**Tuning a Semantic Segmentation Model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

**Metrics Computed by the Semantic Segmentation Algorithm**

The semantic segmentation algorithm reports two validation metrics. When tuning hyperparameter values, choose one of these metrics as the objective.

Use Reinforcement Learning with Amazon SageMaker

Reinforcement learning (RL) combines fields such as computer science, neuroscience, and psychology to determine how to map situations to actions to maximize a numerical reward signal. This notion of a reward signal in RL stems from neuroscience research into how the human brain makes decisions about which actions maximize reward and minimize punishment. In most situations, humans are not given explicit instructions on which actions to take, but instead must learn both which actions yield the most immediate rewards, and how those actions influence future situations and consequences.

The problem of RL is formalized using Markov decision processes (MDPs) that originate from dynamical systems theory. MDPs aim to capture high-level details of a real problem that a learning agent encounters over some period of time in attempting to achieve some ultimate goal. The learning agent should be able to determine the current state of its environment and identify possible actions that affect the learning agent's current state. Furthermore, the learning agent's goals should correlate strongly to the state of the environment. A solution to a problem formulated in this way is known as a reinforcement learning method.

What are the differences between reinforcement, supervised, and unsupervised learning paradigms?

Machine learning can be divided into three distinct learning paradigms: supervised, unsupervised, and reinforcement.

In supervised learning, an external supervisor provides a training set of labeled examples. Each example contains information about a situation, belongs to a category, and has a label identifying the category to which it belongs. The goal of supervised learning is to generalize in order to predict correctly in situations that are not present in the training data.

In contrast, RL deals with interactive problems, making it infeasible to gather all possible examples of situations with correct labels that an agent might encounter. This type of learning is most promising when an agent is able to accurately learn from its own experience and adjust accordingly.

In unsupervised learning, an agent learns by uncovering structure within unlabeled data. While a RL agent might benefit from uncovering structure based on its experiences, the sole purpose of RL is to maximize a reward signal.

Why is Reinforcement Learning Important?

RL is well-suited for solving large, complex problems, such as supply chain management, HVAC systems, industrial robotics, game artificial intelligence, dialog systems, and autonomous vehicles. Because RL models learn by a continuous process of receiving rewards and punishments for every action taken by the agent, it is possible to train systems to make decisions under uncertainty and in dynamic environments.
Markov Decision Process (MDP)

RL is based on models called Markov Decision Processes (MDPs). An MDP consists of a series of time steps. Each time step consists of the following:

Environment

Defines the space in which the RL model operates. This can be either a real-world environment or a simulator. For example, if you train a physical autonomous vehicle on a physical road, that would be a real-world environment. If you train a computer program that models an autonomous vehicle driving on a road, that would be a simulator.

State

Specifies all information about the environment and past steps that is relevant to the future. For example, in an RL model in which a robot can move in any direction at any time step, the position of the robot at the current time step is the state, because if we know where the robot is, it isn't necessary to know the steps it took to get there.

Action

What the agent does. For example, the robot takes a step forward.

Reward

A number that represents the value of the state that resulted from the last action that the agent took. For example, if the goal is for a robot to find treasure, the reward for finding treasure might be 5, and the reward for not finding treasure might be 0. The RL model attempts to find a strategy that optimizes the cumulative reward over the long term. This strategy is called a policy.

Observation

Information about the state of the environment that is available to the agent at each step. This might be the entire state, or it might be just a part of the state. For example, the agent in a chess-playing model would be able to observe the entire state of the board at any step, but a robot in a maze might only be able to observe a small portion of the maze that it currently occupies.

Typically, training in RL consists of many episodes. An episode consists of all of the time steps in an MDP from the initial state until the environment reaches the terminal state.

Key Features of Amazon SageMaker RL

To train RL models in SageMaker RL, use the following components:

- An RL environment. You can use custom environments, open-source environments, or commercial environments. For information, see RL Environments in Amazon SageMaker (p. 1811).

The following diagram shows the RL components that are supported in SageMaker RL.
Reinforcement Learning Sample Notebooks

For complete code examples, see the reinforcement learning sample notebooks in the SageMaker Examples repository.

Sample RL Workflow Using Amazon SageMaker RL

The following example describes the steps for developing RL models using Amazon SageMaker RL.

1. **Formulate the RL problem**—First, formulate the business problem into an RL problem. For example, auto scaling enables services to dynamically increase or decrease capacity depending on conditions that you define. Currently, this requires setting up alarms, scaling policies, thresholds, and other manual steps. To solve this with RL, we define the components of the Markov Decision Process:
   a. **Objective**—Scale instance capacity so that it matches the desired load profile.
   b. **Environment**—A custom environment that includes the load profile. It generates a simulated load with daily and weekly variations and occasional spikes. The simulated system has a delay between when new resources are requested and when they become available for serving requests.
   c. **State**—The current load, number of failed jobs, and number of active machines.
   d. **Action**—Remove, add, or keep the same number of instances.
   e. **Reward**—A positive reward for successful transactions and a high penalty for failing transactions beyond a specified threshold.

2. **Define the RL environment**—The RL environment can be the real world where the RL agent interacts or a simulation of the real world. You can connect open source and custom environments developed using Gym interfaces and commercial simulation environments such as MATLAB and Simulink.

3. **Define the presets**—The presets configure the RL training jobs and define the hyperparameters for the RL algorithms.

4. **Write the training code**—Write training code as a Python script and pass the script to a SageMaker training job. In your training code, import the environment files and the preset files, and then define the main() function.

5. **Train the RL Model**—Use the SageMaker RLEstimator in the Amazon SageMaker Python SDK to start an RL training job. If you are using local mode, the training job runs on the notebook instance. When you use SageMaker for training, you can select GPU or CPU instances. Store the output from the training job in a local directory if you train in local mode, or on Amazon S3 if you use SageMaker training.

   The RLEstimator requires the following information as parameters.
   a. The source directory where the environment, presets, and training code are uploaded.
   b. The path to the training script.
   c. The RL toolkit and deep learning framework you want to use. This automatically resolves to the Amazon ECR path for the RL container.
   d. The training parameters, such as the instance count, job name, and S3 path for output.
   e. Metric definitions that you want to capture in your logs. These can also be visualized in CloudWatch and in SageMaker notebooks.

6. **Visualize training metrics and output**—After a training job that uses an RL model completes, you can view the metrics you defined in the training jobs in CloudWatch. You can also plot the metrics in a notebook by using the Amazon SageMaker Python SDK analytics library. Visualizing metrics helps you understand how the performance of the model as measured by the reward improves over time.

   **Note**
   If you train in local mode, you can’t visualize metrics in CloudWatch.
7. **Evaluate the model**—Checkpointed data from the previously trained models can be passed on for evaluation and inference in the checkpoint channel. In local mode, use the local directory. In SageMaker training mode, you need to upload the data to S3 first.

8. **Deploy RL models**—Finally, deploy the trained model on an endpoint hosted on SageMaker containers or on an edge device by using AWS IoT Greengrass.

For more information on RL with SageMaker, see [Using RL with the SageMaker Python SDK](#).

**RL Environments in Amazon SageMaker**

Amazon SageMaker RL uses environments to mimic real-world scenarios. Given the current state of the environment and an action taken by the agent or agents, the simulator processes the impact of the action, and returns the next state and a reward. Simulators are useful in cases where it is not safe to train an agent in the real world (for example, flying a drone) or if the RL algorithm takes a long time to converge (for example, when playing chess).

The following diagram shows an example of the interactions with a simulator for a car racing game.

![Diagram of RL training and simulation](image)

The simulation environment consists of an agent and a simulator. Here, a convolutional neural network (CNN) consumes images from the simulator and generates actions to control the game controller. With multiple simulations, this environment generates training data of the form \( \text{state}_t, \text{action}, \text{state}_{t+1}, \text{reward}_{t+1} \). Defining the reward is not trivial and impacts the RL model quality. We want to provide a few examples of reward functions, but would like to make it user-configurable.

**Topics**

- [Use OpenAI Gym Interface for Environments in SageMaker RL](#) (p. 1812)
- [Use Open-Source Environments](#) (p. 1812)
- [Use Commercial Environments](#) (p. 1812)
Use OpenAI Gym Interface for Environments in SageMaker RL

To use OpenAI Gym environments in SageMaker RL, use the following API elements. For more information about OpenAI Gym, see Gym Documentation.

- **env.action_space**—Defines the actions the agent can take, specifies whether each action is continuous or discrete, and specifies the minimum and maximum if the action is continuous.
- **env.observation_space**—Defines the observations the agent receives from the environment, as well as minimum and maximum for continuous observations.
- **env.reset()**—Initializes a training episode. The reset() function returns the initial state of the environment, and the agent uses the initial state to take its first action. The action is then sent to step() repeatedly until the episode reaches a terminal state. When step() returns done = True, the episode ends. The RL toolkit re-initializes the environment by calling reset().
- **step()**—Takes the agent action as input and outputs the next state of the environment, the reward, whether the episode has terminated, and an info dictionary to communicate debugging information. It is the responsibility of the environment to validate the inputs.
- **env.render()**—Used for environments that have visualization. The RL toolkit calls this function to capture visualizations of the environment after each call to the step() function.

Use Open-Source Environments

You can use open-source environments, such as EnergyPlus and RoboSchool, in SageMaker RL by building your own container. For more information about EnergyPlus, see https://energyplus.net/. For more information about RoboSchool, see https://github.com/openai/roboschool. The HVAC and RoboSchool examples in the SageMaker examples repository show how to build a custom container to use with SageMaker RL:

Use Commercial Environments

You can use commercial environments, such as MATLAB and Simulink, in SageMaker RL by building your own container. You need to manage your own licenses.

Distributed Training with Amazon SageMaker RL

Amazon SageMaker RL supports multi-core and multi-instance distributed training. Depending on your use case, training and/or environment rollout can be distributed. For example, SageMaker RL works for the following distributed scenarios:

- Single training instance and multiple rollout instances of the same instance type. For an example, see the Neural Network Compression example in the SageMaker examples repository.
- Single trainer instance and multiple rollout instances, where different instance types for training and rollouts. For an example, see the AWS DeepRacer / AWS RoboMaker example in the SageMaker examples repository.
- Single trainer instance that uses multiple cores for rollout. For an example, see the Roboschool example in the SageMaker examples repository. This is useful if the simulation environment is lightweight and can run on a single thread.
- Multiple instances for training and rollouts. For an example, see the Roboschool example in the SageMaker examples repository.

Hyperparameter Tuning with Amazon SageMaker RL

You can run a hyperparameter tuning job to optimize hyperparameters for Amazon SageMaker RL. The Roboschool example in the sample notebooks in the SageMaker examples repository shows how you
can do this with RL Coach. The launcher script shows how you can abstract parameters from the Coach
preset file and optimize them.

Run your local code as a SageMaker training job

You can run your local machine learning (ML) Python code as a large single-node Amazon SageMaker
training job or as multiple parallel jobs. You can do this by annotating your code with an @remote
decorator, as shown in the following code example. Distributed training (across multiple instances) are
not supported with remote functions.

```python
@remote(**settings)
def divide(x, y):
    return x / y
```

The SageMaker Python SDK will automatically translate your existing workspace environment and any
associated data processing code and datasets into a SageMaker training job that runs on the SageMaker
training platform. You can also activate a persistent cache feature, which will further reduce job start
latency by caching previously downloaded dependency packages. This reduction in job latency is greater
than the reduction in latency from using SageMaker managed warm pools alone. For more information,
see Using persistent cache (p. 2309).

**Note**
Distributed training jobs are not supported by remote functions.

The following sections show how to annotate your local ML code with an @remote decorator and tailor
your experience for your use case. This includes customizing your environment and integrating with
SageMaker Experiments.

**Topics**
- Set up your environment (p. 1813)
- Invoking a function (p. 1819)
- Configuration file (p. 1827)
- Customize your runtime environment (p. 1828)
- Container image compatibility (p. 1829)
- Logging parameters and metrics with Amazon SageMaker Experiments (p. 1832)
- Using modular code with the @remote decorator (p. 1835)
- Private repository for runtime dependencies (p. 1836)
- Example notebooks (p. 1837)

**Set up your environment**

Choose one of the following three options to set up your environment.

**Run your code from Amazon SageMaker Studio**

You can annotate and run your local ML code from SageMaker Studio by creating a SageMaker Notebook
and attaching any image available on SageMaker Studio image. The following instructions help you
create a SageMaker Notebook, install the SageMaker Python SDK, and annotate your code with the
decorator.
1. Create a SageMaker Notebook and attach an image in SageMaker Studio as follows:
   a. Follow the instructions in [Launch Amazon SageMaker Studio](https://docs.aws.amazon.com/sagemaker/latest/dg/amzn-ssm-get-started.html) in the Amazon SageMaker Developer Guide.
   b. Select Studio from the left navigation pane. This opens a new window.
   c. In the **Get Started** dialog box, select a user profile from the down arrow. This opens a new window.
   d. Select Open Studio.
   e. Select Open Launcher from the main working area. This opens a new page.
   f. Select Create notebook from the main working area.
   g. Select **Base Python 3.0** from the down arrow next to **Image** in the **Change environment** dialog box.

The `@remote` decorator automatically detects the image attached to the SageMaker Studio notebook and uses it to run the SageMaker training job. If `image_uri` is specified either as an argument in the decorator or in the configuration file, then the value specified in `image_uri` will be used instead of the detected image.

For more information about how to create a notebook in SageMaker Studio, see the **Create a Notebook from the File Menu** section in [Create or Open an Amazon SageMaker Studio Notebook](https://docs.aws.amazon.com/sagemaker/latest/dg/amzn-ssm-create-or-open-notebook.html).

For a list of available images, see [Supported Docker images](https://docs.aws.amazon.com/sagemaker/latest/dg/sagemaker-environment-variables.html).

2. Install the SageMaker Python SDK.

To annotate your code with the `@remote` function inside a SageMaker Studio Notebook, you must have the SageMaker Python SDK installed. Install the SageMaker Python SDK, as shown in the following code example.

```bash
!pip install sagemaker
```

3. Use `@remote` decorator to run functions in a SageMaker training job.

To run your local ML code, first create a dependencies file to instruct SageMaker where to locate your local code. To do so, follow these steps:

a. From the SageMaker Studio Launcher main working area, in **Utilities and files**, choose **Text file**. This opens a new tab with a text file called untitled.txt.

   For more information about the SageMaker Studio user interface (UI), see [Amazon SageMaker Studio UI Overview](https://docs.aws.amazon.com/sagemaker/latest/dg/amzn-ssm-ui-overview.html).

b. Rename untitled.txt to requirements.txt.

c. Add all the dependencies required for the code along with the SageMaker library to requirements.txt.

A minimal code example for `requirements.txt` for the example `divide` function is provided in the following section, as follows.

```python
sagemaker
```

d. Run your code with the remote decorator by passing the dependencies file, as follows.

```python
from sagemaker.remote_function import remote

@remote(instance_type='ml.m5.xlarge', dependencies='./requirements.txt')
def divide(x, y):
    return x / y

divide(2, 3.0)
```
Run your code from an Amazon SageMaker notebook

You can annotate your local ML code from a SageMaker notebook instance. The following instructions show how to create a notebook instance with a custom kernel, install the SageMaker Python SDK, and annotate your code with the decorator.

1. Create a notebook instance with a custom conda kernel.

You can annotate your local ML code with an @remote decorator to use inside of a SageMaker training job. First you must create and customize a SageMaker notebook instance to use a kernel with Python version 3.7 or higher, up to 3.10.x. To do so, follow these steps:

b. In the left navigation panel, choose Notebook to expand its options.
c. Choose Notebook Instances from the expanded options.
d. Choose the Create Notebook Instance button. This opens a new page.
e. For Notebook instance name, enter a name with a maximum of 63 characters and no spaces. Valid characters: A-Z, a-z, 0-9, and:=-@_/\%-

f. In the Notebook instance settings dialog box, expand the right arrow next to Additional Configuration.
g. Under Lifecycle configuration - optional, expand the down arrow and select Create a new lifecycle configuration. This opens a new dialog box.
h. Under Name, enter a name for your configuration setting.
i. In the Scripts dialog box, in the Start notebook tab, replace the existing contents of the text box with the following script.

```bash
#!/bin/bash
set -e

sudo -u ec2-user -i <<'EOF'
unset SUDO_UID
WORKING_DIR=/home/ec2-user/SageMaker/custom-miniconda/
source "$WORKING_DIR/miniconda/bin/activate"
for env in "$WORKING_DIR/miniconda/envs/*"; do
    BASENAME=$(basename "$env")
    source activate "$BASENAME"
    python -m ipykernel install --user --name "$BASENAME" --display-name "Custom ($BASENAME)"
done
EOF

echo "Restarting the Jupyter server..."
# restart command is dependent on current running Amazon Linux and JupyterLab
CURR_VERSION_AL=$(cat /etc/system-release)
CURR_VERSION_JS=$(jupyter --version)
if [[ $CURR_VERSION_JS == "$jupyter_core : 4.9.1"* ]] & & [[ $CURR_VERSION_AL == * "$ release 2018"* ]]; then
    sudo initctl restart jupyter-server --no-wait
else
```
j. In the **Scripts** dialog box, in the **Create notebook** tab, replace the existing contents of the text box with the following script.

```bash
#!/bin/bash
set -e

sudo -u ec2-user -i <<'EOF'
unset SUDO_UID
# Install a separate conda installation via Miniconda
WORKING_DIR=/home/ec2-user/SageMaker/custom-miniconda
mkdir -p "$WORKING_DIR"
wget https://repo.anaconda.com/miniconda/Miniconda3-4.6.14-Linux-x86_64.sh -O ""$WORKING_DIR/miniconda.sh"
bash "$WORKING_DIR/miniconda.sh" -b -u -p "$WORKING_DIR/miniconda"
rm -rf "$WORKING_DIR/miniconda.sh"
# Create a custom conda environment
source "$WORKING_DIR/miniconda/bin/activate"
KERNEL_NAME="custom_python310"
PYTHON="3.10"
conda create --yes --name "$KERNEL_NAME" python="$PYTHON" pip
conda activate "$KERNEL_NAME"
pip install --quiet ipykernel
# Customize these lines as necessary to install the required packages
EOF
```

k. Choose the **Create configuration** button on the bottom right of the window.

l. Choose the **Create notebook instance** button on the bottom right of the window.

m. Wait for the notebook instance **Status** to change from **Pending** to **InService**.

2. Create a Jupyter notebook in the notebook instance.

The following instructions show how to create a Jupyter notebook using Python 3.10 in your newly created SageMaker instance.

a. After the notebook instance **Status** from the previous step is **InService**, do the following:

i. Select **Open Jupyter** under **Actions** in the row containing your newly created notebook instance **Name**. This opens a new Jupyter server.

b. In the Jupyter server, select **New** from the top right menu.

c. From the down arrow, select **conda_custom_python310**. This creates a new Jupyter notebook that uses a Python 3.10 kernel. This new Jupyter notebook can now be used similarly to a local Jupyter notebook.

3. Install the SageMaker Python SDK.

After your virtual environment is running, install the SageMaker Python SDK by using the following code example.

```bash
!pip install sagemaker
```

4. Use an @remote decorator to run functions in a SageMaker training job.

When you annotate your local ML code with an @remote decorator inside the SageMaker notebook, SageMaker training will automatically interpret the function of your code and run it as a SageMaker training job. Set up your notebook by doing the following:

a. Select the kernel name in the notebook menu from the SageMaker notebook instance that you created in step 1, **Create a SageMaker Notebook instance with a custom kernel**.
For more information, see Change an Image or a Kernel.
b. From the down arrow, choose the a custom conda kernel that uses a version of Python that is 3.7 or higher.
   As an example, selecting conda_custom_python310 chooses the kernel for Python 3.10.
c. Choose Select.
d. Wait for the kernel's status to show as idle, which indicates that the kernel has started.
e. In the Jupyter Server Home, select New from the top right menu.
f. Next to the down arrow, select Text file. This creates a new text file called untitled.txt.
g. Rename untitled.txt to requirements.txt and add any dependencies required for the code along with sagemaker.
h. Run your code with the remote decorator by passing the dependencies file as shown below.

```python
from sagemaker.remote_function import remote
@remote(instance_type="ml.m5.xlarge", dependencies='./requirements.txt')
def divide(x, y):
    return x / y
divide(2, 3.0)
```

See the sample notebook quick_start.ipynb for additional code examples.

Run your code from within your local IDE

You can annotate your local ML code with an @remote decorator inside your preferred local IDE. The following steps show the necessary prerequisites, how to install the Python SDK, and how to annotate your code with the @remote decorator.

1. Install prerequisites by setting up the AWS Command Line Interface (AWS CLI) and creating a role, as follows:
   • Onboard to a SageMaker domain following the instructions in the AWS CLI Prerequisites section of Set Up Amazon SageMaker Prerequisites.
   • Create an IAM role following the Create execution role section of SageMaker Roles.
2. Create a virtual environment by using either PyCharm or conda and using Python version 3.7 or higher, up to 3.10.x.
   • Set up a virtual environment using PyCharm as follows:
     a. Select File from the main menu.
     b. Choose New Project.
     c. Choose Conda from the down arrow under New environment using.
     d. In the field for Python version use the down arrow to select a version of Python that is 3.7 or above. You can go up to 3.10.x from the list.
If you have Anaconda installed, you can set up a virtual environment using `conda`, as follows:

1. Open an Anaconda prompt terminal interface.
2. Create and activate a new `conda` environment using a Python version of 3.7 or higher, up to 3.10x. The following code example shows how to create a `conda` environment using Python version 3.10.

   ```bash
   conda create -n sagemaker_jobs_quick_start python=3.10 pip
   conda activate sagemaker_jobs_quick_start
   ```
3. Install the SageMaker Python SDK.

   To package your code from your preferred IDE, you must have a virtual environment set up using Python 3.7 or higher, up to 3.10x. You also need a compatible container image. Install the SageMaker Python SDK using the following code example.

   ```bash
   pip install sagemaker
   ```
4. Wrap your code inside the `@remote` decorator. The SageMaker Python SDK will automatically interpret the function of your code and run it as a SageMaker training job. The following code examples show how to import the necessary libraries, set up a SageMaker session, and annotate a function with the `@remote` decorator.

   You can run your code by either providing the dependencies needed directly, or by using dependencies from the active `conda` environment.
   - To provide the dependencies directly, do the following:
     - Create a `requirements.txt` file in the working directory that the code resides in.
     - Add all of the dependencies required for the code along with the SageMaker library. The following section provides a minimal code example for `requirements.txt` for the example `divide` function.
Run your code with the `@remote` decorator by passing the dependencies file. In the following code example, replace `The IAM role name` with an AWS Identity and Access Management (IAM) role ARN that you would like SageMaker to use to run your job.

```python
import boto3
import sagemaker
from sagemaker.remote_function import remote

sm_session = sagemaker.Session(boto_session=boto3.session.Session(region_name="us-west-2"))
settings = dict(
    sagemaker_session=sm_session,
    role="The IAM role name",
    instance_type="ml.m5.xlarge",
    dependencies='./requirements.txt'
)

@remote(**settings)
def divide(x, y):
    return x / y

if __name__ == '__main__':
    print(divide(2, 3.0))
```

To use dependencies from the active conda environment, use the value `auto_capture` for the `dependencies` parameter, as shown in the following.

```python
import boto3
import sagemaker
from sagemaker.remote_function import remote

sm_session = sagemaker.Session(boto_session=boto3.session.Session(region_name="us-west-2"))
settings = dict(
    sagemaker_session=sm_session,
    role="The IAM role name",
    instance_type="ml.m5.xlarge",
    dependencies="auto_capture"
)

@remote(**settings)
def divide(x, y):
    return x / y

if __name__ == '__main__':
    print(divide(2, 3.0))
```

**Note**
You can also implement the previous code inside a Jupyter notebook. PyCharm Professional Edition supports Jupyter natively. For more guidance, see Jupyter notebook support in PyCharm’s documentation.

**Invoking a function**

To invoke a function inside the `@remote` decorator, use either of the following methods:
• **Use an @remote decorator to invoke a function** (p. 1820).
• **Use the RemoteExecutor API to invoke a function** (p. 1826).

If you use the @remote decorator method to invoke a function, the training job will wait for the function to complete before starting a new task. However, if you use the RemoteExecutor API, you can run more than one job in parallel. The following sections show both ways of invoking a function.

### Use an @remote decorator to invoke a function

You can use the @remote decorator to annotate a function. SageMaker will transform the code inside the decorator into a SageMaker training job. The training job will then invoke the function inside the decorator and wait for the job to complete. The following code example shows how to import the required libraries, start a SageMaker instance, and annotate a matrix multiplication with the @remote decorator.

```python
from sagemaker.remote_function import remote
import numpy as np
@remote(instance_type="ml.m5.large")
def matrix_multiply(a, b):
    return np.matmul(a, b)
a = np.array([[1, 0],
              [0, 1]])
b = np.array([1, 2])
assert (matrix_multiply(a, b) == np.array([1,2])).all()
```

The decorator is defined as follows.

```python
def remote(*, **kwarg):
    ...
```

When you invoke a decorated function, SageMaker Python SDK loads any exceptions raised by an error into local memory. In the following code example, the first call to the divide function completes successfully and the result is loaded into local memory. In the second call to the divide function, the code returns an error and this error is loaded into local memory.

```python
from sagemaker.remote_function import remote
import pytest
@remote()
def divide(a, b):
    return a/b
# the underlying job is completed successfully
# and the function return is loaded
assert divide(10, 5) == 2
# the underlying job fails with "AlgorithmError"
# and the function exception is loaded into local memory
with pytest.raises(ZeroDivisionError):
    divide(10, 0)
```

**Note**
The decorated function is run as a remote job. If the thread is interrupted, the underlying job will not be stopped.
How to change the value of a local variable

The decorator function is run on a remote machine. Changing a non-local variable or input arguments inside a decorated function will not change the local value.

In the following code example, a list and a dict are appended inside the decorator function. This does not change when the decorator function is invoked.

```python
a = []
@remote
def func():
    a.append(1)

# when func is invoked, a in the local memory is not modified
func()
func()

# a stays as []

a = {}
@remote
def func(a):
    # append new values to the input dictionary
    a["key-2"] = "value-2"

a = {"key": "value"}
func(a)

# a stays as {"key": "value"}
```

To change the value of a local variable declared inside of a decorator function, return the variable from the function. The following code example shows that the value of a local variable is changed when it is returned from the function.

```python
a = {"key-1": "value-1"}
@remote
def func(a):
    a["key-2"] = "value-2"
    return a

a = func(a)
-> {"key-1": "value-1", "key-2": "value-2"}
```

Data serialization and deserialization

When you invoke a remote function, SageMaker automatically serializes your function arguments during the input and output stages. Function arguments and returns are serialized using cloudpickle. SageMaker supports serializing the following Python objects and functions.

- Built-in Python objects including dicts, lists, floats, ints, strings, boolean values and tuples
- Numpy arrays
- Pandas Dataframes
- Scikit-learn datasets and estimators
- PyTorch models
- TensorFlow models
- The Booster class for XGBoost
The following can be used with some limitations.

- Dask DataFrames
- The XGBoost Dmatrix class
- TensorFlow datasets and subclasses
- PyTorch models

The following section contains best practices for using the previous Python classes with some limitations in your remote function, information about where SageMaker stores your serialized data and how to manage access to it.

**Best practices for Python classes with limited support for remote data serialization**

You can use the Python classes listed in this section with limitations. The next sections discuss best practices for how to use the following Python classes.

- Dask DataFrames
- The XGBoost DMatrix class
- TensorFlow datasets and subclasses
- PyTorch models

**Best practices for Dask**

Dask is an open-source library used for parallel computing in Python. This section shows the following.

- How to pass a Dask DataFrame into your remote function
- How to convert summary statistics from a Dask DataFrame into a Pandas DataFrame

**How to pass a Dask DataFrame into your remote function**

Dask DataFrames are often used to process large datasets because they can hold datasets that require more memory than is available. This is because a Dask DataFrame does not load your local data into memory. If you pass a Dask DataFrame as a function argument to your remote function, Dask may pass a reference to the data in your local disk or cloud storage, instead of the data itself. The following code shows an example of passing a Dask DataFrame inside your remote function that will operate on an empty DataFrame.

```python
# Do not pass a Dask DataFrame to your remote function as follows
def clean(df: dask.DataFrame):
    cleaned = df[] ...
```

Dask will load the data from the Dask DataFrame into memory only when you use the DataFrame. If you want to use a Dask DataFrame inside a remote function, provide the path to the data. Then Dask will read the dataset directly from the data path that you specify when the code runs.

The following code example shows how to use a Dask DataFrame inside the remote function clean. In the code example, `raw_data_path` is passed to clean instead of the Dask DataFrame. When the code runs, the dataset is read directly from the location of an Amazon S3 bucket specified in `raw_data_path`. Then the persist function keeps the dataset in memory to facilitate the subsequent random_split function and written back to the output data path in an S3 bucket using Dask DataFrame API functions.

```python
import dask.dataframe as dd
@remote(
```
# Invoking a function

```python
instance_type='ml.m5.24xlarge',
volume_size=300,
keep_alive_period_in_seconds=600)
# pass the data path to your remote function rather than the Dask DataFrame itself
def clean(raw_data_path: str, output_data_path: str: split_ratio: list[float]):
    df = dd.read_parquet(raw_data_path) # pass the path to your DataFrame
    cleaned = df[(df.column_a >= 1) & (df.column_a < 5)]
    .drop(['column_b', 'column_c'], axis=1)
    .persist() # keep the data in memory to facilitate the following random_split operation
    train_df, test_df = cleaned.random_split(split_ratio, random_state=10)
    train_df.to_parquet(os.path.join(output_data_path, 'train'))
    test_df.to_parquet(os.path.join(output_data_path, 'test'))
clean("s3://my-bucket/raw/", "s3://my-bucket/cleaned/", split_ratio=[0.7, 0.3])
```

## How to convert summary statistics from a Dask DataFrame into a Pandas DataFrame

Summary statistics from a Dask DataFrame can be converted into a Pandas DataFrame by invoking the `compute` method as shown in the following example code. In the example, the S3 bucket contains a large Dask DataFrame that cannot fit into memory or into a Pandas data frame. In the following example, a remote function scans the data set and returns a Dask DataFrame containing the output statistics from `describe` to a Pandas DataFrame.

```python
executor = RemoteExecutor(
    instance_type='ml.m5.24xlarge',
    volume_size=300,
    keep_alive_period_in_seconds=600)

future = executor.submit(lambda: dd.read_parquet("s3://my-bucket/raw/").describe().compute())
future.result()
```

## Best practices for the XGBoost DMatrix class

DMatrix is an internal data structure used by XGBoost to load data. A DMatrix object can’t be pickled in order to move easily between compute sessions. Directly passing DMatrix instances will fail with a `SerializationError`.

