor.run_explainability(
    data_config=cv_data_config,
    model_config=ic_model_config,
    model_scores=ic_prediction_config,
    explainability_config=ic_shap_config,
)
```

For a sample notebook that uses SageMaker Clarify to classify images and explain its classification, see Explaining Image Classification with SageMaker Clarify.
How to explain an object detection model

A SageMaker Clarify processing job can detect and classify objects in an image and then provide an explanation for the detected object. The process for explanation is as follows.

1. Image objects are first categorized into one of the classes in a specified collection. For example, if an object detection model can recognize cat, dog and fish, then these three classes are in a collection. This collection is specified by the `label_headers` parameter as follows.

   ```python
   clarify.ModelPredictedLabelConfig(
       label_headers=object_categories,
   )
   ```

2. The SageMaker Clarify processing job produces a confidence score for each object. A high confidence score indicates that it belongs to one of the classes in a specified collection. The SageMaker Clarify processing job also produces the coordinates of a bounding box that delimits the object. For more information about confidence scores and bounding boxes, see `Response Formats` (p. 1788).

3. SageMaker Clarify then provides an explanation for the detection of an object in the image scene. It uses the methods described in the `How to explain an image classification model` section.

In the following configuration example, a SageMaker object detection model `your_cv_od_model` is trained on JPEG images to identify the animals on them.

```python
od_model_config = clarify.ModelConfig(
    model_name=your_cv_od_model,
    instance_type="ml.p2.xlarge",
    instance_count=1,
    content_type="image/jpeg",
    accept_type="application/json",
)
```

The `ModelConfig` object in the previous configuration example instructs the SageMaker Clarify processing job to deploy the SageMaker model to an ephemeral endpoint. For accelerated imaging, this endpoint uses one `ml.p2.xlarge` inference instance equipped with a GPU.

In the following example configuration, the `ModelPredictedLabelConfig` object provides the name of each category for classification.

```python
ic_prediction_config = clarify.ModelPredictedLabelConfig(
    label_headers=['bird', 'cat', 'dog'],
)
```

The following example SHAP configuration shows how to generate explanations for an object detection.

```python
od_image_config = clarify.ImageConfig(
    model_type="OBJECT_DETECTION",
    num_segments=20,
    segment_compactness=5,
    max_objects=5,
    iou_threshold=0.5,
    context=1.0,
)
od_shap_config = clarify.SHAPConfig(
    num_samples=100,
    image_config=image_config,
)
In the previous example configuration, the ImageConfig object activates the analysis. The model_type parameter indicates that the type of problem is object detection. For a detailed description of the other parameters, see Configure the Analysis (p. 3144).

The following code example launches a SageMaker Clarify processing job to generate heat maps for your images. Positive heat map values show that the feature increased the confidence score of detecting the object. Negative values indicate that the feature decreased the confidence score.

```python
clarify_processor.run_explainability(
    data_config=cv_data_config,
    model_config=od_model_config,
    model_scores=od_prediction_config,
    explainability_config=od_shap_config,
)
```

For a sample notebook that uses SageMaker Clarify to detect objects in an image and explain its predictions, see Explaining object detection models with Amazon SageMaker Clarify.

**How to run parallel SageMaker Clarify processing jobs**

When working with large datasets, you can use Apache Spark to increase the speed of your SageMaker Clarify processing jobs. Spark is a unified analytics engine for large-scale data processing. When you request more than one instance per SageMaker Clarify processor, SageMaker Clarify uses the distributed computing capabilities from Spark.

The following configuration example shows how to use SageMakerClarifyProcessor to create a SageMaker Clarify processor with 5 compute instances. To run any jobs associated with the SageMakerClarifyProcessor, SageMaker Clarify using Spark distributed processing.

```python
from sagemaker import clarify

spark_clarify_processor = clarify.SageMakerClarifyProcessor(
    role=role,
    instance_count=5,
    instance_type='ml.c5.xlarge',
)
```

If you set the save_local_shap_values parameter of SHAPConfig to True, the SageMaker Clarify processing job saves the local SHAP value as multiple part files in the job output location.

To associate the local SHAP values to the input dataset instances, use the joinsource parameter of DataConfig. If you add more compute instances, we recommend that you also increase the instance_count of ModelConfig for the ephemeral endpoint. This prevents Spark workers' concurrent inference requests from overwhelming the endpoint. Specifically, we recommend that you use a one-to-one ratio of endpoint-to-processing instances.

**Get Analysis Results**

This topic shows how to get analysis results that SageMaker Clarify generates. After the SageMaker Clarify processing job is finished, you can download the output files to inspect, or visualize the results in SageMaker Studio.

The SageMaker Clarify processing job output directory contains the following files:
• analysis.json – A file that contains bias metrics and feature importance in JSON format.
• report.ipynb – A static notebook that contains code to help you visualize bias metrics and feature importance.
• explanations_shap/out.csv – A directory that is created and contains automatically generated files based on your specific analysis configurations. For example, if you activate the save_local_shap_values parameter, then per-instance local SHAP values will be saved to the explanations_shap directory. As another example, if your analysis configuration does not contain a value for the SHAP baseline parameter, the SageMaker Clarify explainability job computes a baseline by clustering the input dataset. It then saves the generated baseline to the directory.

The following sections provide detailed information about the schema and the report that’s generated by bias analysis, SHAP analysis, computer vision explainability analysis, and partial dependence plots (PDPs) analysis. If the configuration analysis contains parameters to compute multiple analyses, then the results are aggregated into one analysis and one report file.

Topics
• Bias analysis (p. 3197)
• SHAP analysis (p. 3199)
• Computer vision (CV) explainability analysis (p. 3202)
• Partial dependence plots (PDPs) analysis (p. 3203)

Bias analysis

Amazon SageMaker Clarify uses the terminology documented in Amazon SageMaker Clarify Terms for Bias and Fairness (p. 3208) to discuss bias and fairness.

Schema for the analysis file

The analysis file is in JSON format and is organized into two sections: pre-training bias metrics and post-training bias metrics. The parameters for pre-training and post-training bias metrics are as follows.

• pre_training_bias_metrics – Parameters for pre-training bias metrics. For more information, see Measure Pre-training Bias (p. 3209) and Configure the Analysis (p. 3144).
• label – The ground truth label name defined by the label parameter of the analysis configuration.
• label_value_or_threshold – A string containing the label values or interval defined by the label_values_or_threshold parameter of the analysis configuration. For example, if value 1 is provided for binary classification problem, then the string will be 1. If multiple values [1, 2] are provided for multi-class problem, then the string will be 1, 2. If a threshold 40 is provided for regression problem, then the string will be an internal like (40, 68] in which 68 is the maximum value of the label in the input dataset.
• facets – The section contains several key-value pairs, where the key corresponds to the facet name defined by the name_or_index parameter of the facet configuration, and the value is an array of facet objects. Each facet object has the following members:
• value_or_threshold – A string containing the facet values or interval defined by the value_or_threshold parameter of the facet configuration.
• metrics – The section contains an array of bias metric elements, and each bias metric element has the following attributes:
• name – The short name of the bias metric. For example, CI.
• description – The full name of the bias metric. For example, Class Imbalance (CI).
• value – The bias metric value, or JSON null value if the bias metric is not computed for a particular reason. The values ±∞ are represented as strings ∞ and -∞ respectively.
• error – An optional error message that explains why the bias metric was not computed.
• post_training_bias_metrics – The section contains the post-training bias metrics and it follows a similar layout and structure to the pre-training section. For more information, see Measure Post-training Data and Model Bias (p. 3220).

The following is an example of an analysis configuration that will calculate both pre-training and post-training bias metrics.

```json
{
   "version": "1.0",
   "pre_training_bias_metrics": {
      "label": "Target",
      "label_value_or_threshold": "1",
      "facets": {
         "Gender": [{
            "value_or_threshold": "0",
            "metrics": [
               {
                  "name": "CDDL",
                  "description": "Conditional Demographic Disparity in Labels (CDDL)",
                  "value": -0.06
               },
               { "name": "CI",
                "description": "Class Imbalance (CI)",
                "value": 0.6
               },
               ... ]
         }]
      }
   },
   "post_training_bias_metrics": {
      "label": "Target",
      "label_value_or_threshold": "1",
      "facets": {
         "Gender": [{
            "value_or_threshold": "0",
            "metrics": [
               { "name": "AD",
                "description": "Accuracy Difference (AD)",
                "value": -0.13
               },
               { "name": "CDDPL",
                "description": "Conditional Demographic Disparity in Predicted Labels (CDDPL)",
                "value": 0.04
               },
               ... ]
         }]
      }
   }
}
```

Bias analysis report

The bias analysis report includes several tables and diagrams that contain detailed explanations and descriptions. These include, but are not limited to, the distribution of label values, the distribution of...
facet values, high-level model performance diagram, a table of bias metrics, and their descriptions. For more information about bias metrics and how to interpret them, see the [Learn How Amazon SageMaker Clarify Helps Detect Bias](#).

### SHAP analysis

SageMaker Clarify processing jobs use the Kernel SHAP algorithm to compute feature attributions. The SageMaker Clarify processing job produces both local and global SHAP values. These help to determine the contribution of each feature towards model predictions. Local SHAP values represent the feature importance for each individual instance, while global SHAP values aggregate the local SHAP values across all instances in the dataset. For more information about SHAP values and how to interpret them, see [Feature Attributions that Use Shapley Values (p. 3242)](#).

#### Schema for the SHAP analysis file

Global SHAP analysis results are stored in the explanations section of the analysis file, under the `kernel_shap` method. The different parameters of the SHAP analysis file are as follows:

- **explanations** – The section of the analysis file that contains the feature importance analysis results.
- **kernel_shap** – The section of the analysis file that contains the global SHAP analysis result.
  - **global_shap_values** – A section of the analysis file that contains several key-value pairs. Each key in the key-value pair represents a feature name from the input dataset. Each value in the key-value pair corresponds to the feature's global SHAP value. The global SHAP value is obtained by aggregating the per-instance SHAP values of the feature using the `agg_method` configuration.
    - If the `use_logit` configuration is activated, then the value is calculated using the logistic regression coefficients, which can be interpreted as log-odds ratios.
  - **expected_value** – The mean prediction of the baseline dataset. If the `use_logit` configuration is activated, then the value is calculated using the logistic regression coefficients.
  - **global_top_shap_text** – (For NLP explainability analysis). A section of the analysis file that includes a set of key-value pairs. SageMaker Clarify processing jobs aggregate the SHAP values of each token and then select the top tokens based on their global SHAP values. The `max_top_tokens` configuration defines the number of tokens to be selected.

    Each of the selected top tokens has a key-value pair. The key in the key-value pair corresponds to a top token's text feature name. Each value in the key-value pair is the global SHAP values of the top token. For an example of a `global_top_shap_text` key-value pair, see the output that follows.

The following is example output from the SHAP analysis of a tabular dataset.

```json
{
  "version": "1.0",
  "explanations": {
    "kernel_shap": {
      "Target": {
        "global_shap_values": {
          "Age": 0.022486410860333206,
          "Gender": 0.007381025261958729,
          "Income": 0.006843906804137847,
          "Occupation": 0.006843906804137847,
          ...
        },
        "expected_value": 0.508233428001
      }
    }
  }
}
```
The following is example output from the SHAP analysis of a text dataset. The output corresponding to the column Comments is an example of output that is generated after analysis of a text feature.

```
{
    "version": "1.0",
    "explanations": {
        "kernel_shap": {
            "Target": {
                "global_shap_values": {
                    "Rating": 0.022486410860333206,  // Example rating SHAP value
                    "Comments": 0.058612104851485144,  // Example comments SHAP value
                    ...
                },
                "expected_value": 0.46700941970297033,
                "global_top_shap_text": {
                    "charming": 0.04127962903247833,
                    "brilliant": 0.02450240786522321,
                    "enjoyable": 0.024093569652715457,
                    ...
                }
            }
        }
    }
}
```

**Schema for the generated baseline file**

When a SHAP baseline configuration is not provided, the SageMaker Clarify processing job generates a baseline dataset. SageMaker Clarify uses a distance-based clustering algorithm to generate a baseline dataset from clusters created from the input dataset. The resulting baseline dataset is saved in a CSV file, located at `explanations_shap/baseline.csv`. This output file contains a header row and several instances based on the `num_clusters` parameter that is specified in the analysis configuration. The baseline dataset only consists of feature columns. An example of a baseline created by clustering the input dataset follows.

```
Age,Gender,Income,Occupation
35,0,2883,1
40,1,6178,2
42,0,4621,0
```

**Schema for local SHAP values from tabular dataset explainability analysis**

For tabular datasets, if a single compute instance is used, the SageMaker Clarify processing job saves the local SHAP values to a CSV file named `explanations_shap/out.csv`. If you use multiple compute instances, local SHAP values are saved to several CSV files in the `explanations_shap` directory.

An output file containing local SHAP values has a row containing the local SHAP values for each column that is defined by the headers. The headers follow the naming convention of `Feature_Label` where the feature name is appended by an underscore, followed by the name of your target variable.

For multi-class problems, the feature names in the header vary first, then labels. For example, two features F1, F2, and two classes L1 and L2, in headers are F1_L1, F2_L1, F1_L2, and F2_L2. If the analysis configuration contains a value for the `joinsource_name_or_index` parameter, then the key column used in the join is appended to the end of the header name. This allows mapping of the local SHAP values to instances of the input dataset. An example of an output file containing SHAP values follows.

```
Age_Target,Gender_Target,Income_Target,Occupation_Target
0.003937908,0.001388849,0.00242389,0.00274234
```
Schema for local SHAP values from NLP explainability analysis

For NLP explainability analysis, if a single compute instance is used, the SageMaker Clarify processing job saves local SHAP values to a JSON Lines file named explanations_shap/out.jsonl. If you use multiple compute instances, the local SHAP values are saved to several JSON Lines files in the explanations_shap directory.

Each file containing local SHAP values has several data lines, and each line is a valid JSON object. The JSON object has the following attributes:

- **explanations** – The section of the analysis file that contains an array of Kernel SHAP explanations for a single instance. Each element in the array has the following members:
  - **feature_name** – The header name of the features provided by the headers configuration.
  - **data_type** – The feature type inferred by the SageMaker Clarify processing job. Valid values for text features include numerical, categorical, and free_text (for text features).
  - **attributions** – A feature-specific array of attribution objects. A text feature can have multiple attribution objects, each for a unit defined by the granularity configuration. The attribution object has the following members:
    - **attribution** – A class-specific array of probability values.
    - **description** – (For text features) The description of the text units.
    - **partial_text** – The portion of the text explained by the SageMaker Clarify processing job.
    - **start_idx** – A zero-based index to identify the array location indicating the beginning of the partial text fragment.

The following is an example of a single line from a local SHAP values file, beautified to enhance its readability.

```json
[
  {
    "explanations": [
      {
        "feature_name": "Rating",
        "data_type": "categorical",
        "attributions": [
          {
            "attribution": [0.00342270632248735]
          }
        ],
      },
      {
        "feature_name": "Comments",
        "data_type": "free_text",
        "attributions": [
          {
            "attribution": [0.005260534499999983],
            "description": {
              "partial_text": "It's",
              "start_idx": 0
            }
          },
          {
            "attribution": [0.00424190349999996],
            "description": {
              "partial_text": "a",
              "start_idx": 5
            }
          }
        ]
      }
    ]
  }
]```
SHAP analysis report

The SHAP analysis report provides a bar chart of a maximum of 10 top global SHAP values. The following chart example shows the SHAP values for the top 4 features.

![SHAP analysis report](image)

Computer vision (CV) explainability analysis

SageMaker Clarify computer vision explainability takes a dataset consisting of images and treats each image as a collection of super pixels. After analysis, the SageMaker Clarify processing job outputs a dataset of images where each image shows the heat map of the super pixels.

The following example shows an input speed limit sign on the left and a heat map shows the magnitude of SHAP values on the right. These SHAP values were calculated by an image recognition Resnet-18 model that is trained to recognize [German traffic signs](https://www.germantraffic.org). The German Traffic Sign Recognition Benchmark
The (GTSRB) dataset is provided in the paper *Man vs. computer: Benchmarking machine learning algorithms for traffic sign recognition*. In the example output, large positive values indicate that the super pixel has a strong positive correlation with the model prediction. Large negative values indicate that the super pixel has a strong negative correlation with the model prediction. The larger the absolute value of the SHAP value shown in the heat map, the stronger the relationship between the super pixel and model prediction.

For more information, see the sample notebooks *Explaining Image Classification with SageMaker Clarify* and *Explaining object detection models with Amazon SageMaker Clarify*.

Partial dependence plots (PDPs) analysis

Partial dependence plots show the dependence of the predicted target response on a set of input features of interest. These are marginalized over the values of all other input features and are referred to as the complement features. Intuitively, you can interpret the partial dependence as the target response, which is expected as a function of each input feature of interest.

Schema for the analysis file

The PDP values are stored in the explanations section of the analysis file under the pdp method. The parameters for explanations are as follows:

- **explanations** – The section of the analysis files that contains feature importance analysis results.
- **pdp** – The section of the analysis file that contains an array of PDP explanations for a single instance. Each element of the array has the following members:
  - **feature_name** – The header name of the features provided by the headers configuration.
  - **data_type** – The feature type inferred by the SageMaker Clarify processing job. Valid values for data_type include numerical and categorical.
  - **feature_values** – Contains the values present in the feature. If the data_type inferred by SageMaker Clarify is categorical, feature_values contains all of the unique values that the feature could be. If the data_type inferred by SageMaker Clarify is numerical, feature_values contains a list of the central value of generated buckets. The grid_resolution parameter determines the number of buckets used to group the feature column values.
  - **data_distribution** – An array of percentages, where each value is the percentage of instances that a bucket contains. The grid_resolution parameter determines the number of buckets. The feature column values are grouped into these buckets.
  - **model_predictions** – An array of model predictions, where each element of the array is an array of predictions that corresponds to one class in the model's output.
  - **label_headers** – The label headers provided by the label_headers configuration.
  - **error** – An error message generated if the PDP values are not computed for a particular reason. This error message replaces the content contained in the feature_values, data_distributions, and model_predictions fields.
The following is example output from an analysis file containing a PDP analysis result.

```json
{
    "version": "1.0",
    "explanations": {
        "pdp": [
            {
                "feature_name": "Income",
                "data_type": "numerical",
                "feature_values": [1046.9, 2454.7, 3862.5, 5270.2, 6678.0, 8085.9, 9493.6, 10901.5, 12309.3, 13717.1],
                "data_distribution": [0.32, 0.27, 0.17, 0.1, 0.045, 0.05, 0.01, 0.015, 0.01, 0.01],
                "model_predictions": [[0.69, 0.82, 0.82, 0.77, 0.77, 0.46, 0.46, 0.45, 0.41, 0.41]],
                "label_headers": ["Target"]
            }
        ]
    }
}
```

**PDP analysis report**

You can generate an analysis report containing a PDP chart for each feature. The PDP chart plots `feature_values` along the x-axis, and it plots `model_predictions` along the y-axis. For multi-class models, `model_predictions` is an array, and each element of this array corresponds to one of the model prediction classes.

The following is an example of PDP chart for the feature `Age`. In the example output, the PDP shows the number of feature values that are grouped into buckets. The number of buckets is determined by `grid_resolution`. The buckets of feature values are plotted against model predictions. In this example, the higher feature values have the same model prediction values.

**pdp for Age**

*Number of unique grid points: 10*
Troubleshoot SageMaker Clarify Processing Jobs

If you encounter failures with SageMaker Clarify processing jobs, consult the following scenarios to help identify the issue.

Note
The failure reason and exit message are intended to contain descriptive messages and exceptions, if encountered, during the run. A common reason for errors is that parameters are either missing or not valid. If you encounter unclear, confusing, or misleading messages or are unable to find a solution, submit feedback.

Topics
- Processing job fails to finish (p. 3205)
- Processing job is taking too long to run (p. 3205)
- Processing job finishes without results and you get a CloudWatch warning message (p. 3206)
- Error message for invalid analysis configuration (p. 3206)
- Bias metric computation fails for several or all metrics (p. 3206)
- Mismatch between analysis config and dataset/model input/output (p. 3206)
- Model returns 500 Internal Server Error or container falls back to per-record predictions due to model error (p. 3207)
- Execution role is invalid (p. 3207)
- Failed to download data (p. 3207)
- Could not connect to SageMaker (p. 3207)

Processing job fails to finish

If the processing job fails to finish, you can try the following:

- Inspect the job logs directly in the notebook where you ran the job in. The job logs are located in the output of the notebook cell where you initiated the run.
- Inspect the job logs in CloudWatch.
- Add the following line in your notebook to describe the last processing job and look for the failure reason and exit message:
  ```python
  clarify_processor.jobs[-1].describe()
  ```
- Run the following AWS CLI command to describe the processing job and look for the failure reason and exit message:
  ```bash
  aws sagemaker describe-processing-job --processing-job-name <processing-job-id>
  ```

Processing job is taking too long to run

If your processing job is taking too long to run, use the following ways to find the root cause.

Check to see if your resource configuration is sufficient to handle your computing load. To speed up your job, try the following:

- Use a larger instance type. SageMaker Clarify queries the model repeatedly, and a larger instance can significantly reduce your computation time. For a list of available instances, their memory sizes, bandwidth, and other performance details, see Amazon SageMaker Pricing.
- Add more instances. SageMaker Clarify can use multiple instances to explain multiple input data points in parallel. To enable parallel computing, set your instance_count to more than 1 when you call SageMakerClarifyProcessor. For more information, see How to run parallel SageMaker.
Clarify processing jobs (p. 3196). If you increase your instance count, monitor the performance of your endpoint to check that it can deploy the increased load. For more information, see Capture data from real-time endpoint (p. 3054).

- If you’re computing SHapley Additive exPlanations (SHAP) values, reduce the num_samples parameter in your analysis configuration file. The number of samples directly affects the following:
  - The size of the synthetic datasets that are sent to your endpoint
  - Job runtime

Reducing the number of samples can also lead to reduced accuracy in estimating SHAP values. For more information, see Configure the Analysis (p. 3144).

Processing job finishes without results and you get a CloudWatch warning message

If the processing job finishes but no results are found, the CloudWatch logs produce a warning message that says Signal 15 received, cleaning up. This warning indicates that the job was stopped either because a customer request called the StopProcessingJob API, or that the job ran out of the allotted time for its completion. In the latter case, check the maximum runtime in the job configuration (max_runtime_in_seconds) and increase it as needed.

Error message for invalid analysis configuration

- If you get the error message Unable to load analysis configuration as JSON., this means that the analysis configuration input file for the processing job does not contain a valid JSON object. Check the validity of the JSON object using a JSON linter.
- If you get the error message Analysis configuration schema validation error., this means that the analysis configuration input file for the processing job contains unknown fields or invalid types for some field values. Review the configuration parameters in the file and cross-check them with the parameters listed in the analysis configuration file. For more information, see Configure the Analysis.

Bias metric computation fails for several or all metrics

If you receive one of the following error messages No Label values are present in the predicted Label Column, Positive Predicted Index Series contains all False values. or Predicted Label Column series data type is not the same as Label Column series., try the following:

- Check that the correct dataset is being used.
- Check whether the dataset size is too small; whether, for example, it contains only a few rows. This may cause the model outputs to have the same value or the data type is inferred incorrectly.
- Check if the label or facet is treated as continuous or categorical. SageMaker Clarify uses heuristics to determine the DataType. For post-training bias metrics, the data type returned by the model may not match what is in the dataset or SageMaker Clarify may not be able to transform it correctly.
- In the bias report, you should see a single value for categorical columns or an interval for continuous columns.
- For example, if a column has values 0.0 and 1.0 as floats, it will be treated as continuous even if there are too few unique values.

Mismatch between analysis config and dataset/model input/output

- Check that the baseline format in the analysis config is the same as dataset format.
Sample Notebooks

Amazon SageMaker Developer Guide
Sample Notebooks

• If you receive the error message Could not convert string to float., check that the format is correctly specified. It could also indicate that the model predictions have a different format than the label column or it could indicate that the configuration for the label or probabilities is incorrect.
• If you receive the error message Unable to locate the facet. or Headers must contain label. or Headers in config do not match with the number of columns in the dataset. or Feature names not found., check that the headers match the columns.
• If you receive the error message Data must contain features., check the content template for JSON Lines and compare it with the dataset sample if available.

Model returns 500 Internal Server Error or container falls back to per-record predictions due to model error

If you receive the error message Fallback to per-record prediction because of model error., this could indicate that model cannot handle the batch size, or be throttled, or just does not accept the input passed by the container due to serialization problems. You should review the CloudWatch logs for the SageMaker endpoint and look for error messages or tracebacks. For model throttling cases, it may help to use a different instance type or increasing the number of instances for the endpoint.

Execution role is invalid

This indicates that the role provided is incorrect or missing required permissions. Check the role and its permissions that were used to configure the processing job and verify the permission and trust policy for the role.

Failed to download data

This indicates that job inputs could not be downloaded for the job to start. Check the bucket name and permissions for the dataset and the configuration inputs.

Could not connect to SageMaker

This indicates that the job could not reach SageMaker service endpoints. Check the network configuration settings for the processing job and verify virtual private cloud (VPC) configuration.

Sample Notebooks

Amazon SageMaker Clarify provides the following sample notebooks for post-training bias detection and model explainability:

• Fairness and Explainability with SageMaker Clarify – Use SageMaker Clarify to create a processing job for detecting bias and explaining model predictions with feature attributions. You can also see an example notebook to read a dataset in JSON Lines format.
• Additional example notebooks using SageMaker Clarify include the following
  • Bringing your own container
  • Running processing jobs with Spark
  • Partial dependence plots (PDPs)

Detect Pre-training Data Bias

Algorithmic bias, discrimination, fairness, and related topics have been studied across disciplines such as law, policy, and computer science. A computer system might be considered biased if it discriminates against certain individuals or groups of individuals. The machine learning models powering these applications learn from data and this data could reflect disparities or other inherent biases. For example, the training data may not have sufficient representation of various demographic groups or may contain biased labels. The machine learning models trained on datasets that exhibit these biases could end up learning them and then reproduce or even exacerbate those biases in their predictions. The field of machine learning provides an opportunity to address biases by detecting them and measuring them at each stage of the ML lifecycle. You can use Amazon SageMaker Clarify to determine whether data used for training models encodes any bias.

Bias can be measured before training and after training, and monitored against baselines after deploying models to endpoints for inference. Pre-training bias metrics are designed to detect and measure bias in the raw data before it is used to train a model. The metrics used are model-agnostic because they do not depend on any model outputs. However, there are different concepts of fairness that require distinct measures of bias. Amazon SageMaker Clarify provides bias metrics to quantify various fairness criteria.

For additional information about bias metrics, see Learn How Amazon SageMaker Clarify Helps Detect Bias and Fairness Measures for Machine Learning in Finance.

Amazon SageMaker Clarify Terms for Bias and Fairness

SageMaker Clarify uses the following terminology to discuss bias and fairness.

Feature

An individual measurable property or characteristic of a phenomenon being observed, contained in a column for tabular data.

Label

Feature that is the target for training a machine learning model. Referred to as the observed label or observed outcome.

Predicted label

The label as predicted by the model. Also referred to as the predicted outcome.

Sample

An observed entity described by feature values and label value, contained in a row for tabular data.

Dataset

A collection of samples.

Bias

An imbalance in the training data or the prediction behavior of the model across different groups, such as age or income bracket. Biases can result from the data or algorithm used to train your model. For instance, if an ML model is trained primarily on data from middle-aged individuals, it may be less accurate when making predictions involving younger and older people.

Bias metric

A function that returns numerical values indicating the level of a potential bias.

Bias report

A collection of bias metrics for a given dataset, or a combination of a dataset and a model.
Positive label values

Label values that are favorable to a demographic group observed in a sample. In other words, designates a sample as having a positive result.

Negative label values

Label values that are unfavorable to a demographic group observed in a sample. In other words, designates a sample as having a negative result.

Group variable

Categorical column of the dataset that is used to form subgroups for the measurement of Conditional Demographic Disparity (CDD). Required only for this metric with regards to Simpson's paradox.

Facet

A column or feature that contains the attributes with respect to which bias is measured.

Facet value

The feature values of attributes that bias might favor or disfavor.

Predicted probability

The probability, as predicted by the model, of a sample having a positive or negative outcome.

Sample Notebooks

Amazon SageMaker Clarify provides the following sample notebook for bias detection:

- Explainability and bias detection with Amazon SageMaker Clarify – Use SageMaker Clarify to create a processing job for detecting bias and explaining model predictions with feature attributions.

This notebook has been verified to run in Amazon SageMaker Studio only. If you need instructions on how to open a notebook in Amazon SageMaker Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 225). If you're prompted to choose a kernel, choose Python 3 (Data Science).

Topics

- Measure Pre-training Bias (p. 3209)
- Generate Reports for Bias in Pre-training Data in SageMaker Studio (p. 3218)

Measure Pre-training Bias

Measuring bias in ML models is a first step to mitigating bias. Each measure of bias corresponds to a different notion of fairness. Even considering simple concepts of fairness leads to many different measures applicable in various contexts. For example, consider fairness with respect to age, and, for simplicity, that middle-aged and rest of the age groups are the two relevant demographics, referred to as facets. In the case of an ML model for lending, we may want small business loans to be issued to equal numbers of both demographics. Or, when processing job applicants, we may want to see equal numbers of members of each demographic hired. However, this approach may assume that equal numbers of both age groups apply to these jobs, so we may want to condition on the number that apply. Further, we may want to consider not whether equal numbers apply, but whether we have equal numbers of qualified applicants. Or, we may consider fairness to be an equal acceptance rate of qualified applicants across both age demographics, or, an equal rejection rate of applicants, or both. You might use datasets with different proportions of data on the attributes of interest. This imbalance can conflate the bias measure you choose. The models might be more accurate in classifying one facet than in the other. Thus, you need to choose bias metrics that are conceptually appropriate for the application and the situation.
We use the following notation to discuss the bias metrics. The conceptual model described here is for binary classification, where events are labeled as having only two possible outcomes in their sample space, referred to as positive (with value 1) and negative (with value 0). This framework is usually extensible to multiclassification in a straightforward way or to cases involving continuous valued outcomes when needed. In the binary classification case, positive and negative labels are assigned to outcomes recorded in a raw dataset for a favored facet \( a \) and for a disfavored facet \( d \). These labels \( y \) are referred to as observed labels to distinguish them from the predicted labels \( y' \) that are assigned by a machine learning model during the training or inferences stages of the ML lifecycle. These labels are used to define probability distributions \( P_a(y) \) and \( P_d(y) \) for their respective facet outcomes.

- **labels:**
  - \( y \) represents the \( n \) observed labels for event outcomes in a training dataset.
  - \( y' \) represents the predicted labels for the \( n \) observed labels in the dataset by a trained model.

- **outcomes:**
  - A positive outcome (with value 1) for a sample, such as an application acceptance.
  - \( n^{(1)} \) is the number of observed labels for positive outcomes (acceptances).
  - \( n^{(1)}' \) is the number of predicted labels for positive outcomes (acceptances).
  - A negative outcome (with value 0) for a sample, such as an application rejection.
  - \( n^{(0)} \) is the number of observed labels for negative outcomes (rejections).
  - \( n^{(0)}' \) is the number of predicted labels for negative outcomes (rejections).

- **facet values:**
  - facet \( a \) – The feature value that defines a demographic that bias favors.
    - \( n_a \) is the number of observed labels for the favored facet value: \( n_a = n_a^{(1)} + n_a^{(0)} \) the sum of the positive and negative observed labels for the value facet \( a \).
    - \( n_a' \) is the number of predicted labels for the favored facet value: \( n_a' = n_a^{(1)} + n_a^{(0)} \) the sum of the positive and negative predicted outcome labels for the facet value \( a \). Note that \( n_a' = n_a \).
  - facet \( d \) – The feature value that defines a demographic that bias disfavors.
    - \( n_d \) is the number of observed labels for the disfavored facet value: \( n_d = n_d^{(1)} + n_d^{(0)} \) the sum of the positive and negative observed labels for the facet value \( d \).
    - \( n_d' \) is the number of predicted labels for the disfavored facet value: \( n_d' = n_d^{(1)} + n_d^{(0)} \) the sum of the positive and negative predicted labels for the facet value \( d \). Note that \( n_d' = n_d \).

- **probability distributions for outcomes of the labeled facet data outcomes:**
  - \( P_a(y) \) is the probability distribution of the observed labels for facet \( a \). For binary labeled data, this distribution is given by the ratio of the number of samples in facet \( a \) labeled with positive outcomes to the total number, \( P_a(y^{(1)}) = n_a^{(1)}/n_a \), and the ratio of the number of samples with negative outcomes to the total number, \( P_a(y^{(0)}) = n_a^{(0)}/n_a \).
  - \( P_d(y) \) is the probability distribution of the observed labels for facet \( d \). For binary labeled data, this distribution is given by the ratio of the number of samples in facet \( d \) labeled with positive outcomes to the total number, \( P_d(y^{(1)}) = n_d^{(1)}/n_d \), and the ratio of the number of samples with negative outcomes to the total number, \( P_d(y^{(0)}) = n_d^{(0)}/n_d \).

Models trained on data biased by demographic disparities might learn and even exacerbate them. To identify bias in the data before expending resources to train models on it, SageMaker Clarify provides data bias metrics that you can compute on raw datasets before training. All of the pretraining metrics are model-agnostic because they do not depend on model outputs and so are valid for any model. The first bias metric examines facet imbalance, but not outcomes. It determines the extent to which the amount of training data is representative across different facets, as desired for the application. The remaining bias metrics compare the distribution of outcome labels in various ways for facets \( a \) and \( d \) in the data. The metrics that range over negative values can detect negative bias. The following table contains a cheat sheet for quick guidance and links to the pretraining bias metrics.
### Pre-training Bias Metrics

<table>
<thead>
<tr>
<th>Bias metric</th>
<th>Description</th>
<th>Example question</th>
<th>Interpreting metric values</th>
</tr>
</thead>
</table>
| **Class Imbalance (CI) (p. 3214)**               | Measures the imbalance in the number of members between different facet values. | Could there be age-based biases due to not having enough data for the demographic outside a middle-aged facet? | Normalized range: [-1, +1]  
Interpretation:  
• Positive values indicate the facet $a$ has more training samples in the dataset.  
• Values near zero indicate the facets are balanced in the number of training samples in the dataset.  
• Negative values indicate the facet $d$ has more training samples in the dataset. |
| **Difference in Proportions of Labels (DPL) (p. 3214)** | Measures the imbalance of positive outcomes between different facet values. | Could there be age-based biases in ML predictions due to biased labeling of facet values in the data? | Range for normalized binary & multicategory facet labels: [-1, +1]  
Range for continuous labels: (-∞, +∞)  
Interpretation:  
• Positive values indicate facet $a$ has a higher proportion of positive outcomes.  
• Values near zero indicate a more equal proportion of positive outcomes between facets.  
• Negative values indicate facet $d$ has a higher proportion of positive outcomes. |
| **Kullback-Leibler Divergence (KL) (p. 3215)**  | Measures how much the outcome distributions of different facets diverge from each other entropically. | How different are the distributions for loan application outcomes for different demographic groups? | Range for binary, multicategory, continuous: [0, +∞)  
Interpretation: |

</table>
| **Kolmogorov-Smirnov (KS) (p. 3217)** | Measures maximum divergence between outcomes in distributions for different facets in a dataset. | Which college application outcomes manifest the greatest disparities by demographic group? | Range of KS values for binary, multiclass, and continuous outcomes: [0, +1]  
  - Values near zero indicate the labels were evenly distributed between facets in all outcome categories.  
  - Values near one indicate the labels for one category were all in one facet, so very imbalanced.  
  - Intermittent values indicate relative degrees of maximum label imbalance. |
| **Conditional Demographic Disparity (CDD) (p. 3217)** | Measures the disparity of outcomes between different facets as a whole, but also by subgroups. | Do some groups have a larger proportion of rejections for college admission outcomes than their proportion of acceptances? | Range of CDD: [-1, +1]  
  - Positive values indicate outcomes where facet $d$ is rejected more than accepted.  
  - Near zero indicates no demographic disparity on average.  
  - Negative values indicate outcomes where facet $a$ is rejected more than accepted. |

For additional information about bias metrics, see [Fairness Measures for Machine Learning in Finance](#).

**Topics**
- Class Imbalance (CI) (p. 3214)
- Difference in Proportions of Labels (DPL) (p. 3214)
- Kullback-Leibler Divergence (KL) (p. 3215)
- Jensen-Shannon Divergence (JS) (p. 3215)
- Lp-norm (LP) (p. 3216)
- Total Variation Distance (TVD) (p. 3216)
- Kolmogorov-Smirnov (KS) (p. 3217)
- Conditional Demographic Disparity (CDD) (p. 3217)
**Class Imbalance (CI)**

Class imbalance (CI) bias occurs when a facet value $d$ has fewer training samples when compared with another facet $a$ in the dataset. This is because models preferentially fit the larger facets at the expense of the smaller facets and so can result in a higher training error for facet $d$. Models are also at higher risk of overfitting the smaller data sets, which can cause a larger test error for facet $d$. Consider the example where a machine learning model is trained primarily on data from middle-aged individuals (facet $a$), it might be less accurate when making predictions involving younger and older people (facet $d$).

The formula for the (normalized) facet imbalance measure:

$$CI = (n_a - n_d)/(n_a + n_d)$$

Where $n_a$ is the number of members of facet $a$ and $n_d$ the number for facet $d$. Its values range over the interval $[-1, 1]$.

- Positive CI values indicate the facet $a$ has more training samples in the dataset and a value of 1 indicates the data only contains members of the facet $a$.
- Values of CI near zero indicate a more equal distribution of members between facets and a value of zero indicates a perfectly equal partition between facets and represents a balanced distribution of samples in the training data.
- Negative CI values indicate the facet $d$ has more training samples in the dataset and a value of -1 indicates the data only contains members of the facet $d$.
- CI values near either of the extremes values of -1 or 1 are very imbalanced and are at a substantial risk of making biased predictions.

If a significant facet imbalance is found to exist among the facets, you might want to rebalance the sample before proceeding to train models on it.

**Difference in Proportions of Labels (DPL)**

The difference in proportions of labels (DPL) compares the proportion of observed outcomes with positive labels for facet $d$ with the proportion of observed outcomes with positive labels of facet $a$ in a training dataset. For example, you could use it to compare the proportion of middle-aged individuals (facet $a$) and other age groups (facet $d$) approved for financial loans. Machine learning models try to mimic the training data decisions as closely as possible. So a machine learning model trained on a dataset with a high DPL is likely to reflect the same imbalance in its future predictions.

The formula for the difference in proportions of labels is as follows:

$$DPL = (q_a - q_d)$$

Where:

- $q_a = n_a^{(1)}/n_a$ is the proportion of facet $a$ who have an observed label value of 1. For example, the proportion of a middle-aged demographic who get approved for loans. Here $n_a^{(1)}$ represents the number of members of facet $a$ who get a positive outcome and $n_a$ the is number of members of facet $a$.
- $q_d = n_d^{(1)}/n_d$ is the proportion of facet $d$ who have an observed label value of 1. For example, the proportion of people outside the middle-aged demographic who get approved for loans. Here $n_d^{(1)}$ represents the number of members of the facet $d$ who get a positive outcome and $n_d$ the is number of members of the facet $d$.

If DPL is close enough to 0, then we say that demographic parity has been achieved.

For binary and multicategory facet labels, the DPL values range over the interval $(-1, 1)$. For continuous labels, we set a threshold to collapse the labels to binary.
• Positive DPL values indicate that facet $a$ is has a higher proportion of positive outcomes when compared with facet $d$.
• Values of DPL near zero indicate a more equal proportion of positive outcomes between facets and a value of zero indicates perfect demographic parity.
• Negative DPL values indicate that facet $d$ has a higher proportion of positive outcomes when compared with facet $a$.

Whether or not a high magnitude of DPL is problematic varies from one situation to another. In a problematic case, a high-magnitude DPL might be a signal of underlying issues in the data. For example, a dataset with high DPL might reflect historical biases or prejudices against age-based demographic groups that would be undesirable for a model to learn.

**Kullback-Leibler Divergence (KL)**

The Kullback-Leibler divergence (KL) measures how much the observed label distribution of facet $a$, $P_a(y)$, diverges from distribution of facet $d$, $P_d(y)$. It is also known as the relative entropy of $P_a(y)$ with respect to $P_d(y)$ and quantifies the amount of information lost when moving from $P_a(y)$ to $P_d(y)$.

The formula for the Kullback-Leibler divergence is as follows:

$$\text{KL}(P_a \mid \mid P_d) = \sum_y P_a(y) \log \frac{P_a(y)}{P_d(y)}$$

It is the expectation of the logarithmic difference between the probabilities $P_a(y)$ and $P_d(y)$, where the expectation is weighted by the probabilities $P_a(y)$. This is not a true distance between the distributions as it is asymmetric and does not satisfy the triangle inequality. The implementation uses natural logarithms, giving KL in units of nats. Using different logarithmic bases gives proportional results but in different units. For example, using base 2 gives KL in units of bits.

For example, assume that a group of applicants for loans have a 30% approval rate (facet $d$) and that the approval rate for other applicants (facet $a$) is 80%. The Kullback-Leibler formula gives you the label distribution divergence of facet $a$ from facet $d$ as follows:

$$\text{KL} = 0.8 \times \ln(0.8/0.3) + 0.2 \times \ln(0.2/0.7) = 0.53$$

There are two terms in the formula here because labels are binary in this example. This measure can be applied to multiple labels in addition to binary ones. For example, in a college admissions scenario, assume an applicant may be assigned one of three category labels: $y_i = \{y_0, y_1, y_2\} = \{\text{rejected, waitlisted, accepted}\}$.

Range of values for the KL metric for binary, multicategory, and continuous outcomes is $[0, +\infty)$.

• Values near zero mean the outcomes are similarly distributed for the different facets.
• Positive values mean the label distributions diverge, the more positive the larger the divergence.

**Jensen-Shannon Divergence (JS)**

The Jensen-Shannon divergence (JS) measures how much the label distributions of different facets diverge from each other entropically. It is based on the Kullback-Leibler divergence, but it is symmetric.

The formula for the Jensen-Shannon divergence is as follows:

$$\text{JS} = \frac{1}{2} \times [\text{KL}(P_a \mid \mid P) + \text{KL}(P_d \mid \mid P)]$$

Where $P = \frac{1}{2} (P_a + P_d)$, the average label distribution across facets $a$ and $d$.

The range of JS values for binary, multicategory, continuous outcomes is $[0, \ln(2))$.

• Values near zero mean the labels are similarly distributed.
• Positive values mean the label distributions diverge, the more positive the larger the divergence.
This metric indicates whether there is a big divergence in one of the labels across facets.

**L_p-norm (LP)**

The L_p-norm (LP) measures the p-norm distance between the facet distributions of the observed labels in a training dataset. This metric is non-negative and so cannot detect reverse bias.

The formula for the L_p-norm is as follows:

\[ L_p(P_a, P_d) = \left( \sum_{y} |P_a(y) - P_d(y)|^p \right)^{1/p} \]

Where the p-norm distance between the points x and y is defined as follows:

\[ L_p(x, y) = (|x_1-y_1|^p + |x_2-y_2|^p + ... + |x_n-y_n|^p)^{1/p} \]

The 2-norm is the Euclidean norm. Assume you have an outcome distribution with three categories, for example, \( y_i = \{y_0, y_1, y_2\} = \{\text{accepted, waitlisted, rejected}\} \) in a college admissions multicategory scenario. You take the sum of the squares of the differences between the outcome counts for facets a and d. The resulting Euclidean distance is calculated as follows:

\[ L_2(P_a, P_d) = \left( (n_a^{(0)} - n_d^{(0)})^2 + (n_a^{(1)} - n_d^{(1)})^2 + (n_a^{(2)} - n_d^{(2)})^2 \right)^{1/2} \]

Where:

- \( n_a^{(i)} \) is number of the ith category outcomes in facet a: for example \( n_a^{(0)} \) is number of facet a acceptances.
- \( n_d^{(i)} \) is number of the ith category outcomes in facet d: for example \( n_d^{(2)} \) is number of facet d rejections.

The range of LP values for binary, multicategory, and continuous outcomes is \([0, \sqrt{2})\), where:

- Values near zero mean the labels are similarly distributed.
- Positive values mean the label distributions diverge, the more positive the larger the divergence.

**Total Variation Distance (TVD)**

The total variation distance data bias metric (TVD) is half the L_1-norm. The TVD is the largest possible difference between the probability distributions for label outcomes of facets a and d. The L_1-norm is the Hamming distance, a metric used compare two binary data strings by determining the minimum number of substitutions required to change one string into another. If the strings were to be copies of each other, it determines the number of errors that occurred when copying. In the bias detection context, TVD quantifies how many outcomes in facet a would have to be changed to match the outcomes in facet d.

The formula for the Total variation distance is as follows:

\[ \text{TVD} = \frac{1}{2} L_1(P_a, P_d) \]

For example, assume you have an outcome distribution with three categories, \( y_i = \{y_0, y_1, y_2\} = \{\text{accepted, waitlisted, rejected}\} \) in a college admissions multicategory scenario. You take the differences between the counts of facets a and d for each outcome to calculate TVD. The result is as follows:

\[ L_1(P_a, P_d) = |n_a^{(0)} - n_d^{(0)}| + |n_a^{(1)} - n_d^{(1)}| + |n_a^{(2)} - n_d^{(2)}| \]

Where:

- \( n_a^{(i)} \) is number of the ith category outcomes in facet a: for example \( n_a^{(0)} \) is number of facet a acceptances.
- \( n_d^{(i)} \) is number of the ith category outcomes in facet d: for example \( n_d^{(2)} \) is number of facet d rejections.
The range of TVD values for binary, multicategory, and continuous outcomes is \([0, 1)\), where:

- Values near zero mean the labels are similarly distributed.
- Positive values mean the label distributions diverge, the more positive the larger the divergence.

**Kolmogorov-Smirnov (KS)**

The Kolmogorov-Smirnov bias metric (KS) is equal to the maximum divergence between labels in the distributions for facets \(a\) and \(d\) of a dataset. The two-sample KS test implemented by SageMaker Clarify complements the other measures of label imbalance by finding the most imbalanced label.

The formula for the Kolmogorov-Smirnov metric is as follows:

\[
KS = \max(|P_a(y) - P_d(y)|)
\]

For example, assume a group of applicants (facet \(a\)) to college are rejected, waitlisted, or accepted at 40%, 40%, 20% respectively and that these rates for other applicants (facet \(d\)) are 20%, 10%, 70%. Then the Kolmogorov-Smirnov bias metric value is as follows:

\[
KS = \max(|0.4-0.2|, |0.4-0.1|, |0.2-0.7|) = 0.5
\]

This tells us the maximum divergence between facet distributions is 0.5 and occurs in the acceptance rates. There are three terms in the equation because labels are multiclass of cardinality three.

The range of LP values for binary, multicategory, and continuous outcomes is \([0, +1]\), where:

- Values near zero indicate the labels were evenly distributed between facets in all outcome categories. For example, both facets applying for a loan got 50% of the acceptances and 50% of the rejections.
- Values near one indicate the labels for one outcome were all in one facet. For example, facet \(a\) got 100% of the acceptances and facet \(d\) got none.
- Intermittent values indicate relative degrees of maximum label imbalance.

**Conditional Demographic Disparity (CDD)**

The demographic disparity metric (DD) determines whether a facet has a larger proportion of the rejected outcomes in the dataset than of the accepted outcomes. In the binary case where there are two facets, men and women for example, that constitute the dataset, the disfavored one is labelled facet \(d\) and the favored one is labelled facet \(a\). For example, in the case of college admissions, if women applicants comprised 46% of the rejected applicants and comprised only 32% of the accepted applicants, we say that there is demographic disparity because the rate at which women were rejected exceeds the rate at which they are accepted. Women applicants are labelled facet \(d\) in this case. If men applicants comprised 54% of the rejected applicants and 68% of the accepted applicants, then there is not a demographic disparity for this facet as the rate of rejection is less that the rate of acceptance. Men applicants are labelled facet \(a\) in this case.

The formula for the demographic disparity for the less favored facet \(d\) is as follows:

\[
DD_d = n_d^{(0)} / n^{(0)} - n_d^{(1)} / n^{(1)} = P_d R(y^0) - P_d A(y^1)
\]

Where:

- \(n^{(0)} = n_a^{(0)} + n_d^{(0)}\) is the total number of rejected outcomes in the dataset for the favored facet \(a\) and disadvantaged facet \(d\).
- \(n^{(1)} = n_a^{(1)} + n_d^{(1)}\) is the total number of accepted outcomes in the dataset for the favored facet \(a\) and disadvantaged facet \(d\).
- \(P_d R(y^0)\) is the proportion of rejected outcomes (with value 0) in facet \(d\)
Detect Pre-training Data Bias

• $P_d^A(y^1)$ is the proportion of accepted outcomes (value 1) in facet $d$.

For the college admission example, the demographic disparity for women is $DD_d = 0.46 - 0.32 = 0.14$. For men $DD_a = 0.54 - 0.68 = -0.14$.

A conditional demographic disparity (CDD) metric that conditions DD on attributes that define a strata of subgroups on the dataset is needed to rule out Simpson's paradox. The regrouping can provide insights into the cause of apparent demographic disparities for less favored facets. The classic case arose in the case of Berkeley admissions where men were accepted at a higher rate overall than women. The statistics for this case were used in the example calculations of DD. However, when departmental subgroups were examined, women were shown to have higher admission rates than men when conditioned by department. The explanation was that women had applied to departments with lower acceptance rates than men had. Examining the subgrouped acceptance rates revealed that women were actually accepted at a higher rate than men for the departments with lower acceptance rates.

The CDD metric gives a single measure for all of the disparities found in the subgroups defined by an attribute of a dataset by averaging them. It is defined as the weighted average of demographic disparities (DD) for each of the subgroups, with each subgroup disparity weighted in proportion to the number of observations in contains. The formula for the conditional demographic disparity is as follows:

$$CDD = \frac{1}{n} \sum_{i} n_i \cdot DD_i$$

Where:

• $\sum n_i = n$ is the total number of observations and $n_i$ is the number of observations for each subgroup.
• $DD_i = n_i^0/n_i^0 - n_i^1/n_i^1 = P_i^R(y^0) - P_i^A(y^1)$ is the demographic disparity for the $i$th subgroup.

The range of DD values for binary outcomes for the full dataset $DD_d$ or for its conditionalized subgroups $DD_i$ is $[-1, +1]$.

- $+1$: when there are no rejections in facet $a$ or subgroup and no acceptances in facet $d$ or subgroup
- Positive values indicate there is a demographic disparity as facet $d$ or subgroup has a greater proportion of the rejected outcomes in the dataset than of the accepted outcomes. The higher the value the less favored the facet and the greater the disparity.
- Negative values indicate there is not a demographic disparity as facet $d$ or subgroup has a larger proportion of the accepted outcomes in the dataset than of the rejected outcomes. The lower the value the more favored the facet.
- $-1$: when there are no rejections in facet $d$ or subgroup and no acceptances in facet $a$ or subgroup

If you don't condition on anything then CDD is zero if and only if DPL is zero.

This metric is useful for exploring the concepts of direct and indirect discrimination and of objective justification in EU and UK non-discrimination law and jurisprudence. For additional information, see Why Fairness Cannot Be Automated. This paper also contains the relevant data and analysis of the Berkeley admissions case that shows how conditionalizing on departmental admission rate subgroups illustrates Simpson's paradox.

Generate Reports for Bias in Pre-training Data in SageMaker Studio

SageMaker Clarify is integrated with Amazon SageMaker Data Wrangler, which can help you identify bias during data preparation without having to write your own code. Data Wrangler provides an end-to-end
solution to import, prepare, transform, featurize, and analyze data with Amazon SageMaker Studio. For an overview of the Data Wrangler data prep workflow, see Prepare ML Data with Amazon SageMaker Data Wrangler (p. 1167).

You specify attributes of interest, such as gender or age, and SageMaker Clarify runs a set of algorithms to detect the presence of bias in those attributes. After the algorithm runs, SageMaker Clarify provides a visual report with a description of the sources and severity of possible bias so that you can plan steps to mitigate. For example, in a financial dataset that contains few examples of business loans to one age group as compared to others, SageMaker flags the imbalance so that you can avoid a model that disfavors that age group.

To analyze and report on data bias

To get started with Data Wrangler, see Get Started with Data Wrangler (p. 1169).

1. In Amazon SageMaker Studio, from the Home menu in the left panel, navigate to the Data node, then choose Data Wrangler. This opens the Data Wrangler landing page in Studio.

2. Choose the + Import data button to create a new flow.

3. In your flow page, from the Import tab, choose Amazon S3, navigate to your Amazon S3 bucket, find your dataset, then choose Import.

4. After you have imported your data, on the flow graph in the Data flow tab, choose the + sign to the right of the Data types node.

5. Choose Add analysis.

6. On the Create Analysis page, choose Bias Report for the Analysis type.

7. Configure the bias report by providing a report Name, the column to predict and whether it is a value or threshold, the column to analyze for bias (the facet) and whether it is a value or threshold.

8. Continue configuring the bias report by choosing the bias metrics.

9. Choose Check for bias to generate and view the bias report. Scroll down to view all of the reports.
10. Choose the caret to the right of each bias metric description to see documentation that can help you interpret the significance of the metric values.

11. To view a table summary of the bias metric values, choose the Table toggle. To save the report, choose Save in the lower-right corner of the page. You can see the report on the flow graph in the Data flow tab. Double-click on the report to open it.

Detect Post-training Data and Model Bias with Amazon SageMaker Clarify

Post-training bias analysis can help reveal biases that might have emanated from biases in the data, or from biases introduced by the classification and prediction algorithms. These analyses take into consideration the data, including the labels, and the predictions of a model. You assess performance by analyzing predicted labels or by comparing the predictions with the observed target values in the data with respect to groups with different attributes. There are different notions of fairness, each requiring different bias metrics to measure.

There are legal concepts of fairness that might not be easy to capture because they are hard to detect. For example, the US concept of disparate impact that occurs when a group, referred to as a less favored facet $d$, experiences an adverse effect even when the approach taken appears to be fair. This type of bias might not be due to a machine learning model, but might still be detectable by post-training bias analysis.

Amazon SageMaker Clarify tries to ensure a consistent use of terminology. For a list of terms and their definitions, see Amazon SageMaker Clarify Terms for Bias and Fairness (p. 3208).

For additional information about post-training bias metrics, see Learn How Amazon SageMaker Clarify Helps Detect Bias and Fairness Measures for Machine Learning in Finance.

Measure Post-training Data and Model Bias

Amazon SageMaker Clarify provides eleven post-training data and model bias metrics to help quantify various conceptions of fairness. These concepts cannot all be satisfied simultaneously and the selection depends on specifics of the cases involving potential bias being analyzed. Most of these metrics are a combination of the numbers taken from the binary classification confusion matrices for the different demographic groups. Because fairness and bias can be defined by a wide range of metrics, human judgment is required to understand and choose which metrics are relevant to the individual use case, and customers should consult with appropriate stakeholders to determine the appropriate measure of fairness for their application.

We use the following notation to discuss the bias metrics. The conceptual model described here is for binary classification, where events are labeled as having only two possible outcomes in their sample.
space, referred to as positive (with value 1) and negative (with value 0). This framework is usually extensible to multicategory classification in a straightforward way or to cases involving continuous valued outcomes when needed. In the binary classification case, positive and negative labels are assigned to outcomes recorded in a raw dataset for a favored facet $a$ and for a disfavored facet $d$. These labels $y$ are referred to as observed labels to distinguish them from the predicted labels $y'$ that are assigned by a machine learning model during the training or inferences stages of the ML lifecycle. These labels are used to define probability distributions $P_a(y)$ and $P_d(y)$ for their respective facet outcomes.

- **labels:**
  - $y$ represents the $n$ observed labels for event outcomes in a training dataset.
  - $y'$ represents the predicted labels for the $n$ observed labels in the dataset by a trained model.

- **outcomes:**
  - A positive outcome (with value 1) for a sample, such as an application acceptance.
  - $n^{(1)}$ is the number of observed labels for positive outcomes (acceptances).
  - $n^{(1)}$ is the number of predicted labels for positive outcomes (acceptances).
  - A negative outcome (with value 0) for a sample, such as an application rejection.
  - $n^{(0)}$ is the number of observed labels for negative outcomes (rejections).
  - $n^{(0)}$ is the number of predicted labels for negative outcomes (rejections).

- **facet values:**
  - facet $a$ – The feature value that defines a demographic that bias favors.
  - $n_a$ is the number of observed labels for the favored facet value: $n_a = n^{(1)}_a + n^{(0)}_a$ the sum of the positive and negative observed labels for the facet value $a$.
  - $n'_a$ is the number of predicted labels for the favored facet value: $n'_a = n^{(1)}_a + n^{(0)}_a$ the sum of the positive and negative predicted outcome labels for the facet value $a$. Note that $n'_a = n_a$.

  - facet $d$ – The feature value that defines a demographic that bias disfavors.
  - $n_d$ is the number of observed labels for the disfavored facet value: $n_d = n^{(1)}_d + n^{(0)}_d$ the sum of the positive and negative observed labels for the facet value $d$.
  - $n'_d$ is the number of predicted labels for the disfavored facet value: $n'_d = n^{(1)}_d + n^{(0)}_d$ the sum of the positive and negative predicted labels for the facet value $d$. Note that $n'_d = n_d$.

- **probability distributions for outcomes of the labeled facet data outcomes:**
  - $P_a(y)$ is the probability distribution of the observed labels for facet $a$. For binary labeled data, this distribution is given by the ratio of the number of samples in facet $a$ labeled with positive outcomes to the total number, $P_a(y^{(1)}) = n^{(1)}_a / n_a$, and the ratio of the number of samples with negative outcomes to the total number, $P_a(y^{(0)}) = n^{(0)}_a / n_a$.

  - $P_d(y)$ is the probability distribution of the observed labels for facet $d$. For binary labeled data, this distribution is given by the number of samples in facet $d$ labeled with positive outcomes to the total number, $P_d(y^{(1)}) = n^{(1)}_d / n_d$, and the ratio of the number of samples with negative outcomes to the total number, $P_d(y^{(0)}) = n^{(0)}_d / n_d$.

The following table contains a cheat sheet for quick guidance and links to the post-training bias metrics.

### Post-training bias metrics

| Difference in Rejection Rates (DRR) (p. 3236) | Measures the difference in the ratios of the observed negative outcomes (TN) to the predicted negatives (TN + FN) between the disfavored and favored facets. | Does the model have equal precision when predicting loan rejections for unqualified applicants across all age groups? | The range for binary, multicategory facet, and continuous labels is $[-1, +1]$.  
• Positive values indicate a possible bias caused by the occurrence of relatively more false negatives in the favored facet $a$.  
• Values near zero indicate that negative outcomes (rejections) are being predicted with equal precision for both facets.  
• Negative values indicate a possible bias caused by the occurrence of relatively more false negatives in the disfavored facet $d$. |
| Treatment Equality (TE) (p. 3238) | Measures the difference in the ratio of false positives to false negatives between the favored and disfavored facets. | In loan applications, is the relative ratio of false positives to false negatives the same across all age demographics? | The range for binary and multicategory facet labels: $(-\infty, +\infty)$.  
• Positive values occur when the ratio of false positives to false negatives for facet $a$ is greater than that for facet $d$.  
• Values near zero occur when the ratio of false positives to false negatives for facet $a$ is similar to that for facet $d$.  
• Negative values occur when the ratio of false positives to false negatives for facet $a$ is less than that for facet $d$. |
### Post-training bias metric

<table>
<thead>
<tr>
<th>Post-training bias metric</th>
<th>Description</th>
<th>Example question</th>
<th>Interpreting metric values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Generalized entropy (GE) (p. 3241)</td>
<td>Measures the inequality in benefits b assigned to each input by the model predictions.</td>
<td>Of two candidate models for loan application classification, does one lead to a more uneven distribution of desired outcomes than the other?</td>
<td>The range for binary and multicategory labels: (0, 0.5). GE is undefined when the model predicts only false negatives.</td>
</tr>
</tbody>
</table>

- Zero values occur when all predictions are correct or all predictions are false positives.
- Positive values indicate inequality in benefits; 0.5 corresponds to the largest inequality.

For additional information about post-training bias metrics, see [A Family of Fairness Measures for Machine Learning in Finance](#).

#### Topics
- Difference in Positive Proportions in Predicted Labels (DPPL) (p. 3229)
- Disparate Impact (DI) (p. 3230)
- Difference in Conditional Acceptance (DCAcc) (p. 3231)
- Difference in Conditional Rejection (DCR) (p. 3232)
- Specificity difference (SD) (p. 3233)
- Recall Difference (RD) (p. 3234)
- Difference in Acceptance Rates (DAR) (p. 3235)
- Difference in Rejection Rates (DRR) (p. 3236)
- Accuracy Difference (AD) (p. 3237)
- Treatment Equality (TE) (p. 3238)
- Conditional Demographic Disparity in Predicted Labels (CDDPL) (p. 3239)
- Counterfactual Flitertest (FT) (p. 3240)
- Generalized entropy (GE) (p. 3241)

#### Difference in Positive Proportions in Predicted Labels (DPPL)

The difference in positive proportions in predicted labels (DPPL) metric determines whether the model predicts outcomes differently for each facet. It is defined as the difference between the proportion of positive predictions (\(y' = 1\)) for facet \(a\) and the proportion of positive predictions (\(y' = 1\)) for facet \(d\). For example, if the model predictions grant loans to 60% of a middle-aged group (facet \(a\)) and 50% other age groups (facet \(d\)), it might be biased against facet \(d\). In this example, you must determine whether the 10% difference is material to a case for bias. A comparison of DPL with DPPL assesses whether bias initially present in the dataset increases or decreases in the model predictions after training.

The formula for the difference in proportions of predicted labels:

\[
DPPL = q'_a - q'_d
\]
Where:

- \( q'_a = \frac{n'_a(1)}{n_a} \) is the predicted proportion of facet \( a \) who get a positive outcome of value 1. In our example, the proportion of a middle-aged facet predicted to get granted a loan. Here \( n'_a(1) \) represents the number of members of facet \( a \) who get a positive predicted outcome of value 1 and \( n_a \) the is number of members of facet \( a \).

- \( q'_d = \frac{n'_d(1)}{n_d} \) is the predicted proportion of facet \( d \) who get a positive outcome of value 1. In our example, a facet of older and younger people predicted to get granted a loan. Here \( n'_d(1) \) represents the number of members of facet \( d \) who get a positive predicted outcome and \( n_d \) the is number of members of facet \( d \).

If DPPL is close enough to 0, it means that post-training demographic parity has been achieved.

For binary and multicategory facet labels, the normalized DPL values range over the interval \([-1, 1]\). For continuous labels, the values vary over the interval \((-\infty, +\infty)\).

- Positive DPPL values indicate that facet \( a \) has a higher proportion of predicted positive outcomes when compared with facet \( d \). This is referred to as positive bias.

- Values of DPPL near zero indicate a more equal proportion of predicted positive outcomes between facets \( a \) and \( d \) and a value of zero indicates perfect demographic parity.

- Negative DPPL values indicate that facet \( d \) has a higher proportion of predicted positive outcomes when compared with facet \( a \). This is referred to as negative bias.

Disparate Impact (DI)

The difference in positive proportions in the predicted labels metric can be assessed in the form of a ratio.

The comparison of positive proportions in predicted labels metric can be assessed in the form of a ratio instead of as a difference, as it is with the Difference in Positive Proportions in Predicted Labels (DPPL) (p. 3229). The disparate impact (DI) metric is defined as the ratio of the proportion of positive predictions \((y' = 1)\) for facet \( d \) over the proportion of positive predictions \((y' = 1)\) for facet \( a \). For example, if the model predictions grant loans to 60% of a middle-aged group (facet \( a \)) and 50% other age groups (facet \( d \)), then DI = \(.5/.6 = 0.8\), which indicates a positive bias and an adverse impact on the other aged group represented by facet \( d \).

The formula for the ratio of proportions of the predicted labels:

\[
DI = \frac{q'_d}{q'_a}
\]

Where:

- \( q'_a = \frac{n'_a(1)}{n_a} \) is the predicted proportion of facet \( a \) who get a positive outcome of value 1. In our example, the proportion of a middle-aged facet predicted to get granted a loan. Here \( n'_a(1) \) represents the number of members of facet \( a \) who get a positive predicted outcome and \( n_a \) the is number of members of facet \( a \).

- \( q'_d = \frac{n'_d(1)}{n_d} \) is the predicted proportion of facet \( d \) who get a positive outcome of value 1. In our example, a facet of older and younger people predicted to get granted a loan. Here \( n'_d(1) \) represents the number of members of facet \( d \) who get a positive predicted outcome and \( n_d \) the is number of members of facet \( d \).

For binary, multicategory facet, and continuous labels, the DI values range over the interval \([0, \infty)\).
• Values less than 1 indicate that facet $a$ has a higher proportion of predicted positive outcomes than facet $d$. This is referred to as positive bias.
• A value of 1 indicates demographic parity.
• Values greater than 1 indicate that facet $d$ has a higher proportion of predicted positive outcomes than facet $a$. This is referred to as negative bias.

**Difference in Conditional Acceptance (DCAcc)**

This metric compares the observed labels to the labels predicted by the model and assesses whether this is the same across facets for predicted positive outcomes. This metric comes close to mimicking human bias in that it quantifies how many more positive outcomes a model predicted (labels $y'$) for a certain facet as compared to what was observed in the training dataset (labels $y$). For example, if there were more acceptances (a positive outcome) observed in the training dataset for loan applications for a middle-aged group (facet $a$) than predicted by the model based on qualifications as compared to the facet containing other age groups (facet $d$), this might indicate potential bias in the way loans were approved favoring the middle-aged group.

The formula for the difference in conditional acceptance:

$$DCAcc = c_a - c_d$$

Where:

• $c_a = n_a^{(1)} / n_a^{(1)}$ is the ratio of the observed number of positive outcomes of value 1 (acceptances) of facet $a$ to the predicted number of positive outcome (acceptances) for facet $a$.
• $c_d = n_d^{(1)} / n_d^{(1)}$ is the ratio of the observed number of positive outcomes of value 1 (acceptances) of facet $d$ to the predicted number of predicted positive outcomes (acceptances) for facet $d$.

The DCAcc metric can capture both positive and negative biases that reveal preferential treatment based on qualifications. Consider the following instances of age-based bias on loan acceptances.

**Example 1: Positive bias**

Suppose we have dataset of 100 middle-aged people (facet $a$) and 50 people from other age groups (facet $d$) who applied for loans, where the model recommended that 60 from facet $a$ and 30 from facet $d$ be given loans. So the predicted proportions are unbiased with respect to the DPPL metric, but the observed labels show that 70 from facet $a$ and 20 from facet $d$ were granted loans. In other words, the model granted loans to 17% fewer from the middle aged facet than the observed labels in the training data suggested ($70/60 = 1.17$) and granted loans to 33% more from other age groups than the observed labels suggested ($20/30 = 0.67$). The calculation of the DCAcc value gives the following:

$$DCAcc = 70/60 - 20/30 = 1/2$$

The positive value indicates that there is a potential bias against the middle-aged facet $a$ with a lower acceptance rate as compared with the other facet $d$ than the observed data (taken as unbiased) indicate is the case.

**Example 2: Negative bias**

Suppose we have dataset of 100 middle-aged people (facet $a$) and 50 people from other age groups (facet $d$) who applied for loans, where the model recommended that 60 from facet $a$ and 30 from facet $d$ be given loans. So the predicted proportions are unbiased with respect to the DPPL metric, but the observed labels show that 50 from facet $a$ and 40 from facet $d$ were granted loans. In other words, the model granted loans to 17% fewer from the middle aged facet than the observed labels in the training data suggested ($50/60 = 0.83$), and granted loans to 33% more from other age groups than the observed labels suggested ($40/30 = 1.33$). The calculation of the DCAcc value gives the following:
DCAcc = 50/60 - 40/30 = -1/2

The negative value indicates that there is a potential bias against facet d with a lower acceptance rate as compared with the middle-aged facet a than the observed data (taken as unbiased) indicate is the case.

Note that you can use DCAcc to help you detect potential (unintentional) biases by humans overseeing the model predictions in a human-in-the-loop setting. Assume, for example, that the predictions y’ by the model were unbiased, but the eventual decision is made by a human (possibly with access to additional features) who can alter the model predictions to generate a new and final version of y’. The additional processing by the human may unintentionally deny loans to a disproportionate number from one facet. DCAcc can help detect such potential biases.

The range of values for differences in conditional acceptance for binary, multicategory facet, and continuous labels is (-∞, +∞).

- Positive values occur when the ratio of the observed number of acceptances compared to predicted acceptances for facet a is higher than the same ratio for facet d. These values indicate a possible bias against the qualified applicants from facet a. The larger the difference of the ratios, the more extreme the apparent bias.
- Values near zero occur when the ratio of the observed number of acceptances compared to predicted acceptances for facet a is the similar to the ratio for facet d. These values indicate that predicted acceptance rates are consistent with the observed values in the labeled data and that qualified applicants from both facets are being accepted in a similar way.
- Negative values occur when the ratio of the observed number of acceptances compared to predicted acceptances for facet a is less than that ratio for facet d. These values indicate a possible bias against the qualified applicants from facet d. The more negative the difference in the ratios, the more extreme the apparent bias.

**Difference in Conditional Rejection (DCR)**

This metric compares the observed labels to the labels predicted by the model and assesses whether this is the same across facets for negative outcomes (rejections). This metric comes close to mimicking human bias, in that it quantifies how many more negative outcomes a model granted (predicted labels y’) to a certain facet as compared to what was suggested by the labels in the training dataset (observed labels y). For example, if there were more observed rejections (a negative outcome) for loan applications for a middle-aged group (facet a) than predicted by the model based on qualifications as compared to the facet containing other age groups (facet d), this might indicate potential bias in the way loans were rejected that favored the middle-aged group over other groups.

The formula for the difference in conditional acceptance:

\[ \text{DCR} = r_d - r_a \]

Where:

- \( r_d = \frac{n_d^{(0)}}{n_d^{(0)}} \) is the ratio of the observed number of negative outcomes of value 0 (rejections) of facet d to the predicted number of negative outcome (rejections) for facet d.
- \( r_a = \frac{n_a^{(0)}}{n_a^{(0)}} \) is the ratio of the observed number of negative outcomes of value 0 (rejections) of facet a to the predicted number of negative outcome of value 0 (rejections) for facet a.

The DCR metric can capture both positive and negative biases that reveal preferential treatment based on qualifications. Consider the following instances of age-based bias on loan rejections.

**Example 1: Positive bias**

Suppose we have dataset of 100 middle-aged people (facet a) and 50 people from other age groups (facet d) who applied for loans, where the model recommended that 60 from facet a and 30 from facet
be rejected for loans. So the predicted proportions are unbiased by the DPPL metric, but the observed labels show that 50 from facet \( a \) and 40 from facet \( d \) were rejected. In other words, the model rejected 17% more loans from the middle aged facet than the observed labels in the training data suggested (50/60 = 0.83), and rejected 33% fewer loans from other age groups than the observed labels suggested (40/30 = 1.33). The DCR value quantifies this difference in the ratio of observed to predicted rejection rates between the facets. The positive value indicates that there is a potential bias favoring the middle aged group with lower rejection rates as compared with other groups than the observed data (taken as unbiased) indicate is the case.

\[
DCR = \frac{40}{30} - \frac{50}{60} = \frac{1}{2}
\]

**Example 2: Negative bias**

Suppose we have a dataset of 100 middle-aged people (facet \( a \)) and 50 people from other age groups (facet \( d \)) who applied for loans, where the model recommended that 60 from facet \( a \) and 30 from facet \( d \) be rejected for loans. So the predicted proportions are unbiased by the DPPL metric, but the observed labels show that 70 from facet \( a \) and 20 from facet \( d \) were rejected. In other words, the model rejected 17% fewer loans from the middle aged facet than the observed labels in the training data suggested (70/60 = 1.17), and rejected 33% more loans from other age groups than the observed labels suggested (20/30 = 0.67). The negative value indicates that there is a potential bias favoring facet \( a \) with lower rejection rates as compared with the middle-aged facet \( a \) than the observed data (taken as unbiased) indicate is the case.

\[
DCR = \frac{20}{30} - \frac{70}{60} = -\frac{1}{2}
\]

The range of values for differences in conditional rejection for binary, multicategory facet, and continuous labels is \((-\infty, +\infty)\).

- **Positive values** occur when the ratio of the observed number of rejections compared to predicted rejections for facet \( d \) is greater than that ratio for facet \( a \). These values indicate a possible bias against the qualified applicants from facet \( a \). The larger the value of DCR metric, the more extreme the apparent bias.
- **Values near zero** occur when the ratio of the observed number of rejections compared to predicted acceptances for facet \( a \) is similar to the ratio for facet \( d \). These values indicate that predicted rejections rates are consistent with the observed values in the labeled data and that the qualified applicants from both facets are being rejected in a similar way.
- **Negative values** occur when the ratio of the observed number of rejections compared to predicted rejections for facet \( d \) is less than that ratio for facet \( a \). These values indicate a possible bias against the qualified applicants from facet \( d \). The larger magnitude of the negative DCR metric, the more extreme the apparent bias.

### Specificity difference (SD)

The specificity difference (SD) is the difference in specificity between the favored facet \( a \) and disfavored facet \( d \). Specificity measures how often the model correctly predicts a negative outcome (\( y' = 0 \)). Any difference in these specificities is a potential form of bias.

Specificity is perfect for a facet if all of the \( y = 0 \) cases are correctly predicted for that facet. Specificity is greater when the model minimizes false positives, known as a Type I error. For example, the difference between a low specificity for lending to facet \( a \), and high specificity for lending to facet \( d \), is a measure of bias against facet \( d \).

The following formula is for the difference in the specificity for facets \( a \) and \( d \).

\[
SD = \frac{TN_d}{(TN_d + FP_d)} - \frac{TN_a}{(TN_a + FP_a)} = TNR_d - TNR_a
\]

The following variables used to calculated SD are defined as follows:
• TN\(_d\) are the true negatives predicted for facet \(d\).
• FP\(_d\) are the false positives predicted for facet \(d\).
• TN\(_a\) are the true negatives predicted for facet \(a\).
• FP\(_a\) are the false positives predicted for facet \(a\).
• TNR\(_a\) = TN\(_a\)/(TN\(_a\) + FP\(_a\)) is the true negative rate, also known as the specificity, for facet \(a\).
• TNR\(_d\) = TN\(_d\)/(TN\(_d\) + FP\(_d\)) is the true negative rate, also known as the specificity, for facet \(d\).

For example, consider the following confusion matrices for facets \(a\) and \(d\).

**Confusion matrix for the favored facet \(a\)**

<table>
<thead>
<tr>
<th>Class (a) predictions</th>
<th>Actual outcome 0</th>
<th>Actual outcome 1</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>20</td>
<td>5</td>
<td>25</td>
</tr>
<tr>
<td>1</td>
<td>10</td>
<td>65</td>
<td>75</td>
</tr>
<tr>
<td>Total</td>
<td>30</td>
<td>70</td>
<td>100</td>
</tr>
</tbody>
</table>

**Confusion matrix for the disfavored facet \(d\)**

<table>
<thead>
<tr>
<th>Class (d) predictions</th>
<th>Actual outcome 0</th>
<th>Actual outcome 1</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>18</td>
<td>7</td>
<td>25</td>
</tr>
<tr>
<td>1</td>
<td>5</td>
<td>20</td>
<td>25</td>
</tr>
<tr>
<td>Total</td>
<td>23</td>
<td>27</td>
<td>50</td>
</tr>
</tbody>
</table>

The value of the specificity difference is \(SD = 18/(18+5) - 20/(20+10) = 0.7826 - 0.6667 = 0.1159\), which indicates a bias against facet \(d\).

The range of values for the specificity difference between facets \(a\) and \(d\) for binary and multicategory classification is \([-1, +1]\). This metric is not available for the case of continuous labels. Here is what different values of SD imply:

• Positive values are obtained when there is higher specificity for facet \(d\) than for facet \(a\). This suggests that the model finds less false positives for facet \(d\) than for facet \(a\). A positive value indicates bias against facet \(d\).
• Values near zero indicate that the specificity for facets that are being compared is similar. This suggests that the model finds a similar number of false positives in both of these facets and is not biased.
• Negative values are obtained when there is higher specificity for facet \(a\) than for facet \(d\). This suggests that the model finds more false positives for facet \(a\) than for facet \(d\). A negative value indicates bias against facet \(a\).

**Recall Difference (RD)**

The recall difference (RD) metric is the difference in recall of the model between the favored facet \(a\) and disfavored facet \(d\). Any difference in these recalls is a potential form of bias. Recall is the true positive rate (TPR), which measures how often the model correctly predicts the cases that should receive a positive outcome. Recall is perfect for a facet if all of the \(y=1\) cases are correctly predicted as \(y'=1\) for that facet. Recall is greater when the model minimizes false negatives known as the Type II error. For example, how many of the people in two different groups (facets \(a\) and \(d\)) that should qualify for loans
are detected correctly by the model? If the recall rate is high for lending to facet $a$, but low for lending to facet $d$, the difference provides a measure of this bias against the group belonging to facet $d$.

The formula for difference in the recall rates for facets $a$ and $d$:

$$RD = \frac{TP_a}{TP_a + FN_a} - \frac{TP_d}{TP_d + FN_d} = TPR_a - TPR_d$$

Where:

- $TP_a$ are the true positives predicted for facet $a$.
- $FN_a$ are the false negatives predicted for facet $a$.
- $TP_d$ are the true positives predicted for facet $d$.
- $FN_d$ are the false negatives predicted for facet $d$.
- $TPR_a = \frac{TP_a}{TP_a + FN_a}$ is the recall for facet $a$, or its true positive rate.
- $TPR_d = \frac{TP_d}{TP_d + FN_d}$ is the recall for facet $d$, or its true positive rate.

For example, consider the following confusion matrices for facets $a$ and $d$.

Confusion Matrix for the Favored Facet $a$

<table>
<thead>
<tr>
<th>Class $a$ predictions</th>
<th>Actual outcome 0</th>
<th>Actual outcome 1</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>20</td>
<td>5</td>
<td>25</td>
</tr>
<tr>
<td>1</td>
<td>10</td>
<td>65</td>
<td>75</td>
</tr>
<tr>
<td>Total</td>
<td>30</td>
<td>70</td>
<td>100</td>
</tr>
</tbody>
</table>

Confusion Matrix for the Disfavored Facet $d$

<table>
<thead>
<tr>
<th>Class $d$ predictions</th>
<th>Actual outcome 0</th>
<th>Actual outcome 1</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>18</td>
<td>7</td>
<td>25</td>
</tr>
<tr>
<td>1</td>
<td>5</td>
<td>20</td>
<td>25</td>
</tr>
<tr>
<td>Total</td>
<td>23</td>
<td>27</td>
<td>50</td>
</tr>
</tbody>
</table>

The value of the recall difference is $RD = \frac{65}{70} - \frac{20}{27} = 0.93 - 0.74 = 0.19$ which indicates a bias against facet $d$.

The range of values for the recall difference between facets $a$ and $d$ for binary and multicategory classification is $[-1, +1]$. This metric is not available for the case of continuous labels.

- Positive values are obtained when there is higher recall for facet $a$ than for facet $d$. This suggests that the model finds more of the true positives for facet $a$ than for facet $d$, which is a form of bias.
- Values near zero indicate that the recall for facets being compared is similar. This suggests that the model finds about the same number of true positives in both of these facets and is not biased.
- Negative values are obtained when there is higher recall for facet $d$ than for facet $a$. This suggests that the model finds more of the true positives for facet $d$ than for facet $a$, which is a form of bias.

Difference in Acceptance Rates (DAR)

The difference in acceptance rates (DAR) metric is the difference in the ratios of the true positive (TP) predictions to the observed positives (TP + FP) for facets $a$ and $d$. This metric measures the difference
in the precision of the model for predicting acceptances from these two facets. Precision measures the fraction of qualified candidates from the pool of qualified candidates that are identified as such by the model. If the model precision for predicting qualified applicants diverges between the facets, this is a bias and its magnitude is measured by the DAR.

The formula for difference in acceptance rates between facets $a$ and $d$:

$$DAR = \frac{TP_a}{TP_a + FP_a} - \frac{TP_d}{TP_d + FP_d}$$

Where:
- $TP_a$ are the true positives predicted for facet $a$.
- $FP_a$ are the false positives predicted for facet $a$.
- $TP_d$ are the true positives predicted for facet $d$.
- $FP_d$ are the false positives predicted for facet $d$.

For example, suppose the model accepts 70 middle-aged applicants (facet $a$) for a loan (predicted positive labels) of whom only 35 are actually accepted (observed positive labels). Also suppose the model accepts 100 applicants from other age demographics (facet $d$) for a loan (predicted positive labels) of whom only 40 are actually accepted (observed positive labels). Then $DAR = 35/70 - 40/100 = 0.10$, which indicates a potential bias against qualified people from the second age group (facet $d$).

The range of values for DAR for binary, multicategory facet, and continuous labels is $[-1, +1]$.

- Positive values occur when the ratio of the predicted positives (acceptances) to the observed positive outcomes (qualified applicants) for facet $a$ is larger than the same ratio for facet $d$. These values indicate a possible bias against the disfavored facet $d$ caused by the occurrence of relatively more false positives in facet $d$. The larger the difference in the ratios, the more extreme the apparent bias.
- Values near zero occur when the ratio of the predicted positives (acceptances) to the observed positive outcomes (qualified applicants) for facets $a$ and $d$ have similar values indicating the observed labels for positive outcomes are being predicted with equal precision by the model.
- Negative values occur when the ratio of the predicted positives (acceptances) to the observed positive outcomes (qualified applicants) for facet $d$ is larger than the ratio facet $a$. These values indicate a possible bias against the favored facet $a$ caused by the occurrence of relatively more false positives in facet $a$. The more negative the difference in the ratios, the more extreme the apparent bias.

**Difference in Rejection Rates (DRR)**

The difference in rejection rates (DRR) metric is the difference in the ratios of the true negative (TN) predictions to the observed negatives (TN + FN) for facets $a$ and $d$. This metric measures the difference in the precision of the model for predicting rejections from these two facets. Precision measures the fraction of unqualified candidates from the pool of unqualified candidates that are identified as such by the model. If the model precision for predicting unqualified applicants diverges between the facets, this is a bias and its magnitude is measured by the DRR.

The formula for difference in rejection rates between facets $a$ and $d$:

$$DRR = \frac{TN_d}{TN_d + FN_d} - \frac{TN_a}{TN_a + FN_a}$$

The components for the previous DRR equation are as follows.
- $TN_d$ are the true negatives predicted for facet $d$.
- $FN_d$ are the false negatives predicted for facet $d$.
- $TP_a$ are the true negatives predicted for facet $a$. 
• FN\textsubscript{a} are the false negatives predicted for facet \textit{a}.

For example, suppose the model rejects 100 middle-aged applicants (facet \textit{a}) for a loan (predicted negative labels) of whom 80 are actually unqualified (observed negative labels). Also suppose the model rejects 50 applicants from other age demographics (facet \textit{d}) for a loan (predicted negative labels) of whom only 40 are actually unqualified (observed negative labels). Then \text{DRR} = 40/50 - 80/100 = 0, so no bias is indicated.

The range of values for \text{DRR} for binary, multicategory facet, and continuous labels is [-1, +1].

• Positive values occur when the ratio of the predicted negatives (rejections) to the observed negative outcomes (unqualified applicants) for facet \textit{d} is larger than the same ratio for facet \textit{a}. These values indicate a possible bias against the favored facet \textit{a} caused by the occurrence of relatively more false negatives in facet \textit{a}. The larger the difference in the ratios, the more extreme the apparent bias.

• Values near zero occur when the ratio of the predicted negatives (rejections) to the observed negative outcomes (unqualified applicants) for facets \textit{a} and \textit{d} have similar values, indicating the observed labels for negative outcomes are being predicted with equal precision by the model.

• Negative values occur when the ratio of the predicted negatives (rejections) to the observed negative outcomes (unqualified applicants) for facet \textit{a} is larger than the ratio facet \textit{d}. These values indicate a possible bias against the disfavored facet \textit{d} caused by the occurrence of relatively more false positives in facet \textit{d}. The more negative the difference in the ratios, the more extreme the apparent bias.

**Accuracy Difference (AD)**

Accuracy difference (AD) metric is the difference between the prediction accuracy for different facets. This metric determines whether the classification by the model is more accurate for one facet than the other. AD indicates whether one facet incurs a greater proportion of Type I and Type II errors. But it cannot differentiate between Type I and Type II errors. For example, the model may have equal accuracy for different age demographics, but the errors may be mostly false positives (Type I errors) for one age-based group and mostly false negatives (Type II errors) for the other.

Also, if loan approvals are made with much higher accuracy for a middle-aged demographic (facet \textit{a}) than for another age-based demographic (facet \textit{d}), either a greater proportion of qualified applicants in the second group are denied a loan (FN) or a greater proportion of unqualified applicants from that group get a loan (FP) or both. This can lead to within group unfairness for the second group, even if the proportion of loans granted is nearly the same for both age-based groups, which is indicated by a DPPL value that is close to zero.

The formula for AD metric is the difference between the prediction accuracy for facet \textit{a}, ACC\textsubscript{a}, minus that for facet \textit{d}, ACC\textsubscript{d}:

\[
AD = ACC_a - ACC_d
\]

Where:

- ACC\textsubscript{a} = (\text{TP}_a + \text{TN}_a)/(\text{TP}_a + \text{TN}_a + \text{FP}_a + \text{FN}_a)
  - TP\textsubscript{a} are the true positives predicted for facet \textit{a}
  - TN\textsubscript{a} are the true negatives predicted for facet \textit{a}
  - FP\textsubscript{a} are the false positives predicted for facet \textit{a}
  - FN\textsubscript{a} are the false negatives predicted for facet \textit{a}
- ACC\textsubscript{d} = (\text{TP}_d + \text{TN}_d)/(\text{TP}_d + \text{TN}_d + \text{FP}_d + \text{FN}_d)
  - TP\textsubscript{d} are the true positives predicted for facet \textit{d}
  - TN\textsubscript{d} are the true negatives predicted for facet \textit{d}
  - FP\textsubscript{d} are the false positives predicted for facet \textit{d}
• FN_d are the false negatives predicted for facet d

For example, suppose a model approves loans to 70 applicants from facet a of 100 and rejected the other 30. 10 should not have been offered the loan (FP_a) and 60 were approved that should have been (TP_a). 20 of the rejections should have been approved (FN_a) and 10 were correctly rejected (TN_a). The accuracy for facet a is as follows:

$$ACCA = \frac{(60 + 10)}{(60 + 10 + 20 + 10)} = 0.7$$

Next, suppose a model approves loans to 50 applicants from facet d of 100 and rejected the other 50. 10 should not have been offered the loan (FP_d) and 40 were approved that should have been (TP_d). 40 of the rejections should have been approved (FN_d) and 10 were correctly rejected (TN_d). The accuracy for facet d is determined as follows:

$$ACCD = \frac{(40 + 10)}{(40 + 10 + 40 + 10)} = 0.5$$

The accuracy difference is thus AD = ACC_a - ACC_d = 0.7 - 0.5 = 0.2. This indicates there is a bias against facet d as the metric is positive.

The range of values for AD for binary and multicategory facet labels is [-1, +1].

• Positive values occur when the prediction accuracy for facet a is greater than that for facet d. It means that facet d suffers more from some combination of false positives (Type I errors) or false negatives (Type II errors). This means there is a potential bias against the disfavored facet d.

• Values near zero occur when the prediction accuracy for facet a is similar to that for facet d.

• Negative values occur when the prediction accuracy for facet d is greater than that for facet a. It means that facet a suffers more from some combination of false positives (Type I errors) or false negatives (Type II errors). This means the is a bias against the favored facet a.

Treatment Equality (TE)

The treatment equality (TE) is the difference in the ratio of false negatives to false positives between facets a and d. The main idea of this metric is to assess whether, even if the accuracy across groups is the same, is it the case that errors are more harmful to one group than another? Error rate comes from the total of false positives and false negatives, but the breakdown of these two maybe very different across facets. TE measures whether errors are compensating in the similar or different ways across facets.

The formula for the treatment equality:

$$TE = \frac{FN_d}{FP_d} - \frac{FN_a}{FP_a}$$

Where:

• FN_d are the false negatives predicted for facet d.
• FP_d are the false positives predicted for facet d.
• FN_a are the false negatives predicted for facet a.
• FP_a are the false positives predicted for facet a.

Note the metric becomes unbounded if FP_a or FP_d is zero.

For example, suppose that there are 100 loan applicants from facet a and 50 from facet d. For facet a, 8 were wrongly denied a loan (FN_a) and another 6 were wrongly approved (FP_a). The remaining predictions were true, so TP_a + TN_a = 86. For facet d, 5 were wrongly denied (FN_d) and 2 were wrongly approved (FP_d). The remaining predictions were true, so TP_d + TN_d = 43. The ratio of false negatives to false positives equals 8/6 = 1.33 for facet a and 5/2 = 2.5 for facet d. Hence TE = 2.5 - 1.33 = 1.167, even though both facets have the same accuracy.
ACC_a = (86)/(86 + 8 + 6) = 0.86
ACC_d = (43)/(43 + 5 + 2) = 0.86

The range of values for differences in conditional rejection for binary and multicategory facet labels is \((-\infty, +\infty)\). The TE metric is not defined for continuous labels. The interpretation of this metric depends on the relative important of false positives (Type I error) and false negatives (Type II error).

- Positive values occur when the ratio of false negatives to false positives for facet \(d\) is greater than that for facet \(a\).
- Values near zero occur when the ratio of false negatives to false positives for facet \(a\) is similar to that for facet \(d\).
- Negative values occur when the ratio of false negatives to false positives for facet \(d\) is less than that for facet \(a\).

**Note**
A previous version stated that the Treatment Equality metric is computed as \(FP_a / FN_a - FP_d / FN_d\) instead of \(FN_d / FP_d - FN_a / FP_a\). While either of the versions can be used. For more information, see [Fairness measures for Machine Learning in Finance](#).

### Conditional Demographic Disparity in Predicted Labels (CDDPL)

The demographic disparity metric (DDPL) determines whether facet \(d\) has a larger proportion of the predicted rejected labels than of the predicted accepted labels. It enables a comparison of difference in predicted rejection proportion and predicted acceptance proportion across facets. This metric is exactly the same as the pre-training CDD metric except that it is computed off the predicted labels instead of the observed ones. This metric lies in the range \((-1,+1)\).

The formula for the demographic disparity predictions for labels of facet \(d\) is as follows:

\[
DDPL_d = \frac{n'_d(0)/n'(0) - n'_d(1)/n'(1)}{P_d^R(y'_0) - P_d^A(y'_1)}
\]

Where:
- \(n'_d(0) = n'_a(0) + n'_d(0)\) is the number of predicted rejected labels for facets \(a\) and \(d\).
- \(n'_d(1) = n'_a(1) + n'_d(1)\) is the number of predicted accepted labels for facets \(a\) and \(d\).
- \(P_d^R(y'_0)\) is the proportion of predicted rejected labels (value 0) in facet \(d\).
- \(P_d^A(y'_1)\) is the proportion of predicted accepted labels (value 1) in facet \(d\).

A conditional demographic disparity in predicted labels (CDDPL) metric that conditions DDPL on attributes that define a strata of subgroups on the dataset is needed to rule out Simpson's paradox. The regrouping can provide insights into the cause of apparent demographic disparities for less favored facets. The classic case arose in the case of Berkeley admissions where men were accepted at a higher rate overall than women. But when departmental subgroups were examined, women were shown to have higher admission rates than men by department. The explanation was that women had applied to departments with lower acceptance rates than men had. Examining the subgroup acceptance rates revealed that women were actually accepted at a higher rate than men for the departments with lower acceptance rates.

The CDDPL metric gives a single measure for all of the disparities found in the subgroups defined by an attribute of a dataset by averaging them. It is defined as the weighted average of demographic disparities in predicted labels (DDPL) for each of the subgroups, with each subgroup disparity weighted in proportion to the number of observations in contains. The formula for the conditional demographic disparity in predicted labels is as follows:

\[
CDDPL = \frac{1}{n}\sum_{i} n_i \cdot DDPL_i
\]
Where:

- \( \sum n_i = n \) is the total number of observations and \( n_i \) is the number of observations for each subgroup.
- \( DDPL_i = \frac{n_i^{(0)}}{n^{(0)}} - \frac{n_i^{(1)}}{n^{(1)}} = P_i^R(y^{0}) - P_i^A(y^{1}) \) is the demographic disparity in predicted labels for the subgroup.

So the demographic disparity for a subgroup in predicted labels (DDPL) are the difference between the proportion of predicted rejected labels and the proportion of predicted accepted labels for each subgroup.

The range of DDPL values for binary, multicategory, and continuous outcomes is \([-1, +1]\).

- +1: when there are no predicted rejection labels for facet \( a \) or subgroup and no predicted acceptances for facet \( d \) or subgroup.
- Positive values indicate there is a demographic disparity in predicted labels as facet \( d \) or subgroup has a larger proportion of the predicted rejected labels than of the predicted accepted labels. The higher the value the greater the disparity.
- Values near zero indicate there is no demographic disparity on average.
- Negative values indicate there is a demographic disparity in predicted labels as facet \( a \) or subgroup has a larger proportion of the predicted rejected labels than of the predicted accepted labels. The lower the value the greater the disparity.
- -1: when there are no predicted rejection label for facet \( d \) or subgroup and no predicted acceptances for facet \( a \) or subgroup.

**Counterfactual Flipped Test (FT)**

The flipped test is an approach that looks at each member of facet \( d \) and assesses whether similar members of facet \( a \) have different model predictions. The members of facet \( a \) are chosen to be \( k \)-nearest neighbors of the observation from facet \( d \). We assess how many nearest neighbors of the opposite group receive a different prediction, where the flipped prediction can go from positive to negative and vice versa.

The formula for the counterfactual flipped test is the difference in the cardinality of two sets divided by the number of members of facet \( d \):

\[
FT = \frac{F^+ - F^-}{n_d}
\]

Where:

- \( F^+ \) is the number of disfavored facet \( d \) members with an unfavorable outcome whose nearest neighbors in favored facet \( a \) received a favorable outcome.
- \( F^- \) is the number of disfavored facet \( d \) members with a favorable outcome whose nearest neighbors in favored facet \( a \) received an unfavorable outcome.
- \( n_d \) is the sample size of facet \( d \).

The range of values for the counterfactual flipped test for binary and multicategory facet labels is \([-1, +1]\). For continuous labels, we set a threshold to collapse the labels to binary.

- Positive values occur when the number of unfavorable counterfactual flipped test decisions for the disfavored facet \( d \) exceeds the favorable ones.
- Values near zero occur when the number of unfavorable and favorable counterfactual flipped test decisions balance out.
- Negative values occur when the number of unfavorable counterfactual flipped test decisions for the disfavored facet \( d \) is less than the favorable ones.
Generalized entropy (GE)

The generalized entropy index (GE) measures the inequality in benefit \( b \) for the predicted label compared to the observed label. A benefit occurs when a false positive is predicted. A false positive occurs when a negative observation (\( y=0 \)) has a positive prediction (\( y'=1 \)). A benefit also occurs when the observed and predicted labels are the same, also known as a true positive and true negative. No benefit occurs when a false negative is predicted. A false negative occurs when a positive observation (\( y=1 \)) is predicted to have a negative outcome (\( y'=0 \)). The benefit \( b \) is defined, as follows.

\[
b = y' - y + 1
\]

Using this definition, a false positive receives a benefit \( b \) of 2, and a false negative receives a benefit of 0. Both a true positive and a true negative receive a benefit of 1.

The GE metric is computed following the Generalized Entropy Index (GE) with the weight \( \alpha \) set to 2. This weight controls the sensitivity to different benefit values. A smaller \( \alpha \) means an increased sensitivity to smaller values.

\[
GE = \frac{1}{2n} \sum_{i=1}^{n} \left[ \left( \frac{b_i}{b'} \right)^2 - 1 \right]
\]

The following variables used to calculate GE are defined as follows:

- \( b_i \) is the benefit received by the \( i^{th} \) data point.
- \( b' \) is the mean of all benefits.

GE can range from 0 to 0.5, where values of zero indicate no inequality in benefits across all data points. This occurs either when all inputs are correctly predicted or when all the predictions are false positives. GE is undefined when all predictions are false negatives.

**Note**
The metric GE does not depend on a facet value being either favored or disfavored.

Amazon SageMaker Clarify Model Explainability

Amazon SageMaker Clarify provides tools to help explain how machine learning (ML) models make predictions. These tools can help ML modelers and developers and other internal stakeholders understand model characteristics as a whole prior to deployment and to debug predictions provided by the model after it’s deployed. Transparency about how ML models arrive at their predictions is also critical to consumers and regulators. They need to trust the model predictions if they are going to accept the decisions based on them. SageMaker Clarify uses a model-agnostic feature attribution approach. You can use this to understand why a model made a prediction after training, and to provide per-instance explanation during inference. The implementation includes a scalable and efficient implementation of SHAP. This is based on the concept of a Shapley value, from the field of cooperative game theory, that assigns each feature an importance value for a particular prediction.

Clarify produces partial dependence plots (PDPs) that show the marginal effect features have on the predicted outcome of a machine learning model. Partial dependence helps explain target response given a set of input features. It also supports both computer vision (CV) and natural language processing (NLP) explainability using the same Shapley Values (SHAP) algorithm as used for tabular data explanations.

What is the function of an explanation in the machine learning context? An explanation can be thought of as the answer to a *Why question* that helps humans understand the cause of a prediction. In the context of an ML model, you might be interested in answering questions such as:

- Why did the model predict a negative outcome such as a loan rejection for a given applicant?
• How does the model make predictions?
• Why did the model make an incorrect prediction?
• Which features have the largest influence on the behavior of the model?

You can use explanations for auditing and meeting regulatory requirements, building trust in the model and supporting human decision-making, and debugging and improving model performance.

The need to satisfy the demands for human understanding about the nature and outcomes of ML inference is key to the sort of explanation needed. Research from philosophy and cognitive science disciplines has shown that people care especially about contrastive explanations, or explanations of why an event X happened instead of some other event Y that did not occur. Here, X could be an unexpected or surprising event that happened and Y corresponds to an expectation based on their existing mental model referred to as a baseline. Note that for the same event X, different people might seek different explanations depending on their point of view or mental model Y. In the context of explainable AI, you can think of X as the example being explained and Y as a baseline that is typically chosen to represent an uninformative or average example in the dataset. Sometimes, for example in the case of ML modeling of images, the baseline might be implicit, where an image whose pixels are all the same color can serves as a baseline.

Sample Notebooks

Amazon SageMaker Clarify provides the following sample notebook for model explainability:

• Amazon SageMaker Clarify Processing – Use SageMaker Clarify to create a processing job for the detecting bias and explaining model predictions with feature attributions. Examples include using CSV and JSON Lines data formats, bringing your own container, and running processing jobs with Spark.
• Explaining Image Classification with SageMaker Clarify – SageMaker Clarify provides you with insights into how your computer vision models classify images.
• Explaining object detection models with SageMaker Clarify – SageMaker Clarify provides you with insights into how your computer vision models detect objects.

This notebook has been verified to run in Amazon SageMaker Studio only. If you need instructions on how to open a notebook in Amazon SageMaker Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 225). If you’re prompted to choose a kernel, choose Python 3 (Data Science).

Topics

• Feature Attributions that Use Shapley Values (p. 3242)
• SHAP Baselines for Explainability (p. 3243)

Feature Attributions that Use Shapley Values

SageMaker Clarify provides feature attributions based on the concept of Shapley value. You can use Shapley values to determine the contribution that each feature made to model predictions. These attributions can be provided for specific predictions and at a global level for the model as a whole. For example, if you used an ML model for college admissions, the explanations could help determine whether the GPA or the SAT score was the feature most responsible for the model’s predictions, and then you can determine how responsible each feature was for determining an admission decision about a particular student.

SageMaker Clarify has taken the concept of Shapley values from game theory and deployed it in a machine learning context. The Shapley value provides a way to quantify the contribution of each player to a game, and hence the means to distribute the total gain generated by a game to its players based on their contributions. In this machine learning context, SageMaker Clarify treats the prediction of the model on a given instance as the game and the features included in the model as the players. For a first
approximation, you might be tempted to determine the marginal contribution or effect of each feature by quantifying the result of either **dropping** that feature from the model or **dropping** all other features from the model. However, this approach does not take into account that features included in a model are often not independent from each other. For example, if two features are highly correlated, dropping either one of the features might not alter the model prediction significantly.

To address these potential dependencies, the Shapley value requires that the outcome of each possible combination (or coalition) of features must be considered to determine the importance of each feature. Given \( d \) features, there are \( 2^d \) such possible feature combinations, each corresponding to a potential model. To determine the attribution for a given feature \( f \), consider the marginal contribution of including \( f \) in all feature combinations (and associated models) that do not contain \( f \), and take the average. It can be shown that Shapley value is the unique way of assigning the contribution or importance of each feature that satisfies certain desirable properties. In particular, the sum of Shapley values of each feature corresponds to the difference between the predictions of the model and a dummy model with no features. However, even for reasonable values of \( d \), say 50 features, it is computationally prohibitive and impractical to train \( 2^d \) possible models. As a result, SageMaker Clarify needs to make use of various approximation techniques. For this purpose, SageMaker Clarify uses Shapley Additive exPlanations (SHAP), which incorporates such approximations and devised a scalable and efficient implementation of the Kernel SHAP algorithm through additional optimizations.

For additional information on Shapley values, see [A Unified Approach to Interpreting Model Predictions](#).

### SHAP Baselines for Explainability

Explanations are typically contrastive (that is, they account for deviations from a baseline). As a result, for the same model prediction, you can expect to get different explanations with respect to different baselines. Therefore, your choice of a baseline is crucial. In an ML context, the baseline corresponds to a hypothetical instance that can be either **uninformative** or **informative**. During the computation of Shapley values, SageMaker Clarify generates several new instances between the baseline and the given instance, in which the absence of a feature, is modeled by setting the feature value to that of the baseline and the presence of a feature is modeled by setting the feature value to that of the given instance. Thus, the absence of all features corresponds to the baseline and the presence of all features corresponds to the given instance.

How can you choose good baselines? Often it is desirable to select a baseline with very low information content. For example, you can construct an average instance from the training dataset by taking either the median or average for numerical features and the mode for categorical features. For the college admissions example, you might be interested in explaining why a particular applicant was accepted as compared to a baseline acceptances based on an average applicant. If not provided, a baseline is calculated automatically by SageMaker Clarify using K-means or K-prototypes in the input dataset.

Alternatively, you can choose to generate explanations with respect to informative baselines. For the college admissions scenario, you might want to explain why a particular applicant was rejected when compared with other applicants from similar demographic backgrounds. In this case, you can choose a baseline that represents the applicants of interest, namely those from a similar demographic background. Thus, you can use informative baselines to concentrate the analysis on the specific aspects of a particular model prediction. You can isolate the features for assessment by setting demographic attributes and other features that you can’t act on to the same value as in the given instance.

### Use SageMaker Clarify Explainability with SageMaker Autopilot

Autopilot uses tools provided by Amazon SageMaker Clarify to help provide insights into how machine learning (ML) models make predictions. These tools can help ML engineers, product managers, and
other internal stakeholders understand model characteristics. Both consumers and regulators rely on transparency in machine learning in order to trust and interpret decisions made on model predictions.

The Autopilot explanatory functionality uses a model-agnostic feature attribution approach. This approach determines the contribution of individual features or inputs to the model's output, providing insights into the relevance of different features. You can use it to understand why a model made a prediction after training, or use it to provide per-instance explanation during inference. The implementation includes a scalable implementation of SHAP (Shapley Additive Explanations) based on the concept of a Shapley value from cooperative game theory, which assigns each feature an importance value for a particular prediction.

You can use these explanations for auditing and meeting regulatory requirements, building trust in the model, supporting human decision-making, or debugging and improving model performance.

For additional information on Shapely values and baselines, see SHAP Baselines for Explainability.

For a guide to the Amazon SageMaker Clarify documentation, see Guide to the SageMaker Clarify Documentation.
Use governance to document and track model performance

Model governance is a framework that gives systematic visibility into machine learning (ML) model development, validation, and usage. Amazon SageMaker provides purpose-built ML governance tools for managing control access, activity tracking, and reporting across the ML lifecycle.

Manage least-privilege permissions for ML practitioners using Amazon SageMaker Role Manager, create detailed model documentation using Amazon SageMaker Model Cards, and gain visibility into your models with centralized dashboards using Amazon SageMaker Model Dashboard.

Amazon SageMaker Role Manager

With Amazon SageMaker Role Manager, administrators can define user permissions with least-privilege permissions for common machine learning activities. Use Amazon SageMaker Role Manager to build and manage persona-based IAM roles specific to your business needs.

For more information, see Amazon SageMaker Role Manager (p. 3410).

Amazon SageMaker Model Cards

Use Amazon SageMaker Model Cards to document, retrieve, and share essential model information from conception to deployment. With model cards, model risk managers, data scientists, and ML engineers can create an immutable record of intended model uses, risk ratings, training details, evaluation results, and more.

For more information, see Amazon SageMaker Model Cards (p. 3245).

Amazon SageMaker Model Dashboard

Amazon SageMaker Model Dashboard is a pre-built, visual overview of all the models in your account. SageMaker Model Dashboard integrates valuable information from Amazon SageMaker Model Monitor, Transform Jobs, Endpoints, ML Lineage Tracking and Amazon CloudWatch so you can access high-level model information and track model performance in one unified view.

For more information, see Amazon SageMaker Model Dashboard (p. 3271).

Amazon SageMaker Model Cards

Use Amazon SageMaker Model Cards to document critical details about your machine learning (ML) models in a single place for streamlined governance and reporting.

Catalog details such as the intended use and risk rating of a model, training details and metrics, evaluation results and observations, and additional call-outs such as considerations, recommendations, and custom information. By creating model cards, you can do the following:
Prerequisites

To get started with Amazon SageMaker Model Cards, you must have permission to create, edit, view, and export model cards.

Intended uses of a model

Specifying the intended uses of a model helps ensure that model developers and users have the information they need to train or deploy the model responsibly. The intended uses of a model should describe the scenarios in which the model is appropriate to use as well as the scenarios in which the model is not recommended to use.

We recommend including:

- The general purpose of the model
- Use cases for which the model was intended
- Use cases for which the model was not intended
- Assumptions made when developing the model

The intended uses of a model go beyond technical details and describe how a model should be used in production, the scenarios in which it is appropriate to use a model, and additional considerations such as the type of data to use with the model or any assumptions made during development.

Risk ratings

Developers create ML models for use cases with varying levels of risk. For example, a model that approves loan applications might be a higher risk model than one that detects the category of an email. Given the varied risk profiles of a model, model cards provide a field for you to categorize a model's risk rating.
This risk rating can be unknown, low, medium, or high. Use these risk rating fields to label unknown, low, medium, or high-risk models and help your organization comply with any existing rules about putting certain models into production.

Model card JSON schema

Evaluation details for a model card must be provided in JSON format. If you have existing JSON format evaluation reports generated by SageMaker Clarify or SageMaker Model Monitor, upload them to Amazon S3 and provide an S3 URI to automatically parse evaluation metrics. For more information and sample reports, see the example metrics folder in the Amazon SageMaker Model Governance - Model Cards example notebook.

When creating a model card using the SageMaker Python SDK, model content must be in the model card JSON schema and provided as a string. Provide model content similar to the following example.

Model card JSON schema sample file