## How to pass a data object to your remote function and train with XGBoost

To convert a Pandas DataFrame into a DMatrix instance and use it for training in your remote function, pass it directly to the remote function as shown in the following code example.

```python
import xgboost as xgb
@remote
def train(df, params):
    # Convert a pandas dataframe into a DMatrix DataFrame and use it for training
    dtrain = DMatrix(df)
    return xgb.train(dtrain, params)
```

## Best practices for TensorFlow datasets and subclasses

TensorFlow datasets and subclasses are internal objects used by TensorFlow to load data during training. TensorFlow datasets and subclasses can’t be pickled in order to move easily between compute sessions.
Directly passing Tensorflow datasets or subclasses will fail with a SerializationError. Use the Tensorflow I/O APIs to load data from the storage, as shown in the following code example.

```python
import tensorflow as tf
import tensorflow_io as tfio

@remote
def train(data_path: str, params):
    dataset = tf.data.TextLineDataset(tf.data.Dataset.list_files(data_path + '*.txt'))
    ...
train("s3://my-bucket/data", {})
```

**Best practices for PyTorch models**

PyTorch models are serializable and can be passed between your local environment and remote function. If your local environment and remote environment have different device types, such as (GPUs and CPUs), you cannot return a trained model to your local environment. For example, if the following code is developed in a local environment without GPUs but run in an instance with GPUs, returning the trained model directly will lead to a DeserializationError.

```python
# Do not return a model trained on GPUs to a CPU-only environment as follows
@remote(instance_type='ml.g4dn.xlarge')
def train(...):
    if torch.cuda.is_available():
        device = torch.device("cuda")
    else:
        device = torch.device("cpu") # a device without GPU capabilities

    model = Net().to(device)
    # train the model
    ...
    return model
model = train(...) #returns a DeserializationError if run on a device with GPU
```

To return a model trained in a GPU environment to one that contains only CPU capabilities, use the PyTorch model I/O APIs directly as shown in the code example below.

```python
import s3fs

model_path = "s3://my-bucket/folder/"

@remote(instance_type='ml.g4dn.xlarge')
def train(...):
    if torch.cuda.is_available():
        device = torch.device("cuda")
    else:
        device = torch.device("cpu")

    model = Net().to(device)
    # train the model
    ...
    return model

fs = s3fs.FileSystem()
with fs.open(os.path.join(model_path, 'model.pt'), 'wb') as file:
    # ...
torch.save(model.state_dict(), file) # this writes the model in a device-agnostic way (CPU vs GPU)

train(...) # use the model to train on either CPUs or GPUs

model = Net()
fs = s3fs.FileSystem()
with fs.open(os.path.join(model_path, 'model.pt'), 'rb') as file:
    model.load_state_dict(torch.load(file, map_location=torch.device('cpu')))

---

**Where SageMaker stores your serialized data**

When you invoke a remote function, SageMaker automatically serializes your function arguments and return values during the input and output stages. This serialized data is stored under a root directory in your S3 bucket. You specify the root directory, `<s3_root_uri>`, in a configuration file. The parameter `job_name` is automatically generated for you.

Under the root directory, SageMaker creates a `<job_name>` folder, which holds your current work directory, serialized function, the arguments for your serialized function, results and any exceptions that arose from invoking the serialized function.

Under `<job_name>`, the directory `workdir` contains a zipped archive of your current working directory. The zipped archive includes any Python files in your working directory and the `requirements.txt` file, which specifies any dependencies needed to run your remote function.

The following is an example of the folder structure under an S3 bucket that you specify in your configuration file.

```plaintext
<s3_root_uri>/ # specified by s3_root_uri or S3RootUri
   <job_name>/ # automatically generated for you
      workdir/ # archive of the current working directory (workdir)
      function/ # serialized function
      arguments/ # serialized function arguments
      results/ # returned output from the serialized function including the model
      exception/ # any exceptions from invoking the serialized function
```

The root directory that you specify in your S3 bucket is not meant for long term storage. The serialized data are tightly tied to the Python version and machine learning (ML) framework version that were used during serialization. If you upgrade the Python version or ML framework, you may not be able to use your serialized data. Instead, do the following.

- Store your model and model artifacts in a format that is agnostic to your Python version and ML framework.
- If you upgrade your Python or ML framework, access your model results from your long-term storage.

**Important**

To delete your serialized data after a specified amount of time, set a [lifetime configuration](https://docs.aws.amazon.com/sagemaker/latest/dg/config-file-parameters-reference.html#sagemaker-lifetime-configuration) on your S3 bucket.

**Note**

Files that are serialized with the Python pickle module can be less portable than other data formats including CSV, Parquet and JSON. Be wary of loading pickled files from unknown sources.

For more information about what to include in a configuration file for a remote function, see [Configuration File](https://docs.aws.amazon.com/sagemaker/latest/dg/config-file-parameters-reference.html#sagemaker-configuration-file).

**Access to your serialized data**

Administrators can provide settings for your serialized data, including its location and any encryption settings in a configuration file. By default, the serialized data are encrypted with an AWS Key...
Management Service (AWS KMS) Key. Administrators can also restrict access to the root directory that you specify in your configuration file with a bucket policy. The configuration file can be shared and used across projects and jobs. For more information, see Configuration File.

Use the RemoteExecutor API to invoke a function

You can use the RemoteExecutor API to invoke a function. SageMaker Python SDK will transform the code inside the RemoteExecutor call into a SageMaker training job. The training job will then invoke the function as an asynchronous operation and return a future. If you use the RemoteExecutor API, you can run more than one training job in parallel. For more information about futures in Python, see Futures.

The following code example shows how to import the required libraries, define a function, start a SageMaker instance, and use the API to submit a request to run 2 jobs in parallel.

```python
from sagemaker.remote_function import RemoteExecutor
def matrix_multiply(a, b):
    return np.matmul(a, b)

a = np.array([[1, 0],
              [0, 1]])
b = np.array([1, 2])

with RemoteExecutor(max_parallel_job=2, instance_type="ml.m5.large") as e:
    future = e.submit(matrix_multiply, a, b)

assert (future.result() == np.array([1, 2])).all()
```

The RemoteExecutor class is an implementation of the concurrent.futures.Executor library.

The following code example shows how to define a function and call it using the RemoteExecutor API. In this example, the RemoteExecutor will submit 4 jobs in total, but only 2 in parallel. The last two jobs will reuse the clusters with minimal overhead.

```python
from sagemaker.remote_function.client import RemoteExecutor
def divide(a, b):
    return a/b

with RemoteExecutor(max_parallel_job=2, keep_alive_period_in_seconds=60) as e:
    futures = [e.submit(divide, a, 2) for a in [3, 5, 7, 9]]

for future in futures:
    print(future.result())
```

The max_parallel_job parameter only serves as a rate limiting mechanism without optimizing compute resource allocation. In the previous code example, RemoteExecutor doesn't reserve compute resources for the two parallel jobs before any jobs are submitted. For more information about max_parallel_job or other parameters for the @remote decorator, see Remote function classes and methods specification.

Future class for the RemoteExecutor API

A future class is a public class that represents the return function from the training job when it is invoked asynchronously. The future class implements the concurrent.futures.Future class. This class can be used to do operations on the underlying job and load data into memory.
**Configuration file**

The Amazon SageMaker Python SDK supports setting of default values for AWS infrastructure primitive types. After administrators configure these defaults, they are automatically passed when SageMaker Python SDK calls supported APIs. The arguments for the decorator function can be put inside of configuration files. This is so that you can separate settings that are related to the infrastructure from the code base. For more information about parameters and arguments for the remote function and methods, see [Remote function classes and methods specification](#).

You can set infrastructure settings for the network configuration, IAM roles, Amazon S3 folder for input, output data, and tags inside the configuration file. The configuration file can be used when invoking a function using either the @remote decorator or the RemoteExecutor API.

An example configuration file that defines the dependencies, resources, and other arguments follows. This example configuration file is used to invoke a function that is initiated either using the @remote decorator or the RemoteExecutor API.

```
SchemaVersion: '1.0'
SageMaker:
  PythonSDK:
    Modules:
      RemoteFunction:
        Dependencies: 'path/to/requirements.txt'
        EnableInterContainerTrafficEncryption: true
        EnvironmentVariables: {'EnvVarKey': 'EnvVarValue'}
        ImageUri: '366666666666.dkr.ecr.us-west-2.amazonaws.com/my-image:latest'
        IncludeLocalWorkDir: true
        InstanceType: 'ml.m5.large'
        JobCondaEnvironment: 'your_conda_env'
        PreExecutionCommands:
          - 'command_1'
          - 'command_2'
        PreExecutionScript: 'path/to/script.sh'
        RoleArn: 'arn:aws:iam::366666666666:role/MyRole'
        S3KmsKeyId: 'yourkmskeyid'
        S3RootUri: 's3://my-bucket/my-project'
        VpcConfig:
          SecurityGroupIds:
            - 'sg123'
          Subnets:
            - 'subnet-1234'
          Tags: [{"Key": 'yourTagKey', 'Value':'yourTagValue'}]
        VolumeKmsKeyId: 'yourkmskeyid'
```

The @remote decorator and RemoteExecutor will look for Dependencies in the following configuration files:

- An admin-defined configuration file.
- A user-defined configuration file.

The default locations for these configuration files depend on, and are relative to, your environment. The following code example returns the default location of your admin and user configuration files. These commands must be run in the same environment where you're using the SageMaker Python SDK.

```python
import os
from platformdirs import site_config_dir, user_config_dir

#Prints the location of the admin config file
```
You can override the default locations of these files by setting the `SAGEMAKER_ADMIN_CONFIG_OVERRIDE` and `SAGEMAKER_USER_CONFIG_OVERRIDE` environment variables for the admin-defined and user-defined configuration file paths, respectively.

If a key exists in both the admin-defined and user-defined configuration files, the value in the user-defined file will be used.

## Customize your runtime environment

You can customize your runtime environment to use your preferred local integrated development environments (IDEs), SageMaker notebooks, or SageMaker Studio notebooks to write your ML code. SageMaker will help package and submit your functions and its dependencies as a SageMaker training job. This allows you to access the capacity of the SageMaker training server to run your training jobs.

Both the remote decorator and the `RemoteExecutor` methods to invoke a function allow users to define and customize their runtime environment. You can use either a `requirements.txt` file or a conda environment YAML file.

To customize a runtime environment using both a conda environment YAML file and a `requirements.txt` file, refer to the following code example:

```python
# specify a conda environment inside a yaml file
@remote(instance_type="ml.m5.large",
    image_uri = "my_base_python:latest",
    dependencies = "/environment.yml")
def matrix_multiply(a, b):
    return np.matmul(a, b)

# use a requirements.txt file to import dependencies
@remote(instance_type="ml.m5.large",
    image_uri = "my_base_python:latest",
    dependencies = "/requirements.txt")
def matrix_multiply(a, b):
    return np.matmul(a, b)
```

Alternatively, you can set dependencies to `auto_capture` to let the SageMaker Python SDK capture the installed dependencies in the active conda environment. The following are required for `auto_capture` to work reliably:

- You must have an active conda environment. We recommend not using the base conda environment for remote jobs so that you can reduce potential dependency conflicts. Not using the base conda environment also allows for faster environment setup in the remote job.
- You must not have any dependencies installed using pip with a value for the parameter `--extra-index-url`.
- You must not have any dependency conflicts between packages installed with conda and packages installed with pip in the local development environment.
- Your local development environment must not contain operating system-specific dependencies that are not compatible with Linux.

In case `auto_capture` does not work, we recommend that you pass in your dependencies as a `requirements.txt` or conda environment YAML file, as described in the first coding example in this section.
## Container image compatibility

The following table shows a list of SageMaker training images that are compatible with the @remote decorator.

<table>
<thead>
<tr>
<th>Name</th>
<th>Python Version</th>
<th>Image URI - CPU</th>
<th>Image URI - GPU</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data Science</td>
<td>3.7(py37)</td>
<td>For SageMaker Studio Notebooks only. Python SDK automatically selects the image URI when used as SageMaker Studio Notebook kernel image.</td>

</tbody>
</table>

**Note**

To run jobs locally using AWS Deep Learning Containers (DLC) images, use the image URIs found in the [DLC documentation](#). The DLC images do not support the `auto_capture` value for dependencies.

You can also run remote functions with your custom images. For compatibility with remote functions, custom images should be built with Python version 3.7.x-3.10.x. The following is a minimal Dockerfile example showing you how to use a Docker image with Python 3.10.

FROM python:3.10

#... Rest of the Dockerfile

To create conda environments in your image and use it to run jobs, set the environment variable `SAGEMAKER_JOB_CONDA_ENV` to the conda environment name. If your image has the `SAGEMAKER_JOB_CONDA_ENV` value set, the remote function cannot create a new conda environment during the training job runtime. Refer to the following Dockerfile example that uses a conda environment with Python version 3.10.

FROM continuumio/miniconda3:4.12.0

ENV SHELL=/bin/bash
ENV CONDA_DIR=/opt/conda
ENV SAGEMAKER_JOB_CONDA_ENV=sagemaker-job-env

RUN conda create -n $SAGEMAKER_JOB_CONDA_ENV && conda install -n $SAGEMAKER_JOB_CONDA_ENV python=3.10 -y && conda clean --all -f -y

For SageMaker to use `mamba` to manage your Python virtual environment in the container image, install the [mamba toolkit from miniforge](#). To use mamba, add the following code example to your Dockerfile. Then, SageMaker will detect the mamba availability at runtime and use it instead of conda.

#Mamba Installation

RUN curl -L -O "https://github.com/conda-forge/miniforge/releases/latest/download/Mambaforge-Linux-x86_64.sh" && bash Mambaforge-Linux-x86_64.sh -b -p "/opt/conda" && /opt/conda/bin/conda init bash

Using a custom conda channel on an Amazon S3 bucket is not compatible with mamba when using a remote function. If you choose to use mamba, make sure you are not using a custom conda channel on Amazon S3. For more information, see the [Prerequisites](#) section under Custom conda repository using Amazon S3.

The following is a complete Dockerfile example showing how to create a compatible Docker image.

FROM python:3.10
Logging parameters and metrics with Amazon SageMaker Experiments

This guide shows how to log parameters and metrics with Amazon SageMaker Experiments. A SageMaker experiment consists of runs, and each run consists of all the inputs, parameters, configurations and results for a single model training interaction.

You can log parameters and metrics from a remote function using either the @remote decorator or the RemoteExecutor API.

To log parameters and metrics from a remote function, choose one of the following methods:

- Instantiate a SageMaker experiment run inside a remote function using Run from the SageMaker Experiments library. For more information, see Create an Amazon SageMaker Experiment.
- Use the load_run function inside a remote function from the SageMaker Experiments library. This will load a Run instance that is declared outside of the remote function.

The following sections show how to create and track lineage with SageMaker experiment runs by using the previous listed methods. The sections also describe cases that are not supported by SageMaker training.

Use the @remote decorator to integrate with SageMaker Experiments

You can either instantiate an experiment in SageMaker, or load a current SageMaker experiment from inside a remote function. The following sections show you how to use either method.
Create an experiment with SageMaker Experiments

You can create an experiment run in SageMaker experiment. To do this you pass your experiment name, run name, and other parameters into your remote function.

The following code example imports the name of your experiment, the name of the run, and the parameters to log during each run. The parameters param_1 and param_2 are logged over time inside a training loop. Common parameters may include batch size or epochs. In this example, the metrics metric_a and metric_b are logged for a run over time inside a training loop. Other common metrics may include accuracy or loss.

```python
from sagemaker.remote_function import remote
from sagemaker.experiments.run import Run

# Define your remote function
@remote
def train(value_1, value_2, exp_name, run_name):
    ...
    # Creates the experiment
    with Run(
        experiment_name=exp_name,
        run_name=run_name,
    ) as run:
        ...
    # Define values for the parameters to log
    run.log_parameter("param_1", value_1)
    run.log_parameter("param_2", value_2)
    ...
    # Define metrics to log
    run.log_metric("metric_a", 0.5)
    run.log_metric("metric_b", 0.1)

#Invoke your remote function
train(1.0, 2.0, "my-exp-name", "my-run-name")
```

Load current SageMaker Experiments with a job initiated by the @remote decorator

Use the load_run() function from the SageMaker Experiments library to load the current run object from the run context. You can also use the load_run() function within your remote function. Load the run object initialized locally by the with statement on the run object as shown in the following code example.

```python
from sagemaker.experiments.run import Run, load_run

# Define your remote function
@remote
def train(value_1, value_2):
    ...
    ...
    with load_run() as run:
        run.log_metric("metric_a", value_1)
        run.log_metric("metric_b", value_2)

# Invoke your remote function
with Run(
    experiment_name="my-exp-name",
    run_name="my-run-name",
) as run:
    run.log_metric("metric_a", 0.5)
    run.log_metric("metric_b", 0.1)
```
Load a current experiment run within a job initiated with the RemoteExecutor API

You can also load a current SageMaker experiment run if your jobs were initiated with the RemoteExecutor API. The following code example shows how to use RemoteExecutor API with the SageMaker Experiments load_run function. You do this to load a current SageMaker experiment run and capture metrics in the job submitted by RemoteExecutor.

```python
from sagemaker.experiments.run import Run, load_run

def square(x):
    with load_run() as run:
        result = x * x
        run.log_metric("result", result)
    return result

with RemoteExecutor(
    max_parallel_job=2,
    instance_type="ml.m5.large"
) as e:
    with Run(
        experiment_name="my-exp-name",
        run_name="my-run-name",
    ) as run:
        future_1 = e.submit(square, 2)
```

Unsupported uses for SageMaker Experiments while annotating your code with an @remote decorator

SageMaker does not support passing a Run type object to an @remote function or using global Run objects. The following examples show code that will throw a SerializationError.

The following code example attempts to pass a Run type object to an @remote decorator, and it generates an error.

```python
@remote
def func(run: Run):
    run.log_metrics("metric_a", 1.0)

with Run(...) as run:
    func(run) ---> SerializationError caused by NotImplementedError
```

The following code example attempts to use a global run object instantiated outside of the remote function. In the code example, the train() function is defined inside the with Run context, referencing a global run object from within. When train() is called, it generates an error.

```python
with Run(...) as run:
    @remote
def train(metric_1, value_1, metric_2, value_2):
    run.log_parameter(metric_1, value_1)
    run.log_parameter(metric_2, value_2)
```
train("p1", 1.0, "p2", 0.5) ---> SerializationError caused by NotImplementedException

Using modular code with the @remote decorator

You can organize your code into modules for ease of workspace management during development and still use the @remote function to invoke a function. You can also replicate the local modules from your development environment to the remote job environment. To do so, set the parameter include_local_workdir to True, as shown in the following code example.

```python
@remote(
    include_local_workdir=True,
)
```

**Note**
The @remote decorator and parameter must appear in the main file, rather than in any of the dependent files.

When include_local_workdir is set to True, SageMaker will package all of the Python scripts while maintaining the directory structure in the process's current directory. It will also make the dependencies available in the job's working directory.

As an example, consider the following scenario where a Python script to process the MNIST dataset is divided into a main.py script and a dependent pytorch_mnist.py script. Then, the dependent scripts is called by main.py. In this scenario, the main.py script contains code to import the dependency, as follows.

```python
from mnist_impl.pytorch_mnist import...
```

The main.py file must also contain the @remote decorator, and it must set the include_local_workdir parameter to True.

**Best practices in structuring your working directory**

We recommend the following best practices while using the @remote decorator in your modular code.

- Put the @remote decorator in a file that resides at the root level directory of the workspace.
- Structure the local modules at the root level.

The following example image shows the recommended directory structure. In this example structure, the main.py script is located at the root level directory.

```bash
.
### config.yaml
### data/
### main.py <----------------- @remote used here
### mnist_impl
# ### __pycache__/
# # ### pytorch_mnist.cpython-310.pyc
# ### pytorch_mnist.py <-------- dependency of main.py
### requirements.txt
```

The following example image shows a directory structure that will result in inconsistent behavior when it is used to annotate your code with an @remote decorator.
Private repository for runtime dependencies

You can use pre-execution commands or script to configure a dependency manager like pip or conda in your job environment. To achieve network isolation, use either of these options to redirect your dependency managers to access your private repositories and run remote functions within a VPC. The pre-execution commands or script will run before your remote function runs. You can define them with the @remote decorator, the RemoteExecutor API, or within a configuration file.

The following sections show you how to access a private Python Package Index (PyPI) repository managed with AWS CodeArtifact. The sections also show how to access a custom conda channel hosted on Amazon Simple Storage Service (Amazon S3).

How to use a custom PyPI repository managed with AWS CodeArtifact

To use CodeArtifact to manage a custom PyPI repository, the following prerequisites are required:

- Your private PyPI repository should already have been created. You can utilize AWS CodeArtifact to create and manage your private package repositories. To learn more about CodeArtifact, see the CodeArtifact User Guide.
- Your VPC should have access to your CodeArtifact repository. To allow a connection from your VPC to your CodeArtifact repository, you must do the following:
  - Create VPC endpoints for CodeArtifact.
  - Create an Amazon S3 gateway endpoint for your VPC, which allows CodeArtifact to store package assets.

The following pre-execution command example shows how to configure pip in the SageMaker training job to point to your CodeArtifact repository. For more information, see Configure and use pip with CodeArtifact.
def matrix_multiply(a, b):
    return np.matmul(a, b)

How to use a custom conda channel hosted on Amazon S3

To use Amazon S3 to manage a custom conda repository, the following prerequisites are required:

• Your private conda channel must already be set up in your Amazon S3 bucket, and all dependent packages must be indexed and uploaded to your Amazon S3 bucket. For instructions on how to index your conda packages, see Creating custom channels.

• Your VPC should have access to the Amazon S3 bucket. For more information, see Endpoints for Amazon S3.

• The base conda environment in your job image should have boto3 installed. To check your environment, enter the following in your Anaconda prompt to check that boto3 appears in the resulting generated list.

  conda list -n base

• You job image should be installed with conda, not mamba. To check your environment, ensure that the previous code prompt does not return mamba.

The following pre-execution commands example shows how to configure conda in the SageMaker training job to point to your private channel on Amazon S3. The pre-execution commands removes the defaults channel and adds custom channels to a .condarc conda configuration file.

```python
# specify your dependencies inside a conda yaml file
@remote(
    instance_type="ml.m5.large",
    image_uri = "my_base_python:latest",
    dependencies = "/environment.yml",
    pre_execution_commands=
    ["conda config --remove channels 'defaults'",
     "conda config --add channels 's3://my_bucket/my-conda-repository/conda-forge/'",
     "conda config --add channels 's3://my_bucket/my-conda-repository/main/"
    ]
)
def matrix_multiply(a, b):
    return np.matmul(a, b)
```

Example notebooks

You can transform a training code in an existing workspace environment and any associated data processing code and datasets into a SageMaker training job. The following notebooks show you how to customize your environment, job settings, and more for an image classification problem, using the XGBoost algorithm and Hugging Face.

The quick_start notebook contains the following code examples:

• How to customize your job settings with a configuration file.
• How to invoke Python functions as jobs, asynchronously.
• How to customize the job runtime environment by bringing in additional dependencies.
• How to use local dependencies with the @remote function method.

The following notebooks provide additional code examples for different ML problems types and implementations.
To see code examples to use the @remote decorator for an image classification problem, open the `pytorch_mnist.ipynb` notebook. This classification problem recognizes handwritten digits using the Modified National Institute of Standards and Technology (MNIST) sample dataset.

To see code examples for using the @remote decorator for the previous image classification problem with a script, see the Pytorch MNIST sample script, `train.py`.

To see how the XGBoost algorithm implemented with an @remote decorator: Open the `xgboost_abalone.ipynb` notebook.

To see how Hugging Face is integrated with an @remote decorator: Open the `huggingface.ipynb` notebook.

### Manage Machine Learning with Amazon SageMaker Experiments

Amazon SageMaker Experiments is a capability of Amazon SageMaker that lets you create, manage, analyze, and compare your machine learning experiments.

#### Experimentation in machine learning

Machine learning is an iterative process. You need to experiment with multiple combinations of data, algorithms, and parameters, all while observing the impact of incremental changes on model accuracy. Over time, this iterative experimentation can result in thousands of model training runs and model versions. This makes it hard to track the best performing models and their input configurations. It's also difficult to compare active experiments with past experiments to identify opportunities for further incremental improvements. Use SageMaker Experiments to organize, view, analyze, and compare iterative ML experimentation to gain comparative insights and track your best performing models.

#### Manage ML experimentation with SageMaker Experiments

SageMaker Experiments automatically tracks the inputs, parameters, configurations, and results of your iterations as **runs**. You can assign, group, and organize these runs into **experiments**. SageMaker Experiments is integrated with Amazon SageMaker Studio, providing a visual interface to browse your active and past experiments, compare runs on key performance metrics, and identify the best performing models. SageMaker Experiments tracks all of the steps and artifacts that went into creating a model, and you can quickly revisit the origins of a model when you are troubleshooting issues in production, or auditing your models for compliance verifications.

Use SageMaker Experiments to view, manage, analyze, and compare both custom experiments that you programmatically create and experiments automatically created from SageMaker jobs.

### Supported AWS Regions

SageMaker Experiments is generally available in all AWS commercial **Regions** where Amazon SageMaker Studio is available, except the China Regions.

Create an Amazon SageMaker Experiment

Create an Amazon SageMaker experiment to track your machine learning (ML) workflows with a few lines of code from your preferred development environment. You can then browse your experiments, create visualizations for analysis, and find the best performing model. You can also integrate SageMaker Experiments into your SageMaker training script using the SageMaker Python SDK.

Overview

The following components make up the building blocks of an experiment in Amazon SageMaker.

- **experiment**: An experiment is a collection of runs. When you initialize a run in your training loop, you include the name of the experiment that the run belongs to. Experiment names must be unique within your AWS account.

- **Run**: A run consists of all the inputs, parameters, configurations, and results for one interaction of model training. Initialize an experiment run for tracking a training job with `Run.init()`.

  **Note**
  We recommend that you initialize a `Run` object in a Jupyter Notebook, and create the SageMaker job for your experiment within the context of this Run object initialization. To refer to this Run object in script mode, use the `load_run()` method. For examples, see Example notebooks for Amazon SageMaker Experiments (p. 1849).

  **Note**
  The SageMaker Python SDK automatically turns experiment names and run names to lowercase.

- **load_run**: To run your experiments in script mode, refer to an initialized Run object with `load_run()`. If an experiment for a run exists, `load_run` returns the experiment context. Generally, you use `load_run` with no arguments to track metrics, parameters, and artifacts within a SageMaker training or processing job script.

```python
# Load run from a local script passing experiment and run names
with load_run(experiment_name=experiment_name, run_name=run_name) as run:
    run.log_parameter("param1", "value1")
```

```python
# Load run within a training or processing Job (automated context sharing)
with load_run() as run:
    run.log_parameter("param1", "value1")
```

- **log_parameter**: Log parameters for a run, such as batch size or epochs, over time in a training loop with `run.log_parameter()`. `log_parameter` records a single name-value pair in a run. You can use `run.log_parameters()` to log multiple parameters. If called multiple times within a run for a parameter of the same name, `log_parameter` overwrites any previous value. The name must be a string and the value must be either a string, integer, or float.

```python
# Log a single parameter
run.log_parameter("param1", "value1")
```

```python
# Log multiple parameters
run.log_parameters({
    "param2": "value2",
    "param3": "value3"
})
```
• **log_metric**: Log metrics for a run, such as accuracy or loss, over time in a training loop with `run.log_metric()`. `log_metric` records a name-value pair where the name is a string and the value is an integer or float. To declare the frequency of logging over the course of the run, define a step value. You can then visualize these metrics in the Studio Experiments UI. For more information, see View, search, and compare experiment runs (p. 1843).

```python
# Log a metric over the course of a run
run.log_metric(name="Final_loss", value=finalloss)
```

```python
# Log a metric over the course of a run at each epoch
run.log_metric(name="test:loss", value=loss, step=epoch)
```

• **log_artifact**: Log any input or output artifacts related to a run with `run.log_artifact()`. Log artifacts such as S3 URIs, datasets, models, and more for your experiment to help you keep track of artifacts across multiple runs. `is_output` is True by default. To record the artifact as an input artifact instead of an output artifact, set `is_output` to False.

```python
# Track a string value as an input or output artifact
run.log_artifact(name="training_data", value="data.csv", is_output=False)
```

• **log_file**: Log any input or output files related to a run, such as training or test data, and store them in Amazon S3 with `run.log_file()`. `is_output` is True by default. To record the file as an input artifact instead of an output artifact, set `is_output` to False.

```python
# Upload a local file to S3 and track it as an input or output artifact
run.log_file("training_data.csv", name="training_data", is_output=False)
```

For more information on initializing a Run object, see Experiments in the SageMaker Python SDK documentation. For information on visualizing logged experiment data and automatic logging, see View, search, and compare experiment runs (p. 1843).

### Create an experiment with the SageMaker Python SDK

The following section demonstrates how to create an Amazon SageMaker Experiment using the SageMaker Python SDK. This example uses the Run class to track a Keras model in a notebook environment. The Keras Callback class provides a method on_epoch_end which emits metrics at the end of each epoch. First, define a Callback class.

```python
class ExperimentCallback(keras.callbacks.Callback):
    '''
    
    def __init__(self, run, model, x_test, y_test):
        '''Save params in constructor'''
        self.run = run
        self.model = model
        self.x_test = x_test
        self.y_test = y_test

    def on_epoch_end(self, epoch, logs=None):
        '''
        
        keys = list(logs.keys())
        for key in keys:
            run.log_metric(name=key, value=logs[key], step=epoch)
            print("Epoch: {}\n{} -> {}\n".format(epoch, key, logs[key]))
```

Next, train the Keras model in a notebook environment and track it as an experiment.
Note
This example carries out jobs sequentially. To run SageMaker jobs asynchronously, you may need to increase your resource limit.

```python
from sagemaker.experiments import Run

# The run name is an optional argument to `run.init()`
with Run(experiment_name = 'my-experiment') as run:

    # Define values for the parameters to log
    run.log_parameter("batch_size", batch_size)
    run.log_parameter("epochs", epochs)
    run.log_parameter("dropout", 0.5)

    # Define input artifacts
    run.log_file('datasets/input_train.npy', is_output = False)
    run.log_file('datasets/input_test.npy', is_output = False)
    run.log_file('datasets/input_train_labels.npy', is_output = False)
    run.log_file('datasets/input_test_labels.npy', is_output = False)

    # Train locally
    model.fit(
        x_train,
        y_train,
        batch_size=batch_size,
        epochs=epochs,
        validation_split=0.1,
        callbacks = [ExperimentCallback(run, model, x_test, y_test)]
    )

    score = model.evaluate(x_test, y_test, verbose=0)
    print("Test loss: ", score[0])
    print("Test accuracy: ", score[1])

    # Define metrics to log
    run.log_metric(name = "Final Test Loss", value = score[0])
    run.log_metric(name = "Final Test Accuracy", value = score[1])
```

For more code samples and example notebooks, see Example notebooks for Amazon SageMaker Experiments (p. 1849).

Create an experiment using SageMaker script mode

You can use SageMaker script mode to write your own code to train a model and track it as an experiment. When creating an experiment with script mode, use `load_run()`.

```python
# Make sure that you have the latest version of the SageMaker Python SDK
import os
os.system("pip install -U sagemaker")

# Import additional requirements
import boto3
from sagemaker.session import Session
from sagemaker.experiments.run import load_run

# Define training script
if __name__ == "__main__":
    session = Session(boto3.session.Session(region_name=arg.region))
    with load_run(sagemaker_session=session) as run:
        # Define values for the parameters to log
        run.log_parameters({
            "batch_size": batch_size,
            "epochs": epochs,
```

1841
"dropout": 0.5
}
# Define input artifacts
run.log_file('datasets/input_train.npy', is_output = False)
run.log_file('datasets/input_test.npy', is_output = False)
run.log_file('datasets/input_train_labels.npy', is_output = False)
run.log_file('datasets/input_test_labels.npy', is_output = False)

# Train the model
model.fit(x_train, y_train, batch_size=batch_size, epochs=epochs, validation_split=0.1, callbacks = [ExperimentCallback(run, model, x_test, y_test)])

score = model.evaluate(x_test, y_test, verbose=0)
print("Test loss:", score[0])
print("Test accuracy:", score[1])

# Define metrics to log
run.log_metric(name = "Final Test Loss", value = score[0])
run.log_metric(name = "Final Test Accuracy", value = score[1])

For more code samples and example notebooks on using Amazon SageMaker Experiments in SageMaker script mode, see [Track experiments for SageMaker training jobs using script mode](p. 1850).

For more information on script mode, see [Use script mode in a supported framework](p. 1842). You can also define custom metrics in script mode by specifying a name and regular expression for each metric that a tuning job monitors. See [Use a custom algorithm for training](p. 1842) for more information.

**View your experiment in Studio**

To view the experiment in Studio, in the left sidebar, choose **Experiments**.

Select the name of the experiment to view all associated runs. It might take a moment for the list to refresh and display a new experiment or experiment run. You can click **Refresh** to update the page. Your experiment list should look similar to the following:

![View experiment in Studio](image)

To view the runs that make up your experiment, select the experiment name. For more information, see [View, search, and compare experiment runs](p. 1843).
View unassigned runs

All SageMaker jobs, including training jobs, processing jobs, and transform jobs, correspond to runs and create Run objects by default. If you launch these jobs without explicitly associating them with an experiment, the resulting runs are unassigned and can be viewed in the Unassigned runs section of the Studio Experiments UI.

To clean up the resources you created, see Clean Up Amazon SageMaker Experiment Resources (p. 1851).

View, search, and compare experiment runs

An Amazon SageMaker experiment consists of multiple run groups with a related objective. A run group consists of one or more runs, such as a data preprocessing job and a training job.

You use the experiments browser to display a list of these entities. You can filter the list by entity name, type, and tags. For an overview of the Studio user interface, see Amazon SageMaker Studio UI Overview (p. 205).

Topics

- View experiments and runs (p. 1843)
- Compare and analyze runs (p. 1845)

View experiments and runs

Amazon SageMaker Studio provides an experiments browser that you can use to view lists of experiments and runs. You can choose one of these entities to view detailed information about the entity or choose multiple entities for comparison.

To view experiments and runs

1. To view the experiment in Studio, in the left sidebar, choose Experiments.

   Select the name of the experiment to view all associated runs. You can search experiments by typing directly into the Search bar or filtering for experiment type. You can also choose which columns to display in your experiment or run list.

   It might take a moment for the list to refresh and display a new experiment or experiment run. You can click Refresh to update the page. Your experiment list should look similar to the following:
2. In the experiments list, double-click an experiment to display a list of the runs in the experiment.

   **Note**
   
   Experiment runs that are automatically created by SageMaker jobs and containers are visible in the Experiments Studio UI by default. To hide runs created by SageMaker jobs for a given experiment, choose the settings icon (⚙️) and toggle **Show jobs**.

3. Double-click a run to display information about a specific run.

   In the **Overview** pane, choose any of the following headings to see available information about each run:
   
   - **Metrics** – Metrics that are logged during a run.
   - **Charts** – Build your own charts to compare runs.
   - **Output artifacts** – Any resulting artifacts of the experiment run and the artifact locations in Amazon S3.
   - **Bias reports** – Pe-training or post-training bias reports generated using Clarify.
- **Explainability** – Explainability reports generated using Clarify.
- **Debugs** – A list of debugger rules and any issues found.

## Compare and analyze runs

To analyze experiment runs, select the experiment of your choice in the Amazon SageMaker Studio Experiments UI and then select the runs that you want to compare. You must select between 1 and 20 runs. After you have your runs selected, choose **Analyze** in the upper right-hand corner.

### To compare experiment runs:

1. After navigating to the experiment of your choice, select all the runs that you want to compare. You must choose more than 1 and less than 20 runs to analyze.
2. Choose **Analyze** in the upper right-hand corner.
3. Visualize the comparative metrics of multiple experiment runs in a histogram, line chart, scatter plot, or bar chart. To add a chart, choose **Add Chart**, select values for your chart axes, and choose **Create**.

You can update, download, or delete existing charts.
Log charts

Logging charts and visualizations is available for classification models. You can log a confusion matrix, receiver operating characteristics, or precision and recall graphs.

Log and visualize metrics with the following Python SDK methods:

- `log_confusion_matrix`: Records a confusion matrix artifact that you can view in the Charts section of the Run Overview in Studio.
- `log_roc_curve`: Records a receiver operating characteristic artifact that you can view in the Charts section of the Run Overview in Studio.
- `log_precision_recall`: Records a precision recall graph that you can view in the Charts section of the Run Overview in Studio.

An automatically logged precision recall record creates a chart similar to the following:
SageMaker integrations

Amazon SageMaker Experiments is integrated with a number of SageMaker features. Certain SageMaker jobs automatically create experiments. You can view and manage SageMaker Clarify bias reports or SageMaker Debugger output tensors for specific experiment runs directly in the Studio Experiments UI.

- **Automatic experiment creation** (p. 1847)
- **Bias and explainability reports** (p. 1848)
- **Debugging** (p. 1849)

Automatic experiment creation

Amazon SageMaker automatically creates experiments when running Autopilot jobs, hyperparameter optimization (HPO) jobs, or Pipeline executions. You can view these experiments in the Studio Experiments UI.

**Autopilot**

Amazon SageMaker Experiments is integrated with Amazon SageMaker Autopilot. When you perform an Autopilot job, SageMaker Experiments creates an experiment for that job as well as runs for each of the different combinations of the available run components, parameters, and artifacts. You can find these runs in the SageMaker Experiments UI by filtering for the run type **Autopilot**. For more information, see Automate model development with Amazon SageMaker Autopilot.

**HPO**

Amazon SageMaker Experiments is integrated with HPO jobs. An HPO job automatically creates Amazon SageMaker experiments, runs, and components for each training job that it completes. You can find these runs in the SageMaker Experiments UI by filtering for the run type **HPO**. For more information, see Tune Multiple Algorithms with Hyperparameter Optimization to Find the Best Model.
Pipelines

Amazon SageMaker Model Building Pipelines is closely integrated with Amazon SageMaker Experiments. By default, when SageMaker Pipelines creates and executes a pipeline, experiments, runs, and components are created if they do not already exist. You can find these runs in the SageMaker Experiments UI by filtering for the run type Pipelines. For more information, see Amazon SageMaker Experiments Integration.

Bias and explainability reports

Manage SageMaker Clarify bias and explainability reports for experiment runs directly through Studio. To view reports, find and select the name of the experiment run of your choice in Studio. Choose Bias reports to see any Clarify bias reports associated with the experiment run.

Choose Explanations to see any Clarify explainability reports associated with the experiment run.

You can generate pre-training or post-training bias reports that analyze bias in datasets or model predictions using labels and bias metrics with SageMaker Clarify. You can also use SageMaker Clarify to generate explainability reports that document model behavior for global or local data samples. For more information, see Amazon SageMaker Clarify Bias Detection and Model Explainability.
Debugging

You can debug model training progress with Amazon SageMaker Debugger and view debug output tensors in the Studio Experiments UI. Choose the name of the run associated with the Debugger report and choose Debugger.

Then, choose the training job name to view the associated Amazon SageMaker Debugger dashboard.

For more information, see Debug Training Jobs Using Amazon SageMaker Debugger.

Example notebooks for Amazon SageMaker Experiments

The following tutorials demonstrate how to track runs for various model training experiments. You can view the resulting experiments in Studio after running the notebooks. To clean up the resources created by a notebook, see Clean Up Amazon SageMaker Experiment Resources (p. 1851). For a tutorial that showcases additional features of Studio, see Amazon SageMaker Studio Tour (p. 224).
Track experiments in a notebook environment

To learn more about tracking experiments in a notebook environment, see the following example notebooks:

- Track an experiment while training a Keras model locally
- Track an experiment while training a Pytorch model locally or in your notebook

Track bias and explainability for your experiments with SageMaker Clarify

For a step-by-step guide on tracking bias and explainability for your experiments, see the following example notebook:

- Fairness and Explainability with SageMaker Clarify

Track experiments for SageMaker training jobs using script mode

For more information about tracking experiments for SageMaker training jobs, see the following example notebooks:

- Run a SageMaker Experiment with Pytorch Distributed Data Parallel - MNIST Handwritten Digits Classification
- Track an experiment while training a Pytorch model with a SageMaker Training Job
- Train a TensorFlow model with a SageMaker training job and track it using SageMaker Experiments

Monitor experiment training metrics with AWS CloudTrail

The training metrics for Amazon SageMaker Experiments are integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service. CloudTrail captures all API calls for `BatchPutMetrics` as events. SageMaker automatically calls `BatchPutMetrics` when you create an experiment run using the SageMaker SDK for Python. AWS CloudTrail captures data related to calls for resource type `AWS::SageMaker::ExperimentTrialComponent`.

**Note**

In the Studio Experiments UI, trials are referred to as `run groups` and trial components are referred to as `runs`.

When you create an experiment run, you can also configure the continuous delivery of CloudTrail events to an Amazon S3 bucket. Use CloudTrail to monitor all ingested training metrics for an experiment run, including information such as the metric name, the training step of the recorded metric, the timestamp, and the metric value. CloudTrail events also include the experiment run ARN, the ID of the account that created the run, and the resource type, which should be `AWS::SageMaker::ExperimentTrialComponent`.

To monitor `BatchPutMetrics` API calls as CloudTrail events, you must first set up the logging of data plane API activity in CloudTrail. See Logging data events for trails for more information. For granular control over which API calls you want to selectively log and pay for, you can filter CloudTrail events by resource type. Specify `AWS::SageMaker::ExperimentTrialComponent` as a resource type.
to monitor calls to the BatchPutMetrics API. For more information, see DataResource in the AWS CloudTrail API reference. To learn more about CloudTrail, see the AWS CloudTrail User Guide.

For an in-depth explanation of how Amazon SageMaker works with AWS CloudTrail, see Log Amazon SageMaker API Calls with AWS CloudTrail (p. 3592).

The following is an example CloudTrail event for a training metric in an experiment run:

```
{
  ...
  "eventTime": "2022-12-14T21:53:41Z",
  "eventSource": "metrics-sagemaker.amazonaws.com",
  "eventName": "BatchPutMetrics",
  "awsRegion": "us-east-1",
  "sourceIPAddress": "192.0.2.0",
  "userAgent": "aws-cli/2.7.25 Python/3.9.11 Linux/5.4.214-134.408.amzn2int.x86_64 exe/x86_64.amzn2 prompt/off command/sm-metrics.batch-put-metrics",
  "requestParameters": {
    "trialComponentName": "trial-component-name",
    "metricData": [
      {
        "metricName": "foo",
        "timestamp": 1670366870000,
        "step": 101,
        "value": 0.9
      }
    ],
  },
  ...
  "resources": [
    {
      "accountId": "abcdef01234567890",
      "type": "AWS::SageMaker::ExperimentTrialComponent",
      "ARN": "arn:aws:sagemaker:us-east-1:1234567890abcdef0:experiment-trial-component/trial-component-name"
    }
  ],
  ...
}
```

Clean Up Amazon SageMaker Experiment Resources

To avoid incurring unnecessary charges, delete the Amazon SageMaker Experiment resources you no longer need. You can't delete Experiment resources through the SageMaker Management Console or the Amazon SageMaker Studio UI. This topic shows you how to clean up these resources using the SageMaker Python SDK, Boto3, and the Experiments SDK.

Topics
- Clean Up Using the SageMaker Python SDK (Recommended) (p. 1851)
- Clean Up Using the Python SDK (Boto3) (p. 1852)
- Clean Up Using the Experiments SDK (p. 1852)

Clean Up Using the SageMaker Python SDK (Recommended)

To clean up using the SageMaker Python SDK

```python
from sagemaker.experiments.experiment import Experiment
```
Clean up experiment resources

```
exp = Experiment.load(experiment_name=experiment_name, sagemaker_session=sm_session)
exp._delete_all(action="--force")
```

**Clean Up Using the Python SDK (Boto3)**

**To clean up using Boto 3**

```python
import boto3
sm = boto3.Session().client('sagemaker')

Define cleanup_boto3

def cleanup_boto3(experiment_name):
    trials = sm.list_trials(ExperimentName=experiment_name)['TrialSummaries']
    print('TrialNames: ')
    for trial in trials:
        trial_name = trial['TrialName']
        print(f'
{trial_name}')
        components_in_trial = sm.list_trial_components(TrialName=trial_name)
        print('	TrialComponentNames: ')
        for component in components_in_trial['TrialComponentSummaries']:
            component_name = component['TrialComponentName']
            print(f'	{component_name}')
            sm.disassociate_trial_component(TrialComponentName=component_name, TrialName=trial_name)
    try:
        # comment out to keep trial components
        sm.delete_trial_component(TrialComponentName=component_name)
    except:
        # component is associated with another trial
        continue
        # to prevent throttling
        time.sleep(.5)
    sm.delete_trial(TrialName=trial_name)
    sm.delete_experiment(ExperimentName=experiment_name)
    print(f'
Experiment {experiment_name} deleted')

Call cleanup_boto3

# Use experiment name not display name
experiment_name = "experiment-name"
cleanup_boto3(experiment_name)
```

**Clean Up Using the Experiments SDK**

**To clean up using the Experiments SDK**

```python
import sys
!{sys.executable} -m pip install sagemaker-experiments

import time

from smexperiments.experiment import Experiment
from smexperiments.trial import Trial
```
from smexperiments.trial_component import TrialComponent

Define cleanup_sme_sdk

def cleanup_sme_sdk(experiment):
    for trial_summary in experiment.list_trials():
        trial = Trial.load(trial_name=trial_summary.trial_name)
        for trial_component_summary in trial.list_trial_components():
            tc = TrialComponent.load(
                trial_component_name=trial_component_summary.trial_component_name)
            trial.remove_trial_component(tc)
            try:
                # comment out to keep trial components
                tc.delete()
            except:
                # tc is associated with another trial
                continue
            # to prevent throttling
            time.sleep(.5)
            trial.delete()
        experiment_name = experiment.experiment_name
        experiment.delete()
        print(f"\nExperiment {experiment_name} deleted")

Call cleanup_sme_sdk

experiment_to_cleanup = Experiment.load(
    # Use experiment name not display name
    experiment_name="experiment-name")
cleanup_sme_sdk(experiment_to_cleanup)

Additional supported SDK

Important
As of v2.123.0, SageMaker Experiments is now fully integrated with the SageMaker Python SDK and you no longer need to use the separate SageMaker Experiments SDK. We recommend creating an experiment with sagemaker.experiments.run rather than the following smexperiments module.

The following section describes how to create a SageMaker Experiment with the SageMaker Experiments SDK.

Create an Amazon SageMaker Experiment with the SageMaker Experiments SDK

Create an Amazon SageMaker experiment to track your SageMaker training, processing, and transform jobs.

The following procedure shows you how to create a SageMaker experiment for a SageMaker training, processing, or transform job. Steps labeled as (Studio) describe how to view the experiment in Amazon SageMaker Studio. You don't have to run the experiment in Studio to view the experiment in Studio.

1. Import the sys module to install the SDKs.

import sys
2. (Optional) The Amazon SageMaker Python SDK, comes preinstalled in SageMaker Studio. If you plan to run your code outside Studio, install the SageMaker Python SDK.

```
!{sys.executable} -m pip install sagemaker
```

3. Install the SageMaker Experiments Python SDK.

```
!{sys.executable} -m pip install sagemaker-experiments
```

4. Import modules.

```
import time
from time import strftime
import sagemaker
from smexperiments.experiment import Experiment
from smexperiments.trial import Trial
from smexperiments.trial_component import TrialComponent
from smexperiments.tracker import Tracker
```

5. Get the execution role and create the SageMaker session.

```
role = sagemaker.get_execution_role()
sm_sess = sagemaker.session.Session()
```

6. Create a SageMaker experiment. The experiment name must be unique in your account.

   **Note**
   The tags parameter is optional. You can search for the tag using Studio, the SageMaker console, and the SDK. Tags can also be applied to trials and trial components.

   ```python
create_date = strftime("%Y-%m-%d-%H-%M-%S")
demo_experiment = Experiment.create(experiment_name = "DEMO-{}".format(create_date),
                                      description = "Demo experiment",
                                      tags = [{'Key': 'demo-experiments', 'Value': 'demo1'}])
```

7. (Studio) To view the experiment in SageMaker Studio, in the left sidebar, choose the Experiments.

   After the code runs, the experiment list contains the new experiment. It might take a moment for the list to refresh and display the experiment. The filter on the experiment tag is also displayed. Only experiments that have a matching tag are displayed. Your list should look similar to the following:
8. Create a trial for the experiment. The trial name must be unique in your account.

```python
demo_trial = Trial.create(trial_name = "DEMO-{}".format(create_date),
                        experiment_name = demo_experiment.experiment_name,
                        tags = [{'Key': 'demo-trials', 'Value': 'demo1'}])
```

9. Create a trial component as part of the trial. The trial component is the SageMaker job.

Add the `ExperimentConfig` parameter to the appropriate method. The SageMaker jobs listed in the following table are supported.

<table>
<thead>
<tr>
<th>Job</th>
<th>SageMaker Python SDK method</th>
<th>Boto3 method</th>
</tr>
</thead>
<tbody>
<tr>
<td>Training</td>
<td><code>Estimator.fit</code></td>
<td><code>CreateTrainingJob</code></td>
</tr>
<tr>
<td>Processing</td>
<td><code>Processor.run</code></td>
<td><code>CreateProcessingJob</code></td>
</tr>
<tr>
<td>Transform</td>
<td><code>Transformer.transform</code></td>
<td><code>CreateTransformJob</code></td>
</tr>
</tbody>
</table>

The following examples are for a training job. The `Tags` parameter adds a tag to the trial component. `ExperimentName` isn't specified because the trial was associated with the experiment when the trial was created in an earlier step.

**Using the SageMaker Python SDK**

```python
sagemaker_estimator = Estimator(
...,
    sagemaker_session = sm_sess,
    tags = [{'Key': 'sm_sess', 'Value': 'demo2'}]
)

estimator.fit(
    ...,
    experiment_config = {
        # "ExperimentName": demo_experiment.experiment_name,
        "TrialName" : demo_trial.trial_name,
    }
)`
"TrialComponentDisplayName" : "TrainingJob",
})

**Using Boto3**

```python
create_training_job(
    ...
    "ExperimentConfig": {
        "TrialName" : demo_trial.trial_name,
        "TrialComponentDisplayName" : "TrainingJob",
    },
    "Tags": [['Key': 'demo-jobs', 'Value': 'demo2']]})
```

10. (Studio) In the experiment list, double-click the experiment to display a list of the trials in the experiment. In the Studio UI, trials are referred to as *run groups* and trial components are referred to as *runs*. Your list should look similar to the following:

![Experiment List Screenshot](image)

11. (Studio) To view information about the experiment, trial, and job (trial component), see *View, search, and compare experiment runs* (p. 1843).

To clean up the resources you created, see *Clean Up Amazon SageMaker Experiment Resources* (p. 1851).

**Experiments FAQs**

Refer to the following FAQ items for answers to commonly asked questions about SageMaker Experiments.

**Q. What is the recommended method to create an experiment?**

**A:** Experiments are a collection of runs aimed at finding the best model to solve a problem. To initialize a run within an experiment, use the SageMaker Python SDK Run class. For more examples, see *Create an Amazon SageMaker Experiment* (p. 1839).
Q. Can I create an experiment using SageMaker script mode?

Yes. You can create experiments using SageMaker script mode. In the Jupyter notebook or Python file you are using to define your estimator, initialize a run using the Run class. Within the run, launch an estimator with your custom entry point script. Within that entry point script, use the load_run method to initialize the run you defined within the entry point script and log your metrics. For in-depth examples, see Track experiments for SageMaker training jobs using script mode (p. 1850).

Q. What SageMaker jobs automatically create experiments?

SageMaker Hyperparameter Optimization (HPO) jobs (also known as tuning jobs) automatically create experiments to track all the training jobs launched during a hyperparameter search. All other SageMaker jobs create unassigned runs unless launched from within an experiment.

Q. What kind of SageMaker jobs can I create an experiment for?

You can use SageMaker Experiments to track metrics from training jobs, processing jobs, and transform jobs.

Q. Why do I see experiments and runs in the Experiments Studio UI that I did not create using the SageMaker Python SDK?

Experiment runs that are automatically created by SageMaker jobs and containers are visible in the Experiments Studio UI by default. To hide runs created by SageMaker jobs for a given experiment, choose the settings icon and toggle Show jobs.

Q. Is the SageMaker Experiments SDK still supported?

Yes, the SageMaker Experiments SDK is still supported. However, as of v2.123.0, SageMaker Experiments is fully integrated with the SageMaker Python SDK. We recommend using the SageMaker Python SDK to create experiments and runs. For more information, see Create an Amazon SageMaker Experiment (p. 1839).

Q. Can I use distributed training with my experiments?

A: Yes. However, metrics for distributed training can be logged only at the epoch level. Be sure that you only log metrics generated by the leader node, as shown in the following example:

```python
... 
if rank == 0:
    test_loss, correct, target, pred = test(model, test_loader, device, tracker)
    logger.info( 
        "Test Average loss: {:.4f}, Test Accuracy: {:.0f}%;\n".format( 
            test_loss, test_accuracy) 
    )

    run.log_metric(name = "train_loss", value = loss.item(), step = epoch)
    run.log_metric(name = "test_loss", value = test_loss, step = epoch)
    run.log_metric(name = "test_accuracy", value = test_accuracy, step = epoch)
...
```

For more information, see the Run a SageMaker Experiment with Pytorch Distributed Data Parallel - MNIST Handwritten Digits Classification example notebook.

Q. What are unassigned runs?

A: All jobs in SageMaker (training jobs, processing jobs, transform jobs) correspond to runs. When launching these jobs, TrialComponents are created by default. TrialComponents map directly to
runs. If these jobs are launched without being explicitly associated with an experiment or run, they are created as unassigned runs.

Q. Do I need to pass the experiment run context to the training script when running a SageMaker training job?

A: Yes. You need to load the run context into the training script, along with the SageMaker session information.

```python
from sagemaker.session import Session
from sagemaker.experiments.run import load_run

session = Session(boto3.session.Session(region_name=args.region))

with load_run(sagemaker_session=session) as run:
    run.log_parameters({
        "num_train_samples": len(train_set.data),
        "num_test_samples": len(test_set.data)
    })
```

Q. How do I add a new run to an experiment analysis?

A: If you already created a comparison for your experiment and want to add a new run to analyze, select all the runs from your previous analysis as well as the new run and choose Analyze. If you don’t see your new run in the resulting analysis page, then refresh the Studio browser. Note that refreshing your Studio browser may impact your other open tabs.

**Search Using the Amazon SageMaker Console and API**

Developing a machine learning model typically requires extensive experimenting with different datasets, algorithms, and hyperparameter values. To manage up to thousands of machine learning model experiments, use the search capabilities in SageMaker.

You can use SageMaker search to:

- Organize, find, and evaluate training jobs using properties, hyperparameters, performance metrics, or any metadata.
- Find the best performing model by reviewing training job and model metrics, such as training loss or validation accuracy.
- Trace a model's lineage to the training job and its related resources, such as the training datasets.

This topic covers searching from the SageMaker console and the SageMaker API.

**Topics**

- **Organize, Find, and Evaluate Training Jobs (Console)** (p. 1858)
- **Find and Evaluate Training Jobs (API)** (p. 1860)
- **Verify the Datasets Used by Your Training Jobs** (p. 1862)
- **Trace Model Lineage** (p. 1862)

**Organize, Find, and Evaluate Training Jobs (Console)**

To organize training jobs, assign one or more tags to them.
To find a specific training job, model, or resource, use model tracking to search on keywords assigned to any searchable items. Searchable items include training jobs, models, hyperparameters, metadata, tags, and URLs. To refine your tracking results, you can search using multiple criteria.

To choose the best model for deployment, evaluate how all models performed against one or more metrics. You can use model tracking results to list, sort, and evaluate the performance of the models in your experiments.

**Topics**
- Use Tags to Track Training Jobs (Console) (p. 1859)
- Find Training Jobs (Console) (p. 1859)
- Evaluate Models (Console) (p. 1860)

**Use Tags to Track Training Jobs (Console)**

To group training jobs, create tags with descriptive keys and a value. For example, create tag keys for: project, owner, customer, and industry.

**Add tags to training jobs (console)**
1. Open the Amazon SageMaker console.
2. In the navigation pane, choose Training jobs and Create training job.
3. Scroll to the bottom of the page and enter a key and value for the tag.
4. To add another tag, choose Add tag, and add another key-value pair.

**Find Training Jobs (Console)**

You can search for training jobs using a variety of job attributes. Note that some search parameters appear only if you have created a training job with that attribute. For example, Tags appears only if you have added a tag for a training job.

**To find training jobs (console)**
1. Open the Amazon SageMaker console.
2. In the navigation pane, choose Search.
3. Add Parameters.
   a. In the search box, enter a parameter and choose a parameter type, for example TrainingJobName.
   b. Choose a conditional operation. For numeric values, use operators such as is equals to, lesser than, or or greater than. For text-based values, use operators such as equals to or contains.
   c. Enter a value for the parameter.
4. (Optional) To refine your search, add additional search criteria. Choose **Add row** and enter the parameter values.

5. Choose **Search**.

**Evaluate Models (Console)**

To evaluate a model's performance, review its metadata, hyperparameters, and metrics. To highlight metrics, adjust the view to show only metrics and important hyperparameters.

**To evaluate a model (console)**

1. Open the **Amazon SageMaker console**.
2. In the navigation pane, choose **Search** and search for training jobs by specifying relevant parameters. The results are displayed in a table.

   ![Results: Training jobs](image)

3. Open the preferences window by choosing the settings icon in the search results table.
4. To show or hide a hyperparameter or metric, turn it on or off by choosing **Hyperparameter** or **Metric**.
5. Make necessary changes, then choose **Update view**.
6. After viewing metrics and important hyperparameters, you can compare and contrast the result. Then, you can choose the best model to host or investigate the models that are performing poorly.

**Find and Evaluate Training Jobs (API)**

To find and evaluate training jobs or to get suggestions for items used in experiments that are searchable, you can use the **Search** API.

**Topics**

- [Find Training Jobs (API) (p. 1861)]
- [Evaluate Models (API) (p. 1860)]
- [Get Suggestions for a Search (API) (p. 1861)]
### Find Training Jobs (API)

To find training jobs, create a search parameter using the `search_params` parameter. Then use the search function in the `smclient` subprocess in the AWS SDK for Python (Boto3).

The following example shows how to use the **Search** API to find training jobs.

```python
import boto3

search_params={
    "MaxResults": 10,
    "Resource": "TrainingJob",
    "SearchExpression": {
        "Filters": [{
            "Name": "Tags.Project",
            "Operator": "Equals",
            "Value": "Project_Binary_Classifier"
        }],
        "SortBy": "Metrics.train:binary_classification_accuracy",
        "SortOrder": "Descending"
    }
}

smclient = boto3.client(service_name='sagemaker')
results = smclient.search(**search_params)
```

### Evaluate Models (API)

To evaluate models, run a search as described in **Find Training Jobs (API)** (p. 1861), review model metrics, then, use the AWS SDK for Python (Boto3) to create a table and plot it.

The following example shows how to evaluate models and to display the results in a table.

```python
import pandas

headers=["Training Job Name", "Training Job Status", "Batch Size", "Binary Classification Accuracy"]
rows=[]
for result in results['Results']:
    trainingJob = result['TrainingJob']
    metrics = trainingJob['FinalMetricDataList']
    rows.append([trainingJob['TrainingJobName'],
                 trainingJob['TrainingJobStatus'],
                 trainingJob['HyperParameters']['mini_batch_size'],
                 metrics[[x['MetricName'] for x in metrics].index('train:binary_classification_accuracy')]['Value']])

df = pandas.DataFrame(data=rows,columns=headers)
from IPython.display import display, HTML
display(HTML(df.to_html()))
```

### Get Suggestions for a Search (API)

To get suggestions for a search, use the **GetSearchSuggestions** API.

The following example for AWS SDK for Python (Boto3) is a `get_search_suggestions` request for items containing linear.

```python
search_suggestion_params={
    "Resource": "TrainingJob",
    "SuggestionQuery": {
```
Search using the console and API

```
"PropertyNameQuery": {
  "PropertyNameHint": "linear"
},
```

The following is an example response for a get_search_suggestions request.

```
{
  'PropertyNameSuggestions': [
    {'PropertyName': 'hyperparameters.linear_init_method'},
    {'PropertyName': 'hyperparameters.linear_init_value'},
    {'PropertyName': 'hyperparameters.linear_init_sigma'},
    {'PropertyName': 'hyperparameters.linear_lr'},
    {'PropertyName': 'hyperparameters.linear_wd'}
  ]
}
```

After getting search suggestions, you can use one of the property names in a search.

**Verify the Datasets Used by Your Training Jobs**

You can use model tracking capability to verify which datasets were used in training, where holdout datasets were used, and other details about training jobs. For example, use model tracking capability to verify that a specific dataset was used in a training job for an audit or to verify compliance.

To check whether a specific dataset was used in a training job, you search for the URL to its location in Amazon Simple Storage Service (Amazon S3). Model tracking capability returns the training jobs that used the dataset that you specify. If your search doesn't return the dataset (the result is empty), the dataset wasn't used in a training job. An empty result confirms, for example, that a holdout dataset wasn't used.

**Trace Model Lineage**

You can use model tracking capability to get information about the lineage of training jobs and the model resources that were used for them, including the dataset, algorithm, hyperparameters, and metrics. For example, if you find that the performance of a hosted model has declined, you can review its training job and the resources it used to determine what's causing the problem.

**Topics**
- [Trace Model Lineage (Console) (p. 1862)]
- [Trace Model Lineage (API) (p. 1862)]

**Trace Model Lineage (Console)**

**To trace a model's lineage (console)**

1. Open the Amazon SageMaker console.
2. In the navigation pane, choose **Endpoints**, and choose the relevant endpoint.
3. Scroll to the **Endpoint configuration settings** section. This section lists all of the model versions deployed at the endpoint, with a hyperlink to the training job that created each.

**Trace Model Lineage (API)**

To trace a model's lineage, get the model's name, then use it to search for training jobs.

The following example shows how to trace a model's lineage using the API.
# Get the name of model deployed at endpoint
endpoint_config = smclient.describe_endpoint_config(EndpointConfigName=endpointName)
model_name = endpoint_config['ProductionVariants'][0]['ModelName']

# Get the model's name
model = smclient.describe_model(ModelName=model_name)

# Search the training job by the location of model artifacts in Amazon S3
search_params={
    "MaxResults": 1,
    "Resource": "TrainingJob",
    "SearchExpression": {
        "Filters": [
            {
                "Name": "ModelArtifacts.S3ModelArtifacts",
                "Operator": "Equals",
                "Value": model['PrimaryContainer']['ModelDataUrl']
            }
        ]
    }
}
results = smclient.search(**search_params)

After finding the training job, you can review the resources used to train the model.

### Perform Automatic Model Tuning with SageMaker

Amazon SageMaker automatic model tuning (AMT), also known as hyperparameter tuning, finds the best version of a model by running many training jobs on your dataset. To do this, AMT uses the algorithm and ranges of hyperparameters that you specify. It then chooses the hyperparameter values that creates a model that performs the best, as measured by a metric that you choose.