```json
{
    "$schema": "http://json-schema.org/draft-07/schema#",
    "$id": "http://json-schema.org/draft-07/schema#",

Create a model card

You can create an Amazon SageMaker Model Card using either the SageMaker console or the SageMaker Python SDK. You can also use the API operations directly. For more information about the API operations, see Use model cards through the low-level APIs (p. 3268).

Create a model card using the SageMaker console

Go to the Amazon SageMaker console. In the navigation pane, under Governance, choose Model cards. On the upper right-hand corner, choose Create model card.
Go through the four steps in the Create model card prompt to document details about your model.

**Step 1: Enter model details and intended use**

If your model is an AWS resource, specify the exact model name in this field to auto-populate model details. To browse existing model names, see Models in the Amazon SageMaker console. Each unique model name can have only one associated model card.

If your model is not an AWS resource, provide a unique name for your model. To add a model as an AWS resource, see Create a model in the Amazon SageMaker Developer Guide. Alternatively, you can add your model as a model package using SageMaker Marketplace or SageMaker Model Registry.

For more information on intended uses, see Intended uses of a model (p. 3246). For more information on risk ratings, see Risk ratings (p. 3246).

**Step 2: Enter training details**

Add any training details, training observations, datasets, hyperparameters, and details about the model’s objective function to the model card.

The objective function in a model card can be any function that is optimized during training. This can include, but is not limited to, cost functions, loss functions, or objective metrics. In this section, document the objective function that is most critical to training your model.

We recommend that you catalog the following attributes of your objective function:

- Optimization direction
- Metric
- Description

For example, you might minimize (optimization direction) cross entropy loss (metric) for a binary classification problem (description) or maximize likelihood for logistic regression. Additionally, you can provide notes about why you chose this objective function over others.

**Step 3: Enter evaluation details**

If you have existing evaluation reports generated by SageMaker Clarify or Model Monitor, either provide an S3 URI for those reports or upload them manually to add them to the model card.

For more information on SageMaker Clarify, see Run SageMaker Clarify Processing Jobs for Bias Analysis and Explainability.

For more information on monitoring drift in model quality metrics using Model Monitor, see Monitor model quality.

To add your own evaluation report, choose Generic model card evaluation. All model card evaluation reports must be in the Model card JSON schema (p. 3247).

**Step 4: Enter additional details**

Add custom model card detail fields for any additional information that you want to address on your model card. For example, you might include the custom field Line of business with a value of Personal finance.

**Save model card**

After reviewing the information in your model card, choose Save in the lower right-hand corner to save your model card.
Create a model card using the SageMaker Python SDK

Before creating a model card, you must first define the content of your model card. When using the SageMaker Python SDK, model content consists of a model overview, training details, intended uses, evaluation details, and additional information.

You can create model cards for:

- Models that are hosted within SageMaker
- Model packages (models) within the SageMaker Model Registry
- Models that are hosted or registered outside of SageMaker

You can also create model cards without associating any models to them.

We recommend adding the models that you've trained to the SageMaker Model Registry. The model registry helps you catalog models and track model versions. When you create a model card, the information about the model from the model registry automatically populates the model card. You can edit the model card or add information to it after you create it.

For information about using the model registry, see Register and Deploy Models with Model Registry (p. 2989). For information about creating a model card from a model registry, see Create a model card for your model in the SageMaker Model Registry (p. 3262).

**Note**
To use model cards with the SageMaker Python SDK, you first need to establish a SageMaker Session. For more information, see Session in the SageMaker Python SDK API reference.

To create a model card for models that aren't in the SageMaker Model Registry, see Create a model that isn't in the model registry (p. 3260).

Create a model that isn't in the model registry

Use the information in the following sections to create a model card for a model that you haven't added to the model registry.

**Step 1: Define model overview**

Define an overview of your model.

```python
model_overview = ModelOverview.from_model_name(
    model_name=model_name,
    sagemaker_session=sagemaker_session,
    model_description="A description of your model",
    problem_type="Problem-type", # For example, "Binary Classification"
    algorithm_type="Algorithm-type", # For example, "Logistic Regression"
    model_creator="Name-of-model-creator",
    model_owner="Name-of-model-owner",
)
```

If your model is an AWS resource, then overview information such as the model ARN, inference container URI, and the S3 location of model artifacts is automatically retrievable. Print the associated AWS metadata with the following commands:

```python
print(model_overview.model_id)
print(model_overview.inference_environment.container_image)
print(model_overview.model_artifact)
```
Step 2: Define training details

To define your model's training details, you must first define its objective function.

```python
objective_function = ObjectiveFunction(
    function=Function(
        function=ObjectiveFunctionEnum.MINIMIZE,
        facet=FacetEnum.LOSS,
    ),
    notes="An-explanation-about-objective-function",
)
```

Next, you can define your training details using your existing model overview, session, and objective function. Add any training observations here.

```python
training_details = TrainingDetails.from_model_overview(
    model_overview=model_overview,
    sagemaker_session=sagemaker_session,
    objective_function=objective_function,
    training_observations="Model-training-observations",
)
```

Once again, if your model is an AWS resource, certain training details are autopopulated. Print the training job ARN, training container URI, and training metrics with the following commands:

```python
print(training_details.training_job_details.training_arn)
print(training_details.training_job_details.training_environment.container_image)
print(["name": i.name, "value": i.value} for i in
    training_details.training_job_details.training_metrics]
```

Define evaluation details

To define your model's evaluation details, you must first define one or more metric groups to describe metrics used for any evaluation jobs.

```python
my_metric_group = MetricGroup(
    name="binary classification metrics",
    metric_data=[Metric(name="accuracy", type=MetricTypeEnum.NUMBER, value=0.5])
)
```

Next, you can define your evaluation details using evaluation metrics and datasets for each evaluation job. Add any evaluation observations here and give your evaluation job a unique name.

```python
evaluation_details = [
    EvaluationJob(
        name="Example-evaluation-job",
        evaluation_observation="Evaluation-observations",
        datasets=["s3://path/to/evaluation/data"],
        metric_groups=[my_metric_group],
    )
]
```

If you have existing evaluation reports generated by SageMaker Clarify or SageMaker Model Monitor, upload them to Amazon S3 and provide an S3 URI to automatically parse evaluation metrics. To add your own generic model card evaluation report, provide a report in the evaluation results JSON format.

```python
report_type = "clarify_bias.json"
```
Create a model card

Example evaluation job:
```python
example_evaluation_job.add_metric_group_from_json("example_metrics/{report_type}", EvaluationMetricTypeEnum.CLARIFY_BIAS)
```

**Step 3: Define intended uses**

Define the intended uses of the model, including the general purpose of the model and the use cases for which it was intended. It is also recommended to include any factors that potentially affect the model's efficacy in a particular use case and your organization's risk rating of the model. For more information, see [Intended uses of a model (p. 3246)](https://aws.amazon.com/sagemaker/docs/developer-guide/) and [Risk ratings (p. 3246)](https://aws.amazon.com/sagemaker/docs/developer-guide/).

```python
intended_uses = IntendedUses(
    purpose_of_model="Purpose-of-the-model",
    intended_uses="The-intended-uses-of-this-model",
    factors_affecting_model_efficiency="Any-factors-affecting-model-efficiency",
    risk_rating=RiskRatingEnum.LOW,
    explanations_for_risk_rating="Explanation-for-low-risk-rating",
)
```

**Define additional information**

Lastly, you can add additional custom information to your model card. You can document any ethical considerations, caveats, and recommendations about the model. You can also add any custom details that you would like in the form of key-value pairs.

```python
additional_information = AdditionalInformation(
    ethical_considerations="Any-ethical-considerations",
    caveats_and_recommendations="Any-caveats-and-recommendations",
    custom_details={"custom details1": "details-value"},
)
```

**Step 4: Create model card**

Name your model card, define a model card, and then use that definition to create a model card using the SageMaker Python SDK.

```python
model_card_name = "my-model-card"
my_card = ModelCard(
    name=model_card_name,
    status=ModelCardStatusEnum.DRAFT,
    model_overview=model_overview,
    training_details=training_details,
    intended_uses=intended_uses,
    evaluation_details=evaluation_details,
    additional_information=additional_information,
    sagemaker_session=sagemaker_session,
)
my_card.create()
```

### Create a model card for your model in the SageMaker Model Registry

Before you begin creating a model card, make sure that you've created a model package group and a model package. For more information about using model registry, see [Register and Deploy Models with Model Registry (p. 2989)](https://aws.amazon.com/sagemaker/docs/developer-guide/).

**Important**

You must have permissions to use the operations in SageMaker Model Registry. We recommend using [AmazonSageMakerModelRegistryFullAccess](https://aws.amazon.com/sagemaker/docs/developer-guide/) AWS managed policy. For more information about the managed policy, see [AWS Managed Policies for Model Registry (p. 3472)](https://aws.amazon.com/sagemaker/docs/developer-guide/).
Use the SageMaker Python SDK to create a model card for a model package within the SageMaker Model Registry. A model package is a model that you’ve trained. When you create a model card, Amazon SageMaker Model Cards automatically imports the data from the model package into the model card.

When you create a model card for a model package, Amazon SageMaker Model Card uses the DescribeModelPackage operation to add the data from the model package to the model card. The following are examples of the fields that can be imported from a model package into a model card:

- ModelDataUrl
- ModelPackageDescription
- ModelPackageGroupName
- ModelPackageStatus
- ModelPackageVersion

Use the following code to define the model package and create a model card from it:

```python
mp_details = ModelPackage.from_model_package_arn(
    model_package_arn="example_model_package_arn",
    sagemaker_session=sagemaker_session,
)
model_card_name = "example-model-card"
my_card = ModelCard(
    name=model_card_name,
    status=ModelCardStatusEnum.status,
    model_package_details=mp_details,
    sagemaker_session=sagemaker_session,
)
my_card.create()
```

For status, you're specifying the approval status of the model card. If you don't specify a status, SageMaker Model Cards uses the default value of DRAFT. If you don't specify a SageMaker session, SageMaker Model Cards uses the default SageMaker session.

You must specify a name for the model and the Amazon Resource Name (ARN) of the model package. For information about getting the Amazon Resource Name (ARN) for the model package, see View the Details of a Model Version (Boto3) (p. 2999).

The model card that you've created from the model package might have information that is either missing or inaccurate. You can add information to the model card or edit it. For more information about managing your model cards, see Manage model cards (p. 3264).

SageMaker Model Registry supports versioning of your model packages. You can version your model package and create a model card for each version. The information from model cards of preceding versions carry over to model cards created from subsequent versions. For example, you could have version 1, version 2, and version 3 of a model package. Suppose you've already created a model card for version 1, but you haven't created one for version 2. If you create a model card for version 3, Amazon SageMaker Model Cards automatically carries over the information from the model card for version 1 to the model card for version 3.

**Note**

You can also create model cards for model packages that don't use versioning. However, most machine learning workflows involve multiple versions of the same model, so we recommend doing the following:

1. Creating a version for each model package

3263
2. Creating a model card for each version of the model package

Manage model cards

After you've created a model card, you can manage them. Managing model cards include the following actions:

- Editing a model card
- Deleting a model card
- Exporting a model card to a PDF

You can manage using either the Amazon SageMaker console or the SageMaker Python SDK.

Manage model cards using the console

Use the information in the following sections to manage your model cards with the Amazon SageMaker console.

Edit a model card

To edit a model card, navigate to the model card of your choice by selecting its name in the Amazon SageMaker Model Card console and choose Edit.

After you save a model card, you cannot edit the name of that model card. After you save a model card version, you cannot update that version of the model card. Any edits that you need to make are saved as a subsequent version in order to have an immutable record of model changes.

To view different versions of the model card, choose Actions, Select version, and then choose the version that you want to view.

Export a model card

Follow these steps to export a model card.

1. Go to the Amazon SageMaker Model Card console.
2. Choose the name of the model card you want to export.
3. In the model card overview, choose Actions and then Export PDF.
4. Enter an S3 URI or browse available S3 buckets for your model card PDF.
5. If your model card exports successfully, you can either choose Download PDF in the resulting banner or download your PDF directly from Amazon S3.

Delete a model card

Follow these steps to permanently delete one or more model cards.

1. Go to the Amazon SageMaker Model Cards console.
2. Check the box to the left of the name of the card(s) you want to delete.
3. Choose Delete in the upper right-hand corner.
4. Confirm your request to permanently delete one or more cards.

You can also delete a model card when viewing the model card overview in the console by choosing Actions and then Delete model card.
Manage model cards using the SageMaker Python SDK

Use the information in the following sections to manage your model cards with the Amazon SageMaker Python SDK.

Use model cards through the SageMaker Python SDK

You can create an Amazon SageMaker Model Card programmatically through the SageMaker Python SDK. For more information see Amazon SageMaker Model Cards in the SageMaker Python SDK API reference.

Edit a model card

You can edit a model card using the `model_card.update()` method. Updating a model card creates a new model card version in order to have an immutable record of model changes. You cannot update the name of a model card.

```
my_card.model_overview.model_description = "updated-model-description"
my_card.update()
```

Export a model card

Specify an S3 output path and export your model card PDF to it with the following commands:

```
s3_output_path = f"s3://[bucket]/[prefix]/export"
pdf_s3_url = my_card.export_pdf(s3_output_path=s3_output_path).delete()
```

Delete a model card

Permanently delete a model card with the following command:

```
my_card.delete()
```

Sample notebooks

For more information on working with model cards through the SageMaker Python SDK, see the Amazon SageMaker Model Governance - Model Card example notebook.

Cross-account support for Amazon SageMaker Model Cards

Use cross-account support in Amazon SageMaker Model Cards to share model cards between AWS accounts. The account where the model cards are created is the model card account. Users in the model card account share them with the shared accounts. The users in a shared account can update the model cards or create PDFs of them.

Users in the model card account share their model cards through AWS Resource Access Manager (AWS RAM). AWS RAM helps you share resources across AWS accounts. For an introduction to AWS RAM, see What is AWS Resource Access Manager?

The following is the process to share model cards:

1. A user in the model card account sets up the cross-account model card sharing using AWS Resource Access Manager.
2. If the model cards are encrypted with AWS KMS keys, the user setting up model sharing must also provide users in the shared account with AWS KMS permissions.
3. A user in the shared account accepts the invite to the resource share.
4. A user in the shared account provides the other users with permissions to access the model cards.

If you're a user in the model card account, see the following sections:

- Set up cross-account model card sharing (p. 3266)
- Set up AWS KMS permissions for the shared account (p. 3267)
- Get responses to your resource share invitation (p. 3267)

If you're a user in the shared account, see Set up IAM user permissions in the shared account (p. 3268) about setting up permissions for yourself and the other users in the account.

**Set up cross-account model card sharing**

Use AWS Resource Access Manager (AWS RAM) to grant users in your AWS account access to view or update model cards created in a different AWS account.

To set up model card sharing, you must create a resource share. A resource share specifies:

- The resources being shared
- Who or what has access to the resources
- Managed permissions for the resources

For more information about resource shares, see Terms and concepts for AWS RAM. We recommend taking the time to understand AWS RAM conceptually before you go through the process of creating a resource share.

**Important**

You must have permissions to create a resource share. For more information about permissions, see How AWS RAM works with IAM.

For procedures to create a resource share and additional information about them, see Create a resource share.

When you go through the procedure of creating a resource share, you specify `sagemaker:ModelCard` as the resource type. You must also specify the Amazon Resource Number (ARN) of the AWS RAM resource-based policy. You can specify either the default policy or the policy that has additional permissions to create a PDF of the model card.

With the default `AWSRAMPermissionSageMakerModelCards` resource-based policy, the users in the shared account have permissions to do the following operations:

- DescribeModelCard
- ListModelCardVersions
- UpdateModelCard

With the `AWSRAMPermissionSageMakerModelCardsAllowExport` resource-based policy, the users in the shared account have permissions to do all of the preceding actions. They also have permissions to create a model card export job and describe it through the following operations:

- CreateModelCardExportJob
- DescribeModelCardExportJob

The users in the shared account can create an export job to generate a PDF of a model card. They can also describe an export job that has been created to find the PDF's Amazon S3 URI.
Model cards and export jobs are resources. The model card account owns the export jobs created by a
user in the shared account. For example, a user in account A shares model card X with shared account
B. A user in account B creates export job Y for model card X that stores the output in an Amazon S3
location that the user in account B specifies. Even though account B created export job Y, it belongs to
account A.

Each AWS account has resource quotas. For information about quotas related to model cards, see
Amazon SageMaker endpoints and quotas.

Set up AWS KMS permissions for the shared account

If the model cards that you're sharing have been encrypted with AWS Key Management Service keys,
you also need to share the access to the keys with the shared account. Otherwise, the users in the
shared account can't view, update, or export the model cards. For an overview of AWS KMS, see AWS Key
Management Service.

To provide AWS KMS permissions to users in the shared account, update your key policy with the
following statement:

```
{
  "Effect": "Allow",
  "Principal": {
    "AWS": [
      "arn:aws:iam::shared-account-id::role/example-IAM-role"
    ],
  },
  "Action": [
    "kms:GenerateDataKey",
    "kms:Decrypt",
  ],
KMS-key-id"
  "Condition": {
    "Bool": {"kms:GrantIsForAWSResource": true },
    "StringEquals": {
      "kms:ViaService": ["sagemaker.AWS-Region.amazonaws.com",
                        "s3.AWS-Region.amazonaws.com"],
    },
    "StringLike": {
Region:model-card-account-id:model-card/model-card-name"
    }
  }
}
```

The preceding statement provides users in the shared account with kms:Decrypt and
kms:GenerateDataKey permissions. With kms:Decrypt, users can decrypt the model cards. With
kms:GenerateDataKey, users can encrypt the model cards that they update or the PDFs that they
create.

Get responses to your resource share invitation

After you've created a resource share, the shared accounts that you've specified in the resource share
receive an invitation to join it. They must accept the invite to access the resources.

For information about accepting a resource share invite, see Using shared AWS resources in the AWS
Set up IAM user permissions in the shared account

The following information assumes that you've accepted the resource share invitation from the model card account. For more information about accepting a resource share invitation, see Using shared AWS resources.

You and the other users in your account use an IAM role to access the model cards shared from the model card account. Use the following template to change the policy of the IAM role. You can modify the template for your own use case.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "sagemaker:DescribeModelCard",
                "sagemaker:UpdateModelCard",
                "sagemaker:CreateModelCardExportJob",
                "sagemaker:ListModelCardVersions",
                "sagemaker:DescribeModelCardExportJob"
            ],
            "Resource": [
            ]
        },
        {
            "Effect": "Allow",
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::Amazon-S3-bucket-storing-the-pdf-of-the-model-card/model-card-name/*"
        }
    ]
}
```

To access model cards encrypted using AWS KMS, you must provide users in your account with the following AWS KMS permissions.

```json
{
    "Effect": "Allow",
    "Action": [
        "kms:GenerateDataKey",
        "kms:Decrypt"
    ],
    "Resource": "arn:aws:kms:AWS-Region:AWS-account-id-where-the-model-card-is-created:key/AWS Key Management Service-key-id"
}
```

Use model cards through the low-level APIs

You can create an Amazon SageMaker Model Card directly through the SageMaker API or the AWS Command Line Interface (AWS CLI).
**Note**
When creating a model card with the low-level APIs, the content must be in the model card JSON schema and provided as a string. For more information, see Model card JSON schema (p. 3247).

**SageMaker API**
Use the following SageMaker API commands to work with Amazon SageMaker Model Cards:

- `CreateModelCard`
- `DescribeModelCard`
- `ListModelCards`
- `ListModelCardVersions`
- `UpdateModelCard`
- `CreateModelCardExportJob`
- `DescribeModelCardExportJob`
- `ListModelCardExportJobs`
- `DeleteModelCard`

**AWS CLI**
Use the following AWS CLI commands to work with Amazon SageMaker Model Cards:

- `create-model-card`
- `describe-model-card`
- `list-model-cards`
- `list-model-card-versions`
- `update-model-card`
- `create-model-card-export-job`
- `describe-model-card-export-job`
- `list-model-card-export-jobs`
- `delete-model-card`

**Model card FAQs**
Refer to the following FAQ items for answers to commonly asked questions about Amazon SageMaker Model Card.

**Q. What is model risk?**

A: You can use models for a variety of business applications ranging from predicting cyber attacks and approving loan applications to detecting the category of an email. Each of these applications assumes a different level of risk. For example, incorrectly detecting a cyber attack has much greater business impact than incorrectly categorizing an email. Given these varied risk profiles of a model, you can use model cards to provide a risk rating of low, medium, or high for a model. If you don’t know the risk of your model, you can set the status to unknown. Customers are responsible for assigning the risk profile for each model. Based on the risk rating, organizations may have different rules in place for deploying those models to production. For more information, see Risk ratings (p. 3246).
Q. What is the intended use of a model?

The intended use of a model describes how you should use the model in your production applications. This goes beyond technical requirements like the type of instance to which you should deploy a model and instead refers to the types of applications to create with the model, the scenarios in which you can expect a reasonable performance from the model, or the type of data to use with the model. We recommend providing this information in the model card for better model governance. You can define a kind of model specification in the intended use field and ensure that model developers and consumers follow this specification while training and deploying their models. For more information, see Intended uses of a model (p. 3246).

Q. Does SageMaker autopopulate information in my model card?

When you use the SageMaker Python SDK or the AWS console to create your model card, SageMaker autopopulates details about your SageMaker trained model in the card. This includes details about how the model was trained along with all the model details returned by the describe-model API call.

Q. Can I customize a model card?

Amazon SageMaker Model Cards have a defined structure to them that cannot be modified. This structure gives you guidance on what information should be captured in a model card. While you cannot change the structure of the model card, there is some flexibility introduced through custom properties in the Additional Information section of the model card.

Q. Can I edit a model card once it is created?

Model cards have versions associated with them. A given model version is immutable across all attributes other than the model card status. If you make any other changes to the model card, such as evaluation metrics, description, or intended uses, SageMaker creates a new version of the model card to reflect the updated information. This is to ensure that a model card, once created, cannot be tampered with.

Q. Can I create model cards for models that were not trained using SageMaker?

A: Yes. You can create model cards for models not trained in SageMaker, but no information is automatically populated in the card. You must supply all the information needed in the model card for non-SageMaker models.

Q. Can I export or share model cards?

A: Yes. You can export each version of a model card to a PDF, downloaded, and share it.

Q. Do I need to register my model in the Model Registry to use model cards?

A: No. You can use model cards independently of the Model Registry.

Q. What is the difference between model cards and Model Registry?

A: Model cards are intended to provide organizations with a mechanism to document as much detail about their model as they like by following SageMaker’s prescriptive guidance along with providing their own custom information. You can introduce model cards at the very start of the ML process and use them to define the business problem that the model should solve and any considerations to think about while using the model. After a model is trained, you can populate the model card associated with that model with information about the model and how it was trained. Model cards are associated with models and are immutable once associated with a model. This ensures that the model card is the single source of truth for all the information related to a model, including how it was trained and how it should be used.

The Model Registry is a catalog that stores metadata about your models. Each entry in the model registry corresponds to a unique model version. That model version contains information about the
model such as where the model artifacts are stored in Amazon S3, what container is needed to deploy the model, and custom metadata that should be attached to the model.

Q. Are model card versions related to model versions in the Model Registry?

A: Model card versions and model versions are different entities in SageMaker. Each update to a model card results in a new version of that card. Model versions correspond to incrementally trained models that are registered in the Model Registry. A model card version may be linked to a specific model version in the Model Registry by way of the model ID field in the model card, but this is not necessary.

Q. Are model cards integrated with SageMaker Model Monitor?

A: No. You can upload the performance metrics computed by SageMaker Model Monitor to the model card by uploading a metrics file to Amazon S3 and linking that to the card, but there is no native integration between Model Monitor and model cards. Model dashboards are integrated with Model Monitor. For more information on model dashboards, see Amazon SageMaker Model Dashboard.

Amazon SageMaker Model Dashboard

Amazon SageMaker Model Dashboard is a centralized portal, accessible from the SageMaker console, where you can view, search, and explore all of the models in your account. You can track which models are deployed for inference and if they are used in batch transform jobs or hosted on endpoints. If you set up monitors with Amazon SageMaker Model Monitor, you can also track the performance of your models as they make real-time predictions on live data. You can use the dashboard to find models that violate thresholds you set for data quality, model quality, bias and explainability. The dashboard’s comprehensive presentation of all your monitor results helps you quickly identify models that don’t have these metrics configured.

The Model Dashboard aggregates model-related information from several SageMaker features. In addition to the services provided in Model Monitor, you can view model cards, visualize workflow lineage, and track your endpoint performance. You no longer have to sort through logs, query in notebooks, or access other AWS services to collect the data you need. With a cohesive user experience and integration into existing services, SageMaker's Model Dashboard provides an out-of-the-box model governance solution to help you ensure quality coverage across all your models.

Prerequisites

To use the Model Dashboard, you should have one or more models in your account. You can train models using Amazon SageMaker or import models you've trained elsewhere. To create a model in SageMaker, you can use the CreateModel API. For more information, see CreateModel. You can also use SageMaker-provided ML environments, such as Amazon SageMaker Studio, which provides project templates that set up model training and deployment for you. For information about how to get started with Studio, see Amazon SageMaker Studio.

While this is not a mandatory prerequisite, customers gain the most value out of the dashboard if they set up model monitoring jobs using SageMaker Model Monitor for models deployed to endpoints. For prerequisites and instructions on how to use SageMaker Model Monitor, see Monitor data and model quality (p. 3051).

Model Dashboard elements

The Model Dashboard view extracts high-level details from each model to provide a comprehensive summary of every model in your account. If your model is deployed for inference, the dashboard helps you track the performance of your model and endpoint in real time.

Important details to highlight in this page include:
• **Risk rating**: A user-specified parameter from the model card with a **low**, **medium**, or **high** value. The model card’s risk rating is a categorical measure of the business impact of the model’s predictions. Models are used for a variety of business applications, each of which assumes a different level of risk. For example, incorrectly detecting a cyber attack has much greater business impact than incorrectly categorizing an email. If you don’t know the model risk, you can set it to **unknown**. For information about Amazon SageMaker Model Cards see [Model Cards](#).

• Model Monitor alerts: Model Monitor alerts are a primary focus of the Model Dashboard, and reviewing the existing documentation on the various monitors provided by SageMaker is a helpful way to get started. For an in-depth explanation of the SageMaker Model Monitor feature and sample notebooks, see [Monitor data and model quality](p. 3051).

The Model Dashboard displays Model Monitor status values by the following monitor types:

• **Data Quality**: Compares live data to training data. If they diverge, your model’s inferences may no longer be accurate. For additional details about the Data Quality monitor, see [Monitor data quality](p. 3062).

• **Model Quality**: Compares the predictions that the model makes with the actual Ground Truth labels that the model attempts to predict. For additional details about the Model Quality monitor, see [Monitor model quality](p. 3068).

• **Bias Drift**: Compares the distribution of live data to training data, which can also cause inaccurate predictions. For additional details about the Bias Drift monitor, see [Monitor Bias Drift for Models in Production](p. 3077).

• **Feature Attribution Drift**: Also known as explainability drift. Compares the relative rankings of your features in training data versus live data, which could also be a result of bias drift. For additional details about the Feature Attribution Drift monitor, see [Monitor Feature Attribution Drift for Models in Production](p. 3086).

Each Model Monitor status is one of the following values:

• **None**: No monitor is scheduled

• **Inactive**: A monitor was scheduled, but it was deactivated

• **OK**: A monitor is scheduled and is active, and has not encountered the necessary number of violations in recent model monitor executions to raise an alert

• **Time and date**: An active monitor raised an alert at the specified time and date

• **Endpoint**: The endpoints which host your model for real-time inference. Within the Model Dashboard, you can select the endpoint column to view performance metrics such as CPU, GPU, disk, and memory utilization of your endpoints in real time to help you track the performance of your compute instances.

• **Batch transform job**: The most recent batch transform job that ran using this model. This column helps you determine if a model is actively used for batch inference.

• **Model details**: Each entry in the dashboard links to a model details page where you can dive deeper into an individual model. You can access the model’s lineage graph, which visualizes the workflow from data preparation to deployment, and metadata for each step. You can also create and view the model card, review alert details and history, assess the performance of your real-time endpoints, and access other infrastructure-related details.

### View Model Monitor schedules and alerts

Using the Python SDK, you can create a model monitor for data quality, model quality, bias drift, or feature attribution drift. For more information about using SageMaker Model Monitor, see [Monitor data and model quality](p. 3051). The Model Dashboard populates information from all the monitors you create on all your models in your account. You can track the status of each monitor, which indicates whether your monitor is running as expected or failed due to an internal error. You can also activate or deactivate any monitor in the model details page itself. For instructions about how to view scheduled monitors for a model, see [View scheduled monitors](p. 3273). For instructions about how to activate or deactivate model monitors, see [Activate or deactivate a model monitor](p. 3273).
A properly-configured and actively-running model monitor might raise alerts, in which case the monitoring executions produce violation reports. For details about how alerts work and how to view alert results, history, and links to job reports for debug, see View and edit alerts (p. 3273).

View scheduled monitors

To view a model’s scheduled monitors, complete the following steps:

1. Open the SageMaker console.
2. Choose Governance in the left panel.
3. Choose Model Dashboard.
4. In the Models section of the Model Dashboard, select the model name of the scheduled monitors you want to view.
5. View the scheduled monitors in the Monitor schedule section. You can review the status for each monitor in the Status schedule column, which is one of the following values:
   - Failed: The monitoring schedule failed due to a problem with the configuration or settings (such as incorrect user permissions).
   - Pending: The monitor is in the process of becoming scheduled.
   - Stopped: The schedule is stopped by the user.
   - Scheduled: The schedule is created and runs at the frequency you specified.

Activate or deactivate a model monitor

To activate or deactivate a model monitor, complete the following steps:

1. Open the SageMaker console.
2. Choose Governance in the left panel.
3. Choose Model Dashboard.
4. In the Models section of the Model Dashboard, select the model name of the alert you want to modify.
5. Choose the radio box next to the monitor schedule of the alert you want to modify.
6. (optional) Choose Deactivate monitor schedule if you want to deactivate your monitor schedule.
7. (optional) Choose Activate monitor schedule if you want to activate your monitor schedule.

View and edit alerts

The Model Dashboard displays alerts you configured in Amazon CloudWatch. You can modify the alert criteria within the dashboard itself. The alert criteria depend upon two parameters:

- Datapoints to alert: Within the evaluation period, how many execution failures raise an alert.
- Evaluation period: The number of most recent monitoring executions to consider when evaluating alert status.

The following image shows an example scenario of a series of Model Monitor executions in which we set a hypothetical Evaluation period of 3 and a Datapoints to alert value of 2. After every monitoring execution, the number of failures are counted within the Evaluation period of 3. If the number of failures meets or exceeds the Datapoints to alert value 2, the monitor raises an alert and remains in alert status until the number of failures within the Evaluation period becomes less than 2 in subsequent iterations. In the image, the evaluation windows are red when the monitor raises an alert or remains in alert status, and green otherwise.
Note that even if the evaluation window size has not reached the **Evaluation period** of 3, as shown in the first 2 rows of the image, the monitor still raises an alert if the number of failures meets or exceeds the **Datapoints to alert** value of 2.

Within the monitor details page, you can view your alert history, edit existing alert criteria, and view job reports to help you debug alert failures. For instructions about how to view alert history or job reports for failed monitoring executions, see View alert history or job reports (p. 3274). For instructions about how to edit alert criteria, see Edit alert criteria (p. 3275).

**View alert history or job reports**

To view alert history or job reports of failed executions, complete the following steps:

1. Open the SageMaker console.
2. Choose Governance in the left panel.
3. Choose Model Dashboard.
4. In the Models section of the Model Dashboard, select the model name of the alert history you want to view.
5. In the **Schedule name** column, select the monitor name of the alert history you want to view.
6. To view alert history, select the **Alert history** tab.
7. (optional) To view job reports of monitoring executions, complete the following steps:
   1. In the Alert history tab, choose View executions for the alert you want to investigate.
   2. In the **Execution history** table, choose View report of the monitoring execution you want to investigate.

   The report displays the following information:
   - **Feature**: The user-defined ML feature monitored
   - **Constraint**: The specific check within the monitor
Edit alert criteria

To edit an alert in the Model Dashboard, complete the following steps:

1. Open the SageMaker console.
2. Choose Governance in the left panel.
3. Choose Model Dashboard.
4. In the Models section of the Model Dashboard, select the model name of the alert you want to modify.
5. Choose the radio box next to the monitor schedule of the alert you want to modify.
6. Choose Edit Alert in the Monitor schedule section.
7. (optional) Change Datapoints to alert if you want to change the number of failures within the Evaluation period that initiate an alert.
8. (optional) Change Evaluation period if you want to change the number of most recent monitoring executions to consider when evaluating alert status.

View a model lineage graph

When you train a model, Amazon SageMaker creates a visualization of your entire ML workflow from data preparation to deployment. This visualization is called a model lineage graph and uses entities to represent individual steps in your workflow. For example, a basic model lineage graph might have an entity representing your training set, which is associated with an entity representing your training job, which is associated with another entity representing your model.

In addition, the graph stores information about each step in your workflow. With this information, you can recreate any step in the workflow or track model and dataset lineage. For example, SageMaker Lineage stores the S3 URI of your input data sources with each job so you can perform further analysis of the data sources for compliance verification.

While the model lineage graph can help you view the steps in individual workflows, there are many other capabilities that you can leverage using the AWS SDK. For example, with the AWS SDK you can create or query your entities. For more information about the full set of features in SageMaker Lineage and example notebooks, see Amazon SageMaker ML Lineage Tracking (p. 2973).

Introduction to entities

Amazon SageMaker automatically creates tracking entities for SageMaker jobs, models, model packages, and endpoints if the data is available. For a basic workflow, suppose you train a model using a dataset. SageMaker automatically generates a lineage graph with three entities:

- **Dataset**: A type of artifact, which is an entity representing a URI addressable object or data. An artifact is generally either an input or an output to a trial component or action.
- **TrainingJob**: A type of trial component, which is an entity representing processing, training, and transform jobs.
- **Model**: Another type of artifact. Like the Dataset artifact, a Model is a URI addressable object. In this case, it is an output of the TrainingJob trial component.

Your model lineage graph expands quickly if you add additional steps to your workflow, such as data preprocessing or postprocessing, if you deploy your model to an endpoint, or if you include your model...
in a model package, among many other possibilities. For the complete list of SageMaker entities, see Amazon SageMaker ML Lineage Tracking (p. 2973).

**Entity properties**

Each node in the graph displays the entity type, but you can choose the vertical ellipsis to the right of the entity type to see specific details related to your workflow. In our previous barebones lineage graph, you can choose the vertical ellipsis next to **DataSet** to see specific values for the following properties (common to all artifact entities):

- **Name**: The name of your dataset.
- **Source URI**: The Amazon S3 location of your dataset.

For the **TrainingJob** entity, you can see the specific values for the following properties (common to all **TrialComponent** entities):

- **Name**: The name of the training job.
- **Job ARN**: The Amazon Resource Name (ARN) of your training job.

For the **Model** entity, you see the same properties as listed for **DataSet** since they are both artifact entities. For a list of the entities and their associated properties, see Lineage Tracking Entities (p. 2974).

**Entity queries**

Amazon SageMaker automatically generates graphs of lineage entities as you use them. However if you are running many iterations of an experiment and don't want to view every lineage graph, the AWS SDK can help you perform queries across all your workflows. For example, you can query your lineage entities for all the processing jobs that use an endpoint. Or, you can see all the downstream trails that use an artifact. For a list of all the queries you can perform, see Querying Lineage Entities (p. 2981).

### View a model's lineage graph

**To view the lineage graph for a model, complete the following steps:**

1. Open the [SageMaker console](https://console.aws.amazon.com/sagemaker).  
2. Choose **Governance** in the left panel.  
3. Choose **Model Dashboard**.  
4. In the **Models** section of the Model Dashboard, select the model name of the lineage graph you want to view.  
5. Choose **View lineage** in the **Model Overview** section.

### View Endpoint Status

If you want to use your trained model to perform inference on live data, you deploy your model to a real-time endpoint. To ensure appropriate latency of your predictions, you want to make sure the instances that host your model are running efficiently. Model Dashboard's endpoint monitoring feature displays real-time information about your endpoint configuration and helps you track endpoint performance with metrics.

**Monitor settings**

The Model Dashboard links to existing SageMaker endpoint details pages which display real-time graphs of metrics you can select in Amazon CloudWatch. Within your dashboard, you can track these metrics as your endpoint is handling real-time inference requests. Some metrics you can select are the following:
CpuUtilization: The sum of each individual CPU core's utilization, with each ranging from 0%–100%.

MemoryUtilization: The percentage of memory used by the containers on an instance, ranging from 0%–100%.

DiskUtilization: The percentage of disk space used by the containers on an instance, ranging from 0%–100%.

For the complete list of metrics you can view in real time, see Monitor Amazon SageMaker with Amazon CloudWatch (p. 3577).

Runtime settings

Amazon SageMaker supports automatic scaling (auto scaling) for your hosted models. Auto scaling dynamically adjusts the number of instances provisioned for a model in response to changes in your workload. When the workload increases, auto scaling brings more instances online. When the workload decreases, auto scaling removes unnecessary instances so that you don’t pay for provisioned instances that you aren’t using. You can customize the following runtime settings in the Model Dashboard:

- **Update weights**: Change the amount of workload assigned to each instance with numerical weighting. For more information about instance weighting during auto scaling, see Configure instance weighting for Amazon EC2 Auto Scaling.

- **Update instance count**: Change the number of total instances that can service your workload when it increases.

For more information about endpoint runtime settings, see CreateEndpointConfig.

Endpoint configuration settings

Endpoint configuration settings display the settings you specified when you created the endpoint. These settings inform SageMaker which resources to provision for your endpoint. Some settings included are the following:

- **Data capture**: You can choose to capture information about your endpoint’s inputs and outputs. For example, you may want to sample incoming traffic to see if the results correlate to training data. You can customize your sampling frequency, the format of the stored data, and Amazon S3 location of stored data. For more information about setting up your data capture configuration, see Capture data (p. 3053).

- **Production variants**: See the previous discussion in Runtime settings.

- **Async invocation configuration**: If your endpoint is asynchronous, this section includes the maximum number of concurrent requests sent by the SageMaker client to the model container, the Amazon S3 location of your success and failure notifications, and the output location of your endpoint outputs. For more information about asynchronous outputs, see Create, invoke, and update an Asynchronous Endpoint (p. 2523).

- **Encryption key**: You can enter your encryption key if you want to encrypt your outputs.

For more information about endpoint configuration settings, see CreateEndpointConfig.

View status and configuration for an endpoint

To view the status and configuration for a model’s endpoint, complete the following steps:

1. Open the SageMaker console.
2. Choose Governance in the left panel.
Choose Model Dashboard.

In the Models section of the Model Dashboard, select the model name of the endpoint you want to view.

Select the endpoint name in the Endpoints section.

Model Dashboard FAQ

Refer to the following FAQ topics for answers to commonly asked questions about Amazon SageMaker Model Dashboard.

Q. What is Model Dashboard?

Amazon SageMaker Model Dashboard is a centralized repository of all models created in your account. The models are generally the outputs of SageMaker training jobs, but you can also import models trained elsewhere and host them on SageMaker. Model Dashboard provides a single interface for IT administrators, model risk managers, and business leaders to track all deployed models and aggregates data from multiple AWS services to provide indicators about how your models are performing. You can view details about model endpoints, batch transform jobs, and monitoring jobs for additional insights into model performance. The dashboard's visual display helps you quickly identify which models have missing or inactive monitors so you can ensure all models are periodically checked for data drift, model drift, bias drift, and feature attribution drift. Lastly, the dashboard's ready access to model details helps you dive deep so you can access logs, infrastructure-related information, and resources to help you debug monitoring failures.

Q. What are the prerequisites to use Model Dashboard?

You should have one or more models created in SageMaker, either trained on SageMaker or externally trained. While this is not a mandatory prerequisite, you gain the most value from the dashboard if you set up model monitoring jobs via Amazon SageMaker Model Monitor for models deployed to endpoints.

Q. Who should use Model Dashboard?

Model risk managers, ML practitioners, data scientists and business leaders can get a comprehensive overview of models using the Model Dashboard. The dashboard aggregates and displays data from Amazon SageMaker Model Cards, Endpoints and Model Monitor services to display valuable information such as model metadata from the model card and model registry, endpoints where the models are deployed, and insights from model monitoring.

Q. How do I use Model Dashboard?

Model Dashboard is available out of the box with Amazon SageMaker and does not require any prior configuration. However, if you have set up model monitoring jobs using SageMaker Model Monitor and Clarify, you use Amazon CloudWatch to configure alerts that raise a flag in the dashboard when model performance deviates from an acceptable range. You can create and add new model cards to the dashboard, and view all the monitoring results associated with endpoints. Model Dashboard currently does not support cross-account models.

Q. What is Amazon SageMaker Model Monitor?

With Amazon SageMaker Model Monitor, you can select the data you want to monitor and analyze without writing any code. SageMaker Model Monitor lets you select data, such as prediction output, from a menu of options and captures metadata such as timestamp, model name, and endpoint so you can analyze model predictions. You can specify the sampling rate of data capture as a percentage of overall traffic in the case of high volume real-time predictions. This data is stored in your own Amazon
S3 bucket. You can also encrypt this data, configure fine-grained security, define data retention policies, and implement access control mechanisms for secure access.

Q. What types of model monitors does SageMaker support?

SageMaker Model Monitor provides the following types of model monitors:

- **Data Quality**: Monitor drift in data quality.
- **Model Quality**: Monitor drift in model quality metrics, such as accuracy.
- **Bias Drift for Models in Production**: Monitor bias in your model's predictions by comparing the distribution of training and live data.
- **Feature Attribution Drift for Models in Production**: Monitor drift in feature attribution by comparing the relative rankings of features in training and live data.

Q. What inference methods does SageMaker Model Monitor support?

Model Monitor currently supports endpoints that host a single model for real-time inference and does not support monitoring of multi-model endpoints.

Q. How can I get started with SageMaker Model Monitor?

You can use the following resources to get started with model monitoring:

- **Data quality monitor example notebook**
- **Model quality monitor example notebook**
- **Bias drift monitor example notebook**
- **Feature attribution drift monitor example notebook**

For more examples of model monitoring, see the GitHub repository [amazon-sagemaker-examples](https://github.com/aws-sagemaker-examples).

Q. How does Model Monitor work?

Amazon SageMaker Model Monitor automatically monitors machine learning models in production, using rules to detect drift in your model. Model Monitor notifies you when quality issues arise through alerts. To learn more, see [How Model Monitor Works](https://docs.aws.amazon.com/sagemaker/latest/dg/model-monitor-working.html).

Q. When and how do you bring your own container (BYOC) for Model Monitor?

Model Monitor computes model metrics and statistics on tabular data only. For use cases other than tabular datasets, such as images or text, you can bring your own containers (BYOC) to monitor your data and models. For example, you can use BYOC to monitor an image classification model that takes images as input and outputs a label. To learn more about container contracts, see [Bring Your Own Containers](https://docs.aws.amazon.com/sagemaker/latest/dg/bring-your-own-container-bysm.html).

Q. Where can I find examples of BYOC for Model Monitor?

You can find helpful BYOC examples in the following links:

- **Monitor data and model quality**
- **GitHub example repository**
- **Bring Your Own Containers**
- **Detecting data drift in NLP using BYOC Model Monitor**
- **Detecting and analyzing incorrect predictions in CV**
Q. How do I integrate Model Monitor with SageMaker Pipelines?

For details about how to integrate Model Monitor and SageMaker Pipelines, see Amazon SageMaker Pipelines now integrates with SageMaker Model Monitor and SageMaker Clarify.

For an example, see the GitHub sample notebook SageMaker Pipelines integration with Model Monitor and Clarify.

Q. Are there any performance concerns using DataCapture?

When turned on, data capture occurs asynchronously on the SageMaker endpoints. To prevent impact to inference requests, DataCapture stops capturing requests at high levels of disk usage. It is recommended you keep your disk utilization below 75% to ensure DataCapture continues capturing requests.
Use Docker containers to build models

Amazon SageMaker makes extensive use of Docker containers for build and runtime tasks. SageMaker provides pre-built Docker images for its built-in algorithms and the supported deep learning frameworks used for training and inference. Using containers, you can train machine learning algorithms and deploy models quickly and reliably at any scale. The topics in this section show how to deploy these containers for your own use cases. For information about how to bring your own containers for use with Amazon SageMaker Studio, see Bring your own SageMaker image (p. 257).

Topics
- Scenarios for Running Scripts, Training Algorithms, or Deploying Models with SageMaker (p. 3281)
- Docker Container Basics (p. 3283)
- Use Pre-built SageMaker Docker images (p. 3284)
- Adapting your own Docker container to work with SageMaker (p. 3297)
- Create a container with your own algorithms and models (p. 3316)
- Examples and More Information: Use Your Own Algorithm or Model (p. 3338)
- Troubleshooting your Docker containers (p. 3340)

Scenarios for Running Scripts, Training Algorithms, or Deploying Models with SageMaker

Amazon SageMaker always uses Docker containers when running scripts, training algorithms, and deploying models. Your level of engagement with containers depends on your use case.

Use cases for using pre-built Docker containers with SageMaker

Consider the following use cases when using containers with SageMaker:

- Pre-built SageMaker algorithm – Use the image that comes with the built-in algorithm. See Use Amazon SageMaker Built-In Algorithms or Pre-trained Models for more information.
- Custom model with pre-built SageMaker container – If you train or deploy a custom model, but use a framework that has a pre-built SageMaker container including TensorFlow and PyTorch, choose one of the following options:
  - If you don't need a custom package, and the container already includes all required packages: Use the pre-built Docker image associated with your framework. For more information, see Use Pre-built SageMaker Docker images (p. 3284).
  - If you need a custom package installed into one of the pre-built containers: Confirm that the pre-built Docker image allows a requirements.txt file, or extend the pre-built container based on the following use cases.

3281
Use cases for extending a pre-built Docker container

The following are use cases for extending a pre-built Docker container:

- **You can't import the dependencies** – Extend the pre-built Docker image associated with your framework. See [Extend a Pre-built Container](p. 3289) for more information.
- **You can't import the dependencies in the pre-built container and the pre-built container supports requirements.txt** – Add all the required dependencies in requirements.txt. The following frameworks support using requirements.txt.
  - TensorFlow
  - Chainer
  - Sci-kit learn
  - PyTorch
  - Apache MXNet

Use case for building your own container

If you build or train a custom model and require custom framework that does not have a pre-built image, build a custom container.

The following decision tree illustrates the information in the previous three lists: Use cases for using pre-built Docker containers with SageMaker; Use cases for extending a pre-built Docker container; Use case for building your own container.

As a customer use case example, to train and deploy a TensorFlow model, refer to the previous sections of Use cases to decide which container that you need. The following are considerations that you can make to choose your container:
• A TensorFlow model is a custom model.
• Because a TensorFlow model is going to be built in the TensorFlow framework, use the TensorFlow pre-built framework container to train and host the model.
• If you require custom packages in either your `entrypoint` script or `inference script`, either extend the pre-built container or use a `requirements.txt` file to install dependencies at runtime.

After you determine the type of container that you need, the following information provides details about the previously listed options.

• **Use a built-in SageMaker algorithm or framework.** For most use cases, you can use the built-in algorithms and frameworks without worrying about containers. You can train and deploy these algorithms from the SageMaker console, the AWS Command Line Interface (AWS CLI), a Python notebook, or the Amazon SageMaker Python SDK. You can do that by specifying the algorithm or framework version when creating your Estimator. The available built-in algorithms are itemized and described in the Use Amazon SageMaker Built-in Algorithms or Pre-trained Models (p. 1528) topic. For more information about the available frameworks, see ML Frameworks and Languages (p. 3610). For an example of how to train and deploy a built-in algorithm using a Jupyter notebook running in a SageMaker notebook instance, see the Get started (p. 8) topic.

• **Use pre-built SageMaker container images.** Alternatively, you can use the built-in algorithms and frameworks using Docker containers. SageMaker provides containers for its built-in algorithms and pre-built Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. For a full list of the available SageMaker Images, see Available Deep Learning Containers Images. It also supports machine learning libraries such as scikit-learn and SparkML. If you use the Amazon SageMaker Python SDK, you can deploy the containers by passing the full container URI to their respective SageMaker SDK Estimator class. For the full list of deep learning frameworks that are currently supported by SageMaker, see Prebuilt SageMaker Docker Images for Deep Learning (p. 3284). For information about the scikit-learn and SparkML pre-built container images, see Prebuilt Amazon SageMaker Docker Images for Scikit-learn and Spark ML (p. 3285). For more information about using frameworks with the Amazon SageMaker Python SDK, see their respective topics in Machine Learning Frameworks and Languages (p. 3610).

• **Extend a pre-built SageMaker container image.** If you would like to extend a pre-built SageMaker algorithm or model Docker image, you can modify the SageMaker image to satisfy your needs. For an example, see Extending our PyTorch containers.

• **Adapt an existing container image:** If you would like to adapt a pre-existing container image to work with SageMaker, you must modify the Docker container to enable either the SageMaker Training or Inference toolkit. For an example that shows how to build your own containers to train and host an algorithm, see Bring Your Own R Algorithm.

**Docker Container Basics**

Docker is a program that performs operating system-level virtualization for installing, distributing, and managing software. It packages applications and their dependencies into virtual containers that provide isolation, portability, and security. With Docker, you can ship code faster, standardize application operations, seamlessly move code, and economize by improving resource utilization. For more general information about Docker, see Docker overview.

The following information outlines the most significant aspects of using Docker containers with Amazon SageMaker.

**SageMaker Functions**

SageMaker uses Docker containers in the backend to manage training and inference processes. SageMaker abstracts away from this process, so it happens automatically when an estimator is used.
While you don't need to use Docker containers explicitly with SageMaker for most use cases, you can use Docker containers to extend and customize SageMaker functionality.

Containers with SageMaker Studio

SageMaker Studio runs from a Docker container and uses it to manage functionality. As a result, you must create your Docker container following the steps in Bring your own SageMaker image (p. 257).

Use Pre-built SageMaker Docker images

Amazon SageMaker provides containers for its built-in algorithms and pre-built Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. It also supports machine learning libraries such as scikit-learn and SparkML.

You can use these images from your SageMaker notebook instance or SageMaker Studio. You can also extend the pre-built SageMaker images to include libraries and needed functionality. The following topics give information about the available images and how to use them.

For the Docker registry path and other parameters for each of the Amazon SageMaker provided algorithms and Deep Learning Containers (DLC), see Docker Registry Paths and Example Code.

Note
For information on Docker images for developing reinforcement learning (RL) solutions in SageMaker, see SageMaker RL Containers.

Topics
• Prebuilt SageMaker Docker Images for Deep Learning (p. 3284)
• Prebuilt Amazon SageMaker Docker Images for Scikit-learn and Spark ML (p. 3285)
• Train a Deep Graph Network (p. 3286)
• Extend a Pre-built Container (p. 3289)

Prebuilt SageMaker Docker Images for Deep Learning

Amazon SageMaker provides prebuilt Docker images that include deep learning frameworks and other dependencies needed for training and inference. For a complete list of the prebuilt Docker images managed by SageMaker, see Docker Registry Paths and Example Code.

Using the SageMaker Python SDK

With the SageMaker Python SDK, you can train and deploy models using these popular deep learning frameworks. For instructions on installing and using the SDK, see Amazon SageMaker Python SDK. The following table lists the available frameworks and instructions on how to use them with the SageMaker Python SDK:

<table>
<thead>
<tr>
<th>Framework</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>TensorFlow</td>
<td>Using TensorFlow with the SageMaker Python SDK</td>
</tr>
<tr>
<td>MXNet</td>
<td>Using MXNet with the SageMaker Python SDK</td>
</tr>
<tr>

</tr>
<tr>
<td>Chainer</td>
<td>Using Chainer with the SageMaker Python SDK</td>
</tr>
<tr>
<td>Hugging Face</td>
<td>Using Hugging Face with the SageMaker Python SDK</td>
</tr>
</tbody>
</table>
Extending Prebuilt SageMaker Docker Images

You can customize these prebuilt containers or extend them to handle any additional functional requirements for your algorithm or model that the prebuilt SageMaker Docker image doesn't support. For an example, see Fine-tuning and deploying a BERTopic model on SageMaker with your own scripts and dataset, by extending existing PyTorch containers.

You can also use prebuilt containers to deploy your custom models or models that have been trained in a framework other than SageMaker. For an overview of the process of bringing the trained model artifacts into SageMaker and hosting them at an endpoint, see Bring Your Own Pretrained MXNet or TensorFlow Models into Amazon SageMaker.

Prebuilt Amazon SageMaker Docker Images for Scikit-learn and Spark ML

SageMaker provides prebuilt Docker images that install the scikit-learn and Spark ML libraries. These libraries also include the dependencies needed to build Docker images that are compatible with SageMaker using the Amazon SageMaker Python SDK. With the SDK, you can use scikit-learn for machine learning tasks and use Spark ML to create and tune machine learning pipelines. For instructions on installing and using the SDK, see SageMaker Python SDK.

Using the SageMaker Python SDK

The following table contains links to the GitHub repositories with the source code for the scikit-learn and Spark ML containers. The table also contains links to instructions that show how use these containers with Python SDK estimators to run your own training algorithms and hosting your own models.

<table>
<thead>
<tr>
<th>Library</th>
<th>Prebuilt Docker Image Source Code</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>scikit-learn</td>
<td>SageMaker Scikit-learn Containers</td>
<td>Using Scikit-learn with the Amazon SageMaker Python SDK</td>
</tr>
<tr>
<td>Spark ML</td>
<td>SageMaker Spark ML Serving Containers</td>
<td>SparkML Python SDK Documentation</td>
</tr>
</tbody>
</table>

For more information and links to github repositories, see Use Scikit-learn with Amazon SageMaker (p. 3625) and Use SparkML Serving with Amazon SageMaker (p. 3627).

Specifying the Prebuilt Images Manually

If you are not using the SageMaker Python SDK and one of its estimators to manage the container, you have to retrieve the relevant prebuilt container manually. The SageMaker prebuilt Docker images are stored in Amazon Elastic Container Registry (Amazon ECR). You can push or pull them using their fullname registry addresses. SageMaker uses the following Docker Image URL patterns for scikit-learn and Spark ML:

- `<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/sagemaker-scikit-learn:<SCIKIT-LEARN_VERSION>-cpu-py<PYTHON_VERSION>`

  For example, `746614075791.dkr.ecr.us-west-1.amazonaws.com/sagemaker-scikit-learn:1.2.1-cpu-py3`

- `<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/sagemaker-sparkml-serving:<SPARK-ML_VERSION>`

  For example, `746614075791.dkr.ecr.us-west-1.amazonaws.com/sagemaker-sparkml-serving:2.3.1-cpu-py3`
For example, 341280168497.dkr.ecr.ca-central-1.amazonaws.com/sagemaker-sparkml-serving:2.4

For account IDs and AWS Region names, see Docker Registry Paths and Example Code.

Finding Available Images

Use the following commands to find out which versions of the images are available. For example, use the following to find the available sagemaker-sparkml-serving image in the ca-central-1 Region:

```
aws ecr describe-images
--region ca-central-1
--registry-id 341280168497
--repository-name sagemaker-sparkml-serving
```

Train a Deep Graph Network

In this overview, you learn how to get started with a deep graph network by using one of the DGL containers in Amazon Elastic Container Registry (Amazon ECR). You can also see links to practical examples for deep graph networks.

What Is a Deep Graph Network?

Deep graph networks refer to a type of neural network that is trained to solve graph problems. A deep graph network uses an underlying deep learning framework like PyTorch or MXNet. The potential for graph networks in practical AI applications is highlighted in the Amazon SageMaker tutorials for Deep Graph Library (DGL). Examples for training models on graph datasets include social networks, knowledge bases, biology, and chemistry.
Several examples are provided using Amazon SageMaker's deep learning containers that are preconfigured with DGL. If you have special modules you want to use with DGL, you can also build your own container. The examples involve heterographs, which are graphs that have multiple types of nodes and edges, and draw on a variety of applications across disparate scientific fields, such as bioinformatics and social network analysis. DGL provides a wide array of graph neural network implementations for different types models. Some of the highlights include:

- Graph convolutional network (GCN)
- Relational graph convolutional network (R-GCN)
- Graph attention network (GAT)
- Deep generative models of graphs (DGMG)
- Junction tree neural network (JTNN)

**Get Started**

DGL is available as a deep learning container in Amazon ECR. You can select deep learning containers when you write your estimator function in an Amazon SageMaker notebook. You can also craft your own custom container with DGL by following the Bring Your Own Container guide. The easiest way to get started with a deep graph network uses one of the DGL containers in Amazon ECR.

**Note**

Backend framework support is limited to PyTorch and MXNet.

**Setup**

Figure 1. The DGL ecosystem
If you are using Amazon SageMaker Studio, you need to clone the examples repository first. If you are using a notebook instance, you can find the examples by choosing the SageMaker icon at bottom of the left toolbar.

**To clone the Amazon SageMaker SDK and notebook examples repository**

1. From the **JupyterLab** view in Amazon SageMaker, go to the **File Browser** at the top of the left toolbar. From the **File Browser panel**, you can see a new navigation at the top of the panel.
2. Choose the icon on the far right to clone a Git repository.
3. Add the repository URL: https://github.com/awslabs/amazon-sagemaker-examples.git
4. Browse the newly added folder and its contents. The DGL examples are stored in the **sagemaker-python-sdk** folder.

**Run a Graph Network Training Example**

**To train a deep graph network**

1. From the **JupyterLab** view in Amazon SageMaker, browse the example notebooks and look for DGL folders. Several files may be included to support an example. Examine the README for any prerequisites.
2. Run the .ipynb notebook example.
3. Find the estimator function, and note the line where it is using an Amazon ECR container for DGL and a specific instance type. You may want to update this to use a container in your preferred Region.
4. Run the function to launch the instance and use the DGL container for training a graph network. Charges are incurred for launching this instance. The instance self-terminates when the training is complete.

**Examples**

An example of knowledge graph embedding (KGE) is provided. It uses the Freebase dataset, a knowledge base of general facts. An example use case would be to graph the relationships of persons and predict their nationality.

An example implementation of a graph convolutional network (GCN) shows how you can train a graph network to predict toxicity. A physiology dataset, Tox21, provides toxicity measurements for how substances affect biological responses.

Another GCN example shows you how to train a graph network on a scientific publications bibliography dataset, known as Cora. You can use it to find relationships between authors, topics, and conferences.

The last example is a recommender system for movie reviews. It uses a graph convolutional matrix completion (GCMC) network trained on the MovieLens datasets. These datasets consist of movie titles, genres, and ratings by users.

**Use a Deep Learning Container with DGL**

The following example uses preconfigured deep learning containers. This is the easiest to try since it works out of the box on Amazon SageMaker.

- **Semi-supervised classification of a knowledge base using a GCN**
Bring Your Own Container with DGL

The following examples enable you to bring your own container (BYOC). Read the BYOC guide and familiarize yourself with that process before trying these. Configuration is required.

- Molecular property prediction of toxicity using a GCN
- Recommender system for movies using a GCMC implementation

Extend a Pre-built Container

If a pre-built SageMaker container doesn't fulfill all of your requirements, you can extend the existing image to accommodate your needs. Even if there is direct support for your environment or framework, you may want to add additional functionality or configure your container environment differently. By extending a pre-built image, you can leverage the included deep learning libraries and settings without having to create an image from scratch. You can extend the container to add libraries, modify settings, and install additional dependencies.

The following tutorial shows how to extend a pre-built SageMaker image and publish it to Amazon ECR.

Topics

- Requirements to Extend a Pre-built Container (p. 3289)
- Extend SageMaker Containers to Run a Python Script (p. 3289)

Requirements to Extend a Pre-built Container

To extend a pre-built SageMaker image, you need to set the following environment variables within your Dockerfile. For more information on environment variables with SageMaker containers, see the SageMaker Training Toolkit GitHub repo.

- SAGEMAKER_SUBMIT_DIRECTORY: The directory within the container in which the Python script for training is located.
- SAGEMAKER_PROGRAM: The Python script that should be invoked and used as the entry point for training.

You can also install additional libraries by including the following in your Dockerfile:

```bash
RUN pip install <library>
```

The following tutorial shows how to use these environment variables.

Extend SageMaker Containers to Run a Python Script

In this tutorial, you learn how to extend the SageMaker PyTorch container with a Python file that uses the CIFAR-10 dataset. By extending the SageMaker PyTorch container, you utilize the existing training solution made to work with SageMaker. This tutorial extends a training image, but the same steps can be taken to extend an inference image. For a full list of the available images, see Available Deep Learning Containers Images.

To run your own training model using the SageMaker containers, build a Docker container through a SageMaker Notebook instance.

Step 1: Create an SageMaker Notebook Instance

1. Open the SageMaker console.
2. In the left navigation pane, choose Notebook, choose Notebook instances, and then choose Create notebook instance.

3. On the Create notebook instance page, provide the following information:
   a. For Notebook instance name, enter RunScriptNotebookInstance.
   b. For Notebook Instance type, choose ml.t2.medium.
   c. In the Permissions and encryption section, do the following:
      i. For IAM role, choose Create a new role.
      ii. On the Create an IAM role page, choose Specific S3 buckets, specify an Amazon S3 bucket named sagemaker-run-script, and then choose Create role.

      SageMaker creates an IAM role named AmazonSageMaker-ExecutionRole-YYYYMMDDTHHmnnSS, such as AmazonSageMaker-ExecutionRole-20190429T110788. Note that the execution role naming convention uses the date and time when the role was created, separated by a T.
   d. For Root Access, choose Enable.
   e. Choose Create notebook instance.

4. On the Notebook instances page, the Status is Pending. It can take a few minutes for Amazon CloudWatch Internet Monitor to launch a machine learning compute instance—in this case, it launches a notebook instance—and attach an ML storage volume to it. The notebook instance has a preconfigured Jupyter notebook server and a set of Anaconda libraries. For more information, see CreateNotebookInstance.

5. In the Permissions and encryption section, copy the IAM role ARN number, and paste it into a notepad file to save it temporarily. You use this IAM role ARN number later to configure a local training estimator in the notebook instance. The IAM role ARN number looks like the following: 'arn:aws:iam::111122223333:role/service-role/AmazonSageMaker-ExecutionRole-20190429T110788'

6. After the status of the notebook instance changes to InService, choose Open JupyterLab.

Step 2: Create and Upload the Dockerfile and Python Training Scripts

1. After JupyterLab opens, create a new folder in the home directory of your JupyterLab. In the upper-left corner, choose the New Folder icon, and then enter the folder name docker_test_folder.

2. Create a Dockerfile text file in the docker_test_folder directory.
   a. Choose the New Launcher icon (+) in the upper-left corner.
   b. In the right pane under the Other section, choose Text File.
   c. Paste the following Dockerfile sample code into your text file.