For example, suppose that you want to solve a binary classification problem on a marketing dataset. Your goal is to maximize the area under the curve (AUC) metric of the algorithm by training an XGBoost Algorithm (p. 1617) model. You want to find which values for the eta, alpha, min_child_weight, and max_depth hyperparameters that will train the best model. Specify a range of values for these hyperparameters. Then, SageMaker hyperparameter tuning searches within these ranges to find a combination of values that creates a training job that creates a model with the highest AUC. To conserve resources or meet a specific model quality expectation, you can also set up completion criteria to stop tuning after the criteria have been met.

You can use SageMaker AMT with built-in algorithms, custom algorithms, or SageMaker pre-built containers for machine learning frameworks.

SageMaker AMT can use an Amazon EC2 Spot instance to optimize costs when running training jobs. For more information, see Use Managed Spot Training in Amazon SageMaker (p. 2305).

Before you start using hyperparameter tuning, you should have a well-defined machine learning problem, including the following:

- A dataset
- An understanding of the type of algorithm that you need to train
- A clear understanding of how you measure success

Prepare your dataset and algorithm so that they work in SageMaker and successfully run a training job at least once. For information about setting up and running a training job, see Get started (p. 8).

### Topics

- How Hyperparameter Tuning Works (p. 1864)
How Hyperparameter Tuning Works

When you build complex machine learning systems like deep learning neural networks, exploring all of the possible combinations is impractical. Hyperparameter tuning can accelerate your productivity by trying many variations of a model. It looks for the best model automatically by focusing on the most promising combinations of hyperparameter values within the ranges that you specify. To get good results, you must choose the right ranges to explore.

Use the API reference guide to understand how to interact with hyperparameter tuning. The examples on this page can be found in the `HyperParameterTuningJobConfig` and `HyperbandStrategyConfig` APIs.

**Note**
Because the algorithm itself is stochastic, it's possible that the hyperparameter tuning model will fail to converge on the best answer. This can occur even if the best possible combination of values is within the ranges that you choose.

**Grid Search**

When using grid search, hyperparameter tuning chooses combinations of values from the range of categorical values that you specify when you create the job. Only categorical parameters are supported when using the grid search strategy. You do not need to specify the `MaxNumberOfTrainingJobs`. The number of training jobs created by the tuning job will be automatically calculated to be the total number of distinct categorical combinations possible. If specified, the value of `MaxNumberOfTrainingJobs` should equal the total number of distinct categorical combinations possible.

**Random Search**

When using random search, hyperparameter tuning chooses a random combination of values from within the ranges that you specify for hyperparameters for each training job it launches. Because the choice of hyperparameter values doesn't depend on the results of previous training jobs, you can run the maximum number of concurrent training jobs without affecting the performance of the tuning.

For an example notebook that uses random search, see the Random search and hyperparameter scaling with SageMaker XGBoost and Automatic Model Tuning notebook.

**Bayesian Optimization**

Bayesian optimization treats hyperparameter tuning like a regression problem. Given a set of input features (the hyperparameters), hyperparameter tuning optimizes a model for the metric that you choose. To solve a regression problem, hyperparameter tuning makes guesses about which hyperparameter combinations are likely to get the best results, and runs training jobs to test these values. After testing a set of hyperparameter values, hyperparameter tuning uses regression to choose the next set of hyperparameter values to test.
Hyperparameter tuning uses an Amazon SageMaker implementation of Bayesian optimization.

When choosing the best hyperparameters for the next training job, hyperparameter tuning considers everything that it knows about this problem so far. Sometimes it chooses a combination of hyperparameter values close to the combination that resulted in the best previous training job to incrementally improve performance. This allows hyperparameter tuning to exploit the best known results. Other times, it chooses a set of hyperparameter values far removed from those it has tried. This allows it to explore the range of hyperparameter values to try to find new areas that are not yet well understood. The explore/exploit trade-off is common in many machine learning problems.

**Hyperband**

Hyperband is a multi-fidelity based tuning strategy that dynamically reallocates resources. Hyperband uses both intermediate and final results of training jobs to re-allocate epochs to well-utilized hyperparameter configurations and automatically stops those that underperform. It also seamlessly scales to using many parallel training jobs. These features can significantly speed up hyperparameter tuning over random search and Bayesian optimization strategies.

Hyperband should only be used to tune iterative algorithms that publish results at different resource levels. For example, Hyperband can be used to tune a neural network for image classification which publishes accuracy metrics after every epoch.

For more information about Hyperband, see the following links:

Hyperband with early stopping

Training jobs can be stopped early when they are unlikely to improve the objective metric of the hyperparameter tuning job. This can help reduce compute time and avoid overfitting your model. Hyperband uses an advanced internal mechanism to apply early stopping. Thus, the parameter TrainingJobEarlyStoppingType in the HyperParameterTuningJobConfig API must be set to OFF when using the Hyperband internal early stopping feature.

Note
Hyperparameter tuning might not improve your model. It is an advanced tool for building machine solutions. As such, it should be considered part of the scientific development process.

Define metrics and environment variables

A tuning job optimizes hyperparameters for training jobs that it launches by using a metric to evaluate performance. This guide shows how to define metrics so that you can use a custom algorithm for training, or use a built-in algorithm from Amazon SageMaker. This guide also shows how to specify environment variables during an Automatic model tuning (AMT) job.

Define metrics

Amazon SageMaker hyperparameter tuning parses your machine learning algorithm's stdout and stderr streams to find metrics, such as loss or validation-accuracy. The metrics show how well the model is performing on the dataset.

The following sections describe how to use two types of algorithms for training: built-in and custom.

Use a built-in algorithm for training

If you use one of the SageMaker built-in algorithms, metrics are already defined for you. In addition, built-in algorithms automatically send metrics to hyperparameter tuning for optimization. These metrics are also written to Amazon CloudWatch logs. For more information, see Log Amazon SageMaker Events with Amazon CloudWatch.

For the objective metric for the tuning job, choose one of the metrics that the built-in algorithm emits. For a list of available metrics, see the model tuning section for the appropriate algorithm in Use Amazon SageMaker Built-in Algorithms or Pre-trained Models.

You can choose up to 40 metrics to monitor in your tuning job. Select one of those metrics to be the objective metric. The hyperparameter tuning job returns the training job that performed the best against the objective metric.

Note
Hyperparameter tuning automatically sends an additional hyperparameter _tuning_objective_metric to pass your objective metric to the tuning job for use during training.

Use a custom algorithm for training

This section shows how to define your own metrics to use your own custom algorithm for training. When doing so, make sure that your algorithm writes at least one metric to stdout or stderr. Hyperparameter tuning parses these streams to find algorithm metrics that show how well the model is performing on the dataset.

You can define custom metrics by specifying a name and regular expression for each metric that your tuning job monitors. Then, pass these metric definitions to the CreateHyperParameterTuningJob API in the TrainingJobDefinition parameter in the MetricDefinitions field of AlgorithmSpecification.
The following shows sample output from a log written to stderr or stdout by a training algorithm.

```
GAN_loss=0.138318;  Scaled_reg=2.654134; disc:[-0.017371,0.102429] real 93.3% gen 0.0%
disc-combined=0.000000; disc_train_loss=1.374587; Loss = 16.020744; Iteration 0 took 0.704s; Elapsed=0s
```

The following code example shows how to use regular expressions in Python (regex). This is used to search the sample log output and capture the numeric values of four different metrics.

```
[
  {
    "Name": "ganloss",
    "Regex": "GAN_loss=(.*?);",
  },
  {
    "Name": "disc-combined",
    "Regex": "disc-combined=(.*?);",
  },
  {
    "Name": "discloss",
    "Regex": "disc_train_loss=(.*?);",
  },
  {
    "Name": "loss",
    "Regex": "Loss = (.*?);",
  }
]
```

In regular expressions, parenthesis () are used to group parts of the regular expression together.

- For the loss metric that is defined in the code example, the expression (.*?); captures any character between the exact text “Loss=” and the first semicolon (;) character.
- The character . instructs the regular expression to match any character.
- The character * means to match zero or more characters.
- The character ? means capture only until the first instance of the ; character.

The loss metric defined in the code sample will capture `Loss = 16.020744` from the sample output.

Choose one of the metrics that you define as the objective metric for the tuning job. If you are using the SageMaker API, specify the value of the name key in the `HyperParameterTuningJobObjective` field of the `HyperParameterTuningJobConfig` parameter that you send to the `CreateHyperParameterTuningJob` operation.

**Specify environment variables**

SageMaker AMT optimizes hyperparameters within a tuning job to find the best parameters for model performance. You can use environment variables to configure your tuning job to change its behavior. You can also use environment variables that you used during training inside your tuning job.

If you want to use an environment variable from your tuning job or specify a new environment variable, input a string value for Environment within the SageMaker `HyperParameterTrainingJobDefinition` API. Pass this training job definition to the `CreateHyperParameterTuningJob` API.

For example, the environment variable `SM_LOG_LEVEL` can be set to the following values to tailor the output from a Python container:

```
NOTSET=0
DEBUG=10
```
Define Hyperparameter Ranges

As an example, to set the log level to 10 to debug your container logs, set the environment variable inside the HyperParameterTrainingJobDefinition, as follows.

```json
{
    "HyperParameterTuningJobConfig": {
        ...
    },
    "TrainingJobDefinition": {
        "Environment": [
            {
                "SM_LOG_LEVEL": 10
            }
        ],
        ...
    }
}
```

Define Hyperparameter Ranges

This guide shows how to use SageMaker APIs to define hyperparameter ranges. It also provides a list of hyperparameter scaling types that you can use.

Choosing hyperparameters and ranges significantly affects the performance of your tuning job. Hyperparameter tuning finds the best hyperparameter values for your model by searching over a range of values that you specify for each tunable hyperparameter. You can also specify up to 100 static hyperparameters that do not change over the course of the tuning job. You can use up to 100 hyperparameters in total (static + tunable). For guidance on choosing hyperparameters and ranges, see Best Practices for Hyperparameter Tuning (p. 1901). You can also use autotune to find optimal tuning job settings. For more information, see the following Autotune section.

Note

SageMaker Automatic Model Tuning (AMT) may add additional hyperparameters(s) that contribute to the limit of 100 total hyperparameters. Currently, to pass your objective metric to the tuning job for use during training, SageMaker adds _tuning_objective_metric automatically.

Static hyperparameters

Use static hyperparameters for the following cases: For example, you can use AMT to tune your model using param1 (a tunable parameter) and param2 (a static parameter). If you do, then use a search space for param1 that lies between two values, and pass param2 as a static hyperparameter, as follows.

```
param1: ["range_min","range_max"]
param2: "static_value"
```

Static hyperparameters have the following structure:

```
"StaticHyperParameters": {
    "objective": "reg:squarederror",
    "dropout_rate": "0.3"
}
```
You can use the Amazon SageMaker API to specify key value pairs in the `StaticHyperParameters` field of the `HyperParameterTrainingJobDefinition` parameter that you pass to the `CreateHyperParameterTuningJob` operation.

### Dynamic hyperparameters

You can use the SageMaker API to define hyperparameter ranges. Specify the names of hyperparameters and ranges of values in the `ParameterRanges` field of the `HyperParameterTuningJobConfig` parameter that you pass to the `CreateHyperParameterTuningJob` operation.

The `ParameterRanges` field has three subfields: categorical, integer, and continuous. You can define up to 30 total (categorical + integer + continuous) tunable hyperparameters to search over.

#### Note

Each categorical hyperparameter can have at most 30 different values.

Dynamic hyperparameters have the following structure:

```json
"ParameterRanges": {
    "CategoricalParameterRanges": [
        {
            "Name": "tree_method",
            "Values": ["auto", "exact", "approx", "hist"]
        }
    ],
    "ContinuousParameterRanges": [
        {
            "Name": "eta",
            "MaxValue": "0.5",
            "MinValue": "0",
            "ScalingType": "Auto"
        }
    ],
    "IntegerParameterRanges": [
        {
            "Name": "max_depth",
            "MaxValue": "10",
            "MinValue": "1",
            "ScalingType": "Auto"
        }
    ]
}
```

If you create a tuning job with a Grid strategy, you can only specify categorical values. You don't need to provide the `MaxNumberOfTrainingJobs`. This value is inferred from the total number of configurations that can be produced from your categorical parameters. If specified, the value of `MaxNumberOfTrainingJobs` should be equal to the total number of distinct categorical combinations possible.

### Autotune

To save time and resources searching for hyperparameter ranges, resources or objective metrics, autotune can automatically guess optimal values for some hyperparameter fields. Use autotune to find optimal values for the following fields:

- **ParameterRanges** – The names and ranges of hyperparameters that a tuning job can optimize.
- **ResourceLimits** – The maximum resources to be used in a tuning job. These resources can include the maximum number of training jobs, maximum runtime of a tuning job, and the maximum number of training jobs that can be run at the same time.
- **TrainingJobEarlyStoppingType** – A flag that stops a training job if a job is not significantly improving against an objective metric. Defaults to enabled. For more information, see Stop Training Jobs Early (p. 1894).
- **RetryStrategy** – The number of times to retry a training job. Non-zero values for RetryStrategy can increase the likelihood that your job will complete successfully.
- **Strategy** – Specifies how hyperparameter tuning chooses the combinations of hyperparameter values to use for the training job that it launches.
- **ConvergenceDetected** – A flag to indicate that Automatic Model Tuning (AMT) has detected model convergence.

To use autotune, do the following:

1. Specify the hyperparameter and an example value in the AutoParameters field of the ParameterRanges API.
2. Enable autotune.

AMT will determine if your hyperparameters and example values are eligible for autotune. Hyperparameters that can be used in autotune are automatically assigned to the appropriate parameter range type. Then, AMT uses ValueHint to select an optimal range for you. You can use the DescribeHyperParameterTrainingJob API to view these ranges.

The following example shows you how to configure a tuning job that uses autotune. In the configuration example, the hyperparameter `max_depth` has ValueHint containing an example value of 4.

```python
config = {
    'Autotune': {'Mode': 'Enabled'},
    'HyperParameterTuningJobName': 'my-autotune-job',
    'HyperParameterTuningJobConfig': {
        'HyperParameterTuningJobObjective': {'Type': 'Minimize', 'MetricName': 'validation:rmse'},
        'ResourceLimits': {'MaxNumberOfTrainingJobs': 5, 'MaxParallelTrainingJobs': 1},
        'ParameterRanges': {
            'AutoParameters': [
                {'Name': 'max_depth', 'ValueHint': '4'}
            ]
        }
    },
    'TrainingJobDefinition': {
        ...
    }
}
```

Continuing the previous example, a tuning job is created after the previous configuration is included in a call to the CreateHyperParameterTuningJob API. Then, autotune converts the `max_depth` hyperparameter in AutoParameters to the hyperparameter IntegerParameterRanges. The following response from a DescribeHyperParameterTrainingJob API shows that the optimal IntegerParameterRanges for `max_depth` are between 2 and 8.

```json
{
    'HyperParameterTuningJobName': 'my_job',
    'HyperParameterTuningJobConfig': {
        'ParameterRanges': {
            'IntegerParameterRanges': [
                {'Name': 'max_depth', 'MinValue': '2', 'MaxValue': '8'},
            ],
        },
        'TrainingJobDefinition': {
            ...
        }
    }
}
```
Hyperparameter scaling types

For integer and continuous hyperparameter ranges, you can choose the scale that you want hyperparameter tuning to use. For example, to search the range of values, you can specify a value for the `ScalingType` field of the hyperparameter range. You can choose from the following hyperparameter scaling types:

Auto

SageMaker hyperparameter tuning chooses the best scale for the hyperparameter.

Linear

Hyperparameter tuning searches the values in the hyperparameter range by using a linear scale. Typically, you choose this if the range of all values from the lowest to the highest is relatively small (within one order of magnitude). Uniformly searching values from the range provides a reasonable exploration of the entire range.

Logarithmic

Hyperparameter tuning searches the values in the hyperparameter range by using a logarithmic scale.

Logarithmic scaling works only for ranges that have values greater than 0.

Choose logarithmic scaling when you're searching a range that spans several orders of magnitude.

For example, if you're tuning a Tune a linear learner model (p. 1593) model, and you specify a range of values between .0001 and 1.0 for the `learning_rate` hyperparameter, consider the following: Searching uniformly on a logarithmic scale gives you a better sample of the entire range than searching on a linear scale would. This is because searching on a linear scale would, on average, devote 90 percent of your training budget to only the values between .1 and 1.0. As a result, that leaves only 10 percent of your training budget for the values between .0001 and .1.

ReverseLogarithmic

Hyperparameter tuning searches the values in the hyperparameter range by using a reverse logarithmic scale. Reverse logarithmic scaling is supported only for continuous hyperparameter ranges. It is not supported for integer hyperparameter ranges.

Choose reverse logarithmic scaling when you are searching a range that is highly sensitive to small changes that are very close to 1.

Reverse logarithmic scaling works only for ranges that are entirely within the range 0<=x<1.0.

For an example notebook that uses hyperparameter scaling, see these Amazon SageMaker hyperparameter examples on GitHub.

Track and set completion criteria for your tuning job

You can use completion criteria to instruct Automatic model tuning (AMT) to stop your tuning job if certain conditions are met. With these conditions, you can set a minimum model performance or maximum number of training jobs that don't improve when evaluated against the objective metric. You can also track the progress of your tuning job and decide to let it continue or to stop it manually. This guide shows you how to set completion criteria, check the progress of and stop your tuning job manually.
Set completion criteria for your tuning job

During hyperparameter optimization, a tuning job will launch several training jobs inside a loop. The tuning job will do the following.

- Check your training jobs for completion and update statistics accordingly
- Decide what combination of hyperparameters to evaluate next.

AMT will continuously check the training jobs that were launched from your tuning job to update statistics. These statistics include tuning job runtime and best training job. Then, AMT determines whether it should stop the job according to your completion criteria. You can also check these statistics and stop your job manually. For more information about stopping a job manually, see the Stopping your tuning job manually (p. 1874) section.

As an example, if your tuning job meets your objective, you can stop tuning early to conserve resources or ensure model quality. AMT checks your job performance against your completion criteria and stops the tuning job if any have been met.

You can specify the following kinds of completion criteria:

- **MaxNumberOfTrainingJobs** – The maximum number of training jobs to be run before tuning is stopped.
- **MaxNumberOfTrainingJobsNotImproving** – The maximum number of training jobs that do not improve performance against the objective metric from the current best training job. As an example, if the best training job returned an objective metric that had an accuracy of 90%, and MaxNumberOfTrainingJobsNotImproving is set to 10. In this example, tuning will stop after 10 training jobs fail to return an accuracy higher than 90%.
- **MaxRuntimeInSeconds** – The upper limit of wall clock time in seconds of how long a tuning job can run.
- **TargetObjectiveMetricValue** – The value of the objective metric against which the tuning job is evaluated. Once this value is met, AMT stops the tuning job.
- **CompleteOnConvergence** – A flag to stop tuning after an internal algorithm determines that the tuning job is unlikely to improve more than 1% over the objective metric from the best training job.

Selecting completion criteria

You can choose one or multiple completion criteria to stop your hyperparameter tuning job after a condition has been meet. The following instructions show you how to select completion criteria and how to decide which is the most appropriate for your use case.

- Use MaxNumberOfTrainingJobs in the ResourceLimits API to set an upper limit for the number of training jobs that can be run before your tuning job is stopped. Start with a large number and adjust it based on model performance against your tuning job objective. Most users input values of around 50 or more training jobs to find an optimal hyperparameter configuration. Users looking for higher levels of model performance will use 200 or more training jobs.
- Use MaxNumberOfTrainingJobsNotImproving in the BestObjectiveNotImproving API field to stop training if model performance fails to improve after a specified number of jobs. Model performance is evaluated against an objective function. After the MaxNumberOfTrainingJobsNotImproving is met, AMT will stop the tuning job. Tuning jobs tend to make the most progress in the beginning of the job. Improving model performance against an objective function will require a larger number of training jobs towards the end of tuning. Select a value for MaxNumberOfTrainingJobsNotImproving by checking the performance of similar training jobs against your objective metric.
• Use **MaxRuntimeInSeconds** in the **ResourceLimits** API to set an upper limit for the amount of wall clock time that the tuning job may take. Use this field to meet a deadline by which the tuning job must complete or to limit compute resources.

To get an estimated total compute time in seconds for a tuning job, use the following formula:

\[
\text{Estimated max compute time in seconds} = \text{MaxRuntimeInSeconds} \times \text{MaxParallelTrainingJobs} \times \text{MaxInstancesPerTrainingJob}
\]

*Note*

The actual duration of a tuning job may deviate slightly from the value specified in this field.

• Use **TargetObjectiveMetricValue** in the **TuningJobCompletionCriteria** API to stop your tuning job. You stop the tuning job after any training job that is launched by the tuning job reaches this objective metric value. Use this field if your use case depends on reaching a specific performance level, rather than spending compute resources to find the best possible model.

• Use **CompleteOnConvergence** in the **TuningJobCompletionCriteria** API to stop a tuning job after AMT has detected that the tuning job has converged, and is unlikely to make further significant progress. Use this field when it is not clear what values for any of the other completion criteria should be used. AMT determines convergence based on an algorithm developed and tested on a wide range of diverse benchmarks. A tuning job is defined to have converged when none of the training jobs return significant improvement (1% or less). Improvement is measured against the objective metric returned by the highest performing job, so far.

**Combining different completion criteria**

You can also combine any of the different completion criteria in the same tuning job. AMT will stop the tuning job when any one of the completion criteria is met. For example, if you want to tune your model until it meets an objective metric, but don't want to keep tuning if your job has converged, use the following guidance.

• Specify **TargetObjectiveMetricValue** in the **TuningJobCompletionCriteria** API to set a target objective metrics value to reach.

• Set **CompleteOnConvergence** to **Enabled** to stop a tuning job if AMT has determined that model performance is unlikely to improve.

**Track tuning job progress**

You can use the **DescribeHyperParameterTuningJob** API to track the progress of your tuning job at any time while it is running. You don't have to specify completion criteria to obtain tracking information for your tuning job. Use the following fields to obtain statistics about your tuning job.

• **BestTrainingJob** – An object that describes the best training job obtained so far, evaluated against your objective metric. Use this field to check your current model performance and the value of the objective metric of this best training job.

• **ObjectiveStatusCounters** – An object that specifies the total number of training jobs completed in a tuning job. To estimate average duration of a tuning job, use **ObjectiveStatusCounters** and the total runtime of a tuning job. You can use the average duration to estimate how much longer your tuning job will run.

• **ConsumedResources** – The total resources, such as **RunTimeInSeconds**, consumed by your tuning job. Compare **ConsumedResources**, found in the **DescribeHyperParameterTuningJob** API, against **BestTrainingJob** in the same API. You can also compare **ConsumedResources** against the response from the **ListTrainingJobsForHyperParameterTuningJob** API to assess if your tuning job is making satisfactory progress given the resources being consumed.

• **TuningJobCompletionDetails** – Tuning job completion information that includes the following:
• The timestamp of when convergence is detected if the job has converged.
• The number of training jobs that have not improved model performance. Model performance is evaluated against the objective metric from the best training job.

Use the tuning job completion criteria to assess how likely your tuning job is to improve your model performance. Model performance is evaluated against the best objective metric if it ran to completion.

**Stopping your tuning job manually**

You can determine if you should let the tuning job run until it completes or if you should stop the tuning job manually. To determine this, use the information returned by the parameters in the DescribeHyperParameterTuningJob API, as shown in the previous Tracking tuning job progress section. As an example, if your model performance does not improve after several training jobs complete, you may choose to stop the tuning job. Model performance is evaluated against the best objective metric.

To stop the tuning job manually, use the StopHyperParameterTuningJob API and provide the name of the tuning job to be stopped.

**Tune Multiple Algorithms with Hyperparameter Optimization to Find the Best Model**

To create a new hyperparameter optimization (HPO) job with Amazon SageMaker that tunes multiple algorithms, you must provide job settings that apply to all of the algorithms to be tested and a training definition for each of these algorithms. You must also specify the resources you want to use for the tuning job.

• The job settings to configure include warm starting, early stopping, and the tuning strategy. Warm starting and early stopping are available only when tuning a single algorithm.
• The training job definition to specify the name, algorithm source, objective metric, and the range of values, when required, to configure the set of hyperparameter values for each training job. It configures the channels for data inputs, data output locations, and any checkpoint storage locations for each training job. The definition also configures the resources to deploy for each training job, including instance types and counts, managed spot training, and stopping conditions.
• The tuning job resources: to deploy, including the maximum number of concurrent training jobs that a hyperparameter tuning job can run concurrently and the maximum number of training jobs that the hyperparameter tuning job can run.

**Get Started**

You can create a new hyperparameter tuning job, clone a job, add, or edit tags to a job from the console. You can also use the search feature to find jobs by their name, creation time, or status. Alternatively, you can also hyperparameter tuning jobs with the SageMaker API.

• **In the console**: To create a new job, open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/, choose Hyperparameter tuning jobs from the Training menu, and then choose Create hyperparameter tuning job. Then following the configuration steps to create a training job for each algorithm that you want to use. These steps are documented in the Create a Hyperparameter Optimization Tuning Job for One or More Algorithms (Console) topic.

  **Note**
  When you start the configuration steps, note that the warm start and early stopping features are not available to use with multi-algorithm HPO. If you want to use these features, you can only tune a single algorithm at a time.
With the API: For instructions on using the SageMaker API to create a hyperparameter tuning job, see Example: Hyperparameter Tuning Job. When you call CreateHyperParameterTuningJob to tune multiple algorithms, you must provide a list of training definitions using TrainingJobDefinitions instead of specifying a single TrainingJobDefinition. You must provide job settings that apply to all of the algorithms to be tested and a training definition for each of these algorithms. You must also specify the resources that you want to use for the tuning job. Choose only one of these definition types depending on the number of algorithms that are being tuned.

Topics
- Create a Hyperparameter Optimization Tuning Job for One or More Algorithms (Console) (p. 1875)
- Manage Hyperparameter Tuning and Training Jobs (p. 1881)

Create a Hyperparameter Optimization Tuning Job for One or More Algorithms (Console)

This guide shows you how to create a new hyperparameter optimization (HPO) tuning job for one or more algorithms. To create an HPO job, define the settings for the tuning job, and create training job definitions for each algorithm being tuned. Next, configure the resources for and create the tuning job. The following sections provide details about how to complete each step. We provide an example of how to tune multiple algorithms using the SageMaker SDK for Python client at the end of this guide.

Components of a tuning job

An HPO tuning job contains the following three components:

- Tuning job settings
- Training job definitions
- Tuning job configuration

The way that these components are included in your HPO tuning job depends on whether your tuning job contains one or multiple training algorithms. The following guide describes each of the components and gives an example of both types of tuning jobs.

Tuning job settings

Your tuning job settings are applied across all of the algorithms in the HPO tuning job. Warm start and early stopping are available only when you're tuning a single algorithm. After you define the job settings, you can create individual training definitions for each algorithm or variation that you want to tune.

Warm start

If you cloned this job, you can use the results from a previous tuning job to improve the performance of this new tuning job. This is the warm start feature, and it's only available when tuning a single algorithm. With the warm start option, you can choose up to five previous hyperparameter tuning jobs to use. Alternatively, you can use transfer learning to add additional data to the parent tuning job. When you select this option, you choose one previous tuning job as the parent.

Note

Warm start is compatible only with tuning jobs that were created after October 1, 2018. For more information, see Run a warm start job.

Early stopping

To reduce compute time and avoid overfitting your model, you can stop training jobs early. Early stopping is helpful when the training job is unlikely to improve the current best objective metric of
the hyperparameter tuning job. Like warm start, this feature is only available when tuning a single algorithm. This is an automatic feature without configuration options, and it’s disabled by default. For more information about how early stopping works, the algorithms that support it, and how to use it with your own algorithms, see Stop Training Jobs Early.

**Tuning strategy**

Tuning strategy can be either random, Bayesian, or Hyperband. These selections specify how automatic tuning algorithms search specified hyperparameter ranges that are selected in a later step. Random search chooses random combinations of values from the specified ranges and can be run sequentially or in parallel. Bayesian optimization chooses values based on what is likely to get the best result according to the known history of previous selections. Hyperband uses a multi-fidelity strategy that dynamically allocates resources toward well-utilized jobs and automatically stops those that underperform. The new configuration that starts after stopping other configurations is chosen randomly.

Hyperband can only be used with iterative algorithms, or algorithms that run steps in iterations, such as XGBoost or Random Cut Forest. Hyperband can’t be used with non-iterative algorithms, such as decision trees or k-Nearest Neighbors. For more information about search strategies, see How Hyperparameter Tuning Works.

**Note**

Hyperband uses an advanced internal mechanism to apply early stopping. Therefore, when you use the Hyperband internal early stopping feature, the parameter TrainingJobEarlyStoppingType in the HyperParameterTuningJobConfig API must be set to OFF.

**Tags**

To help you manage tuning jobs, you can enter tags as key-value pairs to assign metadata to tuning jobs. Values in the key-value pair are not required. You can use the key without values. To see the keys associated with a job, choose the Tags tab on the details page for tuning job. For more information about using tags for tuning jobs, see Manage Hyperparameter Tuning and Training Jobs (p. 1881).

**Training job definitions**

To create a training job definition, you must configure the algorithm and parameters, define the data input and output, and configure resources. Provide at least one TrainingJobDefinition for each HPO tuning job. Each training definition specifies the configuration for an algorithm.

To create several definitions for your training job, you can clone a job definition. Cloning a job can save time because it copies all of the job settings, including data channels and Amazon S3 storage locations for output artifacts. You can edit a cloned job to change what you need for your use case.

**Topics**

- Configure algorithm and parameters (p. 1876)
- Define data input and output (p. 1877)
- Configure training job resources (p. 1878)
- Add or clone a training job (p. 1878)

**Configure algorithm and parameters**

The following list describes what you need to configure the set of hyperparameter values for each training job.

- A name for your tuning job
- Permission to access services
- Parameters for any algorithm options
• An objective metric
• The range of hyperparameter values, when required

Name
Provide a unique name for the training definition.

Permissions
Amazon SageMaker requires permissions to call other services on your behalf. Choose an AWS Identity and Access Management (IAM) role, or let AWS create a role with the AmazonSageMakerFullAccess IAM policy attached.

Optional security settings
The network isolation setting prevents the container from making any outbound network calls. This is required for AWS Marketplace machine learning offerings.

You can also choose to use a virtual private cloud (VPC).

Note
Inter-container encryption is only available when you create a job definition from the API.

Algorithm options
You can choose built-in algorithms, your own algorithm, your own container with an algorithm, or you can subscribe to an algorithm from AWS Marketplace.

• If you choose a built-in algorithm, it has the Amazon Elastic Container Registry (Amazon ECR) image information pre-populated.
• If you choose your own container, you must specify the (Amazon ECR) image information. You can select the input mode for the algorithm as file or pipe.
• If you plan to supply your data using a CSV file from Amazon S3, you should select the file.

Metrics
When you choose a built-in algorithm, metrics are provided for you. If you choose your own algorithm, you must define your metrics. You can define up to 20 metrics for your tuning job to monitor. You must choose one metric as the objective metric. For more information about how to define a metric for a tuning job, see Define metrics (p. 1866).

Objective metric
To find the best training job, set an objective metric and whether to maximize or minimize it. After the training job is complete, you can view the tuning job detail page. The detail page provides a summary of the best training job that is found using this objective metric.

Hyperparameter configuration
When you choose a built-in algorithm, the default values for its hyperparameters are set for you, using ranges that are optimized for the algorithm that's being tuned. You can change these values as you see fit. For example, instead of a range, you can set a fixed value for a hyperparameter by setting the parameter's type to static. Each algorithm has different required and optional parameters. For more information, see Best Practices for Hyperparameter Tuning and Define Hyperparameter Ranges.

Define data input and output
Each training job definition for a tuning job must configure the channels for data inputs, data output locations, and optionally, any checkpoint storage locations for each training job.
Input data configuration

Input data is defined by channels. Each channel has its own source location (Amazon S3 or Amazon Elastic File System), compression, and format options. You can define up to 20 channels of input sources. If the algorithm that you choose supports multiple input channels, you can specify those, too. For example, when you use the XGBoost churn prediction notebook, you can add two channels: train and validation.

Checkpoint configuration

Checkpoints are periodically generated during training. For the checkpoints to be saved, you must choose an Amazon S3 location. Checkpoints are used in metrics reporting, and are also used to resume managed spot training jobs. For more information, see Use Checkpoints in Amazon SageMaker (p. 2330).

Output data configuration

Define an Amazon S3 location for the artifacts of the training job to be stored. You have the option of adding encryption to the output using an AWS Key Management Service (AWS KMS) key.

Configure training job resources

Each training job definition for a tuning job must configure the resources to deploy, including instance types and counts, managed spot training, and stopping conditions.

Resource configuration

Each training definition can have a different resource configuration. You choose the instance type and number of nodes.

Managed spot training

You can save computer costs for jobs if you have flexibility in start and end times by allowing SageMaker to use spare capacity to run jobs. For more information, see Use Managed Spot Training in Amazon SageMaker (p. 2305).

Stopping condition

The stopping condition specifies the maximum duration that's allowed for each training job.

Add or clone a training job

After you create a training job definition for a tuning job, you will return to the Training Job Definition(s) panel. This panel is where you can create additional training job definitions to train additional algorithms. You can select the Add training job definition and work through the steps to define a training job again.

Alternatively, to replicate an existing training job definition and edit it for the new algorithm, choose Clone from the Action menu. The clone option can save time because it copies all of the job's settings, including the data channels and Amazon S3 storage locations. For more information about cloning, see Manage Hyperparameter Tuning and Training Jobs (p. 1881).

Tuning job configuration

Resource Limits

You can specify the maximum number of concurrent training jobs that a hyperparameter tuning job can run concurrently (10 at most). You can also specify the maximum number of training jobs that the hyperparameter tuning job can run (500 at most). The number of parallel jobs should not exceed the number of nodes that you have requested across all of your training definitions. The total number of jobs can't exceed the number of jobs that your definitions are expected to run.

Review the job settings, the training job definitions, and the resource limits. Then select Create hyperparameter tuning job.
HPO tuning job example

To run a hyperparameter optimization (HPO) training job, first create a training job definition for each algorithm that's being tuned. Next, define the tuning job settings and configure the resources for the tuning job. Finally, run the tuning job.

If your HPO tuning job contains a single training algorithm, the SageMaker tuning function will call the `HyperparameterTuner` API directly and pass in your parameters. If your HPO tuning job contains multiple training algorithms, your tuning function will call the `create` function of the `HyperparameterTuner` API. The `create` function tells the API to expect a dictionary containing one or more estimators.

In the following section, code examples show how to tune a job containing either a single training algorithm or multiple algorithms using the SageMaker Python SDK.

Create training job definitions

When you create a tuning job that includes multiple training algorithms, your tuning job configuration will include the estimators and metrics and other parameters for your training jobs. Therefore, you need to create the training job definition first, and then configure your tuning job.

The following code example shows how to retrieve two SageMaker containers containing the built-in algorithms XGBoost and Linear Learner. If your tuning job contains only one training algorithm, omit one of the containers and one of the estimators.

```python
import sagemaker
from sagemaker import image_uris
from sagemaker.estimator import Estimator

sess = sagemaker.Session()
region = sess.boto_region_name
role = sagemaker.get_execution_role()

bucket = sess.default_bucket()
prefix = "sagemaker/multi-algo-hpo"

# Define the training containers and initialize the estimators
xgb_container = image_uris.retrieve("xgboost", region, "latest")
ll_container = image_uris.retrieve("linear-learner", region, "latest")

xgb_estimator = Estimator(
    xgb_container,
    role=role,
    instance_count=1,
    instance_type="ml.m4.xlarge",
    output_path='s3://{}/xgb_output'.format(bucket, prefix),
    sagemaker_session=sess,
)

ll_estimator = Estimator(
    ll_container,
    role=role,
    instance_count=1,
    instance_type="ml.c4.xlarge",
    output_path='s3://{}/ll_output'.format(bucket, prefix),
    sagemaker_session=sess,
)

# Set static hyperparameters
ll_estimator.set_hyperparameters(predictor_type="binary_classifier")
xgb_estimator.set_hyperparameters(
    eval_metric="auc",
)```
Next, define your input data by specifying the training, validation, and testing datasets, as shown in the following code example. This example shows how to tune multiple training algorithms.

```python
training_data = sagemaker.inputs.TrainingInput(
    s3_data="s3://{}/train".format(bucket, prefix), content_type="csv"
)
validation_data = sagemaker.inputs.TrainingInput(
    s3_data="s3://{}/validate".format(bucket, prefix), content_type="csv"
)
test_data = sagemaker.inputs.TrainingInput(
    s3_data="s3://{}/test".format(bucket, prefix), content_type="csv"
)
train_inputs = {
    "estimator-1": {
        "train": training_data,
        "validation": validation_data,
        "test": test_data,
    },
    "estimator-2": {
        "train": training_data,
        "validation": validation_data,
        "test": test_data,
    },
}
```

If your tuning algorithm contains only one training algorithm, your `train_inputs` should contain only one estimator.

You must upload the inputs for the training, validation, and training datasets to your Amazon S3 bucket before you use those in an HPO tuning job.

### Define resources and settings for your tuning job

This section shows how to initialize a tuner, define resources, and specify job settings for your tuning job. If your tuning job contains multiple training algorithms, these settings are applied to all of the algorithms that are contained inside your tuning job. This section provides two code examples to define a tuner. The code examples show you how to optimize a single training algorithm followed by an example of how to tune multiple training algorithms.

### Tune a single training algorithm

The following code example shows how to initialize a tuner and set hyperparameter ranges for one SageMaker built-in algorithm, XGBoost.

```python
from sagemaker.tuner import HyperparameterTuner
from sagemaker.parameter import ContinuousParameter, IntegerParameter

hyperparameter_ranges = {
    "max_depth": IntegerParameter(1, 10),
    "eta": ContinuousParameter(0.1, 0.3),
}
objective_metric_name = "validation:accuracy"
tuner = HyperparameterTuner(
    xgb_estimator,
    ...
Tune multiple training algorithms

Each training job requires different configurations, and these are specified using a dictionary. The following code example shows how to initialize a tuner with configurations for two SageMaker built-in algorithms, XGBoost and Linear Learner. The code example also shows how to set a tuning strategy and other job settings, such as the compute resources for the tuning job. The following code example uses `metric_definitions_dict`, which is optional.

```python
from sagemaker.tuner import HyperparameterTuner
from sagemaker.parameter import ContinuousParameter, IntegerParameter

# Initialize your tuner
estimator_dict={
    "estimator-1": xgb_estimator,
    "estimator-2": ll_estimator,
},
objective_metric_name_dict={
    "estimator-1": "validation:auc",
    "estimator-2": "test:binary_classification_accuracy",
},
hyperparameter_ranges_dict={
    "estimator-1": {"eta": ContinuousParameter(0.1, 0.3)},
    "estimator-2": {"learning_rate": ContinuousParameter(0.1, 0.3)},
},
metric_definitions_dict={
    "estimator-1": [
        {"Name": "validation:auc", "Regex": "Overall test accuracy: (.*);"}
    ],
    "estimator-2": [
        {"Name": "test:binary_classification_accuracy",
        "Regex": "Overall test accuracy: (.*);"},
    ],
},
strategy="Bayesian",
max_jobs=10,
max_parallel_jobs=3,
)

Run your HPO tuning job

Now you can run your tuning job by passing your training inputs to the `fit` function of the `HyperparameterTuner` class. The following code example shows how to pass the `train_inputs` parameter, that is defined in a previous code example, to your tuner.

```python
tuner.fit(inputs=train_inputs, include_cls_metadata ={}, estimator_kw_args ={})
```

Manage Hyperparameter Tuning and Training Jobs

A tuning job can contain many training jobs and creating and managing these jobs and their definitions can become a complex and onerous task. SageMaker provides tools to help facilitate the management of these jobs. Tuning jobs you have run can be accessed from the Amazon SageMaker console at https://
Example: Hyperparameter Tuning Job

This example shows how to create a new notebook for configuring and launching a hyperparameter tuning job. The tuning job uses the XGBoost Algorithm to train a model to predict whether a customer will enroll for a term deposit at a bank after being contacted by phone.

You use the low-level SDK for Python (Boto3) to configure and launch the hyperparameter tuning job, and the AWS Management Console to monitor the status of hyperparameter tuning jobs. You can also use the Amazon SageMaker high-level Amazon SageMaker Python SDK to configure, run, monitor, and analyze hyperparameter tuning jobs. For more information, see https://github.com/aws/sagemaker-python-sdk.

Prerequisites

To run the code in this example, you need

- An AWS account and an administrator user (p. 9)
- An Amazon S3 bucket for storing your training dataset and the model artifacts created during training
- A running SageMaker notebook instance (p. 299)

Topics

- Create a Notebook Instance (p. 1883)
- Get the Amazon SageMaker Boto 3 Client (p. 1883)
- Get the SageMaker Execution Role (p. 1883)
- Use an Amazon S3 bucket for input and output (p. 1884)
- Download, Prepare, and Upload Training Data (p. 1884)
- Configure and Launch a Hyperparameter Tuning Job (p. 1885)
- Clean up (p. 1893)
Create a Notebook Instance

Create a Jupyter notebook that contains a pre-installed environment with the default Anaconda installation and Python3.

To create a Jupyter notebook

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Open a running notebook instance, by choosing Open next to its name. The Jupyter notebook server page appears:

   ![Jupyter Notebook Server Page]

3. To create a notebook, choose Files, New, and conda_python3.
4. Name the notebook.

Next Step

Get the Amazon SageMaker Boto 3 Client (p. 1883)

Get the Amazon SageMaker Boto 3 Client

Import Amazon SageMaker Python SDK, AWS SDK for Python (Boto3), and other Python libraries. In a new Jupyter notebook, paste the following code to the first cell:

```python
import sagemaker
import boto3
import numpy as np  # For performing matrix operations and numerical processing
import pandas as pd  # For manipulating tabular data
from time import gmtime, strftime
import os
region = boto3.Session().region_name
smclient = boto3.Session().client('sagemaker')
```

The preceding code cell defines region and smclient objects that you will use to call the built-in XGBoost algorithm and set the SageMaker hyperparameter tuning job.

Next Step

Get the SageMaker Execution Role (p. 1883)

Get the SageMaker Execution Role

Get the execution role for the notebook instance. This is the IAM role that you created for your notebook instance. You pass the role to the tuning job.
from sagemaker import get_execution_role
role = get_execution_role()
print(role)

Next Step

Use an Amazon S3 bucket for input and output (p. 1884)

Use an Amazon S3 bucket for input and output

Set up a S3 bucket to upload training datasets and save training output data for your hyperparameter tuning job.

To use a default S3 bucket

Use the following code to specify the default S3 bucket allocated for your SageMaker session. prefix is the path within the bucket where SageMaker stores the data for the current training job.

```python
sess = sagemaker.Session()
bucket = sess.default_bucket()  # Set a default S3 bucket
prefix = 'DEMO-automatic-model-tuning-xgboost-dm'
```

To use a specific S3 bucket (Optional)

If you want to use a specific S3 bucket, use the following code and replace the strings to the exact name of the S3 bucket. The name of the bucket must contain `sagemaker`, and be globally unique. The bucket must be in the same AWS Region as the notebook instance that you use for this example.

```python
bucket = "sagemaker-your-preferred-s3-bucket"

sess = sagemaker.Session(
    default_bucket = bucket
)
```

Note

The name of the bucket doesn't need to contain `sagemaker` if the IAM role that you use to run the hyperparameter tuning job has a policy that gives the `S3FullAccess` permission.

Next Step

Download, Prepare, and Upload Training Data (p. 1884)

Download, Prepare, and Upload Training Data

For this example, you use a training dataset of information about bank customers that includes the customer's job, marital status, and how they were contacted during the bank's direct marketing campaign. To use a dataset for a hyperparameter tuning job, you download it, transform the data, and then upload it to an Amazon S3 bucket.

For more information about the dataset and the data transformation that the example performs, see the `hpo_xgboost_direct_marketing_sagemaker_APIs` notebook in the Hyperparameter Tuning section of the SageMaker Examples tab in your notebook instance.

Download and Explore the Training Dataset

To download and explore the dataset, run the following code in your notebook:
Example: Hyperparameter Tuning Job

Prepare and Upload Data

Before creating the hyperparameter tuning job, prepare the data and upload it to an S3 bucket where the hyperparameter tuning job can access it.

Run the following code in your notebook:

```
!unzip -o bank-additional.zip
data = pd.read_csv('./bank-additional/bank-additional-full.csv', sep=';')
pd.set_option('display.max_columns', 500)  # Make sure we can see all of the columns
pd.set_option('display.max_rows', 5)     # Keep the output on one page
data
```

Prepare and Upload Data

Before creating the hyperparameter tuning job, prepare the data and upload it to an S3 bucket where the hyperparameter tuning job can access it.

Run the following code in your notebook:

```
data['no_previous_contact'] = np.where(data['pdays'] == 999, 1, 0)  # Indicator variable to capture when pdays takes a value of 999
data['not_working'] = np.where(np.in1d(data['job'], ['student', 'retired', 'unemployed']), 1, 0)  # Indicator for individuals not actively employed
model_data = pd.get_dummies(data)  # Convert categorical variables to sets of indicators
model_data
model_data = model_data.drop(['duration', 'emp.var.rate', 'cons.price.idx', 'cons.conf.idx', 'euribor3m', 'nr.employed'], axis=1)
train_data, validation_data, test_data = np.split(model_data.sample(frac=1, random_state=1729), [int(0.7 * len(model_data)), int(0.9*len(model_data))])
pd.concat([train_data['y_yes'], train_data.drop(['y_no', 'y_yes'], axis=1), axis=1]).to_csv('train.csv', index=False, header=False)
pd.concat([validation_data['y_yes'], validation_data.drop(['y_no', 'y_yes'], axis=1), axis=1]).to_csv('validation.csv', index=False, header=False)
pd.concat([test_data['y_yes'], test_data.drop(['y_no', 'y_yes'], axis=1), axis=1]).to_csv('validation.csv', index=False, header=False)
boto3.Session().resource('s3').Bucket(bucket).Object(os.path.join(prefix, 'train/train.csv')).upload_file('train.csv')
boto3.Session().resource('s3').Bucket(bucket).Object(os.path.join(prefix, 'validation/validation.csv')).upload_file('validation.csv')
```

Next Step

Configure and Launch a Hyperparameter Tuning Job (p. 1885)

Configure and Launch a Hyperparameter Tuning Job

A hyperparameter is a high-level parameter that influences the learning process during model training. To get the best model predictions, you can optimize a hyperparameter configuration or set hyperparameter values. The process of finding an optimal configuration is called hyperparameter tuning. To configure and launch a hyperparameter tuning job, complete the steps in these guides.

Topics

- Settings for the hyperparameter tuning job (p. 1886)
- Configure the training jobs (p. 1887)
- Name and launch the hyperparameter tuning job (p. 1889)
- Monitor the Progress of a Hyperparameter Tuning Job (p. 1890)
- View the Status of the Training Jobs (p. 1892)
- View the Best Training Job (p. 1893)
Settings for the hyperparameter tuning job

To specify settings for the hyperparameter tuning job, define a JSON object when you create the tuning job. Pass this JSON object as the value of the `HyperParameterTuningJobConfig` parameter to the `CreateHyperParameterTuningJob` API.

In this JSON object, specify the following:

- **HyperParameterTuningJobObjective** – The objective metric used to evaluate the performance of the training job launched by the hyperparameter tuning job.
- **ParameterRanges** – The range of values that a tunable hyperparameter can use during optimization. For more information, see Define Hyperparameter Ranges (p. 1868)
- **RandomSeed** – A value used to initialize a pseudo-random number generator. Setting a random seed will allow the hyperparameter tuning search strategies to produce more consistent configurations for the same tuning job (optional).
- **ResourceLimits** – The maximum number of training and parallel training jobs that the hyperparameter tuning job can use.

**Note**

If you use your own algorithm for hyperparameter tuning, rather than a SageMaker built-in algorithm, you must define metrics for your algorithm. For more information, see Define metrics (p. 1866).

The following code example shows how to configure a hyperparameter tuning job using the built-in XGBoost algorithm. The code example shows how to define ranges for the `eta`, `alpha`, `min_child_weight`, and `max_depth` hyperparameters. For more information about these and other hyperparameters see XGBoost Parameters.

In this code example, the objective metric for the hyperparameter tuning job finds the hyperparameter configuration that maximizes `validation:auc`. SageMaker built-in algorithms automatically write the objective metric to CloudWatch Logs. The following code example also shows how to set a RandomSeed.

```json
tuning_job_config = {
    "ParameterRanges": {
        "CategoricalParameterRanges": [],
        "ContinuousParameterRanges": [
            {
                "MaxValue": "1",
                "MinValue": "0",
                "Name": "eta"
            },
            {
                "MaxValue": "2",
                "MinValue": "0",
                "Name": "alpha"
            },
            {
                "MaxValue": "10",
                "MinValue": "1",
                "Name": "min_child_weight"
            }
        ],
        "IntegerParameterRanges": [
            {
                "MaxValue": "10",
                "MinValue": "1",
                "Name": "max_depth"
            }
        ]
    }
}
```
Example: Hyperparameter Tuning Job

},
"ResourceLimits": {
    "MaxNumberOfTrainingJobs": 20,
    "MaxParallelTrainingJobs": 3
},
"Strategy": "Bayesian",
"HyperParameterTuningJobObjective": {
    "MetricName": "validation:auc",
    "Type": "Maximize"
},
"RandomSeed" : 123
}

Configure the training jobs

The hyperparameter tuning job will launch training jobs to find an optimal configuration of hyperparameters. These training jobs should be configured using the SageMaker CreateHyperParameterTuningJob API.

To configure the training jobs, define a JSON object and pass it as the value of the TrainingJobDefinition parameter inside CreateHyperParameterTuningJob.

In this JSON object, you can specify the following:

- **AlgorithmSpecification** – The registry path of the Docker image containing the training algorithm and related metadata. To specify an algorithm, you can use your own custom built algorithm inside a Docker container or a SageMaker built-in algorithm (required).
- **InputDataConfig** – The input configuration, including the ChannelName, ContentType, and data source for your training and test data (required).
- **InputDataConfig** – The input configuration, including the ChannelName, ContentType, and data source for your training and test data (required).
- The storage location for the algorithm's output. Specify the S3 bucket where you want to store the output of the training jobs.
- **RoleArn** – The Amazon Resource Name (ARN) of an AWS Identity and Access Management (IAM) role that SageMaker uses to perform tasks. Tasks include reading input data, downloading a Docker image, writing model artifacts to an S3 bucket, writing logs to Amazon CloudWatch Logs, and writing metrics to Amazon CloudWatch (required).
- **StoppingCondition** – The maximum runtime in seconds that a training job can run before being stopped. This value should be greater than the time needed to train your model (required).
- **MetricDefinitions** – The name and regular expression that defines any metrics that the training jobs emit. Define metrics only when you use a custom training algorithm. The example in the following code uses a built-in algorithm, which already has metrics defined. For information about defining metrics (optional), see Define metrics (p. 1866).
- **TrainingImage** – The Docker container image that specifies the training algorithm (optional).
- **StaticHyperParameters** – The name and values of hyperparameters that are not tuned in the tuning job (optional).

The following code example sets static values for the eval_metric, num_round, objective, rate_drop, and tweedie_variance_power parameters of the XGBoost Algorithm (p. 1617) built-in algorithm.

SageMaker Python SDK v1

```python
from sagemaker.amazon.amazon_estimator import get_image_uri
training_image = get_image_uri(region, 'xgboost', repo_version='1.0-1')
```
s3_input_train = 's3:///{}/train'.format(bucket, prefix)
s3_input_validation = 's3:///{}/validation/'.format(bucket, prefix)

training_job_definition = {
    "AlgorithmSpecification": {
        "TrainingImage": training_image,
        "TrainingInputMode": "File"
    },
    "InputDataConfig": [
        {
            "ChannelName": "train",
            "CompressionType": "None",
            "ContentType": "csv",
            "DataSource": {
                "S3DataSource": {
                    "S3DataDistributionType": "FullyReplicated",
                    "S3DataType": "S3Prefix",
                    "S3Uri": s3_input_train
                }
            }
        },
        {
            "ChannelName": "validation",
            "CompressionType": "None",
            "ContentType": "csv",
            "DataSource": {
                "S3DataSource": {
                    "S3DataDistributionType": "FullyReplicated",
                    "S3DataType": "S3Prefix",
                    "S3Uri": s3_input_validation
                }
            }
        }
    ],
    "OutputDataConfig": {
        "S3OutputPath": "s3://{}/output".format(bucket, prefix)
    },
    "ResourceConfig": {
        "InstanceCount": 2,
        "InstanceType": "ml.c4.2xlarge",
        "VolumeSizeInGB": 10
    },
    "RoleArn": role,
    "StaticHyperParameters": {
        "eval_metric": "auc",
        "num_round": "100",
        "objective": "binary:logistic",
        "rate_drop": "0.3",
        "tweedie_variance_power": "1.4"
    },
    "StoppingCondition": {
        "MaxRuntimeInSeconds": 43200
    }
}

Training image:

```
sagemaker.image_uris.retrieve('xgboost', region, '1.0-1')
```

Example: Hyperparameter Tuning Job

```
s3_input_train = 's3:///{}/train'.format(bucket, prefix)
s3_input_validation = 's3:///{}/validation/'.format(bucket, prefix)

training_job_definition = {
    "AlgorithmSpecification": {
```
"TrainingImage": training_image,
"TrainingInputMode": "File"
],
"InputDataConfig": [
{
"ChannelName": "train",
"CompressionType": "None",
"ContentType": "csv",
"DataSource": {
  "S3DataSource": {
    "S3DataDistributionType": "FullyReplicated",
    "S3DataType": "S3Prefix",
    "S3Uri": s3_input_train
  }
}
},
{
"ChannelName": "validation",
"CompressionType": "None",
"ContentType": "csv",
"DataSource": {
  "S3DataSource": {
    "S3DataDistributionType": "FullyReplicated",
    "S3DataType": "S3Prefix",
    "S3Uri": s3_input_validation
  }
}
},
"OutputDataConfig": {
  "S3OutputPath": "s3:///{}/output".format(bucket,prefix)
},
"ResourceConfig": {
  "InstanceCount": 2,
  "InstanceType": "ml.c4.2xlarge",
  "VolumeSizeInGB": 10
},
"RoleArn": role,
"StaticHyperParameters": {
  "eval_metric": "auc",
  "num_round": "100",
  "objective": "binary:logistic",
  "rate_drop": "0.3",
  "tweedie_variance_power": "1.4"
},
"StoppingCondition": {
  "MaxRuntimeInSeconds": 43200
}
}

Name and launch the hyperparameter tuning job

After you configure the hyperparameter tuning job, you can launch it by calling the
CreateHyperParameterTuningJob API. The following code example uses tuning_job_config
and training_job_definition. These were defined in the previous two code examples to create a
hyperparameter tuning job.

```
tuning_job_name = "MyTuningJob"
smclient.create_hyper_parameter_tuning_job(HyperParameterTuningJobName = tuning_job_name,
   HyperParameterTuningJobConfig = tuning_job_config,
   TrainingJobDefinition = training_job_definition)
```
Monitor the Progress of a Hyperparameter Tuning Job

To monitor the progress of a hyperparameter tuning job and the training jobs that it launches, use the Amazon SageMaker console.

Topics
- View the Status of the Hyperparameter Tuning Job (p. 1890)

View the Status of the Hyperparameter Tuning Job

To view the status of the hyperparameter tuning job

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Choose Hyperparameter tuning jobs.
Amazon SageMaker Developer Guide
Example: Hyperparameter Tuning Job

SageMaker Domain
- Studio
- RStudio
- Canvas

Images
- Ground Truth
- Notebook
- Processing
- Training
  - Algorithms
  - Training jobs
    - Hyperparameter tuning jobs
- Inference
- Edge Manager
- Augmented AI
- AWS Marketplace
3. In the list of hyperparameter tuning jobs, check the status of the hyperparameter tuning job you launched. A tuning job can be:

- **Completed**—The hyperparameter tuning job successfully completed.
- **InProgress**—The hyperparameter tuning job is in progress. One or more training jobs are still running.
- **Failed**—The hyperparameter tuning job failed.
- **Stopped**—The hyperparameter tuning job was manually stopped before it completed. All training jobs that the hyperparameter tuning job launched are stopped.
- **Stopping**—The hyperparameter tuning job is in the process of stopping.

### View the Status of the Training Jobs

**To view the status of the training jobs that the hyperparameter tuning job launched**

1. In the list of hyperparameter tuning jobs, choose the job that you launched.
2. Choose **Training jobs**.

![Training job status counter](image)

3. View the status of each training job. To see more details about a job, choose it in the list of training jobs. To view a summary of the status of all of the training jobs that the hyperparameter tuning job launched, see **Training job status counter**.

A training job can be:

- **Completed**—The training job successfully completed.
- **InProgress**—The training job is in progress.
- **Stopped**—The training job was manually stopped before it completed.
- **Failed (Retryable)**—The training job failed, but can be retried. A failed training job can be retried only if it failed because an internal service error occurred.
- **Failed (Non-retryable)**—The training job failed and can't be retried. A failed training job can't be retried when a client error occurs.
Note
Hyperparameter tuning jobs can be stopped and the underlying resources deleted, but the jobs themselves cannot be deleted.

View the Best Training Job

A hyperparameter tuning job uses the objective metric that each training job returns to evaluate training jobs. While the hyperparameter tuning job is in progress, the best training job is the one that has returned the best objective metric so far. After the hyperparameter tuning job is complete, the best training job is the one that returned the best objective metric.

To view the best training job, choose **Best training job**.

To deploy the best training job as a model that you can host at a SageMaker endpoint, choose **Create model**.

Next Step

**Clean up (p. 1893)**

Clean up

To avoid incurring unnecessary charges, when you are done with the example, use the AWS Management Console to delete the resources that you created for it.

**Note**
If you plan to explore other examples, you might want to keep some of these resources, such as your notebook instance, S3 bucket, and IAM role.

1. Open the SageMaker console at https://console.aws.amazon.com/sagemaker/ and delete the notebook instance. Stop the instance before deleting it.
2. Open the Amazon S3 console at https://console.aws.amazon.com/s3/ and delete the bucket that you created to store model artifacts and the training dataset.
3. Open the IAM console at https://console.aws.amazon.com/iam/ and delete the IAM role. If you created permission policies, you can delete them, too.

4. Open the Amazon CloudWatch console at https://console.aws.amazon.com/cloudwatch/ and delete all of the log groups that have names starting with /aws/sagemaker/.

Stop Training Jobs Early

Stop the training jobs that a hyperparameter tuning job launches early when they are not improving significantly as measured by the objective metric. Stopping training jobs early can help reduce compute time and helps you avoid overfitting your model. To configure a hyperparameter tuning job to stop training jobs early, do one of the following:

- If you are using the AWS SDK for Python (Boto3), set the TrainingJobEarlyStoppingType field of the HyperParameterTuningJobConfig object that you use to configure the tuning job to AUTO.
- If you are using the Amazon SageMaker Python SDK, set the early_stopping_type parameter of the HyperParameterTuner object to Auto.
- In the Amazon SageMaker console, in the Create hyperparameter tuning job workflow, under Early stopping, choose Auto.

For a sample notebook that demonstrates how to use early stopping, see https://github.com/awslabs/amazon-sagemaker-examples/blob/master/hyperparameter_tuning/image_classification_early_stopping/hpo_image_classification_early_stopping.ipynb or open the hpo_image_classification_early_stopping.ipynb notebook in the Hyperparameter Tuning section of the SageMaker Examples in a notebook instance. For information about using sample notebooks in a notebook instance, see Example Notebooks (p. 330).

How Early Stopping Works

When you enable early stopping for a hyperparameter tuning job, SageMaker evaluates each training job the hyperparameter tuning job launches as follows:

- After each epoch of training, get the value of the objective metric.
- Compute the running average of the objective metric for all previous training jobs up to the same epoch, and then compute the median of all of the running averages.
- If the value of the objective metric for the current training job is worse (higher when minimizing or lower when maximizing the objective metric) than the median value of running averages of the objective metric for previous training jobs up to the same epoch, SageMaker stops the current training job.

Algorithms That Support Early Stopping

To support early stopping, an algorithm must emit objective metrics for each epoch. The following built-in SageMaker algorithms support early stopping:

- LightGBM (p. 1583)
- CatBoost (p. 1556)
- AutoGluon-Tabular (p. 1548)
- TabTransformer (p. 1610)
- Linear Learner Algorithm (p. 1593)—Supported only if you use objective_loss as the objective metric.
Run a Warm Start Hyperparameter Tuning Job

Use warm start to start a hyperparameter tuning job using one or more previous tuning jobs as a starting point. The results of previous tuning jobs are used to inform which combinations of hyperparameters to search over in the new tuning job. Hyperparameter tuning uses either Bayesian or random search to choose combinations of hyperparameter values from ranges that you specify. For more information, see How Hyperparameter Tuning Works (p. 1864). Using information from previous hyperparameter tuning jobs can help increase the performance of the new hyperparameter tuning job by making the search for the best combination of hyperparameters more efficient.

Note
Warm start tuning jobs typically take longer to start than standard hyperparameter tuning jobs, because the results from the parent jobs have to be loaded before the job can start. The increased time depends on the total number of training jobs launched by the parent jobs.

Reasons to consider warm start include the following:

• To gradually increase the number of training jobs over several tuning jobs based on results after each iteration.
• To tune a model using new data that you received.
- To change hyperparameter ranges that you used in a previous tuning job, change static hyperparameters to tunable, or change tunable hyperparameters to static values.
- You stopped a previous hyperparameter job early or it stopped unexpectedly.

Topics
- Types of Warm Start Tuning Jobs (p. 1896)
- Warm Start Tuning Restrictions (p. 1896)
- Warm Start Tuning Sample Notebook (p. 1897)
- Create a Warm Start Tuning Job (p. 1897)

Types of Warm Start Tuning Jobs

There are two different types of warm start tuning jobs:

IDENTICAL_DATA_AND_ALGORITHM

The new hyperparameter tuning job uses the same input data and training image as the parent tuning jobs. You can change the hyperparameter ranges to search and the maximum number of training jobs that the hyperparameter tuning job launches. You can also change hyperparameters from tunable to static, and from static to tunable, but the total number of static plus tunable hyperparameters must remain the same as it is in all parent jobs. You cannot use a new version of the training algorithm, unless the changes in the new version do not affect the algorithm itself. For example, changes that improve logging or adding support for a different data format are allowed.

Use identical data and algorithm when you use the same training data as you used in a previous hyperparameter tuning job, but you want to increase the total number of training jobs or change ranges or values of hyperparameters.

When you run an warm start tuning job of type IDENTICAL_DATA_AND_ALGORITHM, there is an additional field in the response to DescribeHyperParameterTuningJob named OverallBestTrainingJob. The value of this field is the TrainingJobSummary for the training job with the best objective metric value of all training jobs launched by this tuning job and all parent jobs specified for the warm start tuning job.

TRANSFER_LEARNING

The new hyperparameter tuning job can include input data, hyperparameter ranges, maximum number of concurrent training jobs, and maximum number of training jobs that are different than those of its parent hyperparameter tuning jobs. You can also change hyperparameters from tunable to static, and from static to tunable, but the total number of static plus tunable hyperparameters must remain the same as it is in all parent jobs. The training algorithm image can also be a different version from the version used in the parent hyperparameter tuning job. When you use transfer learning, changes in the dataset or the algorithm that significantly affect the value of the objective metric might reduce the usefulness of using warm start tuning.

Warm Start Tuning Restrictions

The following restrictions apply to all warm start tuning jobs:

- A tuning job can have a maximum of 5 parent jobs, and all parent jobs must be in a terminal state (Completed, Stopped, or Failed) before you start the new tuning job.
- The objective metric used in the new tuning job must be the same as the objective metric used in the parent jobs.
• The total number of static plus tunable hyperparameters must remain the same between parent jobs and the new tuning job. Because of this, if you think you might want to use a hyperparameter as tunable in a future warm start tuning job, you should add it as a static hyperparameter when you create a tuning job.

• The type of each hyperparameter (continuous, integer, categorical) must not change between parent jobs and the new tuning job.

• The number of total changes from tunable hyperparameters in the parent jobs to static hyperparameters in the new tuning job, plus the number of changes in the values of static hyperparameters cannot be more than 10. For example, if the parent job has a tunable categorical hyperparameter with the possible values red and blue, you change that hyperparameter to static in the new tuning job, that counts as 2 changes against the allowed total of 10. If the same hyperparameter had a static value of red in the parent job, and you change the static value to blue in the new tuning job, it also counts as 2 changes.

• Warm start tuning is not recursive. For example, if you create MyTuningJob3 as a warm start tuning job with MyTuningJob2 as a parent job, and MyTuningJob2 is itself an warm start tuning job with a parent job MyTuningJob1, the information that was learned when running MyTuningJob1 is not used for MyTuningJob3. If you want to use the information from MyTuningJob1, you must explicitly add it as a parent for MyTuningJob3.

• The training jobs launched by every parent job in a warm start tuning job count against the 500 maximum training jobs for a tuning job.

• Hyperparameter tuning jobs created before October 1, 2018 cannot be used as parent jobs for warm start tuning jobs.

Warm Start Tuning Sample Notebook

For a sample notebook that shows how to use warm start tuning, see https://github.com/awslabs/amazon-sagemaker-examples/blob/master/hyperparameter_tuning/image_classification_warmstart/hpo_image_classification_warmstart.ipynb. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Example Notebooks (p. 330). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The warm start tuning example notebook is located in the Hyperparameter tuning section, and is named hpo_image_classification_warmstart.ipynb. To open a notebook, click on its Use tab and select Create copy.

Create a Warm Start Tuning Job

You can use either the low-level AWS SDK for Python (Boto 3) or the high-level SageMaker Python SDK to create a warm start tuning job.

Topics

• Create a Warm Start Tuning Job (Low-level SageMaker API for Python (Boto 3)) (p. 1897)
• Create a Warm Start Tuning Job (SageMaker Python SDK) (p. 1898)

Create a Warm Start Tuning Job (Low-level SageMaker API for Python (Boto 3))

To use warm start tuning, you specify the values of a HyperParameterTuningJobWarmStartConfig object, and pass that as the WarmStartConfig field in a call to CreateHyperParameterTuningJob.

The following code shows how to create a HyperParameterTuningJobWarmStartConfig object and pass it to CreateHyperParameterTuningJob job by using the low-level SageMaker API for Python (Boto 3).

Create the HyperParameterTuningJobWarmStartConfig object:
Create the warm start tuning job:

```python
smclient = boto3.Session().client('sagemaker')
smclient.create_hyper_parameter_tuning_job(HyperParameterTuningJobName = 'MyWarmStartTuningJob',
    HyperParameterTuningJobConfig = tuning_job_config, # See notebook for tuning configuration
    TrainingJobDefinition = training_job_definition, # See notebook for job definition
    WarmStartConfig = warm_start_config)
```

### Create a Warm Start Tuning Job (SageMaker Python SDK)

To use the Amazon SageMaker Python SDK to run a warm start tuning job, you:

- Specify the parent jobs and the warm start type by using a WarmStartConfig object.
- Pass the WarmStartConfig object as the value of the `warm_start_config` argument of a `HyperparameterTuner` object.
- Call the `fit` method of the `HyperparameterTuner` object.

For more information about using the Amazon SageMaker Python SDK for hyperparameter tuning, see [https://github.com/aws/sagemaker-python-sdk#sagemaker-automatic-model-tuning](https://github.com/aws/sagemaker-python-sdk#sagemaker-automatic-model-tuning).

This example uses an estimator that uses the Image Classification - MXNet (p. 1754) algorithm for training. The following code sets the hyperparameter ranges that the warm start tuning job searches within to find the best combination of values. For information about setting hyperparameter ranges, see Define Hyperparameter Ranges (p. 1868).

```python
hyperparameter_ranges = {'learning_rate': ContinuousParameter(0.0, 0.1),
                        'momentum': ContinuousParameter(0.0, 0.99)}
```

The following code configures the warm start tuning job by creating a WarmStartConfig object.

```python
from sagemaker.tuner import WarmStartConfig, WarmStartTypes
parent_tuning_job_name = "MyParentTuningJob"
warm_start_config = WarmStartConfig(warm_start_type=WarmStartTypes.IDENTICAL_DATA_AND_ALGORITHM,
                                  parents=[parent_tuning_job_name])
```

Now set the values for static hyperparameters, which are hyperparameters that keep the same value for every training job that the warm start tuning job launches. In the following code, `imageclassification` is an estimator that was created previously.

```python
imageclassification.set_hyperparameters(num_layers=18,
                                      image_shape='3,224,224',
                                      num_classes=257,
                                      num_training_samples=15420,
                                      mini_batch_size=128,
                                      )
```
Now create the `HyperparameterTuner` object and pass the `WarmStartConfig` object that you previously created as the `warm_start_config` argument.

```python
tuner_warm_start = HyperparameterTuner(imageclassification,
    'validation:accuracy',
    hyperparameter_ranges,
    objective_type='Maximize',
    max_jobs=10,
    max_parallel_jobs=2,
    base_tuning_job_name='warmstart',
    warm_start_config=warm_start_config)
```

Finally, call the `fit` method of the `HyperparameterTuner` object to launch the warm start tuning job.

```python
tuner_warm_start.fit(
    {'train': s3_input_train, 'validation': s3_input_validation},
    include_cls_metadata=False)
```

### Resource Limits for Automatic Model Tuning

SageMaker sets the following default limits for resources used by automatic model tuning:

<table>
<thead>
<tr>
<th>Resource</th>
<th>Regions</th>
<th>Default limits</th>
<th>Can be increased to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of parallel (concurrent) hyperparameter tuning jobs</td>
<td>All</td>
<td>100</td>
<td>N/A</td>
</tr>
<tr>
<td>Number of hyperparameters that can be searched *</td>
<td>All</td>
<td>30</td>
<td>N/A</td>
</tr>
<tr>
<td>Number of metrics defined per hyperparameter tuning job</td>
<td>All</td>
<td>20</td>
<td>N/A</td>
</tr>
<tr>
<td>Number of parallel training jobs per hyperparameter tuning job</td>
<td>All</td>
<td>10</td>
<td>100</td>
</tr>
<tr>
<td>[Bayesian optimization] Number of training jobs per hyperparameter tuning job</td>
<td>All</td>
<td>750</td>
<td>N/A</td>
</tr>
<tr>
<td>[Random search] Number of training jobs</td>
<td>All</td>
<td>750</td>
<td>10000</td>
</tr>
<tr>
<td>Resource</td>
<td>Regions</td>
<td>Default limits</td>
<td>Can be increased to</td>

* Each categorical hyperparameter can have at most 30 different values.

**Resource limit example**

When you plan hyperparameter tuning jobs, you also have to take into account the limits on training resources. For information about the default resource limits for SageMaker training jobs, see SageMaker Limits. Every concurrent training instance on which all of your hyperparameter tuning jobs run counts against the total number of training instances allowed. For example, if you run 10 concurrent hyperparameter tuning jobs, each of those hyperparameter tuning jobs runs 100 total training jobs and 20 concurrent training jobs. Each of those training jobs runs on one ml.m4.xlarge instance. The following limits apply:

- Number of concurrent hyperparameter tuning jobs: You don't need to increase the limit, because 10 tuning jobs is below the limit of 100.
- Number of training jobs per hyperparameter tuning job: You don't need to increase the limit, because 100 training jobs is below the limit of 750.
- Number of concurrent training jobs per hyperparameter tuning job: You need to request a limit increase to 20, because the default limit is 10.
- SageMaker training ml.m4.xlarge instances: You need to request a limit increase to 200, because you have 10 hyperparameter tuning jobs, each of which is running 20 concurrent training jobs. The default limit is 20 instances.
- SageMaker training total instance count: You need to request a limit increase to 200, because you have 10 hyperparameter tuning jobs, each of which is running 20 concurrent training jobs. The default limit is 20 instances.

**To request a quota increase:**

1. Open the AWS Support Center page, sign in if necessary, and then choose Create case.
2. On the Create case page, choose Service limit increase.
3. On the Case details panel, select SageMaker Automatic Model Tuning [Hyperparameter Optimization] for the Limit type
4. On the Requests panel for Request 1, select the Region, the resource Limit to increase and the New Limit value you are requesting. Select Add another request if you have additional requests for quota increases.
In the **Case description** panel, provide a description of your use case.

6. In the **Contact options** panel, select your preferred **Contact methods** (Web, Chat or Phone) and then choose **Submit**.

### Best Practices for Hyperparameter Tuning

Hyperparameter optimization (HPO) is not a fully-automated process. To improve optimization, follow these best practices for hyperparameter tuning.

**Topics**

- [Choosing a tuning strategy](#)
- [Choosing the number of hyperparameters](#)
- [Choosing hyperparameter ranges](#)
- [Using the correct scales for hyperparameters](#)
- [Choosing the best number of parallel training jobs](#)
- [Running training jobs on multiple instances](#)
- [Using a random seed to reproduce hyperparameter configurations](#)

### Choosing a tuning strategy

For large jobs, using the **Hyperband** tuning strategy can reduce computation time. Hyperband has an early stopping mechanism to stop under-performing jobs. Hyperband can also reallocate resources...
towards well-utilized hyperparameter configurations and run parallel jobs. For smaller training jobs using less runtime, use either random search or Bayesian optimization.

Use Bayesian optimization to make increasingly informed decisions about improving hyperparameter configurations in the next run. Bayesian optimization uses information gathered from prior runs to improve subsequent runs. Because of its sequential nature, Bayesian optimization cannot massively scale.

Use random search to run a large number of parallel jobs. In random search, subsequent jobs do not depend on the results from prior jobs and can be run independently. Compared to other strategies, random search is able to run the largest number of parallel jobs.

Use grid search to reproduce results of a tuning job, or if simplicity and transparency of the optimization algorithm are important. You can also use grid search to explore the entire hyperparameter search space evenly. Grid search methodically searches through every hyperparameter combination to find optimal hyperparameter values. Unlike grid search, Bayesian optimization, random search and Hyperband all draw hyperparameters randomly from the search space. Because grid search analyzes every combination of hyperparameters, optimal hyperparameter values will be identical between tuning jobs that use the same hyperparameters.

Choosing the number of hyperparameters

During optimization, the computational complexity of a hyperparameter tuning job depends on the following:

- The number of hyperparameters
- The range of values that Amazon SageMaker has to search

Although you can simultaneously specify up to 30 hyperparameters, limiting your search to a smaller number can reduce computation time. Reducing computation time allows SageMaker to converge more quickly to an optimal hyperparameter configuration.

Choosing hyperparameter ranges

The range of values that you choose to search can adversely affect hyperparameter optimization. For example, a range that covers every possible hyperparameter value can lead to large compute times and a model that doesn't generalize well to unseen data. If you know that using a subset of the largest possible range is appropriate for your use case, consider limiting the range to that subset.

Using the correct scales for hyperparameters

During hyperparameter tuning, SageMaker attempts to infer if your hyperparameters are log-scaled or linear-scaled. Initially, SageMaker assumes linear scaling for hyperparameters. If hyperparameters are log-scaled, choosing the correct scale will make your search more efficient. You can also select Auto for ScalingType in the CreateHyperParameterTuningJob API if you want SageMaker to detect the scale for you.

Choosing the best number of parallel training jobs

You can use the results of previous trials to improve the performance of subsequent trials. Choose the largest number of parallel jobs that would provide a meaningful incremental result that is also within your region and account compute constraints. Use the MaxParallelTrainingJobs field to limit the number of training jobs that a hyperparameter tuning job can launch in parallel. For more information, see Running multiple HPO jobs in parallel on Amazon SageMaker.
Running training jobs on multiple instances

When a training job runs on multiple machines in distributed mode, each machine emits an objective metric. HPO can only use one of these emitted objective metrics to evaluate model performance. In distributed mode, HPO uses the objective metric that was reported by the last running job across all instances.

Using a random seed to reproduce hyperparameter configurations

You can specify an integer as a random seed for hyperparameter tuning and use that seed during hyperparameter generation. Later, you can use the same seed to reproduce hyperparameter configurations that are consistent with your previous results. For random search and Hyperband strategies, using the same random seed can provide up to 100% reproducibility of the previous hyperparameter configuration for the same tuning job. For Bayesian strategy, using the same random seed will improve reproducibility for the same tuning job.

Debug and improve model performance

The essence of training machine learning models, deep learning neural networks, transformer models is in achieving stable model convergence, and as such, state-of-the-art models have millions, billions, or trillions of model parameters. The number of operations to update the gigantic number of model parameters during each iteration can easily become astronomical. To identify model convergence issues, it is important to be able to access the model parameters, activations, and gradients computed during optimization processes.

Amazon SageMaker provides two debugging tools to help identify such convergence issues and gain visibility into your models.

Amazon SageMaker with TensorBoard

To offer a greater compatibility with the open-source community tools within the SageMaker Training platform, SageMaker hosts TensorBoard as an application in SageMaker Domain. You can bring your training jobs to SageMaker and keep using the TensorBoard summary writer to collect the model output tensors. Because TensorBoard is implemented into SageMaker Domain, it also gives you more options to manage user profiles under the SageMaker Domain in your AWS account, and provides fine control over the user profiles by granting access to specific actions and resources. To learn more, see the section called “Use TensorBoard” (p. 1904).

Amazon SageMaker Debugger

Amazon SageMaker Debugger is a capability of SageMaker that provides tools to register hooks to callbacks to extract model output tensors and save them in Amazon Simple Storage Service. It provides built-in rules for detecting model convergence issues, such as overfitting, saturated activation functions, vanishing gradients, and more. You can also set up the built-in rules with Amazon CloudWatch Events and AWS Lambda for taking automated actions against detected issues, and set up Amazon Simple Notification Service to receive email or text notifications. To learn more, see the section called “Use SageMaker Debugger” (p. 1916).

Topics

- Use TensorBoard to debug and analyze training jobs in Amazon SageMaker (p. 1904)
- Use Amazon SageMaker Debugger to debug and improve model performance (p. 1916)
- Release notes for debugging capabilities of Amazon SageMaker (p. 2035)
Use TensorBoard to debug and analyze training jobs in Amazon SageMaker

Amazon SageMaker with TensorBoard is a capability of Amazon SageMaker that brings the visualization tools of TensorBoard to SageMaker, integrated with SageMaker Training and Domain. It provides options to administer your AWS account and users belonging to the account through SageMaker Domain, to give the Domain users access to the TensorBoard data with appropriate permissions to Amazon S3, and help the Domain users perform model debugging tasks using the TensorBoard visualization plugins. SageMaker with TensorBoard is extended with the SageMaker Data Manager plugin, with which Domain users can access a number of training jobs in one place within the TensorBoard application.

**Note**
This feature is for training and debugging deep learning models using the PyTorch or TensorFlow framework.

**For data scientists**

Training large models can have scientific problems that require data scientists to debug and resolve them in order to improve model convergence and stabilize gradient descent processes.

When you encounter model training issues, such as loss not converging, or vanishing or exploding weights and gradients, you need to access tensor data to dive deep and analyze the model parameters, scalars, and any custom metrics. Using SageMaker with TensorBoard, you can visualize model output tensors extracted from training jobs. As you experiment with different models, multiple training runs, and model hyperparameters, you can select multiple training jobs in TensorBoard and compare them in one place.

**For administrators**

Through the TensorBoard landing page in the SageMaker console or SageMaker Domain, you can manage TensorBoard application users if you are an administrator of an AWS account or SageMaker Domain. Each Domain user can access their own TensorBoard application given the granted permissions. As a SageMaker Domain administrator and Domain user, you can create and delete the TensorBoard application given the permission level you have.

**Supported frameworks and AWS Regions**

This feature supports the following machine learning frameworks and AWS Regions.

**Frameworks**
- PyTorch
- TensorFlow
- Hugging Face Transformers

**AWS Regions**
- US East (N. Virginia) (us-east-1)
- US East (Ohio) (us-east-2)
- US West (Oregon) (us-west-2)
- Europe (Frankfurt) (eu-central-1)
- Europe (Ireland) (eu-west-1)
Note
Amazon SageMaker with TensorBoard runs the TensorBoard application on an ml.r5.large instance and incurs charges after the SageMaker free tier or the free trial period of the feature. For more information, see Amazon SageMaker Pricing.

Prerequisites
The following list shows the prerequisites to start using SageMaker with TensorBoard.

- A SageMaker Domain that's set up with Amazon VPC in your AWS account.
  
  For instructions on setting up a Domain, see Onboard to Amazon SageMaker Domain using quick setup. You also need to add Domain user profiles for individual users to access the TensorBoard on SageMaker. For more information, see Add and remove SageMaker Domain user profiles.

- The following list is the minimum set of permissions for using TensorBoard on SageMaker.
  
  - sagemaker:CreateApp
  - sagemaker:DeleteApp
  - sagemaker:DescribeTrainingJob
  - sagemaker:Search
  - s3:GetObject
  - s3:ListBucket

Prepare a training job with a TensorBoard output data configuration

A typical training job for deep learning in SageMaker consists of two main steps: preparing a training script and configuring a SageMaker Training job launcher. In this section, you can check the required changes to collect TensorBoard-compatible data from SageMaker Training.

Step 1: Modify your training script

Make sure you determine which output tensors and scalars to collect, and modify code lines in your training script using any of the following tools: TensorBoardX, TensorFlow Summary Writer, PyTorch Summary Writer, or SageMaker Debugger.

Also make sure that you specify the TensorBoard data output path as the log directory (log_dir) for callback in the training container.

For more information about callbacks per framework, see the following resources.

- For PyTorch, use torch.utils.tensorboard.SummaryWriter. See also the Using TensorBoard in PyTorch and Log scalars sections in the PyTorch tutorials. Alternatively, you can use TensorFlowX Summary Writer.

```
LOG_DIR="/opt/ml/output/tensorboard"
tensorboard_callback=torch.utils.tensorboard.writer.SummaryWriter(log_dir=LOG_DIR)
```

- For TensorFlow, use the native callback for TensorBoard, tf.keras.callbacks.TensorBoard.

```
LOG_DIR="/opt/ml/output/tensorboard"
tensorboard_callback=tf.keras.callbacks.TensorBoard(
    log_dir=LOG_DIR, histogram_freq=1)
```

- For Transformers with PyTorch, you can use transformers.integrations.TensorBoardCallback.
For Transformers with TensorFlow, use the `tf.keras.tensorboard.callback`, and pass that to the `keras` callback in transformers.

**Tip**  
You can also use a different container local output path. However, in Step 2: Construct a SageMaker training launcher with TensorBoard data configuration (p. 1906), you must map the paths correctly for SageMaker to successfully search the local path and save the TensorBoard data to the S3 output bucket.

- For guidance on modifying training scripts using the SageMaker Debugger Python library, see the section called “Step 1: Adapt Your Training Script to Register a Hook” (p. 1931).

### Step 2: Construct a SageMaker training launcher with TensorBoard data configuration

Use the `sagemaker.debugger.TensorBoardOutputConfig` while configuring a SageMaker framework estimator. This configuration API maps the S3 bucket you specify for saving TensorBoard data with the local path in the training container `/opt/ml/output/tensorboard`. Pass the object of the module to the `tensorboard_output_config` parameter of the estimator class. The following code snippet shows an example of preparing a TensorFlow estimator with the TensorBoard output configuration parameter.

**Note**  
This example assumes that you use the SageMaker Python SDK. If you use the low-level SageMaker API, you should include the following to the request syntax of the `CreateTrainingJob` API.

```json
"TensorBoardOutputConfig": {
   "LocalPath": "/opt/ml/output/tensorboard",
   "S3OutputPath": "s3_output_bucket"
}
```

```python
def get_output_path(s3_output_bucket):
    LOG_DIR="/opt/ml/output/tensorboard"
    output_path = os.path.join(
        s3_output_bucket, "sagemaker-output", "date_str", "your-training_job_name")
    tensorboard_output_config = TensorBoardOutputConfig(
        s3_output_path=os.path.join(output_path, 'tensorboard'),
        container_local_output_path=LOG_DIR)

    estimator = TensorFlow(
        entry_point="train.py",
        source_dir="src",
        role=role,
        image_uri=image_uri,
        instance_count=1,
        instance_type="ml.c5.xlarge",
        base_job_name="your-training_job_name",
        tensorboard_output_config=tensorboard_output_config,
        hyperparameters=hyperparameters
    )
```
How to access TensorBoard on SageMaker

You can access TensorBoard by two methods: programmatically using the `sagemaker.interactive_apps.tensorboard` module that generates an unsigned or a presigned URL, or using the TensorBoard landing page in the SageMaker console. After you open TensorBoard, SageMaker runs the TensorBoard plugin and automatically finds all training job output data in TensorBoard-compatible file format.

Topics
- Open TensorBoard using the `sagemaker.interactive_apps.tensorboard` module (p. 1907)
- Open TensorBoard using the `get_app_url` function as an estimator class method (p. 1909)
- Open TensorBoard through the SageMaker console (p. 1910)

Open TensorBoard using the `sagemaker.interactive_apps.tensorboard` module

The `sagemaker.interactive_apps.tensorboard` module provides a function called `get_app_url` that generates unsigned or presigned URLs to open the TensorBoard application in any environment in SageMaker or Amazon EC2. This is to provide a unified experience for both Studio and non-Studio users. For the Studio environment, you can open TensorBoard by running the `get_app_url()` function as it is, or you can also specify a job name to start tracking as the TensorBoard application opens. For non-Studio environments, you can open TensorBoard by providing your Domain and user profile information to the utility function. With this functionality, regardless of where or how you run training code and launch training jobs, you can directly access TensorBoard by running the `get_app_url` function in your Jupyter notebook or terminal.

Note
This functionality is available in the SageMaker Python SDK v2.184.0 and later. To use this functionality, make sure that you upgrade the SDK by running `pip install sagemaker --upgrade`.

Topics
- Option 1: For SageMaker Studio (p. 1907)
- Option 2: For non-Studio environments (p. 1908)

Option 1: For SageMaker Studio

If you are using SageMaker Studio, you can directly open the TensorBoard application or retrieve an unsigned URL by running the `get_app_url` function as follows. As you are already within the Studio environment and signed in as a Domain user, `get_app_url()` generates unsigned URL because it is not necessary to authenticate again.

To open the TensorBoard application

The following code automatically opens the TensorBoard application from the unsigned URL that the `get_app_url()` function returns in your environment's default web browser.

```python
from sagemaker.interactive_apps import tensorboard
region = "us-west-2"
app = tensorboard.TensorBoardApp(region)
app.get_app_url()
```
training_job_name="your-training_job_name" # Optional. Specify the job name to track a specific training job
)

To retrieve an unsigned URL and open the TensorBoard application manually

The following code prints an unsigned URL that you can copy to a web browser and open the TensorBoard application.

```
from sagemaker.interactive_apps import tensorboard

region = "us-west-2"
app = tensorboard.TensorBoardApp(region)
print("Navigate to the following URL:")
print(app.get_app_url(
    training_job_name="your-training_job_name", # Optional. Specify the name of the job to track.
    open_in_default_web_browser=False # Set to False to print the URL to terminal.
    )
)
```

Note that if you run the preceding two code samples outside the SageMaker Studio environment, the function will return a URL to the TensorBoard landing page in the SageMaker console, because these do not have sign-in information to your Domain and user profile. For creating a presigned URL, see Option 2 in the following section.

Option 2: For non-Studio environments

If you use non-Studio environments, such as SageMaker Notebook instance or Amazon EC2, and want to open TensorBoard directly from the environment you are in, you need to generate a URL presigned with your Domain and user profile information. A presigned URL is a URL that’s signed in to Amazon SageMaker Studio while the URL is being created with your Domain and user profile, and therefore granted access to all of the Domain applications and files associated with your Domain. To open TensorBoard through a presigned URL, use the `get_app_url` function with your Domain and user profile name as follows.

Note that this option requires the Domain user to have the `sagemaker:CreatePresignedDomainUrl` permission. Without the permission, the Domain user will receive an exception error.

**Important**
Do not share any presigned URLs. The `get_app_url` function creates presigned URLs, which automatically authenticates with your Domain and user profile and gives access to any applications and files associated with your Domain.

```
print(app.get_app_url(
    training_job_name="your-training_job_name", # Optional. Specify the name of the job to track.
    create_presigned_domain_url=True, # Required to be set to True for creating a presigned URL.
    domain_id="your-domain-id", # Required if creating a presigned URL
    create_presigned_domain_url=True,
    user_profile_name="your-user-profile-name", # Required if creating a presigned URL
    create_presigned_domain_url=True,
    open_in_default_web_browser=False, # Optional. Set to False to print the URL to terminal.
    optional_create_presigned_url_kwargs={} # Optional. Add any additional args for Boto3 create_presigned_domain_url
)
```
Tip
The `get_app_url` function runs the `SageMaker.Client.create_presigned_domain_url` API in the AWS SDK for Python (Boto3) in the backend. As the Boto3 `create_presigned_domain_url` API creates presigned domain URLs that expire in 300 seconds by default, presigned TensorBoard application URLs also expire in 300 seconds. If you want to extend the expiration time, pass the `ExpiresInSeconds` argument to the `optional_create_presigned_url_kwargs` argument of the `get_app_url` function as follows.

```python
optional_create_presigned_url_kwargs={"ExpiresInSeconds": 1500}
```

Note
If any of your input passed to the arguments of `get_app_url` is invalid, the function outputs a URL to the TensorBoard landing page instead of opening the TensorBoard application. The output message would be similar to the following.

Navigate to the following URL:

Open TensorBoard using the `get_app_url` function as an estimator class method

If you are in the process of running a training job using the `estimator` class of the SageMaker Python SDK and have an active object of the `estimator` class, you can also access the `get_app_url` function as a class method of the `estimator` class. Open the TensorBoard application or retrieve an unsigned URL by running the `get_app_url` method as follows. The `get_app_url` class method pulls the training job name from the `estimator` and opens the TensorBoard application with the specified job.

Note
This functionality is available in the SageMaker Python SDK v2.184.0 and later. To use this functionality, make sure that you upgrade the SDK by running `pip install sagemaker --upgrade`.

Topics
- Option 1: For SageMaker Studio (p. 1909)
- Option 2: For non-Studio environments (p. 1910)

Option 1: For SageMaker Studio

To open the TensorBoard application

The following code automatically opens the TensorBoard application from the unsigned URL that the `get_app_url()` method returns in the your environment's default web browser.