```
# SageMaker PyTorch image
FROM 763104351884.dkr.ecr.us-east-1.amazonaws.com/pytorch-training:1.5.1-cpu-py36-ubuntu16.04

ENV PATH="/opt/ml/code:${PATH}"

# this environment variable is used by the SageMaker PyTorch container to determine our user code directory.
ENV SAGEMAKER_SUBMIT_DIRECTORY /opt/ml/code

# /opt/ml and all subdirectories are utilized by SageMaker, use the /code subdirectory to store your user code.
COPY cifar10.py /opt/ml/code/cifar10.py
```
# Defines cifar10.py as script entrypoint
ENV SAGEMAKER_PROGRAM cifar10.py

The Dockerfile script performs the following tasks:

- FROM 763104351884.dkr.ecr.us-east-1.amazonaws.com/pytorch-training:1.5.1-cpu-py36-ubuntu16.04 – Downloads the SageMaker PyTorch base image. You can replace this with any SageMaker base image you want to bring to build containers.

- ENV SAGEMAKER_SUBMIT_DIRECTORY /opt/ml/code – Sets /opt/ml/code as the training script directory.

- COPY cifar10.py /opt/ml/code/cifar10.py – Copies the script to the location inside the container that is expected by SageMaker. The script must be located in this folder.

- ENV SAGEMAKER_PROGRAM cifar10.py – Sets your cifar10.py training script as the entrypoint script.

d. On the left directory navigation pane, the text file name might automatically be named untitled.txt. To rename the file, right-click the file, choose Rename, rename the file as Dockerfile without the .txt extension, and then press Ctrl+s or Command+s to save the file.

3. Create or upload a training script cifar10.py in the docker_test_folder. You can use the following example script for this exercise.

```python
import ast
import argparse
import logging
import os
import torch
import torch.distributed as dist
import torch.nn as nn
import torch.nn.parallel
import torch.optim
import torch.utils.data
import torch.utils.data.distributed
import torchvision
import torchvision.models
import torchvision.transforms as transforms
import torch.nn.functional as F

logger=logging.getLogger(__name__)
logger.setLevel(logging.DEBUG)

                        help='momentum (default: 0.9)')
    parser.add_argument('--dist-backend', type=str, default='gloo', help='distributed
                        backend (default: gloo)')

    # The parameters below retrieve their default values from SageMaker environment
    # variables, which are
    # instantiated by the SageMaker containers framework.
    # https://github.com/aws/sagemaker-containers#how-a-script-is-executed-inside-the-
    # container
    parser.add_argument('--hosts', type=str,
                        default=ast.literal_eval(os.environ['SM_HOSTS']))
    parser.add_argument('--current-host', type=str,
                        default=os.environ['SM_CURRENT_HOST'])
    parser.add_argument('--model-dir', type=str,
                        default=os.environ['SM_MODEL_DIR'])
    parser.add_argument('--data-dir', type=str,
                        default=os.environ['SM_CHANNEL_TRAINING'])
Step 3: Build the Container

1. In the JupyterLab home directory, open a Jupyter notebook. To open a new notebook, choose the **New Launch** icon and then choose **conda_pytorch_p39** in the **Notebook** section.

2. Run the following command in the first notebook cell to change to the `docker_test_folder` directory:

   ```bash
   % cd ~/SageMaker/docker_test_folder
   ```

   This returns your current directory as follows:

   ```bash
   ! pwd
   ```

   output: /home/ec2-user/SageMaker/docker_test_folder

3. Log in to Docker to access the base container:

   ```bash
   ! aws ecr get-login-password --region us-east-1 | docker login --username AWS --password-stdin 763104351884.dkr.ecr.us-east-1.amazonaws.com
   ```

4. To build the Docker container, run the following Docker build command, including the space followed by a period at the end:

   ```bash
   ! docker build -t pytorch-extended-container-test .
   ```

   The Docker build command must be run from the Docker directory you created, in this case `docker_test_folder`.

   **Note**

   If you get the following error message that Docker cannot find the Dockerfile, make sure the Dockerfile has the correct name and has been saved to the directory.

   ```bash
   unable to prepare context: unable to evaluate symlinks in Dockerfile path: lstat /home/ec2-user/SageMaker/docker/Dockerfile: no such file or directory
   ```

   Remember that docker looks for a file specifically called Dockerfile without any extension within the current directory. If you named it something else, you can pass in the file name manually with the `-f` flag. For example, if you named your Dockerfile `Dockerfile-text.txt`, run the following command:

   ```bash
   ! docker build -t tf-custom-container-test -f Dockerfile-text.txt .
   ```

Step 4: Test the Container

1. To test the container locally in the notebook instance, open a Jupyter notebook. Choose **New Launcher** and choose **Notebook** in **conda_pytorch_p39** framework. The rest of the code snippets must run from the Jupyter notebook instance.

2. Download the CIFAR-10 dataset.
import torch
import torchvision
import torchvision.transforms as transforms

def _get_transform():
    return transforms.Compose([transforms.ToTensor(),
                               transforms.Normalize((0.5, 0.5, 0.5), (0.5, 0.5, 0.5))])

def get_train_data_loader(data_dir='/tmp/pytorch/cifar-10-data'):
    transform=_get_transform()
    trainset=torchvision.datasets.CIFAR10(root=data_dir, train=True,
                                           download=True, transform=transform)
    return torch.utils.data.DataLoader(trainset, batch_size=4,
                                        shuffle=True, num_workers=2)

def get_test_data_loader(data_dir='/tmp/pytorch/cifar-10-data'):
    transform=_get_transform()
    testset=torchvision.datasets.CIFAR10(root=data_dir, train=False,
                                          download=True, transform=transform)
    return torch.utils.data.DataLoader(testset, batch_size=4,
                                         shuffle=False, num_workers=2)

trainloader=get_train_data_loader('/tmp/pytorch-example/cifar-10-data')
testloader=get_test_data_loader('/tmp/pytorch-example/cifar-10-data')

3. Set role to the role used to create your Jupyter notebook. This is used to configure your SageMaker Estimator.

```python
from sagemaker import get_execution_role
role=get_execution_role()
```

4. Paste the following example script into the notebook code cell to configure a SageMaker Estimator using your extended container.

```python
from sagemaker.estimator import Estimator
hyperparameters={'epochs': 1}
estimator=Estimator(
    image_uri='pytorch-extended-container-test',
    role=role,
    instance_count=1,
    instance_type='local',
    hyperparameters=hyperparameters)
estimator.fit('file:///tmp/pytorch-example/cifar-10-data')
```

5. Run the code cell. This test outputs the training environment configuration, the values used for the environmental variables, the source of the data, and the loss and accuracy obtained during training.

**Step 5: Push the Container to Amazon Elastic Container Registry (Amazon ECR)**

1. After you successfully run the local mode test, you can push the Docker container to Amazon ECR and use it to run training jobs.
Run the following command lines in a notebook cell.

```bash
# Specify an algorithm name
algorithm_name=pytorch-extended-container-test
account=$(aws sts get-caller-identity --query Account --output text)

# Get the region defined in the current configuration (default to us-west-2 if none defined)
region=$(aws configure get region)

fullname="${account}.dkr.ecr.${region}.amazonaws.com/${algorithm_name}:latest"

# If the repository doesn't exist in ECR, create it.
aws ecr describe-repositories --repository-names "${algorithm_name}" > /dev/null 2>&1
if [ $? -ne 0 ]
    then
    aws ecr create-repository --repository-name "${algorithm_name}" > /dev/null
fi

# Log into Docker
aws ecr get-login-password --region ${region}|docker login --username AWS --password-stdin ${fullname}

# Build the docker image locally with the image name and then push it to ECR
# with the full name.
docker build -t ${algorithm_name} .
docker tag ${algorithm_name} ${fullname}
docker push ${fullname}
```

2. After you push the container, you can call the Amazon ECR image from anywhere in the SageMaker environment. Run the following code example in the next notebook cell.

If you want to use this training container with SageMaker Studio to use its visualization features, you can also run the following code in a Studio notebook cell to call the Amazon ECR image of your training container.

```python
import boto3

client=boto3.client('sts')
account=client.get_caller_identity()['Account']

my_session=boto3.session.Session()
region=my_session.region_name

algorithm_name="pytorch-extended-container-test"
ecr_image='{}.dkr.ecr.{}.amazonaws.com/{}:latest'.format(account, region, algorithm_name)

# This should return something like
# 12-digits-of-your-account.dkr.ecr.us-east-2.amazonaws.com/tf-2.2-test:latest
```

3. Use the `ecr_image` retrieved from the previous step to configure a SageMaker estimator object. The following code sample configures a SageMaker PyTorch estimator.

```python
import sagemaker
```
from sagemaker import get_execution_role
from sagemaker.estimator import Estimator

estimator=Estimator(
    image_uri=ecr_image,
    role=get_execution_role(),
    base_job_name='pytorch-extended-container-test',
    instance_count=1,
    instance_type='ml.p2.xlarge'
)

# start training
estimator.fit()

# deploy the trained model
predictor=estimator.deploy(1, instance_type)

---

**Step 6: Clean up Resources**

**To clean up resources when done with the Get Started example**

1. Open the [SageMaker console](https://console.aws.amazon.com/sagemaker), choose the notebook instance RunScriptNotebookInstance, choose **Actions**, and choose **Stop**. It can take a few minutes for the instance to stop.

2. After the instance **Status** changes to **Stopped**, choose **Actions**, choose **Delete**, and then choose **Delete** in the dialog box. It can take a few minutes for the instance to be deleted. The notebook instance disappears from the table when it has been deleted.

3. Open the [Amazon S3 console](https://console.aws.amazon.com/s3) and delete the bucket that you created for storing model artifacts and the training dataset.

4. Open the [IAM console](https://console.aws.amazon.com/iam) and delete the IAM role. If you created permission policies, you can delete them, too.

   **Note**
   The Docker container shuts down automatically after it has run. You don't need to delete it.

---

**Adapting your own Docker container to work with SageMaker**

You can adapt an existing Docker image to work with SageMaker. You may need to use an existing, external Docker image with SageMaker when you have a container that satisfies feature or safety requirements that are not currently supported by a pre-built SageMaker image. There are two toolkits that allow you to bring your own container and adapt it to work with SageMaker:

- [SageMaker Training Toolkit](https://console.aws.amazon.com/sagemaker)
- [SageMaker Inference Toolkit](https://console.aws.amazon.com/sagemaker)

The following topics show how to adapt your existing image using the SageMaker Training and Inference toolkits:

**Topics**

- [Individual Framework Libraries](https://console.aws.amazon.com/sagemaker)
- [Using the SageMaker Training and Inference Toolkits](https://console.aws.amazon.com/sagemaker)
- [Adapting your own training container](https://console.aws.amazon.com/sagemaker)
Individual Framework Libraries

In addition to the SageMaker Training Toolkit and SageMaker Inference Toolkit, SageMaker also provides toolkits specialized for TensorFlow, MXNet, PyTorch, and Chainer. The following table provides links to the GitHub repositories that contain the source code for each framework and their respective serving toolkits. The instructions linked are for using the Python SDK to run training algorithms and host models on SageMaker. The functionality for these individual libraries is included in the SageMaker Training Toolkit and SageMaker Inference Toolkit.

<table>

</tbody>
</table>

Using the SageMaker Training and Inference Toolkits

The SageMaker Training and SageMaker Inference toolkits implement the functionality that you need to adapt your containers to run scripts, train algorithms, and deploy models on SageMaker. When installed, the library defines the following for users:

- The locations for storing code and other resources.
- The entry point that contains the code to run when the container is started. Your Dockerfile must copy the code that needs to be run into the location expected by a container that is compatible with SageMaker.
- Other information that a container needs to manage deployments for training and inference.

SageMaker Toolkits Containers Structure

When SageMaker trains a model, it creates the following file folder structure in the container's /opt/ml directory.

```bash
/opt/ml
  ### input
  #   ### config
  #   #   ### hyperparameters.json
  #   #   ### resourceConfig.json
  #   ### data
  #       ### <channel_name>
  #           ### <input data>
  ### model
  #
```

3298
When you run a model training job, the SageMaker container uses the /opt/ml/input/ directory, which contains the JSON files that configure the hyperparameters for the algorithm and the network layout used for distributed training. The /opt/ml/input/ directory also contains files that specify the channels through which SageMaker accesses the data, which is stored in Amazon Simple Storage Service (Amazon S3). The SageMaker containers library places the scripts that the container will run in the /opt/ml/code/ directory. Your script should write the model generated by your algorithm to the /opt/ml/model/ directory. For more information, see Use Your Own Training Algorithms (p. 3316).

When you host a trained model on SageMaker to make inferences, you deploy the model to an HTTP endpoint. The model makes real-time predictions in response to inference requests. The container must contain a serving stack to process these requests.

In a hosting or batch transform container, the model files are located in the same folder to which they were written during training.

For more information, see Use your own inference code (p. 3327).

Single Versus Multiple Containers

You can either provide separate Docker images for the training algorithm and inference code or you can use a single Docker image for both. When creating Docker images for use with SageMaker, consider the following:

- Providing two Docker images can increase storage requirements and cost because common libraries might be duplicated.
- In general, smaller containers start faster for both training and hosting. Models train faster and the hosting service can react to increases in traffic by automatically scaling more quickly.
- You might be able to write an inference container that is significantly smaller than the training container. This is especially common when you use GPUs for training, but your inference code is optimized for CPUs.
- SageMaker requires that Docker containers run without privileged access.
- Both Docker containers that you build and those provided by SageMaker can send messages to the Stdout and Stderr files. SageMaker sends these messages to Amazon CloudWatch logs in your AWS account.

For more information about how to create SageMaker containers and how scripts are executed inside them, see the SageMaker Training Toolkit and SageMaker Inference Toolkit repositories on GitHub. They also provide lists of important environmental variables and the environmental variables provided by SageMaker containers.

Adapting your own training container

To run your own training model, build a Docker container using the Amazon SageMaker Training Toolkit through an Amazon SageMaker notebook instance.
Step 1: Create a SageMaker notebook instance

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the left navigation pane, choose Notebook, choose Notebook instances, and then choose Create notebook instance.
3. On the Create notebook instance page, provide the following information:
   a. For Notebook instance name, enter RunScriptNotebookInstance.
   b. For Notebook Instance type, choose ml.t2.medium.
   c. In the Permissions and encryption section, do the following:
      i. For IAM role, choose Create a new role. This opens a new window.
      ii. On the Create an IAM role page, choose Specific S3 buckets, specify an Amazon S3 bucket named sagemaker-run-script, and then choose Create role.
         SageMaker creates an IAM role named AmazonSageMaker-ExecutionRole-YYYYMMDDTHHmmSS. For example, AmazonSageMaker-ExecutionRole-20190429T110788. Note that the execution role naming convention uses the date and time at which the role was created, separated by a T.
   d. For Root Access, choose Enable.
   e. Choose Create notebook instance.
4. On the Notebook instances page, the Status is Pending. It can take a few minutes for Amazon SageMaker to launch a notebook instance—and attach an ML storage volume to it. The notebook instance has a preconfigured Jupyter notebook server and a set of Anaconda libraries. For more information, see CreateNotebookInstance.
5. Click on the Name of the notebook you just created. This opens a new page.
6. In the Permissions and encryption section, copy the IAM role ARN number, and paste it into a notepad file to save it temporarily. You use this IAM role ARN number later to configure a local training estimator in the notebook instance.
   The IAM role ARN number looks like the following: 'arn:aws:iam::111122223333:role/service-role/AmazonSageMaker-ExecutionRole-20190429T110788'
7. After the status of the notebook instance changes to InService, choose Open JupyterLab.

Step 2: Create and upload the Dockerfile and Python training scripts

1. After JupyterLab opens, create a new folder in the home directory of your JupyterLab. In the upper-left corner, choose the New Folder icon, and then enter the folder name docker_test_folder.
2. Create a Dockerfile text file in the docker_test_folder directory.
   a. Choose the New Launcher icon (+) in the upper-left corner.
   b. In the right pane under the Other section, choose Text File.
   c. Paste the following Dockerfile sample code into your text file.

```
#Download an open source TensorFlow Docker image
FROM tensorflow/tensorflow:latest-gpu-jupyter

# Install sagemaker-training toolkit that contains the common functionality necessary to create a container compatible with SageMaker and the Python SDK.
RUN pip3 install sagemaker-training
```
Adapting your own training container

The Dockerfile script performs the following tasks:

- FROM tensorflow/tensorflow:latest-gpu-jupyter –Downloads the latest TensorFlow Docker base image. You can replace this with any Docker base image you want to bring to build containers, as well as with AWS pre-built container base images.
- RUN pip install sagemaker-training –Installs SageMaker Training Toolkit that contains the common functionality necessary to create a container compatible with SageMaker.
- COPY train.py /opt/ml/code/train.py –Copies the script to the location inside the container that is expected by SageMaker. The script must be located in this folder.
- ENV SAGEMAKER_PROGRAM train.py – Takes your training script train.py as the entrypoint script copied in the /opt/ml/code folder of the container. This is the only environmental variable that you must specify when you build your own container.

3. Upload a training script train.py to the docker_test_folder. You can use the following example script to create a model that reads handwritten digits trained on the MNIST dataset for this exercise.

```python
import tensorflow as tf
import os

mnist = tf.keras.datasets.mnist
(x_train, y_train), (x_test, y_test) = mnist.load_data()
x_train, x_test = x_train / 255.0, x_test / 255.0

model = tf.keras.models.Sequential([tf.keras.layers.Flatten(input_shape=(28, 28)),
                                      tf.keras.layers.Dense(128, activation='relu'),
                                      tf.keras.layers.Dropout(0.2),
                                      tf.keras.layers.Dense(10, activation='softmax')])

model.compile(optimizer='adam',
               loss='sparse_categorical_crossentropy',
               metrics=['accuracy'])

model.fit(x_train, y_train, epochs=1)
model_save_dir = f"{os.environ.get('SM_MODEL_DIR')}/1"
model.evaluate(x_test, y_test)
tf.saved_model.save(model, model_save_dir)
```
Step 3: Build the container

1. In the JupyterLab home directory, open a Jupyter notebook. To open a new notebook, choose the New Launch icon and then choose the latest version of conda_tensorflow2 in the Notebook section.

2. Run the following command in the first notebook cell to change to the docker_test_folder directory:

   ```bash
   cd ~/SageMaker/docker_test_folder
   ```

   This returns your current directory as follows:

   ```bash
   ! pwd
   ```

   output: /home/ec2-user/SageMaker/docker_test_folder

3. To build the Docker container, run the following Docker build command, including the space followed by a period at the end:

   ```bash
   ! docker build -t tf-custom-container-test .
   ```

   The Docker build command must be run from the Docker directory you created, in this case docker_test_folder.

   **Note**
   If you get the following error message that Docker cannot find the Dockerfile, make sure the Dockerfile has the correct name and has been saved to the directory.

   ```text
   unable to prepare context: unable to evaluate symlinks in Dockerfile path: lstat /home/ec2-user/SageMaker/docker/Dockerfile: no such file or directory
   ```

   Remember that docker looks for a file specifically called Dockerfile without any extension within the current directory. If you named it something else, you can pass in the file name manually with the -f flag. For example, if you named your Dockerfile as Dockerfile-text.txt, run the following command:

   ```bash
   ! docker build -t tf-custom-container-test -f Dockerfile-text.txt .
   ```

Step 4: Test the container

1. To test the container locally in the notebook instance, open a Jupyter notebook. Choose New Launcher and choose the latest version of conda_tensorflow2 in the Notebook section.

2. Paste the following example script into the notebook code cell to configure a SageMaker Estimator.

   ```python
   import sagemaker
   from sagemaker.estimator import Estimator

   estimator = Estimator(image_uri='tf-custom-container-test',
                         role=sagemaker.get_execution_role(),
                         instance_count=1,
                         instance_type='local')

   estimator.fit()
   ```
In the preceding code example, `sagemaker.get_execution_role()` is specified to the role argument to automatically retrieve the role set up for the SageMaker session. You can also replace it with the string value of the IAM role ARN number you used when you configured the notebook instance. The ARN should look like the following: 'arn:aws:iam::111122223333:role/service-role/AmazonSageMaker-ExecutionRole-20190429T110788'.

3. Run the code cell. This test outputs the training environment configuration, the values used for the environmental variables, the source of the data, and the loss and accuracy obtained during training.

**Step 5: Push the container to Amazon Elastic Container Registry (Amazon ECR)**

1. After you successfully run the local mode test, you can push the Docker container to Amazon ECR and use it to run training jobs. If you want to use a private Docker registry instead of Amazon ECR, see [Push your training container to a private registry](#).

Run the following command lines in a notebook cell.

```bash
# Specify an algorithm name
algorithm_name=tf-custom-container-test

account=$(aws sts get-caller-identity --query Account --output text)

# Get the region defined in the current configuration (default to us-west-2 if none defined)
region=$(aws configure get region)
region=${region:-us-west-2}

fullname="${account}.dkr.ecr.${region}.amazonaws.com/${algorithm_name}:latest"

# If the repository doesn't exist in ECR, create it.
aws ecr describe-repositories --repository-names "${algorithm_name}" > /dev/null 2>&1
if [ $? -ne 0 ]
then
  aws ecr create-repository --repository-name "${algorithm_name}" > /dev/null
fi

# Get the login command from ECR and execute it directly
aws ecr get-login-password --region ${region}|docker login --username AWS --password-stdin ${fullname}

# Build the docker image locally with the image name and then push it to ECR with the full name.
docker build -t ${algorithm_name} .
docker tag ${algorithm_name} ${fullname}
docker push ${fullname}
```

**Note**
This bash shell script may raise a permission issue similar to the following error message:

```
denied: User: [ARN] is not authorized to perform: ecr:InitiateLayerUpload on resource:
```
Adapting your own training container

If this error occurs, you need to attach the AmazonEC2ContainerRegistryFullAccess policy to your IAM role. Go to the IAM console, choose Roles from the left navigation pane, look up the IAM role you used for the Notebook instance. Under the Permission tab, choose the Attach policies button, and search the AmazonEC2ContainerRegistryFullAccess policy. Mark the check box of the policy, and choose Add permissions to finish.

2. Run the following code in a Studio notebook cell to call the Amazon ECR image of your training container.

```python
import boto3

account_id = boto3.client('sts').get_caller_identity().get('Account')
ecr_repository = 'tf-custom-container-test'
tag = ':latest'

region = boto3.session.Session().region_name
uri_suffix = 'amazonaws.com'
if region in ['cn-north-1', 'cn-northwest-1']:
    uri_suffix = 'amazonaws.com.cn'

byoc_image_uri = '{}.dkr.ecr.{}.{}/{}'.format(account_id, region, uri_suffix, ecr_repository + tag)

byoc_image_uri
# This should return something like
# 111122223333.dkr.ecr.us-east-2.amazonaws.com/sagemaker-byoc-test:latest
```

3. Use the ecr_image retrieved from the previous step to configure a SageMaker estimator object. The following code sample configures a SageMaker estimator with the byoc_image_uri and initiates a training job on an Amazon EC2 instance.

SageMaker Python SDK v1

```python
import sagemaker
from sagemaker import get_execution_role

estimator = Estimator(image_uri=byoc_image_uri,
                      role=get_execution_role(),
                      base_job_name='tf-custom-container-test-job',
                      instance_count=1,
                      instance_type='ml.g4dn.xlarge')

#train your model
estimator.fit()
```

SageMaker Python SDK v2

```python
import sagemaker
from sagemaker import get_execution_role

estimator = Estimator(image_uri=byoc_image_uri,
                      role=get_execution_role(),
                      base_job_name='tf-custom-container-test-job',
                      instance_count=1,
                      instance_type='ml.g4dn.xlarge')
```
#train your model
estimator.fit()

4. If you want to deploy your model using your own container, refer to Adapting Your Own Inference Container. You can also use an AWS framework container that can deploy a TensorFlow model. To deploy the example model to read handwritten digits, enter the following example script into the same notebook that you used to train your model in the previous sub-step to obtain the image URIs (universal resource identifiers) needed for deployment, and deploy the model.

```python
import boto3
import sagemaker

#obtain image uris
from sagemaker import image_uris
container = image_uris.retrieve(framework='tensorflow', region='us-west-2', version='2.11.0',
                                image_scope='inference', instance_type='ml.g4dn.xlarge')

#create the model entity, endpoint configuration and endpoint
predictor = estimator.deploy(1, instance_type='ml.g4dn.xlarge', image_uri=container)
```

Test your model using a sample handwritten digit from the MNIST dataset using the following code example.

```python
#Retrieve an example test dataset to test
import numpy as np
import matplotlib.pyplot as plt
from keras.datasets import mnist

# Load the MNIST dataset and split it into training and testing sets
(x_train, y_train), (x_test, y_test) = mnist.load_data()
# Select a random example from the training set
example_index = np.random.randint(0, x_train.shape[0])
example_image = x_train[example_index]
example_label = y_train[example_index]

# Print the label and show the image
print(f"Label: {example_label}")
plt.imshow(example_image, cmap='gray')
plt.show()

Convert the test handwritten digit into a form that TensorFlow can ingest and make a test prediction.

```python
from sagemaker.serializers import JSONSerializer

data ={"instances": example_image.tolist()}
predictor.serializer=JSONSerializer() #update the predictor to use the JSONSerializer
predictor.predict(data) #make the prediction
```

For a full example that shows how to test a custom container locally and push it to an Amazon ECR image, see the Building Your Own TensorFlow Container example notebook.

**Tip**
To profile and debug training jobs to monitor system utilization issues (such as CPU bottlenecks and GPU underutilization) and identify training issues (such as overfitting, overtraining, exploding tensors, and vanishing gradients), use Amazon SageMaker Debugger. For more information, see Use Debugger with Custom Training Containers (p. 2010).
Step 6: Clean up resources

To clean up resources when done with the get started example

1. Open the SageMaker console, choose the notebook instance RunScriptNotebookInstance, choose Actions, and choose Stop. It can take a few minutes for the instance to stop.
2. After the instance Status changes to Stopped, choose Actions, choose Delete, and then choose Delete in the dialog box. It can take a few minutes for the instance to be deleted. The notebook instance disappears from the table when it has been deleted.
3. Open the Amazon S3 console and delete the bucket that you created for storing model artifacts and the training dataset.
4. Open the IAM console and delete the IAM role. If you created permission policies, you can delete them, too.

Note
The Docker container shuts down automatically after it has run. You don’t need to delete it.

Blogs and Case Studies

The following blogs discuss case studies about using custom training containers in Amazon SageMaker.

- Why bring your own container to Amazon SageMaker and how to do it right, Medium (January 20th, 2023)

Adapt your training job to access images in a private Docker registry

You can use a private Docker registry instead of an Amazon Elastic Container Registry (Amazon ECR) to host your images for SageMaker Training. The following instructions show you how to create a Docker registry, configure your virtual private cloud (VPC) and training job, store images, and give SageMaker access to the training image in the private docker registry. These instructions also show you how to use a Docker registry that requires authentication for a SageMaker training job.

Create and store your images in a private Docker registry

Create a private Docker registry to store your images. Your registry must:

- use the Docker Registry HTTP API protocol
- be accessible from the same VPC specified in the VpcConfig parameter in the CreateTrainingJob API. Input VpcConfig when you create your training job.
- secured with a TLS certificate from a known public certificate authority.

For more information about creating a Docker registry, see Deploy a registry server.

Configure your VPC and SageMaker training job

SageMaker uses a network connection within your VPC to access images in your Docker registry. To use the images in your Docker registry for training, the registry must be accessible from an Amazon VPC in your account. For more information, see Use a Docker registry that requires authentication for training (p. 3310).

You must also configure your training job to connect to the same VPC to which your Docker registry has access. For more information, see Configure a Training Job for Amazon VPC Access.
Create a training job using an image from your private Docker registry

To use an image from your private Docker registry for training, use the following guide to configure your image, configure and create a training job. The code examples that follow use the AWS SDK for Python (Boto3) client.

1. Create a training image configuration object and input Vpc the TrainingRepositoryAccessMode field as follows.

   ```python
   training_image_config = {
       'TrainingRepositoryAccessMode': 'Vpc'
   }
   
   Note
   If your private Docker registry requires authentication, you must add a TrainingRepositoryAuthConfig object to the training image configuration object. You must also specify the Amazon Resource Name (ARN) of an AWS Lambda function that provides access credentials to SageMaker using the TrainingRepositoryCredentialsProviderArn field of the TrainingRepositoryAuthConfig object. For more information, see the example code structure below.

   ```python
   training_image_config = {
       'TrainingRepositoryAccessMode': 'Vpc',
       'TrainingRepositoryAuthConfig': {
           'TrainingRepositoryCredentialsProviderArn':
           'arn:aws:lambda:Region:Acct:function:FunctionName'
       }
   }
   
   For information about how to create the Lambda function to provide authentication, see Use a Docker registry that requires authentication for training (p. 3310).

   2. Use a Boto3 client to create a training job and pass the correct configuration to the create_training_job API. The following instructions show you how to configure the components and create a training job.

   a. Create the AlgorithmSpecification object that you want to pass to create_training_job.

      Use the training image configuration object that you created in the previous step, as shown in the following code example.

      ```python
      algorithm_specification = {
          'TrainingImage': 'myteam.myorg.com/docker-local/my-training-image:<IMAGE-TAG>',
          'TrainingImageConfig': training_image_config,
          'TrainingInputMode': 'File'
      }
      
      Note
      To use a fixed, rather than an updated version of an image, refer to the image's digest instead of by name or tag.

   b. Specify the name of the training job and role that you want to pass to create_training_job, as shown in the following code example.

      ```python
      training_job_name = 'private-registry-job'
      execution_role_arn = 'arn:aws:iam::123456789012:role/SageMakerExecutionRole'
      ```
c. Specify a security group and subnet for the VPC configuration for your training job. Your private Docker registry must allow inbound traffic from the security groups that you specify, as shown in the following code example.

```python
vpc_config = {
    'SecurityGroupIds': ['sg-0123456789abcdef0'],
    'Subnets': ['subnet-0123456789abcdef0','subnet-0123456789abcdef1']
}
```

**Note**
If your subnet is not in the same VPC as your private Docker registry, you must set up a networking connection between the two VPCs. See Connect VPCs using VPC peering for more information.

d. Specify the resource configuration, including machine learning compute instances and storage volumes to use for training, as shown in the following code example.

```python
resource_config = {
    'InstanceType': 'ml.m4.xlarge',
    'InstanceCount': 1,
    'VolumeSizeInGB': 10
}
```
e. Specify the input and output data configuration, where the training dataset is stored, and where you want to store model artifacts, as shown in the following code example.

```python
input_data_config = [
    {
        "ChannelName": "training",
        "DataSource": {
            "S3DataSource": {
                "S3DataDistributionType": "FullyReplicated",
                "S3DataType": "S3Prefix",
                "S3Uri": "s3://your-training-data-bucket/training-data-folder"
            }
        }
    }
]
output_data_config = {
    'S3OutputPath': 's3://your-output-data-bucket/model-folder'
}
```
f. Specify the maximum number of seconds that a model training job can run as shown in the following code example.

```python
stopping_condition = {
    'MaxRuntimeInSeconds': 1800
}
```
g. Finally, create the training job using the parameters you specified in the previous steps as shown in the following code example.

```python
import boto3
sm = boto3.client('sagemaker')
try:
    resp = sm.create_training_job(
        TrainingJobName=training_job_name,
        AlgorithmSpecification=algorithm_specification,
        ...
Use a SageMaker estimator to run a training job

You can also use an estimator from the SageMaker Python SDK to handle the configuration and running of your SageMaker training job. The following code examples show how to configure and run an estimator using images from a private Docker registry.

1. Import the required libraries and dependencies, as shown in the following code example.

```python
import boto3
import sagemaker
from sagemaker.estimator import Estimator

session = sagemaker.Session()
role = sagemaker.get_execution_role()
```

2. Provide a Uniform Resource Identifier (URI) to your training image, security groups and subnets for the VPC configuration for your training job, as shown in the following code example.

```python
image_uri = "myteam.myorg.com/docker-local/my-training-image:<IMAGE-TAG>"
security_groups = ["sg-0123456789abcdef0"]
subnets = ["subnet-0123456789abcdef0", "subnet-0123456789abcdef0"]
```

For more information about security_group_ids and subnets, see the appropriate parameter description in the Estimators section of the SageMaker Python SDK.

**Note**
SageMaker uses a network connection within your VPC to access images in your Docker registry. To use the images in your Docker registry for training, the registry must be accessible from an Amazon VPC in your account.

3. Optionally, if your Docker registry requires authentication, you must also specify the Amazon Resource Name (ARN) of an AWS Lambda function that provides access credentials to SageMaker. The following code example shows how to specify the ARN.

```python
```

For more information about using images in a Docker registry requiring authentication, see **Use a Docker registry that requires authentication for training** below.

4. Use the code examples from the previous steps to configure an estimator, as shown in the following code example.

```python
# The training repository access mode must be 'Vpc' for private docker registry jobs
training_repository_access_mode = "Vpc"
```
# Specify the instance type, instance count you want to use
instance_type="ml.m5.xlarge"
instance_count=1

# Specify the maximum number of seconds that a model training job can run
max_run_time = 1800

# Specify the output path for the model artifacts
output_path = "s3://your-output-bucket/your-output-path"

estimator = Estimator(
    image_uri=image_uri,
    role=role,
    subnets=subnets,
    security_group_ids=security_groups,
    training_repository_access_mode=training_repository_access_mode,
    training_repository_credentials_provider_arn=training_repository_credentials_provider_arn,
    instance_type=instance_type,
    instance_count=instance_count,
    output_path=output_path,
    max_run=max_run_time
)

5. Start your training job by calling estimator.fit with your job name and input path as parameters, as shown in the following code example.

```python
input_path = "s3://your-input-bucket/your-input-path"
job_name = "your-job-name"

estimator.fit(
    inputs=input_path,
    job_name=job_name
)
```

Use a Docker registry that requires authentication for training

If your Docker registry requires authentication, you must create an AWS Lambda function that provides access credentials to SageMaker. Then, create a training job and provide the ARN of this Lambda function inside the create_training_job API. Lastly, you can optionally create an interface VPC endpoint so that your VPC can communicate with your Lambda function without sending traffic over the internet. The following guide shows how to create a Lambda function, assign it the correct role and create an interface VPC endpoint.

Create the Lambda function

Create an AWS Lambda function that passes access credentials to SageMaker and returns a response. The following code example creates the Lambda function handler, as follows.

```python
def handler(event, context):
    response = {
        "Credentials": {}
    }
    return response
```

The type of authentication used to set up your private Docker registry determines the contents of the response returned by your Lambda function as follows.
• If your private Docker registry uses basic authentication, the Lambda function will return the username and password needed in order to authenticate to the registry.

• If your private Docker registry uses bearer token authentication, the username and password are sent to your authorization server, which then returns a bearer token. This token is then used to authenticate to your private Docker registry.

Note
If you have more than one Lambda functions for your registries in the same account, and the execution role is the same for your training jobs, then training jobs for registry one would have access to the Lambda functions for other registries.

Grant the correct role permission to your Lambda function

The IAM role that you use in the create_training_job API must have permission to call an AWS Lambda function. The following code example shows how to extend permissions policy of an IAM role to call myLambdaFunction.

```json
{
  "Effect": "Allow",
  "Action": [
    "lambda:InvokeFunction"
  ],
  "Resource": [
    "arn:aws:lambda:*:*:function:*myLambdaFunction*"
  ]
}
```

For information about editing a role permissions policy, see Modifying a role permissions policy (console) in the AWS Identity and Access Management User Guide.

Note
An IAM role with an attached AmazonSageMakerFullAccess managed policy has permission to call any Lambda function with "SageMaker" in its name.

Create an interface VPC endpoint for Lambda

If you create an interface endpoint, your Amazon VPC can communicate with your Lambda function without sending traffic over the internet. For more information, see Configuring interface VPC endpoints for Lambda in the AWS Lambda Developer Guide.

After your interface endpoint is created, SageMaker training will call your Lambda function by sending a request through your VPC to lambda.region.amazonaws.com. If you select Enable DNS Name when you create your interface endpoint, Amazon Route 53 routes the call to the Lambda interface endpoint. If you use a different DNS provider, you must map lambda.region.amazonaws.com, to your Lambda interface endpoint.

Adapting Your Own Inference Container

If none of the Amazon SageMaker pre-built inference containers suffice for your situation, you can build your own Docker container and use it inside SageMaker for training and inference. For more information and an example of how to build your own Docker container for training and inference with SageMaker, see Building your own algorithm container.

You can also use the SageMaker Inference Toolkit to adapt your container to work with SageMaker hosting. The following guide shows you how to use the SageMaker Inference Toolkit to adapt your inference container.
Using the SageMaker inference toolkit

To adapt your container to work with SageMaker hosting, create the inference code in one or more Python script files and use a Dockerfile that imports the inference toolkit.

The inference code for the inference toolkit should include an inference handler, a handler service, and an entrypoint. In this example, they are stored as three separate Python files. All three of these Python files must be in the same directory as your Dockerfile.

For an example Jupyter notebook that shows a complete example of extending a container by using the SageMaker inference toolkit, see Amazon SageMaker Multi-Model Endpoints using your own algorithm container.

Step 1: Create an Inference Handler

The SageMaker inference toolkit is built on the multi-model server (MMS). MMS expects a Python script that implements the following functions:

- Load the model.
- Pre-process input data.
- Get predictions from the model.
- Process the output data in a model handler.

Optionally, you can use the context argument in the functions you implement to access additional serving information, such as a GPU ID or the batch size. If you are using multiple GPUs, you must specify the context argument in the predict_fn function to select a GPU for prediction. For more information about the context argument and how to use it, see the examples in The SageMaker PyTorch Model Server in the SageMaker Python SDK.

The model_fn Function

The model_fn function loads your model. There are default implementations for the model_fn function, named default_model_fn, on the SageMaker PyTorch and MXNet Inference toolkits. The default implementation loads models saved using torchscript, of the form .pt or .pth. If your model requires custom methods to load, or you want to perform extra steps when loading your model, you must implement the model_fn function. The following simple example shows an implementation of a model_fn function that loads a PyTorch model:

```python
def model_fn(self, model_dir):
    import torch
    logger.info('model_fn')
    device = "cuda" if torch.cuda.is_available() else "cpu"
    with open(os.path.join(model_dir, 'model.pth'), 'rb') as f:
        model = torch.jit.load(f)
    return model.to(device)
```

The input Function

The input_fn pre-processes input data. Specifically, the input_fn function is responsible for deserializing your input data so that it can be passed to your model. It takes input data and content type as parameters, and returns deserialized data. The SageMaker inference toolkit provides a default implementation that deserializes the following content types:

- JSON
- CSV
• Numpy array
• NPZ

If your model requires a different content type, or you want to preprocess your input data before sending it to the model, you must implement the `input_fn` function. The following example shows a simple implementation of the `input_fn` function.

```python
from sagemaker_inference import content_types, decoder
def input_fn(self, input_data, content_type):
    """A default input_fn that can handle JSON, CSV and NPZ formats.
    Args:
        input_data: the request payload serialized in the content_type format
        content_type: the request content_type
    Returns: input_data deserialized into torch.FloatTensor or torch.cuda.FloatTensor depending if cuda is available.
    ""
    return decoder.decode(input_data, content_type)
```

The `predict_fn` Function

The `predict_fn` function is responsible for getting predictions from the model. It takes the model and the data returned from `input_fn` as parameters, and returns the prediction. There is no default implementation for the `predict_fn`. You must implement it yourself. The following is a simple implementation of the `predict_fn` function for a PyTorch model.

```python
def predict_fn(self, data, model):
    """A default predict_fn for PyTorch. Calls a model on data deserialized in `input_fn`.
    Runs prediction on GPU if cuda is available.
    Args:
        data: input data (torch.Tensor) for prediction deserialized by input_fn
        model: PyTorch model loaded in memory by model_fn
    Returns: a prediction
    ""
    return model(data)
```

The `output_fn` Function

The `output_fn` function processes the output data in a model handler. A model handler contains functions that are defined at the model level. The `output_fn` function is responsible for serializing the data that the `predict_fn` function returns as a prediction. The SageMaker inference toolkit implements a default `output_fn` function that serializes Numpy arrays, JSON, and CSV. If your model outputs any other content type, or you want to perform other post-processing of your data before sending it to the user, you must implement your own `output_fn` function. The following shows a simple `output_fn` function for a PyTorch model.

```python
from sagemaker_inference import encoder
def output_fn(self, prediction, accept):
    """A default output_fn for PyTorch. Serializes predictions from predict_fn to JSON, CSV or NPY format.
    Args:
        prediction: a prediction result from predict_fn
        accept: type which the output data needs to be serialized
    """
Returns: output data serialized

```python
return encoder.encode(prediction, accept)
```

## Step 2: Implement a Handler Service

The handler service implements initialize and handle methods, and is run by the model server. The initialize method is invoked when the model server starts, and the handle method is invoked for all incoming inference requests to the model server. For more information, see [Custom Service](#) in the Multi-model server documentation. The following is an example of a handler service for a PyTorch model server.

```python
from sagemaker_inference.default_handler_service import DefaultHandlerService
from sagemaker_inference.transformer import Transformer
from sagemaker_pytorch_serving_container.default_inference_handler import
    DefaultPytorchInferenceHandler

class HandlerService(DefaultHandlerService):
    """Handler service that is executed by the model server.
    Determines specific default inference handlers to use based on model being used.
    This class extends `DefaultHandlerService`, which define the following:
    - The `handle` method is invoked for all incoming inference requests to the model
      server.
    - The `initialize` method is invoked at model server start up.
    Based on: https://github.com/awslabs/mxnet-model-server/blob/master/docs/custom_service.md
    """

    def __init__(self):
        transformer = Transformer(default_inference_handler=DefaultPytorchInferenceHandler())
        super(HandlerService, self).__init__(transformer=transformer)
```

## Step 3: Implement an Entrypoint

An entrypoint starts the model server by invoking the handler service. Specify the location of the entrypoint in your Dockerfile. The following is an example of an entrypoint.

```python
from sagemaker_inference import model_server
model_server.start_model_server(handler_service=HANDLER_SERVICE)
```

## Step 4: Write a Dockerfile

Write a Dockerfile. For a full example of a Dockerfile for an inference container, see [Dockerfile](#). In your Dockerfile, copy the model handler from Step 2 and specify the Python file from the previous step as the entrypoint in your Dockerfile. The following is an example of the lines you can add to your Dockerfile to copy the model handler and specify the entrypoint.

```bash
# Copy the default custom service file to handle incoming data and inference requests
COPY model_handler.py /home/model-server/model_handler.py

# Define an entrypoint script for the docker image
ENTRYPOINT ["python", "/usr/local/bin/entrypoint.py"]
```

## Step 5: Build and Register Your Container

Last, build your container and register it. The following shell script from the sample notebook builds the container and uploads it to an Amazon ECR repository in your AWS account.
Note
SageMaker hosting supports using inference containers that are stored in repositories other than Amazon ECR. For information, see Use a Private Docker Registry for Real-Time Inference Containers (p. 3332).

The following shell script shows how to build and register a container.

```sh
# The name of our algorithm
algorithm_name=demo-sagemaker-multimodel
cd container
account=$(aws sts get-caller-identity --query Account --output text)
# Get the region defined in the current configuration (default to us-west-2 if none defined)
region=$(aws configure get region)
region=${region:-us-west-2}
fullname="${account}.dkr.ecr.${region}.amazonaws.com/${algorithm_name}:latest"
# If the repository doesn't exist in ECR, create it.
aws ecr describe-repositories --repository-names "$algorithm_name" > /dev/null 2>&1
if [ $? -ne 0 ]
    then
        aws ecr create-repository --repository-name "$algorithm_name" > /dev/null
# Get the login command from ECR and execute it directly
aws ecr get-login-password --region ${region} | docker login --username AWS --password-stdin
    ${fullname}
# Build the Docker image locally with the image name and then push it to ECR
# with the full name.
docker build -q -t ${algorithm_name} .
docker tag ${algorithm_name} ${fullname}
docker push ${fullname}
```

You can now use this container to deploy endpoints in SageMaker.

Additional Information

For an example of how to deploy an endpoint in SageMaker, see Amazon SageMaker Multi-Model Endpoints using your own algorithm container.

For an introductory tutorial about deploying a model to a real-time inference endpoint, see Deploy a Machine Learning Model to a Real-Time Inference Endpoint.

For information about how to deploy a custom Docker image in SageMaker in an API gateway, see Creating a machine learning-powered REST API with Amazon API Gateway mapping templates and Amazon SageMaker.
Create a container with your own algorithms and models

If none of the existing SageMaker containers meet your needs and you don't have an existing container of your own, you may need to create a new Docker container. The following sections show how to create Docker containers with your training and inference algorithms for use with SageMaker.

Topics

- Use Your Own Training Algorithms (p. 3316)
- Use your own inference code (p. 3327)

Use Your Own Training Algorithms

This section explains how Amazon SageMaker interacts with a Docker container that runs your custom training algorithm. Use this information to write training code and create a Docker image for your training algorithms.

Topics

- How Amazon SageMaker Runs Your Training Image (p. 3316)
- How Amazon SageMaker Provides Training Information (p. 3321)
- Run Training with EFA (p. 3324)
- How Amazon SageMaker Signals Algorithm Success and Failure (p. 3326)
- How Amazon SageMaker Processes Training Output (p. 3327)

How Amazon SageMaker Runs Your Training Image

You can use a custom entrypoint script to automate infrastructure to train in a production environment. If you pass your entrypoint script into your Docker container, you can also run it as a standalone script without rebuilding your images. SageMaker processes your training image using a Docker container entrypoint script.

This section shows you how to use a custom entrypoint without using the training toolkit. If you want to use a custom entrypoint but are unfamiliar with how to manually configure a Docker container, we recommend that you use the SageMaker training toolkit library instead. For more information about how to use the training toolkit, see Adapting your own training container (p. 3299).

By default, SageMaker looks for a script called train inside your container. You can also manually provide your own custom entrypoint by using the ContainerArguments and ContainerEntrypoint parameters of the AlgorithmSpecification API.

You have the following two options to manually configure your Docker container to run your image.

- Use the CreateTrainingJob API and a Docker container with an entrypoint instruction contained inside of it.
- Use the CreateTrainingJob API, and pass your training script from outside of your Docker container.

If you pass your training script from outside your Docker container, you don't need to rebuild the Docker container when you update your script. You can also use several different scripts to run in the same container.
Your entrypoint script should contain training code for your image. If you use the optional `source_dir` parameter inside an `estimator`, it should reference the relative Amazon S3 path to the folder containing your entrypoint script. You can reference multiple files using the `source_dir` parameter. If you do not use `source_dir`, you can specify the entrypoint using the `entry_point` parameter. For an example of a custom entrypoint script that contains an estimator, see Bring Your Own Model with SageMaker Script Mode.

**Run a training job with an entrypoint script bundled inside the Docker container**

SageMaker can run an entrypoint script bundled inside your Docker container.

- By default, Amazon SageMaker runs the following container.

  ```
  docker run image train
  ```

- SageMaker overrides any default `CMD` statements in a container by specifying the `train` argument after the image name. In your Docker container, use the following `exec` form of the `ENTRYPOINT` instruction.

  ```
  ENTRYPOINT ["executable", "param1", "param2", ...]
  ```

  The following example shows how to specify a python entrypoint instruction called `k-means-algorithm.py`.

  ```
  ENTRYPOINT ["python", "k-means-algorithm.py"]
  ```

  The `exec` form of the `ENTRYPOINT` instruction starts the executable directly, not as a child of `/bin/sh`. This enables it to receive signals like SIGTERM and SIGKILL from SageMaker APIs. The following conditions apply when using the SageMaker APIs.

  - The `CreateTrainingJob` API has a stopping condition that directs SageMaker to stop model training after a specific time.
  - The following shows the `StopTrainingJob` API. This API issues the equivalent of the `docker stop`, with a 2-minute timeout command to gracefully stop the specified container.

    ```
    docker stop -t 120
    ```

    The command attempts to stop the running container by sending a SIGTERM signal. After the 2-minute timeout, the API sends SIGKILL and forcibly stops the containers. If the container handles the SIGTERM gracefully and exits within 120 seconds from receiving it, no SIGKILL is sent.

    If you want access to the intermediate model artifacts after SageMaker stops the training, add code to handle saving artifacts in your SIGTERM handler.

    - If you plan to use GPU devices for model training, make sure that your containers are `nvidia-docker` compatible. Include only the CUDA toolkit on containers; don’t bundle NVIDIA drivers with the image. For more information about `nvidia-docker`, see `NVIDIA/nvidia-docker`.
    - You can’t use the `tini` initializer as your entrypoint script in SageMaker containers because it gets confused by the `train` and `serve` arguments.
    - `/opt/ml` and all subdirectories are reserved by SageMaker training. When building your algorithm’s Docker image, make sure that you don’t place any data that’s required by your algorithm in this directory. Because if you do, the data may no longer be visible during training.

    To bundle your shell or Python scripts inside your Docker image, or to provide the script in an Amazon S3 bucket or by using the AWS Command Line Interface (CLI), continue to the following section.
Bundle your shell script in a Docker container

If you want to bundle a custom shell script inside your Docker image, use the following steps.

1. Copy your shell script from your working directory to inside your Docker container. The following code snippet copies a custom entrypoint script `custom_entrypoint.sh` from the current working directory to a Docker container located in `mydir`. The following example assumes that the base Docker image has Python installed.

```bash
FROM <base-docker-image>:<tag>

# Copy custom entrypoint from current dir to /mydir on container
COPY ./custom_entrypoint.sh /mydir/
```

2. Build and push a Docker container to the Amazon Elastic Container Registry (Amazon ECR) by following the instructions at Pushing a Docker image in the Amazon ECR User Guide.

3. Launch the training job by running the following AWS CLI command.

```bash
aws --region <your-region> sagemaker create-training-job \
--training-job-name <your-training-job-name> \
--role-arn <your-execution-role-arn> \
--algorithm-specification '{ \
  "TrainingInputMode": "File", \
  "TrainingImage": "<your-ecr-image>", \
  "ContainerEntrypoint": ["/bin/sh"], \
  "ContainerArguments": ["/mydir/custom_entrypoint.sh"]}' \
--output-data-config '{"S3OutputPath": "s3://custom-entrypoint-output-bucket/"}' \
--resource-config '{"VolumeSizeInGB": 10, "InstanceCount": 1, "InstanceType": "ml.m5.2xlarge"}'} \
--stopping-condition '{"MaxRuntimeInSeconds": 180}'}
```

Bundle your Python script in a Docker container

To bundle a custom Python script inside your Docker image, use the following steps.

1. Copy your Python script from your working directory to inside your Docker container. The following code snippet copies a custom entrypoint script `custom_entrypoint.py` from the current working directory to a Docker container located in `mydir`.

```bash
FROM <base-docker-image>:<tag>

# Copy custom entrypoint from current dir to /mydir on container
COPY ./custom_entrypoint.py /mydir/
```

2. Launch the training job by running the following AWS CLI command.

```bash
aws --region <your-region> sagemaker create-training-job \
--training-job-name <your-training-job-name> \
--role-arn <your-execution-role-arn> \
--algorithm-specification '{ \
  "TrainingInputMode": "File", \
  "TrainingImage": "<your-ecr-image>", \
  "ContainerEntrypoint": ["python"], \
  "ContainerArguments": ["/mydir/custom_entrypoint.py"]}' \
```

Run a training job with an entrypoint script outside the Docker container

You can use your own Docker container for training and pass in an entrypoint script from outside the Docker container. There are some benefits to structuring your entrypoint script outside the container. If you update your entrypoint script, you don't need to rebuild the Docker container. You can also use several different scripts to run in the same container.
Specify the location of your training script using the `ContainerEntrypoint` and `ContainerArguments` parameters of the `AlgorithmSpecification` API. These entrypoints and arguments behave in the same manner as Docker entrypoints and arguments. The values in these parameters override the corresponding `ENTRYPOINT` or `CMD` provided as part of the Docker container.

When you pass your custom entrypoint script to your Docker training container, the inputs that you provide determine the behavior of the container.

- For example, if you provide only `ContainerEntrypoint`, the request syntax using the `CreateTrainingJob` API is as follows.

```json
{
   "AlgorithmSpecification": {
      "ContainerEntrypoint": ["string"],
      ...
   }
}
```

Then, the SageMaker training backend runs your custom entrypoint as follows.

```
docker run --entrypoint <ContainerEntrypoint> image
```

**Note**

If `ContainerEntrypoint` is provided, the SageMaker training backend runs the image with the given entrypoint and overrides the default `ENTRYPOINT` in the image.

- If you provide only `ContainerArguments`, SageMaker assumes that the Docker container contains an entrypoint script. The request syntax using the `CreateTrainingJob` API is as follows.

```json
{
   "AlgorithmSpecification": {
      "ContainerArguments": ["arg1", "arg2"],
      ...
   }
}
```

The SageMaker training backend runs your custom entrypoint as follows.

```
docker run image <ContainerArguments>
```

- If you provide both the `ContainerEntrypoint` and `ContainerArguments`, then the request syntax using the `CreateTrainingJob` API is as follows.

```json
{
   "AlgorithmSpecification": {
      "ContainerEntrypoint": ["string"],
      "ContainerArguments": ["arg1", "arg2"],
      ...
   }
}
```

The SageMaker training backend runs your custom entrypoint as follows.

```
docker run --entrypoint <ContainerEntrypoint> image <ContainerArguments>
```
You can use any supported InputDataConfig source in the CreateTrainingJob API to provide an entrypoint script to run your training image.

Provide your entrypoint script in an Amazon S3 bucket

To provide a custom entrypoint script using an S3 bucket, use the S3DataSource parameter of the DataSource API to specify the location of the script. If you use the S3DataSource parameter, the following are required.

- The InputMode must be of the type File.
- The S3DataDistributionType must be FullyReplicated.

The following example has a script called custom_entrypoint.sh placed in a path to an S3 bucket s3://<bucket-name>/<bucket_prefix>/custom_entrypoint.sh.

```bash
#!/bin/bash
echo "Running custom_entrypoint.sh"
echo "Hello you have provided the following arguments: " "$@
```

Next, you must set the configuration of the input data channel to run a training job. Do this either by using the AWS CLI directly or with a JSON file.

Configure the input data channel using AWS CLI with a JSON file

To configure your input data channel with a JSON file, use AWS CLI as shown in the following code structure. Ensure that all of the following fields use the request syntax defined in the CreateTrainingJob API.

```json
// run-my-training-job.json
{
  "AlgorithmSpecification": {
    "ContainerEntrypoint": ["/bin/sh"],
    "ContainerArguments": ["/opt/ml/input/data/<your_channel_name>/custom_entrypoint.sh"],
    ...
  },
  "InputDataConfig": [
    {
      "ChannelName": "<your_channel_name>",
      "DataSource": {
        "S3DataSource": {
          "S3DataDistributionType": "FullyReplicated",
          "S3DataType": "S3Prefix",
          "S3Uri": "s3://<bucket-name>/<bucket_prefix>"
        }
      },
      "InputMode": "File",
      ...
    }
  ]
}
```

Next, run the AWS CLI command to launch the training job from the JSON file as follows.

```
aws sagemaker create-training-job --cli-input-json file://run-my-training-job.json
```

Configure the input data channel using AWS CLI directly

To configure your input data channel without a JSON file, use the following AWS CLI code structure.
aws --region <your-region> sagemaker create-training-job \
--training-job-name <your-training-job-name> \
--role-arn <your-execution-role-arn> \
--algorithm-specification '{ 
  "TrainingInputMode": "File", 
  "TrainingImage": "<your-ecr-image>", 
  "ContainerEntrypoint": ["/bin/sh"], 
  "ContainerArguments": ["/opt/ml/input/data/<your_channel_name>/custom_entrypoint.sh"]}' \
--input-data-config '{ 
  "ChannelName": "<your_channel_name>", 
  "DataSource": { 
    "S3DataSource": { 
      "S3DataType": "S3Prefix", 
      "S3Uri": "s3://<bucket-name>/<bucket_prefix>" 
    }, 
    "S3DataDistributionType": "FullyReplicated" 
  } 
}' \
--output-data-config '{ "S3OutputPath": "s3://custom-entrypoint-output-bucket/" }' \
--resource-config '{ "VolumeSizeInGB": 10, "InstanceCount": 1, "InstanceType": "ml.m5.2xlarge" }' \
--stopping-condition '{ "MaxRuntimeIn Seconds": 180 }'

How Amazon SageMaker Provides Training Information

This section explains how SageMaker makes training information, such as training data, hyperparameters, and other configuration information, available to your Docker container.

When you send a CreateTrainingJob request to SageMaker to start model training, you specify the Amazon Elastic Container Registry (Amazon ECR) path of the Docker image that contains the training algorithm. You also specify the Amazon Simple Storage Service (Amazon S3) location where training data is stored and algorithm-specific parameters. SageMaker makes this information available to the Docker container so that your training algorithm can use it. This section explains how we make this information available to your Docker container. For information about creating a training job, see CreateTrainingJob. For more information on the way that SageMaker containers organize information, see Using the SageMaker Training and Inference Toolkits (p. 3298).

Topics
- Hyperparameters (p. 3321)
- Environment Variables (p. 3322)
- Input Data Configuration (p. 3322)
- Training Data (p. 3322)
- Distributed Training Configuration (p. 3324)

Hyperparameters

SageMaker makes the hyperparameters in a CreateTrainingJob request available in the Docker container in the /opt/ml/input/config/hyperparameters.json file.

The following is an example of a hyperparameter configuration in hyperparameters.json to specify the num_round and eta hyperparameters in the CreateTrainingJob operation for XGBoost.

```json
{
  "num_round": "128",
  "eta": "0.001"
}
```

For a complete list of hyperparameters that can be used for the SageMaker built-in XGBoost algorithm, see XGBoost Hyperparameters.
The hyperparameters that you can tune depend on the algorithm that you are training. For a list of hyperparameters available for a SageMaker built-in algorithm, find them listed in Hyperparameters under the algorithm link in Use Amazon SageMaker Built-in Algorithms or Pre-trained Models.

**Environment Variables**

SageMaker sets the following environment variables in your container:

- **TRAINING_JOB_NAME** – Specified in the `TrainingJobName` parameter of the `CreateTrainingJob` request.
- **TRAINING_JOB_ARN** – The Amazon Resource Name (ARN) of the training job returned as the `TrainingJobArn` in the `CreateTrainingJob` response.
- All environment variables specified in the `Environment` parameter in the `CreateTrainingJob` request.

**Input Data Configuration**

SageMaker makes the data channel information in the `InputDataConfig` parameter from your `CreateTrainingJob` request available in the `/opt/ml/input/config/inputdataconfig.json` file in your Docker container.

For example, suppose that you specify three data channels (train, evaluation, and validation) in your request. SageMaker provides the following JSON:

```
{
  "train" : {
    "ContentType": "trainingContentType",
    "TrainingInputMode": "File",
    "S3DistributionType": "FullyReplicated",
    "RecordWrapperType": "None"},
  "evaluation" : {
    "ContentType": "evalContentType",
    "TrainingInputMode": "File",
    "S3DistributionType": "FullyReplicated",
    "RecordWrapperType": "None"},
  "validation" : {
    "TrainingInputMode": "File",
    "S3DistributionType": "FullyReplicated",
    "RecordWrapperType": "None"}
}
```

**Note**

SageMaker provides only relevant information about each data channel (for example, the channel name and the content type) to the container, as shown in the previous example. `S3DistributionType` will be set as `FullyReplicated` if you specify EFS or FSxLustre as input data sources.

**Training Data**

The `TrainingInputMode` parameter in the `AlgorithmSpecification` of the `CreateTrainingJob` request specifies how the training dataset is made available to your container. The following input modes are available.

- **File mode**

  If you use File mode as your `TrainingInputMode` value, SageMaker sets the following parameters in your container.

  - Your `TrainingInputMode` parameter is written to `inputdataconfig.json` as "File".

3322
- Your data channel directory is written to `/opt/ml/input/data/channel_name`.

If you use File mode, SageMaker creates a directory for each channel. For example, if you have three channels named training, validation, and testing, SageMaker makes the following three directories in your Docker container:
- `/opt/ml/input/data/training`
- `/opt/ml/input/data/validation`
- `/opt/ml/input/data/testing`

File mode also supports the following data sources.
- Amazon Simple Storage Service (Amazon S3)
- Amazon Elastic File System (Amazon EFS)
- Amazon FSx for Lustre

Note Channels that use file system data sources such as Amazon EFS and Amazon FSx must use File mode. In this case, the directory path provided in the channel is mounted at `/opt/ml/input/data/channel_name`.

- **FastFile mode**

  If you use FastFile mode as your TrainingInputNodeParameter, SageMaker sets the following parameters in your container.
  - Similar to File mode, in FastFile mode, your `TrainingInputMode` parameter is written to `inputdataconfig.json` as "File".
  - Your data channel directory is written to `/opt/ml/input/data/channel_name`.

FastFile mode supports the following data sources.
- Amazon S3

If you use FastFile mode, the channel directory is mounted with read-only permission.

Historically, File mode preceded FastFile mode. To ensure backwards compatibility, algorithms that support File mode can also seamlessly work with FastFile mode as long as the `TrainingInputMode` parameter is set to File in `inputdataconfig.json`.

Note Channels that use FastFile mode must use a S3DataType of "S3Prefix". FastFile mode presents a folder view that uses the forward slash (/) as the delimiter for grouping Amazon S3 objects into folders. S3Uri prefixes must not correspond to a partial folder name. For example, if an Amazon S3 dataset contains `s3://my-bucket/train-01/data.csv`, then neither `s3://my-bucket/train` nor `s3://my-bucket/train-01` are allowed as S3Uri prefixes.

A trailing forward slash is recommended to define a channel corresponding to a folder. For example, the `s3://my-bucket/train-01/` channel for the `train-01` folder. Without the trailing forward slash, the channel would be ambiguous if there existed another folder `s3://my-bucket/train-011/` or file `s3://my-bucket/train-01.txt`.

- **Pipe mode**

  - TrainingInputMode parameter written to `inputdataconfig.json`: "Pipe"
  - Data channel directory in the Docker container: `/opt/ml/input/data/channel_name_epoch_number`
  - Supported data sources: Amazon S3

You need to read from a separate pipe for each channel. For example, if you have three channels named training, validation, and testing, you need to read from the following pipes:
- `/opt/ml/input/data/training_0`, `/opt/ml/input/data/training_1`, ...
Use Your Own Training Algorithms

- /opt/ml/input/data/validation_0, /opt/ml/input/data/validation_1, ...
- /opt/ml/input/data/testing_0, /opt/ml/input/data/testing_1, ...

Read the pipes sequentially. For example, if you have a channel called training, read the pipes in this sequence:
1. Open /opt/ml/input/data/training_0 in read mode and read it to end-of-file (EOF) or, if you are done with the first epoch, close the pipe file early.
2. After closing the first pipe file, look for /opt/ml/input/data/training_1 and read it until you have completed the second epoch, and so on.

If the file for a given epoch doesn't exist yet, your code may need to retry until the pipe is created. There is no sequencing restriction across channel types. For example, you can read multiple epochs for the training channel and only start reading the validation channel when you are ready. Or, you can read them simultaneously if your algorithm requires that.

For an example of a Jupyter notebook that shows how to use Pipe mode when bringing your own container, see Bring your own pipe-mode algorithm to Amazon SageMaker.

Distributed Training Configuration

If you're performing distributed training with multiple containers, SageMaker makes information about all containers available in the /opt/ml/input/config/resourceconfig.json file.

To enable inter-container communication, this JSON file contains information for all containers. SageMaker makes this file available for both File and Pipe mode algorithms. The file provides the following information:

- **current_host**—The name of the current container on the container network. For example, algo-1. Host values can change at any time. Don't write code with specific values for this variable.
- **hosts**—The list of names of all containers on the container network, sorted lexicographically. For example, ["algo-1", "algo-2", "algo-3"] for a three-node cluster. Containers can use these names to address other containers on the container network. Host values can change at any time. Don't write code with specific values for these variables.
- **network_interface_name**—The name of the network interface that is exposed to your container. For example, containers running the Message Passing Interface (MPI) can use this information to set the network interface name.
- **Do not use the information in /etc/hostname or /etc/hosts because it might be inaccurate.**
- **Hostname information may not be immediately available to the algorithm container. We recommend adding a retry policy on hostname resolution operations as nodes become available in the cluster.**

The following is an example file on node 1 in a three-node cluster:

```
{
    "current_host": "algo-1",
    "hosts": ["algo-1","algo-2","algo-3"],
    "network_interface_name": "eth1"
}
```

Run Training with EFA

SageMaker provides integration with EFA devices to accelerate High Performance Computing (HPC) and machine learning applications. This integration allows you to leverage an EFA device when running your distributed training jobs. You can add EFA integration to an existing Docker container that you bring
Use Your Own Training Algorithms

to SageMaker. The following information outlines how to configure your own container to use an EFA device for your distributed training jobs.

Prerequisites

Your container must satisfy the SageMaker Training container specification.

Install EFA and required packages

Your container must download and install the EFA software. This allows your container to recognize the EFA device, and provides compatible versions of Libfabric and Open MPI.

Any tools like MPI and NCCL must be installed and managed inside the container to be used as part of your EFA-enabled training job. The following example shows how to modify the Dockerfile of your EFA-enabled container to install EFA, MPI, OFI, NCCL, and NCCL-TEST.

Note

When using PyTorch with EFA on your container, the NCCL version of your container should match the NCCL version of your PyTorch installation. To verify the PyTorch NCCL version, use the following command:

torch.cuda.nccl.version()
Considerations when creating your container

The EFA device is mounted to the container as /dev/infiniband/uverbs0 under the list of devices accessible to the container. On P4d instances, the container has access to 4 EFA devices. The EFA devices can be found in the list of devices accessible to the container as:

- /dev/infiniband/uverbs0
- /dev/infiniband/uverbs1
- /dev/infiniband/uverbs2
- /dev/infiniband/uverbs3

To get information about hostname, peer hostnames, and network interface (for MPI) from the resourceconfig.json file provided to each container instances, see Distributed Training Configuration. Your container handles regular TCP traffic among peers through the default Elastic Network Interfaces (ENI), while handling OFI (kernel bypass) traffic through the EFA device.

Verify that your EFA device is recognized

To verify that the EFA device is recognized, run the following command from within your container.

```
/opt/amazon/efa/bin/fi_info -p efa
```

Your output should look similar to the following.

```
provider: efa
   fabric: EFA-fe80::e5:56ff:fe34:56a8
   domain: efa_0-rdm
   version: 2.0
   type: FI_EP_RDM
   protocol: FI_PROTO_EFA
provider: efa
   fabric: EFA-fe80::e5:56ff:fe34:56a8
   domain: efa_0-dgrm
   version: 2.0
   type: FI_EP_DGRAM
   protocol: FI_PROTO_EFA
provider: efa;ofi_rxd
   fabric: EFA-fe80::e5:56ff:fe34:56a8
   domain: efa_0-dgrm
   version: 1.0
   type: FI_EP_RDM
   protocol: FI_PROTO_RXD
```

Running a training job with EFA

Once you’ve created an EFA-enabled container, you can run a training job with EFA using a SageMaker Estimator the same way as you would with any other Docker image. For more information on registering your container and using it for training, see Adapting Your Own Training Container.

How Amazon SageMaker Signals Algorithm Success and Failure

A training algorithm indicates whether it succeeded or failed using the exit code of its process.

A successful training execution should exit with an exit code of 0 and an unsuccessful training execution should exit with a non-zero exit code. These will be converted to Completed and Failed in the TrainingJobStatus returned by DescribeTrainingJob. This exit code convention is standard and
is easily implemented in all languages. For example, in Python, you can use `sys.exit(1)` to signal a failure exit, and simply running to the end of the main routine will cause Python to exit with code 0.

In the case of failure, the algorithm can write a description of the failure to the failure file. See next section for details.

**How Amazon SageMaker Processes Training Output**

As your algorithm runs in a container, it generates output including the status of the training job and model and output artifacts. Your algorithm should write this information to the following files, which are located in the container's `/output` directory. Amazon SageMaker processes the information contained in this directory as follows:

- `/opt/ml/model` – Your algorithm should write all final model artifacts to this directory. SageMaker copies this data as a single object in compressed tar format to the S3 location that you specified in the `CreateTrainingJob` request. If multiple containers in a single training job write to this directory they should ensure no file/directory names clash. SageMaker aggregates the result in a TAR file and uploads to S3 at the end of the training job.

- `/opt/ml/output/data` – Your algorithm should write artifacts you want to store other than the final model to this directory. SageMaker copies this data as a single object in compressed tar format to the S3 location that you specified in the `CreateTrainingJob` request. If multiple containers in a single training job write to this directory they should ensure no file/directory names clash. SageMaker aggregates the result in a TAR file and uploads to S3 at the end of the training job.

- `/opt/ml/output/failure` – If training fails, after all algorithm output (for example, logging) completes, your algorithm should write the failure description to this file. In a `DescribeTrainingJob` response, SageMaker returns the first 1024 characters from this file as `FailureReason`.

**Use your own inference code**

You can use Amazon SageMaker to interact with Docker containers and run your own inference code in one of two ways:

- To use your own inference code with a persistent endpoint to get one prediction at a time, use SageMaker hosting services.
- To use your own inference code to get predictions for an entire dataset, use SageMaker batch transform.

**Use Your Own Inference Code with Hosting Services**

This section explains how Amazon SageMaker interacts with a Docker container that runs your own inference code for hosting services. Use this information to write inference code and create a Docker image.

**Use Your Own Inference Code with Batch Transform**

This section explains how Amazon SageMaker interacts with a Docker container that runs your own inference code for batch transform. Use this information to write inference code and create a Docker image.

**Topics**

- Use Your Own Inference Code with Hosting Services (p. 3327)
- Use Your Own Inference Code with Batch Transform (p. 3335)

- How SageMaker Runs Your Inference Image (p. 3328)
- How SageMaker Loads Your Model Artifacts (p. 3329)
- How Your Container Should Respond to Inference Requests (p. 3329)
How SageMaker Runs Your Inference Image

To configure a container to run as an executable, use an ENTRYPOINT instruction in a Dockerfile. Note the following:

- For model inference, SageMaker runs the container as:

  ```
docker run image serve
  ```

  SageMaker overrides default CMD statements in a container by specifying the serve argument after the image name. The serve argument overrides arguments that you provide with the CMD command in the Dockerfile.

- SageMaker expects all containers to run with root users. Create your container so that it uses only root users. When SageMaker runs your container, users that do not have root-level access can cause permissions issues.

- We recommend that you use the exec form of the ENTRYPOINT instruction:

  ```
ENTRYPOINT ["executable", "param1", "param2"]
  ```

  For example:

  ```
ENTRYPOINT ["python", "k_means_inference.py"]
  ```

  The exec form of the ENTRYPOINT instruction starts the executable directly, not as a child of /bin/sh. This enables it to receive signals like SIGTERM and SIGKILL from the SageMaker API operations, which is a requirement.

  For example, when you use the CreateEndpoint API to create an endpoint, SageMaker provisions the number of ML compute instances required by the endpoint configuration, which you specify in the request. SageMaker runs the Docker container on those instances.

  If you reduce the number of instances backing the endpoint (by calling the UpdateEndpointWeightsAndCapacities API), SageMaker runs a command to stop the Docker container on the instances that are being terminated. The command sends the SIGTERM signal, then it sends the SIGKILL signal thirty seconds later.

  If you update the endpoint (by calling the UpdateEndpoint API), SageMaker launches another set of ML compute instances and runs the Docker containers that contain your inference code on them. Then it runs a command to stop the previous Docker containers. To stop a Docker container, command sends the SIGTERM signal, then it sends the SIGKILL signal 30 seconds later.
• SageMaker uses the container definition that you provided in your CreateModel request to set environment variables and the DNS hostname for the container as follows:

• It sets environment variables using the ContainerDefinition.Environment string-to-string map.
• It sets the DNS hostname using the ContainerDefinition.ContainerHostname.

• If you plan to use GPU devices for model inferences (by specifying GPU-based ML compute instances in your CreateEndpointConfig request), make sure that your containers are nvidia-docker compatible. Don't bundle NVIDIA drivers with the image. For more information about nvidia-docker, see NVIDIA/nvidia-docker.

• You can't use the tini initializer as your entry point in SageMaker containers because it gets confused by the train and serve arguments.

How SageMaker Loads Your Model Artifacts

In your CreateModel API request, you can use either the ModelDataUrl or S3DataSource parameter to identify the S3 location where model artifacts are stored. SageMaker copies your model artifacts from the S3 location to the /opt/ml/model directory for use by your inference code. Your container has read-only access to /opt/ml/model. Do not write to this directory.

The ModelDataUrl must point to a tar.gz file. Otherwise, SageMaker won't download the file.

If you trained your model in SageMaker, the model artifacts are saved as a single compressed tar file in Amazon S3. If you trained your model outside SageMaker, you need to create this single compressed tar file and save it in a S3 location. SageMaker decompresses this tar file into /opt/ml/model directory before your container starts.

For deploying large models, we recommend that you follow Deploying uncompressed models (p. 2579).

How Your Container Should Respond to Inference Requests

To obtain inferences, the client application sends a POST request to the SageMaker endpoint. SageMaker passes the request to the container, and returns the inference result from the container to the client.

For more information about the inference requests that your container will receive, see the following actions in the Amazon SageMaker API Reference:

• InvokeEndpoint
• InvokeEndpointAsync
• InvokeEndpointWithResponseStream

Requirements for inference containers

To respond to inference requests, your container must meet the following requirements:

• SageMaker strips all POST headers except those supported by InvokeEndpoint. SageMaker might add additional headers. Inference containers must be able to safely ignore these additional headers.
• To receive inference requests, the container must have a web server listening on port 8080 and must accept POST requests to the /invocations and /ping endpoints.
• A customer's model containers must accept socket connection requests within 250 ms.
• A customer's model containers must respond to requests within 60 seconds. The model itself can have a maximum processing time of 60 seconds before responding to the /invocations. If your model is going to take 50-60 seconds of processing time, the SDK socket timeout should be set to be 70 seconds.

**Example invocation functions**

The following examples demonstrate how the code in your container can process inference requests. These examples handle requests that client applications send by using the InvokeEndpoint action.

**FastAPI**

FastAPI is a web framework for building APIs with Python.

```python
from fastapi import FastAPI, status, Request, Response

app = FastAPI()

@app.post('/invocations')
async def invocations(request: Request):
    # model() is a hypothetical function that gets the inference output:
    model_resp = await model(Request)
    response = Response(
        content=model_resp,
        status_code=status.HTTP_200_OK,
        media_type="text/plain",
    )
    return response
```

In this example, the invocations function handles the inference request that SageMaker sends to the /invocations endpoint.

**Flask**

Flask is a framework for developing web applications with Python.

```python
import flask

app = flask.Flask(__name__)

@app.route('/invocations', methods=['POST'])
def invoke(request):
    # model() is a hypothetical function that gets the inference output:
    resp_body = model(request)
    return flask.Response(resp_body, mimetype='text/plain')
```

In this example, the invoke function handles the inference request that SageMaker sends to the /invocations endpoint.

**Example invocation functions for streaming requests**

The following examples demonstrate how the code in your inference container can process streaming inference requests. These examples handle requests that client applications send by using the InvokeEndpointWithResponseStream action.

When a container handles a streaming inference request, it returns the model's inference as a series of parts incrementally as the model generates them. Client applications start receiving responses
immediately when they're available. They don't need to wait for the model to generate the entire response. You can implement streaming to support fast interactive experiences, such as chatbots, virtual assistants, and music generators.

FastAPI

FastAPI is a web framework for building APIs with Python.

```python
from starlette.responses import StreamingResponse
from fastapi import FastAPI, status, Request

app = FastAPI()

@app.post('/invocations')
async def invocations(request: Request):
    # Streams inference response using HTTP chunked encoding
    async def generate():
        # model() is a hypothetical function that gets the inference output:
        yield await model(Request)
        yield "\n"

    response = StreamingResponse(
        content=generate(),
        status_code=status.HTTP_200_OK,
        media_type="text/plain",
    )
    return response
```

In this example, the invocations function handles the inference request that SageMaker sends to the /invocations endpoint. To stream the response, the example uses the StreamingResponse class from the Starlette framework.

Flask

Flask is a framework for developing web applications with Python.

```python
import flask

app = flask.Flask(__name__)

@app.route('/invocations', methods=['POST'])
def invocations(request):
    # Streams inference response using HTTP chunked encoding
    def generate():
        # model() is a hypothetical function that gets the inference output:
        yield model(request)
        yield "\n"
    return flask.Response(
        flask.stream_with_context(generate()), mimetype='text/plain')
```

In this example, the invocations function handles the inference request that SageMaker sends to the /invocations endpoint. To stream the response, the example uses the flask.stream_with_context function from the Flask framework.

**How Your Container Should Respond to Health Check (Ping) Requests**

SageMaker launches new inference containers in the following situations:
• Responding to `CreateEndpoint`, `UpdateEndpoint`, and `UpdateEndpointWeightsAnd Capacities` API calls
• Security patching
• Replacing unhealthy instances

Soon after container startup, SageMaker starts sending periodic GET requests to the `/ping` endpoint.

The simplest requirement on the container is to respond with an HTTP 200 status code and an empty body. This indicates to SageMaker that the container is ready to accept inference requests at the `/ invocations` endpoint.

If the container does not begin to pass health checks, by consistently responding with 200s, during the 4 minutes after startup, new instance launch will fail. This will cause `CreateEndpoint` to fail, leaving the endpoint in a failed state. The update requested by `UpdateEndpoint` will not be completed, security patches would not be applied, and unhealthy instances will not be replaced.

While the minimum bar is for the container to return a static 200, a container developer can use this functionality to perform deeper checks. The request timeout on `/ping` attempts is 2 seconds.

**Use a Private Docker Registry for Real-Time Inference Containers**

Amazon SageMaker hosting enables you to use images stored in Amazon ECR to build your containers for real-time inference by default. Optionally, you can build containers for real-time inference from images in a private Docker registry. The private registry must be accessible from an Amazon VPC in your account. Models that you create based on the images stored in your private Docker registry must be configured to connect to the same VPC where the private Docker registry is accessible. For information about connecting your model to a VPC, see [Give SageMaker Hosted Endpoints Access to Resources in Your Amazon VPC (p. 3545)](https://docs.aws.amazon.com/sagemaker/latest/dg/giving-endpoints-access-to-vpc-resources.html).

Your Docker registry must be secured with a TLS certificate from a known public certificate authority (CA).

**Note**

Your private Docker registry must allow inbound traffic from the security groups you specify in the VPC configuration for your model, so that SageMaker hosting is able to pull model images from your registry. SageMaker can pull model images from DockerHub if there's a path to the open internet inside your VPC.

**Store Images in a Private Docker Registry other than Amazon Elastic Container Registry**

To use a private Docker registry to store your images for SageMaker real-time inference, create a private registry that is accessible from your Amazon VPC. For information about creating a Docker registry, see [Deploy a registry server](https://docs.aws.amazon.com/ecs/latest/userguide/running-a-registry.html) in the Docker documentation. The Docker registry must comply with the following:
• The registry must be a Docker Registry HTTP API V2 registry.
• The Docker registry must be accessible from the same VPC that you specify in the VpcConfig parameter that you specify when you create your model.

Use an Image from a Private Docker Registry for Real-time Inference

When you create a model and deploy it to SageMaker hosting, you can specify that it use an image from your private Docker registry to build the inference container. Specify this in the ImageConfig object in the PrimaryContainer parameter that you pass to a call to the create_model function.

To use an image stored in your private Docker registry for your inference container

1. Create the image configuration object and specify a value of Vpc for the RepositoryAccessMode field.

   ```python
   image_config = {
       'RepositoryAccessMode': 'Vpc'
   }
   ```

2. If your private Docker registry requires authentication, add a RepositoryAuthConfig object to the image configuration object. For the RepositoryCredentialsProviderArn field of the RepositoryAuthConfig object, specify the Amazon Resource Name (ARN) of an AWS Lambda function that provides credentials that allows SageMaker to authenticate to your private Docker Registry. For information about how to create the Lambda function to provide authentication, see Allow SageMaker to authenticate to a private Docker registry (p. 3334).

   ```python
   image_config = {
       'RepositoryAccessMode': 'Vpc',
       'RepositoryAuthConfig': {
           'RepositoryCredentialsProviderArn':
               'arn:aws:lambda:Region:Acct:function:FunctionName'
       }
   }
   ```

3. Create the primary container object that you want to pass to create_model, using the image configuration object that you created in the previous step.

   Provide your image in digest form. If you provide your image using the :latest tag, there is a risk that SageMaker pulls a newer version of the image than intended. Using the digest form ensures that SageMaker pulls the intended image version.

   ```python
   primary_container = {
       'ContainerHostname': 'ModelContainer',
       'Image': 'myteam.myorg.com/docker-local/my-inference-image:<IMAGE-TAG>',
       'ImageConfig': image_config
   }
   ```

4. Specify the model name and the execution role that you want to pass to create_model.

   ```python
   model_name = 'vpc-model'
   execution_role_arn = 'arn:aws:iam::123456789012:role/SageMakerExecutionRole'
   ```

5. Specify one or more security groups and subnets for the VPC configuration for your model. Your private Docker registry must allow inbound traffic from the security groups that you specify. The subnets that you specify must be in the same VPC as your private Docker registry.

   ```python
   vpc_config = {
       'SecurityGroupIds': ['sg-0123456789abcdef0'],
   }
   ```

```python
import boto3
sm = boto3.client('sagemaker')
```

7. Create the model by calling `create_model`, using the values you specified in the previous steps for the `PrimaryContainer` and `VpcConfig` parameters.

```python
try:
    resp = sm.create_model(
        ModelName=model_name,
        PrimaryContainer=primary_container,
        ExecutionRoleArn=execution_role_arn,
        VpcConfig=vpc_config,
    )
except Exception as e:
    print(f'error calling CreateModel operation: {e}')
else:
    print(resp)
```

8. Finally, call `create_endpoint_config` and `create_endpoint` to create the hosting endpoint, using the model that you created in the previous step.

```python
endpoint_config_name = 'my-endpoint-config'
sm.create_endpoint_config(
    EndpointConfigName=endpoint_config_name,
    ProductionVariants=[
        {'VariantName': 'MyVariant',
        'ModelName': model_name,
        'InitialInstanceCount': 1,
        'InstanceType': 'ml.t2.medium'},
    ],
)
endpoint_name = 'my-endpoint'
sm.create_endpoint(
    EndpointName=endpoint_name,
    EndpointConfigName=endpoint_config_name,
)
sm.describe_endpoint(EndpointName=endpoint_name)
```

Allow SageMaker to authenticate to a private Docker registry

To pull an inference image from a private Docker registry that requires authentication, create an AWS Lambda function that provides credentials, and provide the Amazon Resource Name (ARN) of the Lambda function when you call `create_model`. When SageMaker runs `create_model`, it calls the Lambda function that you specified to get credentials to authenticate to your Docker registry.

Create the Lambda function

Create an AWS Lambda function that returns a response with the following form:

```python
def handler(event, context):
    response = {
```
Depending on how you set up authentication for your private Docker registry, the credentials that your Lambda function returns can mean either of the following:

- If you set up your private Docker registry to use basic authentication, provide the sign-in credentials to authenticate to the registry.
- If you set up your private Docker registry to use bearer token authentication, the sign-in credentials are sent to your authorization server, which returns a Bearer token that can then be used to authenticate to the private Docker registry.

### Give your execution role permission to Lambda

The execution role that you use to call `create_model` must have permissions to call AWS Lambda functions. Add the following to the permissions policy of your execution role:

```json
{
    "Effect": "Allow",
    "Action": [
        "lambda:InvokeFunction"
    ],
    "Resource": [
        "arn:aws:lambda:*::*:function:*myLambdaFunction*"
    ]
}
```

Where `myLambdaFunction` is the name of your Lambda function. For information about editing a role permissions policy, see [Modifying a role permissions policy (console)](https://aws.amazon.com/) in the [AWS Identity and Access Management User Guide](https://aws.amazon.com/).

**Note**

An execution role with the `AmazonSageMakerFullAccess` managed policy attached to it has permission to call any Lambda function with `SageMaker` in its name.

### Create an interface VPC endpoint for Lambda

Create an interface endpoint so that your Amazon VPC can communicate with your AWS Lambda function without sending traffic over the internet. For information about how to do this, see [Configuring interface VPC endpoints for Lambda](https://aws.amazon.com/) in the [AWS Lambda Developer Guide](https://aws.amazon.com/).

SageMaker hosting sends a request through your VPC to `lambda.region.amazonaws.com`, to call your Lambda function. If you choose Private DNS Name when you create your interface endpoint, Amazon Route 53 routes the call to the Lambda interface endpoint. If you use a different DNS provider, make sure to map `lambda.region.amazonaws.com` to your Lambda interface endpoint.

### Use Your Own Inference Code with Batch Transform

This section explains how Amazon SageMaker interacts with a Docker container that runs your own inference code for batch transform. Use this information to write inference code and create a Docker image.

**Topics**

- [How SageMaker Runs Your Inference Image](#)
- [How SageMaker Loads Your Model Artifacts](#)
How SageMaker Runs Your Inference Image

To configure a container to run as an executable, use an ENTRYPOINT instruction in a Dockerfile. Note the following:

• For batch transforms, SageMaker invokes the model on your behalf. SageMaker runs the container as:

```bash
docker run image serve
```

The input to batch transforms must be of a format that can be split into smaller files to process in parallel. These formats include CSV, JSON, JSON Lines, TFRecord and RecordIO.

SageMaker overrides default CMD statements in a container by specifying the serve argument after the image name. The serve argument overrides arguments that you provide with the CMD command in the Dockerfile.

• We recommend that you use the exec form of the ENTRYPOINT instruction:

```bash
ENTRYPOINT ["executable", "param1", "param2"]
```

For example:

```bash
ENTRYPOINT ["python", "k_means_inference.py"]
```

• SageMaker sets environment variables specified in CreateModel and CreateTransformJob on your container. Additionally, the following environment variables are populated:

  • SAGEMAKER_BATCH is set to true when the container runs batch transforms.
  • SAGEMAKER_MAX_PAYLOAD_IN_MB is set to the largest size payload that is sent to the container via HTTP.
  • SAGEMAKER_BATCH_STRATEGY is set to SINGLE_RECORD when the container is sent a single record per call to invocations and MULTI_RECORD when the container gets as many records as will fit in the payload.
  • SAGEMAKER_MAX_CONCURRENT_TRANSFORMS is set to the maximum number of /invocations requests that can be opened simultaneously.

  **Note**
  The last three environment variables come from the API call made by the user. If the user doesn't set values for them, they aren't passed. In that case, either the default values or the values requested by the algorithm (in response to the /execution-parameters) are used.

• If you plan to use GPU devices for model inferences (by specifying GPU-based ML compute instances in your CreateTransformJob request), make sure that your containers are nvidia-docker compatible. Don't bundle NVIDIA drivers with the image. For more information about nvidia-docker, see NVIDIA/nvidia-docker.

• You can’t use the init initializer as your entry point in SageMaker containers because it gets confused by the train and serve arguments.
How SageMaker Loads Your Model Artifacts

In a `CreateModel` request, container definitions include the `ModelDataUrl` parameter, which identifies the location in Amazon S3 where model artifacts are stored. When you use SageMaker to run inferences, it uses this information to determine from where to copy the model artifacts. It copies the artifacts to the `/opt/ml/model` directory in the Docker container for use by your inference code.

The `ModelDataUrl` parameter must point to a tar.gz file. Otherwise, SageMaker can't download the file. If you train a model in SageMaker, it saves the artifacts as a single compressed tar file in Amazon S3. If you train a model in another framework, you need to store the model artifacts in Amazon S3 as a compressed tar file. SageMaker decompresses this tar file and saves it in the `/opt/ml/model` directory in the container before the batch transform job starts.

How Containers Serve Requests

Containers must implement a web server that responds to invocations and ping requests on port 8080. For batch transforms, you have the option to set algorithms to implement execution-parameters requests to provide a dynamic runtime configuration to SageMaker. SageMaker uses the following endpoints:

- ping—Used to periodically check the health of the container. SageMaker waits for an HTTP 200 status code and an empty body for a successful ping request before sending an invocations request. You might use a ping request to load a model into memory to generate inference when invocations requests are sent.
- (Optional) execution-parameters—Allows the algorithm to provide the optimal tuning parameters for a job during runtime. Based on the memory and CPUs available for a container, the algorithm chooses the appropriate `MaxConcurrentTransforms`, `BatchStrategy`, and `MaxPayloadInMB` values for the job.

Before calling the invocations request, SageMaker attempts to invoke the execution-parameters request. When you create a batch transform job, you can provide values for the `MaxConcurrentTransforms`, `BatchStrategy`, and `MaxPayloadInMB` parameters. SageMaker determines the values for these parameters using this order of precedence:

1. The parameter values that you provide when you create the `CreateTransformJob` request.
2. The values that the model container returns when SageMaker invokes the execution-parameters endpoint
3. The default parameter values, listed in the following table.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>MaxConcurrentTransforms</td>
<td>1</td>
</tr>
<tr>
<td>BatchStrategy</td>
<td>MULTI_RECORD</td>
</tr>
<tr>
<td>MaxPayloadInMB</td>
<td>6</td>
</tr>
</tbody>
</table>

The response for a GET execution-parameters request is a JSON object with keys for `MaxConcurrentTransforms`, `BatchStrategy`, and `MaxPayloadInMB` parameters. This is an example of a valid response:

```json
{
}
```
Examples and More Information: Use Your Own Algorithm or Model

The following Jupyter notebooks and added information show how to use your own algorithms or pretrained models from an Amazon SageMaker notebook instance. For links to the GitHub repositories with the prebuilt Dockerfiles for the TensorFlow, MXNet, Chainer, and PyTorch frameworks and instructions on using the AWS SDK for Python (Boto3) estimators to run your own training algorithms on SageMaker Learner and your own models on SageMaker hosting, see Prebuilt SageMaker Docker Images for Deep Learning (p. 3284)

Setup

1. Create a SageMaker notebook instance. For instructions on how to create and access Jupyter notebook instances, see Amazon SageMaker Notebook Instances (p. 298).
2. Open the notebook instance you created.
3. Choose the SageMaker Examples tab for a list of all SageMaker example notebooks.
4. Open the sample notebooks from the Advanced Functionality section in your notebook instance or from GitHub using the provided links. To open a notebook, choose its Use tab, then choose Create copy.

Host models trained in Scikit-learn

To learn how to host models trained in Scikit-learn for making predictions in SageMaker by injecting them into first-party k-means and XGBoost containers, see the following sample notebooks.

- kmeansbring_your_own_model
Package TensorFlow and Scikit-learn models for use in SageMaker

To learn how to package algorithms that you have developed in TensorFlow and scikit-learn frameworks for training and deployment in the SageMaker environment, see the following notebooks. They show you how to build, register, and deploy your own Docker containers using Dockerfiles.

- `xgboost_bring_your_own_model`
- `tensorflow_bring_your_own`
- `scikit_bring_your_own`

Train and deploy a neural network on SageMaker

To learn how to train a neural network locally using MXNet or TensorFlow, and then create an endpoint from the trained model and deploy it on SageMaker, see the following notebooks. The MXNet model is trained to recognize handwritten numbers from the MNIST dataset. The TensorFlow model is trained to classify irises.

- `mxnet_mnist_byom`
- `tensorflow_BYOM_iris`

Training using pipe mode

To learn how to use a Dockerfile to build a container that calls the `train.py` script and uses pipe mode to custom train an algorithm, see the following notebook. In pipe mode, the input data is transferred to the algorithm while it is training. This can decrease training time compared to using file mode.

- `pipe_bring_your_own`

Bring your own R model

To learn how to use add a custom R image to build and train a model in a AWS SMS notebook, see the following blog post. This blog post uses a sample R Dockerfile from a library of SageMaker Studio Custom Image Samples.

- `Bringing your own R environment to Amazon SageMaker Studio`

Extend a pre-built PyTorch container Image

To learn how to extend a prebuilt SageMaker PyTorch container image when you have additional functional requirements for your algorithm or model that the prebuilt Docker image doesn't support, see the following notebook.

- `BERTtopic_extending_container`

For more information about extending a container, see Extend a Pre-built Container.
Train and debug training jobs on a custom container

To learn how to train and debug training jobs using SageMaker Debugger, see the following notebook. A training script provided through this example uses the TensorFlow Keras ResNet 50 model and the CIFAR10 dataset. A Docker custom container is built with the training script and pushed to Amazon ECR. While the training job is running, Debugger collects tensor outputs and identifies debugging problems. With smdebug client library tools, you can set a smdebug trial object that calls the training job and debugging information, check the training and Debugger rule status, and retrieve tensors saved in an Amazon S3 bucket to analyze training issues.

- build_your_own_container_with_debugger

Troubleshooting your Docker containers

The following are common errors that you might run into when using Docker containers with SageMaker. Each error is followed by a solution to the error.

- **Error: SageMaker has lost the Docker daemon.**

  To fix this error, restart Docker using the following command.

  ```sh
  sudo service docker restart
  ```

- **Error: The /tmp directory of your Docker container has run out of space.**

  Docker containers use the / and /tmp partitions to store code. These partitions can fill up easily when using large code modules in local mode. The SageMaker Python SDK supports specifying a custom temp directory for your local mode root directory to avoid this issue.

  To specify the custom temp directory in the EBS volume storage, create a file at the following path ~/.sagemaker/config.yaml and add the following configuration. The directory that you specify as container_root must already exist. The SageMaker Python SDK will not try to create it.

  ```yaml
  local:
    container_root: /home/ec2-user/SageMaker/temp
  ```

  With this configuration, local mode uses the /temp directory and not the default /tmp directory.
Configure security in Amazon SageMaker

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that is built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS compliance programs. To learn about the compliance programs that apply to Amazon SageMaker, see AWS Services in Scope by Compliance Program.
- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your company’s requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using SageMaker. The following topics show you how to configure SageMaker to meet your security and compliance objectives. You also learn how to use other AWS services that help you to monitor and secure your SageMaker resources.

**Topics**

- [Access Control](#)
- [Data Protection in Amazon SageMaker](#)
- [Identity and Access Management for Amazon SageMaker](#)
- [Logging and Monitoring](#)
- [Compliance validation for Amazon SageMaker](#)
- [Resilience in Amazon SageMaker](#)
- [Infrastructure Security in Amazon SageMaker](#)

**Access Control**

Amazon SageMaker Studio notebooks and SageMaker notebook instances differ in their runtime environments. The following topics describe how to control root access to these notebooks.

**Topics**

- [Access control and SageMaker Studio notebooks](#)
- [Control root access to a SageMaker notebook instance](#)

**Access control and SageMaker Studio notebooks**

Amazon SageMaker Studio uses filesystem and container permissions for access control and isolation of Studio users and notebooks. This is one of the major differences between Studio notebooks and
SageMaker notebook instances. This topic describes how permissions are set up to avoid security threats, what SageMaker does by default, and how the customer can customize the permissions. For more information about Studio notebooks and their runtime environment, see Use Amazon SageMaker Studio Notebooks (p. 221).

**SageMaker app permissions**

A *run-as user* is a POSIX user/group which is used to run the JupyterServer app and KernelGateway apps inside the container.

The run-as user for the JupyterServer app is sagemaker-user (1000) by default. This user has sudo permissions to enable the installation of dependencies such as yum packages.

The run-as user for the KernelGateway apps is root (0) by default. This user is able to install dependencies using pip/apt-get/conda.

Due to user remapping, neither user is able to access resources or make changes to the host instance.

**User remapping**

SageMaker performs user-remapping to map a user inside the container to a user on the host instance outside the container. The range of user IDs (0 - 65535) in the container are mapped to non-privileged user IDs above 65535 on the instance. For example, sagemaker-user (1000) inside the container might map to user (200001) on the instance, where the number in parentheses is the user ID. If the customer creates a new user/group inside the container, it won't be privileged on the host instance regardless of the user/group ID. The root user of the container is also mapped to a non-privileged user on the instance. For more information, see Isolate containers with a user namespace.

**Note**

Files created by the user sagemaker-user may look like they are owned by sagemaker-studio (uid 65534). This is a side effect of a fast app creation mode where SageMaker container images are pre-pulled, allowing applications to start in under a minute. If your application requires the file owner uid and the process owner uid to match, ask the customer service to remove your account number from the image pre-pull feature.

**Custom image permissions**

Customers can bring their own custom SageMaker images. These images can specify a different run-as user/group to launch the KernelGateway app. The customer can implement fine grained permission control inside the image, for example, to disable root access or perform other actions. The same user remapping applies here. For more information, see Bring your own SageMaker image (p. 257).

**Container isolation**

Docker keeps a list of default capabilities that the container can use. SageMaker doesn’t add additional capabilities. SageMaker adds specific route rules to block requests to Amazon EFS and the instance metadata service (IMDS) from the container. Customers can’t change these route rules from the container. For more information, see Runtime privilege and Linux capabilities.

**App metadata access**

Metadata used by running apps are mounted to the container with read-only permission. Customers aren’t able to modify this metadata from the container. For the available metadata, see Get Studio Notebook and App Metadata (p. 232).

**User isolation on EFS**

When you onboard to Studio, SageMaker creates an Amazon Elastic File System (EFS) volume for your domain that is shared by all Studio users in the domain. Each user gets their own private home directory.
on the EFS volume. This home directory is used to store the user's notebooks, Git repositories, and other
data. To prevent other users in the domain from accessing the user's data, SageMaker creates a globally
unique user ID for the user's profile and applies it as a POSIX user/group ID for the user's home directory.

**EBS access**

An Amazon Elastic Block Store (Amazon EBS) volume is attached to the host instance and shared across
all images. It's used for the root volume of the notebooks and stores temporary data that's generated
inside the container. The storage isn't persisted when the instance running the notebooks is deleted. The
root user inside the container can't access the EBS volume.

**IMDS access**

Due to security concerns, access to the Amazon Elastic Compute Cloud (Amazon EC2) Instance Metadata
Service (IMDS) is unavailable in SageMaker Studio. For more information on IMDS, see [Instance metadata
and user data](#).

**Control root access to a SageMaker notebook instance**

By default, when you create a notebook instance, users that log into that notebook instance have root
access. Data science is an iterative process that might require the data scientist to test and use different
software tools and packages, so many notebook instance users need to have root access to be able to
install these tools and packages. Because users with root access have administrator privileges, users can
access and edit all files on a notebook instance with root access enabled.

If you don't want users to have root access to a notebook instance, when you call
`CreateNotebookInstance` or `UpdateNotebookInstance` operations, set the `RootAccess` field to
`Disabled`. You can also disable root access for users when you create or update a notebook instance in
the Amazon SageMaker console. For information, see [Step 1: Create an Amazon SageMaker Notebook
Instance](#) (p. 299).

**Note**

Lifecycle configurations need root access to be able to set up a notebook instance. Because of
this, lifecycle configurations associated with a notebook instance always run with root access
even if you disable root access for users.

**Note**

For security reasons, Rootless Docker is installed on root-disabled notebook instances instead of
regular Docker. For more information, see [Run the Docker daemon as a non-root user (Rootless
mode)](#)

**Data Protection in Amazon SageMaker**

The AWS [shared responsibility model](#) applies to data protection in Amazon SageMaker. As described in
this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud.
You are responsible for maintaining control over your content that is hosted on this infrastructure. This
content includes the security configuration and management tasks for the AWS services that you use. For
more information about data privacy, see the [Data Privacy FAQ](#). For information about data protection in
Europe, see the [AWS Shared Responsibility Model and GDPR](#) blog post on the [AWS Security Blog](#).

For data protection purposes, we recommend that you protect AWS account credentials and set up
individual users with AWS IAM Identity Center or AWS Identity and Access Management (IAM). That way,
each user is given only the permissions necessary to fulfill their job duties. We also recommend that you
secure your data in the following ways:
• Use multi-factor authentication (MFA) with each account.
• Use SSL/TLS to communicate with AWS resources. We require TLS 1.2 and recommend TLS 1.3.
• Set up API and user activity logging with AWS CloudTrail.
• Use AWS encryption solutions, along with all default security controls within AWS services.
• Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
• If you require FIPS 140-2 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-2.

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form text fields such as a Name field. This includes when you work with Amazon SageMaker or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into tags or free-form text fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

Topics
• Protect Data at Rest Using Encryption (p. 3344)
• Protecting Data in Transit with Encryption (p. 3346)
• Key Management (p. 3348)
• Internetwork Traffic Privacy (p. 3349)

Protect Data at Rest Using Encryption

To protect your Amazon SageMaker Studio notebooks and SageMaker notebook instances, along with your model-building data and model artifacts, SageMaker encrypts the notebooks, as well as output from Training and Batch Transform jobs. SageMaker encrypts these by default using the AWS Managed Key for Amazon S3. This AWS Managed Key for Amazon S3 cannot be shared for cross-account access. For cross-account access, specify your customer managed key while creating SageMaker resources so that it can be shared for cross-account access. For more information on AWS KMS, see What is AWS Key Management Service?

Topics
• Studio notebooks (p. 3344)
• Notebook instances, SageMaker jobs, and Endpoints (p. 3345)
• SageMaker geospatial capabilities (p. 3346)

Studio notebooks

In Amazon SageMaker Studio, your SageMaker Studio notebooks and data can be stored in the following locations:

• An S3 bucket – When you onboard to Studio and enable shareable notebook resources, SageMaker shares notebook snapshots and metadata in an Amazon Simple Storage Service (Amazon S3) bucket.
• An EFS volume – When you onboard to Studio, SageMaker attaches an Amazon Elastic File System (Amazon EFS) volume to your domain for storing your Studio notebooks and data files. The EFS volume persists after the domain is deleted.
• An EBS volume – When you open a notebook in Studio, an Amazon Elastic Block Store (Amazon EBS) is attached to the instance that the notebook runs on. The EBS volume persists for the duration of the instance.
SageMaker uses the AWS Key Management Service (AWS KMS) to encrypt the S3 bucket and both volumes. By default, it uses an AWS managed key. For more control, you can specify your own customer managed key when you onboard to Studio or through the SageMaker API. For more information, see Onboard to Amazon SageMaker Domain (p. 10) and CreateDomain.

In the CreateDomain API, you use the S3KmsKeyId parameter to specify the customer managed key for shareable notebooks. You use the KmsKeyId parameter to specify the customer managed key for the EFS and EBS volumes. The same customer managed key is used for both volumes. The customer managed key for shareable notebooks can be the same customer managed key as used for the volumes or a different customer managed key.

**Notebook instances, SageMaker jobs, and Endpoints**

To encrypt the machine learning (ML) storage volume that is attached to notebooks, processing jobs, training jobs, hyperparameter tuning jobs, batch transform jobs, and endpoints, you can pass a AWS KMS key to SageMaker. If you don't specify a KMS key, SageMaker encrypts storage volumes with a transient key and discards it immediately after encrypting the storage volume. For notebook instances, if you don't specify a KMS key, SageMaker encrypts both OS volumes and ML data volumes with a system-managed KMS key.

You can use an AWS managed AWS KMS key to encrypt all instance OS volumes. You can encrypt all ML data volumes for all SageMaker instances with a AWS KMS key that you specify. ML storage volumes are mounted as follows:

- **Notebooks** - `/home/ec2-user/SageMaker`
- **Processing** - `/opt/ml/processing` and `/tmp/`
- **Training** - `/opt/ml/` and `/tmp/`
- **Batch** - `/opt/ml/` and `/tmp/`
- **Endpoints** - `/opt/ml/` and `/tmp/`

Processing, batch transform, and training job containers and their storage are ephemeral in nature. When the job completes, output is uploaded to Amazon S3 using AWS KMS encryption with an optional AWS KMS key that you specify and the instance is torn down. If a AWS KMS Key is not provided in the job request, the output is encrypted by default using your AWS Managed Key for Amazon S3.

**Note**
The key policy for an AWS Managed Key for Amazon S3 cannot be edited, so cross-account permissions cannot be granted for these key policies. If the output Amazon S3 bucket for the request is from another account, specify your own AWS KMS Customer Key in the job request and ensure that the job's execution role has permissions to encrypt data with it.

**Important**
Sensitive data that needs to be encrypted with a KMS key for compliance reasons should be stored in the ML storage volume or in Amazon S3, both of which can be encrypted using a KMS key you specify.

When you open a notebook instance, SageMaker saves it and any files associated with it in the SageMaker folder in the ML storage volume by default. When you stop a notebook instance, SageMaker creates a snapshot of the ML storage volume. Any customizations to the operating system of the stopped instance, such as installed custom libraries or operating system level settings, are lost. Consider using a lifecycle configuration to automate customizations of the default notebook instance. When you terminate an instance, the snapshot and the ML storage volume are deleted. Any data that you need to persist beyond the lifespan of the notebook instance should be transferred to an Amazon S3 bucket.

**Note**
Certain Nitro-based SageMaker instances include local storage, depending on the instance type. Local storage volumes are encrypted using a hardware module on the instance. You can't use...
a KMS key on an instance type with local storage. For a list of instance types that support local
instance storage, see Instance Store Volumes. For more information about storage volumes on
Nitro-based instances, see Amazon EBS and NVMe on Linux Instances.
For more information about local instance storage encryption, see SSD Instance Store Volumes.

**SageMaker geospatial capabilities**

You can protect your data at rest using encryption for SageMaker geospatial.

**Server-Side Encryption with Amazon SageMaker geospatial owned key (Default)**

Amazon SageMaker geospatial capabilities encrypts all your data, including computational results from
your EarthObservationJobs and VectorEnrichmentJobs along with all your service metadata.
There is no data that is stored within Amazon SageMaker unencrypted. It uses a default AWS owned key
to encrypt all your data.

**Server-Side Encryption with KMS Keys Stored in AWS Key Management Service (SSE-KMS)**

Amazon SageMaker geospatial capabilities supports encryption using a customer-owned KMS key. For
more information, see Use AWS KMS Permissions for Amazon SageMaker geospatial capabilities.

**Protecting Data in Transit with Encryption**

All internetwork data in transit supports TLS 1.2 encryption. We recommend that you use TLS 1.3.

With Amazon SageMaker, machine learning (ML) model artifacts and other system artifacts are
encrypted in transit and at rest. Requests to the SageMaker API and console are made over a secure (SSL)
connection. You pass AWS Identity and Access Management roles to SageMaker to provide permissions
to access resources on your behalf for training and deployment.

Some intranetwork data in transit (inside the service platform) is unencrypted. This includes:

- Command and control communications between the service control plane and training job instances
  (not customer data).
- Communications between nodes in distributed processing jobs (intranetwork).
- Communications between nodes in distributed training jobs (intranetwork).

There are no inter-node communications for batch processing.

You can choose to encrypt communication between nodes in a training cluster.

**Note**
For use cases in the healthcare sector, the best practice for security is to encrypt communication
between the nodes.

For information about how to encrypt communication, see the next topic at Protect Communications
Between ML Compute Instances in a Distributed Training Job (p. 3347).

**Note**
Encrypting inter-container traffic can increase training time, especially if you use distributed
deep learning algorithms. For affected algorithms, this additional level of security also increases
cost. The training time for most SageMaker built-in algorithms, such as XGBoost, DeepAR, and
linear learner, typically aren't affected.

FIPS validated endpoints are available for the SageMaker API and request router for hosted models
(runtime). For information about FIPS compliant endpoints, see Federal Information Processing Standard
Protect Communications with RStudio on Amazon SageMaker

RStudio on Amazon SageMaker provides encryption for all communications that involve SageMaker components. However, the previous version did not support encryption between the RStudioServerPro and RSessio apps.

RStudio released version 2022.02.2-485.pro2 in April 2022. This version supports encryption between RStudioServerPro and RSessio apps to enable end-to-end encryption. The version upgrade, however, is not completely backward compatible. As a result, you must update all of your RStudioServerPro and RSessio apps. For information about how to update your apps, see Upgrade the RStudio Version (p. 605).

Protect Communications Between ML Compute Instances in a Distributed Training Job

By default, Amazon SageMaker runs training jobs in an Amazon Virtual Private Cloud (Amazon VPC) to help keep your data secure. You can add another level of security to protect your training containers and data by configuring a private VPC. Distributed ML frameworks and algorithms usually transmit information that is directly related to the model, such as weights, not the training dataset. When performing distributed training, you can further protect data that is transmitted between instances. This can help you to comply with regulatory requirements. To do this, use inter-container traffic encryption.

Note
For use cases in the healthcare sector, the best practice for security is to encrypt communication between the nodes.

Enabling inter-container traffic encryption can increase training time, especially if you are using distributed deep learning algorithms. Enabling inter-container traffic encryption doesn't affect training jobs with a single compute instance. However, for training jobs with several compute instances, the effect on training time depends on the amount of communication between compute instances. For affected algorithms, adding this additional level of security also increases cost. The training time for most SageMaker built-in algorithms, such as XGBoost, DeepAR, and linear learner, typically aren't affected.

You can enable inter-container traffic encryption for training jobs or hyperparameter tuning jobs. You can use SageMaker APIs or console to enable inter-container traffic encryption.

For information about running training jobs in a private VPC, see Give SageMaker Training Jobs Access to Resources in Your Amazon VPC (p. 3542).

Enable Inter-container Traffic Encryption (API)

Before enabling inter-container traffic encryption on training or hyperparameter tuning jobs with APIs, add inbound and outbound rules to your private VPC's security group.

To enable inter-container traffic encryption (API)

1. Add the following inbound and outbound rules in the security group for your private VPC:

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port Range</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>UDP</td>
<td>500</td>
<td>Self Security Group ID</td>
</tr>
<tr>
<td>ESP</td>
<td>N/A</td>
<td>Self Security Group ID</td>
</tr>
</tbody>
</table>

2. When you send a request to the CreateTrainingJob or CreateHyperParameterTuningJob API, specify True for the EnableInterContainerTrafficEncryption parameter.
Note
For the ESP 50 protocol, the AWS Security Group Console might display the port range as "All". However, Amazon EC2 ignores the specified port range because it is not applicable for the ESP 50 IP protocol.

Enable Inter-container Traffic Encryption (Console)

Enable Inter-container Traffic Encryption in a Training Job

To enable inter-container traffic encryption in a training job
1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose Training, then choose Training jobs.
3. Choose Create training job.
4. Under Network, choose a VPC. You can use the default VPC or one that you have created.
5. Choose Enable inter-container traffic encryption.

After you enable inter-container traffic encryption, finish creating the training job. For more information, see Step 4: Train a Model (p. 305).

Enable Inter-container Traffic Encryption in a Hyperparameter Tuning Job

To enable inter-container traffic encryption in a hyperparameter tuning job
1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose Training, then choose Hyperparameter tuning jobs.
3. Choose Create hyperparameter tuning job.
4. Under Network, choose a VPC. You can use the default VPC or one that you created.
5. Choose Enable inter-container traffic encryption.

After enabling inter-container traffic encryption, finish creating the hyperparameter tuning job. For more information, see Configure and Launch a Hyperparameter Tuning Job (p. 1885).

Key Management

Customers can specify AWS KMS keys, including bring your own keys (BYOK), to use for envelope encryption with Amazon S3 input/output buckets and machine learning (ML) Amazon EBS volumes. ML volumes for notebook instances and for processing, training, and hosted model Docker containers can be optionally encrypted by using AWS KMS customer-owned keys. All instance OS volumes are encrypted with an AWS-managed AWS KMS key.

Note
Certain Nitro-based instances include local storage, dependent on the instance type. Local storage volumes are encrypted using a hardware module on the instance. You can't request a VolumeKmsKeyId when using an instance type with local storage.

For a list of instance types that support local instance storage, see Instance Store Volumes. For more information about local instance storage encryption, see SSD Instance Store Volumes.

For more information about storage volumes on nitro-based instances, see Amazon EBS and NVMe on Linux Instances.

For information about AWS KMS keys see What is AWS Key Management Service? in the AWS Key Management Service Developer Guide.
Internetwork Traffic Privacy

This topic describes how Amazon SageMaker secures connections from the service to other locations.

Internetwork communications support TLS 1.2 encryption between all components and clients. We recommend TLS 1.3.

Instances can be connected to Customer VPC, providing access to S3 VPC endpoints or customer repositories. Internet egress can be managed through this interface by the customer if service platform internet egress is disabled for notebooks. For training and hosting, egress through the service platform is not available when connected to the customer's VPC.

By default, API calls made to published endpoints traverse the public network to the request router. SageMaker supports Amazon Virtual Private Cloud interface endpoints powered by AWS PrivateLink for private connectivity between the customer's VPC and the request router to access hosted model endpoints. For information about Amazon VPC, see Connect to SageMaker Within your VPC (p. 3526).

Identity and Access Management for Amazon SageMaker

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be authenticated (signed in) and authorized (have permissions) to use SageMaker resources. IAM is an AWS service that you can use with no additional charge.

Topics
- Audience (p. 3349)
- Authenticating with Identities (p. 3350)
- Managing Access Using Policies (p. 3352)
- How Amazon SageMaker Works with IAM (p. 3353)

- AWS Managed Policies for Amazon SageMaker (p. 3442)
- Troubleshooting Amazon SageMaker Identity and Access (p. 3518)

Audience

How you use AWS Identity and Access Management (IAM) differs, depending on the work that you do in SageMaker.

Service user – If you use the SageMaker service to do your job, then your administrator provides you with the credentials and permissions that you need. As you use more SageMaker features to do your work, you might need additional permissions. Understanding how access is managed can help you request the right permissions from your administrator. If you cannot access a feature in SageMaker, see Troubleshooting Amazon SageMaker Identity and Access (p. 3518).

Service administrator – If you're in charge of SageMaker resources at your company, you probably have full access to SageMaker. It's your job to determine which SageMaker features and resources your service
users should access. You must then submit requests to your IAM administrator to change the permissions of your service users. Review the information on this page to understand the basic concepts of IAM. To learn more about how your company can use IAM with SageMaker, see How Amazon SageMaker Works with IAM (p. 3353).

IAM administrator – If you’re an IAM administrator, you might want to learn details about how you can write policies to manage access to SageMaker. To view example SageMaker identity-based policies that you can use in IAM, see Amazon SageMaker Identity-Based Policy Examples (p. 3356).

Authenticating with Identities

Authentication is how you sign in to AWS using your identity credentials. You must be authenticated (signed in to AWS) as the AWS account root user, as an IAM user, or by assuming an IAM role.

You can sign in to AWS as a federated identity by using credentials provided through an identity source. AWS IAM Identity Center (IAM Identity Center) users, your company’s single sign-on authentication, and your Google or Facebook credentials are examples of federated identities. When you sign in as a federated identity, your administrator previously set up identity federation using IAM roles. When you access AWS by using federation, you are indirectly assuming a role.

Depending on the type of user you are, you can sign in to the AWS Management Console or the AWS access portal. For more information about signing in to AWS, see How to sign in to your AWS account in the AWS Sign-In User Guide.

If you access AWS programmatically, AWS provides a software development kit (SDK) and a command line interface (CLI) to cryptographically sign your requests by using your credentials. If you don’t use AWS tools, you must sign requests yourself. For more information about using the recommended method to sign requests yourself, see Signing AWS API requests in the IAM User Guide.

Regardless of the authentication method that you use, you might be required to provide additional security information. For example, AWS recommends that you use multi-factor authentication (MFA) to increase the security of your account. To learn more, see Multi-factor authentication in the AWS IAM Identity Center User Guide and Using multi-factor authentication (MFA) in AWS in the IAM User Guide.

AWS account root user

When you create an AWS account, you begin with one sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account root user and is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you don’t use the root user for your everyday tasks. Safeguard your root user credentials and use them to perform the tasks that only the root user can perform. For the complete list of tasks that require you to sign in as the root user, see Tasks that require root user credentials in the IAM User Guide.

Federated identity

As a best practice, require human users, including users that require administrator access, to use federation with an identity provider to access AWS services by using temporary credentials.

A federated identity is a user from your enterprise user directory, a web identity provider, the AWS Directory Service, the Identity Center directory, or any user that accesses AWS services by using credentials provided through an identity source. When federated identities access AWS accounts, they assume roles, and the roles provide temporary credentials.

For centralized access management, we recommend that you use AWS IAM Identity Center. You can create users and groups in IAM Identity Center, or you can connect and synchronize to a set of users and groups in your own identity source for use across all your AWS accounts and applications. For
IAM Users and Groups

An IAM user is an identity within your AWS account that has specific permissions for a single person or application. Where possible, we recommend relying on temporary credentials instead of creating IAM users who have long-term credentials such as passwords and access keys. However, if you have specific use cases that require long-term credentials with IAM users, we recommend that you rotate access keys. For more information, see Rotate access keys regularly for use cases that require long-term credentials in the IAM User Guide.

An IAM group is an identity that specifies a collection of IAM users. You can't sign in as a group. You can use groups to specify permissions for multiple users at a time. Groups make permissions easier to manage for large sets of users. For example, you could have a group named IAMAdmins and give that group permissions to administer IAM resources.

Users are different from roles. A user is uniquely associated with one person or application, but a role is intended to be assumable by anyone who needs it. Users have permanent long-term credentials, but roles provide temporary credentials. To learn more, see When to create an IAM user (instead of a role) in the IAM User Guide.

IAM Roles

An IAM role is an identity within your AWS account that has specific permissions. It is similar to an IAM user, but is not associated with a specific person. You can temporarily assume an IAM role in the AWS Management Console by switching roles. You can assume a role by calling an AWS CLI or AWS API operation or by using a custom URL. For more information about methods for using roles, see Using IAM roles in the IAM User Guide.

IAM roles with temporary credentials are useful in the following situations:

- **Federated user access** – To assign permissions to a federated identity, you create a role and define permissions for the role. When a federated identity authenticates, the identity is associated with the role and is granted the permissions that are defined by the role. For information about roles for federation, see Creating a role for a third-party Identity Provider in the IAM User Guide. If you use IAM Identity Center, you configure a permission set. To control what your identities can access after they authenticate, IAM Identity Center correlates the permission set to a role in IAM. For information about permissions sets, see Permission sets in the AWS IAM Identity Center User Guide.

- **Temporary IAM user permissions** – An IAM user or role can assume an IAM role to temporarily take on different permissions for a specific task.

- **Cross-account access** – You can use an IAM role to allow someone (a trusted principal) in a different account to access resources in your account. Roles are the primary way to grant cross-account access. However, with some AWS services, you can attach a policy directly to a resource (instead of using a role as a proxy). To learn the difference between roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the IAM User Guide.

- **Cross-service access** – Some AWS services use features in other AWS services. For example, when you make a call in a service, it's common for that service to run applications in Amazon EC2 or store objects in Amazon S3. A service might do this using the calling principal's permissions, using a service role, or using a service-linked role.

- **Principal permissions** – When you use an IAM user or role to perform actions in AWS, you are considered a principal. Policies grant permissions to a principal. When you use some services, you might perform an action that then triggers another action in a different service. In this case, you must have permissions to perform both actions. To see whether an action requires additional dependent actions in a policy, see Actions, Resources, and Condition Keys for Amazon SageMaker in the Service Authorization Reference.
• **Service role** – A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.

• **Service-linked role** – A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

• **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see Using an IAM role to grant permissions to applications running on Amazon EC2 instances in the IAM User Guide.

To learn whether to use IAM roles or IAM users, see When to create an IAM role (instead of a user) in the IAM User Guide.

### Managing Access Using Policies

You control access in AWS by creating policies and attaching them to AWS identities or resources. A policy is an object in AWS that, when associated with an identity or resource, defines their permissions. AWS evaluates these policies when a principal (user, root user, or role session) makes a request. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in AWS as JSON documents. For more information about the structure and contents of JSON policy documents, see Overview of JSON policies in the IAM User Guide.

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

By default, users and roles have no permissions. To grant users permission to perform actions on the resources that they need, an IAM administrator can create IAM policies. The administrator can then add the IAM policies to roles, and users can assume the roles.

IAM policies define permissions for an action regardless of the method that you use to perform the operation. For example, suppose that you have a policy that allows the `iam:GetRole` action. A user with that policy can get role information from the AWS Management Console, the AWS CLI, or the AWS API.

### Identity-Based Policies

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Creating IAM policies in the IAM User Guide.

Identity-based policies can be further categorized as inline policies or managed policies. Inline policies are embedded directly into a single user, group, or role. Managed policies are standalone policies that you can attach to multiple users, groups, and roles in your AWS account. Managed policies include AWS managed policies and customer managed policies. To learn how to choose between a managed policy or an inline policy, see Choosing between managed policies and inline policies in the IAM User Guide.

### Resource-Based Policies

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM role trust policies and Amazon S3 bucket policies. In services that support resource-
based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must specify a principal in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

Resource-based policies are inline policies that are located in that service. You can’t use AWS managed policies from IAM in a resource-based policy.

**Access Control Lists (ACLs)**

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

Amazon S3, AWS WAF, and Amazon VPC are examples of services that support ACLs. To learn more about ACLs, see [Access control list (ACL) overview](#) in the Amazon Simple Storage Service Developer Guide.

**Other Policy Types**

AWS supports additional, less-common policy types. These policy types can set the maximum permissions granted to you by the more common policy types.

- **Permissions boundaries** – A permissions boundary is an advanced feature in which you set the maximum permissions that an identity-based policy can grant to an IAM entity (IAM user or role). You can set a permissions boundary for an entity. The resulting permissions are the intersection of an entity’s identity-based policies and its permissions boundaries. Resource-based policies that specify the user or role in the Principal field are not limited by the permissions boundary. An explicit deny in any of these policies overrides the allow. For more information about permissions boundaries, see [Permissions boundaries for IAM entities](#) in the IAM User Guide.

- **Service control policies (SCPs)** – SCPs are JSON policies that specify the maximum permissions for an organization or organizational unit (OU) in AWS Organizations. AWS Organizations is a service for grouping and centrally managing multiple AWS accounts that your business owns. If you enable all features in an organization, then you can apply service control policies (SCPs) to any or all of your accounts. The SCP limits permissions for entities in member accounts, including each AWS account root user. For more information about Organizations and SCPs, see [How SCPs work](#) in the AWS Organizations User Guide.

- **Session policies** – Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary session for a role or federated user. The resulting session’s permissions are the intersection of the user or role’s identity-based policies and the session policies. Permissions can also come from a resource-based policy. An explicit deny in any of these policies overrides the allow. For more information, see [Session policies](#) in the IAM User Guide.

**Multiple Policy Types**

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see [Policy evaluation logic](#) in the IAM User Guide.

**How Amazon SageMaker Works with IAM**

Before you use IAM to manage access to SageMaker, you should understand what IAM features are available to use with SageMaker. To get a high-level view of how SageMaker and other AWS services work with IAM, see [AWS Services That Work with IAM](#) in the IAM User Guide.
SageMaker Identity-Based Policies

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. SageMaker supports specific actions, resources, and condition keys. To learn about all of the elements that you use in a JSON policy, see IAM JSON Policy Elements Reference in the IAM User Guide.

Actions

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

The Action element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Policy actions usually have the same name as the associated AWS API operation. There are some exceptions, such as permission-only actions that don't have a matching API operation. There are also some operations that require multiple actions in a policy. These additional actions are called dependent actions.

Include actions in a policy to grant permissions to perform the associated operation.

Policy actions in SageMaker use the following prefix before the action: sagemaker:. For example, to grant someone permission to run a SageMaker training job with the SageMaker CreateTrainingJob API operation, you include the sagemaker:CreateTrainingJob action in their policy. Policy statements must include either an Action or NotAction element. SageMaker defines its own set of actions that describe tasks that you can perform with this service.

To specify multiple actions in a single statement, separate them with commas as follows:

```
"Action": [
   "sagemaker:action1",
   "sagemaker:action2"
]
```

You can specify multiple actions using wildcards (*). For example, to specify all actions that begin with the word Describe, include the following action:

```
"Action": "sagemaker:Describe*"
```

To see a list of SageMaker actions, see Actions, resources, and condition keys for Amazon SageMaker in the Service Authorization Reference.

Resources

SageMaker does not support specifying resource ARNs in a policy.

Condition Keys

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

The Condition element (or Condition block) lets you specify conditions in which a statement is in effect. The Condition element is optional. You can create conditional expressions that use condition operators, such as equals or less than, to match the condition in the policy with values in the request.
If you specify multiple Condition elements in a statement, or multiple keys in a single Condition element, AWS evaluates them using a logical AND operation. If you specify multiple values for a single condition key, AWS evaluates the condition using a logical OR operation. All of the conditions must be met before the statement’s permissions are granted.

You can also use placeholder variables when you specify conditions. For example, you can grant an IAM user permission to access a resource only if it is tagged with their IAM user name. For more information, see IAM policy elements: variables and tags in the IAM User Guide.

AWS supports global condition keys and service-specific condition keys. To see all AWS global condition keys, see AWS global condition context keys in the IAM User Guide.

SageMaker defines its own set of condition keys and also supports using some global condition keys. To see all AWS global condition keys, see AWS Global Condition Context Keys in the IAM User Guide.

SageMaker supports a number of service-specific condition keys that you can use for fine-grained access control for the following operations:

- CreateProcessingJob
- CreateTrainingJob
- CreateModel
- CreateEndpointConfig
- CreateTransformJob
- CreateHyperParameterTuningJob
- CreateLabelingJob
- CreateNotebookInstance
- UpdateNotebookInstance

To see a list of SageMaker condition keys, see Condition keys for Amazon SageMaker in the IAM User Guide. To learn with which actions and resources you can use a condition key, see Actions defined by Amazon SageMaker.

For examples of using SageMaker condition keys, see the following: Control Creation of SageMaker Resources with Condition Keys (p. 3366).

Examples

To view examples of SageMaker identity-based policies, see Amazon SageMaker Identity-Based Policy Examples (p. 3356).

SageMaker Resource-Based Policies

SageMaker does not support resource-based policies.

Authorization Based on SageMaker Tags

You can attach tags to SageMaker resources or pass tags in a request to SageMaker. To control access based on tags, you provide tag information in the condition element of a policy using the sagemaker:ResourceTag/key-name, aws:RequestTag/key-name, or aws:TagKeys condition keys. For more information about tagging SageMaker resources, see Control Access to SageMaker Resources by Using Tags (p. 3376).

To view an example identity-based policy for limiting access to a resource based on the tags on that resource, see Control Access to SageMaker Resources by Using Tags (p. 3376).
SageMaker IAM Roles

An IAM role is an entity within your AWS account that has specific permissions.

Using Temporary Credentials with SageMaker

You can use temporary credentials to sign in with federation, assume an IAM role, or to assume a cross-account role. You obtain temporary security credentials by calling AWS STS API operations such as AssumeRole or GetFederationToken.

SageMaker supports using temporary credentials.

Service-Linked Roles

SageMaker partially supports service-linked roles. Service-linked roles are currently available for SageMaker Studio and SageMaker training jobs.

Service Roles

This feature allows a service to assume a service role on your behalf. This role allows the service to access resources in other services to complete an action on your behalf. Service roles appear in your IAM account and are owned by the account. This means that an IAM administrator can change the permissions for this role. However, doing so might break the functionality of the service.

SageMaker supports service roles.

Choosing an IAM Role in SageMaker

When you create a notebook instance, processing job, training job, hosted endpoint, or batch transform job resource in SageMaker, you must choose a role to allow SageMaker to access SageMaker on your behalf. If you have previously created a service role or service-linked role, then SageMaker provides you with a list of roles to choose from. It's important to choose a role that allows access to the AWS operations and resources you need. For more information, see SageMaker Roles (p. 3387).

Amazon SageMaker Identity-Based Policy Examples

By default, IAM users and roles don't have permission to create or modify SageMaker resources. They also can't perform tasks using the AWS Management Console, AWS CLI, or AWS API. An IAM administrator must create IAM policies that grant users and roles permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the IAM users or groups that require those permissions. To learn how to attach policies to an IAM user or group, see Adding and Removing IAM Identity Permissions in the IAM User Guide.

To learn how to create an IAM identity-based policy using these example JSON policy documents, see Creating Policies on the JSON Tab in the IAM User Guide.

Topics

- Policy Best Practices (p. 3357)
- Using the SageMaker Console (p. 3357)
- Allow Users to View Their Own Permissions (p. 3366)
- Control Creation of SageMaker Resources with Condition Keys (p. 3366)
- Control Access to the SageMaker API by Using Identity-based Policies (p. 3373)
- Limit Access to SageMaker API and Runtime Calls by IP Address (p. 3375)
- Limit Access to a Notebook Instance by IP Address (p. 3375)
- Control Access to SageMaker Resources by Using Tags (p. 3376)
Policy Best Practices

Identity-based policies determine whether someone can create, access, or delete SageMaker resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- **Provide Permissions for Tagging SageMaker Resources Upon Creation** (p. 3378)

**Using the SageMaker Console**

To access the Amazon SageMaker console, you must have a minimum set of permissions. These permissions must allow you to list and view details about the SageMaker resources in your AWS account. If you create an identity-based policy that is more restrictive than the minimum required permissions, the console won't function as intended for entities (users or roles) with that policy.

To ensure that those entities can still use the SageMaker console, also attach the following AWS managed policy to the entities. For more information, see **Adding Permissions to a User** in the IAM User Guide:

You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the AWS API. Instead, allow access to only the actions that match the API operation that you're trying to perform.
Permissions Required to Use the Amazon SageMaker Console

The permissions reference table lists the Amazon SageMaker API operations and shows the required permissions for each operation. For more information about Amazon SageMaker API operations, see Amazon SageMaker API Permissions: Actions, Permissions, and Resources Reference (p. 3422).

To use the Amazon SageMaker console, you need to grant permissions for additional actions. Specifically, the console needs permissions that allow the ec2 actions to display subnets, VPCs, and security groups. Optionally, the console needs permission to create execution roles for tasks such as CreateNotebook, CreateTrainingJob, and CreateModel. Grant these permissions with the following permissions policy:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "SageMakerApis",
            "Effect": "Allow",
            "Action": [
                "sagemaker:*"
            ],
            "Resource": "*"
        },
        {
            "Sid": "VpcConfigurationForCreateForms",
            "Effect": "Allow",
            "Action": [
                "ec2:DescribeVpcs",
                "ec2:DescribeSubnets",
                "ec2:DescribeSecurityGroups"
            ],
            "Resource": "*"
        },
        {
            "Sid": "KmsKeysForCreateForms",
            "Effect": "Allow",
            "Action": [
                "kms:DescribeKey",
                "kms:ListAliases"
            ],
            "Resource": "*"
        },
        {
            "Sid": "AccessAwsMarketplaceSubscriptions",
            "Effect": "Allow",
            "Action": [
                "aws-marketplace:ViewSubscriptions"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "codecommit:BatchGetRepositories",
                "codecommit:CreateRepository",
                "codecommit:GetRepository",
                "codecommit:ListRepositories",
                "codecommit:ListBranches",
                "secretsmanager:CreateSecret"
            ],
            "Resource": "*"
        }
    ]
}
```
Permissions Required to Use the Amazon SageMaker Ground Truth Console

To use the Amazon SageMaker Ground Truth console, you need to grant permissions for additional resources. Specifically, the console needs permissions for the AWS Marketplace to view subscriptions, Amazon Cognito operations to manage your private workforce, Amazon S3 actions for access to your input and output files, and AWS Lambda actions to list and invoke functions. Grant these permissions with the following permissions policy:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "GroundTruthConsole",
            "Effect": "Allow",
            "Action": [
                "aws-marketplace:DescribeListings",
                "aws-marketplace:ViewSubscriptions",
                "cognito-idp:AdminAddUserToGroup",
                "cognito-idp:AdminCreateUser",
                "cognito-idp:AdminDeleteUser",
                "cognito-idp:AdminDisableUser",
                "cognito-idp:AdminEnableUser",
```
Permissions Required to Use the Amazon Augmented AI (Preview) Console

To use the Augmented AI console, you need to grant permissions for additional resources. Grant these permissions with the following permissions policy:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [

Identity-Based Policy Examples

Allow Users to View Their Own Permissions

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the AWS CLI or AWS API.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "ViewOwnUserInfo",
         "Effect": "Allow",
         "Action": [
            "iam:GetUserPolicy",
            "iam:ListGroupsForUser",
            "iam:ListAttachedUserPolicies",
            "iam:ListUserPolicies",
            "iam:GetUser"
         ],
         "Resource": ["arn:aws:iam::*:user/${aws:username}"
      },
      {
         "Sid": "NavigateInConsole",
         "Effect": "Allow",
         "Action": [
            "iam:GetGroupPolicy",
            "iam:GetPolicyVersion",
            "iam:GetPolicy",
            "iam:ListAttachedGroupPolicies",
            "iam:ListGroupPolicies",
            "iam:ListPolicyVersions",
            "iam:ListPolicies",
            "iam:ListUsers"
         ],
         "Resource": "*"
      }
   ]
}
```

Control Creation of SageMaker Resources with Condition Keys

Control fine-grained access to allow the creation of SageMaker resources by using SageMaker-specific condition keys. For information about using condition keys in IAM policies, see IAM JSON Policy Elements: Condition in the IAM User Guide.

The condition keys, along with related API actions, and links to relevant documentation are listed in Condition Keys for SageMaker in the IAM User Guide.
The following examples show how to use the SageMaker condition keys to control access.

Topics
- Control Access to SageMaker Resources by Using File System Condition Keys (p. 3367)
- Restrict Training to a Specific VPC (p. 3369)
- Restrict Access to Workforce Types for Ground Truth Labeling Jobs and Amazon A2I Human Review Workflows (p. 3369)
- Enforce Encryption of Input Data (p. 3370)
- Enforce Encryption of Notebook Instance Storage Volume (p. 3371)
- Enforce Network Isolation for Training Jobs (p. 3371)
- Enforce a Specific Instance Type for Training Jobs (p. 3372)
- Enforce a Specific EI Accelerator for Training Jobs (p. 3372)
- Enforce Disabling Internet Access and Root Access for Creating Notebook Instances (p. 3373)

Control Access to SageMaker Resources by Using File System Condition Keys

SageMaker training provides a secure infrastructure for the training algorithm to run in, but for some cases you may want increased defense in depth. For example, you minimize the risk of running untrusted code in your algorithm, or you have specific security mandates in your organization. For these scenarios, you can use the service-specific condition keys in the Condition element of an IAM policy to scope down the user to specific file systems, directories, access modes (read-write, read-only) and security groups.

Topics
- Restrict an IAM User to Specific Directories and Access Modes (p. 3367)
- Restrict a User to a Specific File System (p. 3368)

Restrict an IAM User to Specific Directories and Access Modes

The policy below restricts a user to the /sagemaker/xgboost-dm/train and /sagemaker/xgboost-dm/validation directories of an EFS file system to ro (read-only) AccessMode:

**Note**

When a directory is allowed, all of its subdirectories are also accessible by the training algorithm. POSIX permissions are ignored.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AccessToElasticFileSystem",
            "Effect": "Allow",
            "Action": [
                "sagemaker:CreateTrainingJob",
                "sagemaker:CreateHyperParameterTuningJob"
            ],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "sagemaker:FileSystemId": "fs-12345678",
                    "sagemaker:FileSystemAccessMode": "ro",
                    "sagemaker:FileSystemType": "EFS",
                    "sagemaker:FileSystemDirectoryPath": "/sagemaker/xgboost-dm/train"
                }
            }
        },
        {
            "Sid": "AccessToElasticFileSystemValidation",
```
"Effect": "Allow",
"Action": [
    "sagemaker:CreateTrainingJob",
    "sagemaker:CreateHyperParameterTuningJob"
],
"Resource": "*",
"Condition": {
    "StringEquals": {
        "sagemaker:FileSystemId": "fs-12345678",
        "sagemaker:FileSystemAccessMode": "ro",
        "sagemaker:FileSystemType": "EFS",
        "sagemaker:FileSystemDirectoryPath": "/sagemaker/xgboost-dm/validation"
    }
}
]
]

Restrict a User to a Specific File System

To prevent a malicious algorithm using a user space client from accessing any file system directly in your account, you can restrict networking traffic by allowing ingress from a specific security group. In the following example, the user can only use the specified security group to access the file system:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AccessToLustreFileSystem",
            "Effect": "Allow",
            "Action": [
                "sagemaker:CreateTrainingJob",
                "sagemaker:CreateHyperParameterTuningJob"
            ],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "sagemaker:FileSystemId": "fs-12345678",
                    "sagemaker:FileSystemAccessMode": "ro",
                    "sagemaker:FileSystemType": "FSxLustre",
                    "sagemaker:FileSystemDirectoryPath": "/fsx/sagemaker/xgboost/train"
                },
                "ForAllValues:StringEquals": {
                    "sagemaker:VpcSecurityGroupIds": [
                        "sg-12345678"
                    ]
                }
            }
        }
    ]
}
```

Although the above example can restrict an algorithm to a specific file system, it does not prevent an algorithm from accessing any directory within that file system using the user space client. To mitigate this, you can:

- Ensure that the file system only contains data that you trust your users to access
- Create an IAM role that restricts your users to launching training jobs with algorithms from approved ECR repositories

For more information on how to use roles with SageMaker, see SageMaker Roles.
Restrict Training to a Specific VPC

Restrict an AWS user to creating training jobs from within a Amazon VPC. When a training job is created within a VPC, you can use VPC flow logs to monitor all traffic to and from the training cluster. For information about using VPC flow logs, see VPC Flow Logs in the Amazon Virtual Private Cloud User Guide.

The following policy enforces that a training job is created by a user calling CreateTrainingJob from within a VPC:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowFromVpc",
            "Effect": "Allow",
            "Action": [
                "sagemaker:CreateTrainingJob",
                "sagemaker:CreateHyperParameterTuningJob"
            ],
            "Resource": "*",
            "Condition": {
                "ForAllValues:StringEquals": {
                    "sagemaker:VpcSubnets": ["subnet-a1234"],
                    "sagemaker:VpcSecurityGroupIds": ["sg12345", "sg-67890"]
                },
                "Null": {
                    "sagemaker:VpcSubnets": "false",
                    "sagemaker:VpcSecurityGroupIds": "false"
                }
            }
        }
    ]
}
```

Restrict Access to Workforce Types for Ground Truth Labeling Jobs and Amazon A2I Human Review Workflows

Amazon SageMaker Ground Truth and Amazon Augmented AI work teams fall into one of three workforce types: public (with Amazon Mechanical Turk), private, and vendor. To restrict user access to a specific work team using one of these types or the work team ARN, use the sagemaker:WorkteamType and/or the sagemaker:WorkteamArn condition keys. For the sagemaker:WorkteamType condition key, use string condition operators. For the sagemaker:WorkteamArn condition key, use Amazon Resource Name (ARN) condition operators. If the user attempts to create a labeling job with a restricted work team, SageMaker returns an access denied error.

The policies below demonstrate different ways to use the sagemaker:WorkteamType and sagemaker:WorkteamArn condition keys with appropriate condition operators and valid condition values.

The following example uses the sagemaker:WorkteamType condition key with the StringEquals condition operator to restrict access to a public work team. It accepts condition values in the following format: workforcetype-crowd, where workforcetype can equal public, private, or vendor.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "RestrictWorkteamType",
            "Effect": "Allow",
            "Action": ["sagemaker:*"],
            "Resource": "*",
            "Condition": {
                "StringEquals": {"sagemaker:WorkteamType": "workforcetype-crowd"}
            }
        }
    ]
}
```
Identity-Based Policy Examples

The following policies show how to restrict access to a public work team using the `sagemaker:WorkteamArn` condition key. The first shows how to use it with a valid IAM regex-variant of the work team ARN and the `ArnLike` condition operator. The second shows how to use it with the `ArnEquals` condition operator and the work team ARN.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "RestrictWorkteamType",
      "Effect": "Deny",
      "Action": "sagemaker:CreateLabelingJob",
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "sagemaker:WorkteamType": "public-crowd"
        }
      }
    }
  ]
}
```

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "RestrictWorkteamType",
      "Effect": "Deny",
      "Action": "sagemaker:CreateLabelingJob",
      "Resource": "*",
      "Condition": {
        "ArnLike": {
          "sagemaker:WorkteamArn": "arn:aws:sagemaker:*:*:workteam/public-crowd/*"
        }
      }
    }
  ]
}
```

Enforce Encryption of Input Data

The following policy restricts a user to specify an AWS KMS key to encrypt input data when creating training, hyperparameter tuning, and labeling jobs by using the `sagemaker:VolumeKmsKey` condition key:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "RestrictWorkteamType",
      "Effect": "Deny",
      "Action": "sagemaker:CreateLabelingJob",
      "Resource": "*",
      "Condition": {
        "ArnEquals": {
        }
      }
    }
  ]
}
```
Enforce Encryption of Notebook Instance Storage Volume

The following policy restricts a user to specify an AWS KMS key to encrypt the attached storage volume when creating or updating a notebook instance by using the `sagemaker:VolumeKmsKey` condition key:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "EnforceEncryption",
         "Effect": "Allow",
         "Action": [
            "sagemaker:CreateNotebookInstance"
         ],
         "Resource": "*",
         "Condition": {
            "ArnLike": {
               "sagemaker:VolumeKmsKey": "*key/volume-kms-key-12345"
            }
         }
      }
   ]
}
```

Enforce Network Isolation for Training Jobs

The following policy restricts a user to enable network isolation when creating training jobs by using the `sagemaker:NetworkIsolation` condition key:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "EnforceIsolation",
         "Effect": "Allow",
         "Action": [
            "sagemaker:CreateTrainingJob",
            "sagemaker:CreateHyperParameterTuningJob"
         ],
         "Resource": "*",
         "Condition": {
            "ArnEquals": {
               "sagemaker:VolumeKmsKey": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"
            }
         }
      }
   ]
}
```
Enforce a Specific Instance Type for Training Jobs

The following policy restricts a user to use a specific instance type when creating training jobs by using the `sagemaker:InstanceTypes` condition key:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "EnforceInstanceType",
            "Effect": "Allow",
            "Action": [
                "sagemaker:CreateTrainingJob",
                "sagemaker:CreateHyperParameterTuningJob"
            ],
            "Resource": "*",
            "Condition": {
                "ForAllValues:StringLike": {
                    "sagemaker:InstanceTypes": ["ml.c5.*"]
                }
            }
        }
    ]
}
```

Enforce a Specific EI Accelerator for Training Jobs

The following policy restricts a user to use a specific elastic inference (EI) accelerator, if an accelerator is provided, when creating or updating notebook instances and when creating endpoint configurations by using the `sagemaker:AcceleratorTypes` condition key:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "EnforceAcceleratorType",
            "Effect": "Allow",
            "Action": [
                "sagemaker:CreateNotebookInstance",
                "sagemaker:UpdateNotebookInstance",
                "sagemaker:CreateEndpointConfig"
            ],
            "Resource": "*",
            "Condition": {
                "ForAllValues:StringEquals": {
                    "sagemaker:AcceleratorTypes": ["ml.eia1.medium"]
                }
            }
        }
    ]
}
```
Identity-Based Policy Examples

Enforce Disabling Internet Access and Root Access for Creating Notebook Instances

You can disable both internet access and root access to notebook instances to help make them more secure. For information about controlling root access to a notebook instance, see Control root access to a SageMaker notebook instance (p. 3343). For information about disabling internet access for a notebook instance, see Connect a Notebook Instance in a VPC to External Resources (p. 3524).

The following policy requires a user to disable network access when creating instance, and disable root access when creating or updating a notebook instance.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "LockDownCreateNotebookInstance",
            "Effect": "Allow",
            "Action": ["sagemaker:CreateNotebookInstance"],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "sagemaker:DirectInternetAccess": "Disabled",
                    "sagemaker:RootAccess": "Disabled"
                },
                "Null": {
                    "sagemaker:VpcSubnets": "false",
                    "sagemaker:VpcSecurityGroupIds": "false"
                }
            }
        },
        {
            "Sid": "LockDownUpdateNotebookInstance",
            "Effect": "Allow",
            "Action": ["sagemaker:UpdateNotebookInstance"],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "sagemaker:RootAccess": "Disabled"
                }
            }
        }
    ]
}
```

Control Access to the SageMaker API by Using Identity-based Policies

To control access to SageMaker API calls and calls to SageMaker hosted endpoints, use identity-based IAM policies.

Topics

- Restrict Access to SageMaker API and Runtime to Calls from Within Your VPC (p. 3374)
Restrict Access to SageMaker API and Runtime to Calls from Within Your VPC

If you set up an interface endpoint in your VPC, individuals outside the VPC can still connect to the SageMaker API and runtime over the internet unless you attach an IAM policy that restricts access to calls coming from within the VPC to all users and groups that have access to your SageMaker resources. For information about creating a VPC interface endpoint for the SageMaker API and runtime, see Connect to SageMaker Within your VPC (p. 3526).

Important
If you apply an IAM policy similar to one of the following, users can't access the specified SageMaker APIs through the console.

To restrict access to only connections made from within your VPC, create an AWS Identity and Access Management policy that restricts access to only calls that come from within your VPC. Then add that policy to every AWS Identity and Access Management user, group, or role used to access the SageMaker API or runtime.

Note
This policy allows connections only to callers within a subnet where you created an interface endpoint.

```json
{
    "Id": "api-example-1",
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "EnableAPIAccess",
            "Effect": "Allow",
            "Action": ["sagemaker:*"],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "aws:SourceVpc": "vpc-111bbaaa"
                }
            }
        }
    ]
}
```

If you want to restrict access to the API to only calls made using the interface endpoint, use the `aws:SourceVpce` condition key instead of `aws:SourceVpc`:

```json
{
    "Id": "api-example-1",
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "EnableAPIAccess",
            "Effect": "Allow",
            "Action": ["sagemaker:CreatePresignedNotebookInstanceUrl"],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "aws:SourceVpce": [
                        "vpce-111bbccc",
                        "vpce-111bbddd"
                    ]
                }
            }
        }
    ]
}
```
Limit Access to SageMaker API and Runtime Calls by IP Address

To allow access to SageMaker API calls and runtime invocations only from IP addresses in a list that you specify, attach an IAM policy that denies access to the API unless the call comes from an IP address in the list to every AWS Identity and Access Management user, group, or role used to access the API or runtime. For information about creating IAM policies, see Creating IAM Policies in the AWS Identity and Access Management User Guide. To specify the list of IP addresses that you want to have access to the API call, use the IPAddress condition operator and the aws:SourceIP condition context key. For information about IAM condition operators, see IAM JSON Policy Elements: Condition Operators in the AWS Identity and Access Management User Guide. For information about IAM condition context keys, see AWS Global Condition Context Keys.

For example, the following policy allows access to the CreateTrainingJob only from IP addresses in the ranges 192.0.2.0-192.0.2.255 and 203.0.113.0-203.0.113.255:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "sagemaker:CreateTrainingJob",
      "Resource": "*",
      "Condition": {
        "IpAddress": {
          "aws:SourceIp": [
            "192.0.2.0/24",
            "203.0.113.0/24"
          ]
        }
      }
    }
  ]
}
```

Limit Access to a Notebook Instance by IP Address

To allow access to a notebook instance only from IP addresses in a list that you specify, attach an IAM policy that denies access to CreatePresignedNotebookInstanceUrl unless the call comes from an IP address in the list to every AWS Identity and Access Management user, group, or role used to access the notebook instance. For information about creating IAM policies, see Creating IAM Policies in the AWS Identity and Access Management User Guide. To specify the list of IP addresses that you want to have access to the notebook instance, use the IPAddress condition operator and the aws:SourceIP condition context key. For information about IAM condition operators, see IAM JSON Policy Elements: Condition Operators in the AWS Identity and Access Management User Guide. For information about IAM condition context keys, see AWS Global Condition Context Keys.

For example, the following policy allows access to a notebook instance only from IP addresses in the ranges 192.0.2.0-192.0.2.255 and 203.0.113.0-203.0.113.255:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "sagemaker:CreatePresignedNotebookInstanceUrl",
      "Resource": "*",
      "Condition": {
        "IpAddress": {
          "aws:SourceIp": [
            "192.0.2.0/24",
            "203.0.113.0/24"
          ]
        }
      }
    }
  ]
}
```
The policy restricts access to both the call to CreatePresignedNotebookInstanceUrl and to the URL that the call returns. The policy also restricts access to opening a notebook instance in the console and is enforced for every HTTP request and WebSocket frame that attempts to connect to the notebook instance.

**Note**
Using this method to filter by IP address is incompatible when connecting to SageMaker through a VPC interface endpoint. For information about restricting access to a notebook instance when connecting through a VPC interface endpoint, see Connect to a Notebook Instance Through a VPC Interface Endpoint (p. 3535).