```python
estimator.get_app_url(
    app_type=SupportedInteractiveAppTypes.TENSORBOARD # Required.
)
```

To retrieve an unsigned URL and open the TensorBoard application manually

The following code prints an unsigned URL that you can copy to a web browser and open the TensorBoard application.
print(
    estimator.get_app_url(
        app_type=SupportedInteractiveAppTypes.TENSORBOARD, # Required.
        open_in_default_web_browser=False, # Optional. Set to False to print the URL to
terminal.
    )
)

Note that if you run the preceding two code samples outside the SageMaker Studio environment, the
function will return a URL to the TensorBoard landing page in the SageMaker console, because these do
not have sign-in information to your Domain and user profile. For creating a presigned URL, see Option 2
in the following section.

**Option 2: For non-Studio environments**

If you use non-Studio environments, such as SageMaker Notebook instance and Amazon EC2, and want
to generate a presigned URL to open the TensorBoard application, use the `get_app_url` method with
your Domain and user profile information as follows.

Note that this option requires the Domain user to have the `sagemaker:CreatePresignedDomainUrl`
permission. Without the permission, the Domain user will receive an exception error.

**Important**

Do not share any presigned URLs. The `get_app_url` function creates presigned URLs,
which automatically authenticates with your Domain and user profile and gives access to any
applications and files associated with your Domain.

print(
    estimator.get_app_url(
        app_type=SupportedInteractiveAppTypes.TENSORBOARD, # Required
        create_presigned_domain_url=True,           # Required to be set to True for
creating a presigned URL.
        domain_id="your-domain-id",                # Required if creating a presigned URL
(creator_presigned_domain_url=True).
        user_profile_name="your-user-profile-name", # Required if creating a presigned URL
(creator_presigned_domain_url=True).
        open_in_default_web_browser=False,            # Optional. Set to False to print the
URL to terminal.
        optional_create_presigned_url_kwargs={}       # Optional. Add any additional args
for Boto3 create_presigned_domain_url
    )
)

Open TensorBoard through the SageMaker console

You can also use the SageMaker console UI to open the TensorBoard application. There are two options
to open the TensorBoard application through the SageMaker console.

**Topics**

- Option 1: Launch TensorBoard from the Domain details page (p. 1910)
- Option 2: Launch TensorBoard from the TensorBoard landing page (p. 1911)

**Option 1: Launch TensorBoard from the Domain details page**

**Navigate to the Domain details page**

The following procedure shows how to navigate to the Domain details page.

Use TensorBoard

2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **Domains**.
4. From the list of Domains, select the Domain in which you want to launch the TensorBoard application.

**Launch a user profile application**

The following procedure shows how to launch a Studio application that is scoped to a user profile.

1. On the Domain details page, choose the **User profiles** tab.
2. Identify the user profile for which you want to launch the Studio application.
3. Choose **Launch** for your selected user profile, then choose **TensorBoard**.

**Option 2: Launch TensorBoard from the TensorBoard landing page**

The following procedure describes how to launch a TensorBoard application from the TensorBoard landing page.

2. On the left navigation pane, choose **TensorBoard**.
3. Under **Get started**, select the Domain in which you want to launch the Studio application. If your user profile only belongs to one Domain, you do not see the option for selecting a Domain.
4. Select the user profile for which you want to launch the Studio application. If there is no user profile in the Domain, choose **Create user profile**. For more information, see [Add and Remove User Profiles](#).
5. Choose **Open TensorBoard**.

The following screenshot shows the location of TensorBoard in the left navigation pane of the SageMaker console and the SageMaker with TensorBoard landing page in the main pane.

**Access and visualize training output data in TensorBoard**

You can conduct an online or offline analysis by loading collected output tensors from S3 buckets paired with training jobs during or after training.

When you open the TensorBoard application, TensorBoard opens with the **SageMaker Data Manager** tab. The following screenshot shows the full view of the SageMaker Data Manager tab in the TensorBoard application.
Use TensorBoard

In the SageMaker Data Manager tab, you can select any training job and load TensorBoard-compatible training output data from Amazon S3.

1. In the Search training jobs section, use the filters to narrow down the list of training jobs you want to find, load, and visualize.

2. In the List of training jobs section, use the check boxes to choose training jobs from which you want to pull data and visualize for debugging.

3. Choose Add selected jobs. The selected jobs should appear in the Tracked training jobs section, as shown in the following screenshot.

The SageMaker Data Manager plugin provides a user interface to manage SageMaker training jobs with TensorBoard data. For your training job to be listed here, you must enable TensorBoard by using the TensorBoardOutputConfig parameter in your SageMaker Training job launcher. To learn how to activate TensorBoard data collection, see Use TensorBoard to debug and analyze training jobs in Amazon SageMaker.

The TensorBoard data of the following jobs is loaded to the TensorBoard application. To check if loading the TensorBoard data is complete, see the percentage of the file loading progress in the Data size column. After the file loading is complete, the application auto-refreshes, and the visualization plug-ins appear. If it doesn’t auto-refresh, click the refresh button in the upper-right corner to manually refresh the TensorBoard page. Refresh the page every 30 seconds. To unload jobs, use the check boxes to select the jobs you want to remove and choose Remove selected jobs.
Note
The SageMaker Data Manager tab only shows training jobs configured with the TensorBoardOutputConfig parameter. Make sure you have configured the SageMaker estimator with this parameter. For more information, see Step 2: Construct a SageMaker training launcher with TensorBoard data configuration (p. 1906).

Note
The visualization tabs might not appear if you are using SageMaker with TensorBoard for the first time or no data is loaded from a previous use. After adding training jobs and waiting for a few seconds, refresh the viewer by choosing the clockwise circular arrow on the upper-right corner. The visualization tabs should appear after the job data are successfully loaded. You can also set to auto-refresh using the Settings button next to the refresh button in the upper right corner.

Explore training output data visualized in TensorBoard

In the graphics tabs, you can see the list of the loaded training jobs in the left pane. You can also use the check boxes of the training jobs to show or hide visualizations. The TensorBoard dynamic plugins are activated dynamically depending on how you have set your training script to include summary writers and pass callbacks for tensor and scalar collection, and therefore the graphics tabs also appear dynamically. The following screenshots show example views of each tab with visualization of two training jobs that collected metrics for time series, scalar, graph, distribution, and histogram plugins.

The TIME SERIES tab view

The SCALARS tab view
The GRAPHS tab view

The DISTRIBUTIONS tab view
Delete unused TensorBoard applications

After you are done with monitoring and experimenting with jobs in TensorBoard, shut the TensorBoard application down.

1. Open the SageMaker console.
2. On the left navigation pane, choose Admin configurations.
3. Under Admin configurations, choose Domains.
4. Choose your domain.
5. Choose your user profile.
7. Choose Yes, delete app.
8. Type delete in the text box, then choose Delete.
9. A blue message should appear at the top of the screen: default is being deleted.

Considerations

Consider the following when using SageMaker with TensorBoard.

- You cannot share the TensorBoard applications for collaboration purposes because SageMaker Domain does not allow application sharing among users. Users can share the output tensors saved in an S3 bucket, if they have access to the bucket.
- The visualization plugins might not appear when you first launch the TensorBoard application. After you select training jobs in the SageMaker Data Manager plugin, the TensorBoard application loads the TensorBoard data and populates the visualization plugins.
- The TensorBoard applications automatically shuts down after 1 hour of inactivity. If you want to shut the application down when you are done using it, make sure to manually shut down TensorBoard to avoid paying for the instance hosting it. For instructions on deleting the application, see Delete unused TensorBoard applications (p. 1915).

Use Amazon SageMaker Debugger to debug and improve model performance

Use Amazon SageMaker Debugger to debug and improve model performance

Debug model output tensors from machine learning training jobs in real time and detect non-converging issues using Amazon SageMaker Debugger.

Amazon SageMaker Debugger Features

Amazon SageMaker Debugger Features

A machine learning (ML) training job can have problems such as overfitting, saturated activation functions, and vanishing gradients, which can compromise model performance.

SageMaker Debugger provides tools to debug training jobs and resolve such problems to improve the performance of your model. Debugger also offers tools to send alerts when training anomalies are found, take actions against the problems, and identify the root cause of them by visualizing collected metrics and tensors.

SageMaker Debugger supports the Apache MXNet, PyTorch, TensorFlow, and XGBoost frameworks. For more information about available frameworks and versions supported by SageMaker Debugger, see Supported Frameworks and Algorithms (p. 1917).

The high-level Debugger workflow is as follows:
1. Modify your training script with the sagemaker-debugger Python SDK if needed.

2. Configure a SageMaker training job with SageMaker Debugger.
   - Configure using the SageMaker Estimator API (for Python SDK).
   - Configure using the SageMaker `CreateTrainingJob` request (for Boto3 or CLI).
   - Configure custom training containers (p. 2010) with SageMaker Debugger.

3. Start a training job and monitor training issues in real time.

4. Get alerts and take prompt actions against the training issues.
   - Receive texts and emails and stop training jobs when training issues are found using Debugger Built-in Actions for Rules (p. 1964).
   - Set up your own actions using Amazon CloudWatch Events and AWS Lambda (p. 1968).

5. Explore deep analysis of the training issues.
   - For debugging model output tensors, see Visualize Debugger Output Tensors in TensorBoard (p. 1954).

6. Fix the issues, consider the suggestions provided by Debugger, and repeat steps 1–5 until you optimize your model and achieve target accuracy.

The SageMaker Debugger developer guide walks you through the following topics.

Topics
- Supported Frameworks and Algorithms (p. 1917)
- Amazon SageMaker Debugger Architecture (p. 1919)
- Get Started with Debugger Tutorials (p. 1921)
- Debug Training Jobs Using Amazon SageMaker Debugger (p. 1930)
- List of Debugger Built-in Rules (p. 1975)
- Create Debugger Custom Rules for Training Job Analysis (p. 2008)
- Use Debugger with Custom Training Containers (p. 2010)
- Configure Debugger Using Amazon SageMaker API (p. 2014)
- Best Practices for Amazon SageMaker Debugger (p. 2024)
- Amazon SageMaker Debugger Advanced Topics and Reference Documentation (p. 2027)

### Supported Frameworks and Algorithms

The following table shows SageMaker machine learning frameworks and algorithms supported by Debugger.

<table>
<thead>
<tr>
<th>SageMaker-supported frameworks and algorithms</th>
<th>Debugging output tensors</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>TensorFlow</strong></td>
<td>AWS TensorFlow deep learning containers 1.15.4 or later</td>
</tr>
<tr>
<td><strong>PyTorch</strong></td>
<td>AWS PyTorch deep learning containers 1.5.0 or later</td>
</tr>
<tr>
<td><strong>MXNet</strong></td>
<td>AWS MXNet deep learning containers 1.6.0 or later</td>
</tr>
</tbody>
</table>
Use SageMaker Debugger

- **Debugging output tensors** – Track and debug model parameters, such as weights, gradients, biases, and scalar values of your training job. Available deep learning frameworks are Apache MXNet, TensorFlow, PyTorch, and XGBoost.

  **Important**
  For the TensorFlow framework with Keras, SageMaker Debugger deprecates the zero code change support for debugging models built using the tf.keras modules of TensorFlow 2.6 and later. This is due to breaking changes announced in the TensorFlow 2.6.0 release note. For instructions on how to update your training script, see the section called “TensorFlow” (p. 1933).

  **Important**
  From PyTorch v1.12.0 and later, SageMaker Debugger deprecates the zero code change support for debugging models. This is due to breaking changes that cause SageMaker Debugger to interfere with the torch.jit functionality. For instructions on how to update your training script, see the section called “PyTorch” (p. 1931).

If the framework or algorithm that you want to train and debug is not listed in the table, go to the AWS Discussion Forum and leave feedback on SageMaker Debugger.

**AWS Regions**

Amazon SageMaker Debugger is available in all regions where Amazon SageMaker is in service except the following region.

- Asia Pacific (Jakarta): ap-southeast-3

To find if Amazon SageMaker is in service in your AWS Region, see AWS Regional Services.

**Use Debugger with Custom Training Containers**

Bring your training containers to SageMaker and gain insights into your training jobs using Debugger. Maximize your work efficiency by optimizing your model on Amazon EC2 instances using the monitoring and debugging features.

For more information about how to build your training container with the sagemaker-debugger client library, push it to the Amazon Elastic Container Registry (Amazon ECR), and monitor and debug, see Use Debugger with Custom Training Containers (p. 2010).

**Debugger Open-Source GitHub Repositories**

Debugger APIs are provided through the SageMaker Python SDK and designed to construct Debugger hook and rule configurations for the SageMaker CreateTrainingJob and DescribeTrainingJob API operations. The sagemaker-debugger client library provides tools to register hooks and access the training data through its trial feature, all through its flexible and powerful API operations. It supports the machine learning frameworks TensorFlow, PyTorch, MXNet, and XGBoost on Python 3.6 and later.

For direct resources about the Debugger and sagemaker-debugger API operations, see the following links:
Use SageMaker Debugger

- The Amazon SageMaker Python SDK documentation
- The Amazon SageMaker Python SDK - Debugger APIs
- The sagemaker-debugger Python SDK documentation for the Amazon SageMaker Debugger open source client library
- The sagemaker-debugger PyPI

If you use the SDK for Java to conduct SageMaker training jobs and want to configure Debugger APIs, see the following references:

- Amazon SageMaker Debugger API Operations (p. 2027)
- Configure Debugger Using Amazon SageMaker API (p. 2014)

Amazon SageMaker Debugger Architecture

This topic walks you through a high-level overview of the Amazon SageMaker Debugger workflow.

Debugger supports profiling functionality for performance optimization to identify computation issues, such as system bottlenecks and underutilization, and to help optimize hardware resource utilization at scale.

Debugger's debugging functionality for model optimization is about analyzing non-converging training issues that can arise while minimizing the loss functions using optimization algorithms, such as gradient descent and its variations.

The following diagram shows the architecture of SageMaker Debugger. The blocks with bold boundary lines are what Debugger manages to analyze your training job.
Debugger stores the following data from your training jobs in your secured Amazon S3 bucket:

- **Output tensors** – Collections of scalars and model parameters that are continuously updated during the forward and backward passes while training ML models. The output tensors include scalar values (accuracy and loss) and matrices (weights, gradients, input layers, and output layers).

  **Note**

  By default, Debugger monitors and debugs SageMaker training jobs without any Debugger-specific parameters configured in SageMaker estimators. Debugger collects system metrics every 500 milliseconds and basic output tensors (scalar outputs such as loss and accuracy) every 500 steps. It also runs the ProfilerReport rule to analyze the system metrics and aggregate the Studio Debugger insights dashboard and a profiling report. Debugger saves the output data in your secured Amazon S3 bucket.
The Debugger built-in rules run on processing containers, which are designed to evaluate machine
learning models by processing the training data collected in your S3 bucket (see Process Data and
Evaluate Models). The built-in rules are fully managed by Debugger. You can also create your own rules
customized to your model to watch for any issues you want to monitor.

Get Started with Debugger Tutorials

The following topics walk you through tutorials from the basics to advanced use cases of monitoring,
profiling, and debugging SageMaker training jobs using Debugger. Explore the Debugger features and
learn how you can debug and improve your machine learning models efficiently by using Debugger.

Topics
- Debugger Tutorial Videos (p. 1921)
- Debugger Example Notebooks (p. 1922)
- Debugger Advanced Demos and Visualization (p. 1924)

Debugger Tutorial Videos

The following videos provide a tour of Amazon SageMaker Debugger capabilities using SageMaker
Studio and SageMaker notebook instances.

Topics
- Analyze, Detect, and Get Alerted on Problems with Training Runs Using Amazon SageMaker Debugger (p. 1921)
- Debug Models with Amazon SageMaker Debugger in Studio (p. 1921)
- Deep Dive on Amazon SageMaker Debugger and SageMaker Model Monitor (p. 1922)

Analyze, Detect, and Get Alerted on Problems with Training Runs Using Amazon SageMaker Debugger

Emily Webber, AWS Machine Learning Specialist | Length: 13 minutes 54 seconds

This tutorial video gives you a tour of Amazon SageMaker Debugger to capture, debug, and visualize
model output data from a training model with MXNet. Learn how Amazon SageMaker Debugger makes
the training process transparent by automatically capturing metrics, analyzing training runs, and
detecting problems.

Analyze, Detect, and Get Alerted on Problems with Training Runs Using Amazon SageMaker Debugger

You can find the example notebook in this video at Visualizing Debugging Tensors of MXNet training in
the Amazon SageMaker Examples GitHub repository.

Debug Models with Amazon SageMaker Debugger in Studio

Julien Simon, AWS Technical Evangelist | Length: 14 minutes 17 seconds

This tutorial video demonstrates how to use Amazon SageMaker Debugger to capture and inspect
debugging information from a training model. The example training model used in this video is a simple
convolutional neural network (CNN) based on Keras with the TensorFlow backend. SageMaker in a
TensorFlow framework and Debugger enable you to build an estimator directly using the training script
and debug the training job.

Debug Models with Amazon SageMaker Debugger (part 1)

You can find the example notebook in the video in this Studio Demo repository provided by the author.
You need to clone the debugger.ipynb notebook file and the mnist_keras_t_f.py training script
to your SageMaker Studio or a SageMaker notebook instance. After you clone the two files, specify the
Use SageMaker Debugger

path keras_script_path to the mnist_keras_tf.py file inside the debugger.ipynb notebook. For example, if you cloned the two files in the same directory, set it as keras_script_path = "mnist_keras_tf.py".

Deep Dive on Amazon SageMaker Debugger and SageMaker Model Monitor

Julien Simon, AWS Technical Evangelist | Length: 44 minutes 34 seconds

This video session explores advanced features of Debugger and SageMaker Model Monitor that help boost productivity and the quality of your models. First, this video shows how to detect and fix training issues, visualize tensors, and improve models with Debugger. Next, at 22:41, the video shows how to monitor models in production and identify prediction issues such as missing features or data drift using SageMaker Model Monitor. Finally, it offers cost optimization tips to help you make the most of your machine learning budget.

Debug Models with Debugger (part 2)

You can find the example notebook in the video in this AWS Dev Days 2020 repository offered by the author.

Debugger Example Notebooks

SageMaker Debugger example notebooks are provided in the aws/amazon-sagemaker-examples repository. The Debugger example notebooks walk you through basic to advanced use cases of debugging and profiling training jobs.

We recommend that you run the example notebooks on SageMaker Studio or a SageMaker Notebook instance because most of the examples are designed for training jobs in the SageMaker ecosystem, including Amazon EC2, Amazon S3, and Amazon SageMaker Python SDK.

To clone the example repository to SageMaker Studio, follow the instructions at Amazon SageMaker Studio Tour.

To find the examples in a SageMaker Notebook instance, follow the instructions at SageMaker Notebook Instance Example Notebooks.

Important

To use the new Debugger features, you need to upgrade the SageMaker Python SDK and the SMDebug client library. In your iPython kernel, Jupyter Notebook, or JupyterLab environment, run the following code to install the latest versions of the libraries and restart the kernel.

```python
import sys
import IPython
!{sys.executable} -m pip install -U sagemaker smdebug
IPython.Application.instance().kernel.do_shutdown(True)
```

Debugger Example Notebooks for Profiling Training Jobs

To find advanced visualizations of model parameters and use cases, see the next topic at Debugger Advanced Demos and Visualization (p. 1924).

**Debugger Advanced Demos and Visualization**

The following demos walk you through advanced use cases and visualization scripts using Debugger.

**Topics**

- [Train and Tune Your Models with Amazon SageMaker Experiments and Debugger](p. 1924)
- [Using SageMaker Debugger to Monitor a Convolutional Autoencoder Model Training](p. 1927)
- [Using SageMaker Debugger to Monitor Attentions in BERT Model Training](p. 1927)
- [Using SageMaker Debugger to Visualize Class Activation Maps in Convolutional Neural Networks (CNNs)](p. 1930)

**Train and Tune Your Models with Amazon SageMaker Experiments and Debugger**

*Dr. Nathalie Rauschmayr, AWS Applied Scientist | Length: 49 minutes 26 seconds*

**Train and Prune Models with SageMaker Experiments and Debugger**

Find out how Amazon SageMaker Experiments and Debugger can simplify the management of your training jobs. Amazon SageMaker Debugger provides transparent visibility into training jobs and saves training metrics into your Amazon S3 bucket. SageMaker Experiments enables you to call the training information as *trials* through SageMaker Studio and supports visualization of the training job. This helps you keep model quality high while reducing less important parameters based on importance rank.

This video demonstrates a *model pruning* technique that makes pre-trained ResNet50 and AlexNet models lighter and affordable while keeping high standards for model accuracy.

SageMaker Estimator trains those algorithms supplied from the PyTorch model zoo in an AWS Deep Learning Containers with PyTorch framework, and Debugger extracts training metrics from the training process.

The video also demonstrates how to set up a Debugger custom rule to watch the accuracy of a pruned model, to trigger an Amazon CloudWatch event and an AWS Lambda function when the accuracy hits a threshold, and to automatically stop the pruning process to avoid redundant iterations.
Learning objectives are as follows:

- Learn how to use SageMaker to accelerate ML model training and improve model quality.
- Understand how to manage training iterations with SageMaker Experiments by automatically capturing input parameters, configurations, and results.
- Discover how Debugger makes the training process transparent by automatically capturing real-time tensor data from metrics such as weights, gradients, and activation outputs of convolutional neural networks.
- Use CloudWatch to trigger Lambda when Debugger catches issues.
- Master the SageMaker training process using SageMaker Experiments and Debugger.

You can find the notebooks and training scripts used in this video from [SageMaker Debugger PyTorch Iterative Model Pruning](https://github.com/aws-samples/sagemaker-iterative-model-pruning).

The following image shows how the iterative model pruning process reduces the size of AlexNet by cutting out the 100 least significant filters based on importance rank evaluated by activation outputs and gradients.

The pruning process reduced the initial 50 million parameters to 18 million. It also reduced the estimated model size from 201 MB to 73 MB.

Pruning iteration: 0

</tbody>
</table>

---

You also need to track model accuracy, and the following image shows how you can plot the model pruning process to visualize changes in model accuracy based on the number of parameters in SageMaker Studio.
In SageMaker Studio, choose the **Experiments** tab, select a list of tensors saved by Debugger from the pruning process, and then compose a **Trial Component List** panel. Select all ten iterations and then choose **Add chart** to create a **Trial Component Chart**. After you decide on a model to deploy, choose the trial component and choose a menu to perform an action or choose **Deploy model**.

**Note**

To deploy a model through SageMaker Studio using the following notebook example, add a line at the end of the `train` function in the `train.py` script.

```python
# In the train.py script, look for the train function in line 58.
def train(epochs, batch_size, learning_rate):
    ...
    print('acc: {:.4f}'.format(correct/total))
    hook.save_scalar("accuracy", correct/total, sm_metric=True)

    # Add the following code to line 128 of the train.py script to save the pruned models
    # under the current SageMaker Studio model directory
    torch.save(model.state_dict(), os.environ[‘SM_MODEL_DIR’] + ‘/model.pt’)
```
Using SageMaker Debugger to Monitor a Convolutional Autoencoder Model Training

This notebook demonstrates how SageMaker Debugger visualizes tensors from an unsupervised (or self-supervised) learning process on a MNIST image dataset of handwritten numbers.

The training model in this notebook is a convolutional autoencoder with the MXNet framework. The convolutional autoencoder has a bottleneck-shaped convolutional neural network that consists of an encoder part and a decoder part.

The encoder in this example has two convolution layers to produce compressed representation (latent variables) of the input images. In this case, the encoder produces a latent variable of size (1, 20) from an original input image of size (28, 28) and significantly reduces the size of data for training by 40 times.

The decoder has two deconvolutional layers and ensures that the latent variables preserve key information by reconstructing output images.

The convolutional encoder powers clustering algorithms with smaller input data size and the performance of clustering algorithms such as k-means, k-NN, and t-Distributed Stochastic Neighbor Embedding (t-SNE).

This notebook example demonstrates how to visualize the latent variables using Debugger, as shown in the following animation. It also demonstrates how the t-SNE algorithm classifies the latent variables into ten clusters and projects them into a two-dimensional space. The scatter plot color scheme on the right side of the image reflects the true values to show how well the BERT model and t-SNE algorithm organize the latent variables into the clusters.

Using SageMaker Debugger to Monitor Attentions in BERT Model Training

Bidirectional Encode Representations from Transformers (BERT) is a language representation model. As the name of model reflects, the BERT model builds on transfer learning and the Transformer model for natural language processing (NLP).

The BERT model is pre-trained on unsupervised tasks such as predicting missing words in a sentence or predicting the next sentence that naturally follows a previous sentence. The training data contains 3.3 billion words (tokens) of English text, from sources such as Wikipedia and electronic books. For a simple example, the BERT model can give a high attention to appropriate verb tokens or pronoun tokens from a subject token.

The pre-trained BERT model can be fine-tuned with an additional output layer to achieve state-of-the-art model training in NLP tasks, such as automated responses to questions, text classification, and many others.
Debugger collects tensors from the fine-tuning process. In the context of NLP, the weight of neurons is called *attention*.

This notebook demonstrates how to use the [pre-trained BERT model from the GluonNLP model zoo](https://gluon-nlp.com/) on the Stanford Question and Answering dataset and how to set up SageMaker Debugger to monitor the training job.

Plotting *attention scores* and individual neurons in the query and key vectors can help to identify causes of incorrect model predictions. With SageMaker Debugger, you can retrieve the tensors and plot the *attention-head view* in real time as training progresses and understand what the model is learning.

The following animation shows the attention scores of the first 20 input tokens for ten iterations in the training job provided in the notebook example.
Using SageMaker Debugger to Visualize Class Activation Maps in Convolutional Neural Networks (CNNs)

This notebook demonstrates how to use SageMaker Debugger to plot class activation maps for image detection and classification in convolutional neural networks (CNNs). In deep learning, a convolutional neural network (CNN or ConvNet) is a class of deep neural networks, most commonly applied to analyzing visual imagery. One of the applications that adopts the class activation maps is self-driving cars, which require instantaneous detection and classification of images such as traffic signs, roads, and obstacles.

In this notebook, the PyTorch ResNet model is trained on the German Traffic Sign Dataset, which contains more than 40 classes of traffic-related objects and more than 50,000 images in total.

During the training process, SageMaker Debugger collects tensors to plot the class activation maps in real time. As shown in the animated image, the class activation map (also called as a saliency map) highlights regions with high activation in red color.

Using tensors captured by Debugger, you can visualize how the activation map evolves during the model training. The model starts by detecting the edge on the lower-left corner at the beginning of the training job. As the training progresses, the focus shifts to the center and detects the speed limit sign, and the model successfully predicts the input image as Class 3, which is a class of speed limit 60km/h signs, with a 97% confidence level.

Debug Training Jobs Using Amazon SageMaker Debugger

To prepare your training script and run training jobs with SageMaker Debugger to debug model training progress, you follow the typical two-step process: modify your training script using the sagemaker-debugger Python SDK, and construct a SageMaker estimator using the SageMaker Python SDK. Go through the following topics to learn how to use SageMaker Debugger’s debugging functionality.

Topics
- Step 1: Adapt Your Training Script to Register a Hook (p. 1931)
- Step 2: Launch and Debug Training Jobs Using SageMaker Python SDK (p. 1935)
- SageMaker Debugger Interactive Report for XGBoost (p. 1950)
- Action on Amazon SageMaker Debugger Rules (p. 1964)
- Visualize Amazon SageMaker Debugger Output Tensors in TensorBoard (p. 1973)
Step 1: Adapt Your Training Script to Register a Hook

Amazon SageMaker Debugger comes with a client library called the sagemaker-debugger Python SDK. The sagemaker-debugger Python SDK provides tools for adapting your training script before training and analysis tools after training. In this page, you'll learn how to adapt your training script using the client library.

The sagemaker-debugger Python SDK provides wrapper functions that help register a hook to extract model tensors, without altering your training script. To get started with collecting model output tensors and debug them to find training issues, make the following modifications in your training script.

Tip
While you're following this page, use the sagemaker-debugger open source SDK documentation for API references.

Topics
- Adapt Your PyTorch Training Script (p. 1931)
- Adapt Your TensorFlow Training Script (p. 1933)

Adapt Your PyTorch Training Script

To start collecting model output tensors and debug training issues, make the following modifications to your PyTorch training script.

For PyTorch 1.12.0

If you bring a PyTorch training script, you can run the training job and extract model output tensors with a few additional code lines in your training script. You need to use the hook APIs in the sagemaker-debugger client library. Walk through the following instructions that break down the steps with code examples.

1. Create a hook.

(Recommended) For training jobs within SageMaker

```python
import smdebug.pytorch as smd
hook=smd.get_hook(create_if_not_exists=True)
```

When you launch a training job in the section called “Step 2: Launch and Debug Training Jobs Using SageMaker Python SDK” (p. 1935) with any of the DebuggerHookConfig, TensorBoardConfig, or Rules in your estimator, SageMaker adds a JSON configuration file to your training instance that is picked up by the get_hook function. Note that if you do not include any of the configuration APIs in your estimator, there will be no configuration file for the hook to find, and the function returns None.

(Optional) For training jobs outside SageMaker

If you run training jobs in local mode, directly on SageMaker Notebook instances, Amazon EC2 instances, or your own local devices, use smd.Hook class to create a hook. However, this approach can only store the tensor collections and usable for TensorBoard visualization. SageMaker Debugger's built-in Rules don't work with the local mode because the Rules require SageMaker ML training instances and S3 to store outputs from the remote instances in real time. The smd.get_hook API returns None in this case.

If you want to create a manual hook to save tensors in local mode, use the following code snippet with the logic to check if the smd.get_hook API returns None and create a manual hook using the smd.Hook class. Note that you can specify any output directory in your local machine.

```python
import smdebug.pytorch as smd
```
Use SageMaker Debugger

```python
hook = smd.get_hook(create_if_not_exists=True)

if hook is None:
    hook = smd.Hook(
        out_dir='/path/to/your/local/output/',
        export_tensorboard=True
    )
```

2. Wrap your model with the hook's class methods.

   The `hook.register_module()` method takes your model and iterates through each layer, looking for any tensors that match with regular expressions that you'll provide through the configuration in the section called "Step 2: Launch and Debug Training Jobs Using SageMaker Python SDK" (p. 1935). The collectable tensors through this hook method are weights, biases, activations, gradients, inputs, and outputs.

   ```python
   hook.register_module(model)
   ```

   **Tip**
   If you collect the entire output tensors from a large deep learning model, the total size of those collections can exponentially grow and might cause bottlenecks. If you want to save specific tensors, you can also use the `hook.save_tensor()` method. This method helps you pick the variable for the specific tensor and save to a custom collection named as you want. For more information, see step 7 (p. 1932) of this instruction.

3. Warp the loss function with the hook's class methods.

   The `hook.register_loss` method is to wrap the loss function. It extracts loss values every `save_interval` that you'll set during configuration in the section called "Step 2: Launch and Debug Training Jobs Using SageMaker Python SDK" (p. 1935), and saves them to the "losses" collection.

   ```python
   hook.register_loss(loss_function)
   ```

4. Add `hook.set_mode(ModeKeys.TRAIN)` in the train block. This indicates the tensor collection is extracted during the training phase.

   ```python
def train():
    ...
    hook.set_mode(ModeKeys.TRAIN)
   ```

5. Add `hook.set_mode(ModeKeys.EVAL)` in the validation block. This indicates the tensor collection is extracted during the validation phase.

   ```python
def validation():
    ...
    hook.set_mode(ModeKeys.EVAL)
   ```

6. Use `hook.save_scalar()` to save custom scalars. You can save scalar values that aren't in your model. For example, if you want to record the accuracy values computed during evaluation, add the following line of code below the line where you calculate accuracy.

   ```python
   hook.save_scalar("accuracy", accuracy)
   ```

   Note that you need to provide a string as the first argument to name the custom scalar collection. This is the name that'll be used for visualizing the scalar values in TensorBoard, and can be any string you want.

7. Use `hook.save_tensor()` to save custom tensors. Similarly to `hook.save_scalar()`, you can save additional tensors, defining your own tensor collection. For example, you can extract input image data
that are passed into the model and save as a custom tensor by adding the following code line, where "images" is an example name of the custom tensor, image_inputs is an example variable for the input image data.

```python
hook.save_tensor("images", image_inputs)
```

Note that you must provide a string to the first argument to name the custom tensor. `hook.save_tensor()` has the third argument `collections_to_write` to specify the tensor collection to save the custom tensor. The default is `collections_to_write="default"`. If you don't explicitly specify the third argument, the custom tensor is saved to the "default" tensor collection.

After you have completed adapting your training script, proceed to the section called “Step 2: Launch and Debug Training Jobs Using SageMaker Python SDK” (p. 1935).

Adapt Your TensorFlow Training Script

To start collecting model output tensors and debug training issues, make the following modifications to your TensorFlow training script.

Create a hook for training jobs within SageMaker

```python
import smdebug.tensorflow as smd
hook=smd.get_hook(hook_type="keras", create_if_not_exists=True)
```

This creates a hook when you start a SageMaker training job. When you launch a training job in the section called “Step 2: Launch and Debug Training Jobs Using SageMaker Python SDK” (p. 1935) with any of the DebuggerHookConfig, TensorBoardConfig, or Rules in your estimator, SageMaker adds a JSON configuration file to your training instance that is picked up by the `smd.get_hook` method. Note that if you do not include any of the configuration APIs in your estimator, there will be no configuration file for the hook to find, and the function returns None.

(Optional) Create a hook for training jobs outside SageMaker

If you run training jobs in local mode, directly on SageMaker Notebook instances, Amazon EC2 instances, or your own local devices, use `smd.Hook` class to create a hook. However, this approach can only store the tensor collections and usable for TensorBoard visualization. SageMaker Debugger's built-in Rules don't work with the local mode. The `smd.get_hook` method also returns None in this case.

If you want to create a manual hook, use the following code snippet with the logic to check if the hook returns None and create a manual hook using the `smd.Hook` class.