Control Access to SageMaker Resources by Using Tags

Specify tags within an IAM policy to control access to groups of SageMaker resources. Use tags to implement attribute based access control (ABAC). Using tags helps you partition access to resources to specific groups of users. You can have one team with access to one group of resources and a different team with access to another set of resources. You can provide ResourceTag conditions in IAM policies to provide access for each group.

**Note**
Tag-based policies don't work to restrict the following API calls:

- DeleteImageVersion
- DescribeImageVersion
- ListAlgorithms
- ListCodeRepositories
- ListCompilationJobs
- ListEndpointConfigs
- ListEndpoints
- ListFlowDefinitions
- ListHumanTaskUis
- ListHyperparameterTuningJobs
- ListLabelingJobs
- ListLabelingJobsForWorkteam
- ListModelPackages
- ListModels
- ListNotebookInstanceLifecycleConfigs
- ListNotebookInstances
- ListSubscribedWorkteams
- ListTags
A simple example can help you understand how you can use tags to partition resources. Suppose that you've defined two different IAM groups, named DevTeam1 and DevTeam2, in your AWS account. You've created 10 notebook instances as well. You're using 5 of the notebook instances for one project. You're using the other 5 for a second project. You can provide DevTeam1 with permissions to make API calls on the notebook instances that you're using for the first project. You can provide DevTeam2 to make API calls on notebook instances used for the second project.

The following procedure provides a simple example that helps you understand the concept of adding tags. You can use it to implement the solution described in the preceding paragraph.

**To control access to API calls (example)**

1. Add a tag with the key `Project` and value `A` to the notebook instances used for the first project. For information about adding tags to SageMaker resources, see [AddTags](#).
2. Add a tag with the key `Project` and value `B` to the notebook instances used for the second project.
3. Create an IAM policy with a `ResourceTag` condition that denies access to the notebook instances used for the second project, and attach that policy to DevTeam1. The following is an example of a policy that denies all API calls on any notebook instance that has a tag with a key of `Project` and a value of `B`:

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Action": "sagemaker:*",
         "Resource": "*"
       },
       {
         "Effect": "Deny",
         "Action": "sagemaker:*",
         "Resource": "*",
         "Condition": {
           "StringEquals": {
             "sagemaker:ResourceTag/Project": "B"
           }
         }
       },
       {
         "Effect": "Deny",
         "Action": ["sagemaker:AddTags", "sagemaker:DeleteTags"],
         "Resource": "*"
       }
     ]
   }
   ```

   For information about creating IAM policies and attaching them to identities, see [Controlling Access Using Policies](#) in the AWS Identity and Access Management User Guide.

---

*ListProcessingJobs*
*ListTrainingJobs*
*ListTrainingJobsForHyperParameterTuningJob*
*ListTransformJobs*
*ListWorkteams*
*Search*
4. Create an IAM policy with a ResourceTag condition that denies access to the notebook instances used for the first project, and attach that policy to DevTeam2. The following is an example of a policy that denies all API calls on any notebook instance that has a tag with a key of Project and a value of A:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": "sagemaker:*",
         "Resource": "*"
      },
      {
         "Effect": "Deny",
         "Action": "sagemaker:*",
         "Resource": "*",
         "Condition": {
            "StringEquals": {
               "sagemaker:ResourceTag/Project": "A"
            }
         }
      },
      {
         "Effect": "Deny",
         "Action": [
            "sagemaker:AddTags",
            "sagemaker:DeleteTags"
         ],
         "Resource": "*"
      }
   ]
}
```

**Provide Permissions for Tagging SageMaker Resources Upon Creation**

There are many Amazon SageMaker operations that let your users specify tags when you create a resource. Use resource tags to implement attributed based access control (ABAC). Using tags helps you partition access to resources to specific groups of users. You can have one team with access to one group of resources and a different team with access to another set of resources. You can provide ResourceTag conditions in IAM policies to provide access for each group.

You must give your users access to the permissions that they’re using to create the resource. For users that need to create a processing job, you must give them access to `sagemaker:CreateProcessingJob` within the policy. If your users are tagging the resources that they create, you must also give tagging permissions.

**Important**

You can only give your users permissions to add tags to resources that they create. They can’t add tags to resources that have already been created.

The following are operations where you can’t give them resources to add tags:

- DeleteImageVersion
- DescribeImageVersion
- ListAlgorithms
- ListCodeRepositories
- ListCompilationJobs
• ListEndpointConfigs
• ListEndpoints
• ListFlowDefinitions
• ListHumanTaskUis
• ListHyperparameterTuningJobs
• ListLabelingJobs
• ListLabelingJobsForWorkteam
• ListModelPackages
• ListModels
• ListNotebookInstanceLifecycleConfigs
• ListNotebookInstances
• ListSubscribedWorkteams
• ListTags
• ListProcessingJobs
• ListTrainingJobs
• ListTrainingJobsForHyperParameterTuningJob
• ListTransformJobs
• ListWorkteams
• Search

You can control access to the operations that the user can tag or the tags that they can use. You can specify permissions for the following use cases:

- Adding permissions to tag the resources created using any operation and permissions to use any tag
- Adding permissions to tag the resources created using specific operations and permissions to use any tag
- Adding permissions to tag the resources created using any operation and permissions to specific tags
- Adding permissions to tag the resources created using specific operations and permissions to specific tags

Permissions for any operation and any tag

Add the following statement to an IAM policy to grant your users permissions to add any tag for any operation.

```
{
   "Statement": [
       {
           "Effect": "Allow",
           "Action": [
               "sagemaker:Create*
           ],
           "Resource": "*"
       },
       {
           "Effect": "Allow",
           "Action": [
               "sagemaker:AddTags"
           ],
           "Resource": "*"
       }
   ]
}
```
Permissions for a specific operation with specific tags

The following statement gives the user permission to add the cc123 tag to resources created using the `CreateModel` operation. You can modify the statement to suit your own needs and add it to the IAM policy attached to the role of your users.

```json
{
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "sagemaker:CreateModel"
            ],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "aws:RequestTag/cost-center": [ "cc123" ]
                },
                "ForAnyValue:StringEquals": {
                    "aws:TagKeys": [ "purpose" ]
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": [
                "sagemaker:AddTags"
            ],
            "Resource": "arn:aws:sagemaker:region:account:*/*",
            "Condition": {
                "Null": {
                    "sagemaker:TaggingAction" : "false"
                }
            }
        }
    ]
}
```

Permissions for a specific operation and any tag

The following statement gives your users permissions to add any tag to resources created using the `CreateModel` operation.

```json
{
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "sagemaker:CreateModel"
            ],
            "Resource": "*",
            "Condition": {
                "Null": {
                    "sagemaker:TaggingAction" : "false"
                }
            }
        }
    ]
}
```
Cross-Service Confused Deputy Prevention

The confused deputy problem is a security issue where an entity that doesn’t have permission to perform an action can coerce a more-privileged entity to perform the action. In AWS, cross-service impersonation can result in the confused deputy problem. Cross-service impersonation can occur when one service (the calling service) calls another service (the called service). The calling service can be manipulated to use its permissions to act on another customer's resources in a way it should not otherwise have permission to access. To prevent this, AWS provides tools that help you protect your data for all services with service principals that have been given access to resources in your account.

Read on for general guidance or navigate to an example for a specific SageMaker feature:

- SageMaker Processing Jobs (p. 3385)
- SageMaker Studio (p. 3386)
- SageMaker Training Jobs (p. 3386)

Limit Permissions With Global Condition Keys

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition keys in resource policies to limit the permissions to the resource that Amazon SageMaker gives another service. If you use both global condition keys and the `aws:SourceArn` value contains the account ID, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement. Use `aws:SourceArn` if you want only one resource to be associated with the cross-service access. Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.
The most effective way to protect against the confused deputy problem is to use the `aws:SourceArn` global condition key with the full ARN of the resource. If you don't know the full ARN of the resource or if you are specifying multiple resources, use the `aws:SourceArn` global condition key with wildcards (*) for the unknown portions of the ARN. For example, `arn:aws:sagemaker:*:123456789012:*`.

The following example shows how you can use the `aws:SourceArn` and `aws:SourceAccount` global condition keys in SageMaker to prevent the confused deputy problem.

```json
{
  "Version": "2012-10-17",
  "Statement": {
    "Sid": "ConfusedDeputyPreventionExamplePolicy",
    "Effect": "Allow",
    "Principal": {
      "Service": "sagemaker.amazonaws.com"
    },
    # Specify an action and resource policy for another service
    "Action": "service:ActionName",
    "Resource": [
      "arn:aws:service:::ResourceName/*"
    ],
    "Condition": {
      "ArnLike": {
        "aws:SourceArn": "arn:partition:sagemaker:region:123456789012:*"
      },
      "StringEquals": {
        "aws:SourceAccount": "123456789012"
      }
    }
  }
}
```

**SageMaker Edge Manager**

The following example shows how you can use the `aws:SourceArn` global condition key to prevent the cross-service confused deputy problem for SageMaker Edge Manager created by account number `123456789012` in the `us-west-2` Region.

```json
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Principal": { "Service": "sagemaker.amazonaws.com" },
    "Action": "sts:AssumeRole",
    "Condition": {
      "ArnLike": {
        "aws:SourceArn": "arn:aws:sagemaker:us-west-2:123456789012:*"
      }
    }
  }
}
```

You can replace the `aws:SourceArn` in this template with the full ARN of one specific packaging job to further limit permissions.

**SageMaker Images**

The following example shows how you can use the `aws:SourceArn` global condition key to prevent the cross-service confused deputy problem for SageMaker Images. Use this template with either `Image` or `ImageVersion`. This example uses an `ImageVersion` record ARN with the account number `3382`.

```json
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Principal": { "Service": "sagemaker.amazonaws.com" },
    "Action": "sts:AssumeRole",
    "Condition": {
      "ArnLike": {
        "aws:SourceArn": "arn:partition:sagemaker:region:3382:123456789012:*"
      },
      "StringEquals": {
        "aws:SourceAccount": "3382"
      }
    }
  }
}
```
Note that because the account number is part of the `aws:SourceArn` value, you do not need to specify an `aws:SourceAccount` value.

```json
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Principal": { "Service": "sagemaker.amazonaws.com" },
    "Action": "sts:AssumeRole",
    "Condition": {
      "ArnLike": {
      }
    }
  }
}
```

Do not replace the `aws:SourceArn` in this template with the full ARN of a specific image or image version. The ARN must be in the format provided above and specify either `image` or `image-version`. The partition placeholder should designate either an AWS commercial partition (`aws`) or an AWS in China partition (`aws-cn`), depending on where the image or image version is running. Similarly, the region placeholder in the ARN can be any valid Region where SageMaker images are available.

### SageMaker Inference

The following example shows how you can use the `aws:SourceArn` global condition key to prevent the cross-service confused deputy problem for SageMaker real-time, serverless, and asynchronous inference. Note that because the account number is part of the `aws:SourceArn` value, you do not need to specify an `aws:SourceAccount` value.

```json
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Principal": { "Service": "sagemaker.amazonaws.com" },
    "Action": "sts:AssumeRole",
    "Condition": {
      "ArnLike": {
        "aws:SourceArn": "arn:aws:sagemaker:us-west-2:123456789012:*"
      }
    }
  }
}
```

Do not replace the `aws:SourceArn` in this template with the full ARN of a specific model or endpoint. The ARN must be in the format provided above. The asterisk in the ARN template does not stand for wildcard and should not be changed.

### SageMaker Batch Transform Jobs

The following example shows how you can use the `aws:SourceArn` global condition key to prevent the cross-service confused deputy problem for SageMaker batch transform jobs created by account number `123456789012` in the `us-west-2` Region. Note that because the account number is in the ARN, you do not need to specify an `aws:SourceAccount` value.

```json
{
  "Version": "2012-10-17",
  "Statement": [
```
You can replace the `aws:SourceArn` in this template with the full ARN of one specific batch transform job to further limit permissions.

**SageMaker Marketplace**

The following example shows how you can use the `aws:SourceArn` global condition key to prevent the cross-service confused deputy problem for SageMaker Marketplace resources created by account number 123456789012 in the `us-west-2` Region. Note that because the account number is in the ARN, you do not need to specify an `aws:SourceAccount` value.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "sagemaker.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "ArnLike": {
        }
      }
    }
  ]
}
```

Do not replace the `aws:SourceArn` in this template with the full ARN of a specific algorithm or model package. The ARN must be in the format provided above. The asterisk in the ARN template does stand for wildcard and covers all training jobs, models, and batch transform jobs from validation steps, as well as algorithm and model packages published to SageMaker Marketplace.

**SageMaker Neo**

The following example shows how you can use the `aws:SourceArn` global condition key to prevent the cross-service confused deputy problem for SageMaker Neo compilation jobs created by account number 123456789012 in the `us-west-2` Region. Note that because the account number is in the ARN, you do not need to specify an `aws:SourceAccount` value.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "sagemaker.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "ArnLike": {
          "aws:SourceArn": "arn:aws:sagemaker:us-west-2:123456789012:*"
        }
      }
    }
  ]
}
```
"Principal": {  
  "Service": "sagemaker.amazonaws.com"
},  
"Action": "sts:AssumeRole",
"Condition": {  
  "ArnLike": {  
  }
}
]
}
]

You can replace the `aws:SourceArn` in this template with the full ARN of one specific compilation job to further limit permissions.

**SageMaker Pipelines**

The following example shows how you can use the `aws:SourceArn` global condition key to prevent the cross-service confused deputy problem for SageMaker Pipelines using pipeline execution records from one or more pipelines. Note that because the account number is in the ARN, you do not need to specify an `aws:SourceAccount` value.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {  
        "Service": "sagemaker.amazonaws.com"
      },  
      "Action": "sts:AssumeRole",
      "Condition": {  
        "ArnLike": {  
          "aws:SourceArn": "arn:partition:sagemaker:region:123456789012:pipeline/mypipeline/*"
        }
      }
    }
  ]
}
```

Do not replace the `aws:SourceArn` in this template with the full ARN of a specific pipeline execution. The ARN must be in the format provided above. The `partition` placeholder should designate either an AWS commercial partition (aws) or an AWS in China partition (aws-cn), depending on where the pipeline is running. Similarly, the `region` placeholder in the ARN can be any valid Region where SageMaker Pipelines is available.

The asterisk in the ARN template does stand for wildcard and covers all pipeline executions of a pipeline named `mypipeline`. If you want to allow the AssumeRole permissions for all pipelines in account `123456789012` rather than one specific pipeline, then the `aws:SourceArn` would be `arn:aws:sagemaker:*:123456789012:Pipeline/*`.

**SageMaker Processing Jobs**

The following example shows how you can use the `aws:SourceArn` global condition key to prevent the cross-service confused deputy problem for SageMaker processing jobs created by account number `123456789012` in the `us-west-2` Region. Note that because the account number is in the ARN, you do not need to specify an `aws:SourceAccount` value.
You can replace the `aws:SourceArn` in this template with the full ARN of one specific processing job to further limit permissions.

**SageMaker Studio**

The following example shows how you can use the `aws:SourceArn` global condition key to prevent the cross-service confused deputy problem for SageMaker Studio created by account number `123456789012` in the `us-west-2` Region. Note that because the account number is part of the `aws:SourceArn` value, you do not need to specify an `aws:SourceAccount` value.

Do not replace the `aws:SourceArn` in this template with the full ARN of a specific Studio application, user profile, or domain. The ARN must be in the format provided in the previous example. The asterisk in the ARN template does not stand for wildcard and should not be changed.

**SageMaker Training Jobs**

The following example shows how you can use the `aws:SourceArn` global condition key to prevent the cross-service confused deputy problem for SageMaker training jobs created by account number `123456789012` in the `us-west-2` Region. Note that because the account number is in the ARN, you do not need to specify an `aws:SourceAccount` value.
"Statement": [
  {
    "Effect": "Allow",
    "Principal": {
      "Service": "sagemaker.amazonaws.com"
    },
    "Action": "sts:AssumeRole",
    "Condition": {
      "ArnLike": {
      }
    }
  }
]
}

You can replace the `aws:SourceArn` in this template with the full ARN of one specific training job to further limit permissions.

Next Up

For more information on managing execution roles, see SageMaker Roles.

SageMaker Roles

Amazon SageMaker performs operations on your behalf using other AWS services. You must grant SageMaker permissions to use these services and the resources they act upon. You grant SageMaker these permissions using an AWS Identity and Access Management (IAM) execution role. For more information on IAM roles, see IAM roles.

To create and use an execution role, you can use the following procedures.

Create execution role

Use the following procedure to create an execution role with the IAM managed policy, AmazonSageMakerFullAccess, attached. If your use case requires more granular permissions, use other sections on this page to create an execution role that meets your business needs. You can create an execution role using the SageMaker console or the AWS CLI.

**Important**

The IAM managed policy, AmazonSageMakerFullAccess, used in the following procedure only grants the execution role permission to perform certain Amazon S3 actions on buckets or objects with SageMaker, Sagemaker, sagemaker, or aws-glue in the name. To learn how to add an additional policy to an execution role to grant it access to other Amazon S3 buckets and objects, see Add Additional Amazon S3 Permissions to a SageMaker Execution Role (p. 3389).

**Note**

You can create an execution role directly when you create a SageMaker domain or a notebook instance.

- For information on how to create a SageMaker domain, see Onboard to Amazon SageMaker Domain using IAM Identity Center (p. 35).
- For information on how to create a notebook instance, see Step 1: Create an Amazon SageMaker Notebook Instance (p. 299).

To create a new execution role from the SageMaker console

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. Choose **Roles** and then choose **Create role**.
3. Keep **AWS service** as the **Trusted entity type** and then use the down arrow to find **SageMaker** in **Use cases for other AWS services**.
4. Choose **SageMaker – Execution** and then choose **Next**.
5. The IAM managed policy, AmazonSageMakerFullAccess, is automatically attached to the role. To see the permissions included in this policy, choose the plus (+) sign next to the policy name. Choose **Next**.
6. Enter a **Role name** and a **Description**.
7. (Optional) Add additional permissions and tags to the role.
8. Choose **Create role**.
9. On the **Roles** section of the IAM console, find the role you just created. If needed, use the text box to search for the role using the role name.
10. On the role summary page, make note of the ARN.

**To create a new execution role from the AWS CLI**

Before you create an execution role using the AWS CLI, make sure to update and configure it by following the instructions in **AWS CLI Prerequisites (p. 9)**, then continue with the instructions in **Onboard from the AWS CLI (p. 37)**.

Once you have created an execution role, you can associate it with a SageMaker domain, a user profile, or with a Jupyter notebook instance.

- To learn about how to associate an execution role with an existing SageMaker domain, see **Edit Domain settings (p. 20)**.
- To learn about how to associate an execution role with an existing user profile, see **Add and Remove User Profiles (p. 24)**.
- To learn about how to associate an execution role with an existing notebook instance, see **Update a Notebook Instance (p. 322)**.

You can also pass the ARN of an execution role to your API call. For example, using **Amazon SageMaker Python SDK**, you can pass the ARN of your execution role to an estimator. In the code sample that follows, we create an estimator using the XGBoost algorithm container and pass the ARN of the execution role as a parameter. For the full example on GitHub, see **Customer Churn Prediction with XGBoost**.

```python
import sagemaker, boto3
from sagemaker import image_uris

sess = sagemaker.Session()
region = sess.boto_region_name
bucket = sess.default_bucket()
prefix = "sagemaker/DEMO-xgboost-churn"
container = sagemaker.image_uris.retrieve("xgboost", region, "1.7-1")

xgb = sagemaker.estimator.Estimator(
    container,
    execution_role_ARN,
    instance_count=1,
    instance_type="ml.m4.xlarge",
    output_path="s3://{}/{}/output".format(bucket, prefix),
    sagemaker_session=sess,
)
...
```
Add Additional Amazon S3 Permissions to a SageMaker Execution Role

When you use a SageMaker feature with resources in Amazon S3, such as input data, the execution role you specify in your request (for example CreateTrainingJob) is used to access these resources.

If you attach the IAM managed policy, AmazonSageMakerFullAccess, to an execution role, that role has permission to perform certain Amazon S3 actions on buckets or objects with SageMaker, Sagemaker, sagemaker, or aws-glue in the name. It also has permission to perform the following actions on any Amazon S3 resource:

```
"s3:CreateBucket",
"s3:GetBucketLocation",
"s3:ListBucket",
"s3:ListAllMyBuckets",
"s3:GetBucketCors",
"s3:PutBucketCors"
```

To give an execution role permissions to access one or more specific buckets in Amazon S3, you can attach a policy similar to the following to the role. This policy grants an IAM role permission to perform all actions that AmazonSageMakerFullAccess allows but restricts this access to the buckets DOC-EXAMPLE-BUCKET1 and DOC-EXAMPLE-BUCKET2. Refer to the security documentation for the specific SageMaker feature you are using to learn more about the Amazon S3 permissions required for that feature.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject",
                "s3:PutObject",
                "s3:DeleteObject",
                "s3:AbortMultipartUpload"
            ],
            "Resource": [
                "arn:aws:s3:::DOC-EXAMPLE-BUCKET1/*",
                "arn:aws:s3:::DOC-EXAMPLE-BUCKET2/*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:CreateBucket",
                "s3:GetBucketLocation",
                "s3:ListBucket",
                "s3:ListAllMyBuckets",
                "s3:GetBucketCors",
                "s3:PutBucketCors"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetBucketAcl",
                "s3:PutObjectAcl"
            ],
            "Resource": [
                "arn:aws:s3:::DOC-EXAMPLE-BUCKET1",
                "arn:aws:s3:::DOC-EXAMPLE-BUCKET2"
            ]
        }
    ]
}
```
Get execution role

You can use the SageMaker console or the AWS CLI to retrieve the ARN of the execution role attached to a SageMaker domain, a user profile, or a notebook instance.

- To find the ARN of the IAM execution role attached to a SageMaker domain, see View and Edit Domains (p. 20).
- To find the ARN of the IAM execution role attached to a user profile, see View User Profiles and User Profile Details (p. 26).
- To find the ARN of the IAM execution role attached to a notebook instance:
  1. Open the IAM console at https://console.aws.amazon.com/iam/.
  2. On the left navigation pane, choose Notebook then Notebook instances.
  3. From the list of notebooks, select the notebook that you want to view.
  4. The ARN is in the Permissions and encryption section.

Alternatively, Amazon SageMaker Python SDK users can retrieve the ARN of the execution role attached to their user profile or a notebook instance by running the following code:

```python
import sagemaker
sagemaker_session = sagemaker.Session()
role = sagemaker.get_execution_role()
```

**Note**

The execution role is available only when running a notebook within SageMaker. If you run `get_execution_role` in a notebook not on SageMaker, expect a "region" error.

Passing Roles

Actions like passing a role between services are a common function within SageMaker. You can find more details on Actions, Resources, and Condition Keys for SageMaker in the IAM User Guide.

You pass the role (iam:PassRole) when making these API calls: CreateAutoMLJob, CreateCompilationJob, CreateDomain, CreateFeatureGroup, CreateFlowDefinition, CreateHyperParameterTuningJob, CreateImage, CreateLabelingJob, CreateModel, CreateMonitoringSchedule, CreateNotebookInstance, CreateProcessingJob, CreateTrainingJob, CreateUserProfile, RenderUiTemplate, and UpdateImage.

You attach the following trust policy to the IAM role which grants SageMaker principal permissions to assume the role, and is the same for all of the execution roles:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "sagemaker.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```
The permissions that you need to grant to the role vary depending on the API that you call. The following sections explain these permissions.

**Note**
Instead of managing permissions by crafting a permission policy, you can use the AWS-managed AmazonSageMakerFullAccess permission policy. The permissions in this policy are fairly broad, to allow for any actions you might want to perform in SageMaker. For a listing of the policy including information about the reasons for adding many of the permissions, see [AWS managed policy: AmazonSageMakerFullAccess](p. 3443). If you prefer to create custom policies and manage permissions to scope the permissions only to the actions you need to perform with the execution role, see the following topics.

**Important**
If you're running into issues, see [Troubleshooting Amazon SageMaker Identity and Access](p. 3518).

For more information about IAM roles, see [IAM Roles](p. 3404) in the IAM User Guide.

- [CreateProcessingJob API: Execution Role Permissions](p. 3399)
- [CreateTrainingJob API: Execution Role Permissions](p. 3402)
- [CreateModel API: Execution Role Permissions](p. 3404)
- SageMaker geospatial capabilities roles (p. 3406)

**CreateAutoMLJob API: Execution Role Permissions**

For an execution role that you can pass in a CreateAutoMLJob API request, you can attach the following minimum permission policy to the role:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "iam:PassRole"
            ],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "iam:PassedToService": "sagemaker.amazonaws.com"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": [
                "sagemaker:DescribeEndpointConfig",
                "sagemaker:DescribeModel",
                "sagemaker:InvokeEndpoint",
                "sagemaker:ListTags",
                "sagemaker:DescribeEndpoint",
                "sagemaker:CreateModel"
            ]
        }
    ]
}
```
If you specify a private VPC for your AutoML job, add the following permissions:

```
{
  "Effect": "Allow",
  "Action": [
    "ec2:CreateNetworkInterface",
    "ec2:CreateNetworkInterfacePermission",
    "ec2:DeleteNetworkInterface",
    "ec2:DeleteNetworkInterfacePermission",
    "ec2:DescribeNetworkInterfaces",
    "ec2:DescribeVpcs",
    "ec2:DescribeDhcpOptions",
    "ec2:DescribeSubnets",
    "ec2:DescribeSecurityGroups"
  ],
  "Resource": "*"
}
```

If your input is encrypted using server-side encryption with an AWS KMS–managed key (SSE-KMS), add the following permissions:

```
{
  "Effect": "Allow",
  "Action": [
    "kms:Decrypt"
  ]
}
```

If you specify a KMS key in the output configuration of your AutoML job, add the following permissions:

```
{
  "Effect": "Allow",
  "Action": [
    "kms:Encrypt"
  ]
}
```

If you specify a volume KMS key in the resource configuration of your AutoML job, add the following permissions:
CreateDomain API: Execution Role Permissions

The execution role for domains with IAM Identity Center and the user/execution role for IAM domains need the following permissions when you pass an AWS KMS customer managed key as the KmsKeyId in the CreateDomain API request. The permissions are enforced during the CreateApp API call.

For an execution role that you can pass in the CreateDomain API request, you can attach the following permission policy to the role:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "kms:CreateGrant",
                "kms:DescribeKey"
            ],
            "Resource": "arn:aws:kms:region:account-id:key/kms-key-id"
        }
    ]
}
```

Alternatively, if the permissions are specified in a KMS policy, you can attach the following policy to the role:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Allow use of the key",
            "Effect": "Allow",
            "Principal": {
                "AWS": ["arn:aws:iam::account-id:role/ExecutionRole"
            ],
            "Action": [
                "kms:CreateGrant",
                "kms:DescribeKey"
            ],
            "Resource": "*"
        }
    ]
}
```

CreateImage and UpdateImage APIs: Execution Role Permissions

For an execution role that you can pass in a CreateImage or UpdateImage API request, you can attach the following permission policy to the role:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "kms:CreateGrant",
                "kms:DescribeKey"
            ],
            "Resource": "*"
        }
    ]
}
```
CreateNotebookInstance API: Execution Role Permissions

The permissions that you grant to the execution role for calling the CreateNotebookInstance API depend on what you plan to do with the notebook instance. If you plan to use it to invoke SageMaker APIs and pass the same role when calling the CreateTrainingJob and CreateModel APIs, attach the following permissions policy to the role:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "sagemaker:*",
        "ecr:GetAuthorizationToken",
        "ecr:GetDownloadUrlForLayer",
        "ecr:BatchGetImage",
        "ecr:BatchCheckLayerAvailability",
        "ecr:SetRepositoryPolicy",
        "ecr:CompleteLayerUpload",
        "ecr:BatchDeleteImage",
        "ecr:UploadLayerPart",
        "ecr:DeleteRepositoryPolicy",
        "ecr:InitiateLayerUpload",
        "ecr:DeleteRepository",
        "ecr:PutImage",
        "ecr:CreateRepository",
        "cloudwatch:PutMetricData",
        "cloudwatch:GetMetricData",
        "cloudwatch:GetMetricStatistics",
        "cloudwatch:ListMetrics",
        "logs:CreateLogGroup",
        "logs:CreateLogStream",
        "logs:DescribeLogStreams",
        "logs:PutLogEvents",
        "logs:GetLogEvents",
        "s3:CreateBucket",
        "s3:ListBucket",
        "s3:GetBucketLocation"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "iam:PassedToService": "sagemaker.amazonaws.com"
        }
      }
    }
  ]
}
```
To tighten the permissions, limit them to specific Amazon S3 and Amazon ECR resources, by restricting "Resource": "*", as follows:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "sagemaker:*",
        "ecr:GetAuthorizationToken",
        "cloudwatch:PutMetricData",
        "logs:CreateLogGroup",
        "logs:CreateLogStream",
        "logs:DescribeLogStreams",
        "logs:PutLogEvents",
        "logs:GetLogEvents"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "iam:PassRole"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "iam:PassedToService": "sagemaker.amazonaws.com"
        }
      }
    }
  ]
}
```
If you plan to access other resources, such as Amazon DynamoDB or Amazon Relational Database Service, add the relevant permissions to this policy.

In the preceding policy, you scope the policy as follows:

- Scope the **s3:ListBucket** permission to the specific bucket that you specify as `InputDataConfig.DataSource.S3DataSource.S3Uri` in a `CreateTrainingJob` request.
- Scope **s3:GetObject**, **s3:PutObject**, and **s3:DeleteObject** permissions as follows:
  - Scope to the following values that you specify in a `CreateTrainingJob` request:
    
    ```
    InputDataConfig.DataSource.S3DataSource.S3Uri
    OutputDataConfig.S3OutputPath
    ```
  - Scope to the following values that you specify in a `CreateModel` request:
PrimaryContainer.ModelDataUrl
SuplementalContainers.ModelDataUrl
- Scope ecr permissions as follows:
  - Scope to the AlgorithmSpecification.TrainingImage value that you specify in a CreateTrainingJob request.
  - Scope to the PrimaryContainer.Image value that you specify in a CreateModel request.

The cloudwatch and logs actions are applicable for "*" resources. For more information, see CloudWatch Resources and Operations in the Amazon CloudWatch User Guide.

CreateHyperParameterTuningJob API: Execution Role Permissions

For an execution role that you can pass in a CreateHyperParameterTuningJob API request, you can attach the following permission policy to the role:

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "cloudwatch:PutMetricData",
            "logs:CreateLogStream",
            "logs:PutLogEvents",
            "logs:CreateLogGroup",
            "logs:DescribeLogStreams",
            "s3:GetObject",
            "s3:PutObject",
            "s3:ListBucket",
            "ecr:GetAuthorizationToken",
            "ecr:BatchCheckLayerAvailability",
            "ecr:GetDownloadUrlForLayer",
            "ecr:GetDownloadUrlForLayer",
            "ecr:BatchGetImage"
         ],
         "Resource": "*"
      }
   ]
}
```

Instead of specifying "Resource": "*", you could scope these permissions to specific Amazon S3, Amazon ECR, and Amazon CloudWatch Logs resources:

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "cloudwatch:PutMetricData",
            "ecr:GetAuthorizationToken"
         ],
         "Resource": "*"
      },
      {
         "Effect": "Allow",
         "Action": [
            "cloudwatch:PutMetricData",
            "ecr:GetAuthorizationToken"
         ],
         "Resource": "*"
      }
   ]
}
```
If the training container associated with the hyperparameter tuning job needs to access other data sources, such as DynamoDB or Amazon RDS resources, add relevant permissions to this policy.

In the preceding policy, you scope the policy as follows:

- Scope the `s3:ListBucket` permission to a specific bucket that you specify as the `InputDataConfig.DataSource.S3DataSource.S3Uri` in a `CreateTrainingJob` request.
- Scope the `s3:GetObject` and `s3:PutObject` permissions to the following objects that you specify in the input and output data configuration in a `CreateHyperParameterTuningJob` request:
  - `InputDataConfig.DataSource.S3DataSource.S3Uri`
  - `OutputDataConfig.S3OutputPath`
- Scope Amazon ECR permissions to the registry path (`AlgorithmSpecification.TrainingImage`) that you specify in a `CreateHyperParameterTuningJob` request.
- Scope Amazon CloudWatch Logs permissions to log group of SageMaker training jobs.

The cloudwatch actions are applicable for "*" resources. For more information, see CloudWatch Resources and Operations in the Amazon CloudWatch User Guide.

If you specify a private VPC for your hyperparameter tuning job, add the following permissions:
If your input is encrypted using server-side encryption with an AWS KMS–managed key (SSE-KMS), add the following permissions:

```
{
  "Effect": "Allow",
  "Action": [
    "kms:Decrypt"
  ]
}
```

If you specify a KMS key in the output configuration of your hyperparameter tuning job, add the following permissions:

```
{
  "Effect": "Allow",
  "Action": [
    "kms:Encrypt"
  ]
}
```

If you specify a volume KMS key in the resource configuration of your hyperparameter tuning job, add the following permissions:

```
{
  "Effect": "Allow",
  "Action": [
    "kms:CreateGrant"
  ]
}
```

**CreateProcessingJob API: Execution Role Permissions**

For an execution role that you can pass in a `CreateProcessingJob` API request, you can attach the following permission policy to the role:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "cloudwatch:PutMetricData",
        "logs:CreateLogStream",
        "logs:PutLogEvents",
```
Instead of the specifying "Resource": "*", you could scope these permissions to specific Amazon S3 and Amazon ECR resources:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "cloudwatch:PutMetricData",
                "logs:CreateLogStream",
                "logs:PutLogEvents",
                "logs:CreateLogGroup",
                "logs:DescribeLogStreams",
                "ecr:GetAuthorizationToken"
            ],
            "Resource": "*
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:ListBucket"
            ],
            "Resource": [
                "arn:aws:s3:::inputbucket"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject",
                "s3:PutObject"
            ],
            "Resource": [
                "arn:aws:s3:::inputbucket/object",
                "arn:aws:s3:::outputbucket/path"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "ecr:BatchCheckLayerAvailability",
                "ecr:GetDownloadUrlForLayer",
                "ecr:BatchGetImage"
            ],
            "Resource": "arn:aws:ecr::repository/my-repo"
        }
    ]
}
```
If `CreateProcessingJob.AppSpecification.ImageUri` needs to access other data sources, such as DynamoDB or Amazon RDS resources, add relevant permissions to this policy.

In the preceding policy, you scope the policy as follows:

- Scope the `s3:ListBucket` permission to a specific bucket that you specify as the `ProcessingInputs` in a `CreateProcessingJob` request.
- Scope the `s3:GetObject` and `s3:PutObject` permissions to the objects that will be downloaded or uploaded in the `ProcessingInputs` and `ProcessingOutputConfig` in a `CreateProcessingJob` request.
- Scope Amazon ECR permissions to the registry path (`AppSpecification.ImageUri`) that you specify in a `CreateProcessingJob` request.

The `cloudwatch` and `logs` actions are applicable for `*` resources. For more information, see [CloudWatch Resources and Operations](https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/cloudwatch-resource-list.html) in the Amazon CloudWatch User Guide.

If you specify a private VPC for your processing job, add the following permissions. Don't scope in the policy with any conditions or resource filters. Otherwise, the validation checks that occur during the creation of the processing job fail.

```json
{
  "Effect": "Allow",
  "Action": [
    "ec2:CreateNetworkInterface",
    "ec2:CreateNetworkInterfacePermission",
    "ec2:DeleteNetworkInterface",
    "ec2:DeleteNetworkInterfacePermission",
    "ec2:DescribeNetworkInterfaces",
    "ec2:DescribeSecurityGroups"
  ]
}
```

If your input is encrypted using server-side encryption with an AWS KMS–managed key (SSE-KMS), add the following permissions:

```json
[
  "Effect": "Allow",
  "Action": [
    "kms:Decrypt"
  ]
]
```

If you specify a KMS key in the output configuration of your processing job, add the following permissions:

```json
[
  "Effect": "Allow",
  "Action": [
    "kms:Encrypt"
  ]
]
```

If you specify a volume KMS key in the resource configuration of your processing job, add the following permissions:
CreateTrainingJob API: Execution Role Permissions

For an execution role that you can pass in a CreateTrainingJob API request, you can attach the following permission policy to the role:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "cloudwatch:PutMetricData",
        "logs:CreateLogStream",
        "logs:PutLogEvents",
        "logs:CreateLogGroup",
        "logs:DescribeLogStreams",
        "s3:GetObject",
        "s3:PutObject",
        "s3:ListBucket",
        "ecr:GetAuthorizationToken",
        "ecr:BatchCheckLayerAvailability",
        "ecr:GetDownloadUrlForLayer",
        "ecr:BatchGetImage"
      ],
      "Resource": "*"
    }
  ]
}
```

Instead of the specifying "Resource": "*", you could scope these permissions to specific Amazon S3 and Amazon ECR resources:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "cloudwatch:PutMetricData",
        "logs:CreateLogStream",
        "logs:PutLogEvents",
        "logs:CreateLogGroup",
        "logs:DescribeLogStreams",
        "ecr:GetAuthorizationToken"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:ListBucket"
      ],
      "Resource": [
        "arn:aws:s3:::inputbucket"
      ]
    }
  ]
}
```
If `CreateTrainingJob.AlgorithmSpecifications.TrainingImage` needs to access other data sources, such as DynamoDB or Amazon RDS resources, add relevant permissions to this policy.

In the preceding policy, you scope the policy as follows:

- Scope the `s3:ListBucket` permission to a specific bucket that you specify as the `InputDataConfig.DataSource.S3DataSource.S3Uri` in a `CreateTrainingJob` request.
- Scope the `s3:GetObject` and `s3:PutObject` permissions to the following objects that you specify in the input and output data configuration in a `CreateTrainingJob` request:
  
  InputDataConfig.DataSource.S3DataSource.S3Uri
  
  OutputDataConfig.S3OutputPath
- Scope Amazon ECR permissions to the registry path (`AlgorithmSpecification.TrainingImage`) that you specify in a `CreateTrainingJob` request.

The `cloudwatch` and `logs` actions are applicable for "*" resources. For more information, see CloudWatch Resources and Operations in the Amazon CloudWatch User Guide.

If you specify a private VPC for your training job, add the following permissions:

```json
[
  "Effect": "Allow",
  "Action": [ 
    "ec2:CreateNetworkInterface",
    "ec2:CreateNetworkInterfacePermission",
    "ec2:DeleteNetworkInterface",
    "ec2:DeleteNetworkInterfacePermission",
    "ec2:DescribeNetworkInterfaces",
    "ec2:DescribeVpcs",
    "ec2:DescribeDhcpOptions",
    "ec2:DescribeSubnets",
    "ec2:DescribeSecurityGroups"
  ]
]
```
If your input is encrypted using server-side encryption with an AWS KMS–managed key (SSE-KMS), add the following permissions:

```json
{
    "Effect": "Allow",
    "Action": [
        "kms:Decrypt"
    ]
}
```

If you specify a KMS key in the output configuration of your training job, add the following permissions:

```json
{
    "Effect": "Allow",
    "Action": [
        "kms:Encrypt"
    ]
}
```

If you specify a volume KMS key in the resource configuration of your training job, add the following permissions:

```json
{
    "Effect": "Allow",
    "Action": [
        "kms:CreateGrant"
    ]
}
```

### CreateModel API: Execution Role Permissions

For an execution role that you can pass in a `CreateModel` API request, you can attach the following permission policy to the role:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "cloudwatch:PutMetricData",
                "logs:CreateLogStream",
                "logs:PutLogEvents",
                "logs:CreateLogGroup",
                "logs:DescribeLogStreams",
                "s3:GetObject",
                "s3:ListBucket",
                "ecr:GetAuthorizationToken",
                "ecr:BatchCheckLayerAvailability",
                "ecr:GetDownloadUrlForLayer",
                "ecr:BatchGetImage"
            ],
            "Resource": "*"
        }
    ]
}
```

Instead of specifying "Resource": "*", you can scope these permissions to specific Amazon S3 and Amazon ECR resources:
If `CreateModel.PrimaryContainer.Image` need to access other data sources, such as Amazon DynamoDB or Amazon RDS resources, add relevant permissions to this policy.

In the preceding policy, you scope the policy as follows:

- Scope S3 permissions to objects that you specify in the `PrimaryContainer.ModelDataUrl` in a `CreateModel` request.
- Scope Amazon ECR permissions to a specific registry path that you specify as the `PrimaryContainer.Image` and `SecondaryContainer.Image` in a `CreateModel` request.

The `cloudwatch` and `logs` actions are applicable for "*" resources. For more information, see `CloudWatch Resources and Operations` in the Amazon CloudWatch User Guide.

**Note**

If you plan to use the SageMaker deployment guardrails feature for model deployment in production, ensure that your execution role has permission to perform the `cloudwatch:DescribeAlarms` action on your auto-rollback alarms.

If you specify a private VPC for your model, add the following permissions:

```json
{
  "Effect": "Allow",
  "Action": [
    "ec2:DescribeVpcs",
    "ec2:DescribeSubnets",
    "ec2:DescribeSecurityGroups",
    "ec2:DescribeInstances",
    "ec2:DescribeVPCs",
    "ec2:DescribeNetworkInterfaces"
  ],
  "Resource": "*"
}
```
SageMaker geospatial capabilities roles

As a managed service, Amazon SageMaker geospatial capabilities performs operations on your behalf on the AWS hardware that is managed by SageMaker. Use AWS Identity and Access Management to grant users, groups, and roles access to SageMaker geospatial.

An IAM Administrator can grant these permissions to user, group, or role using the AWS Management Console, AWS CLI, or one of the AWS SDKs.

To use SageMaker geospatial you need the following IAM somethings...

1. An SageMaker execution role.

   To use the SageMaker geospatial specific API operations your SageMaker execution role must include the SageMaker geospatial service principal, sagemaker-geospatial.amazonaws.com in the execution role's trust policy. This allows the SageMaker execution role to perform actions in your AWS account on your behalf.

2. A user, group, or role that has access Amazon SageMaker Studio and SageMaker geospatial

   To get started with SageMaker geospatial you can use the AWS managed policy: AmazonSageMakerGeospatialFullAccess. This grants will grant a user, group, or role full access to SageMaker geospatial. To see the policy and learn more about which actions, resources, and conditions are available, see [AWS managed policy: AmazonSageMakerFullAccess](p. 3443).

   To get started with Studio and creating a Amazon SageMaker Domain, see [Onboard to Amazon SageMaker Domain](p. 10).

Use the following topics to create a new SageMaker execution role, update an existing SageMaker execution role, and learn how to manage permissions using SageMaker geospatial specific IAM actions, resources, and conditions.

Topics

- [Creating an new SageMaker execution role](p. 3406)
- [Adding the SageMaker geospatial service principal to an existing SageMaker execution role](p. 3407)
- [StartEarthObservationJob API: Execution role permissions](p. 3408)
- [StartVectorEnrichmentJob API: Execution role permissions](p. 3408)
- [ExportEarthObservationJob API: Execution role permissions](p. 3409)
- [ExportVectorEnrichmentJob API: Execution Role Permissions](p. 3409)

Creating an new SageMaker execution role

To work with SageMaker geospatial capabilities, you must set up a user, group, or role, and an execution role. A user role is an AWS identity with permissions policies that determine what the user can and
cannot do within AWS. An execution role is an IAM role that grants the service permission to access your AWS resources. An execution role consists of permissions and trust policy. The trust policy specifies which principals have the permission to assume the role.

SageMaker geospatial also requires a different service principal, sagemaker-geospatial.amazonaws.com. If you are an existing SageMaker customer, you must add this additional service principal to your trust policy.

Use the following procedure to create a new execution role with the IAM managed policy, AmazonSageMakerGeospatialFullAccess, attached. If your use case requires more granular permissions, use other sections of this guide to create an execution role that meets your business needs.

**Important**
The IAM managed policy, AmazonSageMakerGeospatialFullAccess, used in the following procedure, only grants the execution role permission to perform certain Amazon S3 actions on buckets or objects with SageMaker, Sagemaker, sagemaker, or aws-glue in the name. To learn how to update the execution role's policy to grant it access to other Amazon S3 buckets and objects, see [Add Additional Amazon S3 Permissions to a SageMaker Execution Role](p. 3389).

**To create a new role**

2. Select **Roles** and then select **Create role**.
3. Select **SageMaker**.
4. Select **Next: Permissions**.
5. The IAM managed policy, AmazonSageMakerGeospatialFullAccess is automatically attached to this role. To see the permissions included in this policy, select the sideways arrow next to the policy name. Select **Next: Tags**.
6. (Optional) Add tags and select **Next: Review**.
7. Give the role a name in the text field under **Role name** and select **Create role**.
8. In the **Roles** section of the IAM console, select the role you just created in step 7. If needed, use the text box to search for the role using the role name you entered in step 7.
9. On the role summary page, make note of the ARN.

**Adding the SageMaker geospatial service principal to an existing SageMaker execution role**

To use the SageMaker geospatial specific API operations your SageMaker execution role must include the SageMaker geospatial service principal, sagemaker-geospatial.amazonaws.com in the execution role's trust policy. This allows the SageMaker execution role to perform actions in your AWS account on your behalf.

Actions like passing a role between services are common within SageMaker. For more details,

To add the SageMaker geospatial service principal to an existing SageMaker execution role update the existing policy to include the SageMaker geospatial service principal as shown in the following trust policy. By attaching the service principal to the trust policy a SageMaker execution role can now run the SageMaker geospatial specific APIs on your behalf.

To learn more about SageMaker geospatial specific IAM actions, resources, and conditions, see [Actions, Resources, and Condition Keys for SageMaker](in the IAM User Guide).

```json
{
    "Version": "2012-10-17",
}
StartEarthObservationJob API: Execution role permissions

For an execution role that you can pass in a StartEarthObservationJob API request, you can attach the following minimum permissions policy to the role:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:AbortMultipartUpload",
                "s3:PutObject",
                "s3:GetObject",
                "s3:ListBucketMultipartUploads"
            ],
            "Resource": [
                "arn:aws:s3:::*SageMaker*",
                "arn:aws:s3:::*Sagemaker*",
                "arn:aws:s3:::*sagemaker*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": "sagemaker-geospatial:GetEarthObservationJob",
            "Resource": "arn:aws:sagemaker-geospatial:*:*:earth-observation-job/*"
        },
        {
            "Effect": "Allow",
            "Action": "sagemaker-geospatial:GetRasterDataCollection",
        }
    ]
}
```

If your input Amazon S3 bucket is encrypted using server-side encryption with an AWS KMS managed key (SSE-KMS), see Using Amazon S3 Bucket Keys for more information.

StartVectorEnrichmentJob API: Execution role permissions

For an execution role that you can pass in a StartVectorEnrichmentJob API request, you can attach the following minimum permissions policy to the role:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": [
                    "sagemaker-geospatial.amazonaws.com",
                    "sagemaker.amazonaws.com"
                ]
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```
],  "Resource": [  "arn:aws:s3:::*SageMaker*",  "arn:aws:s3:::*Sagemaker*",  "arn:aws:s3:::*sagemaker*"
}
]

If your input Amazon S3 bucket is encrypted using server-side encryption with an AWS KMS managed key (SSE-KMS), see Using Amazon S3 Bucket Keys for more information.

ExportEarthObservationJob API: Execution role permissions

For an execution role that you can pass in an ExportEarthObservationJob API request, you can attach the following minimum permissions policy to the role:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
        ],  "Resource": [  "arn:aws:s3:::*SageMaker*",  "arn:aws:s3:::*Sagemaker*",  "arn:aws:s3:::*sagemaker*"
        ]
    },
    {
      "Effect": "Allow",
      "Action": "sagemaker-geospatial:GetEarthObservationJob",
      "Resource": "arn:aws:sagemaker-geospatial:*:*:earth-observation-job/*/"
    }
  ]
}
```

If your input Amazon S3 bucket is encrypted using server-side encryption with an AWS KMS managed key (SSE-KMS), see Using Amazon S3 Bucket Keys for more information.

ExportVectorEnrichmentJob API: Execution Role Permissions

For an execution role that you can pass in an ExportVectorEnrichmentJob API request, you can attach the following minimum permissions policy to the role:

```
{
  "Version": "2012-10-17",
  "Statement": [  
    {
      "Effect": "Allow",
        ],  "Resource": [  "arn:aws:s3:::*SageMaker*",  "arn:aws:s3:::*Sagemaker*",  "arn:aws:s3:::*sagemaker*"
        ]
    },
    {
      "Effect": "Allow",
      "Action": "sagemaker-geospatial:GetVectorEnrichmentJob",
      "Resource": "arn:aws:sagemaker-geospatial:*:*:vector-enrichment-job/*/"
    }
  ]
}
```

If your input Amazon S3 bucket is encrypted using server-side encryption with an AWS KMS managed key (SSE-KMS), see Using Amazon S3 Bucket Keys for more information.
Amazon SageMaker Role Manager

Machine learning (ML) administrators striving for least-privilege permissions with Amazon SageMaker must account for a diversity of industry perspectives, including the unique least-privilege access needs required for personas such as data scientists, machine learning operation (MLOps) engineers, and more. Use Amazon SageMaker Role Manager to build and manage persona-based IAM roles for common machine learning needs directly through the Amazon SageMaker console.

Amazon SageMaker Role Manager provides 3 preconfigured role personas and predefined permissions for 12 common ML activities. Explore the provided personas and their suggested policies, or create and maintain roles for personas unique to your business needs. If you require additional customization, specify networking and encryption permissions for Amazon Virtual Private Cloud resources and AWS Key Management Service encryption keys in Step 1. Enter role information (p. 3412) of the Amazon SageMaker Role Manager.

Topics
- Using the role manager (console) (p. 3410)
- Using the role manager (AWS CDK) (p. 3413)
- Persona reference (p. 3417)
- ML activity reference (p. 3418)
- Launch Studio (p. 3419)
- Role Manager FAQs (p. 3421)

Using the role manager (console)

You can use the Amazon SageMaker Role Manager from the following locations on the left-hand navigation of the Amazon SageMaker console:

- Getting started – Quickly add permissions policies for your users.
- Domains – Add permissions policies for users within a Amazon SageMaker Domain.

If your input Amazon S3 bucket is encrypted using server-side encryption with an AWS KMS managed key (SSE-KMS), see Using Amazon S3 Bucket Keys.
• **Notebooks** – Add least permissions for users who create and run notebooks.
• **Training** – Add least permissions for users who create and manage training jobs.
• **Inference** – Add least permissions for users who deploy and manage models for inference.

You can use the following are procedures to start the process of creating a role from different locations in the SageMaker console.

**Getting started**

If you're using SageMaker for the first time, we recommend creating a role from the **Getting started** section.

To create a role using Amazon SageMaker Role Manager, do the following.

1. Open the Amazon SageMaker console.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **Role manager**.
4. Choose **Create a role**.

**Domains**

You can create a role using Amazon SageMaker Role Manager when you start the process of creating a Amazon SageMaker Domain.

To create a role using Amazon SageMaker Role Manager, do the following.

1. Open the Amazon SageMaker console.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **Domains**.
4. Choose **Create domain**.
5. Choose **Create role using the role creation wizard**.

**Notebook**

You can create a role using Amazon SageMaker Role Manager when you start the process of creating a notebook.

To create a role using Amazon SageMaker Role Manager, do the following.

1. Open the Amazon SageMaker console.
2. On the left-hand navigation, select **Notebook**.
3. Choose **Notebook instances**.
4. Choose **Create notebook instance**.
5. Choose **Create role using the role creation wizard**.

**Training**

You can create a role using Amazon SageMaker Role Manager when you start the process of creating a training job.

To create a role using Amazon SageMaker Role Manager, do the following.

1. Open the Amazon SageMaker console.
2. On the left-hand navigation, choose **Training**.
3. Select **Training jobs**.
4. Choose **Create training job**.
5. Choose **Create role using the role creation wizard**.

### Inference

You can create a role using Amazon SageMaker Role Manager when you start the process of deploying a model for inference.

To create a role using Amazon SageMaker Role Manager, do the following.

1. Open the Amazon SageMaker console.
2. On the left-hand navigation, choose **Inference**.
3. Select **Models**.
4. Choose **Create model**.
5. Choose **Create role using the role creation wizard**.

After you've completed one of the preceding procedures, use the information in the following sections to help you create the role.

### Prerequisites

To use Amazon SageMaker Role Manager, you must have permission to create an IAM role. This permission is usually available to ML administrators and roles with least-privilege permissions for ML practitioners.

You can temporarily assume an IAM role in the AWS Management Console by [switching roles](#). For more information about methods for using roles, see [Using IAM roles](#) in the *IAM User Guide*.

### Step 1. Enter role information

Provide a name to use as the unique suffix of your new SageMaker role. By default, the prefix "sagemaker-" is added to every role name for easier search in the IAM console. For example, if you name your role `test-123` during role creation, your role shows up as `sagemaker-test-123` in the IAM console. You can optionally add a description of your role to provide additional details.

Then, choose from one of the available personas to get suggested permissions for personas such as data scientists, data engineers, or machine learning operations (MLOps) engineers. For information on available personas and their suggested permissions, see [Persona reference](#). To create a role without any suggested permissions to guide you, choose **Custom Role Settings**.

**Note**

We recommend that you first use the role manager to create a SageMaker Compute Role so that SageMaker compute resources have the ability to perform tasks such as training and inference. Use the SageMaker Compute Role persona to create this role with the role manager. After creating a SageMaker Compute Role, take note of its ARN for future use.

### Network and encryption conditions

We recommend that you activate VPC customization to use VPC configurations, subnets, and security groups with IAM policies associated with your new role. When VPC customization is activated, IAM policies for ML activities that interact with VPC resources are scoped down for least-privilege access. VPC customization is not activated by default. For more details on recommended networking architecture, see [Networking architecture](#) in the *AWS Technical Guide*.
You can also use a KMS key to encrypt, decrypt, and re-encrypt data for regulated workloads with highly sensitive data. When AWS KMS customization is activated, IAM policies for ML activities that support custom encryption keys are scoped down for least-privilege access. For more information, see Encryption with AWS KMS in the AWS Technical Guide.

**Step 2. Configure ML activities**

Each Amazon SageMaker Role Manager ML activity includes suggested IAM permissions to provide access to relevant AWS resources. Some ML activities require that you add service role ARNs to complete setup. For information on predefined ML activities and their permissions, see ML activity reference (p. 3418). For information on adding service roles, see Service roles (p. 3413).

Based on the chosen persona, certain ML activities are already selected. You can deselect any suggested ML activities or select additional activities to create your own role. If you selected the Custom Role Settings persona, then no ML activities are preselected in this step.

You can add any additional AWS or customer-managed IAM policies to your role in **Step 3: Add additional policies and tags** (p. 3413).

**Service roles**

Some AWS services require a service role to perform actions on your behalf. If the ML activity that you selected requires you to pass a service role, then you must provide the ARN for that service role.

You can either create a new service role or use an existing one, such as a service role created with the SageMaker Compute Role persona. You can find the ARN of an existing role by selecting the role name in the Roles section of the IAM console. To learn more about service roles, see Creating a role for an AWS service.

**Step 3: Add additional policies and tags**

You can add any existing AWS or customer-managed IAM policies to your new role. For information on existing SageMaker policies, see AWS Managed Policies for Amazon SageMaker. You can also check your existing policies in the Roles section of the IAM console.

Optionally, use tag-based policy conditions to assign metadata information to categorize and manage AWS resources. Each tag is represented by a key-value pair. For more information, see Controlling access to AWS resources using tags.

**Review role**

Take the time to review all of the information associated with your new role. Choose Previous to go back and edit any of the information. When you are ready to create your role, choose Create role. This generates a role with permissions for your selected ML activities. You can view your new role in the Roles section of the IAM console.

**Using the role manager (AWS CDK)**

Use the AWS Cloud Development Kit (AWS CDK) with Amazon SageMaker Role Manager to programmatically create roles and set permissions. You can use the AWS CDK to accomplish any task that you could perform using the AWS Management Console. The programmatic access of the CDK makes it easier to provide permissions that give your users access to specific resources. For more information about the AWS CDK, see What is AWS CDK?

**Important**

You must use the SageMaker Compute Role persona to create a SageMaker Compute Role. For more information about the compute persona, see SageMaker compute persona (p. 3418). For code that you can use to create the compute role within the AWS CDK, see Grant permissions to a Compute persona (p. 3414).
The following are examples of tasks that you can perform in the AWS CDK:

- Create IAM roles with granular permissions for machine learning (ML) personas, such as Data Scientists and MLOps Engineers.
- Grant permissions to CDK constructs from ML personas or ML activities.
- Set ML activity condition parameters.
- Enable global Amazon VPC and AWS Key Management Service conditions and set values for them.
- Choose from all versions of the ML activities for your users without causing disruptions in their access.

There are common AWS tasks related to machine learning (ML) with SageMaker that require specific IAM permissions. The permissions to perform the tasks are defined as ML activities in Amazon SageMaker Role Manager. ML activities specify a set of permissions that are linked to the IAM role. For example, the ML activity for Amazon SageMaker Studio has all of the permissions that a user needs to access Studio. For more information about ML activities, see ML activity reference (p. 3418).

When you're creating roles, you first define the constructs for the ML persona or the ML activity. A construct is a resource within the AWS CDK stack. For example, a construct could be an Amazon S3 bucket, an Amazon VPC subnet, or an IAM role.

As you're creating the persona or activity, you can limit the permissions associated with that persona or activity to specific resources. For example, you can customize the activity to only provide permissions for a specific subnet within an Amazon VPC.

After you've defined permissions, you can create roles and then pass those roles to create other resources, such as SageMaker notebook instances.

The following are code examples in Typescript for tasks that you can accomplish using the CDK. When you create an activity, you specify an ID and the options for the activity's construct. The options are dictionaries that specify the required parameters for the activities, such as an Amazon S3. You pass an empty dictionary for activities that don't have required parameters.

**Grant permissions to a Compute persona**

The following code creates a Data Scientist ML persona with a set of ML activities specific to the persona. The permissions from ML activities only apply to the Amazon VPC and AWS KMS configurations specified in the persona construct. The following code creates a class for a Data Scientist persona. The ML activities are defined in the activities list. The VPC permissions and the KMS permissions are defined as optional parameters outside of the activities list.

After you've defined the class, you can create a role as a construct within the AWS CDK stack. You can also create a notebook instance. The person who is using the IAM role that you've created in the following code can access the notebook instance when they log in to their AWS account.

```typescript
export class myCDKStack extends cdk.Stack {
  constructor(scope: cdk.App, id: string, props?: cdk.StackProps) {
    super(scope, id, props);

    const persona = new Persona(this, 'example-persona-id', {
      activities: [
        Activity.accessAwsServices(this, 'example-ld1', {}) // example-id is the ID for the activity
      ]
    });

    const role = persona.createRole(this, 'example-IAM-role-id', 'example-IAM-role-name');
  }
}
```
Grant permissions to a Data Scientist persona

The following code creates a Data Scientist ML persona with a set of ML activities specific to the persona. The permissions from ML activities only apply to the VPC and KMS configurations specified in the persona construct. The following code creates a class for a Data Scientist persona. The ML activities are defined in the activities list. The Amazon VPC permissions and the AWS KMS permissions are defined as optional parameters outside of the activities list.

After you've defined the class, you can create a role as a construct within the AWS CDK stack. You can also create a notebook instance. The person who is using the IAM role that you've created in the following code can access the notebook instance when they log in to their AWS account.

```typescript
export class myCDKStack extends cdk.Stack {
  constructor(scope: cdk.App, id: string, props?: cdk.StackProps) {
    super(scope, id, props);
    const persona = new Persona(this, 'example-persona-id', {
      activities: [
        Activity.runStudioAppsV2(this, 'example-id1', {}),
        Activity.manageJobs(this, 'example-id2', {rolesToPass: [iam.Role.fromRoleName('example-IAM-role-name')]},
        Activity.manageModels(this, 'example-id3', {rolesToPass: [iam.Role.fromRoleName('example-IAM-role-name')]},
        Activity.manageExperiments(this, 'example-id4', {}),
        Activity.visualizeExperiments(this, 'example-id5', {}),
        Activity.accessS3Buckets(this, 'example-id6', {s3buckets: [s3.S3Bucket.fromBucketName('DOC-EXAMPLE-BUCKET')]})
      ],
      // optional: to configure VPC permissions
      subnets: [ec2.Subnet.fromSubnetId('example-VPC-subnet-id')],
      securityGroups: [ec2.SecurityGroup.fromSecurityGroupId('example-VPC-security-group-id')],
      // optional: to configure KMS permissions
      dataKeys: [kms.Key.fromKeyArn('example-KMS-key-ARN')],
      volumeKeys: [kms.Key.fromKeyArn('example-KMS-key-ARN')]
    });
    const role = persona.createRole(this, 'example-IAM-role-id', 'example-IAM-role-name');
    const notebookInstance = new CfnNotebookInstance(this, 'example-notebook-instance-name', { RoleArn: role.RoleArn, ...});
  }
}
```

Grant permissions to an ML Ops persona

The following code creates an ML Ops persona with a set of ML activities specific to the persona. The permissions from ML activities only apply to the Amazon VPC and AWS KMS configurations specified in the persona construct. The following code creates a class for an ML Ops persona. The ML activities are defined in the activities list. The VPC permissions and the KMS permissions are defined as optional parameters outside of the activities list.

After you've defined the class, you can create a role as a construct within the AWS CDK stack. You can also create an Amazon SageMaker Studio user profile. The person who is using the IAM role that you've created in the following code can open SageMaker Studio when they log in to their AWS account.

```typescript
export class myCDKStack extends cdk.Stack {
  constructor(scope: cdk.App, id: string, props?: cdk.StackProps) {
    super(scope, id, props);
    const persona = new Persona(this, 'example-persona-id', {
      activities: [
        Activity.runStudioAppsV2(this, 'example-id1', {}),
        Activity.manageJobs(this, 'example-id2', {rolesToPass: [iam.Role.fromRoleName('example-IAM-role-name')]},
        Activity.manageModels(this, 'example-id3', {rolesToPass: [iam.Role.fromRoleName('example-IAM-role-name')]},
        Activity.manageExperiments(this, 'example-id4', {}),
        Activity.visualizeExperiments(this, 'example-id5', {}),
        Activity.accessS3Buckets(this, 'example-id6', {s3buckets: [s3.S3Bucket.fromBucketName('DOC-EXAMPLE-BUCKET')]})
      ],
      // optional: to configure VPC permissions
      subnets: [ec2.Subnet.fromSubnetId('example-VPC-subnet-id')],
      securityGroups: [ec2.SecurityGroup.fromSecurityGroupId('example-VPC-security-group-id')],
      // optional: to configure KMS permissions
      dataKeys: [kms.Key.fromKeyArn('example-KMS-key-ARN')],
      volumeKeys: [kms.Key.fromKeyArn('example-KMS-key-ARN')]
    });
    const role = persona.createRole(this, 'example-IAM-role-id', 'example-IAM-role-name');
    const notebookInstance = new CfnNotebookInstance(this, 'example-notebook-instance-name', { RoleArn: role.RoleArn, ...});
  }
}
```
Grant permissions to a construct

The following code creates an ML Ops persona with a set of ML activities specific to the persona. The following code creates a class for a ML Ops persona. The ML activities are defined in the activities list.

After you've defined the class, you can create a role as a construct within the AWS CDK stack. You can also create a notebook instance. The code grants permissions from the ML activities to the IAM role of the Lambda function.
Grant permissions for a single ML activity

The following code creates an ML activity and creates a role from the activity. The permissions from the activity only apply to the VPC and KMS configuration that you specify for the user.

```typescript
export class myCDKStack extends cdk.Stack {
  constructor(scope: cdk.App, id: string, props?: cdk.StackProps) {
    super(scope, id, props);

    const activity = Activity.manageJobs(this, 'example-activity-id', {
      rolesToPass: [iam.Role.fromRoleName('example-IAM-role-name')],
      subnets: [ec2.Subnet.fromSubnetId('example-VPC-subnet-id')],
      securityGroups: [ec2.SecurityGroup.fromSecurityGroupId('example-VPC-security-group-id')],
      dataKeys: [kms.Key.fromKeyArn('example-KMS-key-ARN')],
      volumeKeys: [kms.Key.fromKeyArn('example-KMS-key-ARN')],
    });

    const role = activity.createRole(this, 'example-IAM-role-id', 'example-IAM-role-name');
  }
}
```

Create a role and give it permissions for a single activity

The following code creates an IAM role for a single ML activity.

```typescript
export class myCDKStack extends cdk.Stack {
  constructor(scope: cdk.App, id: string, props?: cdk.StackProps) {
    super(scope, id, props);

    const activity = Activity.manageJobs(this, 'example-activity-id', {
      rolesToPass: [iam.Role.fromRoleName('example-IAM-role-name')],
    });

    activity.create_role(this, 'example-IAM-role-id', 'example-IAM-role-name');
  }
}
```

Persona reference

Amazon SageMaker Role Manager provides suggested permissions for a number of ML personas. These include user execution roles for common ML practitioner responsibilities as well as service execution roles for common AWS service interactions needed to work with SageMaker.

Each persona has suggested permissions in the form of selected ML activities. For information on predefined ML activities and their permissions, see [ML activity reference](p. 3418).

Data scientist persona

Use this persona to configure permissions to perform general machine learning development and experimentation in a SageMaker environment. This persona includes the following preselected ML activities:

- Run Studio Applications
- Manage ML Jobs
• Manage Models
• Manage Experiments
• Search and Visualize Experiments
• Amazon S3 Bucket Access

**MLOps persona**

Choose this persona to configure permissions for operational activities. This persona includes the following preselected ML activities:

• Run Studio Applications
• Manage Models
• Manage Endpoints
• Manage Pipelines
• Search and Visualize Experiments

**SageMaker compute persona**

*Note*

We recommend that you first use the role manager to create a SageMaker Compute Role so that SageMaker compute resources can perform tasks such as training and inference. Use the SageMaker Compute Role persona to create this role with the role manager. After creating a SageMaker Compute Role, take note of its ARN for future use.

This persona includes the following preselected ML activity:

• Access Required AWS Services

**ML activity reference**

ML activities are common AWS tasks related to machine learning with SageMaker that require specific IAM permissions. Each persona suggests related ML activities when creating a role with Amazon SageMaker Role Manager. You can select any additional ML activities or deselect any suggested ML activities to create a role that meets your unique business needs.

Amazon SageMaker Role Manager provides predefined permissions for the following ML activities:

<table>
<thead>
<tr>
<th>ML activity</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access Required AWS Services</td>

<tr>
<td>Query Athena Workgroups</td>
<td>Permissions to run and manage Amazon Athena queries.</td>
</tr>
</tbody>
</table>

### Launch Studio

Use your persona-focused roles to launch Studio. If you are an administrator, you can give your users access to Studio and have them assume their persona role either directly through the AWS Management Console or through the AWS IAM Identity Center.

**Launch Studio with AWS Management Console**

For data scientists or other users to assume their given persona through the AWS Management Console, they require a console role to get to the Studio environment.

You cannot use Amazon SageMaker Role Manager to create a role that grants permissions to the AWS Management Console. However, after creating a service role in the role manager, you can go to the IAM console to edit the role and add a user access role. The following is an example of a role that provides user access to the AWS Management Console:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DescribeCurrentDomain",
      "Effect": "Allow",
      "Action": "sagemaker:DescribeDomain",
    },
    {
      "Sid": "RemoveErrorMessagesFromConsole",
      "Effect": "Allow",
      "Action":
      ["servicecatalog:ListAcceptedPortfolioShares",
       "sagemaker:GetSagemakerServicecatalogPortfolioStatus",
       "sagemaker:ListModels",
       "sagemaker:ListTrainingJobs",
       ...
    }
  ]
}
```
In the Studio control panel, choose **Add User** to create a new user. In the **General Settings** section, give your user a name and set the **Default execution role** for the user to be the role that you created using Amazon SageMaker Role Manager.

On the next screen, choose the appropriate Jupyter Lab version, and whether to turn on SageMaker Jumpstart and SageMaker Project templates. Then choose **Next**. On the SageMaker Canvas settings page, choose whether to turn on SageMaker Canvas support, and additionally whether to allow for timeseries forecasting in SageMaker Canvas. Then choose **Submit**.

Your new user should now be visible in the Studio control panel. To test this user, choose **Studio** from the **Launch app** dropdown list in the same row as the user’s name.

**Launch Studio with IAM Identity Center**

To assign IAM Identity Center users to execution roles, the user must first exist in the IAM Identity Center directory. For more information, see Manage identities in IAM Identity Center in the AWS IAM Identity Center.

**Note**

Your IAM Identity Center Authentication directory and Studio Domain must be in the same AWS Region.

1. To assign IAM Identity Center users to your Studio Domain, choose **Assign users and Groups** in the Studio control panel. On the Assign users and groups screen select your data scientist user, and then choose **Assign Users and Groups**.
2. After the user is added to the Studio control panel, choose the user to open the user details screen.
3. On the User details screen, choose **Edit**.
4. On the Edit user profile screen, under **General settings**, modify the **Default execution role** to match the user execution role you've created for your data scientists.
5. Choose **Next** through the rest of the settings pages, and choose **Submit** to save your changes.

When your data scientist or other user logs into the IAM Identity Center portal, they see a tile for this Studio Domain. Choosing that tile logs them into Studio with their assigned user execution role.
Role Manager FAQs

Refer to the following FAQ items for answers to commonly asked questions about Amazon SageMaker Role Manager.

Q. How can I access Amazon SageMaker Role Manager?
A: You can access Amazon SageMaker Role Manager through multiple location in the Amazon SageMaker console. For information about accessing role manager and using it to create a role, see Using the role manager (console) (p. 3410).

Q. What are personas?
A: Personas are preconfigured groups of permissions based on common machine learning (ML) responsibilities. For example, the data science persona suggests permissions for general machine learning development and experimentation in a SageMaker environment, while the MLOps persona suggests permissions for ML activities related to operations.

Q. What are ML activities?
A: ML activities are common AWS tasks related to machine learning with SageMaker that require specific IAM permissions. Each persona suggests related ML activities when creating a role with Amazon SageMaker Role Manager. ML activities include tasks such as Amazon S3 full access or searching and visualizing experiments. For more information, see ML activity reference (p. 3418).

Q. Are the roles that I create with the role manager AWS Identity and Access Management (IAM) roles?
A: Yes. Roles created using the Amazon SageMaker Role Manager are IAM roles with customized access policies. You can view created roles in the Roles section of the IAM console.

Q. How can I view the roles that I created using Amazon SageMaker Role Manager?
A: You can view created roles in the Roles section of the IAM console. By default, the prefix "sagemaker-" is added to every role name for easier search in the IAM console. For example, if you named your role test-123 during role creation, your role shows up as sagemaker-test-123 in the IAM console.

Q. Can I modify a role made with Amazon SageMaker Role Manager once it is created?
A: Yes. You can modify the roles and policies created by Amazon SageMaker Role Manager through the IAM console. For more information, see Modifying a role in the AWS Identity and Access Management User Guide.

Q. Can I attach my own policies to roles created using Amazon SageMaker Role Manager?
A: Yes. You can attach any AWS or customer-managed IAM policies from your account to the role that you create using Amazon SageMaker Role Manager.

Q. How many policies can I add to a role that I create with Amazon SageMaker Role Manager?
A: The maximum limit for attaching managed policies to an IAM role or user is 20. The maximum character size limit for managed policies is 6,144. For more information, see IAM object quotas and IAM and AWS Security Token Service quotas name requirements, and character limits.

Q. Can I add conditions to ML activities?
A: Any conditions that you provide in Step 1. Enter role information (p. 3412) of the Amazon SageMaker Role Manager, such as subnets, security groups, or KMS keys, are automatically passed to any ML activities selected in Step 2. Configure ML activities (p. 3413). You can also add additional conditions to ML activities if necessary. For example, you might also add InstanceTypes or IntercontainerTrafficEncryption conditions to the Manage Training Jobs activity.
Q. Can I use tagging to manage access to any AWS resource?
A: You can add tags to your role in Step 3: Add additional policies and tags (p. 3413) of the Amazon SageMaker Role Manager. To successfully manage AWS resources using tags, you must add the same tag to both the role and any associated policies. For example, you can add a tag to a role and to an Amazon S3 bucket. Then, because the role passes the tag to the SageMaker session, only a user with that role can access that S3 bucket. You can add tags to a policy through the IAM console. For more information, see Tagging IAM roles in the AWS Identity and Access Management User Guide.

Q. Can I use Amazon SageMaker Role Manager to create a role to access the AWS Management Console?
A: No. However, after creating a service role in the role manager, you can go to the IAM console to edit the role and add a human access role in IAM console.

Q. What is difference between a user federation role and a SageMaker execution role?
A: A user federation role is directly assumed by a user to access AWS resources such as access to the AWS Management Console. A SageMaker execution role is assumed by the SageMaker service to perform a function on behalf of a user or an automation tool. For example, when a user opens a Studio instance, Studio assumes the execution role associated with the user profile in order to access AWS resources on the behalf of the user. If the user profile does not specify an execution role, then the execution role is specified at the Amazon SageMaker Domain level.

Q. If I am using a custom web application that accesses Studio through a presigned url, what role is used?
A: If you use a custom web application to access Studio, then you have a hybrid user federation role and SageMaker execution role. Be sure that this role has least privilege permissions for both what the user can do and what Studio can do on the associated user's behalf.

Q: Can I use Amazon SageMaker Role Manager with AWS IAM Identity Center authentication for my Studio domain?
A: AWS IAM Identity Center Studio Cloud Applications use a Studio execution role to grant permissions to federated users. This execution role can be specified at the Studio IAM Identity Center user profile level or the default domain level. User identities and groups must be synchronized into IAM Identity Center and the Studio user profile must be created with IAM Identity Center user assignment using CreateUserProfile. For more information, see Launch Studio with IAM Identity Center (p. 3420).

Amazon SageMaker API Permissions: Actions, Permissions, and Resources Reference

When you are setting up access control and writing a permissions policy that you can attach to an IAM identity (an identity-based policy), use the following as a reference. The each Amazon SageMaker API operation, the corresponding actions for which you can grant permissions to perform the action, and the AWS resource for which you can grant the permissions. You specify the actions in the policy's Action field, and you specify the resource value in the policy's Resource field.

Note
Except for the ListTags API, resource-level restrictions are not available on List- calls. Any user calling a List- API will see all resources of that type in the account.

To express conditions in your Amazon SageMaker policies, you can use AWS-wide condition keys. For a complete list of AWS-wide keys, see Available Keys in the IAM User Guide.

Warning
Some SageMaker API actions may still be accessible through the Search API. For example, if a user has an IAM policy that denies permissions to a Describe call for a particular SageMaker resource, that user can still access the description information through the Search API. To fully
restrict user access to Describe calls, you must also restrict access to the Search API. For a list of SageMaker resources that are accessible through the Search API, see the SageMaker Search AWS CLI Command Reference.

API Operation: **UpdateNotebookInstance**

Required Permissions (API Action): sagemaker:UpdateNotebookInstance, iam:PassRole

Resources: arn:aws:sagemaker:region:account-id:notebook-instance/notebookInstanceName

API Operation: **UpdateWorkteam**

Required Permissions (API Action): sagemaker:UpdateWorkteam
AWS Managed Policies for Amazon SageMaker

To add permissions to users, groups, and roles, it is easier to use AWS managed policies than to write policies yourself. It takes time and expertise to create IAM customer managed policies that provide your team with only the permissions they need. To get started quickly, you can use our AWS managed policies. These policies cover common use cases and are available in your AWS account. For more information about AWS managed policies, see AWS managed policies in the IAM User Guide.

AWS services maintain and update AWS managed policies. You can't change the permissions in AWS managed policies. Services occasionally add additional permissions to an AWS managed policy to support new features. This type of update affects all identities (users, groups, and roles) to which the policy is attached. Services are most likely to update an AWS managed policy when a new feature is launched or when new operations become available. Services do not remove permissions from an AWS managed policy, so policy updates won't break your existing permissions.

Additionally, AWS supports managed policies for job functions that span multiple services. For example, the ReadOnlyAccess AWS managed policy provides read-only access to all AWS services and resources. When a service launches a new feature, AWS adds read-only permissions for new operations and resources. For a list and descriptions of job function policies, see AWS managed policies for job functions in the IAM User Guide.

Important
We recommend that you use the most restricted policy that allows you to perform your use case.

The following AWS managed policies, which you can attach to users in your account, are specific to Amazon SageMaker:

- **AmazonSageMakerFullAccess** – Grants full access to Amazon SageMaker and SageMaker geospatial resources and the supported operations. This does not provide unrestricted Amazon S3 access, but supports buckets and objects with specific sagemaker tags. This policy allows all IAM roles to be passed to Amazon SageMaker, but only allows IAM roles with "AmazonSageMaker" in them to be passed to the AWS Glue, AWS Step Functions, and AWS RoboMaker services.

- **AmazonSageMakerReadOnly** – Grants read-only access to Amazon SageMaker resources.

The following AWS managed policies can be attached to users in your account but are not recommended:

- **AdministratorAccess** – Grants all actions for all AWS services and for all resources in the account.
- **DataScientist** – Grants a wide range of permissions to cover most of the use cases (primarily for analytics and business intelligence) encountered by data scientists.

You can review these permissions policies by signing in to the IAM console and searching for them.

You can also create your own custom IAM policies to allow permissions for Amazon SageMaker actions and resources as you need them. You can attach these custom policies to the users or groups that require them.

Topics

- AWS managed policy: AmazonSageMakerFullAccess (p. 3443)
- AWS managed policy: AmazonSageMakerReadOnly (p. 3452)
- AWS managed policies for Amazon SageMaker Canvas (p. 3453)
- AWS managed policies for Amazon SageMaker Feature Store (p. 3462)
AWS managed policy: AmazonSageMakerFullAccess

This policy grants administrative permissions that allow a principal full access to all Amazon SageMaker and SageMaker geospatial resources and operations. The policy also provides select access to related services. This policy allows all IAM roles to be passed to Amazon SageMaker, but only allows IAM roles with "AmazonSageMaker" in them to be passed to the AWS Glue, AWS Step Functions, and AWS RoboMaker services. This policy does not include permissions to create an Amazon SageMaker domain. For information on the policy needed to create a domain, see Create an Administrative User and Group (p. 9).

Permissions details

This policy includes the following permissions.

- application-autoscaling – Allows principals to automatically scale a SageMaker real-time inference endpoint.
- athena – Allows principals to query a list of data catalogs, databases, and table metadata from Amazon Athena.
- aws-marketplace – Allows principals to view AWS AI Marketplace subscriptions. You need this if you want to access SageMaker software subscribed in AWS Marketplace.
- cloudformation – Allows principals to get AWS CloudFormation templates for using SageMaker JumpStart solutions and Pipelines. SageMaker JumpStart creates resources necessary to run end-to-end machine learning solutions that tie SageMaker to other AWS services. SageMaker Pipelines creates new projects that are backed by Service Catalog.
- cloudwatch – Allows principals to post CloudWatch metrics, interact with alarms, and upload logs to CloudWatch Logs in your account.
- codebuild – Allows principals to store AWS CodeBuild artifacts for SageMaker Pipeline and Projects.
- codecommit – Needed for AWS CodeCommit integration with SageMaker notebook instances.
- cognito-idp – Needed for Amazon SageMaker Ground Truth to define private workforce and work teams.
- ec2 – Needed for SageMaker to manage Amazon EC2 resources and network interfaces when you specify an Amazon VPC for your SageMaker jobs, models, endpoints, and notebook instances.
- ecr – Needed to pull and store Docker artifacts for Amazon SageMaker Studio (custom images), training, processing, batch inference, and inference endpoints. This is also required to use your own container in SageMaker. Additional permissions for SageMaker JumpStart solutions are required to create and remove custom images on behalf of users.
- elastic-inference – Allows principals to connect to Amazon Elastic Inference for using SageMaker notebook instances and endpoints.
- elasticfilesystem – Allows principals to access Amazon Elastic File System. This is needed for SageMaker to use data sources in Amazon Elastic File System for training machine learning models.
- fsx – Allows principals to access Amazon FSx. This is needed for SageMaker to use data sources in Amazon FSx for training machine learning models.
• glue – Needed for inference pipeline pre-processing from within SageMaker notebook instances.
• groundtruthlabeling – Needed for Ground Truth labeling jobs. The groundtruthlabeling endpoint is accessed by the Ground Truth console.
• iam – Needed to give the SageMaker console access to available IAM roles and create service-linked roles.
• kms – Needed to give the SageMaker console access to available AWS KMS keys and retrieve them for any specified AWS KMS aliases in jobs and endpoints.
• lambda – Allows principals to invoke and get a list of AWS Lambda functions.
• logs – Needed to allow SageMaker jobs and endpoints to publish log streams.
• redshift – Allows principals to access Amazon Redshift cluster credentials.
• redshift-data – Allows principals to use data from Amazon Redshift to run, describe, and cancel statements; get statement results; and list schemas and tables.
• robomaker – Allows principals to have full access to create, get descriptions, and delete AWS RoboMaker simulation applications and jobs. This is also needed to run reinforcement learning examples on notebook instances.
• s3 – Allows principals to have full access to Amazon S3 resources pertaining to SageMaker, but not all of Amazon S3.
• sagemaker – Allows principals to list tags on SageMaker user profiles and add tags to SageMaker apps. Allows access only to SageMaker flow-definitions of sagemaker:WorkteamType "private-crowd" or "vendor-crowd".
• sagemaker and sagemaker-geospatial – Allows principals read-only access to SageMaker domains, user profiles, and spaces.
• secretsmanager – Allows principals to have full access to AWS Secrets Manager. The principals can securely encrypt, store, and retrieve credentials for databases and other services. This is also needed for SageMaker notebook instances with SageMaker code repositories that use GitHub.
• servicecatalog – Allows principals to use Service Catalog. The principals can create, get a list of, update, or terminate provisioned products, such as servers, databases, websites, or applications deployed using AWS resources. This is needed for SageMaker JumpStart and Projects to find and read service catalog products and launch AWS resources in users.
• sns – Allows principals to get a list of Amazon SNS topics. This is needed for endpoints with Async Inference enabled for notifying users that their inference has completed.
• states – Needed for SageMaker JumpStart and Pipelines to use a service catalog to create step function resources.
• tag – Needed for SageMaker Pipelines to render in Studio. Studio needs resources tagged with particular sagemaker:project-id tag-key. This requires the tag:GetResources permission.

AWS managed policy: AmazonSageMakerReadOnly

This policy grants read-only access to Amazon SageMaker through the AWS Management Console and SDK.

Permissions details

This policy includes the following permissions.

- **application-autoscaling** – Allows users to browse descriptions of scalable SageMaker real-time inference endpoints.
- **aws-marketplace** – Allows users to view AWS AI Marketplace subscriptions.
- **cloudwatch** – Allows users to receive CloudWatch alarms.
- **cognito-aside** – Needed for Amazon SageMaker Ground Truth to browse descriptions and lists of private workforce and work teams.
- **ecr** – Needed to read Docker artifacts for training and inference.

{
  "Version": "2012-10-17",
}
AWS managed policies for Amazon SageMaker Canvas

These AWS managed policies add permissions required to use Amazon SageMaker Canvas. The policies are available in your AWS account and are used by execution roles created from the SageMaker console.

Topics

- AWS managed policy: AmazonSageMakerCanvasFullAccess (p. 3453)
- AWS managed policy: AmazonSageMakerCanvasDirectDeployAccess (p. 3459)
- AWS managed policy: AmazonSageMakerCanvasForecastAccess (p. 3460)
- AWS managed policy: AmazonSageMakerCanvasAI SERVICESAccess (p. 3460)
- Amazon SageMaker updates to Amazon SageMaker Canvas managed policies (p. 3461)

AWS managed policy: AmazonSageMakerCanvasFullAccess

This policy grants permissions that allow full access to Amazon SageMaker Canvas through the AWS Management Console and SDK. The policy also provides select access to related services [for example,
This policy is intended to help customers experiment and get started with all the capabilities of SageMaker Canvas. For more fine-grained control, we suggest customers build their own scoped down versions as they move to production workloads. For more information, see IAM policy types: How and when to use them.

Permissions details

This AWS managed policy includes the following permissions.

- **sagemaker** – Allows principals to create and host SageMaker models on resources whose ARN contains "Canvas", "canvas", or "model-compilation-". Additionally, users can register their SageMaker Canvas model to SageMaker Model Registry in the same AWS account.
- **ec2** – Allows principals to create Amazon VPC endpoints.
- **ecr** – Allows principals to get information about a container image.
- **glue** – Allows principals to retrieve the tables in the catalog.
- **iam** – Allows principals to pass an IAM role to Amazon SageMaker and Amazon Forecast.
- **logs** – Allows principals to publish logs from training jobs and endpoints.
- **s3** – Allows principals to add and retrieve objects from Amazon S3 buckets. These objects are limited to those whose name includes "SageMaker", "Sagemaker", or "sagemaker". Also allows principals to retrieve objects from Amazon S3 buckets whose ARN starts with "jumpstart-cache-prod-" in specific regions.
- **secretsmanager** – Allows principals to store customer credentials to connect to a Snowflake database using Secrets Manager.
- **redshift** – Allows principals to get credentials for a "sagemaker_access*" dbuser on any Amazon Redshift cluster if that user exists.
- **redshift-data** – Allows principals to run queries on Amazon Redshift using the Amazon Redshift Data API. This only provides access to the Redshift Data APIs themselves and does not directly provide access to your Amazon Redshift clusters. For more information, see Using the Amazon Redshift Data API.
- **forecast** – Allows principals to use Amazon Forecast.
- **application-autoscaling** – Allows principals to automatically scale a SageMaker inference endpoint.
- **rds** – Allows principals to return information about provisioned Amazon RDS instances.

AWS managed policy: AmazonSageMakerCanvasDirectDeployAccess

This policy grants permissions needed for Amazon SageMaker Canvas to create and manage Amazon SageMaker endpoints.

Permissions details

This AWS managed policy includes the following permissions.

- **sagemaker** – Allows principals to create and manage SageMaker endpoints with an ARN resource name that starts with "Canvas" or "canvas".
- **cloudwatch** – Allows principals to retrieve Amazon CloudWatch metric data.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "SageMakerEndpointPerms",

            "Resource": "*"
        }
    ]
}
```
AWS managed policy: AmazonSageMakerCanvasForecastAccess

This policy grants permissions commonly needed to use Amazon SageMaker Canvas with Amazon Forecast.

Permissions details

This AWS managed policy includes the following permissions.

- **s3** – Allows principals to add and retrieve objects from Amazon S3 buckets. These objects are limited to those whose name starts with "sagemaker-".

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [

            "s3:PutObject"
         ],
         "Resource": [
            "arn:aws:s3:::sagemaker-*/Canvas",
            "arn:aws:s3:::sagemaker-*/canvas"
         ]
      },
      {
         "Effect": "Allow",
         "Action": [
            "s3:ListBucket"
         ],
         "Resource": [
            "arn:aws:s3:::sagemaker-*"
         ]
      }
   ]
}
```

AWS managed policy: AmazonSageMakerCanvasAIServicesAccess

This policy grants permissions for Amazon SageMaker Canvas to use Amazon Textract, Amazon Rekognition, and Amazon Comprehend.

Permissions details

This AWS managed policy includes the following permissions.

- **textract** – Allows principals to use Amazon Textract to detect documents, expenses, and identities within an image.
- **rekognition** – Allows principals to use Amazon Rekognition to detect labels and text within an image.
- **comprehend** – Allows principals to use Amazon Comprehend to detect sentiment and dominant language, and named and personally identifiable information (PII) entities within a text document.
- **bedrock** – Allows principals to use Amazon Bedrock to list and invoke foundation models.

**AWS managed policies for Amazon SageMaker Feature Store**

These AWS managed policies add permissions required to use Feature Store. The policies are available in your AWS account and are used by execution roles created from the SageMaker console.
Topics

- AWS managed policy: AmazonSageMakerFeatureStoreAccess (p. 3463)
- Amazon SageMaker updates to Amazon SageMaker Feature Store managed policies (p. 3464)

AWS managed policy: AmazonSageMakerFeatureStoreAccess

This policy grants permissions required to enable the offline store for an Amazon SageMaker Feature Store feature group.

Permissions details

This AWS managed policy includes the following permissions.

- s3 – Allows principals to write data into an offline store Amazon S3 bucket. These buckets are limited to those whose name includes "SageMaker", "Sagemaker", or "sagemaker".
- s3 – Allows principals to read existing manifest files maintained in the metadata folder of an offline store S3 bucket.
- glue – Allows principals to read and update AWS Glue tables. These permissions are limited to tables in the sagemaker_featurestore folder.

AWS managed policies for Amazon SageMaker geospatial

These AWS managed policies add permissions required to use SageMaker geospatial. The policies are available in your AWS account and are used by execution roles created from the SageMaker console.

Topics
- AWS managed policy: AmazonSageMakerGeospatialFullAccess (p. 3464)
- AWS managed policy: AmazonSageMakerGeospatialExecutionRole (p. 3465)
- Amazon SageMaker updates to Amazon SageMaker geospatial managed policies (p. 3465)

AWS managed policy: AmazonSageMakerGeospatialFullAccess

This policy grants permissions that allow full access to Amazon SageMaker geospatial through the AWS Management Console and SDK.

Permissions details

This AWS managed policy includes the following permissions.

- sagemaker-geospatial – Allows principals full access to all SageMaker geospatial resources.
- iam – Allows principals to pass an IAM role to SageMaker geospatial.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "sagemaker-geospatial:*",
            "Resource": "*"
        },
        {
```
"Effect": "Allow",
"Action": ["iam:PassRole"],
"Resource": "arn:aws:iam::*:role/*",
"Condition": {
  "StringEquals": {
    "iam:PassedToService": [
      "sagemaker-geospatial.amazonaws.com"
    ]
  }
}
]}

AWS managed policy: AmazonSageMakerGeospatialExecutionRole

This policy grants permissions commonly needed to use SageMaker geospatial.

Permissions details

This AWS managed policy includes the following permissions.

- **s3** – Allows principals to add and retrieve objects from Amazon S3 buckets. These objects are limited to those whose name contains "SageMaker", "Sagemaker", or "sagemaker".
- **sagemaker-geospatial** – Allows principals to access Earth observation jobs through the `GetEarthObservationJob` API.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      ]
    },
    {
      "Effect": "Allow",
      "Action": "sagemaker-geospatial:GetEarthObservationJob",
      "Resource": "arn:aws:sagemaker-geospatial:*:*:earth-observation-job/*"
    },
    {
      "Effect": "Allow",
      "Action": "sagemaker-geospatial:GetRasterDataCollection",
    }
  ]
}
```

Amazon SageMaker updates to Amazon SageMaker geospatial managed policies

AWS Managed Policies for Amazon SageMaker Ground Truth

These AWS managed policies add permissions required to use SageMaker Ground Truth. The policies are available in your AWS account and are used by execution roles created from the SageMaker console.

Topics

- AWS managed policy: AmazonSageMakerGroundTruthExecution (p. 3466)
- AWS managed policy: GroundTruthSyntheticConsoleFullAccess (p. 3469)
- AWS managed policy: GroundTruthSyntheticConsoleReadOnlyAccess (p. 3469)
- Amazon SageMaker updates to SageMaker Ground Truth managed policies (p. 3470)

AWS managed policy: AmazonSageMakerGroundTruthExecution

This AWS managed policy grants permissions commonly needed to use SageMaker Ground Truth.

Permissions details

This policy includes the following permissions.

- **lambda** – Allows principals to invoke Lambda functions whose name includes "sagemaker" (case-insensitive), "GtRecipe", or "LabelingFunction".
- **s3** – Allows principals to add and retrieve objects from Amazon S3 buckets. These objects are limited to those whose case-insensitive name contains "groundtruth" or "sagemaker", or are tagged with "SageMaker".
- **cloudwatch** – Allows principals to post CloudWatch metrics.
- **logs** – Allows principals to create and access log streams, and post log events.
- **sqs** – Allows principals to create Amazon SQS queues, and send and receive Amazon SQS messages. These permissions are limited to queues whose name includes "GroundTruth".
- **sns** – Allows principals to subscribe to and publish messages to Amazon SNS topics whose case-insensitive name contains "groundtruth" or "sagemaker".
- **ec2** – Allows principals to create, describe, and delete Amazon VPC endpoints whose VPC endpoint service name contains "sagemaker-task-resources" or "labeling".

```json
{
  "Version": "2012-10-17",

}
AWS managed policy: GroundTruthSyntheticConsoleFullAccess

This AWS managed policy grants permissions needed to use most features of the SageMaker Ground Truth synthetic data console. The policy is available in your AWS account. In order to use all features of the console, users must add "s3:GetObject" permissions to allow SageMaker Ground Truth synthetic data console to display data from their S3 buckets. This can be done by attaching the AmazonS3ReadOnlyAccess managed policy to their role or by adding "s3:GetObject" for specific S3 resources to their role.

Permissions details

This policy includes the following permissions.

- **s3** – Allows the retrieval of objects from Amazon S3 buckets to display data in the console.
- **sagemaker-groundtruth-synthetic** – Allows the console to call SageMaker Ground Truth synthetic data APIs.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "sagemaker-groundtruth-synthetic:*",
            "s3:ListBucket"
         ],
         "Resource": "*"
      }
   ]
}
```

AWS managed policy: GroundTruthSyntheticConsoleReadOnlyAccess

This AWS managed policy grants read-only access to SageMaker Ground Truth synthetic data via the AWS Management Console. In order to use all features of the console, users must add "s3:GetObject" permissions to allow SageMaker Ground Truth synthetic data console to display data from their S3 buckets. This can be done by attaching the AmazonS3ReadOnlyAccess managed policy to their role or by adding "s3:GetObject" for specific S3 resources to their role.

Permissions details

This policy includes the following permissions.

- **s3** – Allows the retrieval of objects from Amazon S3 buckets to display data in the console.
- **sagemaker-groundtruth-synthetic** – Allows the console to call SageMaker Ground Truth synthetic data ReadOnly APIs.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "sagemaker-groundtruth-synthetic:*",
            "s3:ListBucket"
         ],
         "Resource": "*"
      }
   ]
}
```

AWS Managed Policies for SageMaker Model Governance

This AWS managed policy adds permissions required to use SageMaker Model Governance. The policy is available in your AWS account and is used by execution roles created from the SageMaker console.

Topics

- AWS managed policy: AmazonSageMakerModelGovernanceUseAccess (p. 3470)
- Amazon SageMaker updates to SageMaker Model Governance managed policies (p. 3472)

AWS managed policy: AmazonSageMakerModelGovernanceUseAccess

This AWS managed policy grants permissions needed to use all Amazon SageMaker Governance features. The policy is available in your AWS account.
This policy includes the following permissions.

- **s3** – Retrieve objects from Amazon S3 buckets. Retrievable objects are limited to those whose case-insensitive name contains the string "sagemaker".
- **kms** – List the AWS KMS keys to use for content encryption.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [

AWS Managed Policies for Model Registry

These AWS managed policies adds permissions required to use Model Registry. The policies are available in your AWS account and are used by execution roles created from the Amazon SageMaker console.

Topics

- AWS managed policy: AmazonSageMakerModelRegistryFullAccess (p. 3472)
- Amazon SageMaker updates to Model Registry managed policies (p. 3475)

AWS managed policy: AmazonSageMakerModelRegistryFullAccess

This AWS managed policy grants permissions needed to use all Model Registry features inside an Amazon SageMaker domain. This policy is attached to an execution role when configuring Model Registry settings to enable Model Registry permissions.

This policy includes the following permissions.

- `ecr` – Allows principals to retrieve information, including metadata, about Amazon Elastic Container Registry (Amazon ECR) images.
- `iam` – Allows principals to pass the execution role to the Amazon SageMaker service.
- `resource-groups` – Allows principals to create, list, tag, and delete AWS Resource Groups.
- `s3` – Allows principals to retrieve objects from the Amazon Simple Storage Service (Amazon S3) buckets where model versions are stored. Retrievable objects are limited to those whose case-insensitive name contains the string "sagemaker". 
• **sagemaker** – Allows principals to catalog, manage, and deploy models using the SageMaker model registry.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "sagemaker:DescribeAction",
                "sagemaker:DescribeInferenceRecommendationsJob",
                "sagemaker:DescribeModelPackage",
                "sagemaker:DescribeModelPackageGroup",
                "sagemaker:DescribePipeline",
                "sagemaker:DescribePipelineExecution",
                "sagemaker:ListAssociations",
                "sagemaker:ListArtifacts",

AWS Managed Policies for SageMaker Notebooks

These AWS managed policies add permissions required to use SageMaker Notebooks. The policies are available in your AWS account and are used by execution roles created from the SageMaker console.

Topics
- AWS managed policy: AmazonSageMakerNotebooksServiceRolePolicy (p. 3475)
- Amazon SageMaker updates to SageMaker Notebooks managed policies (p. 3477)

AWS managed policy: AmazonSageMakerNotebooksServiceRolePolicy

This AWS managed policy grants permissions commonly needed to use Amazon SageMaker Notebooks. The policy is added to the AmazonSageMaker-ExecutionRole that is created when you onboard to Amazon SageMaker Studio. For more information on service-linked roles, see Service-Linked Roles (p. 3356).

Permissions details

This policy includes the following permissions.

- elasticfilesystem – Allows principals to create and delete Amazon Elastic File System (EFS) file systems, access points, and mount targets. These are limited to those tagged with the key ManagedByAmazonSageMakerResource. Allows principals to describe all EFS file systems, access points, and mount targets. Allows principals to create or overwrite tags for EFS access points and mount targets.
- ec2 – Allows principals to create network interfaces and security groups for Amazon Elastic Compute Cloud (EC2) instances. Also allows principals to create and overwrite tags for these resources.
- sso – Allows principals to add and delete managed application instances to AWS IAM Identity Center.
- sagemaker – Allows principals to create and read SageMaker user profiles.

**AWS Managed Policies for SageMaker Pipelines**

These AWS managed policies add permissions required to use SageMaker Pipelines. The policies are available in your AWS account and are used by execution roles created from the SageMaker console.

**Topics**
- AWS managed policy: AmazonSageMakerPipelinesIntegrations (p. 3478)
- Amazon SageMaker updates to SageMaker Pipelines managed policies (p. 3480)

**AWS managed policy: AmazonSageMakerPipelinesIntegrations**

This AWS managed policy grants permissions commonly needed to use Callback steps and Lambda steps in SageMaker Pipelines. The policy is added to the AmazonSageMaker-ExecutionRole that is created when you onboard to Amazon SageMaker Studio. The policy can be attached to any role used for authoring or executing a pipeline.

This policy grants appropriate AWS Lambda, Amazon Simple Queue Service (Amazon SQS), Amazon EventBridge, and IAM permissions needed when building pipelines that invoke Lambda functions or include callback steps, which can be used for manual approval steps or running custom workloads.

The Amazon SQS permissions allow you to create the Amazon SQS queue needed for receiving callback messages, and also to send messages to that queue.

The Lambda permissions allow you to create, read, update, and delete the Lambda functions used in the pipeline steps, and also to invoke those Lambda functions.

This policy grants the Amazon EMR permissions needed to run a pipelines Amazon EMR step.

**Permissions details**

This policy includes the following permissions.

- `elasticmapreduce` – Read, add, and cancel steps in a running Amazon EMR cluster. Read, create, and terminate a new Amazon EMR cluster.
- `events` – Read, create, update, and add targets to an EventBridge rule named SageMakerPipelineExecutionEMRStepStatusUpdateRule and SageMakerPipelineExecutionEMRClusterStatusUpdateRule.
- `iam` – Pass an IAM role to the AWS Lambda service, Amazon EMR and Amazon EC2.
- `lambda` – Create, read, update, delete, and invoke Lambda functions. These permissions are limited to functions whose name includes "sagemaker".
- `sqs` – Create an Amazon SQS queue; send an Amazon SQS message. These permissions are limited to queues whose name includes "sagemaker".

AWS Managed Policies for SageMaker projects and JumpStart

These AWS managed policies add permissions to use built-in Amazon SageMaker project templates and JumpStart solutions. The policies are available in your AWS account and are used by execution roles created from the SageMaker console.

SageMaker projects and JumpStart use AWS Service Catalog to provision AWS resources in customers' accounts. Some created resources need to assume an execution role. For example, if AWS Service Catalog creates a CodePipeline pipeline on behalf of a customer for a SageMaker machine learning CI/CD project, then that pipeline requires an IAM role.

The `AmazonSageMakerServiceCatalogProductsLaunchRole` role has the permissions required to launch the SageMaker portfolio of products from AWS Service Catalog. The `AmazonSageMakerServiceCatalogProductsUseRole` role has the permissions required to use the SageMaker portfolio of products from AWS Service Catalog. The `AmazonSageMakerServiceCatalogProductsLaunchRole` role passes an
AmazonSageMakerServiceCatalogProductsUseRole role to the provisioned AWS Service Catalog product resources.

- AWS managed policy: AmazonSageMakerServiceCatalogProductsFirehoseServiceRolePolicy
- AWS managed policy: AmazonSageMakerServiceCatalogProductsGlueServiceRolePolicy
- AWS managed policy: AmazonSageMakerServiceCatalogProductsLambdaServiceRolePolicy
- Amazon SageMaker updates to AWS Service Catalog AWS managed policies

**AWS managed policy: AmazonSageMakerAdmin-ServiceCatalogProductsServiceRolePolicy**

This service role policy is used by the AWS Service Catalog service to provision products from the Amazon SageMaker portfolio. The policy grants permissions to a set of related AWS services including AWS CodePipeline, AWS CodeBuild, AWS CodeCommit, AWS Glue, AWS CloudFormation, and others.

The AmazonSageMakerAdmin-ServiceCatalogProductsServiceRolePolicy policy is intended to be used by the AmazonSageMakerServiceCatalogProductsLaunchRole role created from the SageMaker console. The policy adds permissions to provision AWS resources for SageMaker projects and JumpStart using Service Catalog to a customer's account.

**Permissions details**

This policy includes the following permissions.

- **apigateway** – Allows the role to call API Gateway endpoints that are tagged with sagemaker:launch-source.
- **cloudformation** – Allows AWS Service Catalog to create, update and delete CloudFormation stacks.
- **codebuild** – Allows the role assumed by AWS Service Catalog and passed to CloudFormation to create, update and delete CodeBuild projects.
- **codecommit** – Allows the role assumed by AWS Service Catalog and passed to CloudFormation to create, update and delete CodeCommit repositories.
- **codepipeline** – Allows the role assumed by AWS Service Catalog and passed to CloudFormation to create, update and delete CodePipelines.
• codestar-connections – Allows the role to pass AWS CodeStar connections.
• cognito-idp – Allows the role to create, update, and delete groups and user pools. Also allows tagging resources.
• ecr – Allows the role assumed by AWS Service Catalog and passed to CloudFormation to create and delete Amazon ECR repositories. Also allows tagging resources.
• events – Allows the role assumed by AWS Service Catalog and passed to CloudFormation to create and delete EventBridge rules. Used for tying together the various components of the CICD pipeline.
• firehose – Allows the role to interact with Kinesis Data Firehose streams.
• glue – Allows the role to interact with AWS Glue.
• iam – Allows the role to pass roles prepended with AmazonSageMakerServiceCatalog. This is needed when Projects provisions a AWS Service Catalog product, as a role needs to be passed to AWS Service Catalog.
• lambda – Allows the role to interact with AWS Lambda. Also allows tagging resources.
• logs – Allows the role to create, delete and access log streams.
• s3 – Allows the role assumed by AWS Service Catalog and passed to CloudFormation to access Amazon S3 buckets where the Project template code is stored.
• sagemaker – Allows the role to interact with various SageMaker services. This is done both in CloudFormation during template provisioning, as well as in CodeBuild during CICD pipeline execution. Also allows tagging the following resources: endpoints, endpoint configurations, models, pipelines, projects, and model packages.
• states – Allows the role to create, delete, and update Step Functions prepended with sagemaker.

        },
        "StringEquals": {
          "aws:ResourceAccount": "${aws:PrincipalAccount}"}
      }
    }
  ]
}
```

AWS managed policy:
AmazonSageMakerPartnerServiceCatalogProductsCloudFormationServiceRolePolicy

This policy is used by AWS CloudFormation within the AWS Service Catalog provisioned products from the Amazon SageMaker portfolio. The policy is intended to be attached to an IAM role that the AmazonSageMakerServiceCatalogProductsLaunchRole passes to the AWS resources created by AWS CloudFormation that require a role.
Permissions details

This policy includes the following permissions.

- **iam** – Pass the AmazonSageMakerServiceCatalogProductsLambdaRole and AmazonSageMakerServiceCatalogProductsApiGatewayRole roles.
- **lambda** – Create, update, delete, and invoke AWS Lambda functions; retrieve, publish, and delete versions of a Lambda layer.
- **apigateway** – Create, update, and delete Amazon API Gateway resources.
- **s3** – Retrieve the lambda-auth-code/layer.zip file from an Amazon Simple Storage Service (Amazon S3) bucket.

AWS managed policy: 
AmazonSageMakerPartnerServiceCatalogProductsLambdaServiceRolePolicy

This policy is used by AWS Lambda within the AWS Service Catalog provisioned products from the Amazon SageMaker portfolio. The policy is intended to be attached to an IAM role that the AmazonSageMakerServiceCatalogProductsLaunchRole passes to the AWS resources created by Lambda that require a role.

Permissions details

This policy includes the following permissions.

- secretsmanager – Retrieve data from partner provided secrets for a partner template.

```json
{
"Version": "2012-10-17",
"Statement": [
{
"Effect": "Allow",
"Action": ["secretsmanager:GetSecretValue"],
"Resource": ["arn:aws:secretsmanager:*:*:secret:*"],
"Condition": {
"Null": {
"aws:ResourceTag/sagemaker:partner": false
},
"StringEquals": {
"aws:ResourceAccount": "${aws:PrincipalAccount}"
}
}
]
}
```
AWS managed policy: AmazonSageMakerServiceCatalogProductsApiGatewayServiceRolePolicy

This policy is used by Amazon API Gateway within the AWS Service Catalog provisioned products from the Amazon SageMaker portfolio. The policy is intended to be attached to an IAM role that the AmazonSageMakerServiceCatalogProductsLaunchRole passes to the AWS resources created by API Gateway that require a role.

Permissions details

This policy includes the following permissions.

- **Logs** – Create and read CloudWatch Logs groups, streams, and events; update events; describe various resources.

  These permissions are limited to resources whose log group prefix starts with "aws/apigateway/".

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "logs:CreateLogDelivery",

AWS managed policy:
AmazonSageMakerServiceCatalogProductsCodeBuildServiceRolePolicy

This policy is used by AWS CodeBuild within the AWS Service Catalog provisioned products from the Amazon SageMaker portfolio. The policy is intended to be attached to an IAM role that the AmazonSageMakerServiceCatalogProductsLaunchRole passes to the AWS resources created by CodeBuild that require a role.

Permissions details

This policy includes the following permissions.

- *sagemaker* – Allow access to various SageMaker resources.
- *codecommit* – Upload CodeCommit archives to CodeBuild pipelines, get upload status, and cancel uploads; get branch and commit information. These permissions are limited to resources whose name starts with "sagemaker-".
- *ecr* – Create Amazon ECR repositories and container images; upload image layers. These permissions are limited to repositories whose name starts with "sagemaker-".
  - *ecr* – Read all resources.
- *iam* – Pass the following roles:
  - AmazonSageMakerServiceCatalogProductsCloudformationRole to AWS CloudFormation.
  - AmazonSageMakerServiceCatalogProductsCodeBuildRole to AWS CodeBuild.
• AmazonSageMakerServiceCatalogProductsCodePipelineRole to AWS CodePipeline.
• AmazonSageMakerServiceCatalogProductsEventsRole to Amazon EventBridge.
• AmazonSageMakerServiceCatalogProductsExecutionRole to Amazon SageMaker.

• logs – Create and read CloudWatch Logs groups, streams, and events; update events; describe various resources.

These permissions are limited to resources whose name prefix starts with "aws/codebuild/".

• s3 – Create, read, and list Amazon S3 buckets. These permissions are limited to buckets whose name starts with "sagemaker-".

AWS managed policy:
AmazonSageMakerServiceCatalogProductsCodePipelineServiceRolePolicy

This policy is used by AWS CodePipeline within the AWS Service Catalog provisioned products from the Amazon SageMaker portfolio. The policy is intended to be attached to an IAM role that the AmazonSageMakerServiceCatalogProductsLaunchRole passes to the AWS resources created by CodePipeline that require a role.

Permissions details

This policy includes the following permissions.

- **cloudformation** – Create, read, delete, and update CloudFormation stacks; create, read, delete, and execute change sets; set stack policy. These permissions are limited to resources whose name starts with "sagemaker-".
- **s3** – Create, read, list, and delete Amazon S3 buckets; add, read, and delete objects from the buckets; read and set the CORS configuration; read the access control list (ACL); and read the AWS Region the bucket resides in.
  
  These permissions are limited to buckets whose name starts with "sagemaker-" or "aws-glue-".
- **iam** – Pass the AmazonSageMakerServiceCatalogProductsCloudformationRole role.
- **codebuild** – Get CodeBuild build information and start builds. These permissions are limited to project and build resources whose name starts with "sagemaker-".
- **codecommit** – Upload CodeCommit archives to CodeBuild pipelines, get upload status, and cancel uploads; get branch and commit information.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "cloudformation:CreateChangeSet",
        "cloudformation:CreateStack",
        "cloudformation:DescribeChangeSet",
        "cloudformation:DeleteChangeSet",
        "cloudformation:DeleteStack",
        "cloudformation:DescribeStacks",
        "cloudformation:ExecuteChangeSet",
      ]
    }
  ]
}
```
AWS managed policy:
AmazonSageMakerServiceCatalogProductsEventsServiceRolePolicy

This policy is used by Amazon EventBridge within the AWS Service Catalog provisioned products from the Amazon SageMaker portfolio. The policy is intended to be attached to an IAM role that the AmazonSageMakerServiceCatalogProductsLaunchRole passes to the AWS resources created by EventBridge that require a role.

Permissions details

This policy includes the following permissions.
• codepipeline – Start a CodeBuild execution. These permissions are limited to pipelines whose name starts with "sagemaker-".

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["codepipeline:StartPipelineExecution"],
      "Resource": "arn:aws:codepipeline:*:*:sagemaker-*"
    }
  ]
}
```

**AWS managed policy:**
**AmazonSageMakerServiceCatalogProductsFirehoseServiceRolePolicy**

This policy is used by Amazon Kinesis Data Firehose within the AWS Service Catalog provisioned products from the Amazon SageMaker portfolio. The policy is intended to be attached to an IAM role that the AmazonSageMakerServiceCatalogProductsLaunchRole passes to the AWS resources created by Kinesis Data Firehose that require a role.

**Permissions details**

This policy includes the following permissions.

• firehose – Send Kinesis Data Firehose records. These permissions are limited to resources whose delivery stream name starts with "sagemaker-".

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": ["firehose:PutRecord", "firehose:PutRecordBatch"],
      "Resource": "arn:aws:firehose::*:*:deliverystream/sagemaker-*"
    }
  ]
}
```

**AWS managed policy:**
**AmazonSageMakerServiceCatalogProductsGlueServiceRolePolicy**

This policy is used by AWS Glue within the AWS Service Catalog provisioned products from the Amazon SageMaker portfolio. The policy is intended to be attached to an IAM role that the AmazonSageMakerServiceCatalogProductsLaunchRole passes to the AWS resources created by Glue that require a role.

**Permissions details**

This policy includes the following permissions.

• glue – Create, read, and delete AWS Glue partitions, tables, and table versions. These permissions are limited to those resources whose name starts with "sagemaker-". Create and read AWS Glue databases.
These permissions are limited to databases whose name is "default", "global_temp", or starts with "sagemaker-". Get user defined functions.

- **s3** – Create, read, list, and delete Amazon S3 buckets; add, read, and delete objects from the buckets; read and set the CORS configuration; read the access control list (ACL), and read the AWS Region the bucket resides in.

  These permissions are limited to buckets whose name starts with "sagemaker-" or "aws-glue-".

- **logs** – Create, read, and delete CloudWatch Logs log group, streams, and deliveries; and create a resource policy.

  These permissions are limited to resources whose name prefix starts with "aws/glue".

```json
{
  "Version": "2012-10-17",

      "s3:ListBucket",
      "s3:ListBucketMultipartUploads",
      "s3:PutBucketCors"
    ]
  }
}
```
AWS Managed Policies for SageMaker

AWS managed policy:
**AmazonSageMakerServiceCatalogProductsLambdaServiceRolePolicy**

This policy is used by AWS Lambda within the AWS Service Catalog provisioned products from the Amazon SageMaker portfolio. The policy is intended to be attached to an IAM role that the **AmazonSageMakerServiceCatalogProductsLaunchRole** passes to the AWS resources created by Lambda that require a role.

**Permissions details**

This policy includes the following permissions.

- **sagemaker** – Allow access to various SageMaker resources.
- **ecr** – Create and delete Amazon ECR repositories; create, read, and delete container images; upload image layers. These permissions are limited to repositories whose name starts with "sagemaker-".
- **events** – Create, read, and delete Amazon EventBridge rules; and create and remove targets. These permissions are limited to rules whose name starts with "sagemaker-".
- **s3** – Create, read, list, and delete Amazon S3 buckets; add, read, and delete objects from the buckets; read and set the CORS configuration; read the access control list (ACL), and read the AWS Region the bucket resides in.

These permissions are limited to buckets whose name starts with "sagemaker-" or "aws-glue-".
• **iam** – Pass the `AmazonSageMakerServiceCatalogProductsExecutionRole` role.
• **logs** – Create, read, and delete CloudWatch Logs log group, streams, and deliveries; and create a resource policy.

These permissions are limited to resources whose name prefix starts with "aws/lambda/".

### Troubleshooting Amazon SageMaker Identity and Access

Use the following information to help you diagnose and fix common issues that you might encounter when working with SageMaker and IAM.

#### Topics
- I Am Not Authorized to Perform an Action in SageMaker (p. 3518)
- I Am Not Authorized to Perform iam:PassRole (p. 3519)
- I Want to Allow People Outside of My AWS Account to Access My SageMaker Resources (p. 3519)

### I Am Not Authorized to Perform an Action in SageMaker

If the AWS Management Console tells you that you're not authorized to perform an action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your sign-in credentials.

The following example error occurs when the mateojackson IAM user tries to use the console to view details about a training job but does not have sagemaker:sagemaker:DescribeTrainingJob permissions.

```
User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform: sagemaker:DescribeTrainingJob on resource: my-example-widget
```

In this case, Mateo asks his administrator to update his policies to allow him to access the TrainingJob resource using the sagemaker:DescribeTrainingJob action.
I Am Not Authorized to Perform `iam:PassRole`

If you receive an error that you're not authorized to perform the `iam:PassRole` action, your policies must be updated to allow you to pass a role to SageMaker.

Some AWS services allow you to pass an existing role to that service instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named `marymajor` tries to use the console to perform an action in SageMaker. However, the action requires the service to have permissions that are granted by a service role. Mary does not have permissions to pass the role to the service.

```plaintext
User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform: iam:PassRole
```

In this case, Mary's policies must be updated to allow her to perform the `iam:PassRole` action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

I Want to Allow People Outside of My AWS Account to Access My SageMaker Resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether SageMaker supports these features, see [How Amazon SageMaker Works with IAM](p. 3353).
- To learn how to provide access to your resources across AWS accounts that you own, see [Providing access to an IAM user in another AWS account that you own](in the IAM User Guide).
- To learn how to provide access to your resources to third-party AWS accounts, see [Providing access to AWS accounts owned by third parties](in the IAM User Guide).
- To learn how to provide access through identity federation, see [Providing access to externally authenticated users (identity federation)](in the IAM User Guide).
- To learn the difference between using roles and resource-based policies for cross-account access, see [How IAM roles differ from resource-based policies](in the IAM User Guide).

Logging and Monitoring

You can monitor Amazon SageMaker using Amazon CloudWatch, which collects raw data and processes it into readable, near real-time metrics. These statistics are kept for 15 months, so that you can access historical information and gain a better perspective on how your web application or service is performing. You can also set alarms that watch for certain thresholds and send notifications or take actions when those thresholds are met. For more information, see [Monitor Amazon SageMaker with Amazon CloudWatch](p. 3577).

Amazon CloudWatch Logs enables you to monitor, store, and access your log files from Amazon EC2 instances, AWS CloudTrail, and other sources. You can collect and track metrics, create customized dashboards, and set alarms that notify you or take actions when a specified metric reaches a threshold that you specify. CloudWatch Logs can monitor information in the log files and notify you when certain
thresholds are met. You can also archive your log data in highly durable storage. For more information, see Log Amazon SageMaker Events with Amazon CloudWatch (p. 3591).

AWS CloudTrail provides a record of actions taken by a user, role, or an AWS service in SageMaker. Using the information collected by CloudTrail, you can determine the request that was made to SageMaker, the IP address from which the request was made, who made the request, when it was made, and additional details. For more information, see Log Amazon SageMaker API Calls with AWS CloudTrail (p. 3592).

**Note**
CloudTrail does not monitor calls to `runtime_InvokeEndpoint`.

You can create rules in Amazon CloudWatch Events to react to status changes in status in a SageMaker training, hyperparameter tuning, or batch transform job. For more information, see Automating Amazon SageMaker with Amazon EventBridge (p. 3597).

---

**Compliance validation for Amazon SageMaker**

To learn whether an AWS service is within the scope of specific compliance programs, see AWS services in Scope by Compliance Program and choose the compliance program that you are interested in. For general information, see AWS Compliance Programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading Reports in AWS Artifact.

Your compliance responsibility when using AWS services is determined by the sensitivity of your data, your company's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- **Security and Compliance Quick Start Guides** – These deployment guides discuss architectural considerations and provide steps for deploying baseline environments on AWS that are security and compliance focused.
- **Architecting for HIPAA Security and Compliance on Amazon Web Services** – This whitepaper describes how companies can use AWS to create HIPAA-eligible applications.

**Note**
Not all AWS services are HIPAA eligible. For more information, see the HIPAA Eligible Services Reference.

- **AWS Compliance Resources** – This collection of workbooks and guides might apply to your industry and location.
- **Evaluating Resources with Rules** in the AWS Config Developer Guide – The AWS Config service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- **AWS Security Hub** – This AWS service provides a comprehensive view of your security state within AWS. Security Hub uses security controls to evaluate your AWS resources and to check your compliance against security industry standards and best practices. For a list of supported services and controls, see Security Hub controls reference.
- **AWS Audit Manager** – This AWS service helps you continuously audit your AWS usage to simplify how you manage risk and compliance with regulations and industry standards.

---

**Resilience in Amazon SageMaker**

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between Availability Zones without interruption.
Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about AWS Regions and Availability Zones, see AWS Global Infrastructure.

In addition to the AWS global infrastructure, Amazon SageMaker offers several features to help support your data resiliency and backup needs.

**Infrastructure Security in Amazon SageMaker**

As a managed service, Amazon SageMaker is protected by AWS global network security. For information about AWS security services and how AWS protects infrastructure, see AWS Cloud Security. To design your AWS environment using the best practices for infrastructure security, see Infrastructure Protection in Security Pillar AWS Well-Architected Framework.

You use AWS published API calls to access Amazon SageMaker through the network. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.
- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

Topics

- SageMaker Scans AWS Marketplace Training and Inference Containers for Security Vulnerabilities (p. 3521)
- Connect to Resources From Within a VPC (p. 3521)
- Run Training and Inference Containers in Internet-Free Mode (p. 3525)
- Connect to SageMaker Within your VPC (p. 3526)
- Give SageMaker Access to Resources in your Amazon VPC (p. 3538)

**SageMaker Scans AWS Marketplace Training and Inference Containers for Security Vulnerabilities**

To meet our security requirements, all the pre-built SageMaker images, including AWS Deep Learning Containers, the SageMaker machine learning framework containers, and the SageMaker built-in algorithm containers, and algorithms and model packages listed in AWS Marketplace are scanned for Common Vulnerabilities and Exposures (CVE). CVE is a list of publicly known information about security vulnerability and exposure. The National Vulnerability Database (NVD) provides CVE details such as severity, impact rating, and fix information. Both CVE and NVD are available for public consumption and free for security tools and services to use. For more information, see CVE Frequently Asked Questions (FAQs).

**Connect to Resources From Within a VPC**

Amazon SageMaker Studio and SageMaker notebook instances allow direct internet access by default. This allows you to download popular packages and notebooks, customize your development
environment, and work efficiently. However, this could provide an additional avenue for unauthorized access to your data. For example, if you install malicious code on your computer in the form of a publicly available notebook or a publicly available source code library, it could access your data. You can choose to restrict which traffic can access the internet by launching your Amazon SageMaker Studio and SageMaker notebook instances in an Amazon Virtual Private Cloud (Amazon VPC) of your choosing.

An Amazon Virtual Private Cloud is a virtual network dedicated to your AWS account. With an Amazon VPC, you can control the network access and internet connectivity of your Amazon SageMaker Studio and notebook instances. You can disable direct internet access to add an additional layer of security.

The following topics describe how to connect your SageMaker Studio instances and notebook instances to resources in a VPC.

Topics

• Connect SageMaker Studio Notebooks in a VPC to External Resources (p. 3522)
• Connect a Notebook Instance in a VPC to External Resources (p. 3524)

Connect SageMaker Studio Notebooks in a VPC to External Resources

The following topic gives information on how to connect Studio Notebooks in a VPC to external resources.

Default communication with the internet

By default, SageMaker Studio provides a network interface that allows communication with the internet through a VPC managed by SageMaker. Traffic to AWS services like Amazon S3 and CloudWatch goes through an internet gateway, as does traffic that accesses the SageMaker API and SageMaker runtime. Traffic between the domain and your Amazon EFS volume goes through the VPC that you specified when you onboarded to Studio or called the CreateDomain API. The following diagram shows the default configuration.

VPC only communication with the internet

To prevent SageMaker from providing internet access to your Studio notebooks, you can disable internet access by specifying the VPC only network access type when you onboard to Studio or call the CreateDomain API. As a result, you won't be able to run a Studio notebook unless your VPC has an
interface endpoint to the SageMaker API and runtime, or a NAT gateway with internet access, and your security groups allow outbound connections. The following diagram shows a configuration for using VPC-only mode.

![Diagram of VPC configuration]

**Requirements to use VPC only mode**

When you choose `VpcOnly`, follow these steps:

1. You must use private subnets only. You cannot use public subnets in `VpcOnly` mode.
2. Ensure your subnets have the required number of IP addresses needed. The expected number of IP addresses needed per user can vary based on use case. We recommend between 2 and 4 IP addresses per user. The total IP address capacity for a Studio domain is the sum of available IP addresses for each subnet provided when the domain is created. Ensure that your estimated IP address usage does not exceed the capacity supported by the number of subnets you provide. Additionally, using subnets distributed across many availability zones can aid in IP address availability. For more information, see [VPC and subnet sizing for IPv4](#).

   **Note**
   You can configure only subnets with a default tenancy VPC in which your instance runs on shared hardware. For more information on the tenancy attribute for VPCs, see [Dedicated Instances](#).

3. **Warning**
   When using `VpcOnly` mode, you partly own the networking configuration for the domain. We recommend the security best practice of applying least-privilege permissions to the inbound and outbound access that security group rules provide. Overly permissive inbound rule configurations could allow users with access to the VPC to interact with the applications of other user profiles without authentication.

   Set up one or more security groups with inbound and outbound rules that allow the following traffic:

   - **NFS traffic over TCP on port 2049** between the domain and the Amazon EFS volume.
   - **TCP traffic within the security group**. This is required for connectivity between the Jupyter Server application and the Kernel Gateway applications. You must allow access to at least ports in the range 8192–65535.

   Create a distinct security group for each user profile and add inbound access from that same security group. We do not recommend reusing a domain-level security group for user profiles. If the domain-
level security group allows inbound access to itself, then all applications in the domain would have access to all other applications in the domain.

4. If you want to allow internet access, you must use a **NAT gateway** with access to the internet, for example through an **internet gateway**.

5. If you don't want to allow internet access, **create interface VPC endpoints (AWS PrivateLink)** to allow Studio to access the following services with the corresponding service names. You must also associate the security groups for your VPC with these endpoints.

   • SageMaker API: `com.amazonaws.region.sagemaker.api`
   • SageMaker runtime: `com.amazonaws.region.sagemaker.runtime`. This is required to run Studio notebooks and to train and host models.
   • Amazon S3: `com.amazonaws.region.s3`
   • To use SageMaker Projects: `com.amazonaws.region.servicecatalog`.
   • Any other AWS services you require.

If you use the **SageMaker Python SDK** to run remote training jobs, you must also create the following Amazon VPC endpoints.

   • AWS Security Token Service: `com.amazonaws.region.sts`
   • Amazon CloudWatch: `com.amazonaws.region.logs`. This is required to allow SageMaker Python SDK to get the remote training job status from Amazon CloudWatch.

**Note**

For a customer working within VPC mode, company firewalls can cause connection issues with SageMaker Studio or between JupyterServer and the KernelGateway. Make the following checks if you encounter one of these issues when using SageMaker Studio from behind a firewall.

   • Check that the Studio URL is in your networks allowlist.
   • Check that the websocket connections are not blocked. Jupyter uses websocket under the hood. If the KernelGateway application is InService, JupyterServer may not be able to connect to the KernelGateway. You should see this problem when opening System Terminal as well.

**For more information**

- [Securing Amazon SageMaker Studio connectivity using a private VPC](#).
- [Security groups for your VPC](#).
- [Connect to SageMaker Within your VPC (p. 3526)](#).
- [VPC with public and private subnets (NAT)](#).

**Connect a Notebook Instance in a VPC to External Resources**

The following topic gives information on how to connect your notebook instance in a VPC to external resources.

**Default communication with the internet**

When your notebook allows **direct internet access**, SageMaker provides a network interface that allows the notebook to communicate with the internet through a VPC managed by SageMaker. Traffic within your VPC's CIDR goes through elastic network interface created in your VPC. All the other traffic goes through the network interface created by SageMaker, which is essentially through the public internet. Traffic to gateway VPC endpoints like Amazon S3 and DynamoDB goes through the public internet, while
traffic to interface VPC interface endpoints still goes through your VPC. If you want to use gateway VPC endpoints, you might want to disable direct internet access.

**VPC communication with the internet**

To disable direct internet access, you can specify a VPC for your notebook instance. By doing so, you prevent SageMaker from providing internet access to your notebook instance. As a result, the notebook instance can’t train or host models unless your VPC has an interface endpoint (AWS PrivateLink) or a NAT gateway and your security groups allow outbound connections.

For information about creating a VPC interface endpoint to use AWS PrivateLink for your notebook instance, see [Connect to a Notebook Instance Through a VPC Interface Endpoint](p. 3535). For information about setting up a NAT gateway for your VPC, see [VPC with Public and Private Subnets (NAT)] in the Amazon Virtual Private Cloud User Guide. For information about security groups, see [Security Groups for Your VPC](p. 3525). For more information about networking configurations in each networking mode and configuring network on premise, see [Understanding Amazon SageMaker notebook instance networking configurations and advanced routing options](p. 3525).

**Security and Shared Notebook Instances**

A SageMaker notebook instance is designed to work best for an individual user. It is designed to give data scientists and other users the most power for managing their development environment.

A notebook instance user has root access for installing packages and other pertinent software. We recommend that you exercise judgement when granting individuals access to notebook instances that are attached to a VPC that contains sensitive information. For example, you might grant a user access to a notebook instance with an IAM policy, as shown in the following example:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "sagemaker:CreatePresignedNotebookInstanceUrl",
    }
  ]
}
```

**Run Training and Inference Containers in Internet-Free Mode**

SageMaker training and deployed inference containers are internet-enabled by default. This allows containers to access external services and resources on the public internet as part of your training and inference workloads. However, this could provide an avenue for unauthorized access to your data. For example, a malicious user or code that you accidentally install on the container (in the form of a publicly available source code library) could access your data and transfer it to a remote host.

If you use an Amazon VPC by specifying a value for the VpcConfig parameter when you call `CreateTrainingJob`, `CreateHyperParameterTuningJob`, or `CreateModel`, you can protect your data and resources by managing security groups and restricting internet access from your VPC. However, this comes at the cost of additional network configuration, and has the risk of configuring your network incorrectly. If you do not want SageMaker to provide external network access to your training or inference containers, you can enable network isolation.
Network Isolation

You can enable network isolation when you create your training job or model by setting the value of the `EnableNetworkIsolation` parameter to `True` when you call `CreateTrainingJob`, `CreateHyperParameterTuningJob`, or `CreateModel`.

**Note**

Network isolation is required to run training jobs and models using resources from AWS Marketplace.

If you enable network isolation, the containers can’t make any outbound network calls, even to other AWS services such as Amazon S3. Additionally, no AWS credentials are made available to the container runtime environment. In the case of a training job with multiple instances, network inbound and outbound traffic is limited to the peers of each training container. SageMaker still performs download and upload operations against Amazon S3 using your SageMaker execution role in isolation from the training or inference container.

The following managed SageMaker containers do not support network isolation because they require access to Amazon S3:

- Chainer
- SageMaker Reinforcement Learning

Network isolation with a VPC

Network isolation can be used in conjunction with a VPC. In this scenario, the download and upload of customer data and model artifacts are routed through your VPC subnet. However, the training and inference containers themselves continue to be isolated from the network, and do not have access to any resource within your VPC or on the internet.

Connect to SageMaker Within your VPC

You can connect directly to the SageMaker API or to Amazon SageMaker Runtime through an interface endpoint in your virtual private cloud (VPC) instead of connecting over the internet. When you use a VPC interface endpoint, communication between your VPC and the SageMaker API or Runtime is conducted entirely and securely within an AWS network.

Connect to SageMaker through a VPC interface endpoint

The SageMaker API and SageMaker Runtime support Amazon Virtual Private Cloud (Amazon VPC) interface endpoints that are powered by AWS PrivateLink. Each VPC endpoint is represented by one or more Elastic Network Interfaces with private IP addresses in your VPC subnets. For example, an application inside your VPC uses AWS PrivateLink to communicate with SageMaker Runtime. SageMaker Runtime in turn communicates with the SageMaker endpoint. Using AWS PrivateLink allows you to invoke your SageMaker endpoint from within your VPC, as shown in the following diagram.
The VPC interface endpoint connects your VPC directly to the SageMaker API or SageMaker Runtime using AWS PrivateLink without using an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. The instances in your VPC do not need to connect to the public internet in order to communicate with the SageMaker API or SageMaker Runtime.

You can create an AWS PrivateLink interface endpoint to connect to SageMaker or to SageMaker Runtime using either the AWS Management Console or AWS Command Line Interface (AWS CLI). For instructions, see Creating an Interface Endpoint.

If you haven't enabled a private Domain Name System (DNS) hostname for your VPC endpoint, after you have created a VPC endpoint, specify the internet endpoint URL to the SageMaker API or SageMaker Runtime. Example code using AWS CLI commands to specify the endpoint-url parameter follows.

```bash
aws sagemaker list-notebook-instances --endpoint-url VPC_Endpoint_ID.api.sagemaker.Region.vpce.amazonaws.com
aws sagemaker list-training-jobs --endpoint-url VPC_Endpoint_ID.api.sagemaker.Region.vpce.amazonaws.com
aws sagemaker-runtime invoke-endpoint --endpoint-url VPC_Endpoint_ID.runtime.sagemaker.Region.vpce.amazonaws.com --endpoint-name Endpoint_Name --body "Endpoint_Body" --content-type "Content_Type" Output_File
```

If you enable private DNS hostnames for your VPC endpoint, you don't need to specify the endpoint URL because the default hostname (https://api.sagemaker.Region.amazonaws.com) resolves to your VPC endpoint. Similarly, the default SageMaker Runtime DNS hostname (https://runtime.sagemaker.Region.amazonaws.com) also resolves to your VPC endpoint.

The SageMaker API and SageMaker Runtime support VPC endpoints in all AWS Regions where both Amazon VPC and SageMaker are available. SageMaker supports making calls to all of its Operations inside your VPC. The result AuthorizedUrl from the CreatePresignedNotebookInstanceUrl command is not supported by AWS PrivateLink. For information about how to enable AWS PrivateLink for the authorized URL that users use to connect to a notebook instance, see Connect to a Notebook Instance Through a VPC Interface Endpoint (p. 3535).

**Note**

When setting up a VPC interface endpoint for the SageMaker Runtime service (https://runtime.sagemaker.Region.amazonaws.com), you must ensure that the VPC interface endpoint...
is activated in the Availability Zone of your client in order for private DNS resolution to work. Otherwise, you may see DNS failures when attempting to resolve the URL.

To learn more about AWS PrivateLink, see the AWS PrivateLink documentation. Refer to AWS PrivateLink Pricing for the price of VPC endpoints. To learn more about VPC and endpoints, see Amazon VPC. For information about how to use identity-based AWS Identity and Access Management policies to restrict access to the SageMaker API and SageMaker Runtime, see Control Access to the SageMaker API by Using Identity-based Policies (p. 3373).

Using SageMaker training and hosting with resources inside your VPC

SageMaker uses your execution role to download and upload information from an Amazon S3 bucket and Amazon Elastic Container Registry (Amazon ECR), in isolation from your training or inference container. If you have resources that are located inside your VPC, you can still grant SageMaker access to those resources. The following sections explain how to make your resources available to SageMaker with or without network isolation.

Without network isolation enabled

If you haven’t set network isolation on your training job or model, SageMaker can access resources using either of the following methods.

- SageMaker training and deployed inference containers can access the internet by default. SageMaker containers are able to access external services and resources on the public internet as part of your training and inference workloads. SageMaker containers are not able to access resources inside your VPC without a VPC configuration, as shown in the following illustration.

- Use a VPC configuration to communicate with resources inside your VPC through an elastic network interface (ENI). The communication between the container and the resources in your VPC takes place securely within your VPC network, as shown in the following illustration. In this case, you manage networking access to your VPC resources and internet.
With network isolation

If you employ network isolation, the SageMaker container can't communicate with resources inside your VPC or make any network calls, as shown in the following illustration. If you provide a VPC configuration, the download and upload operations will be run through your VPC. For more information about hosting and training with network isolation while using a VPC, see Network Isolation (p. 3526).
Create a VPC Endpoint Policy for SageMaker

You can create a policy for Amazon VPC endpoints for SageMaker to specify the following:

- The principal that can perform actions.
- The actions that can be performed.
- The resources on which actions can be performed.

For more information, see Controlling Access to Services with VPC Endpoints in the Amazon VPC User Guide.

**Note**
VPC endpoint policies aren't supported for Federal Information Processing Standard (FIPS) SageMaker runtime endpoints for `runtime_InvokeEndpoint`.

The following example VPC endpoint policy specifies that all users who have access to the VPC interface endpoint are allowed to invoke the SageMaker hosted endpoint named `myEndpoint`.

```json
{
    "Statement": [
        {
            "Action": "sagemaker:InvokeEndpoint",
            "Effect": "Allow",
            "Principal": "*"
        }
    ]
}
```

In this example, the following are denied:

- Other SageMaker API actions, such as `sagemaker:CreateEndpoint` and `sagemaker:CreateTrainingJob`.
- Invoking SageMaker hosted endpoints other than `myEndpoint`.

**Note**
In this example, users can still take other SageMaker API actions from outside the VPC. For information about how to restrict API calls to those from within the VPC, see Control Access to the SageMaker API by Using Identity-based Policies (p. 3373).

Create a VPC Endpoint Policy for Amazon SageMaker Feature Store

To create a VPC Endpoint for Amazon SageMaker Feature Store, use the following endpoint template, substituting your `VPC_Endpoint_ID.api` and `Region`:

`VPC_Endpoint_ID.api.featurestore-runtime.sagemaker.Region.vpce.amazonaws.com`

Connect to SageMaker Studio Through an Interface VPC Endpoint

You can connect to Amazon SageMaker Studio from your Amazon Virtual Private Cloud (Amazon VPC) through an interface endpoint in your VPC instead of connecting over the internet. When you use an interface VPC endpoint (interface endpoint), communication between your VPC and Studio is conducted entirely and securely within the AWS network.
SageMaker Studio supports interface endpoints that are powered by AWS PrivateLink. Each interface endpoint is represented by one or more Elastic network interfaces with private IP addresses in your VPC subnets.

Studio supports interface endpoints in all AWS Regions where both Amazon SageMaker and Amazon VPC are available.

Topics
• Create a VPC Endpoint (p. 3531)
• Create a VPC Endpoint Policy for SageMaker Studio (p. 3531)
• Allow Access Only from Within Your VPC (p. 3532)

Create a VPC Endpoint

You can create an interface endpoint to connect to Studio with either the AWS console or the AWS Command Line Interface (AWS CLI). For instructions, see Creating an interface endpoint. Make sure that you create interface endpoints for all of the subnets in your VPC from which you want to connect to Studio.

When you create an interface endpoint, ensure that the security groups on your endpoint allow inbound access for HTTPS traffic from the security groups associated with SageMaker Studio. For more information, see Control access to services with VPC endpoints.

Note
In addition to creating an interface endpoint to connect to SageMaker Studio, create an interface endpoint to connect to the Amazon SageMaker API. When users call CreatePresignedDomainUrl to get the URL to connect to Studio, that call goes through the interface endpoint used to connect to the SageMaker API.

When you create the interface endpoint, specify aws.sagemaker.Region.studio as the service name. After you create the interface endpoint, enable private DNS for your endpoint. When you connect to SageMaker Studio from within the VPC using the SageMaker API, the AWS CLI, or the console, you connect through the interface endpoint instead of the public internet. You also need to set up a custom DNS with private hosted zones for the Amazon VPC endpoint so SageMaker Studio can access the SageMaker API using the api.sagemaker.$region.amazonaws.com endpoint rather than using the VPC endpoint URL. For instructions on setting up a private hosted zone, see Working with private hosted zones.

Create a VPC Endpoint Policy for SageMaker Studio

You can attach an Amazon VPC endpoint policy to the interface VPC endpoints that you use to connect to SageMaker Studio. The endpoint policy controls access to Studio. You can specify the following:

• The principal that can perform actions.
• The actions that can be performed.
• The resources on which actions can be performed.

To use a VPC endpoint with SageMaker Studio, your endpoint policy must allow the CreateApp operation on the KernelGateway app type. This allows traffic that is routed to through the VPC endpoint to call the CreateApp API. The following example VPC endpoint policy shows how to allow the CreateApp operation.

```json
{
    "Statement": [
        {
            "Action": "sagemaker:CreateApp",
```
Connect to SageMaker Within your VPC

"Effect": "Allow",
"Principal": "*"
]
]

For more information, see Controlling access to services with VPC endpoints.

The following example of a VPC endpoint policy specifies that all users that have access to the endpoint are allowed to access the user profiles in the SageMaker Studio domain with the specified domain ID. Access to other domains is denied.

```
{
  "Statement": [
    {
      "Action": "sagemaker:CreatePresignedDomainUrl",
      "Effect": "Allow",
      "Principal": "*"
    }
  ]
}
```

Allow Access Only from Within Your VPC

Users outside your VPC can connect to SageMaker Studio over the internet even if you set up an interface endpoint in your VPC.

To allow access to only connections made from within your VPC, create an AWS Identity and Access Management (IAM) policy to that effect. Add that policy to every user, group, or role used to access Studio. This feature is only supported in IAM mode, and is not supported in IAM Identity Center mode. The following examples demonstrate how to create such policies.

**Important**

If you apply an IAM policy similar to one of the following examples, users can't access SageMaker Studio or the specified SageMaker APIs through the SageMaker console. To access Studio, users must use a presigned URL or call the SageMaker APIs directly.

**Example 1: Allow connections only within the subnet of an interface endpoint**

The following policy allows connections only to callers within the subnet where you created the interface endpoint.

```
{
  "Id": "sagemaker-studio-example-1",
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Enable SageMaker Studio Access",
      "Effect": "Allow",
      "Action": [
        "sagemaker:CreatePresignedDomainUrl",
        "sagemaker:DescribeUserProfile"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "aws:SourceVpc": "vpc-111bbaaa"
        }
      }
    }
  ]
}
```
Example 2: Allow connections only through interface endpoints using `aws:sourceVpce`

The following policy allows connections only to those made through the interface endpoints specified by the `aws:sourceVpce` condition key. For example, the first interface endpoint could allow access through the SageMaker Studio Control Panel. The second interface endpoint could allow access through the SageMaker API.

```json
{
    "Id": "sagemaker-studio-example-2",
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Enable SageMaker Studio Access",
            "Effect": "Allow",
            "Action": [
                "sagemaker:CreatePresignedDomainUrl",
                "sagemaker:DescribeUserProfile"
            ],
            "Resource": "*",
            "Condition": {
                "ForAnyValue:StringEquals": {
                    "aws:sourceVpce": [
                        "vpce-111bbcccc",
                        "vpce-111bbdddd"
                    ]
                }
            }
        }
    ]
}
```

This policy includes the `DescribeUserProfile` action. Typically you call `DescribeUserProfile` to make sure that the status of the user profile is `InService` before you try to connect to the domain. For example:

```bash
aws sagemaker describe-user-profile
  --domain-id domain-id
  --user-profile-name profile-name
```

Response:

```json
{
    "DomainId": "domain-id",
    "UserProfileName": "profile-name",
    "HomeEfsFileSystemUid": "200001",
    "Status": "InService",
    "LastModifiedTime": 1605418785.555,
    "CreationTime": 1605418477.297
}
```

```bash
aws sagemaker create-presigned-domain-url
  --domain-id domain-id
  --user-profile-name profile-name
```

Response:
For both of these calls, if you are using a version of the AWS SDK that was released before August 13, 2018, you must specify the endpoint URL in the call. For example, the following example shows a call to `create-presigned-domain-url`:

```bash
aws sagemaker create-presigned-domain-url
--domain-id domain-id
--user-profile-name profile-name
--endpoint-url vpc-endpoint-id.api.sagemaker.Region.vpce.amazonaws.com
```

---

**Example 3: Allow connections from IP addresses using **aws:**SourceIp**

The following policy allows connections only from the specified range of IP addresses using the `aws:SourceIp` condition key.

```json
{
    "Id": "sagemaker-studio-example-3",
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Enable SageMaker Studio Access",
            "Effect": "Allow",
            "Action": [
                "sagemaker:CreatePresignedDomainUrl",
                "sagemaker:DescribeUserProfile"
            ],
            "Resource": "*",
            "Condition": {
                "IpAddress": {
                    "aws:SourceIp": [
                        "192.0.2.0/24",
                        "203.0.113.0/24"
                    ]
                }
            }
        }
    ]
}
```

---

**Example 4: Allow connections from IP addresses through an interface endpoint using **aws:**VpcSourceIp**

If you are accessing SageMaker Studio through an interface endpoint, you can use the `aws:VpcSourceIp` condition key to allow connections only from the specified range of IP addresses within the subnet where you created the interface endpoint as shown in the following policy:

```json
{
    "Id": "sagemaker-studio-example-4",
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Enable SageMaker Studio Access",
            "Effect": "Allow",
            "Action": [
                "sagemaker:CreatePresignedDomainUrl",
                "sagemaker:DescribeUserProfile"
            ],
            "Resource": "*",
            "Condition": {
                "IpAddress": {
                    "aws:VpcSourceIp": [
                        "192.0.2.0/24",
                        "203.0.113.0/24"
                    ]
                }
            }
        }
    ]
}
```
Connect to a Notebook Instance Through a VPC Interface Endpoint

You can connect to your notebook instance from your VPC through an interface endpoint in your Virtual Private Cloud (VPC) instead of connecting over the public internet. When you use a VPC interface endpoint, communication between your VPC and the notebook instance is conducted entirely and securely within the AWS network.

SageMaker notebook instances support Amazon Virtual Private Cloud (Amazon VPC) interface endpoints that are powered by AWS PrivateLink. Each VPC endpoint is represented by one or more Elastic Network Interfaces with private IP addresses in your VPC subnets.

Note
Before you create an interface VPC endpoint to connect to a notebook instance, create an interface VPC endpoint to connect to the SageMaker API. That way, when users call CreatePresignedNotebookInstanceUrl to get the URL to connect to the notebook instance, that call also goes through the interface VPC endpoint. For information, see Connect to SageMaker Within your VPC (p. 3526).

You can create an interface endpoint to connect to your notebook instance with either the AWS Management Console or AWS Command Line Interface (AWS CLI) commands. For instructions, see Creating an Interface Endpoint. Make sure that you create an interface endpoint for all of the subnets in your VPC from which you want to connect to the notebook instance.

When you create the interface endpoint, specify aws.sagemaker.Region.notebook as the service name. After you create a VPC endpoint, enable private DNS for your VPC endpoint. Anyone using the SageMaker API, the AWS CLI, or the console to connect to the notebook instance from within the VPC connects to the notebook instance through the VPC endpoint instead of the public internet.

SageMaker notebook instances support VPC endpoints in all AWS Regions where both Amazon VPC and SageMaker are available.

Topics
- Connect Your Private Network to Your VPC (p. 3535)
- Create a VPC Endpoint Policy for SageMaker Notebook Instances (p. 3536)
- Restrict Access to Connections from Within Your VPC (p. 3536)

Connect Your Private Network to Your VPC

To connect to your notebook instance through your VPC, you either have to connect from an instance that is inside the VPC, or connect your private network to your VPC by using an AWS Virtual Private
Connect to SageMaker Within your VPC

Network (AWS VPN) or AWS Direct Connect. For information about AWS VPN, see VPN Connections in the Amazon Virtual Private Cloud User Guide. For information about AWS Direct Connect, see Creating a Connection in the AWS Direct Connect User Guide.

Create a VPC Endpoint Policy for SageMaker Notebook Instances

You can create a policy for Amazon VPC endpoints for SageMaker notebook instances to specify the following:

- The principal that can perform actions.
- The actions that can be performed.
- The resources on which actions can be performed.

For more information, see Controlling Access to Services with VPC Endpoints in the Amazon VPC User Guide.

The following example of a VPC endpoint policy specifies that all users that have access to the endpoint are allowed to access the notebook instance named myNotebookInstance.

```
{
    "Statement": [
        {
            "Action": "sagemaker:CreatePresignedNotebookInstanceUrl",
            "Effect": "Allow",
            "Principal": "*
        }
    ]
}
```

Access to other notebook instances is denied.

Restrict Access to Connections from Within Your VPC

Even if you set up an interface endpoint in your VPC, individuals outside the VPC can connect to the notebook instance over the internet.

Important
If you apply an IAM policy similar to one of the following, users can't access the specified SageMaker APIs or the notebook instance through the console.

To restrict access to only connections made from within your VPC, create an AWS Identity and Access Management policy that restricts access to only calls that come from within your VPC. Then add that policy to every AWS Identity and Access Management user, group, or role used to access the notebook instance.

Note
This policy allows connections only to callers within a subnet where you created an interface endpoint.

```
{
    "Id": "notebook-example-1",
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Enable Notebook Access",
            "Effect": "Allow",
            "Action": "sagemaker:CreatePresignedNotebookInstanceUrl",
```
If you want to restrict access to the notebook instance to only connections made using the interface endpoint, use the `aws:SourceVpce` condition key instead of `aws:SourceVpc`:

```json
{
  "Id": "notebook-example-1",
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Enable Notebook Access",
      "Effect": "Allow",
      "Action": [
        "sagemaker:CreatePresignedNotebookInstanceUrl",
        "sagemaker:DescribeNotebookInstance"
      ],
      "Resource": "*",
      "Condition": {
        "ForAnyValue:StringEquals": {
          "aws:sourceVpce": [
            "vpce-111bbccc",
            "vpce-111bbddd"
          ]
        }
      }
    }
  ]
}
```

Both of these policy examples assume that you have also created an interface endpoint for the SageMaker API. For more information, see Connect to SageMaker Within your VPC (p. 3526). In the second example, one of the values for `aws:SourceVpce` is the ID of the interface endpoint for the notebook instance. The other is the ID of the interface endpoint for the SageMaker API.

The policy examples here include `DescribeNotebookInstance`, because typically you would call DescribeNotebookInstance to make sure that the `NotebookInstanceStatus` is `InService` before you try to connect to it. For example:

```
aws sagemaker describe-notebook-instance \
  --notebook-instance-name myNotebookInstance
```

```json
{
  "NotebookInstanceArn":
  "NotebookInstanceName": "myNotebookInstance",
  "NotebookInstanceStatus": "InService",
  "Url": "mynotebookinstance.notebook.us-west-2.sagemaker.aws",
  "InstanceType": "ml.m4.xlarge",
  "RoleArn":
    "arn:aws:iam::1234567890ab:role/service-role/AmazonSageMaker-ExecutionRole-12345678T1234563",
```
aws sagemaker create-presigned-notebook-instance-url --notebook-instance-name myNotebookInstance

{
  "AuthorizedUrl": "https://mynotebookinstance.notebook.us-west-2.sagemaker.aws?
authToken=AuthToken"
}

**Note**
The presigned-notebook-instance-url, AuthorizedUrl, generated can be used from anywhere on the internet.

For both of these calls, if you did not enable private DNS hostnames for your VPC endpoint, or if you are using a version of the AWS SDK that was released before August 13, 2018, you must specify the endpoint URL in the call. For example, the call to create-presigned-notebook-instance-url is:

```bash
aws sagemaker create-presigned-notebook-instance-url
--notebook-instance-name myNotebookInstance
--endpoint-url VPC_Endpoint_ID.api.sagemaker.Region.vpce.amazonaws.com
```

### Connect Your Private Network to Your VPC

To call the SageMaker API and SageMaker Runtime through your VPC, you have to connect from an instance that is inside the VPC or connect your private network to your VPC by using an AWS Virtual Private Network (AWS VPN) or AWS Direct Connect. For information about AWS VPN, see [VPN Connections](https://docs.aws.amazon.com/vpc/userguide/vpc-connections.html) in the *Amazon Virtual Private Cloud User Guide*. For information about AWS Direct Connect, see [Creating a Connection](https://docs.aws.amazon.com/directconnect/latest/userguide/creating-a-connection.html) in the *AWS Direct Connect User Guide*.

### Give SageMaker Access to Resources in your Amazon VPC

SageMaker runs the following job types in an Amazon Virtual Private Cloud by default.

- Processing
- Training
- Model hosting
- Batch transform
- Amazon SageMaker Clarify
- SageMaker Compilation

However, containers for these jobs access AWS resources—such as the Amazon Simple Storage Service (Amazon S3) buckets where you store training data and model artifacts—over the internet.

To control access to your data and job containers, we recommend that you create a private VPC and configure it so that they aren’t accessible over the internet. For information about creating and configuring a VPC, see [Getting Started With Amazon VPC](https://docs.aws.amazon.com/vpc/latest/userguide/getting-started.html) in the *Amazon VPC User Guide*. Using a VPC helps to protect your job containers and data because you can configure your VPC so that it is not connected to the internet. Using a VPC also allows you to monitor all network traffic in and out of your job containers by using VPC flow logs. For more information, see [VPC Flow Logs](https://docs.aws.amazon.com/vpc/latest/userguide/flow-logs.html) in the *Amazon VPC User Guide*. 

You specify your private VPC configuration when you create jobs by specifying subnets and security groups. When you specify the subnets and security groups, SageMaker creates elastic network interfaces that are associated with your security groups in one of the subnets. Network interfaces allow your job containers to connect to resources in your VPC. For information about network interfaces, see Elastic Network Interfaces in the Amazon VPC User Guide.

Topics
- Give SageMaker Processing Jobs Access to Resources in Your Amazon VPC (p. 3539)
- Give SageMaker Training Jobs Access to Resources in Your Amazon VPC (p. 3542)
- Give SageMaker Hosted Endpoints Access to Resources in Your Amazon VPC (p. 3545)
- Give Batch Transform Jobs Access to Resources in Your Amazon VPC (p. 3548)
- Give Amazon SageMaker Clarify Jobs Access to Resources in Your Amazon VPC (p. 3551)

Give SageMaker Processing Jobs Access to Resources in Your Amazon VPC

To control access to your data and processing jobs, create a Amazon VPC with private subnets. For information about creating and configuring a VPC, see Get Started With Amazon VPC in the Amazon VPC User Guide.

You can monitor all network traffic in and out of your processing containers by using VPC flow logs. For more information, see VPC Flow Logs in the Amazon VPC User Guide.

This document explains how to add Amazon VPC configurations for processing jobs.

Configure a Processing Job for Amazon VPC Access

You configure the processing job by specifying the subnets and security group IDs within the VPC. You don't need to specify the subnet for the processing container. Amazon SageMaker automatically pulls the processing container from Amazon ECR. For more information about processing containers, see Process data (p. 1399).

When creating a processing job, you can specify subnets and security groups in your VPC using either the SageMaker console or the API.

To use the API, you specify the subnets and security group IDs in the NetworkConfig.VpcConfig parameter of the CreateProcessingJob operation. SageMaker uses the subnet and security group details to create the network interfaces and attaches them to the processing containers. The network interfaces provide the processing containers with a network connection within your VPC. This allows the processing job to connect to resources that exist in your VPC.

The following is an example of the VpcConfig parameter that you include in your call to the CreateProcessingJob operation:

```json
VpcConfig: {
    "Subnets": [
        "subnet-0123456789abcdef0",
        "subnet-0123456789abcdef1",
        "subnet-0123456789abcdef2"
    ],
    "SecurityGroupIds": [
        "sg-0123456789abcdef0"
    ]
}
```
Configure Your Private VPC for SageMaker Processing

When configuring the private VPC for your SageMaker processing jobs, use the following guidelines. For information about setting up a VPC, see Working with VPCs and Subnets in the Amazon VPC User Guide.

Topics
- Ensure That Subnets Have Enough IP Addresses (p. 3540)
- Create an Amazon S3 VPC Endpoint (p. 3540)
- Use a Custom Endpoint Policy to Restrict Access to S3 (p. 3540)
- Configure Route Tables (p. 3541)
- Configure the VPC Security Group (p. 3541)
- Connect to Resources Outside Your VPC (p. 3541)
- Monitor Amazon SageMaker Processing Jobs with CloudWatch Logs and Metrics (p. 3542)

Ensure That Subnets Have Enough IP Addresses

Your VPC subnets should have at least two private IP addresses for each instance in a processing job. For more information, see VPC and Subnet Sizing for IPv4 in the Amazon VPC User Guide.

Create an Amazon S3 VPC Endpoint

If you configure your VPC so that processing containers don't have access to the internet, they can't connect to the Amazon S3 buckets that contain your data unless you create a VPC endpoint that allows access. By creating a VPC endpoint, you allow your processing containers to access the buckets where you store your data. We recommend that you also create a custom policy that allows only requests from your private VPC to access to your S3 buckets. For more information, see Endpoints for Amazon S3.

To create an S3 VPC endpoint:

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Endpoints, then choose Create Endpoint
3. For Service Name, choose com.amazonaws.region.s3, where region is the name of the region where your VPC resides.
4. For VPC, choose the VPC you want to use for this endpoint.
5. For Configure route tables, select the route tables to be used by the endpoint. The VPC service automatically adds a route to each route table you select that points any S3 traffic to the new endpoint.
6. For Policy, choose Full Access to allow full access to the S3 service by any user or service within the VPC. Choose Custom to restrict access further. For information, see Use a Custom Endpoint Policy to Restrict Access to S3 (p. 3540).

Use a Custom Endpoint Policy to Restrict Access to S3

The default endpoint policy allows full access to S3 for any user or service in your VPC. To further restrict access to S3, create a custom endpoint policy. For more information, see Using Endpoint Policies for Amazon S3. You can also use a bucket policy to restrict access to your S3 buckets to only traffic that comes from your Amazon VPC. For information, see Using Amazon S3 Bucket Policies.

Restrict Package Installation on the Processing Container

The default endpoint policy allows users to install packages from the Amazon Linux and Amazon Linux 2 repositories on the processing container. If you don't want users to install packages from that repository,
create a custom endpoint policy that explicitly denies access to the Amazon Linux and Amazon Linux 2 repositories. The following is an example of a policy that denies access to these repositories:

```json
{
  "Statement": [
    {
      "Sid": "AmazonLinuxAMIRepositoryAccess",
      "Principal": "*",
      "Action": [
        "s3:GetObject"
      ],
      "Effect": "Deny",
      "Resource": [
        "arn:aws:s3:::packages.*.amazonaws.com/*",
        "arn:aws:s3:::repo.*.amazonaws.com/*"
      ]
    }
  ]
}
{
  "Statement": [
    {
      "Sid": "AmazonLinux2AMIRepositoryAccess",
      "Principal": "*",
      "Action": [
        "s3:GetObject"
      ],
      "Effect": "Deny",
      "Resource": [
        "arn:aws:s3:::amazonlinux.*.amazonaws.com/*"
      ]
    }
  ]
}
```

Configure Route Tables

Use default DNS settings for your endpoint route table, so that standard Amazon S3 URLs (for example, http://s3-aws-region.amazonaws.com/MyBucket) resolve. If you don't use default DNS settings, ensure that the URLs that you use to specify the locations of the data in your processing jobs resolve by configuring the endpoint route tables. For information about VPC endpoint route tables, see Routing for Gateway Endpoints in the Amazon VPC User Guide.

Configure the VPC Security Group

In distributed processing, you must allow communication between the different containers in the same processing job. To do that, configure a rule for your security group that allows inbound connections between members of the same security group. For more information, see Security Group Rules.

Connect to Resources Outside Your VPC

If you're connecting your models to resources outside the VPC that they're running in, do one of the following:

- **Connect to other AWS services** – If your model needs access to an AWS service that supports interface Amazon VPC endpoints, create an endpoint to connect to that service. For a list of services that support interface endpoints, see AWS services that integrate with AWS PrivateLink in the AWS PrivateLink User Guide. For information about creating an interface VPC endpoint, see Access an AWS service using an interface VPC endpoint in the AWS PrivateLink User Guide.

- **Connect to resources over the internet** – If your models are running on instances in an Amazon VPC that does not have a subnet with access to the internet, the models won't have access to resources
on the internet. If your model needs access to an AWS service that doesn't support interface VPC endpoints, or to a resource outside of AWS, ensure that you are running your models in a private subnet that has access to the internet using a public NAT gateway in a public subnet. After you have your models running in the private subnet, configure your security groups and network access control lists (NACLS) to allow outbound connections from the private subnet to the public NAT gateway in the public subnet. For information, see NAT gateways in the Amazon VPC User Guide.

Monitor Amazon SageMaker Processing Jobs with CloudWatch Logs and Metrics

Amazon SageMaker provides Amazon CloudWatch logs and metrics to monitor training jobs. CloudWatch provides CPU, GPU, memory, GPU memory, and disk metrics, and event logging. For more information about monitoring Amazon SageMaker processing jobs, see Monitor Amazon SageMaker with Amazon CloudWatch (p. 3577) and SageMaker Jobs and Endpoint Metrics (p. 3582).

Give SageMaker Training Jobs Access to Resources in Your Amazon VPC

Note
For training jobs, you can configure only subnets with a default tenancy VPC in which your instance runs on shared hardware. For more information on the tenancy attribute for VPCs, see Dedicated Instances.

Configure a Training Job for Amazon VPC Access

To control access to your training jobs, run them in an Amazon VPC with private subnets that don't have internet access.

You configure the training job to run in the VPC by specifying its subnets and security group IDs. You don't need to specify the subnet for the container of the training job. Amazon SageMaker automatically pulls the training container image from Amazon ECR.

When you create a training job, you can specify the subnets and security groups in your VPC using the Amazon SageMaker console or the API.

To use the API, you specify the subnets and security group IDs in the VpcConfig parameter of the CreateTrainingJob operation. SageMaker uses the subnet and security group details to create the network interfaces and attaches them to the training containers. The network interfaces provide the training containers with a network connection within your VPC. This allows the training job to connect to resources that exist in your VPC.

The following is an example of the VpcConfig parameter that you include in your call to the CreateTrainingJob operation:

```
VpcConfig: {
    "Subnets": [
        "subnet-0123456789abcdef0",
        "subnet-0123456789abcdef1",
        "subnet-0123456789abcdef2"
    ],
    "SecurityGroupIds": [
        "sg-0123456789abcdef0"
    ]
}
```

Configure Your Private VPC for SageMaker Training

When configuring the private VPC for your SageMaker training jobs, use the following guidelines. For information about setting up a VPC, see Working with VPCs and Subnets in the Amazon VPC User Guide.
Topics

- **Ensure That Subnets Have Enough IP Addresses (p. 3543)**
- **Create an Amazon S3 VPC Endpoint (p. 3543)**
- **Use a Custom Endpoint Policy to Restrict Access to S3 (p. 3543)**
- **Configure Route Tables (p. 3544)**
- **Configure the VPC Security Group (p. 3544)**
- **Connect to Resources Outside Your VPC (p. 3544)**
- **Monitor Amazon SageMaker Training Jobs with CloudWatch Logs and Metrics (p. 3545)**

**Ensure That Subnets Have Enough IP Addresses**

Training instances that *don't use* an Elastic Fabric Adapter (EFA) should have at least 2 private IP addresses. Training instances that use an EFA should have at least 5 private IP addresses. For more information, see **Multiple IP addresses** in the Amazon EC2 User Guide.

Your VPC subnets should have at least two private IP addresses for each instance in a training job. For more information, see **VPC and Subnet Sizing for IPv4** in the Amazon VPC User Guide.

**Create an Amazon S3 VPC Endpoint**

If you configure your VPC so that training containers don't have access to the internet, they can't connect to the Amazon S3 buckets that contain your training data unless you create a VPC endpoint that allows access. By creating a VPC endpoint, you allow your training containers to access the buckets where you store your data and model artifacts. We recommend that you also create a custom policy that allows only requests from your private VPC to access to your S3 buckets. For more information, see **Endpoints for Amazon S3**.

**To create an S3 VPC endpoint:**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Endpoints**, then choose **Create Endpoint**
3. For **Service Name**, search for `com.amazonaws.region.s3`, where `region` is the name of the region where your VPC resides.
4. Choose the **Gateway** type.
5. For **VPC**, choose the VPC you want to use for this endpoint.
6. For **Configure route tables**, select the route tables to be used by the endpoint. The VPC service automatically adds a route to each route table you select that points any S3 traffic to the new endpoint.
7. For **Policy**, choose **Full Access** to allow full access to the S3 service by any user or service within the VPC. Choose **Custom** to restrict access further. For information, see **Use a Custom Endpoint Policy to Restrict Access to S3 (p. 3543)**.

**Use a Custom Endpoint Policy to Restrict Access to S3**

The default endpoint policy allows full access to S3 for any user or service in your VPC. To further restrict access to S3, create a custom endpoint policy. For more information, see **Using Endpoint Policies for Amazon S3**. You can also use a bucket policy to restrict access to your S3 buckets to only traffic that comes from your Amazon VPC. For information, see **Using Amazon S3 Bucket Policies**.

**Restrict Package Installation on the Training Container**

The default endpoint policy allows users to install packages from the Amazon Linux and Amazon Linux 2 repositories on the training container. If you don't want users to install packages from that repository,
create a custom endpoint policy that explicitly denies access to the Amazon Linux and Amazon Linux 2 repositories. The following is an example of a policy that denies access to these repositories:

```json
{
    "Statement": [
        {
            "Sid": "AmazonLinuxAMIRepositoryAccess",
            "Principal": "*",
            "Action": ["s3:GetObject"],
            "Effect": "Deny",
            "Resource": [
                "arn:aws:s3:::packages.*.amazonaws.com/*",
                "arn:aws:s3:::repo.*.amazonaws.com/*"
            ]
        }
    ]
}

{
    "Statement": [
        {
            "Sid": "AmazonLinux2AMIRepositoryAccess",
            "Principal": "*",
            "Action": ["s3:GetObject"],
            "Effect": "Deny",
            "Resource": [
                "arn:aws:s3:::amazonlinux.*.amazonaws.com/*"
            ]
        }
    ]
}
```

### Configure Route Tables

Use default DNS settings for your endpoint route table, so that standard Amazon S3 URLs (for example, `http://s3-aws-region.amazonaws.com/MyBucket`) resolve. If you don't use default DNS settings, ensure that the URLs that you use to specify the locations of the data in your training jobs resolve by configuring the endpoint route tables. For information about VPC endpoint route tables, see [Routing for Gateway Endpoints](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/routing-gateway-endpoints.html) in the *Amazon VPC User Guide*.

### Configure the VPC Security Group

In distributed training, you must allow communication between the different containers in the same training job. To do that, configure a rule for your security group that allows inbound connections between members of the same security group. For EFA-enabled instances, ensure that both inbound and outbound connections allow all traffic from the same security group. For information, see [Security Group Rules](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/using-network-security-groups.html) in the *Amazon Virtual Private Cloud User Guide*.

### Connect to Resources Outside Your VPC

If you configure your VPC so that it doesn't have internet access, training jobs that use that VPC do not have access to resources outside your VPC. If your training job needs access to resources outside your VPC, provide access with one of the following options:

- If your training job needs access to an AWS service that supports interface VPC endpoints, create an endpoint to connect to that service. For a list of services that support interface endpoints, see [VPC Endpoints](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/vpc-endpoints.html) in the *Amazon Virtual Private Cloud User Guide*. For information about creating an interface VPC endpoint, see [Interface VPC Endpoints (AWS PrivateLink)](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/creating-interface-vpc-endpoint.html) in the *Amazon Virtual Private Cloud User Guide*. 

3544
Give SageMaker Access to Resources in your Amazon VPC

- If your training job needs access to an AWS service that doesn't support interface VPC endpoints or to a resource outside of AWS, create a NAT gateway and configure your security groups to allow outbound connections. For information about setting up a NAT gateway for your VPC, see Scenario 2: VPC with Public and Private Subnets (NAT) in the Amazon Virtual Private Cloud User Guide.

Monitor Amazon SageMaker Training Jobs with CloudWatch Logs and Metrics

Amazon SageMaker provides Amazon CloudWatch logs and metrics to monitor training jobs. CloudWatch provides CPU, GPU, memory, GPU memory, and disk metrics, and event logging. For more information about monitoring Amazon SageMaker training jobs, see Monitor Amazon SageMaker with Amazon CloudWatch (p. 3577) and SageMaker Jobs and Endpoint Metrics (p. 3582).

Give SageMaker Hosted Endpoints Access to Resources in Your Amazon VPC

Configure a Model for Amazon VPC Access

To specify subnets and security groups in your private VPC, use the VpcConfig request parameter of the CreateModel API, or provide this information when you create a model in the SageMaker console. SageMaker uses this information to create network interfaces and attach them to your model containers. The network interfaces provide your model containers with a network connection within your VPC that is not connected to the internet. They also enable your model to connect to resources in your private VPC.

Note
You must create at least two subnets in different availability zones in your private VPC, even if you have only one hosting instance.

The following is an example of the VpcConfig parameter that you include in your call to CreateModel:

VpcConfig: {
    "Subnets": [
        "subnet-0123456789abcdef0",
        "subnet-0123456789abcdef1",
        "subnet-0123456789abcdef2"
    ],
    "SecurityGroupIds": [
        "sg-0123456789abcdef0"
    ]
}

Configure Your Private VPC for SageMaker Hosting

When configuring the private VPC for your SageMaker models, use the following guidelines. For information about setting up a VPC, see Working with VPCs and Subnets in the Amazon VPC User Guide.

Topics
- Ensure That Subnets Have Enough IP Addresses (p. 3546)
- Create an Amazon S3 VPC Endpoint (p. 3546)
- Use a Custom Endpoint Policy to Restrict Access to Amazon S3 (p. 3546)
- Add Permissions for Endpoint Access for Containers Running in a VPC to Custom IAM Policies (p. 3547)
- Configure Route Tables (p. 3547)
- Connect to Resources Outside Your VPC (p. 3547)
Ensure That Subnets Have Enough IP Addresses

Training instances that don't use an Elastic Fabric Adapter (EFA) should have at least 2 private IP addresses. Training instances that use an EFA should have at least 5 private IP addresses. For more information, see Multiple IP addresses in the Amazon EC2 User Guide.

Create an Amazon S3 VPC Endpoint

If you configure your VPC so that model containers don't have access to the internet, they can't connect to the Amazon S3 buckets that contain your data unless you create a VPC endpoint that allows access. By creating a VPC endpoint, you allow your model containers to access the buckets where you store your data and model artifacts. We recommend that you also create a custom policy that allows only requests from your private VPC to access to your S3 buckets. For more information, see Endpoints for Amazon S3.

To create an Amazon S3 VPC endpoint:

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Endpoints, then choose Create Endpoint.
3. For Service Name, choose com.amazonaws.region.s3, where region is the name of the AWS Region where your VPC resides.
4. For VPC, choose the VPC that you want to use for this endpoint.
5. For Configure route tables, choose the route tables for the endpoint to use. The VPC service automatically adds a route to each route table that you choose that points Amazon S3 traffic to the new endpoint.
6. For Policy, choose Full Access to allow full access to the Amazon S3 service by any user or service within the VPC. To restrict access further, choose Custom. For more information, see Use a Custom Endpoint Policy to Restrict Access to Amazon S3 (p. 3546).

Use a Custom Endpoint Policy to Restrict Access to Amazon S3

The default endpoint policy allows full access to Amazon Simple Storage Service (Amazon S3) for any user or service in your VPC. To further restrict access to Amazon S3, create a custom endpoint policy. For more information, see Using Endpoint Policies for Amazon S3.

You can also use a bucket policy to restrict access to your S3 buckets to only traffic that comes from your Amazon VPC. For information, see Using Amazon S3 Bucket Policies.

Restrict Package Installation on the Model Container with a Custom Endpoint Policy

The default endpoint policy allows users to install packages from the Amazon Linux and Amazon Linux 2 repositories on the model container. If you don't want users to install packages from those repositories, create a custom endpoint policy that explicitly denies access to the Amazon Linux and Amazon Linux 2 repositories. The following is an example of a policy that denies access to these repositories:

```json
{
    "Statement": [
        {
            "Sid": "AmazonLinuxAMIRepositoryAccess",
            "Principal": "+",
            "Action": [
                "s3:GetObject"
            ],
            "Effect": "Deny",
            "Resource": [
                "arn:aws:s3:::packages.*.amazonaws.com/**",
                "arn:aws:s3:::repo.*.amazonaws.com/**"
            ]
        }
    ]
}
```
Add Permissions for Endpoint Access for Containers Running in a VPC to Custom IAM Policies

The SageMakerFullAccess managed policy includes the permissions that you need to use models configured for Amazon VPC access with an endpoint. These permissions allow SageMaker to create an elastic network interface and attach it to model containers running in a VPC. If you use your own IAM policy, you must add the following permissions to that policy to use models configured for VPC access.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:DescribeVpcEndpoints",
        "ec2:DescribeDhcpOptions",
        "ec2:DescribeVpcs",
        "ec2:DescribeSubnets",
        "ec2:DescribeSecurityGroups",
        "ec2:DescribeNetworkInterfaces",
        "ec2:DeleteNetworkInterfacePermission",
        "ec2:DeleteNetworkInterface",
        "ec2:CreateNetworkInterfacePermission",
        "ec2:CreateNetworkInterface"
      ],
      "Resource": "*"
    }
  ]
}
```

For more information about the SageMakerFullAccess managed policy, see AWS managed policy: AmazonSageMakerFullAccess (p. 3443).

Configure Route Tables

Use default DNS settings for your endpoint route table, so that standard Amazon S3 URLs (for example, http://s3-aws-region.amazonaws.com/MyBucket) resolve. If you don't use default DNS settings, ensure that the URLs that you use to specify the locations of the data in your models resolve by configuring the endpoint route tables. For information about VPC endpoint route tables, see Routing for Gateway Endpoints in the Amazon VPC User Guide.

Connect to Resources Outside Your VPC

If you configure your VPC so that it doesn't have internet access, models that use that VPC do not have access to resources outside your VPC. If your model needs access to resources outside your VPC, provide access with one of the following options:
Give SageMaker Access to Resources in Your Amazon VPC

- If your model needs access to an AWS service that supports interface VPC endpoints, create an endpoint to connect to that service. For a list of services that support interface endpoints, see VPC Endpoints in the Amazon VPC User Guide. For information about creating an interface VPC endpoint, see Interface VPC Endpoints (AWS PrivateLink) in the Amazon VPC User Guide.

- If your model needs access to an AWS service that doesn't support interface VPC endpoints or to a resource outside of AWS, create a NAT gateway and configure your security groups to allow outbound connections. For information about setting up a NAT gateway for your VPC, see Scenario 2: VPC with Public and Private Subnets (NAT) in the Amazon Virtual Private Cloud User Guide.

Give Batch Transform Jobs Access to Resources in Your Amazon VPC

To control access to your data and batch transform jobs, we recommend that you create a private Amazon VPC and configure it so that your jobs aren't accessible over the public internet. You specify your private VPC configuration when you create a model by specifying subnets and security groups. You then specify the same model when you create a batch transform job. When you specify the subnets and security groups, SageMaker creates elastic network interfaces that are associated with your security groups in one of the subnets. Network interfaces allow your model containers to connect to resources in your VPC. For information about network interfaces, see Elastic Network Interfaces in the Amazon VPC User Guide.

This document explains how to add Amazon VPC configurations for batch transform jobs.

Configure a Batch Transform Job for Amazon VPC Access

To specify subnets and security groups in your private VPC, use the VpcConfig request parameter of the CreateModel API, or provide this information when you create a model in the SageMaker console. Then specify the same model in the ModelName request parameter of the CreateTransformJob API, or in the Model name field when you create a transform job in the SageMaker console. SageMaker uses this information to create network interfaces and attach them to your model containers. The network interfaces provide your model containers with a network connection within your VPC that is not connected to the internet. They also enable your transform job to connect to resources in your private VPC.

The following is an example of the VpcConfig parameter that you include in your call to CreateModel:

```json
VpcConfig: {
  "Subnets": [
    "subnet-0123456789abcdef0",
    "subnet-0123456789abcdef1",
    "subnet-0123456789abcdef2"
  ],
  "SecurityGroupIds": [
    "sg-0123456789abcdef0"
  ]
}
```

If you are creating a model using the CreateModel API operation, the IAM execution role that you use to create your model must include the permissions described in CreateModel API: Execution Role Permissions (p. 3404), including the following permissions required for a private VPC:

When creating a model in the console, if you select Create a new role in the Model Settings section, the AmazonSageMakerFullAccess policy used to create the role already contains these permissions. If you select Enter a custom IAM role ARN or Use existing role, the role ARN that you specify must have an execution policy attached with the following permissions.
Configure Your Private VPC for SageMaker Batch Transform

When configuring the private VPC for your SageMaker batch transform jobs, use the following guidelines. For information about setting up a VPC, see Working with VPCs and Subnets in the Amazon VPC User Guide.

Topics

- Ensure That Subnets Have Enough IP Addresses (p. 3549)
- Create an Amazon S3 VPC Endpoint (p. 3549)
- Use a Custom Endpoint Policy to Restrict Access to S3 (p. 3550)
- Configure Route Tables (p. 3550)
- Configure the VPC Security Group (p. 3550)
- Connect to Resources Outside Your VPC (p. 3551)

Ensure That Subnets Have Enough IP Addresses

Your VPC subnets should have at least two private IP addresses for each instance in a transform job. For more information, see VPC and Subnet Sizing for IPv4 in the Amazon VPC User Guide.

Create an Amazon S3 VPC Endpoint

If you configure your VPC so that model containers don't have access to the internet, they can't connect to the Amazon S3 buckets that contain your data unless you create a VPC endpoint that allows access. By creating a VPC endpoint, you allow your model containers to access the buckets where you store your data and model artifacts. We recommend that you also create a custom policy that allows only requests from your private VPC to access to your S3 buckets. For more information, see Endpoints for Amazon S3.

To create an S3 VPC endpoint:

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Endpoints, then choose Create Endpoint
3. For Service Name, choose com.amazonaws.region.s3, where region is the name of the region where your VPC resides.
4. For VPC, choose the VPC you want to use for this endpoint.
5. For Configure route tables, select the route tables to be used by the endpoint. The VPC service automatically adds a route to each route table you select that points any S3 traffic to the new endpoint.
6. For Policy, choose Full Access to allow full access to the S3 service by any user or service within the VPC. Choose Custom to restrict access further. For information, see Use a Custom Endpoint Policy to Restrict Access to S3 (p. 3550).
Use a Custom Endpoint Policy to Restrict Access to S3

The default endpoint policy allows full access to S3 for any user or service in your VPC. To further restrict access to S3, create a custom endpoint policy. For more information, see Using Endpoint Policies for Amazon S3. You can also use a bucket policy to restrict access to your S3 buckets to only traffic that comes from your Amazon VPC. For information, see Using Amazon S3 Bucket Policies.

Restrict Package Installation on the Model Container

The default endpoint policy allows users to install packages from the Amazon Linux and Amazon Linux 2 repositories on the training container. If you don't want users to install packages from that repository, create a custom endpoint policy that explicitly denies access to the Amazon Linux and Amazon Linux 2 repositories. The following is an example of a policy that denies access to these repositories:

```json
{
  "Statement": [
    {
      "Sid": "AmazonLinuxAMIRepositoryAccess",
      "Principal": "*",
      "Action": [
        "s3:GetObject"
      ],
      "Effect": "Deny",
      "Resource": [
        "arn:aws:s3:::packages.*.amazonaws.com/*",
        "arn:aws:s3:::repo.*.amazonaws.com/*"
      ]
    }
  ]
}
{
  "Statement": [
    {
      "Sid": "AmazonLinux2AMIRepositoryAccess",
      "Principal": "*",
      "Action": [
        "s3:GetObject"
      ],
      "Effect": "Deny",
      "Resource": [
        "arn:aws:s3:::amazonlinux.*.amazonaws.com/*"
      ]
    }
  ]
}
```

Configure Route Tables

Use default DNS settings for your endpoint route table, so that standard Amazon S3 URLs (for example, http://s3-aws-region.amazonaws.com/MyBucket) resolve. If you don't use default DNS settings, ensure that the URLs that you use to specify the locations of the data in your batch transform jobs resolve by configuring the endpoint route tables. For information about VPC endpoint route tables, see Routing for Gateway Endpoints in the Amazon VPC User Guide.

Configure the VPC Security Group

In distributed batch transform, you must allow communication between the different containers in the same batch transform job. To do that, configure a rule for your security group that allows inbound and outbound connections between members of the same security group. Members of the same security group should be able to communicate with each other across all ports. For more information, see Security Group Rules.
Connect to Resources Outside Your VPC

If you configure your VPC so that it doesn't have internet access, batch transform jobs that use that VPC do not have access to resources outside your VPC. If your batch transform job needs access to resources outside your VPC, provide access with one of the following options:

- If your batch transform job needs access to an AWS service that supports interface VPC endpoints, create an endpoint to connect to that service. For a list of services that support interface endpoints, see VPC Endpoints in the Amazon VPC User Guide. For information about creating an interface VPC endpoint, see Interface VPC Endpoints (AWS PrivateLink) in the Amazon VPC User Guide.

- If your batch transform job needs access to an AWS service that doesn't support interface VPC endpoints or to a resource outside of AWS, create a NAT gateway and configure your security groups to allow outbound connections. For information about setting up a NAT gateway for your VPC, see Scenario 2: VPC with Public and Private Subnets (NAT) in the Amazon Virtual Private Cloud User Guide.

Give Amazon SageMaker Clarify Jobs Access to Resources in Your Amazon VPC

To control access to your data and SageMaker Clarify jobs, we recommend that you create a private Amazon VPC and configure it so that your jobs aren't accessible over the public internet. For information about creating and configuring an Amazon VPC for processing jobs, see Give SageMaker Processing Jobs Access to Resources in Your Amazon VPC.

This document explains how to add additional Amazon VPC configurations that meet the requirements for SageMaker Clarify jobs.

Topics
- Configure a SageMaker Clarify Job for Amazon VPC Access (p. 3551)
- Configure Your Private Amazon VPC for SageMaker Clarify jobs (p. 3553)

Configure a SageMaker Clarify Job for Amazon VPC Access

You need to specify subnets and security groups when configuring your private Amazon VPC for SageMaker Clarify jobs and to enable the job to get inferences from the SageMaker model when computing post-training bias metrics and feature contributions that help explain model predictions.

Topics
- SageMaker Clarify Job Amazon VPC Subnets and Security Groups (p. 3551)
- Configure a Model Amazon VPC for Inference (p. 3552)

SageMaker Clarify Job Amazon VPC Subnets and Security Groups

Subnets and security groups in your private Amazon VPC can be assigned to a SageMaker Clarify job in various ways, depending on how you create the job.

- **SageMaker console**: Provide this information when you create the job in the SageMaker Dashboard. From the Processing menu, choose Processing jobs, then choose Create processing job. Select the VPC option in the Network panel and provide the subnets and security groups using the drop-down lists. Make sure network isolation option provided in this panel is turned off.

- **SageMaker API**: Use the NetworkConfig.VpcConfig request parameter of the CreateProcessingJob API, as shown in the following example:

```json
"NetworkConfig": {  
  "VpcConfig": {
```
SageMaker uses the information to create network interfaces and attach them to the SageMaker Clarify job. The network interfaces provide a SageMaker Clarify job with a network connection within your Amazon VPC that is not connected to the public internet. They also enable the SageMaker Clarify job to connect to resources in your private Amazon VPC.

**Note**
The network isolation option of the SageMaker Clarify job must be turned off (by default the option is turned off) so that the SageMaker Clarify job can communicate with the shadow endpoint.

### Configure a Model Amazon VPC for Inference

In order to compute post-training bias metrics and explainability, the SageMaker Clarify job needs to get inferences from the SageMaker model that is specified by the `model_name` parameter of the **analysis configuration** for the SageMaker Clarify processing job. Alternatively, if you use the SageMakerClarifyProcessor API in the SageMaker Python SDK, the job needs to get the `model_name` specified by the **ModelConfig** class. To accomplish this, the SageMaker Clarify job creates an ephemeral endpoint with the model, known as a **shadow endpoint**, and then applies the Amazon VPC configuration of the model to the shadow endpoint.

To specify subnets and security groups in your private Amazon VPC to the SageMaker model, use the VpcConfig request parameter of the **CreateModel** API or provide this information when you create the model using the SageMaker dashboard in the console. The following is an example of the VpcConfig parameter that you include in your call to **CreateModel**:

```json
"VpcConfig": { 
  "Subnets": [ 
    "subnet-0123456789abcdef0", 
    "subnet-0123456789abcdef1", 
    "subnet-0123456789abcdef2" 
  ], 
  "SecurityGroupIds": [ 
    "sg-0123456789abcdef0" 
  ]
}
```
You can specify the number of instances of the shadow endpoint to launch with the `initial_instance_count` parameter of the `analysis configuration` for the SageMaker Clarify processing job. Alternatively, if you use the `SageMakerClarifyProcessor` API in the SageMaker Python SDK, the job needs to get the `instance_count` specified by the `ModelConfig` class.

**Note**
Even if you only request one instance when creating the shadow endpoint, you need at least two subnets in the model's `ModelConfig` in distinct availability zones. Otherwise the shadow endpoint creation fails with the following error:
ClientError: Error hosting endpoint sagemaker-clarify-endpoint-XXX: Failed. Reason: Unable to locate at least 2 availability zone(s) with the requested instance type YYY that overlap with SageMaker subnets.

If your model requires model files in Amazon S3, then the model Amazon VPC needs to have an Amazon S3 VPC endpoint. For more information about creating and configuring an Amazon VPC for SageMaker models, see Give SageMaker Hosted Endpoints Access to Resources in Your Amazon VPC (p. 3545).

**Configure Your Private Amazon VPC for SageMaker Clarify jobs**

In general, you can follow the steps in Configure Your Private VPC for SageMaker Processing to configure your private Amazon VPC for SageMaker Clarify jobs. Here are some highlights and special requirements for SageMaker Clarify jobs.

**Topics**

- Connect to Resources Outside Your Amazon VPC (p. 3553)
- Configure the Amazon VPC Security Group (p. 3553)

**Connect to Resources Outside Your Amazon VPC**

If you configure your Amazon VPC so that it does not have public internet access, then some additional setup is required to grant SageMaker Clarify jobs access to resources and services outside of your Amazon VPC. For example, an Amazon S3 VPC endpoint is required because a SageMaker Clarify job needs to load a dataset from an S3 bucket as well as save the analysis results to an S3 bucket. For more information, see Create an Amazon S3 VPC Endpoint for the creation guide. In addition, if a SageMaker Clarify job needs to get inferences from the shadow endpoint, then it needs to call several more AWS services.

- **Create an Amazon SageMaker API service VPC endpoint**: The SageMaker Clarify job needs to call the Amazon SageMaker API service to manipulate the shadow endpoint, or to describe a SageMaker model for Amazon VPC validation. You can follow the guidance provided in the Securing all Amazon SageMaker API calls with AWS PrivateLink blog to create an Amazon SageMaker API VPC endpoint that allows the SageMaker Clarify job to make the service calls. Note that the service name of Amazon SageMaker API service is `com.amazonaws.region.sagemaker.api`, where `region` is the name of the Region where your Amazon VPC resides.

- **Create an Amazon SageMaker Runtime VPC Endpoint**: The SageMaker Clarify job needs to call the Amazon SageMaker runtime service, which routes the invocations to the shadow endpoint. The setup steps are similar to those for the Amazon SageMaker API service. Note that the service name of Amazon SageMaker Runtime service is `com.amazonaws.region.sagemaker.runtime`, where `region` is the name of the Region where your Amazon VPC resides.

**Configure the Amazon VPC Security Group**

SageMaker Clarify jobs support distributed processing when two or more processing instances are specified in one of the following ways:
• **SageMaker console**: The **Instance count** is specified in the **Resource configuration** part of the **Job settings** panel on the Create processing job page.

• **SageMaker API**: The **InstanceCount** is specified when you create the job with the [CreateProcessingJob](https://boto3.amazonaws.com/v1/documentation/api/latest/reference/services/sagemaker.html#SageMaker.Client.CreateProcessingJob) API.

• **SageMaker Python SDK**: The **instance_count** is specified when using the [SageMakerClarifyProcessor](https://sagemaker.mxnet.readthedocs.io/en/stable/) API or the [Processor](https://boto3.amazonaws.com/v1/documentation/api/latest/reference/services/sagemaker.html#SageMaker.Client.create_processor) API.

In distributed processing, you must allow communication between the different instances in the same processing job. To do that, configure a rule for your security group that allows inbound connections between members of the same security group. For information, see [Security group rules](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/vpc-routing-options.html).

### Give SageMaker Compilation Jobs Access to Resources in Your Amazon VPC

**Note**

For compilation jobs, you can configure only subnets with a default tenancy VPC in which your job runs on shared hardware. For more information on the tenancy attribute for VPCs, see [Dedicated Instances](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/).  

#### Configure a Compilation Job for Amazon VPC Access

To specify subnets and security groups in your private VPC, use the VpcConfig request parameter of the [CreateCompilationJob](https://boto3.amazonaws.com/v1/documentation/api/latest/reference/services/sagemaker.html#SageMaker.Client.create_compilation_job) API, or provide this information when you create a compilation job in the SageMaker console. SageMaker Neo uses this information to create network interfaces and attach them to your compilation jobs. The network interfaces provide compilation jobs with a network connection within your VPC that is not connected to the internet. They also enable your compilation job to connect to resources in your private VPC. The following is an example of the VpcConfig parameter that you include in your call to CreateCompilationJob:

```javascript
VpcConfig: {"Subnets": [  "subnet-0123456789abcdef0",  "subnet-0123456789abcdef1",  "subnet-0123456789abcdef2"  ],  "SecurityGroupIds": [  "sg-0123456789abcdef0"  ]}
```

#### Configure Your Private VPC for SageMaker Compilation

When configuring the private VPC for your SageMaker compilation jobs, use the following guidelines. For information about setting up a VPC, see [Working with VPCs and Subnets](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/) in the Amazon VPC User Guide.

**Topics**

- [Ensure That Subnets Have Enough IP Addresses](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/subnet-share-networking-ipv4-addresses.html) (p. 3554)
- [Create an Amazon S3 VPC Endpoint](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/endpoint-s3.html) (p. 3555)
- [Use a Custom Endpoint Policy to Restrict Access to S3](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/endpoints-security-group-policy.html) (p. 3555)
- [Configure Route Tables](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/route-tables.html) (p. 3556)
- [Configure the VPC Security Group](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/whitelist-security-group.html) (p. 3556)

**Ensure That Subnets Have Enough IP Addresses**

Your VPC subnets should have at least two private IP addresses for each instance in a compilation job. For more information, see [VPC and Subnet Sizing for IPv4](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/subnet-share-networking-ipv4-addresses.html) in the Amazon VPC User Guide.
Create an Amazon S3 VPC Endpoint

If you configure your VPC to block access to the internet, SageMaker Neo can't connect to the Amazon S3 buckets that contain your models unless you create a VPC endpoint that allows access. By creating a VPC endpoint, you allow your SageMaker Neo compilation jobs to access the buckets where you store your data and model artifacts. We recommend that you also create a custom policy that allows only requests from your private VPC to access to your S3 buckets. For more information, see Endpoints for Amazon S3.

To create an S3 VPC endpoint:
1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Endpoints, then choose Create Endpoint.
3. For Service Name, search for com.amazonaws.region.s3, where region is the name of the region where your VPC resides.
4. Choose the Gateway type.
5. For VPC, choose the VPC you want to use for this endpoint.
6. For Configure route tables, select the route tables to be used by the endpoint. The VPC service automatically adds a route to each route table you select that points any S3 traffic to the new endpoint.
7. For Policy, choose Full Access to allow full access to the S3 service by any user or service within the VPC. Choose Custom to restrict access further. For information, see Use a Custom Endpoint Policy to Restrict Access to S3 (p. 3543).

Use a Custom Endpoint Policy to Restrict Access to S3

The default endpoint policy allows full access to S3 for any user or service in your VPC. To further restrict access to S3, create a custom endpoint policy. For more information, see Using Endpoint Policies for Amazon S3. You can also use a bucket policy to restrict access to your S3 buckets to only traffic that comes from your Amazon VPC. For information, see Using Amazon S3 Bucket Policies. The following is a sample customized policy:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Principal": {
        "AWS": "*"
      },
      "Action": "s3:GetObject",
      "Resource": [
        "arn:aws:s3:::your-sample-bucket",
        "arn:aws:s3:::your-sample-bucket/*"
      ],
      "Condition": {
        "StringNotEquals": {
          "aws:SourceVpce": [
            "vpce-01234567890123456"
          ]
        }
      }
    }
  ]
}
```
Add Permissions for Compilation Job Running in a Amazon VPC to Custom IAM Policies

The SageMakerFullAccess managed policy includes the permissions that you need to use models configured for Amazon VPC access with an endpoint. These permissions allow SageMaker Neo to create an elastic network interface and attach it to compilation job running in a Amazon VPC. If you use your own IAM policy, you must add the following permissions to that policy to use models configured for Amazon VPC access.

```json
{"Version": "2012-10-17",
"Statement": [
{"Effect": "Allow",
"Action": [
"ec2:DescribeVpcEndpoints",
"ec2:DescribeDhcpOptions",
"ec2:DescribeVpcs",
"ec2:DescribeSubnets",
"ec2:DescribeSecurityGroups",
"ec2:DescribeNetworkInterfaces",
"ec2:DeleteNetworkInterfacePermission",
"ec2:DeleteNetworkInterface",
"ec2:CreateNetworkInterfacePermission",
"ec2:CreateNetworkInterface",
"ec2:ModifyNetworkInterfaceAttribute"
],
"Resource": "*"
}
]
}
```

For more information about the SageMakerFullAccess managed policy, see AWS managed policy: AmazonSageMakerFullAccess (p. 3443).

Configure Route Tables

Use default DNS settings for your endpoint route table, so that standard Amazon S3 URLs (for example, http://s3-aws-region.amazonaws.com/MyBucket) resolve. If you don't use default DNS settings, ensure that the URLs that you use to specify the locations of the data in your compilation jobs resolve by configuring the endpoint route tables. For information about VPC endpoint route tables, see Routing for Gateway Endpoints in the Amazon VPC User Guide.

Configure the VPC Security Group

In your security group for the compilation job, you must allow outbound communication to your Amazon S3 Amazon VPC endpoints and the subnet CIDR ranges used for the compilation job. For information, see Security Group Rules and Control access to services with Amazon VPC endpoints.

Give Inference Recommender Jobs Access to Resources in Your Amazon VPC

**Note**

Inference Recommender requires you to register your model with Model Registry. Note that Model Registry doesn't allow your model artifacts or Amazon ECR image to be VPC restricted. Inference Recommender also has a requirement that your sample payload Amazon S3 object is not VPC restricted. For inference recommendation jobs, you can't create a custom policy that allows only requests from your private VPC to access to your Amazon S3 buckets.

To specify subnets and security groups in your private VPC, use the RecommendationJobVpcConfig request parameter of the CreateInferenceRecommendationsJob API, or specify your subnets and security groups when you create a recommendation job in the SageMaker console.
Inference Recommender uses this information to create endpoints. When provisioning endpoints, SageMaker creates network interfaces and attaches them to your endpoints. The network interfaces provide your endpoints with a network connection to your VPC. The following is an example of the VpcConfig parameter that you include in a call to CreateInferenceRecommendationsJob:

```json
VpcConfig: {
    "Subnets": ["subnet-0123456789abcdef0", "subnet-0123456789abcdef1", "subnet-0123456789abcdef2"],
    "SecurityGroupIds": ["sg-0123456789abcdef0"]
}
```

Refer to the following topics for more information on configuring your Amazon VPC for use with Inference Recommender jobs.

**Topics**

- [Ensure that subnets have enough IP addresses (p. 3557)](#)
- [Create an Amazon S3 VPC endpoint (p. 3557)](#)
- [Add permissions for Inference Recommender jobs running in an Amazon VPC to custom IAM policies (p. 3558)](#)
- [Configure route tables (p. 3558)](#)
- [Configure the VPC security group (p. 3558)](#)

**Ensure that subnets have enough IP addresses**

Your VPC subnets should have at least two private IP addresses for each instance in an inference recommendation job. For more information about subnets and private IP addresses, see [How Amazon VPC works](https://docs.aws.amazon.com/vpc/latest/userguide/what-is-amazon-vpc.html) in the *Amazon VPC User Guide*.

**Create an Amazon S3 VPC endpoint**

If you configure your VPC to block access to the internet, Inference Recommender can’t connect to the Amazon S3 buckets that contain your models unless you create a VPC endpoint that allows access. By creating a VPC endpoint, you allow your SageMaker inference recommendation jobs to access the buckets where you store your data and model artifacts.

To create an Amazon S3 VPC endpoint, use the following procedure:

1. Open the Amazon VPC console.
2. In the navigation pane, choose **Endpoints**, and then choose **Create Endpoint**.
3. For **Service Name**, search for `com.amazonaws.region.s3`, where `region` is the name of the Region where your VPC resides.
4. Choose the **Gateway type**.
5. For **VPC**, choose the VPC you want to use for this endpoint.
6. For **Configure route tables**, select the route tables to be used by the endpoint. The VPC service automatically adds a route to each route table you select that points any Amazon S3 traffic to the new endpoint.
7. For **Policy**, choose **Full Access** to allow full access to the Amazon S3 service by any user or service within the VPC.
Add permissions for Inference Recommender jobs running in an Amazon VPC to custom IAM policies

The AmazonSageMakerFullAccess managed policy includes the permissions that you need to use models configured for Amazon VPC access with an endpoint. These permissions allow Inference Recommender to create an elastic network interface and attach it to the inference recommendation job running in an Amazon VPC. If you use your own IAM policy, you must add the following permissions to that policy to use models configured for Amazon VPC access.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {"Effect": "Allow",
      "Action": [
        "ec2:DescribeVpcEndpoints",
        "ec2:DescribeDhcpOptions",
        "ec2:DescribeVpcs",
        "ec2:DescribeSubnets",
        "ec2:DescribeSecurityGroups",
        "ec2:DescribeNetworkInterfaces",
        "ec2:DeleteNetworkInterfacePermission",
        "ec2:DeleteNetworkInterface",
        "ec2:CreateNetworkInterfacePermission",
        "ec2:CreateNetworkInterface",
        "ec2:ModifyNetworkInterfaceAttribute"
      ],
      "Resource": "*"
    }
  ]
}
```

Configure route tables

Use the default DNS settings for your endpoint route table, so that standard Amazon S3 URLs (for example: http://s3-aws-region.amazonaws.com/MyBucket) resolve. If you don't use the default DNS settings, ensure that the URLs that you use to specify the locations of the data in your inference recommendation jobs resolve by configuring the endpoint route tables. For information about VPC endpoint route tables, see Routing gateway endpoints in the Amazon VPC User Guide.

Configure the VPC security group

In your security group for the inference recommendation job, you must allow outbound communication to your Amazon S3 VPC endpoints and the subnet CIDR ranges used for the inference recommendation job. For information, see Security Group Rules and Control access to services with Amazon VPC endpoints in the Amazon VPC User Guide.
Sell algorithms and packages in the AWS Marketplace

Amazon SageMaker integrates with AWS Marketplace, enabling developers to charge other SageMaker users for the use of their algorithms and model packages. AWS Marketplace is a curated digital catalog that makes it easy for customers to find, buy, deploy, and manage third-party software and services that customers need to build solutions and run their businesses. AWS Marketplace includes thousands of software listings in popular categories, such as security, networking, storage, machine learning, business intelligence, database, and DevOps. It simplifies software licensing and procurement with flexible pricing options and multiple deployment methods.

For information, see AWS Marketplace Documentation.

Topics

- SageMaker Algorithms (p. 3559)
- SageMaker Model Packages (p. 3559)
- Sell Amazon SageMaker Algorithms and Model Packages (p. 3573)
- Find and Subscribe to Algorithms and Model Packages on AWS Marketplace (p. 3576)
- Use Algorithm and Model Package Resources (p. 3566)

SageMaker Algorithms

An algorithm enables you to perform end-to-end machine learning. It has two logical components: training and inference. Buyers can use the training component to create training jobs in SageMaker and build a machine learning model. SageMaker saves the model artifacts generated by the algorithm during training to an Amazon S3 bucket. For more information, see Train a Model with Amazon SageMaker (p. 1521).

Buyers use the inference component with the model artifacts generated during a training job to create a deployable model in their SageMaker account. They can use the deployable model for real-time inference by using SageMaker hosting services. Or, they can get inferences for an entire dataset by running batch transform jobs. For more information, see Deploy a Model in Amazon SageMaker (p. 2339).

SageMaker Model Packages

Buyers use a model package to build a deployable model in SageMaker. They can use the deployable model for real-time inference by using SageMaker hosting services. Or, they can get inferences for an entire dataset by running batch transform jobs. For more information, see Deploy a Model in Amazon SageMaker (p. 2339). As a seller, you can build your model artifacts by training in SageMaker, or you can use your own model artifacts from a model that you trained outside of SageMaker. You can charge buyers for inference.
Use your own algorithms and models with the AWS Marketplace

The following sections show how to create algorithm and model package resources that you can use locally and publish to the AWS Marketplace.

Topics
- Create Algorithm and Model Package Resources (p. 3560)
- Use Algorithm and Model Package Resources (p. 3566)

Create Algorithm and Model Package Resources

After your training and/or inference code is packaged in Docker containers, create algorithm and model package resources that you can use in your Amazon SageMaker account and, optionally, publish on AWS Marketplace.

Topics
- Create an Algorithm Resource (p. 3560)
- Create a Model Package Resource (p. 3563)

Create an Algorithm Resource

To create an algorithm resource that you can use to run training jobs in Amazon SageMaker and publish on AWS Marketplace specify the following information:

- The Docker containers that contains the training and, optionally, inference code.
- The configuration of the input data that your algorithm expects for training.
- The hyperparameters that your algorithm supports.
- Metrics that your algorithm sends to Amazon CloudWatch during training jobs.
- The instance types that your algorithm supports for training and inference, and whether it supports distributed training across multiple instances.
- Validation profiles, which are training jobs that SageMaker uses to test your algorithm's training code and batch transform jobs that SageMaker runs to test your algorithm's inference code.

To ensure that buyers and sellers can be confident that products work in SageMaker, we require that you validate your algorithms before listing them on AWS Marketplace. You can list products in the AWS Marketplace only if validation succeeds. To validate your algorithms, SageMaker uses your validation profile and sample data to run the following validations tasks:

1. Create a training job in your account to verify that your training image works with SageMaker.
2. If you included inference code in your algorithm, create a model in your account using the algorithm's inference image and the model artifacts produced by the training job.
3. If you included inference code in your algorithm, create a transform job in your account using the model to verify that your inference image works with SageMaker.

When you list your product on AWS Marketplace, the inputs and outputs of this validation process persist as part of your product and are made available to your buyers. This helps buyers understand and evaluate the product before they buy it. For example, buyers can inspect the input data that you used, the outputs generated, and the logs and metrics emitted by your code. The more comprehensive your validation specification, the easier it is for customers to evaluate your product.
Note
In your validation profile, provide only data that you want to expose publicly.

Validation can take up to a few hours. To see the status of the jobs in your account, in the SageMaker console, see the Training jobs and Transform jobs pages. If validation fails, you can access the scan and validation reports from the SageMaker console. If any issues are found, you will have to create the algorithm again.

Note
To publish your algorithm on AWS Marketplace, at least one validation profile is required.

You can create an algorithm by using either the SageMaker console or the SageMaker API.

Topics
- Create an Algorithm Resource (Console) (p. 3561)
- Create an Algorithm Resource (API) (p. 3563)

Create an Algorithm Resource (Console)

To create an algorithm resource (console)

2. From the left menu, choose Training.
3. From the dropdown menu, choose Algorithms, then choose Create algorithm.
4. On the Training specifications page, provide the following information:
   a. For Algorithm name, type a name for your algorithm. The algorithm name must be unique in your account and in the AWS region. The name must have 1 to 64 characters. Valid characters are a-z, A-Z, 0-9, and - (hyphen).
   b. Type a description for your algorithm. This description appears in the SageMaker console and in the AWS Marketplace.
   c. For Training image, type the path in Amazon ECR where your training container is stored.
   d. For Support distributed training, Choose Yes if your algorithm supports training on multiple instances. Otherwise, choose No.
   e. For Support instance types for training, choose the instance types that your algorithm supports.
   f. For Channel specification, specify up to 8 channels of input data for your algorithm. For example, you might specify 3 input channels named train, validation, and test. For each channel, specify the following information:
      i. For Channel name, type a name for the channel. The name must have 1 to 64 characters. Valid characters are a-z, A-Z, 0-9, and - (hyphen).
      ii. To require the channel for your algorithm, choose Channel required.
      iii. Type a description for the channel.
      iv. For Supported input modes, choose Pipe mode if your algorithm supports streaming the input data, and File mode if your algorithm supports downloading the input data as a file. You can choose both.
      v. For Supported content types, type the MIME type that your algorithm expects for input data.
      vi. For Supported compression type, choose Gzip if your algorithm supports Gzip compression. Otherwise, choose None.
vii. Choose **Add channel** to add another data input channel, or choose **Next** if you are done adding channels.

5. On the **Tuning specifications** page, provide the following information:

a. For **Hyperparameter specification**, specify the hyperparameters that your algorithm supports by editing the JSON object. For each hyperparameter that your algorithm supports, construct a JSON block similar to the following:

```
{
    "DefaultValue": "5",
    "Description": "The first hyperparameter",
    "IsRequired": true,
    "IsTunable": false,
    "Name": "intRange",
    "Range": {
        "IntegerParameterRangeSpecification": {
            "MaxValue": "10",
            "MinValue": "1"
        },
        "Type": "Integer"
    }
}
```

In the JSON, supply the following:

i. For **DefaultValue**, specify a default value for the hyperparameter, if there is one.

ii. For **Description**, specify a description for the hyperparameter.

iii. For **IsRequired**, specify whether the hyperparameter is required.

iv. For **IsTunable**, specify **true** if this hyperparameter can be tuned when a user runs a hyperparameter tuning job that uses this algorithm. For information, see [Perform Automatic Model Tuning with SageMaker](p. 1863).

v. For **Name**, specify a name for the hyperparameter.

vi. For **Range**, specify one of the following:

- **IntegerParameterRangeSpecification** - the values of the hyperparameter are integers. Specify minimum and maximum values for the hyperparameter.
- **ContinuousParameterRangeSpecification** - the values of the hyperparameter are floating-point values. Specify minimum and maximum values for the hyperparameter.
- **CategoricalParameterRangeSpecification** - the values of the hyperparameter are categorical values. Specify a list of all of the possible values.

vii. For **Type**, specify **Integer**, **Continuous**, or **Categorical**. The value must correspond to the type of **Range** that you specified.

b. For **Metric definitions**, specify any training metrics that you want your algorithm to emit. SageMaker uses the regular expression that you specify to find the metrics by parsing the logs from your training container during training. Users can view these metrics when they run training jobs with your algorithm, and they can monitor and plot the metrics in Amazon CloudWatch. For information, see [Monitor and Analyze Training Jobs Using Amazon CloudWatch Metrics](p. 2315). For each metric, provide the following information:

i. For **Metric name**, type a name for the metric.

ii. For **RegEx**, type the regular expression that SageMaker uses to parse training logs so that it can find the metric value.

iii. For **Objective metric support** choose **Yes** if this metric can be used as the objective metric for a hyperparameter tuning job. For information, see [Perform Automatic Model Tuning with SageMaker](p. 1863).
iv. Choose Add metric to add another metric, or choose Next if you are done adding metrics.

6. On the Inference specifications page, provide the following information if your algorithm supports inference:

   a. For Location of inference image, type the path in Amazon ECR where your inference container is stored.
   b. For Container DNS host name, type the name of a DNS host for your image.
   c. For Supported instance types for real-time inference, choose the instance types that your algorithm supports for models deployed as hosted endpoints in SageMaker. For information, see Deploy models for inference (p. 2335).
   d. For Supported instance types for batch transform jobs, choose the instance types that your algorithm supports for batch transform jobs. For information, see Use Batch Transform (p. 2545).
   e. For Supported content types, type the type of input data that your algorithm expects for inference requests.
   f. For Supported response MIME types, type the MIME types that your algorithm supports for inference responses.
   g. Choose Next.

7. On the Validation specifications page, provide the following information:

   a. For Publish this algorithm on AWS Marketplace, choose Yes to publish the algorithm on AWS Marketplace.
   b. For Validate this resource, choose Yes if you want SageMaker to run training jobs and/or batch transform jobs that you specify to test the training and/or inference code of your algorithm.
      
      Note
      To publish your algorithm on AWS Marketplace, your algorithm must be validated.
   c. For IAM role, choose an IAM role that has the required permissions to run training jobs and batch transform jobs in SageMaker, or choose Create a new role to allow SageMaker to create a role that has the AmazonSageMakerFullAccess managed policy attached. For information, see SageMaker Roles (p. 3387).
   d. For Validation profile, specify the following:

      • A name for the validation profile.
      • A Training job definition. This is a JSON block that describes a training job. This is in the same format as the TrainingJobDefinition input parameter of the CreateAlgorithm API.
      • A Transform job definition. This is a JSON block that describes a batch transform job. This is in the same format as the TransformJobDefinition input parameter of the CreateAlgorithm API.
   e. Choose Create algorithm.

Create an Algorithm Resource (API)

To create an algorithm resource by using the SageMaker API, call the CreateAlgorithm API.

Create a Model Package Resource

To create a model package resource that you can use to create deployable models in Amazon SageMaker and publish on AWS Marketplace specify the following information:

• The Docker container that contains the inference code, or the algorithm resource that was used to train the model.
• The location of the model artifacts. Model artifacts can either be packaged in the same Docker container as the inference code or stored in Amazon S3.

• The instance types that your model package supports for both real-time inference and batch transform jobs.

• Validation profiles, which are batch transform jobs that SageMaker runs to test your model package's inference code.

Before listing model packages on AWS Marketplace, you must validate them. This ensures that buyers and sellers can be confident that products work in Amazon SageMaker. You can list products on AWS Marketplace only if validation succeeds.

The validation procedure uses your validation profile and sample data to run the following validations tasks:

1. Create a model in your account using the model package's inference image and the optional model artifacts that are stored in Amazon S3.

   Note
   A model package is specific to the region in which you create it. The S3 bucket where the model artifacts are stored must be in the same region where your created the model package.

2. Create a transform job in your account using the model to verify that your inference image works with SageMaker.

3. Create a validation profile.

   Note
   In your validation profile, provide only data that you want to expose publicly.

Validation can take up to a few hours. To see the status of the jobs in your account, in the SageMaker console, see the Transform jobs pages. If validation fails, you can access the scan and validation reports from the SageMaker console. After fixing issues, recreate the algorithm. When the status of the algorithm is COMPLETED, find it in the SageMaker console and start the listing process.

   Note
   To publish your model package on AWS Marketplace, at least one validation profile is required.

You can create an model package either by using the SageMaker console or by using the SageMaker API.

Topics
• Create a Model Package Resource (Console) (p. 3564)
• Create a Model Package Resource (API) (p. 3566)

Create a Model Package Resource (Console)

To create a model package in the SageMaker console:

2. From the left menu, choose Inference.
3. Choose Marketplace model packages, then choose Create marketplace model package.
4. On the Inference specifications page, provide the following information:
   a. For Model package name, type a name for your model package. The model package name must be unique in your account and in the AWS region. The name must have 1 to 64 characters. Valid characters are a-z, A-Z, 0-9, and - (hyphen).
b. Type a description for your model package. This description appears in the SageMaker console and in the AWS Marketplace.

c. For Inference specification options, choose Provide the location of the inference image and model artifacts to create a model package by using an inference container and model artifacts. Choose Provide the algorithm used for training and its model artifacts to create a model package from an algorithm resource that you created or subscribe to from AWS Marketplace.

d. If you chose Provide the location of the inference image and model artifacts for Inference specification options, provide the following information for Container definition and Supported resources:

   i. For Location of inference image, type the path to the image that contains your inference code. The image must be stored as a Docker container in Amazon ECR.
   ii. For Location of model data artifacts, type the location in S3 where your model artifacts are stored.
   iii. For Container DNS host name, type the name of the DNS host to use for your container.
   iv. For Supported instance types for real-time inference, choose the instance types that your model package supports for real-time inference from SageMaker hosted endpoints.
   v. For Supported instance types for batch transform jobs, choose the instance types that your model package supports for batch transform jobs.
   vi. Supported content types, type the content types that your model package expects for inference requests.
   vii. For Supported response MIME types, type the MIME types that your model package uses to provide inferences.

e. If you chose Provide the algorithm used for training and its model artifacts for Inference specification options, provide the following information:

   i. For Algorithm ARN, type the Amazon Resource Name (ARN) of the algorithm resource to use to create the model package.
   ii. For Location of model data artifacts, type the location in S3 where your model artifacts are stored.

f. Choose Next.

5. On the Validation and scanning page, provide the following information:

a. For Publish this model package on AWS Marketplace, choose Yes to publish the model package on AWS Marketplace.

b. For Validate this resource, choose Yes if you want SageMaker to run batch transform jobs that you specify to test the inference code of your model package.

   Note
   To publish your model package on AWS Marketplace, your model package must be validated.

c. For IAM role, choose an IAM role that has the required permissions to run batch transform jobs in SageMaker, or choose Create a new role to allow SageMaker to create a role that has the AmazonSageMakerFullAccess managed policy attached. For information, see SageMaker Roles (p. 3387).

d. For Validation profile, specify the following:

   • A name for the validation profile.
   • A Transform job definition. This is a JSON block that describes a batch transform job. This is in the same format as the TransformJobDefinition input parameter of the CreateAlgorithm API.

Create a Model Package Resource (API)

To create a model package by using the SageMaker API, call the `CreateModelPackage` API.

Use Algorithm and Model Package Resources

You can create algorithms and model packages as resources in your Amazon SageMaker account, and you can find and subscribe to algorithms and model packages on AWS Marketplace.

Use algorithms to:

- Run training jobs. For information, see Use an Algorithm to Run a Training Job (p. 3567).
- Run hyperparameter tuning jobs. For information, see Use an Algorithm to Run a Hyperparameter Tuning Job (p. 3569).
- Create model packages. After you use an algorithm resource to run a training job or a hyperparameter tuning job, you can use the model artifacts that these jobs output along with the algorithm to create a model package. For information, see Create a Model Package Resource (p. 3563).

Note

If you subscribe to an algorithm on AWS Marketplace, you must create a model package before you can use it to get inferences by creating hosted endpoint or running a batch transform job.
• Create models that you can use to get real-time inference or run batch transform jobs. For information, see Use a Model Package to Create a Model (p. 3572).
• Create hosted endpoints to get real-time inference. For information, see Deploy the Model to SageMaker Hosting Services (p. 310).
• Create batch transform jobs. For information, see (Optional) Make Prediction with Batch Transform (p. 311).

Topics
• Use an Algorithm to Run a Training Job (p. 3567)
• Use an Algorithm to Run a Hyperparameter Tuning Job (p. 3569)
• Use a Model Package to Create a Model (p. 3572)

Use an Algorithm to Run a Training Job

You can create an algorithm resource to create a training job by using the Amazon SageMaker console, the low-level Amazon SageMaker API, or the Amazon SageMaker Python SDK.

Topics
• Use an Algorithm to Run a Training Job (Console) (p. 3567)
• Use an Algorithm to Run a Training Job (API) (p. 3568)
• Use an Algorithm to Run a Training Job (Amazon SageMaker Python SDK) (p. 3568)

Use an Algorithm to Run a Training Job (Console)

To use an algorithm to run a training job (console)

2. Choose Algorithms.
3. Choose an algorithm that you created from the list on the My algorithms tab or choose an algorithm that you subscribed to on the AWS Marketplace subscriptions tab.
4. Choose Create training job.

The algorithm you chose will automatically be selected.
5. On the Create training job page, provide the following information:
   a. For Job name, type a name for the training job.
   b. For IAM role, choose an IAM role that has the required permissions to run training jobs in SageMaker, or choose Create a new role to allow SageMaker to create a role that has the AmazonSageMakerFullAccess managed policy attached. For information, see SageMaker Roles (p. 3387).
   c. For Resource configuration, provide the following information:
      i. For Instance type, choose the instance type to use for training.
      ii. For Instance count, type the number of ML instances to use for the training job.
      iii. For Additional volume per instance (GB), type the size of the ML storage volume that you want to provision. ML storage volumes store model artifacts and incremental states.
      iv. For Encryption key, if you want Amazon SageMaker to use an AWS Key Management Service key to encrypt data in the ML storage volume attached to the training instance, specify the key.
      v. For Stopping condition, specify the maximum amount of time in seconds, minutes, hours, or days, that you want the training job to run.
d. For VPC, choose a Amazon VPC that you want to allow your training container to access. For more information, see Give SageMaker Training Jobs Access to Resources in Your Amazon VPC (p. 3542).

e. For Hyperparameters, specify the values of the hyperparameters to use for the training job.

f. For Input data configuration, specify the following values for each channel of input data to use for the training job. You can see what channels the algorithm you're using for training support, and the content type, supported compression type, and supported input modes for each channel, under Channel specification section of the Algorithm summary page for the algorithm.

i. For Channel name, type the name of the input channel.

ii. For Content type, type the content type of the data that the algorithm expects for the channel.

iii. For Compression type, choose the data compression type to use, if any.

iv. For Record wrapper, choose RecordIO if the algorithm expects data in the RecordIO format.

v. For S3 data type, S3 data distribution type, and S3 location, specify the appropriate values. For information about what these values mean, see S3DataSource.

vi. For Input mode, choose File to download the data from to the provisioned ML storage volume, and mount the directory to a Docker volume. Choose PipeTo stream data directly from Amazon S3 to the container.

vii. To add another input channel, choose Add channel. If you are finished adding input channels, choose Done.

g. For Output location, specify the following values:

i. For S3 output path, choose the S3 location where the training job stores output, such as model artifacts.

   Note
   You use the model artifacts stored at this location to create a model or model package from this training job.

ii. For Encryption key, if you want SageMaker to use a AWS KMS key to encrypt output data at rest in the S3 location.

h. For Tags, specify one or more tags to manage the training job. Each tag consists of a key and an optional value. Tag keys must be unique per resource.

i. Choose Create training job to run the training job.

Use an Algorithm to Run a Training Job (API)

To use an algorithm to run a training job by using the SageMaker API, specify either the name or the Amazon Resource Name (ARN) as the AlgorithmName field of the AlgorithmSpecification object that you pass to CreateTrainingJob. For information about training models in SageMaker, see Train a Model with Amazon SageMaker (p. 1521).

Use an Algorithm to Run a Training Job (Amazon SageMaker Python SDK)

Use an algorithm that you created or subscribed to on AWS Marketplace to create a training job, create an AlgorithmEstimator object and specify either the Amazon Resource Name (ARN) or the name of the algorithm as the value of the algorithm_arn argument. Then call the fit method of the estimator. For example:

```python
from sagemaker import AlgorithmEstimator
data_path = os.path.join(DATA_DIR, 'marketplace', 'training')
```
Use an Algorithm to Run a Hyperparameter Tuning Job

A hyperparameter tuning job finds the best version of a model by running many training jobs on your dataset using the algorithm and ranges of hyperparameters that you specify. It then chooses the hyperparameter values that result in a model that performs the best, as measured by a metric that you choose. For more information, see Perform Automatic Model Tuning with SageMaker (p. 1863).

You can create use an algorithm resource to create a hyperparameter tuning job by using the Amazon SageMaker console, the low-level Amazon SageMaker API, or the Amazon SageMaker Python SDK.

Topics
- Use an Algorithm to Run a Hyperparameter Tuning Job (Console) (p. 3569)
- Use an Algorithm to Run a Hyperparameter Tuning Job (API) (p. 3571)
- Use an Algorithm to Run a Hyperparameter Tuning Job (Amazon SageMaker Python SDK) (p. 3571)

Use an Algorithm to Run a Hyperparameter Tuning Job (Console)

To use an algorithm to run a hyperparameter tuning job (console)

2. Choose Algorithms.
3. Choose an algorithm that you created from the list on the My algorithms tab or choose an algorithm that you subscribed to on the AWS Marketplace subscriptions tab.
4. Choose Create hyperparameter tuning job.

The algorithm you chose will automatically be selected.

5. On the Create hyperparameter tuning job page, provide the following information:
   a. For Warm start, choose Enable warm start to use the information from previous hyperparameter tuning jobs as a starting point for this hyperparameter tuning job. For more information, see Run a Warm Start Hyperparameter Tuning Job (p. 1895).
      i. Choose Identical data and algorithm if your input data is the same as the input data for the parent jobs of this hyperparameter tuning job, or choose Transfer learning to use additional or different input data for this hyperparameter tuning job.
      ii. For Parent hyperparameter tuning job(s), choose up to 5 hyperparameter tuning jobs to use as parents to this hyperparameter tuning job.
   b. For Hyperparameter tuning job name, type a name for the tuning job.
   c. For IAM role, choose an IAM role that has the required permissions to run hyperparameter tuning jobs in SageMaker, or choose Create a new role to allow SageMaker to create a role that has the AmazonSageMakerFullAccess managed policy attached. For information, see SageMaker Roles (p. 3387).
For **VPC**, choose an Amazon VPC that you want to allow the training jobs that the tuning job launches to access. For more information, see [Give SageMaker Training Jobs Access to Resources in Your Amazon VPC](p. 3542).

**e.** Choose **Next**.

**f.** For **Objective metric**, choose the metric that the hyperparameter tuning job uses to determine the best combination of hyperparameters, and choose whether to minimize or maximize this metric. For more information, see [View the Best Training Job](p. 1893).

**g.** For **Hyperparameter configuration**, choose ranges for the tunable hyperparameters that you want the tuning job to search, and set static values for hyperparameters that you want to remain constant in all training jobs that the hyperparameter tuning job launches. For more information, see [Define Hyperparameter Ranges](p. 1868).

**h.** Choose **Next**.

**i.** For **Input data configuration**, specify the following values for each channel of input data to use for the hyperparameter tuning job. You can see what channels the algorithm you're using for hyperparameter tuning supports, and the content type, supported compression type, and supported input modes for each channel, under **Channel specification** section of the **Algorithm summary** page for the algorithm.

i. For **Channel name**, type the name of the input channel.

ii. For **Content type**, type the content type of the data that the algorithm expects for the channel.

iii. For **Compression type**, choose the data compression type to use, if any.

iv. For **Record wrapper**, choose **RecordIO** if the algorithm expects data in the **RecordIO** format.

v. For **S3 data type**, **S3 data distribution type**, and **S3 location**, specify the appropriate values. For information about what these values mean, see **S3DataSource**.

vi. For **Input mode**, choose **File** to download the data from to the provisioned ML storage volume, and mount the directory to a Docker volume. Choose **Pipe** to stream data directly from Amazon S3 to the container.

vii. To add another input channel, choose **Add channel**. If you are finished adding input channels, choose **Done**.

**j.** For **Output location**, specify the following values:

i. For **S3 output path**, choose the S3 location where the training jobs that this hyperparameter tuning job launches store output, such as model artifacts.

**Note**
You use the model artifacts stored at this location to create a model or model package from this hyperparameter tuning job.

ii. For **Encryption key**, if you want SageMaker to use an AWS KMS key to encrypt output data at rest in the S3 location.

**k.** For **Resource configuration**, provide the following information:

i. For **Instance type**, choose the instance type to use for each training job that the hyperparameter tuning job launches.

ii. For **Instance count**, type the number of ML instances to use for each training job that the hyperparameter tuning job launches.

iii. For **Additional volume per instance (GB)**, type the size of the ML storage volume that you want to provision each training job that the hyperparameter tuning job launches. ML storage volumes store model artifacts and incremental states.

iv. For **Encryption key**, if you want Amazon SageMaker to use an AWS Key Management Service key to encrypt data in the ML storage volume attached to the training instances, specify the key.
l. For **Resource limits**, provide the following information:

   i. For **Maximum training jobs**, specify the maximum number of training jobs that you want the hyperparameter tuning job to launch. A hyperparameter tuning job can launch a maximum of 500 training jobs.

   ii. For **Maximum parallel training jobs**, specify the maximum number of concurrent training jobs that the hyperparameter tuning job can launch. A hyperparameter tuning job can launch a maximum of 10 concurrent training jobs.

   iii. For **Stopping condition**, specify the maximum amount of time in seconds, minutes, hours, or days, that you want each training job that the hyperparameter tuning job launches to run.

m. For **Tags**, specify one or more tags to manage the hyperparameter tuning job. Each tag consists of a key and an optional value. Tag keys must be unique per resource.

n. Choose **Create jobs** to run the hyperparameter tuning job.

### Use an Algorithm to Run a Hyperparameter Tuning Job (API)

To use an algorithm to run a hyperparameter tuning job by using the SageMaker API, specify either the name or the Amazon Resource Name (ARN) of the algorithm as the `AlgorithmName` field of the `AlgorithmSpecification` object that you pass to `CreateHyperParameterTuningJob`. For information about hyperparameter tuning in SageMaker, see [Perform Automatic Model Tuning with SageMaker](p. 1863).

### Use an Algorithm to Run a Hyperparameter Tuning Job (Amazon SageMaker Python SDK)

Use an algorithm that you created or subscribed to on AWS Marketplace to create a hyperparameter tuning job, create an `AlgorithmEstimator` object and specify either the Amazon Resource Name (ARN) or the name of the algorithm as the value of the `algorithm_arn` argument. Then initialize a `HyperparameterTuner` object with the `AlgorithmEstimator` you created as the value of the `estimator` argument. Finally, call the `fit` method of the `AlgorithmEstimator`. For example:

```python
from sagemaker import AlgorithmEstimator
from sagemaker.tuner import HyperparameterTuner

data_path = os.path.join(DATA_DIR, 'marketplace', 'training')

algo = AlgorithmEstimator(
    role='SageMakerRole',
    instance_count=1,
    instance_type='ml.c4.xlarge',
    sagemaker_session=sagemaker_session,
    base_job_name='test-marketplace')

train_input = algo.sagemaker_session.upload_data(
    path=data_path, key_prefix='integ-test-data/marketplace/train')

algo.set_hyperparameters(max_leaf_nodes=10)

tuner = HyperparameterTuner(estimator=algo, base_tuning_job_name='some-name',
                            objective_metric_name='validation:accuracy',
                            hyperparameter_ranges=hyperparameter_ranges,
                            max_jobs=2, max_parallel_jobs=2)

tuner.fit({'training': train_input}, include_cls_metadata=False)

tuner.wait()
```
Use a Model Package to Create a Model

Use a model package to create a deployable model that you can use to get real-time inferences by creating a hosted endpoint or to run batch transform jobs. You can create a deployable model from a model package by using the Amazon SageMaker console, the low-level SageMaker API, or the Amazon SageMaker Python SDK.

Topics
- Use a Model Package to Create a Model (Console) (p. 3572)
- Use a Model Package to Create a Model (API) (p. 3572)
- Use a Model Package to Create a Model (Amazon SageMaker Python SDK) (p. 3573)

Use a Model Package to Create a Model (Console)

To create a deployable model from a model package (console)

2. Choose Model packages.
3. Choose a model package that you created from the list on the My model packages tab or choose a model package that you subscribed to on the AWS Marketplace subscriptions tab.
4. Choose Create model.
5. For Model name, type a name for the model.
6. For IAM role, choose an IAM role that has the required permissions to call other services on your behalf, or choose Create a new role to allow SageMaker to create a role that has the AmazonSageMakerFullAccess managed policy attached. For information, see SageMaker Roles (p. 3387).
7. For VPC, choose a Amazon VPC that you want to allow the model to access. For more information, see Give SageMaker Hosted Endpoints Access to Resources in Your Amazon VPC (p. 3545).
8. Leave the default values for Container input options and Choose model package.
9. For environment variables, provide the names and values of environment variables you want to pass to the model container.
10. For Tags, specify one or more tags to manage the model. Each tag consists of a key and an optional value. Tag keys must be unique per resource.
11. Choose Create model.

After you create a deployable model, you can use it to set up an endpoint for real-time inference or create a batch transform job to get inferences on entire datasets. For information about hosting endpoints in SageMaker, see Deploy Models for Inference.

Use a Model Package to Create a Model (API)

To use a model package to create a deployable model by using the SageMaker API, specify the name or the Amazon Resource Name (ARN) of the model package as the ModelPackageName field of the ContainerDefinition object that you pass to the CreateModel API.

After you create a deployable model, you can use it to set up an endpoint for real-time inference or create a batch transform job to get inferences on entire datasets. For information about hosted endpoints in SageMaker, see Deploy Models for Inference.
Use a Model Package to Create a Model (Amazon SageMaker Python SDK)

To use a model package to create a deployable model by using the SageMaker Python SDK, initialize a ModelPackage object, and pass the Amazon Resource Name (ARN) of the model package as the model_package_arn argument. For example:

```python
from sagemaker import ModelPackage
model = ModelPackage(role='SageMakerRole',
                      model_package_arn='training-job-scikit-decision-trees-1542660466-6f92',
                      sagemaker_session=sagemaker_session)
```

After you create a deployable model, you can use it to set up an endpoint for real-time inference or create a batch transform job to get inferences on entire datasets. For information about hosting endpoints in SageMaker, see Deploy Models for Inference.

Sell Amazon SageMaker Algorithms and Model Packages

Selling Amazon SageMaker algorithms and model packages is a three-step process:

1. Develop your algorithm or model, and package it in a Docker container. For information, see Develop Algorithms and Models in Amazon SageMaker (p. 3574).
2. Create an algorithm or model package resource in SageMaker. For information, see Create Algorithm and Model Package Resources (p. 3560).
3. Register as a seller on AWS Marketplace and list your algorithm or model package on AWS Marketplace. For information about registering as a seller, see Getting Started as a Seller in the User Guide for AWS Marketplace Providers. For information about listing and monetizing your algorithms and model packages, see Listing Algorithms and Model Packages in AWS Marketplace for Machine Learning in the User Guide for AWS Marketplace Providers.
Develop Algorithms and Models in Amazon SageMaker

Before you can create algorithm and model package resources to use in Amazon SageMaker or list on AWS Marketplace, you have to develop them and package them in Docker containers.

**Note**
When algorithms and model packages are created for listing on AWS Marketplace, SageMaker scans the containers for security vulnerabilities on supported operating systems. Only the following operating system versions are supported:

- Debian: 6.0, 7, 8, 9, 10
- CentOS: 5, 6, 7
- Oracle Linux: 5, 6, 7
- Alpine: 3.3, 3.4, 3.5
- Amazon Linux

**Develop Algorithms in SageMaker**

An algorithm should be packaged as a docker container and stored in Amazon ECR to use it in SageMaker. The Docker container contains the training code used to run training jobs and, optionally, the inference code used to get inferences from models trained by using the algorithm.

For information about developing algorithms in SageMaker and packaging them as containers, see [Use Docker containers to build models](https://sagemaker-examples.readthedocs.io/en/latest/advanced_functionality/scikitbring_your_own/scikitbring_your_own.html). For a complete example of how to create an algorithm container, see the sample notebook at https://sagemaker-examples.readthedocs.io/en/latest/advanced_functionality/scikitbring_your_own/scikitbring_your_own.html. You can also find the sample notebook in a SageMaker notebook instance. The notebook is in the Advanced Functionality section, and is named scikitbring_your_own.ipynb. For information about using the sample notebooks in a notebook instance, see [Example Notebooks](p. 330).

Always thoroughly test your algorithms before you create algorithm resources to publish on AWS Marketplace.

**Note**
When a buyer subscribes to your containerized product, the Docker containers run in an isolated (internet-free) environment. When you create your containers, do not rely on making outgoing calls over the internet. Calls to AWS services are also not allowed.
Develop Models in SageMaker

A deployable model in SageMaker consists of inference code, model artifacts, an IAM role that is used to access resources, and other information required to deploy the model in SageMaker. Model artifacts are the results of training a model by using a machine learning algorithm. The inference code must be packaged in a Docker container and stored in Amazon ECR. You can either package the model artifacts in the same container as the inference code, or store them in Amazon S3.

You create a model by running a training job in SageMaker, or by training a machine learning algorithm outside of SageMaker. If you run a training job in SageMaker, the resulting model artifacts are available in the ModelArtifacts field in the response to a call to the DescribeTrainingJob operation. For information about how to develop a SageMaker model container, see Use your own inference code (p. 3327). For a complete example of how to create a model container from a model trained outside of SageMaker, see the sample notebook at https://sagemaker-examples.readthedocs.io/en/latest/advanced_functionality/xgboost_bring_your_own_model/xgboost_bring_your_own_model.html. You can also find the sample notebook in a SageMaker notebook instance. The notebook is in the Advanced Functionality section, and is named xgboost_bring_your_own_model.ipynb. For information about using the sample notebooks in a notebook instance, see Example Notebooks (p. 330).

Always thoroughly test your models before you create model packages to publish on AWS Marketplace.

Note
When a buyer subscribes to your containerized product, the Docker containers run in an isolated (internet-free) environment. When you create your containers, do not rely on making outgoing calls over the internet. Calls to AWS services are also not allowed.

List Your Algorithm or Model Package on AWS Marketplace

After creating and validating your algorithm or model in Amazon SageMaker, list your product on AWS Marketplace. The listing process makes your products available in the AWS Marketplace and the SageMaker console.

To list products on AWS Marketplace, you must be a registered seller. To register, use the self-registration process from the AWS Marketplace Management Portal (AMMP). For information, see Getting Started as a Seller in the User Guide for AWS Marketplace Providers. When you start the product listing process from the Amazon SageMaker console, we check your seller registration status. If you have not registered, we direct you to do so.

To start the listing process, do one of the following:

• From the SageMaker console, choose the product, choose Actions, and choose Publish new ML Marketplace listing. This carries over your product reference, the Amazon Resource Name (ARN), and directs you to the AMMP to create the listing.
• Go to ML listing process, manually enter the Amazon Resource Name (ARN), and start your product listing. This process carries over the product metadata that you entered when creating the product in SageMaker. For an algorithm listing, the information includes the supported instance types and hyperparameters. In addition, you can enter a product description, promotional information, and support information as you would with other AWS Marketplace products.
Find and Subscribe to Algorithms and Model Packages on AWS Marketplace

With AWS Marketplace, you can browse and search for hundreds of machine learning algorithms and models in a broad range of categories, such as computer vision, natural language processing, speech recognition, text, data, voice, image, video analysis, fraud detection, predictive analysis, and more.

To find algorithms on AWS Marketplace

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Choose Algorithms, then choose Find algorithms.

This takes you to the AWS Marketplace algorithms page. For information about finding and subscribing to algorithms on AWS Marketplace, see Machine Learning Products in the AWS Marketplace User Guide for AWS Consumers.

To find model packages on AWS Marketplace

2. Choose Model packages, then choose Find model packages.

This takes you to the AWS Marketplace model packages page. For information about finding and subscribing to model packages on AWS Marketplace, see Machine Learning Products in the AWS Marketplace User Guide for AWS Consumers.

Use Algorithms and Model Packages

For information about using algorithms and model packages that you subscribe to in SageMaker, see Use Algorithm and Model Package Resources (p. 3566).

Note
When you create a training job, inference endpoint, and batch transform job from an algorithm or model package that you subscribe to on AWS Marketplace, the training and inference containers do not have access to the internet. Because the containers do not have access to the internet, the seller of the algorithm or model package does not have access to your data.
Monitor AWS resources provisioned while using Amazon SageMaker

Monitoring is an important part of maintaining the reliability, availability, and performance of SageMaker and your other AWS solutions. AWS provides the following monitoring tools to watch SageMaker, report when something is wrong, and take automatic actions when appropriate:

- **Amazon CloudWatch** monitors your AWS resources and the applications that you run on AWS in real time. You can collect and track metrics, create customized dashboards, and set alarms that notify you or take actions when a specified metric reaches a threshold that you specify. For example, you can have CloudWatch track CPU usage or other metrics of your Amazon EC2 instances and automatically launch new instances when needed. For more information, see the [Amazon CloudWatch User Guide](https://docs.aws.amazon.com/AmazonCloudWatch/latest/UserGuide/).

- **Amazon CloudWatch Logs** enables you to monitor, store, and access your log files from EC2 instances, AWS CloudTrail, and other sources. CloudWatch Logs can monitor information in the log files and notify you when certain thresholds are met. You can also archive your log data in highly durable storage. For more information, see the [Amazon CloudWatch Logs User Guide](https://docs.aws.amazon.com/AmazonCloudWatchLogs/latest/UserGuide/).

- **AWS CloudTrail** captures API calls and related events made by or on behalf of your AWS account and delivers the log files to an Amazon S3 bucket that you specify. You can identify which users and accounts called AWS, the source IP address from which the calls were made, and when the calls occurred. For more information, see the [AWS CloudTrail User Guide](https://docs.aws.amazon.com/AmazonCloudWatchLogs/latest/UserGuide/).

- **CloudWatch Events** delivers a near real-time stream of system events that describe changes in AWS resources. Create CloudWatch Events rules react to a status change in a SageMaker training, hyperparameter tuning, or batch transform job.

**Topics**
- Monitor Amazon SageMaker with Amazon CloudWatch (p. 3577)
- Log Amazon SageMaker Events with Amazon CloudWatch (p. 3591)
- Log Amazon SageMaker API Calls with AWS CloudTrail (p. 3592)
- Monitoring user resource access from Amazon SageMaker Studio (p. 3595)
- Automating Amazon SageMaker with Amazon EventBridge (p. 3597)

Monitor Amazon SageMaker with Amazon CloudWatch

You can monitor Amazon SageMaker using Amazon CloudWatch, which collects raw data and processes it into readable, near real-time metrics. These statistics are kept for 15 months, so that you can access historical information and gain a better perspective on how your web application or service is performing. However, the Amazon CloudWatch console limits the search to metrics that were updated in the last 2 weeks. This limitation ensures that the most current jobs are shown in your namespace. To graph metrics without using a search, specify its exact name in the source view. You can also set alarms that watch for certain thresholds, and send notifications or take actions when those thresholds are met. For more information, see the [Amazon CloudWatch User Guide](https://docs.aws.amazon.com/AmazonCloudWatch/latest/UserGuide/).

**SageMaker Metrics and Dimensions**
SageMaker Endpoint Invocation Metrics

The AWS/SageMaker namespace includes the following request metrics from calls to `InvokeEndpoint`.

Metrics are available at a 1-minute frequency.

The following illustration shows how a SageMaker endpoint interacts with the Amazon SageMaker Runtime API. The overall time between sending a request to an endpoint and receiving a response depends on the following three components.

- **Network latency** – the time that it takes between making a request to the SageMaker Runtime Runtime API and receiving a response back from the SageMaker Runtime Runtime API.
- **Overhead latency** – the time that it takes to transport a request to the model container from the SageMaker Runtime Runtime API and transport the response back to the SageMaker Runtime Runtime API.
- **Model latency** – the time that it takes the model container to process the request and return a response.

For more information about total latency, see [Best practices for load testing Amazon SageMaker real-time inference endpoints](#). For information about how long CloudWatch metrics are retained for, see [GetMetricStatistics](#) in the [Amazon CloudWatch API Reference](#).
## Endpoint Invocation Metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Invocation4XXErrors</td>
<td>The number of InvokeEndpoint requests where the model returned a 4xx HTTP response code. For each 4xx response, 1 is sent; otherwise, 0 is sent. Units: None Valid statistics: Average, Sum</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>Invocation5XXErrors</td>
<td>The number of InvokeEndpoint requests where the model returned a 5xx HTTP response code. For each 5xx response, 1 is sent; otherwise, 0 is sent. Units: None Valid statistics: Average, Sum</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>InvocationModelErrors</td>
<td>The number of model invocation requests which did not result in 2XX HTTP response. This includes 4XX/5XX status codes, low-level socket errors, malformed HTTP responses, and request timeouts. For each error response, 1 is sent; otherwise, 0 is sent. Units: None Valid statistics: Average, Sum</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>Invocations</td>
<td>The number of InvokeEndpoint requests sent to a model endpoint. To get the total number of requests sent to a model endpoint, use the Sum statistic. Units: None Valid statistics: Sum</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>InvocationsPerInstance</td>
<td>The number of invocations sent to a model, normalized by InstanceCount in each ProductionVariant. 1/numberOfInstances is sent as the value on each request, where numberOfInstances is the number of active instances for the ProductionVariant behind the endpoint at the time of the request. Units: None Valid statistics: Sum</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>ModelLatency</td>
<td>The interval of time taken by a model to respond to a SageMaker Runtime API request. This interval includes the local communication times taken to send the request and to fetch the response from the model container and the time taken to complete the inference in the container. Units: Microseconds Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>OverheadLatency</td>
<td>The interval of time added to the time taken to respond to a client request by SageMaker overheads. This interval is measured from the time SageMaker receives the request until it returns a response to the client, minus the ModelLatency. Overhead latency can vary depending on multiple factors, including request and response payload sizes, request frequency, and authentication/authorization of the request.</td>
</tr>
</tbody>
</table>
### Multi-Model Endpoint Metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Units</strong>: Microseconds</td>
</tr>
<tr>
<td></td>
<td><strong>Valid statistics</strong>: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td><strong>ModelSetupTime</strong></td>
<td>The time it takes to launch new compute resources for a serverless endpoint. The time can vary depending on the model size, how long it takes to download the model, and the start-up time of the container.</td>
</tr>
<tr>
<td></td>
<td><strong>Units</strong>: Microseconds</td>
</tr>
<tr>
<td></td>
<td><strong>Valid statistics</strong>: Average, Min, Max, Sample Count, Percentiles</td>
</tr>
</tbody>
</table>

### Dimensions for Endpoint Invocation Metrics

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>EndpointName,</strong></td>
<td>Filters endpoint invocation metrics for a ProductionVariant of the specified endpoint and variant.</td>
</tr>
<tr>
<td><strong>VariantName</strong></td>
<td></td>
</tr>
</tbody>
</table>

### SageMaker Multi-Model Endpoint Metrics

The AWS/SageMaker namespace includes the following model loading metrics from calls to `InvokeEndpoint`.

Metrics are available at a 1-minute frequency.

For information about how long CloudWatch metrics are retained for, see [GetMetricStatistics](https://docs.aws.amazon.com/AmazonCloudWatch/latest/APIReference/API_GetMetricStatistics.html) in the Amazon CloudWatch API Reference.

#### Multi-Model Endpoint Model Loading Metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ModelLoadingWaitTime</strong></td>
<td>The interval of time that an invocation request has waited for the target model to be downloaded, or loaded, or both in order to perform inference.</td>
</tr>
<tr>
<td></td>
<td><strong>Units</strong>: Microseconds</td>
</tr>
<tr>
<td></td>
<td><strong>Valid statistics</strong>: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td><strong>ModelUnloadingTime</strong></td>
<td>The interval of time that it took to unload the model through the container's UnloadModel API call.</td>
</tr>
<tr>
<td></td>
<td><strong>Units</strong>: Microseconds</td>
</tr>
<tr>
<td></td>
<td><strong>Valid statistics</strong>: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td><strong>ModelDownloadingTime</strong></td>
<td>The interval of time that it took to download the model from Amazon Simple Storage Service (Amazon S3).</td>
</tr>
<tr>
<td></td>
<td><strong>Units</strong>: Microseconds</td>
</tr>
<tr>
<td></td>
<td><strong>Valid statistics</strong>: Average, Sum, Min, Max, Sample Count</td>
</tr>
</tbody>
</table>
Amazon SageMaker Developer Guide
Multi-Model Endpoint Metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ModelLoadingTime</td>
<td>The interval of time that it took to load the model through the container's LoadModel API call.</td>
</tr>
<tr>
<td></td>
<td>Units: Microseconds</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td>ModelCacheHit</td>
<td>The number of InvokeEndpoint requests sent to the multi-model endpoint for which the model was already loaded.</td>
</tr>
<tr>
<td></td>
<td>The Average statistic shows the ratio of requests for which the model was already loaded.</td>
</tr>
<tr>
<td></td>
<td>Units: None</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum, Sample Count</td>
</tr>
</tbody>
</table>

Dimensions for Multi-Model Endpoint Model Loading Metrics

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EndpointName, VariantName</td>
<td>Filters endpoint invocation metrics for a ProductionVariant of the specified endpoint and variant.</td>
</tr>
</tbody>
</table>

The /aws/sagemaker/Endpoints namespaces include the following instance metrics from calls to InvokeEndpoint.

Metrics are available at a 1-minute frequency.

For information about how long CloudWatch metrics are retained for, see GetMetricStatistics in the Amazon CloudWatch API Reference.

Multi-Model Endpoint Model Instance Metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LoadedModelCount</td>
<td>The number of models loaded in the containers of the multi-model endpoint. This metric is emitted per instance.</td>
</tr>
<tr>
<td></td>
<td>The Average statistic with a period of 1 minute tells you the average number of models loaded per instance.</td>
</tr>
<tr>
<td></td>
<td>The Sum statistic tells you the total number of models loaded across all instances in the endpoint.</td>
</tr>
<tr>
<td></td>
<td>The models that this metric tracks are not necessarily unique because a model might be loaded in multiple containers at the endpoint.</td>
</tr>
<tr>
<td></td>
<td>Units: None</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
</tbody>
</table>

Dimensions for Multi-Model Endpoint Model Loading Metrics

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EndpointName, VariantName</td>
<td>Filters endpoint invocation metrics for a ProductionVariant of the specified endpoint and variant.</td>
</tr>
</tbody>
</table>

### SageMaker Jobs and Endpoint Metrics

The `/aws/sagemaker/ProcessingJobs`, `/aws/sagemaker/TrainingJobs`, `/aws/sagemaker/TransformJobs`, and `/aws/sagemaker/Endpoints` namespaces include the following metrics for the training jobs and endpoint instances.

Metrics are available at a 1-minute frequency.

**Note**
Amazon CloudWatch supports high-resolution custom metrics and its finest resolution is 1 second. However, the finer the resolution, the shorter the lifespan of the CloudWatch metrics. For the 1-second frequency resolution, the CloudWatch metrics are available for 3 hours. For more information about the resolution and the lifespan of the CloudWatch metrics, see `GetMetricStatistics` in the [Amazon CloudWatch API Reference](https).

**Tip**
If you want to profile your training job with a finer resolution down to 100-millisecond (0.1 second) granularity and store the training metrics indefinitely in Amazon S3 for custom analysis at any time, consider using Amazon SageMaker Debugger. SageMaker Debugger provides built-in rules to automatically detect common training issues; it detects hardware resource utilization issues (such as CPU, GPU, and I/O bottlenecks) and non-converging model issues (such as overfit, vanishing gradients, and exploding tensors). SageMaker Debugger also provides visualizations through Studio and its profiling report. To explore the Debugger visualizations, see [SageMaker Debugger Insights Dashboard Walkthrough](https), [Debugger Profiling Report Walkthrough](https), and [Analyze Data Using the SMDebug Client Library](https).

### Processing Job, Training Job, Batch Transform Job, and Endpoint Instance Metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPUUtilization</td>
<td>The sum of each individual CPU core's utilization. The CPU utilization of each core range is 0–100. For example, if there are four CPUs, the CPUUtilization range is 0%–400%. For processing jobs, the value is the CPU utilization of the processing container on the instance. For training jobs, the value is the CPU utilization of the algorithm container on the instance. For batch transform jobs, the value is the CPU utilization of the transform container on the instance. For endpoint variants, the value is the sum of the CPU utilization of the primary and supplementary containers on the instance. <strong>Note</strong> For multi-instance jobs, each instance reports CPU utilization metrics. However, the default view in CloudWatch shows the average CPU utilization across all instances. Units: Percent</td>
</tr>
<tr>
<td>MemoryUtilization</td>
<td>The percentage of memory that is used by the containers on an instance. This value range is 0%–100%.</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Memory</td>
<td>For processing jobs, the value is the memory utilization of the processing container on the instance. For training jobs, the value is the memory utilization of the algorithm container on the instance. For batch transform jobs, the value is the memory utilization of the transform container on the instance. For endpoint variants, the value is the sum of the memory utilization of the primary and supplementary containers on the instance. Units: Percent</td>
</tr>
<tr>
<td>GPUUtilization</td>
<td>The percentage of GPU units that are used by the containers on an instance. The value can range between 0%–100 and is multiplied by the number of GPUs. For example, if there are four GPUs, the GPUUtilization range is 0%–400%. For processing jobs, the value is the GPU utilization of the processing container on the instance. For training jobs, the value is the GPU utilization of the algorithm container on the instance. For batch transform jobs, the value is the GPU utilization of the transform container on the instance. For endpoint variants, the value is the sum of the GPU utilization of the primary and supplementary containers on the instance. Units: Percent</td>
</tr>
</tbody>
</table>

**Note** For multi-instance jobs, each instance reports memory utilization metrics. However, the default view in CloudWatch shows the average memory utilization across all instances.
<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GPUMemoryUtilization</td>
<td>The percentage of GPU memory used by the containers on an instance. The value range is 0–100 and is multiplied by the number of GPUs. For example, if there are four GPUs, the GPUMemoryUtilization range is 0%–400%. For processing jobs, the value is the GPU memory utilization of the processing container on the instance. For training jobs, the value is the GPU memory utilization of the algorithm container on the instance. For batch transform jobs, the value is the GPU memory utilization of the transform container on the instance. For endpoint variants, the value is the sum of the GPU memory utilization of the primary and supplementary containers on the instance. <strong>Note</strong> For multi-instance jobs, each instance reports GPU memory utilization metrics. However, the default view in CloudWatch shows the average GPU memory utilization across all instances. Units: Percent</td>
</tr>
<tr>
<td>DiskUtilization</td>
<td>The percentage of disk space used by the containers on an instance uses. This value range is 0%–100%. This metric is not supported for batch transform jobs. For processing jobs, the value is the disk space utilization of the processing container on the instance. For training jobs, the value is the disk space utilization of the algorithm container on the instance. For endpoint variants, the value is the sum of the disk space utilization of the primary and supplementary containers on the instance. Units: Percent <strong>Note</strong> For multi-instance jobs, each instance reports disk utilization metrics. However, the default view in CloudWatch shows the average disk utilization across all instances.</td>
</tr>
</tbody>
</table>

**Dimensions for Processing Job, Training Job and Batch Transform Job Instance Metrics**

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>For processing jobs, the value for this dimension has the format [processing-job-name]/algo-[instance-number-in-cluster]. Use this dimension to filter instance metrics for the specified processing job and instance. This dimension format is present only in the /aws/sagemaker/ProcessingJobs namespace. For training jobs, the value for this dimension has the format [training-job-name]/algo-[instance-number-in-cluster]. Use this dimension to filter instance metrics for the specified training job and instance. This dimension format is present only in the /aws/sagemaker/TrainingJobs namespace.</td>
</tr>
</tbody>
</table>
Inference Recommender Metrics

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>For batch transform jobs, the value for this dimension has the format [transform-job-name]/[instance-id]. Use this dimension to filter instance metrics for the specified batch transform job and instance. This dimension format is present only in the /aws/sagemaker/TransformJobs namespace.</td>
<td></td>
</tr>
</tbody>
</table>

SageMaker Inference Recommender Jobs Metrics

The /aws/sagemaker/InferenceRecommendationsJobs namespace includes the following metrics for inference recommendation jobs.

**Inference Recommender Metrics**

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ClientInvocations</td>
<td>The number of InvokeEndpoint requests sent to a model endpoint, as observed by Inference Recommender.</td>
</tr>
<tr>
<td></td>
<td>Units: None</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Sum</td>
</tr>
<tr>
<td>ClientInvocationError</td>
<td>The number of InvokeEndpoint requests that failed, as observed by Inference Recommender.</td>
</tr>
<tr>
<td></td>
<td>Units: None</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Sum</td>
</tr>
<tr>
<td>ClientLatency</td>
<td>The interval of time taken between sending an InvokeEndpoint call and receiving a response as observed by Inference Recommender. Note that the time is in milliseconds, whereas the ModelLatency endpoint invocation metric is in microseconds.</td>
</tr>
<tr>
<td></td>
<td>Units: Milliseconds</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum, Min, Max, Sample Count, Percentiles</td>
</tr>
<tr>
<td>NumberOfUsers</td>
<td>The number of concurrent users sendingInvokeEndpoint requests to the model endpoint.</td>
</tr>
<tr>
<td></td>
<td>Units: None</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Max, Min, Average</td>
</tr>
</tbody>
</table>

**Dimensions for Inference Recommender Job Metrics**

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>JobName</td>
<td>Filters Inference Recommender job metrics for the specified Inference Recommender job.</td>
</tr>
<tr>
<td>EndpointName</td>
<td>Filters Inference Recommender job metrics for the specified endpoint.</td>
</tr>
</tbody>
</table>
# SageMaker Ground Truth Metrics

## Ground Truth Metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
<th>Units</th>
<th>Valid statistics</th>
</tr>
</thead>
<tbody>
<tr>
<td>ActiveWorkers</td>
<td>A single active worker on a private work team submitted, released, or declined a task. To get the total number of active workers, use the Sum statistic. Ground Truth attempts to deliver each individual ActiveWorkers event once. If this delivery is unsuccessful, this metric may not report the total number of active workers.</td>
<td>None</td>
<td>Sum, Sample Count</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>DatasetObjectsAutoAnnotated</td>
<td>The number of dataset objects auto-annotated in a labeling job. This metric is only emitted when automated labeling is enabled. To view the labeling job progress, use the Max metric.</td>
<td>None</td>
<td>Max</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>DatasetObjectsHumanAnnotated</td>
<td>The number of dataset objects annotated by a human in a labeling job. To view the labeling job progress, use the Max metric.</td>
<td>None</td>
<td>Max</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>DatasetObjectsLabelingFailed</td>
<td>The number of dataset objects that failed labeling in a labeling job. To view the labeling job progress, use the Max metric.</td>
<td>None</td>
<td>Max</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>JobsFailed</td>
<td>A single labeling job failed. To get the total number of labeling jobs that failed, use the Sum statistic.</td>
<td>None</td>
<td>Sum, Sample Count</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>JobsSucceeded</td>
<td>A single labeling job succeeded. To get the total number of labeling jobs that succeeded, use the Sum statistic.</td>
<td>None</td>
<td>Sum, Sample Count</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>JobsStopped</td>
<td>A single labeling job was stopped. To get the total number of labeling jobs that were stopped, use the Sum statistic.</td>
<td>None</td>
<td>Sum, Sample Count</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
<td></td>
<td></td>
</tr>
<tr>
<td>---------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TasksAccepted</td>
<td>A single task was accepted by a worker. To get the total number of tasks accepted by workers, use the Sum statistic. Ground Truth attempts to deliver each individual TaskAccepted event once. If this delivery is unsuccessful, this metric may not report the total number of tasks accepted.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Units: None</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Sum, Sample Count</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TasksDeclined</td>
<td>A single task was declined by a worker. To get the total number of tasks declined by workers, use the Sum statistic. Ground Truth attempts to deliver each individual TasksDeclined event once. If this delivery is unsuccessful, this metric may not report the total number of tasks declined.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Units: None</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Valid Statistics: Sum, Sample Count</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TasksReturned</td>
<td>A single task was returned. To get the total number of tasks returned, use the Sum statistic. Ground Truth attempts to deliver each individual TasksReturned event once. If this delivery is unsuccessful, this metric may not report the total number of tasks returned.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Units: None</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Sum, Sample Count</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TasksSubmitted</td>
<td>A single task was submitted/completed by a private worker. To get the total number of tasks submitted by workers, use the Sum statistic. Ground Truth attempts to deliver each individual TasksSubmitted event once. If this delivery is unsuccessful, this metric may not report the total number of tasks submitted.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Units: None</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Sum, Sample Count</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TimeSpent</td>
<td>Time spent on a task completed by a private worker. This metric does not include time when a worker paused or took a break. Ground Truth attempts to deliver each TimeSpent event once. If this delivery is unsuccessful, this metric may not report the total amount of time spent.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Units: Seconds</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Sum, Sample Count</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TotalDatasetObjectsLabeled</td>
<td>The number of dataset objects labeled successfully in a labeling job. To view the labeling job progress, use the Max metric.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

</thead>
<tbody>
<tr>
<td>LabelingJobName</td>
<td>Filters dataset object count metrics for a labeling job.</td>
</tr>
</tbody>
</table>

## Amazon SageMaker Feature Store Metrics

### Feature Store Consumption Metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConsumedReadRequestsUnits</td>
<td>The number of consumed read units over the specified time period. You can retrieve the consumed read units for a feature store runtime operation and its corresponding feature group.</td>
</tr>
<tr>
<td></td>
<td>Units: None</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: All</td>
</tr>
<tr>
<td>ConsumedWriteRequestsUnits</td>
<td>The number of consumed write units over the specified time period. You can retrieve the consumed write units for a feature store runtime operation and its corresponding feature group.</td>
</tr>
<tr>
<td></td>
<td>Units: None</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: All</td>
</tr>
</tbody>
</table>

### Dimensions for Feature Store Consumption Metrics

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FeatureGroupName, OperationName</td>
<td>Filters feature store runtime consumption metrics of the feature group and the operation that you've specified.</td>
</tr>
</tbody>
</table>

### Feature Store Operational Metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Invocations</td>
<td>The number of requests made to the feature store runtime operations over the specified time period.</td>

<tr>
<td></td>
<td>Units: None</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Sum</td>
</tr>
<tr>
<td>Operation4XXErrors</td>
<td>The number of requests made to the Feature Store runtime operations where the operation returned a 4xx HTTP response code. For each 4xx response, 1 is sent; otherwise, 0 is sent.</td>
</tr>
<tr>
<td></td>
<td>Units: None</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum</td>
</tr>
</tbody>
</table>
## SAPPEE Metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operation5XXErrors</td>
<td>The number of requests made to the feature store runtime operations where the operation returned a 5xx HTTP response code. For each 5xx response, 1 is sent; otherwise, 0 is sent.</td>
</tr>
<tr>
<td></td>
<td>Units: None</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum</td>
</tr>
<tr>
<td>ThrottledRequests</td>
<td>The number of requests made to the feature store runtime operations where the request got throttled. For each throttled request, 1 is sent; otherwise, 0 is sent.</td>
</tr>
<tr>
<td></td>
<td>Units: None</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum</td>
</tr>
<tr>
<td>Latency</td>
<td>The time interval to process requests made to the Feature Store runtime operations. This interval is measured from the time SageMaker receives the request until it returns a response to the client.</td>
</tr>
<tr>
<td></td>
<td>Units: Microseconds</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum, Min, Max, Sample Count, Percentiles</td>
</tr>
</tbody>
</table>

## Dimensions for Feature Store Operational Metrics

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FeatureGroupName, OperationName</td>
<td>Filters feature store runtime operational metrics of the feature group and the operation that you’ve specified. You can use these dimensions for non batch operations, such as GetRecord, PutRecord, and DeleteRecord.</td>
</tr>
<tr>
<td>OperationName</td>
<td>Filters feature store runtime operational metrics for the operation that you've specified. You can use this dimension for batch operations such as BatchGetRecord.</td>
</tr>
</tbody>
</table>

## SageMaker Pipelines Metrics

The AWS/Sagemaker/ModelBuildingPipeline namespace includes the following metrics for pipeline executions.

Two categories of Pipelines execution metrics are available:

- **Execution Metrics across All Pipelines** – Account level pipeline execution metrics (for all pipelines in the current account)
- **Execution Metrics by Pipeline** – Pipeline execution metrics per pipeline

Metrics are available at a 1-minute frequency.
<table>
<thead>
<tr>
<th><strong>Metric</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>ExecutionStarted</td>
<td>The number of pipeline executions that started.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum</td>
</tr>
<tr>
<td>ExecutionFailed</td>
<td>The number of pipeline executions that failed.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum</td>
</tr>
<tr>
<td>ExecutionSucceeded</td>

## Log Amazon SageMaker Events with Amazon CloudWatch

To help you debug your compilation jobs, processing jobs, training jobs, endpoints, transform jobs, notebook instances, and notebook instance lifecycle configurations, anything an algorithm container, a model container, or a notebook instance lifecycle configuration sends to `stdout` or `stderr` is also sent to Amazon CloudWatch Logs. In addition to debugging, you can use these for progress analysis.

### Logs

The following table lists all of the logs provided by Amazon SageMaker.

<table>
<thead>
<tr>
<th>Log Group Name</th>
<th>Log Stream Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>/aws/sagemaker/CompilationJobs</td>
<td>[compilation-job-name]</td>
</tr>
<tr>
<td>/aws/sagemaker/Endpoints/ [EndpointName]</td>
<td>[production-variant-name]/[instance-id]</td>
</tr>
<tr>
<td></td>
<td>[production-variant-name]/[instance-id]/[container-name provided in SageMaker model] (For Inference Pipelines)</td>
</tr>
<tr>
<td>/aws/sagemaker/groundtruth/WorkerActivity</td>
<td>aws/sagemaker/groundtruth/worker-activity/[requester-AWS-Id]-[region]/[timestamp]</td>
</tr>
<tr>
<td>Log Group Name</td>

<td>[domain-id]/domain-shared/rstudioserverpro/default</td>
</tr>
<tr>
<td>/aws/sagemaker/TrainingJobs</td>
<td>[training-job-name]/algo-[instance-number-in-cluster]-[epoch_timestamp]</td>
</tr>
<tr>
<td>/aws/sagemaker/TransformJobs</td>
<td>[transform-job-name]/[instance-id]-[epoch_timestamp]</td>
</tr>
<tr>
<td>/aws/sagemaker/TransformJobs</td>
<td>[transform-job-name]/[instance-id]-[epoch_timestamp]/data-log</td>
</tr>
<tr>
<td>/aws/sagemaker/TransformJobs</td>
<td>[transform-job-name]/[instance-id]-[epoch_timestamp]/[container-name provided in SageMaker model] (For Inference Pipelines)</td>
</tr>
</tbody>
</table>

**Note**

1. The /aws/sagemaker/NotebookInstances/[LifecycleConfigHook] log stream is created when you create a notebook instance with a lifecycle configuration. For more information, see [Customize a Notebook Instance Using a Lifecycle Configuration Script](p. 323).
2. For Inference Pipelines, if you don’t provide container names, the platform uses **container-1, container-2**, and so on, corresponding to the order provided in the SageMaker model.

For more information about logging events with CloudWatch logging, see [What is Amazon CloudWatch Logs?](in the Amazon CloudWatch User Guide).

---

Log Amazon SageMaker API Calls with AWS CloudTrail

Amazon SageMaker is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in SageMaker. CloudTrail captures all API calls for SageMaker, with the exception of InvokeEndpoint and InvokeEndpointAsync, as events. The calls captured include calls from the SageMaker console and code calls to the SageMaker API operations. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for SageMaker. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in Event history. Using the information collected by CloudTrail, you can determine the request...
that was made to SageMaker, the IP address from which the request was made, who made the request, when it was made, and additional details.

To learn more about CloudTrail, see the [AWS CloudTrail User Guide](https://docs.aws.amazon.com/AmazonCloudWatch/latest/logs/cloudtrail-event-update.html).

By default, log data is stored in CloudWatch Logs indefinitely. However, you can configure how long to store log data in a log group. For information, see [Change Log Data Retention in CloudWatch Logs](https://docs.aws.amazon.com/AmazonCloudWatch/latest/logs/putlogretention.html) in the Amazon CloudWatch Logs User Guide.

**SageMaker Information in CloudTrail**

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in Amazon SageMaker, that activity is recorded in a CloudTrail event along with other AWS service events in Event history. You can view, search, and download recent events in your AWS account. For more information, see [Viewing Events with CloudTrail Event History](https://docs.aws.amazon.com/AmazonCloudWatch/latest/logs/cloudtrail-event-update.html).

For an ongoing record of events in your AWS account, including events for Amazon SageMaker, create a trail. A trail enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following:

- Overview for Creating a Trail
- CloudTrail Supported Services and Integrations
- Configuring Amazon SNS Notifications for CloudTrail
- Receiving CloudTrail Log Files from Multiple Regions and Receiving CloudTrail Log Files from Multiple Accounts

All SageMaker actions, with the exception of `InvokeEndpoint` and `InvokeEndpointAsync`, are logged by CloudTrail and are documented in the Operations. For example, calls to the `CreateTrainingJob`, `CreateEndpoint` and `CreateNotebookInstance` actions generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or IAM user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the CloudTrail `userIdentity` Element.

**Operations Performed by Automatic Model Tuning**

SageMaker supports logging non-API service events to your CloudTrail log files for automatic model tuning jobs. These events are related to your tuning jobs but, are not the direct result of a customer request to the public AWS API. For example, when you create a hyperparameter tuning job by calling `CreateHyperParameterTuningJob`, SageMaker creates training jobs to evaluate various combinations of hyperparameters to find the best result. Similarly, when you call `StopHyperParameterTuningJob` to stop a hyperparameter tuning job, SageMaker might stop any of the associated running training jobs. Non-API events for your tuning jobs are logged to CloudTrail to help you improve governance, compliance, and operational and risk auditing of your AWS account.

Log entries that result from non-API service events have an `eventType` of `AwsServiceEvent` instead of `AwsApiCall`. 

---

3593
Understanding SageMaker Log File Entries

A trail is a configuration that enables delivery of events as log files to an S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files are not an ordered stack trace of the public API calls, so they do not appear in any specific order.

The following examples a log entry for the CreateEndpoint action, which creates an endpoint to deploy a trained model.

```json
{
"eventVersion":"1.05",
"userIdentity": {
    "type":"IAMUser",
    "principalId":"AIXDAYQEXAMPLEMLNGL",
    "arn":"arn:aws:iam::123456789012:user/intern",
    "accountId":"123456789012",
    "accessKeyId":"ASXIAGXEXAMPLEQULKNXV",
    "userName": "intern"
},
"eventTime": "2018-01-02T13:39:06Z",
"eventSource": "sagemaker.amazonaws.com",
"eventName": "CreateEndpoint",
"awsRegion": "us-west-2",
"sourceIPAddress": "127.0.0.1",
"userAgent": "USER_AGENT",
"requestParameters": {
    "endpointName": "ExampleEndpoint",
    "endpointConfigName": "ExampleEndpointConfig"
},
"responseElements": {
    "endpointArn": "arn:aws:sagemaker:us-west-2:123456789012:endpoint/exampleendpoint"
},
"requestID": "6b1b42b9-EXAMPLE",
"eventID": "a6f85b21-EXAMPLE",
"eventType": "AwsApiCall",
"recipientAccountId": "444455556666"
}
```

The following example is a log entry for the CreateModel action, which creates one or more containers to host a previously trained model.

```json
{
"eventVersion": "1.05",
"userIdentity": {
    "type": "IAMUser",
    "principalId": "AIXDAYQEXAMPLEMLNGL",
    "arn": "arn:aws:iam::123456789012:user/intern",
    "accountId": "123456789012",
    "accessKeyId": "ASXIAGXEXAMPLEQULKNXV",
    "userName": "intern"
},
"eventTime": "2018-01-02T15:23:46Z",
"eventSource": "sagemaker.amazonaws.com",
"eventName": "CreateModel",
"awsRegion": "us-west-2",
"sourceIPAddress": "127.0.0.1",
"userAgent": "USER_AGENT",
"requestParameters": {
    "modelName": "ExampleModel",
    "primaryContainer": {
```
Monitoring user resource access from Amazon SageMaker Studio

With Amazon SageMaker Studio, you can monitor user resource access. To view resource access activity, you can configure AWS CloudTrail to monitor and record user activities by following the steps in Log Amazon SageMaker API Calls with AWS CloudTrail.

However, the AWS CloudTrail logs for resource access only list the Studio execution IAM role as the identifier. This level of logging is enough to audit user activity when each user profile has a distinct execution role. However, when a single execution IAM role is shared between several user profiles, you can't get information about the specific user that accessed the AWS resources.

You can get information about which specific user performed an action in an AWS CloudTrail log when using a shared execution role, using the sourceIdentity configuration to propagate the Studio user profile name. For more information about source identity, see Monitor and control actions taken with assumed roles.

**Prerequisites**

- Install and configure the AWS Command Line Interface following the steps in Installing or updating the latest version of the AWS CLI.
- Ensure that Studio users in your domain don't have a policy that allows them to update or modify the Studio domain.
- To turn on or turn off sourceIdentity propagation, all apps in the domain must be in the Stopped or Deleted state. For more information about how to stop and shut down apps, see Shut down and Update Studio Apps.
- All execution roles must have the following trust policy permissions:
  - Any role that the Studio domain's execution role assumes must have the sts:SetSourceIdentity permission in the trust policy as follows.

  ```json
  {
  "Version": "2012-10-17",
  "Statement": [
  {
  "Effect": "Allow",
  "Principal": {
  "Service": "sagemaker.amazonaws.com"
  },
  "Action": [
  "sts:AssumeRole",
  "sts:SetSourceIdentity"
  
  ```
Considerations when using sourceIdentity

When you make AWS API calls from Studio notebooks, SageMaker Canvas, or Amazon SageMaker Data Wrangler, the sourceIdentity is only recorded in CloudTrail if those calls are made using the Studio execution role (p. 3387) session or any chained role from that session.

When these API calls invoke other services to perform additional operations, sourceIdentity logging depends on the specific implementation of the invoked services.

- Amazon SageMaker Training, Processing, and Pipeline: When you create a job using these features, the job creation APIs are not able to ingest the sourceIdentity that exists in the session. As a result, any AWS API calls made from these jobs do not record sourceIdentity in CloudTrail logs.
- Amazon EMR: When connecting to Amazon EMR from Studio using runtime roles (p. 1384), administrators must explicitly set the PropagateSourceIdentity field. This ensures that Amazon EMR applies the sourceIdentity from the calling credentials to a job or query session. The sourceIdentity is then recorded in CloudTrail logs.

Note
The following exceptions apply when using sourceIdentity.

- AWS API calls made from SageMaker shared spaces do not record sourceIdentity in CloudTrail logs.
- If AWS API calls are made from sessions that are created by users or other services and the sessions are not based on the Studio execution role session, then the sourceIdentity is not recorded in CloudTrail logs.

Turn on sourceIdentity

The ability to propagate the user profile name as the sourceIdentity in Studio is turned off by default.

To enable the ability to propagate the user profile name as the sourceIdentity, use the AWS CLI during domain creation and domain update. This feature is enabled at the domain level and not at the user profile level.

After you enable this configuration, administrators can view the user profile in the AWS CloudTrail log for the service accessed. The user profile is given as the sourceIdentity value in the userIdentity section. For more information about using AWS CloudTrail logs with SageMaker, see Log Amazon SageMaker API Calls with AWS CloudTrail.

You can use the following code to enable the propagation of the user profile name as the sourceIdentity during domain creation using the create-domain API.
You can enable the propagation of the user profile name as the `sourceIdentity` during domain update using the `update-domain` API.

To update this configuration, all apps in the domain must be in the Stopped or Deleted state. For more information about how to stop and shut down apps, see Shut down and Update Studio Apps.

Use the following code to enable the propagation of the user profile name as the `sourceIdentity`.

```
update-domain
--domain-id <value>
[--default-user-settings <value>]
[--domain-settings-for-update "ExecutionRoleIdentityConfig=USER_PROFILE_NAME"]
[--cli-input-json <value>]
[--generate-cli-skeleton <value>]
```

**Turn off sourceIdentity**

You can also turn off the propagation of the user profile name as the `sourceIdentity` using the AWS CLI. This occurs during domain update by passing the `ExecutionRoleIdentityConfig=DISABLED` value for the `--domain-settings-for-update` parameter as part of the `update-domain` API call.

In the AWS CLI, use the following code to disable the propagation of the user profile name as the `sourceIdentity`.

```
update-domain
--domain-id <value>
[--default-user-settings <value>]
[--domain-settings-for-update "ExecutionRoleIdentityConfig=DISABLED"]
[--cli-input-json <value>]
[--generate-cli-skeleton <value>]
```

**Automating Amazon SageMaker with Amazon EventBridge**

Amazon EventBridge monitors status change events in Amazon SageMaker. EventBridge enables you to automate SageMaker and respond automatically to events such as a training job status change or endpoint status change. Events from SageMaker are delivered to EventBridge in near real time. You can write simple rules to indicate which events are of interest to you, and what automated actions to take.
when an event matches a rule. For an example of how to create a rule, see Schedule a Pipeline with Amazon EventBridge (p. 2853).

Note
SageMaker may send multiple events to EventBridge for each state change. This behavior is expected and does not necessarily indicate an error.

Some examples of the actions that can be automatically triggered include the following:

- Invoking an AWS Lambda function
- Invoking Amazon EC2 Run Command
- Relaying the event to Amazon Kinesis Data Streams
- Activating an AWS Step Functions state machine
- Notifying an Amazon SNS topic or an AWS SMS queue

SageMaker events monitored by EventBridge

- SageMaker model state change (p. 3598)
- Training job state change (p. 3598)
- Hyperparameter tuning job state change (p. 3600)
- Transform job state change (p. 3601)
- Endpoint state change (p. 3602)
- Feature group state change (p. 3602)
- Model package state change (p. 3603)
- Pipeline execution state change (p. 3604)
- Pipeline step state change (p. 3605)
- SageMaker image state change (p. 3606)
- SageMaker image version state change (p. 3606)
- Endpoint deployment state change (p. 3607)
- Model card state change (p. 3609)

SageMaker model state change

Indicates a change in the state of a SageMaker model. The state changes when a SageMaker model is either created or deleted.

```
{
  "source": ["aws.sagemaker"],
  "detail-type": ["SageMaker Model State Change"],
  "Resources": ["arn:aws:sagemaker:us-east-1:123456789012:model/model-name"]
}
```

If a model is specified under Resources, an event will be generated and sent to EventBridge when the state of this model changes. If you do not specify a value for Resources, an event will generate when the status of any of the SageMaker models associated with your account changes.

Training job state change

Indicates a change in the status of a SageMaker training job.

If the value of TrainingJobStatus is Failed, the event contains the FailureReason field, which provides a description of why the training job failed.
Hyperparameter tuning job state change

Indicates a change in the status of a SageMaker hyperparameter tuning job.

```json
{
    "version": "0",

                },
                "ResourceConfig": {
                    "InstanceType": "instanceType",
                    "InstanceCount": 10,
                    "3600"
                }
            }
        }
    }
}
```
Transform job state change

Indicates a change in the status of a SageMaker batch transform job.

If the value of TransformJobStatus is Failed, the event contains the FailureReason field, which provides a description of why the training job failed.

```json
{
  "version": "0",
  "id": "844e2571-85d4-695f-b930-0153b71dcb42",
  "detail-type": "SageMaker Transform Job State Change",
  "source": "aws.sagemaker",

        }
      },
      "ContentType": "content type",
      "CompressionType": "compression type",
    }
  }
}
```
Endpoint state change

Indicates a change in the status of a SageMaker hosted real-time inference endpoint.

The following shows an event with an endpoint in the IN_SERVICE state.

```
{
  "version": "0",
  "id": "d29215a-b0ad-cace-a8e3-0f159d018e06",
  "detail-type": "SageMaker Endpoint State Change",
  "source": "aws.sagemaker",
  "account": "123456789012",
  "time": "1583831889050",
  "region": "us-west-2",
  "resources": [
  ],
  "detail": {
    "EndpointName": "MyEndpoint",
    "EndpointConfigName": "MyEndpointConfig",
    "ProductionVariants": [
      {
        "DesiredWeight": 1.0,
        "DesiredInstanceCount": 1.0
      }
    ],
    "EndpointStatus": "IN_SERVICE",
    "CreationTime": 1592411992203.0,
    "LastModifiedTime": 1592411994287.0,
    "Tags": {}
  }
}
```

Feature group state change

Indicates a change either in the FeatureGroupStatus or the OfflineStoreStatus of a SageMaker feature group.

```
Model package state change

Indicates a change in the status of a SageMaker model package.
Pipeline execution state change

Indicates a change in the status of a SageMaker pipeline execution.

currentPipelineExecutionStatus and previousPipelineExecutionStatus can be one the following values:

- Executing
- Succeeded
- Failed
- Stopping
- Stopped
Pipeline step state change

Indicates a change in the status of a SageMaker pipeline step. If there is a cache hit, the event contains the `cacheHitResult` field. `currentStepStatus` and `previousStepStatus` can be one of the following values:

- Starting
- Executing
- Succeeded
- Failed
- Stopping
- Stopped

If the value of `currentStepStatus` is Failed, the event contains the `failureReason` field, which provides a description of why the step failed.
SageMaker image state change

Indicates a change in the status of a SageMaker image.

```
{  
  "version": "0",

For more information, see the Amazon EventBridge User Guide.

**Endpoint deployment state change**

**Important**

The following examples may not work for all endpoints. For a list of features that may exclude your endpoint, see the Exclusions (p. 2606) page.

Indicates a state change for an endpoint deployment. The following example shows an endpoint updating with a blue/green canary deployment.

```json
{
    "version": "0",
    "id": "0bd4a141-0a02-9d8a-f977-3924c3fb259c",
    "detail-type": "SageMaker Endpoint Deployment State Change",
    "source": "aws.sagemaker",
    "account": "123456789012",
    "time": "2021-10-25T01:52:12Z",
    "region": "us-west-2",
    "resources": [
    ],
    "detail": {
        "EndpointName": "sample-endpoint",
        "EndpointConfigName": "sample-endpoint-config-1",
        "ProductionVariants": [
            {
                "VariantName": "AllTraffic",
                "CurrentWeight": 1,
                "DesiredWeight": 1,
                "CurrentInstanceCount": 3,
                "DesiredInstanceCount": 3
            }
        ],
        "EndpointStatus": "UPDATING",
        "CreationTime": 1635195148181,
        "LastModifiedTime": 1635195148181,
        "Tags": {},
        "PendingDeploymentSummary": {
            "EndpointConfigName": "sample-endpoint-config-2",
        }
    }
}
```
The following example indicates a state change for an endpoint deployment, which is being updated with new capacity on an existing endpoint configuration:

```json
{
  "version": "0",
  "id": "0bd4a141-0a02-9d8a-f977-3924c3fb259c",
  "detail-type": "SageMaker Endpoint Deployment State Change",
  "source": "aws.sagemaker",
  "account": "123456789012",
  "time": "2021-10-25T01:52:12Z",
  "region": "us-west-2",
  "resources": [
  ],
  "detail": {
    "EndpointName": "sample-endpoint",
    "EndpointConfigName": "sample-endpoint-config-1",
    "ProductionVariants": [
      {
        "VariantName": "AllTraffic",
        "CurrentWeight": 1,
        "DesiredWeight": 1,
        "CurrentInstanceCount": 3,
        "DesiredInstanceCount": 6,
        "VariantStatus": {
          "Status": "Updating",
          "StatusMessage": "Scaling out desired instance count to 6.",
          "StartTime": 1635195269181,
        }
      }
    ],
    "EndpointStatus": "UPDATING",
    "CreationTime": 1635195148181,
    "LastModifiedTime": 1635195148181,
    "Tags": {}
  }
}
```

The following secondary deployment statuses are also available for endpoints (found in the `VariantStatus` object):
Model card state change

Indicates a change in the status of an Amazon SageMaker Model Card. For more information about model cards, see Amazon SageMaker Model Cards (p. 3245).

```json
{
    "version": "0",
    "id": "aa7a9c4f-2caa-4d04-a6de-e67227ba4302",
    "detail-type": "SageMaker Model Card State Change",
    "source": "aws.sagemaker",
    "account": "123456789012",
    "time": "2022-11-30T00:00:00Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:sagemaker:us-east-1:123456789012:model-card/example-card"
    ],
    "detail": {
        "ModelCardVersion": 2,
        "LastModifiedTime": "2022-12-03T00:09:44.893854735Z",
        "LastModifiedBy": {
            "DomainId": "us-east-1",
            "UserProfileArn": "arn:aws:sagemaker:us-east-1:123456789012:user-profile/user",
            "UserProfileName": "user"
        },

Machine Learning Frameworks and Languages

You can use Python and R natively in Amazon SageMaker notebook kernels. There are also kernels that support specific frameworks. A very popular way to get started with SageMaker is to use the Amazon SageMaker Python SDK. It provides open source Python APIs and containers that make it easy to train and deploy models in SageMaker, as well as examples for use with several different machine learning and deep learning frameworks.

For information about using specific frameworks or how to use R in SageMaker, see the following topics.

Languages SDKs and user guides:

- Amazon SageMaker Python SDK
- R (p. 3623)
- API Reference (p. 3629)

Machine learning and deep learning frameworks guides:

- Apache MXNet (p. 3610)
- Apache Spark (p. 3611)
- Chainer (p. 3620)
- Hugging Face (p. 3620)
- PyTorch (p. 3623)
- Scikit-learn (p. 3625)
- SparkML Serving (p. 3627)
- TensorFlow (p. 3627)
- Triton Inference Server (p. 3628)

Use Apache MXNet with Amazon SageMaker

You can use SageMaker to train and deploy a model using custom MXNet code. The Amazon SageMaker Python SDK MXNet estimators and models and the SageMaker open-source MXNet container make writing a MXNet script and running it in SageMaker easier.

What do you want to do?

I want to train a custom MXNet model in SageMaker.

For a sample Jupyter notebook, see the MXNet example notebooks in the Amazon SageMaker Examples GitHub repository.
For documentation, see [Train a Model with MXNet](#).

I have an MXNet model that I trained in SageMaker, and I want to deploy it to a hosted endpoint.

For more information, see [Deploy MXNet models](#).

I have an MXNet model that I trained outside of SageMaker, and I want to deploy it to a SageMaker endpoint.

For more information, see [Deploy Endpoints from Model Data](#).

I want to see the API documentation for [Amazon SageMaker Python SDK](#) MXNet classes.

For more information, see [MXNet Classes](#).

I want to find the SageMaker MXNet container repository.

For more information, see [SageMaker MXNet Container GitHub repository](#).

I want to find information about MXNet versions supported by AWS Deep Learning Containers.

For more information, see [Available Deep Learning Container Images](#).

For general information about writing MXNet script mode training scripts and using MXNet script mode estimators and models with SageMaker, see [Using MXNet with the SageMaker Python SDK](#).

### Use Apache Spark with Amazon SageMaker

This section provides information for developers who want to use Apache Spark for preprocessing data and Amazon SageMaker for model training and hosting. For information about supported versions of Apache Spark, see the [Getting SageMaker Spark](#) page in the SageMaker Spark GitHub repository.

SageMaker provides an Apache Spark library, in both Python and Scala, that you can use to easily train models in SageMaker using `org.apache.spark.sql.DataFrame` data frames in your Spark clusters. After model training, you can also host the model using SageMaker hosting services.

The SageMaker Spark library, `com.amazonaws.services.sagemaker.sparksdk`, provides the following classes, among others:

- **SageMakerEstimator**—Extends the `org.apache.spark.ml.Estimator` interface. You can use this estimator for model training in SageMaker.
- **SageMakerModel**—Extends the `org.apache.spark.ml.Model` class. You can use this SageMakerModel for model hosting and obtaining inferences in SageMaker.

With SageMaker Studio, you can easily connect to an Amazon EMR cluster. For more information, see [Prepare data at Scale with Studio Notebooks](#).

### Download the SageMaker Spark Library

You have the following options for downloading the Spark library provided by SageMaker:

- You can download the source code for both PySpark and Scala libraries from the [SageMaker Spark](#) GitHub repository.
- For the Python Spark library, you have the following additional options:
  - Use `pip install`:
pip install sagemaker_pyspark

- In a notebook instance, create a new notebook that uses either the Sparkmagic (PySpark) or the Sparkmagic (PySpark3) kernel and connect to a remote Amazon EMR cluster.

  Note
  The EMR cluster must be configured with an IAM role that has the AmazonSageMakerFullAccess policy attached. For information about configuring roles for an EMR cluster, see Configure IAM Roles for Amazon EMR Permissions to AWS Services in the Amazon EMR Management Guide.

- You can get the Scala library from Maven. Add the Spark library to your project by adding the following dependency to your pom.xml file:

```xml
<dependency>
  <groupId>com.amazonaws</groupId>
  <artifactId>sagemaker-spark_2.11</artifactId>
  <version>spark_2.2.0-1.0</version>
</dependency>
```

Integrate Your Apache Spark Application with SageMaker

The following is high-level summary of the steps for integrating your Apache Spark application with SageMaker:

1. Continue data preprocessing using the Apache Spark library that you are familiar with. Your dataset remains a DataFrame in your Spark cluster. Load your data into a DataFrame and preprocess it so that you have a features column with org.apache.spark.ml.linalg.Vector of Doubles, and an optional label column with values of Double type.

2. Use the estimator in the SageMaker Spark library to train your model. For example, if you choose the k-means algorithm provided by SageMaker for model training, you call the KMeansSageMakerEstimator.fit method.

   Provide your DataFrame as input. The estimator returns a SageMakerModel object.

   Note
   SageMakerModel extends the org.apache.spark.ml.Model.

   The fit method does the following:

   a. Converts the input DataFrame to the protobuf format by selecting the features and label columns from the input DataFrame and uploading the protobuf data to an Amazon S3 bucket. The protobuf format is efficient for model training in SageMaker.

   b. Starts model training in SageMaker by sending a SageMaker CreateTrainingJob request. After model training has completed, SageMaker saves the model artifacts to an S3 bucket. SageMaker assumes the IAM role that you specified for model training to perform tasks on your behalf. For example, it uses the role to read training data from an S3 bucket and to write model artifacts to a bucket.

   c. Creates and returns a SageMakerModel object. The constructor does the following tasks, which are related to deploying your model to SageMaker.

      i. Sends a CreateModel request to SageMaker.

      ii. Sends a CreateEndpointConfig request to SageMaker.
ii. Sends a `CreateEndpoint` request to SageMaker, which then launches the specified resources, and hosts the model on them.

3. You can get inferences from your model hosted in SageMaker with the `SageMakerModel.transform` method.

   Provide an input DataFrame with features as input. The `transform` method transforms it to a DataFrame containing inferences. Internally, the `transform` method sends a request to the `InvokeEndpoint` SageMaker API to get inferences. The `transform` method appends the inferences to the input DataFrame.

### Example 1: Use Amazon SageMaker for Training and Inference with Apache Spark

#### Topics
- Use Custom Algorithms for Model Training and Hosting on Amazon SageMaker with Apache Spark (p. 3617)
- Use the `SageMakerEstimator` in a Spark Pipeline (p. 3618)

Amazon SageMaker provides an Apache Spark library (in both Python and Scala) that you can use to integrate your Apache Spark applications with SageMaker. For example, you might use Apache Spark for data preprocessing and SageMaker for model training and hosting. For more information, see Use Apache Spark with Amazon SageMaker (p. 3611). This section provides example code that uses the Apache Spark Scala library provided by SageMaker to train a model in SageMaker using DataFrames in your Spark cluster. The example also hosts the resulting model artifacts using SageMaker hosting services. Specifically, this example does the following:

- Uses the `KMeansSageMakerEstimator` to fit (or train) a model on data

Because the example uses the k-means algorithm provided by SageMaker to train a model, you use the `KMeansSageMakerEstimator`. You train the model using images of handwritten single-digit numbers (from the MNIST dataset). You provide the images as an input DataFrame. For your convenience, SageMaker provides this dataset in an S3 bucket.

In response, the estimator returns a `SageMakerModel` object.

- Obtains inferences using the trained `SageMakerModel`

To get inferences from a model hosted in SageMaker, you call the `SageMakerModel.transform` method. You pass a DataFrame as input. The method transforms the input DataFrame to another DataFrame containing inferences obtained from the model.

For a given input image of a handwritten single-digit number, the inference identifies a cluster that the image belongs to. For more information, see K-Means Algorithm (p. 1733).

This is the example code:
import org.apache.spark.sql.SparkSession
import com.amazonaws.services.sagemaker.sparksdk.IAMRole
import com.amazonaws.services.sagemaker.sparksdk.algorithms
import com.amazonaws.services.sagemaker.sparksdk.algorithms.KMeansSageMakerEstimator

val spark = SparkSession.builder.getOrCreate

// load mnist data as a dataframe from libsvm
val trainingData = spark.read.format("libsvm")
  .option("numFeatures", "784")
  .load(s"s3://sagemaker-sample-data-$region/spark/mnist/train/")
val testData = spark.read.format("libsvm")
  .option("numFeatures", "784")
  .load(s"s3://sagemaker-sample-data-$region/spark/mnist/test/")

val roleArn = "arn:aws:iam::account-id:role/rolename"

val estimator = new KMeansSageMakerEstimator(
  sagemakerRole = IAMRole(roleArn),
  trainingInstanceType = "ml.p2.xlarge",
  trainingInstanceCount = 1,
  endpointInstanceType = "ml.c4.xlarge",
  endpointInitialInstanceCount = 1)
  .setK(10).setFeatureDim(784)

// train
val model = estimator.fit(trainingData)
val transformedData = model.transform(testData)
transformedData.show

The code does the following:

- Loads the MNIST dataset from an S3 bucket provided by SageMaker (awsai-sparksdk-dataset) into a Spark DataFrame (mnistTrainingDataFrame):

```scala
// Get a Spark session.
val spark = SparkSession.builder.getOrCreate

// load mnist data as a dataframe from libsvm
val trainingData = spark.read.format("libsvm")
  .option("numFeatures", "784")
  .load(s"s3://sagemaker-sample-data-$region/spark/mnist/train/")
val testData = spark.read.format("libsvm")
  .option("numFeatures", "784")
  .load(s"s3://sagemaker-sample-data-$region/spark/mnist/test/")

val roleArn = "arn:aws:iam::account-id:role/rolename"

trainingData.show()
```

The show method displays the first 20 rows in the data frame:

```
+-----+--------------------+
| label|            features |
+-----+--------------------+
|  5.0|[784,[152,153,154...| 3614
```
In each row:

- The **label** column identifies the image's label. For example, if the image of the handwritten number is the digit 5, the label value is 5.

- The **features** column stores a vector (org.apache.spark.ml.linalg.Vector) of Double values. These are the 784 features of the handwritten number. (Each handwritten number is a 28 x 28-pixel image, making 784 features.)

- Creates a SageMaker estimator (KMeansSageMakerEstimator)

    The fit method of this estimator uses the k-means algorithm provided by SageMaker to train models using an input DataFrame. In response, it returns a SageMakerModel object that you can use to get inferences.

    **Note**
    The KMeansSageMakerEstimator extends the SageMaker SageMakerEstimator, which extends the Apache Spark Estimator.

    ```java
    val estimator = new KMeansSageMakerEstimator(
        sagemakerRole = IAMRole(roleArn),
        trainingInstanceType = "ml.p2.xlarge",
        trainingInstanceCount = 1,
        endpointInstanceType = "ml.c4.xlarge",
        endpointInitialInstanceCount = 1)
    .setK(10).setFeatureDim(784)
    ```

    The constructor parameters provide information that is used for training a model and deploying it on SageMaker:

    - **trainingInstanceType** and **trainingInstanceCount**—Identify the type and number of ML compute instances to use for model training.

    - **endpointInstanceType**—Identifies the ML compute instance type to use when hosting the model in SageMaker. By default, one ML compute instance is assumed.

    - **endpointInitialInstanceCount**—Identifies the number of ML compute instances initially backing the endpoint hosting the model in SageMaker.
• **sagemakerRole**—SageMaker assumes this IAM role to perform tasks on your behalf. For example, for model training, it reads data from S3 and writes training results (model artifacts) to S3.

  **Note**
  This example implicitly creates a SageMaker client. To create this client, you must provide your credentials. The API uses these credentials to authenticate requests to SageMaker. For example, it uses the credentials to authenticate requests to create a training job and API calls for deploying the model using SageMaker hosting services.

• After the `KMeansSageMakerEstimator` object has been created, you set the following parameters, are used in model training:
  • The number of clusters that the k-means algorithm should create during model training. You specify 10 clusters, one for each digit, 0 through 9.
  • Identifies that each input image has 784 features (each handwritten number is a 28 x 28-pixel image, making 784 features).

• **Calls the estimator fit method**

```scala
// train
val model = estimator.fit(trainingData)
```

You pass the input DataFrame as a parameter. The model does all the work of training the model and deploying it to SageMaker. For more information see, [Integrate Your Apache Spark Application with SageMaker](p. 3612). In response, you get a SageMakerModel object, which you can use to get inferences from your model deployed in SageMaker.

You provide only the input DataFrame. You don't need to specify the registry path to the k-means algorithm used for model training because the `KMeansSageMakerEstimator` knows it.

• **Calls the SageMakerModel.transform method to get inferences from the model deployed in SageMaker.**

The `transform` method takes a DataFrame as input, transforms it, and returns another DataFrame containing inferences obtained from the model.

```scala
val transformedData = model.transform(testData)
transformedData.show
```

For simplicity, we use the same DataFrame as input to the `transform` method that we used for model training in this example. The `transform` method does the following:
  • Serializes the features column in the input DataFrame to protobuf and sends it to the SageMaker endpoint for inference.
  • Deserializes the protobuf response into the two additional columns (`distance_to_cluster` and `closest_cluster`) in the transformed DataFrame.

The `show` method gets inferences to the first 20 rows in the input DataFrame:

```plaintext
+-----+--------------------+-------------------+---------------+
|label|            features|distance_to_cluster|closest_cluster|
+-----+--------------------+-------------------+---------------+
|  5.0|(784,[152,153,154...|  1767.897705078125|            4.0|
```
Use Custom Algorithms for Model Training and Hosting on Amazon SageMaker with Apache Spark

In Example 1: Use Amazon SageMaker for Training and Inference with Apache Spark (p. 3613), you use the kMeansSageMakerEstimator because the example uses the k-means algorithm provided by Amazon SageMaker for model training. You might choose to use your own custom algorithm for model training instead. Assuming that you have already created a Docker image, you can create your own SageMakerEstimator and specify the Amazon Elastic Container Registry path for your custom image.

The following example shows how to create a KMeansSageMakerEstimator from the SageMakerEstimator. In the new estimator, you explicitly specify the Docker registry path to your training and inference code images.

```java
import com.amazonaws.services.sagemaker.sparksdk.IAMRole
import com.amazonaws.services.sagemaker.sparksdk.SageMakerEstimator
import com.amazonaws.services.sagemaker.sparksdk.transformation.serializers.ProtobufRequestRowSerializer
import com.amazonaws.services.sagemaker.sparksdk.transformation.deserializers.KMeansProtobufResponseRowDeserializer

val estimator = new SageMakerEstimator(
    trainingImage = "811284229777.dkr.ecr.us-east-1.amazonaws.com/kmeans:1",
    modelImage = "811284229777.dkr.ecr.us-east-1.amazonaws.com/kmeans:1",
    requestRowSerializer = new ProtobufRequestRowSerializer(),
    responseRowDeserializer = new KMeansProtobufResponseRowDeserializer(),
    hyperParameters = Map("k" -> "10", "feature_dim" -> "784"),
    sagemakerRole = IAMRole(roleArn),
)
```

You can interpret the data, as follows:

- A handwritten number with the label 5 belongs to cluster 4 (closest_cluster).
- A handwritten number with the label 0 belongs to cluster 5.
- A handwritten number with the label 4 belongs to cluster 9.
- A handwritten number with the label 1 belongs to cluster 6.

For more information on how to run these examples, see [https://github.com/aws/sagemaker-spark/blob/master/README.md](https://github.com/aws/sagemaker-spark/blob/master/README.md) on GitHub.
In the code, the parameters in the SageMakerEstimator constructor include:

- **trainingImage** —Identifies the Docker registry path to the training image containing your custom code.
- **modelImage** —Identifies the Docker registry path to the image containing inference code.
- **requestRowSerializer** —Implements `com.amazonaws.services.sagemaker.sparksdk.transformation.RequestRowSerializer`. This parameter serializes rows in the input DataFrame to send them to the model hosted in SageMaker for inference.
- **responseRowDeserializer** —Implements `com.amazonaws.services.sagemaker.sparksdk.transformation.ResponseRowDeserializer`. This parameter deserializes responses from the model, hosted in SageMaker, back into a DataFrame.
- **trainingSparkDataFormat** —Specifies the data format that Spark uses when uploading training data from a DataFrame to S3. For example, "sagemaker" for protobuf format, "csv" for comma-separated values, and "libsvm" for LibSVM format.

You can implement your own RequestRowSerializer and ResponseRowDeserializer to serialize and deserialize rows from a data format that your inference code supports, such as .libsvm or .csv.

**Use the SageMakerEstimator in a Spark Pipeline**

You can use `org.apache.spark.ml.Estimator` estimators and `org.apache.spark.ml.Model` models, and SageMakerEstimator estimators and SageMakerModel models in `org.apache.spark.ml.Pipeline` pipelines, as shown in the following example:

```scala
import org.apache.spark.ml.Pipeline
import org.apache.spark.ml.feature.PCA
import org.apache.spark.sql.SparkSession
import com.amazonaws.services.sagemaker.sparksdk.IAMRole
import com.amazonaws.services.sagemaker.sparksdk.algorithms.KMeansSageMakerEstimator
val spark = SparkSession.builder.getOrCreate

// load mnist data as a dataframe from libsvm
val region = "us-east-1"
val trainingData = spark.read.format("libsvm")
  .option("numFeatures", "784")
  .load(s"s3://sagemaker-sample-data-$region/spark/mnist/train")
val testData = spark.read.format("libsvm")
  .option("numFeatures", "784")
  .load(s"s3://sagemaker-sample-data-$region/spark/mnist/test")

// substitute your SageMaker IAM role here
val roleArn = "arn:aws:iam::account-id:role/rolename"

val pcaEstimator = new PCA()
  .setInputCol("features")
  .setOutputCol("projectedFeatures")
```

```java
// load mnist data as a dataframe from libsvm
val region = "us-east-1"
val trainingData = spark.read.format("libsvm")
  .option("numFeatures", "784")
  .load(s"s3://sagemaker-sample-data-$region/spark/mnist/train")
val testData = spark.read.format("libsvm")
  .option("numFeatures", "784")
  .load(s"s3://sagemaker-sample-data-$region/spark/mnist/test")

// substitute your SageMaker IAM role here
val roleArn = "arn:aws:iam::account-id:role/rolename"

val pcaEstimator = new PCA()
  .setInputCol("features")
  .setOutputCol("projectedFeatures")
```
val kMeansSageMakerEstimator = new KMeansSageMakerEstimator(
  sagemakerRole = IAMRole(integTestingRole),
  requestRowSerializer =
    new ProtobufRequestRowSerializer(featuresColumnName = "projectedFeatures"),
  trainingSparkDataFormatOptions = Map("featuresColumnName" -> "projectedFeatures"),
  trainingInstanceType = "ml.p2.xlarge",
  trainingInstanceCount = 1,
  endpointInstanceType = "ml.c4.xlarge",
  endpointInitialInstanceCount = 1)
.setK(10).setFeatureDim(50)

val pipeline = new Pipeline().setStages(Array(pcaEstimator, kMeansSageMakerEstimator))

// train
val pipelineModel = pipeline.fit(trainingData)
val transformedData = pipelineModel.transform(testData)
transformedData.show()

The parameter trainingSparkDataFormatOptions configures Spark to serialize to protobuf the "projectedFeatures" column for model training. Additionally, Spark serializes to protobuf the "label" column by default.

Because we want to make inferences using the "projectedFeatures" column, we pass the column name into the ProtobufRequestRowSerializer.

The following example shows a transformed DataFrame:

<table>
<thead>
<tr>
<th>label</th>
<th>features</th>
<th>projectedFeatures</th>
<th>distance_to_cluster</th>
<th>closest_cluster</th>
</tr>
</thead>
<tbody>

SDK examples: Use Amazon SageMaker with Apache Spark

The following list is a subset of available examples. Visit the [examples website](#) to see more.

- sagemaker-spark: a Spark library for SageMaker
- SageMaker PySpark K-Means Clustering MNIST Example
Use Chainer with Amazon SageMaker

You can use SageMaker to train and deploy a model using custom Chainer code. The SageMaker Python SDK Chainer estimators and models and the SageMaker open-source Chainer container make writing a Chainer script and running it in SageMaker easier.

What do you want to do?

I want to train a custom Chainer model in SageMaker.

For a sample Jupyter notebook, see the Chainer example notebooks in the Amazon SageMaker Examples GitHub repository.

For documentation, see Train a Model with Chainer.

I have a Chainer model that I trained in SageMaker, and I want to deploy it to a hosted endpoint.

For more information, see Deploy Chainer models.

I have a Chainer model that I trained outside of SageMaker, and I want to deploy it to a SageMaker endpoint

For more information, see Deploy Endpoints from Model Data.

I want to see the API documentation for Amazon SageMaker Python SDK Chainer classes.

For more information, see Chainer Classes.

I want to find information about SageMaker Chainer containers.

For more information, see the SageMaker Chainer Container GitHub repository.

For information about supported Chainer versions, and for general information about writing Chainer training scripts and using Chainer estimators and models with SageMaker, see Using Chainer with the SageMaker Python SDK.

Use Hugging Face with Amazon SageMaker

Amazon SageMaker enables customers to train, fine-tune, and run inference using Hugging Face models for Natural Language Processing (NLP) on SageMaker. You can use Hugging Face for both training and inference. This functionality is available through the development of Hugging Face AWS Deep Learning Containers. These containers include Hugging Face Transformers, Tokenizers and theDatasetslibrary, which allows you to use these resources for your training and inference jobs. For a list of the available Deep Learning Containers images, see Available Deep Learning Containers Images. These Deep Learning Containers images are maintained and regularly updated with security patches.

To use the Hugging Face Deep Learning Containers with the SageMaker Python SDK for training, see the Hugging Face SageMaker Estimator. With the Hugging Face Estimator, you can use the Hugging Face models as you would any other SageMaker Estimator. However, using the SageMaker Python SDK is optional. You can also orchestrate your use of the Hugging Face Deep Learning Containers with the AWS CLI and AWS SDK for Python (Boto3).
For more information on Hugging Face and the models available in it, see the Hugging Face documentation.

**Training**

To run training, you can use any of the thousands of models available in Hugging Face and fine-tune them for your specific use case with additional training. With SageMaker, you can use standard training or take advantage of SageMaker Distributed Data and Model Parallel training. As with other SageMaker training jobs using custom code, you can capture your own metrics by passing a metrics definition to the SageMaker Python SDK as shown in Defining Training Metrics (SageMaker Python SDK). The captured metrics are then accessible via CloudWatch and as a Pandas DataFrame via the TrainingJobAnalytics method. Once your model is trained and fine-tuned, you can use it like any other model to run inference jobs.

**How to run training with the Hugging Face Estimator**

You can implement the Hugging Face Estimator for training jobs using the SageMaker Python SDK. The SageMaker Python SDK is an open source library for training and deploying machine learning models on SageMaker. For more information on the Hugging Face Estimator, see the SageMaker Python SDK documentation.

With the SageMaker Python SDK, you can run training jobs using the Hugging Face Estimator in the following environments:

- **SageMaker Studio**: Amazon SageMaker Studio is the first fully integrated development environment (IDE) for machine learning (ML). SageMaker Studio provides a single, web-based visual interface where you can perform all ML development steps required to prepare, build, train and tune, deploy and manage models. For information on using Jupyter Notebooks in Studio, see Use Amazon SageMaker Studio Notebooks.
- **SageMaker Notebook Instances**: An Amazon SageMaker notebook instance is a machine learning (ML) compute instance running the Jupyter Notebook App. This app lets you run Jupyter Notebooks in your notebook instance to prepare and process data, write code to train models, deploy models to SageMaker hosting, and test or validate your models without SageMaker Studio features like Debugger, Model Monitoring, and a web-based IDE.
- **Locally**: If you have connectivity to AWS and have appropriate SageMaker permissions, you can use the SageMaker Python SDK locally to launch remote training and inference jobs for Hugging Face in SageMaker on AWS. This works on your local machine, as well as other AWS services with a connected SageMaker Python SDK and appropriate permissions.

**Inference**

For inference, you can use your trained Hugging Face model or one of the pretrained Hugging Face models to deploy an inference job with SageMaker. With this collaboration, you only need one line of code to deploy both your trained models and pre-trained models with SageMaker. You can also run inference jobs without having to write any custom inference code. With custom inference code, you can customize the inference logic by providing your own Python script.

**How to deploy an inference job using the Hugging Face Deep Learning Containers**

You have two options for running inference with SageMaker. You can run inference using a model that you trained, or deploy a pre-trained Hugging Face model.

- **Run inference with your trained model**: You have two options for running inference with your own trained model. You can run inference with a model that you trained using an existing Hugging Face
model with the SageMaker Hugging Face Deep Learning Containers, or you can bring your own existing Hugging Face model and deploy it using SageMaker. When you run inference with a model that you trained with the SageMaker Hugging Face Estimator, you can deploy the model immediately after training completes or you can upload the trained model to an Amazon S3 bucket and ingest it when running inference later. If you bring your own existing Hugging Face model, you must upload the trained model to an Amazon S3 bucket and ingest that bucket when running inference as shown in Deploy your Hugging Face Transformers for inference example.

- **Run inference with a pre-trained HuggingFace model:** You can use one of the thousands of pre-trained Hugging Face models to run your inference jobs with no additional training needed. To run inference, you select the pre-trained model from the list of Hugging Face models, as outlined in Deploy pre-trained Hugging Face Transformers for inference example.

**What do you want to do?**

The following Jupyter Notebooks in the Hugging Face notebooks repository illustrate how to use the Hugging Face Deep Learning Containers with SageMaker in various use cases.

I want to train and deploy a text classification model using Hugging Face in SageMaker with PyTorch.

For a sample Jupyter Notebook, see the PyTorch Getting Started Demo.

I want to train and deploy a text classification model using Hugging Face in SageMaker with TensorFlow.

For a sample Jupyter Notebook, see the TensorFlow Getting Started example.

I want to run distributed training with data parallelism using Hugging Face and SageMaker Distributed.

For a sample Jupyter Notebook, see the Distributed Training example.

I want to run distributed training with model parallelism using Hugging Face and SageMaker Distributed.

For a sample Jupyter Notebook, see the Model Parallelism example.

I want to use a spot instance to train and deploy a model using Hugging Face in SageMaker.

For a sample Jupyter Notebook, see the Spot Instances example.

I want to capture custom metrics and use SageMaker Checkpointing when training a text classification model using Hugging Face in SageMaker.

For a sample Jupyter Notebook, see the Training with Custom Metrics example.

I want to train a distributed question-answering TensorFlow model using Hugging Face in SageMaker.

For a sample Jupyter Notebook, see the Distributed TensorFlow Training example.

I want to train a distributed summarization model using Hugging Face in SageMaker.

For a sample Jupyter Notebook, see the Distributed Summarization Training example.

I want to train an image classification model using Hugging Face in SageMaker.

For a sample Jupyter Notebook, see the Vision Transformer Training example.

I want to deploy my trained Hugging Face model in SageMaker.

For a sample Jupyter Notebook, see the Deploy your Hugging Face Transformers for inference example.

I want to deploy a pre-trained Hugging Face model in SageMaker.

For a sample Jupyter Notebook, see the Deploy pre-trained Hugging Face Transformers for inference example.
Use PyTorch with Amazon SageMaker

You can use Amazon SageMaker to train and deploy a model using custom PyTorch code. The SageMaker Python SDK PyTorch estimators and models and the SageMaker open-source PyTorch container make writing a PyTorch script and running it in SageMaker easier.

What do you want to do?

I want to train a custom PyTorch model in SageMaker.

For a sample Jupyter notebook, see the PyTorch example notebook in the Amazon SageMaker Examples GitHub repository.

For documentation, see Train a Model with PyTorch.

I have a PyTorch model that I trained in SageMaker, and I want to deploy it to a hosted endpoint.

For more information, see Deploy PyTorch models.

I have a PyTorch model that I trained outside of SageMaker, and I want to deploy it to a SageMaker endpoint.

For more information, see Deploy your own PyTorch model.

I want to see the API documentation for Amazon SageMaker Python SDK PyTorch classes.

For more information, see PyTorch Classes.

I want to find the SageMaker PyTorch container repository.

For more information, see SageMaker PyTorch Container GitHub repository.

I want to find information about PyTorch versions supported by AWS Deep Learning Containers.

For more information, see Available Deep Learning Container Images.

For general information about writing PyTorch training scripts and using PyTorch estimators and models with SageMaker, see Using PyTorch with the SageMaker Python SDK.

R User Guide to Amazon SageMaker

This document will walk you through ways of leveraging Amazon SageMaker features using R. This guide introduces SageMaker's built-in R kernel, how to get started with R on SageMaker, and finally several example notebooks.

The examples are organized in three levels, Beginner, Intermediate, and Advanced. They start from Getting Started with R on SageMaker, continue to end-to-end machine learning with R on SageMaker, and then finish with more advanced topics such as SageMaker Processing with R script, and Bring-Your-Own (BYO) R algorithm to SageMaker.

For information on how to bring your own custom R image to Studio, see Bring your own SageMaker image (p. 257). For a similar blog article, see Bringing your own R environment to Amazon SageMaker Studio.

RStudio Support in SageMaker

Amazon SageMaker supports RStudio as a fully-managed integrated development environment (IDE) integrated with Amazon SageMaker Domain. With RStudio integration, you can launch an
RStudio environment in the Domain to run your RStudio workflows on SageMaker resources. For more information, see RStudio on Amazon SageMaker (p. 602).

R Kernel in SageMaker

SageMaker notebook instances support R using a pre-installed R kernel. Also, the R kernel has the reticulate library, an R to Python interface, so you can use the features of SageMaker Python SDK from within an R script.

- **reticulatelibary**: provides an R interface to the Amazon SageMaker Python SDK. The reticulate package translates between R and Python objects.

Get Started with R in SageMaker

- **Create a Notebook Instance** using the t2.medium instance type and default storage size. You can pick a faster instance and more storage if you plan to continue using the instance for more advanced examples, or create a bigger instance later.
- **Wait until the status of the notebook is In Service**, and then click Open Jupyter.

- Create a new notebook with R kernel from the list of available environments.

- When the new notebook is created, you should see an R logo in the upper right corner of the notebook environment, and also R as the kernel under that logo. This indicates that SageMaker has successfully launched the R kernel for this notebook.
• Alternatively, when you are in a Jupyter notebook, you can use Kernel menu, and then select R from Change Kernel option.

Example Notebooks

Prerequisites

Getting Started with R on SageMaker: This sample notebook describes how you can develop R scripts using Amazon SageMaker’s R kernel. In this notebook you set up your SageMaker environment and permissions, download the abalone dataset from the UCI Machine Learning Repository, do some basic processing and visualization on the data, then save the data as .csv format to S3.

Beginner Level

SageMaker Batch Transform using R Kernel: This sample Notebook describes how to conduct a batch transform job using SageMaker’s Transformer API and the XGBoost algorithm. The notebook also uses the Abalone dataset.

Intermediate Level

Hyperparameter Optimization for XGBoost in R: This sample notebook extends the previous beginner notebooks that use the abalone dataset and XGBoost. It describes how to do model tuning with hyperparameter optimization. You will also learn how to use batch transform for batching predictions, as well as how to create a model endpoint to make real-time predictions.

Amazon SageMaker Processing with R: SageMaker Processing lets you preprocess, post-process and run model evaluation workloads. This example shows you how to create an R script to orchestrate a Processing job.

Advanced Level

Train and Deploy Your Own R Algorithm in SageMaker: Do you already have an R algorithm, and you want to bring it into SageMaker to tune, train, or deploy it? This example walks you through how to customize SageMaker containers with custom R packages, all the way to using a hosted endpoint for inference on your R-origin model.

Use Scikit-learn with Amazon SageMaker

You can use Amazon SageMaker to train and deploy a model using custom Scikit-learn code. The SageMaker Python SDK Scikit-learn estimators and models and the SageMaker open-source Scikit-learn containers make writing a Scikit-learn script and running it in SageMaker easier.

Requirements

Scikit-learn 1.2 has the following dependencies.
The SageMaker Scikit-learn container supports the following Scikit-learn versions.

<table>
<thead>
<tr>
<th>Supported Scikit-learn version</th>
<th>Minimum Python version</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.2-1</td>
<td>3.8</td>
</tr>
<tr>
<td>1.0-1</td>
<td>3.7</td>
</tr>
<tr>
<td>0.23-1</td>
<td>3.6</td>
</tr>
<tr>
<td>0.20.0</td>
<td>2.7 or 3.4</td>
</tr>
</tbody>
</table>

For general information about writing Scikit-learn training scripts and using Scikit-learn estimators and models with SageMaker, see [Using Scikit-learn with the SageMaker Python SDK](#).

**What do you want to do?**

**Note**

Matplotlib v2.2.3 or newer is required to run the SageMaker Scikit-learn example notebooks.

I want to use Scikit-learn for data processing, feature engineering, or model evaluation in SageMaker.

For documentation, see [ReadTheDocs](#).

I want to train a custom Scikit-learn model in SageMaker.

For documentation, see [Train a Model with Scikit-learn](#).

I have a Scikit-learn model that I trained in SageMaker, and I want to deploy it to a hosted endpoint.

For more information, see [Deploy Scikit-learn models](#).

I have a Scikit-learn model that I trained outside of SageMaker, and I want to deploy it to a SageMaker endpoint.

For more information, see [Deploy Endpoints from Model Data](#).

I want to see the API documentation for [Amazon SageMaker Python SDK](#) Scikit-learn classes.

For more information, see [Scikit-learn Classes](#).

I want to see information about SageMaker Scikit-learn containers.

For more information, see [SageMaker Scikit-learn Container GitHub repository](#)
Use SparkML Serving with Amazon SageMaker

The Amazon SageMaker Python SDK SparkML Serving model and predictor and the Amazon SageMaker open-source SparkML Serving container support deploying Apache Spark ML pipelines serialized with MLearp in SageMaker to get inferences.

For information about using the SparkML Serving container to deploy models to SageMaker, see SageMaker Spark ML Container GitHub repository. For information about the Amazon SageMaker Python SDK SparkML Serving model and predictors, see the SparkML Serving Model and Predictor API documentation.

Use TensorFlow with Amazon SageMaker

Use TensorFlow Version 1.11 and Later

For TensorFlow versions 1.11 and later, the Amazon SageMaker Python SDK supports script mode training scripts.

What do you want to do?

I want to train a custom TensorFlow model in SageMaker.

For a sample Jupyter notebook, see TensorFlow script mode training and serving.

For documentation, see Train a Model with TensorFlow.

I have a TensorFlow model that I trained in SageMaker, and I want to deploy it to a hosted endpoint.

For more information, see Deploy TensorFlow Serving models.

I have a TensorFlow model that I trained outside of SageMaker, and I want to deploy it to a SageMaker endpoint

For more information, see Deploying directly from model artifacts.

I want to see the API documentation for Amazon SageMaker Python SDK TensorFlow classes.

For more information, see TensorFlow Estimator.

I want to find the SageMaker TensorFlow container repository.

For more information, see SageMaker TensorFlow Container GitHub repository.

I want to find information about TensorFlow versions supported by AWS Deep Learning Containers.

For more information, see Available Deep Learning Container Images.

For general information about writing TensorFlow script mode training scripts and using TensorFlow script mode estimators and models with SageMaker, see Using TensorFlow with the SageMaker Python SDK.

Use TensorFlow Legacy Mode for Versions 1.11 and Earlier

The Amazon SageMaker Python SDK provides a legacy mode that supports TensorFlow versions 1.11 and earlier. Use legacy mode TensorFlow training scripts to run TensorFlow jobs in SageMaker if:

- You have existing legacy mode scripts that you do not want to convert to script mode.
- You want to use a TensorFlow version earlier than 1.11.
For information about writing legacy mode TensorFlow scripts to use with the SageMaker Python SDK, see [TensorFlow SageMaker Estimators and Models](#).

**Use Triton Inference Server with Amazon SageMaker**

SageMaker enables customers to deploy a model using custom code with NVIDIA Triton Inference Server. This functionality is available through the development of [Triton Inference Server Containers](#). These containers include NVIDIA Triton Inference Server, support for common ML frameworks, and useful environment variables that let you optimize performance on SageMaker. For a list of all available Deep Learning Containers images, see [Available Deep Learning Containers Images](#). Deep Learning Containers images are maintained and regularly updated with security patches.

You can use the Triton Inference Server Container with SageMaker Python SDK as you would any other container in your SageMaker models. However, using the SageMaker Python SDK is optional. You can use Triton Inference Server Containers with the AWS CLI and AWS SDK for Python (Boto3).

For more information on NVIDIA Triton Inference Server see the [Triton documentation](#).

**Inference**

**Note**
The Triton Python backend uses shared memory (SHMEM) to connect your code to Triton. SageMaker Inference provides up to half of the instance memory as SHMEM so you can use an instance with more memory for larger SHMEM size.

For inference, you can use your trained ML models with Triton Inference Server to deploy an inference job with SageMaker.

Some of the key features of Triton Inference Server Container are:

- **Support for multiple frameworks**: Triton can be used to deploy models from all major ML frameworks. Triton supports TensorFlow GraphDef and SavedModel, ONNX, PyTorch TorchScript, TensorRT, and custom Python/C++ model formats.
- **Model pipelines**: Triton model ensemble represents a pipeline of one model with pre/post processing logic and the connection of input and output tensors between them. A single inference request to an ensemble triggers the execution of the entire pipeline.
- **Concurrent model execution**: Multiple instances of the same model can run simultaneously on the same GPU or on multiple GPUs.
- **Dynamic batching**: For models that support batching, Triton has multiple built-in scheduling and batching algorithms that combine individual inference requests together to improve inference throughput. These scheduling and batching decisions are transparent to the client requesting inference.
- **Diverse CPU and GPU support**: The models can be executed on CPUs or GPUs for maximum flexibility and to support heterogeneous computing requirements.

**What do you want to do?**

I want to deploy my trained PyTorch model in SageMaker.

For a sample Jupyter Notebook, see the [Deploy your PyTorch Resnet50 model with Triton Inference Server example](#).

I want to deploy my trained Hugging Face model in SageMaker.

For a sample Jupyter Notebook, see the [Deploy your PyTorch BERT model with Triton Inference Server example](#).
Programming Model for Amazon SageMaker

Making API calls directly from code is cumbersome, and requires you to write code to authenticate your requests. Amazon SageMaker provides the following alternatives:

- **Use the SageMaker console**—With the console, you don't write any code. You use the console UI to start model training or deploy a model. The console works well for simple jobs, where you use a built-in training algorithm and you don't need to preprocess training data.

- **Modify the example Jupyter notebooks**—SageMaker provides several Jupyter notebooks that train and deploy models using specific algorithms and datasets. Start with a notebook that has a suitable algorithm and modify it to accommodate your data source and specific needs.

- **Write model training and inference code from scratch**—SageMaker provides multiple AWS SDK languages (listed in the overview) and the Amazon SageMaker Python SDK, a high-level Python library that you can use in your code to start model training jobs and deploy the resulting models.

- **The SageMaker Python SDK**—This Python library simplifies model training and deployment. In addition to authenticating your requests, the library abstracts platform specifics by providing simple methods and default parameters. For example:
  
  - To deploy your model, you call only the `deploy()` method. The method creates a SageMaker model artifact, an endpoint configuration, then deploys the model on an endpoint.
  
  - If you use a custom framework script for model training, you call the `fit()` method. The method creates a `.gzip` file of your script, uploads it to an Amazon S3 location, and then runs it for model training, and other tasks. For more information, see [Machine Learning Frameworks and Languages](p. 3610).

  - To set defaults for SageMaker API calls made by the SageMaker Python SDK, you use a default configuration dictionary. For more information, see [Configuring and using defaults with the SageMaker Python SDK](p. 3610).

- **The AWS SDKs**—The SDKs provide methods that correspond to the SageMaker API (see [Operations](p. 3610)). Use the SDKs to programmatically start a model training job and host the model in SageMaker. SDK clients handle authentication for you, so you don't need to write authentication code. They are available in multiple languages and platforms. For more information, see the preceding list in the overview.
In Get started (p. 8), you train and deploy a model using an algorithm provided by SageMaker. That exercise shows how to use both of these libraries. For more information, see Get started (p. 8).

- **Integrate SageMaker into your Apache Spark workflow**—SageMaker provides a library for calling its APIs from Apache Spark. With it, you can use SageMaker-based estimators in an Apache Spark pipeline. For more information, see Use Apache Spark with Amazon SageMaker (p. 3611).

### APIs, CLI, and SDKs

Amazon SageMaker provides APIs, SDKs, and a command line interface that you can use to create and manage notebook instances and train and deploy models.

- Amazon SageMaker Python SDK (Recommended)
- Amazon SageMaker API Reference
- Amazon Augmented AI API Reference
- AWS Command Line Interface
- AWS SDK for .NET
- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java
- AWS SDK for JavaScript
- AWS SDK for PHP
- AWS SDK for Python (Boto)
- AWS SDK for Ruby
- Amazon SageMaker Spark

You can also get code examples from the Amazon SageMaker example notebooks GitHub repository.

- Example notebooks