```python
import smdebug.tensorflow as smd
hook=smd.get_hook(hook_type="keras", create_if_not_exists=True)

if hook is None:
    hook=smd.KerasHook(
        out_dir='/path/to/your/local/output/',
        export_tensorboard=True
    )
```

After adding the hook creation code, proceed to the following topic for TensorFlow Keras.

**Note**

SageMaker Debugger currently supports TensorFlow Keras only.
Register the hook in your TensorFlow Keras training script

The following procedure walks you through how to use the hook and its methods to collect output scalars and tensors from your model and optimizer.

1. Wrap your Keras model and optimizer with the hook’s class methods.

   The hook.register_model() method takes your model and iterates through each layer, looking for any tensors that match with regular expressions that you’ll provide through the configuration in the section called “Step 2: Launch and Debug Training Jobs Using SageMaker Python SDK” (p. 1935). The collectable tensors through this hook method are weights, biases, and activations.

   ```python
   model=tf.keras.Model(...)  
hook.register_model(model)
   ```

2. Wrap the optimizer by the hook.wrap_optimizer() method.

   ```python
   optimizer=tf.keras.optimizers.Adam(...)  
optimizer=hook.wrap_optimizer(optimizer)
   ```

   To collect tensors from the model, such as the input and output tensors of each layer, you must run the training in eager mode. Otherwise, SageMaker Debugger will not be able to collect the tensors. However, other tensors, such as model weights, biases, and the loss, can be collected without explicitly running in eager mode.

   ```python
   model.compile(  
       loss="categorical_crossentropy",  
       optimizer=optimizer,  
       metrics=["accuracy"],  
       # Required for collecting tensors of each layer  
       run_eagerly=True
   )
   ```

4. Register the hook to the tf.keras.Model.fit() method.

   To collect the tensors from the hooks that you registered, add callbacks=[hook] to the Keras model.fit() class method. This will pass the sagemaker-debugger hook as a Keras callback.

   ```python
   model.fit(  
       X_train, Y_train,  
       batch_size=batch_size,  
       epochs=epoch,  
       validation_data=(X_valid, Y_valid),  
       shuffle=True,  
       callbacks=[hook]
   )
   ```

5. TensorFlow 2.x provides only symbolic gradient variables that do not provide access to their values. To collect gradients, wrap tf.GradientTape by the hook.wrap_tape() method, which requires you to write your own training step as follows.

   ```python
   def training_step(model, dataset):
       with hook.wrap_tape(tf.GradientTape()) as tape:
           pred=model(data)  
           loss_value=loss_fn(labels, pred)  
           grads=tape.gradient(loss_value, model.trainable_variables)  
           optimizer.apply_gradients(zip(grads, model.trainable_variables))
   ```
By wrapping the tape, the sagemaker-debugger hook can identify output tensors such as gradients, parameters, and losses. Wrapping the tape ensures that the hook .wrap_tape() method around functions of the tape object, such as push_tape(), pop_tape(), gradient(), will set up the writers of SageMaker Debugger and save tensors that are provided as input to gradient() (trainable variables and loss) and output of gradient() (gradients).

**Note**
To collect with a custom training loop, make sure that you use eager mode. Otherwise, SageMaker Debugger is not able to collect any tensors.

For a full list of actions that the sagemaker debugger hook APIs offer to construct hooks and save tensors, see [Hook Methods](#) in the sagemaker-debugger Python SDK documentation.

After you have completed adapting your training script, proceed to the section called “Step 2: Launch and Debug Training Jobs Using SageMaker Python SDK” (p. 1935).

**Step 2: Launch and Debug Training Jobs Using SageMaker Python SDK**

To configure a SageMaker estimator with SageMaker Debugger, use Amazon SageMaker Python SDK and specify Debugger-specific parameters. To fully utilize the debugging functionality, there are three parameters you need to configure: debugger_hook_config, tensorboard_output_config, and rules.

**Important**
Before constructing and running the estimator fit method to launch a training job, make sure that you adapt your training script following the instructions at the section called “Step 1: Adapt Your Training Script to Register a Hook” (p. 1931).

**Construct a SageMaker Estimator with Debugger-specific parameters**

The code examples in this section show how to construct a SageMaker estimator with the Debugger-specific parameters.

**Note**
The following code examples are templates for constructing the SageMaker framework estimators and not directly executable. You need to proceed to the next sections and configure the Debugger-specific parameters.

**PyTorch**

```python
# An example of constructing a SageMaker PyTorch estimator
import boto3
import sagemaker
from sagemaker.pytorch import PyTorch
from sagemaker.debugger import CollectionConfig, DebuggerHookConfig, Rule, rule_configs

session=boto3.session.Session()
region=session.region_name

driverhook_config=DebuggerHookConfig(

rules=[
    Rule.sagemaker(rule_configs.built_in_rule())
]

estimator=PyTorch(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
)```

1935
framework_version="1.12.0",
py_version="py37",

# Debugger-specific parameters
debugger_hook_config=debugger_hook_config,
rules=rules
)

estimator.fit(wait=False)

TensorFlow

# An example of constructing a SageMaker TensorFlow estimator
import boto3
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import CollectionConfig, DebuggerHookConfig, Rule, rule_configs

session=boto3.session.Session()
region=session.region_name
debugger_hook_config=DebuggerHookConfig(...)
rules=[
    Rule.sagemaker(rule_configs.built_in_rule()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]
estimator=TensorFlow(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="2.9.0",
    py_version="py39",

    # Debugger-specific parameters
debugger_hook_config=debugger_hook_config,
    rules=rules
)

estimator.fit(wait=False)

MXNet

# An example of constructing a SageMaker MXNet estimator
import sagemaker
from sagemaker.mxnet import MXNet
from sagemaker.debugger import CollectionConfig, DebuggerHookConfig, Rule, rule_configs

debugger_hook_config=DebuggerHookConfig(...)
rules=[
    Rule.sagemaker(rule_configs.built_in_rule())
]
estimator=MXNet(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="1.7.0",
    py_version="py37",

    # Debugger-specific parameters
debugger_hook_config=debugger_hook_config,
    rules=rules
)

estimator.fit(wait=False)
# Debugger-specific parameters

debuger_hook_config=debugger_hook_config,
rules=rules

)  
estimator.fit(wait=False)

XGBoost

# An example of constructing a SageMaker XGBoost estimator
import sagemaker  
from sagemaker.xgboost.estimator import XGBoost  
from sagemaker.debugger import CollectionConfig, DebuggerHookConfig, Rule, rule_configs

debuger_hook_config=DebuggerHookConfig(...)  
rules=[  
    Rule.sagemaker(rule_configs.built_in_rule())
]

estimator=XGBoost(  
    entry_point="directory/to/your_training_script.py",  
    role=sagemaker.get_execution_role(),  
    base_job_name="debugger-demo",  
    instance_count=1,  
    instance_type="ml.p3.2xlarge",  
    framework_version="1.5-1",  
    # Debugger-specific parameters  
    debugger_hook_config=debugger_hook_config,  
    rules=rules
)  
estimator.fit(wait=False)

Generic estimator

# An example of constructing a SageMaker generic estimator using the XGBoost algorithm
base image
import boto3  
import sagemaker  
from sagemaker.estimator import Estimator  
from sagemaker import image_uris  
from sagemaker.debugger import CollectionConfig, DebuggerHookConfig, Rule, rule_configs

debuger_hook_config=DebuggerHookConfig(...)  
rules=[  
    Rule.sagemaker(rule_configs.built_in_rule())
]

region=boto3.Session().region_name  
xgboost_container=sagemaker.image_uris.retrieve("xgboost", region, "1.5-1")  
estimator=Estimator(  
    role=sagemaker.get_execution_role(),  
    image_uri=xgboost_container,  
    base_job_name="debugger-demo",  
    instance_count=1,  
    instance_type="ml.m5.2xlarge",  
    # Debugger-specific parameters  
    debugger_hook_config=debugger_hook_config,  
    rules=rules
)
estimator.fit(wait=False)

Configure the following parameters to activate SageMaker Debugger:

- `debugger_hook_config` (an object of `DebuggerHookConfig`) – Required to activate the hook in the adapted training script during the section called "Step 1: Adapt Your Training Script to Register a Hook" (p. 1931). Configure the SageMaker training launcher (estimator) to collect output tensors from your training job, and save the tensors into your secured S3 bucket or local machine. To learn how to configure the `debugger_hook_config` parameter, see Configure SageMaker Debugger to Save Tensors (p. 1938).

- `rules` (a list of `Rule` objects) – Configure this parameter to activate SageMaker Debugger built-in rules that you want to run in real time. The built-in rules are logics that automatically debug the training progress of your model and find training issues by analyzing the output tensors saved in your secured S3 bucket. To learn how to configure the `rules` parameter, see Configure Debugger Built-in Rules (p. 1944). To find a complete list of built-in rules for debugging output tensors, see the section called "Debugger Rule" (p. 1976). If you want to create your own logic to detect any training issues, see the section called "Create Custom Rules" (p. 2008).

  **Note**
  The built-in rules are available only through SageMaker training instances. You cannot use them in local mode.

- `tensorboard_output_config` (an object of `TensorBoardOutputConfig`) – Configure SageMaker Debugger to collect output tensors in the TensorBoard-compatible format and save to your S3 output path specified in the `TensorBoardOutputConfig` object. To learn more, see the section called "Visualize Debugger Output Tensors in TensorBoard" (p. 1973).

  **Note**
  The `tensorboard_output_config` must be configured with the `debugger_hook_config` parameter, which also requires you to adapt your training script by adding the `sagemaker-debugger` hook.

  **Note**
  SageMaker Debugger securely saves output tensors in subfolders of your S3 bucket. For example, the format of the default S3 bucket URI in your account is `s3://sagemaker-<region>-<12digit_account_id>/<base-job-name>/<debugger-subfolders>/`. There are two subfolders created by SageMaker Debugger: `debug-output`, and `rule-output`. If you add the `tensorboard_output_config` parameter, you'll also find `tensorboard-output` folder.

See the following topics to find more examples of how to configure the Debugger-specific parameters in detail.

**Topics**

- Configure SageMaker Debugger to Save Tensors (p. 1938)
- Configure Debugger Built-in Rules (p. 1944)
- Turn Off Debugger (p. 1949)
- Useful SageMaker Estimator Classmethods for Debugger (p. 1949)

**Configure SageMaker Debugger to Save Tensors**

Tensors are data collections of updated parameters from the backward and forward pass of each training iteration. SageMaker Debugger collects the output tensors to analyze the state of a training job. SageMaker Debugger's `CollectionConfig` and `DebuggerHookConfig` API operations provide methods for grouping tensors into `collections` and saving them to a target S3 bucket.
Note
After properly configured and activated, SageMaker Debugger saves the output tensors in a default S3 bucket, unless otherwise specified. The format of the default S3 bucket URI is s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/debug-output/.

While constructing a SageMaker estimator, activate SageMaker Debugger by specifying the debugger_hook_config parameter. The following steps include examples of how to set up the debugger_hook_config using the CollectionConfig and DebuggerHookConfig API operations to pull tensors out of your training jobs and save them.

Configure Tensor Collections Using the CollectionConfig API

Use the CollectionConfig API operation to configure tensor collections. Debugger provides pre-built tensor collections that cover a variety of regular expressions (regex) of parameters if using Debugger-supported deep learning frameworks and machine learning algorithms. As shown in the following example code, add the built-in tensor collections you want to debug.

```python
from sagemaker.debugger import CollectionConfig
collection_configs=[
    CollectionConfig(name="weights"),
    CollectionConfig(name="gradients")
]
```

The preceding collections set up the Debugger hook to save the tensors every 500 steps based on the default "save_interval" value.

For a full list of available Debugger built-in collections, see Debugger Built-in Collections.

If you want to customize the built-in collections, such as changing the save intervals and tensor regex, use the following CollectionConfig template to adjust parameters.

```python
from sagemaker.debugger import CollectionConfig
collection_configs=[
    CollectionConfig(
        name="tensor_collection",
        parameters={
            "key_1": "value_1",
            "key_2": "value_2",
            ...
            "key_n": "value_n"
        }
    )
]
```

For more information about available parameter keys, see CollectionConfig in the Amazon SageMaker Python SDK. For example, the following code example shows how you can adjust the save intervals of the "losses" tensor collection at different phases of training: save loss every 100 steps in training phase and validation loss every 10 steps in validation phase.

```python
from sagemaker.debugger import CollectionConfig
collection_configs=[
    CollectionConfig(
        name="losses",
        parameters={
            "train.save_interval": "100",
            "validation.save_interval": "10"
        }
    )
]
```
"eval.save_interval": "10"
)
]

Tip
This tensor collection configuration object can be used for both DebuggerHookConfig and Rule API operations.

Configure the DebuggerHookConfig API to Save Tensors

Use the DebuggerHookConfig API to create a debugger_hook_config object using the collection_configs object you created in the previous step.

```python
from sagemaker.debugger import DebuggerHookConfig
debugger_hook_config=DebuggerHookConfig(
    collection_configs=collection_configs
)
```

Debugger saves the model training output tensors into the default S3 bucket. The format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/debug-output/`.

If you want to specify an exact S3 bucket URI, use the following code example:

```python
from sagemaker.debugger import DebuggerHookConfig
debugger_hook_config=DebuggerHookConfig(
    s3_output_path="specify-your-s3-bucket-uri",
    collection_configs=collection_configs
)
```

For more information, see DebuggerHookConfig in the Amazon SageMaker Python SDK.

Example Notebooks and Code Samples to Configure Debugger Hook

The following sections provide notebooks and code examples of how to use Debugger hook to save, access, and visualize output tensors.

Topics
- Tensor Visualization Example Notebooks (p. 1940)
- Save Tensors Using Debugger Built-in Collections (p. 1942)
- Save Tensors Using Debugger Modified Built-in Collections (p. 1943)
- Save Tensors Using Debugger Custom Collections (p. 1943)

Tensor Visualization Example Notebooks

The following two notebook examples show advanced use of Amazon SageMaker Debugger for visualizing tensors. Debugger provides a transparent view into training deep learning models.

- Interactive Tensor Analysis in SageMaker Studio Notebook with MXNet

  This notebook example shows how to visualize saved tensors using Amazon SageMaker Debugger. By visualizing the tensors, you can see how the tensor values change while training deep learning algorithms. This notebook includes a training job with a poorly configured neural network and uses Amazon SageMaker Debugger to aggregate and analyze tensors, including gradients, activation
outputs, and weights. For example, the following plot shows the distribution of gradients of a convolutional layer that is suffering from a vanishing gradient problem.

This notebook also illustrates how a good initial hyperparameter setting improves the training process by generating the same tensor distribution plots.

- **Visualizing and Debugging Tensors from MXNet Model Training**

This notebook example shows how to save and visualize tensors from an MXNet Gluon model training job using Amazon SageMaker Debugger. It illustrates that Debugger is set to save all tensors to an Amazon S3 bucket and retrieves ReLu activation outputs for the visualization. The following figure shows a three-dimensional visualization of the ReLu activation outputs. The color scheme is set to blue to indicate values close to 0 and yellow to indicate values close to 1.

In this notebook, the TensorPlot class imported from tensor_plot.py is designed to plot convolutional neural networks (CNNs) that take two-dimensional images for inputs. The
The `tensor_plot.py` script provided with the notebook retrieves tensors using Debugger and visualizes the CNN. You can run this notebook on SageMaker Studio to reproduce the tensor visualization and implement your own convolutional neural network model.

- **Real-time Tensor Analysis in a SageMaker Notebook with MXNet**

  This example guides you through installing required components for emitting tensors in an Amazon SageMaker training job and using the Debugger API operations to access those tensors while training is running. A gluon CNN model is trained on the Fashion MNIST dataset. While the job is running, you will see how Debugger retrieves activation outputs of the first convolutional layer from each of 100 batches and visualizes them. Also, this will show you how to visualize weights after the job is done.

**Save Tensors Using Debugger Built-in Collections**

You can use built-in collections of tensors using the `CollectionConfig` API and save them using the `DebuggerHookConfig` API. The following example shows how to use the default settings of Debugger hook configurations to construct a SageMaker TensorFlow estimator. You can also utilize this for MXNet, PyTorch, and XGBoost estimators.

**Note**

In the following example code, the `s3_output_path` parameter for `DebuggerHookConfig` is optional. If you do not specify it, Debugger saves the tensors at `s3://<output_path>/debug-output/`, where the `<output_path>` is the default output path of SageMaker training jobs. For example:

```
"s3://sagemaker-us-east-1-111122223333/sagemaker-debugger-training-YYYY-MM-DD-HH-MM-SS-123/debug-output"
```

```python
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import DebuggerHookConfig, CollectionConfig

# use Debugger CollectionConfig to call built-in collections
collection_configs=[
    CollectionConfig(name="weights"),
    CollectionConfig(name="gradients"),
    CollectionConfig(name="losses"),
    CollectionConfig(name="biases")
]

# configure Debugger hook
# set a target S3 bucket as you want
sagemaker_session=sagemaker.Session()
BUCKET_NAME=sagemaker_session.default_bucket()
LOCATION_IN_BUCKET='debugger-built-in-collections-hook'

hook_config=DebuggerHookConfig(
    s3_output_path='s3://{BUCKET_NAME}/{LOCATION_IN_BUCKET}'.format(BUCKET_NAME=BUCKET_NAME,
        LOCATION_IN_BUCKET=LOCATION_IN_BUCKET),
    collection_configs=collection_configs
)

# construct a SageMaker TensorFlow estimator
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name='debugger-demo-job',
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="2.9.0",
)```
Use SageMaker Debugger

To see a list of Debugger built-in collections, see Debugger Built-in Collections.

Save Tensors Using Debugger Modified Built-in Collections

You can modify the Debugger built-in collections using the CollectionConfig API operation. The following example shows how to tweak the built-in losses collection and construct a SageMaker TensorFlow estimator. You can also use this for MXNet, PyTorch, and XGBoost estimators.

```python
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import DebuggerHookConfig, CollectionConfig

# use Debugger CollectionConfig to call and modify built-in collections
collection_configs=[
    CollectionConfig(
        name="losses",
        parameters=["save_interval": "50"]
    )
]

# configure Debugger hook
# set a target S3 bucket as you want
sagemaker_session=sagemaker.Session()
BUCKET_NAME=sagemaker_session.default_bucket()
LOCATION_IN_BUCKET='debugger-modified-collections-hook'

hook_config=DebuggerHookConfig(
    s3_output_path='s3://{BUCKET_NAME}/{LOCATION_IN_BUCKET}'.format(BUCKET_NAME=BUCKET_NAME,
                                                                       LOCATION_IN_BUCKET=LOCATION_IN_BUCKET),
    collection_configs=collection_configs
)

# construct a SageMaker TensorFlow estimator
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name='debugger-demo-job',
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="2.9.0",
    py_version="py39",
    debugger_hook_config=hook_config
)

sagemaker_estimator.fit()
```

For a full list of CollectionConfig parameters, see Debugger CollectionConfig API.

Save Tensors Using Debugger Custom Collections

You can also save a reduced number of tensors instead of the full set of tensors (for example, if you want to reduce the amount of data saved in your Amazon S3 bucket). The following example shows how to customize the Debugger hook configuration to specify target tensors that you want to save. You can use this for TensorFlow, MXNet, PyTorch, and XGBoost estimators.

```python
import sagemaker
from sagemaker.debugger import DebuggerHookConfig

# configure Debugger hook
# set a target S3 bucket as you want
sagemaker_session=sagemaker.Session()
BUCKET_NAME=sagemaker_session.default_bucket()
LOCATION_IN_BUCKET='debugger-custom-collections-hook'

hook_config=DebuggerHookConfig(
    s3_output_path='s3://{BUCKET_NAME}/{LOCATION_IN_BUCKET}'.format(BUCKET_NAME=BUCKET_NAME,
                                                                       LOCATION_IN_BUCKET=LOCATION_IN_BUCKET),
    collection_configs=[
        CollectionConfig(
            name="tensors",
            parameters=["save_interval": "50",
                        "tensors_to_save": ["my_tensor1", "my_tensor2"]]
        )
    ]
)

# construct a SageMaker TensorFlow estimator
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name='debugger-demo-job',
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="2.9.0",
    py_version="py39",
    debugger_hook_config=hook_config
)

sagemaker_estimator.fit()
```

For a full list of CollectionConfig parameters, see Debugger CollectionConfig API.
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import DebuggerHookConfig, CollectionConfig

# use Debugger CollectionConfig to create a custom collection
collection_configs=[
    CollectionConfig(
        name="custom_activations_collection",
        parameters={
            "include_regex": "relu|tanh", # Required
            "reductions": "mean,variance,max,abs_mean,abs_variance,abs_max"
        }
    )
]

# configure Debugger hook
# set a target S3 bucket as you want
sagemaker_session=sagemaker.Session()
BUCKET_NAME=sagemaker_session.default_bucket()
LOCATION_IN_BUCKET='debugger-custom-collections-hook'

hook_config=DebuggerHookConfig(
    s3_output_path='s3://{BUCKET_NAME}/{LOCATION_IN_BUCKET}'.format(BUCKET_NAME=BUCKET_NAME,
        LOCATION_IN_BUCKET=LOCATION_IN_BUCKET),
    collection_configs=collection_configs
)

# construct a SageMaker TensorFlow estimator
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name='debugger-demo-job',
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="2.9.0",
    py_version="py39",
    # debugger-specific hook argument below
    debugger_hook_config=hook_config
)

sagemaker_estimator.fit()

For a full list of CollectionConfig parameters, see Debugger CollectionConfig.

Configure Debugger Built-in Rules

Amazon SageMaker Debugger's built-in rules analyze tensors emitted during the training of a model. SageMaker Debugger offers the Rule API operation that monitors training job progress and errors for the success of training your model. For example, the rules can detect whether gradients are getting too large or too small, whether a model is overfitting or overtraining, and whether a training job does not decrease loss function and improve. To see a full list of available built-in rules, see List of Debugger Built-in Rules (p. 1975).

In the following topics, you'll learn how to use the SageMaker Debugger built-in rules.

Topics
- Use Debugger Built-in Rules with the Default Parameter Settings (p. 1945)
- Use Debugger Built-in Rules with Custom Parameter Values (p. 1945)
- Example Notebooks and Code Samples to Configure Debugger Rules (p. 1946)
Use Debugger Built-in Rules with the Default Parameter Settings

To specify Debugger built-in rules in an estimator, you need to configure a list object. The following example code shows the basic structure of listing the Debugger built-in rules:

```python
from sagemaker.debugger import Rule, rule_configs

rules=[
    Rule.sagemaker(rule_configs.built_in_rule_name_1()),
    Rule.sagemaker(rule_configs.built_in_rule_name_2()),
    ...
    Rule.sagemaker(rule_configs.built_in_rule_name_n()),
    ...
]  # You can also append more profiler rules in the ProfilerRule.sagemaker(rule_configs.*()) format.
```

For more information about default parameter values and descriptions of the built-in rule, see List of Debugger Built-in Rules (p. 1975).

To find the SageMaker Debugger API reference, see `sagemaker.debugger.rule_configs` and `sagemaker.debugger.Rule`.

For example, to inspect the overall training performance and progress of your model, construct a SageMaker estimator with the following built-in rule configuration.

```python
from sagemaker.debugger import Rule, rule_configs

rules=[
    Rule.sagemaker(rule_configs.loss_not_decreasing()),
    Rule.sagemaker(rule_configs.overfit()),
    Rule.sagemaker(rule_configs.overtraining()),
    Rule.sagemaker(rule_configs.stalled_training_rule())
]
```

When you start the training job, Debugger collects system resource utilization data every 500 milliseconds and the loss and accuracy values every 500 steps by default. Debugger analyzes the resource utilization to identify if your model is having bottleneck problems. The `loss_not_decreasing`, `overfit`, `overtraining`, and `stalled_training_rule` monitors if your model is optimizing the loss function without those training issues. If the rules detect training anomalies, the rule evaluation status changes to `IssueFound`. You can set up automated actions, such as notifying training issues and stopping training jobs using Amazon CloudWatch Events and AWS Lambda. For more information, see Action on Amazon SageMaker Debugger Rules (p. 1964).

Use Debugger Built-in Rules with Custom Parameter Values

If you want to adjust the built-in rule parameter values and customize tensor collection regex, configure the `base_config` and `rule_parameters` parameters for the `ProfilerRule.sagemaker` and `Rule.sagemaker` classmethods. In case of the `Rule.sagemaker` class methods, you can also customize tensor collections through the `collections_to_save` parameter. The instruction of how to use the `CollectionConfig` class is provided at Configure Tensor Collections Using the CollectionConfig API (p. 1939).

Use the following configuration template for built-in rules to customize parameter values. By changing the rule parameters as you want, you can adjust the sensitivity of the rules to be triggered.

- The `base_config` argument is where you call the built-in rule methods.
- The `rule_parameters` argument is to adjust the default key values of the built-in rules listed in List of Debugger Built-In Rules (p. 1975).
The `collections_to_save` argument takes in a tensor configuration through the `CollectionConfig` API, which requires name and parameters arguments.

To find available tensor collections for name, see [Debugger Built-in Tensor Collections](#).

For a full list of adjustable parameters, see [Debugger CollectionConfig API](#).

For more information about the Debugger rule class, methods, and parameters, see [SageMaker Debugger Rule class](#) in the [Amazon SageMaker Python SDK](#).

```python
from sagemaker.debugger import Rule, ProfilerRule, rule_configs, CollectionConfig

rules=[
    Rule.sagemaker(
        base_config=rule_configs.built_in_rule_name(),
        rule_parameters={
            "key": "value"
        },
        collections_to_save=[
            CollectionConfig(
                name="tensor_collection_name",
                parameters={
                    "key": "value"
                }
            )
        ]
    )
]
```

The parameter descriptions and value customization examples are provided for each rule at [List of Debugger Built-in Rules](#).

**Example Notebooks and Code Samples to Configure Debugger Rules**

In the following sections, notebooks and code samples of how to use Debugger rules to monitor SageMaker training jobs are provided.

**Topics**

- [Debugger Built-in Rules Example Notebooks](#)
- [Debugger Built-in Rules Example Code](#)
- [Use Debugger Built-in Rules with Parameter Modifications](#)

**Debugger Built-in Rules Example Notebooks**

The following example notebooks show how to use Debugger built-in rules when running training jobs with Amazon SageMaker:

- [Using a SageMaker Debugger built-in rule with TensorFlow](#)
- [Using a SageMaker Debugger built-in rule with Managed Spot Training and MXNet](#)
- [Using a SageMaker Debugger built-in rule with parameter modifications for a real-time training job analysis with XGBoost](#)

While running the example notebooks in SageMaker Studio, you can find the training job trial created on the [Studio Experiment List](#) tab. For example, as shown in the following screenshot, you can find and open a [Describe Trial Component](#) window of your current training job. On the Debugger tab, you can check if the Debugger rules, `vanishing_gradient()` and `loss_not_decreasing()`, are monitoring the training session in parallel. For a full instruction of how to find your training job trial components in the Studio UI, see [SageMaker Studio - View Experiments, Trials, and Trial Components](#).
There are two ways of using the Debugger built-in rules in the SageMaker environment: deploy the built-in rules as it is prepared or adjust their parameters as you want. The following topics show you how to use the built-in rules with example codes.

**Debugger Built-in Rules Example Code**

The following code sample shows how to set the Debugger built-in rules using the `Rule.sagemaker` method. To specify built-in rules that you want to run, use the `rules_configs` API operation to call the built-in rules. To find a full list of Debugger built-in rules and default parameter values, see *List of Debugger Built-in Rules* (p. 1975).

```python
import sagemakerrom sagemaker.tensorflow import TensorFlowrom sagemaker.debugger import Rule, CollectionConfig, rule_configs
# call built-in rules that you want to use.
built_in_rules=[
    Rule.sagemaker(rule_configs.vanishing_gradient()),
    Rule.sagemaker(rule_configs.loss_not_decreasing())
]
# construct a SageMaker estimator with the Debugger built-in rules
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    )
```
base_job_name='debugger-built-in-rules-demo',
instance_count=1,
instance_type="ml.p3.2xlarge",
framework_version="2.9.0",
py_version="py39",

# debugger-specific arguments below
rules=built_in_rules
)
sagemaker_estimator.fit()

Note
The Debugger built-in rules run in parallel with your training job. The maximum number of built-in rule containers for a training job is 20.

For more information about the Debugger rule class, methods, and parameters, see the SageMaker Debugger Rule class in the Amazon SageMaker Python SDK.

To find an example of how to adjust the Debugger rule parameters, see the following Use Debugger Built-in Rules with Parameter Modifications (p. 1948) section.

Use Debugger Built-in Rules with Parameter Modifications

The following code example shows the structure of built-in rules to adjust parameters. In this example, the stalled_training_rule collects the losses tensor collection from a training job at every 50 steps and an evaluation stage at every 10 steps. If the training process starts stalling and not collecting tensor outputs for 120 seconds, the stalled_training_rule stops the training job.

import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import Rule, CollectionConfig, rule_configs

# call the built-in rules and modify the CollectionConfig parameters
base_job_name_prefix = 'smdebug-stalled-demo-' + str(int(time.time()))

built_in_rules_modified = [
    Rule.sagemaker(
        base_config=rule_configs.stalled_training_rule(),
        rule_parameters={
            'threshold': '120',
            'training_job_name_prefix': base_job_name_prefix,
            'stop_training_on_fire': 'True'
        },
        collections_to_save=[
            CollectionConfig(
                name="losses",
                parameters={
                    "train.save_interval": "50",
                    "eval.save_interval": "10"
                }
            )
        ]
    )
]

# construct a SageMaker estimator with the modified Debugger built-in rule
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name=base_job_name_prefix,
    instance_count=1,
    instance_type="ml.p3.2xlarge",
)
For an advanced configuration of the Debugger built-in rules using the CreateTrainingJob API, see Configure Debugger Using Amazon SageMaker API (p. 2014).

**Turn Off Debugger**

If you want to completely turn off Debugger, do one of the following:

- Before starting a training job, do the following:

  To stop both monitoring and profiling, include the `disable_profiler` parameter to your estimator and set it to `True`.

  **Warning**
  
  If you disable it, you won’t be able to view the comprehensive Studio Debugger insights dashboard and the autogenerated profiling report.

  To stop debugging, set the `debugger_hook_config` parameter to `False`.

  **Warning**
  
  If you disable it, you won’t be able to collect output tensors and cannot debug your model parameters.

```python
estimator=Estimator(
  ...
  disable_profiler=True
  debugger_hook_config=False
)
```

For more information about the Debugger-specific parameters, see SageMaker Estimator in the Amazon SageMaker Python SDK.

- While a training job is running, do the following:

  To disable both monitoring and profiling while your training job is running, use the following estimator classmethod:

```python
estimator.disable_profiling()
```

To disable framework profiling only and keep system monitoring, use the `update_profiler` method:

```python
estimator.update_profiler(disable_framework_metrics=true)
```

For more information about the estimator extension methods, see the `estimator.disable_profiling` and `estimator.update_profiler` classmethods in the Amazon SageMaker Python SDK documentation.

**Useful SageMaker Estimator Classmethods for Debugger**

The following estimator class methods are useful for accessing your SageMaker training job information and retrieving output paths of training data collected by Debugger. The following methods are executable after you initiate a training job with the `estimator.fit()` method.
• To check the base S3 bucket URI of a SageMaker training job:

`estimator.output_path`

• To check the base job name of a SageMaker training job:

`estimator.latest_training_job.job_name`

• To see a full `CreateTrainingJob` API operation configuration of a SageMaker training job:

`estimator.latest_training_job.describe()`

• To check a full list of the Debugger rules while a SageMaker training job is running:

`estimator.latest_training_job.rule_job_summary()`

• To check the S3 bucket URI where the model parameter data (output tensors) are saved:

`estimator.latest_job_debugger_artifacts_path()`

• To check the S3 bucket URI at where the model performance data (system and framework metrics) are saved:

`estimator.latest_job_profiler_artifacts_path()`

• To check the Debugger rule configuration for debugging output tensors:

`estimator.debugger_rule_configs`

• To check the list of the Debugger rules for debugging while a SageMaker training job is running:

`estimator.debugger_rules`

• To check the Debugger rule configuration for monitoring and profiling system and framework metrics:

`estimator.profiler_rule_configs`

• To check the list of the Debugger rules for monitoring and profiling while a SageMaker training job is running:

`estimator.profiler_rules`

For more information about the SageMaker estimator class and its methods, see [Estimator API](https://docs.aws.amazon.com/sagemaker/latest/dg/estimator-api.html) in the [Amazon SageMaker Python SDK](https://docs.aws.amazon.com/sagemaker/latest/dg/python-sdk.html).

**SageMaker Debugger Interactive Report for XGBoost**

Receive training reports autogenerated by Debugger. The Debugger reports provide insights into your training jobs and suggest recommendations to improve your model performance.

**Note**

You can download a Debugger report while your training job is running or after the job has finished. During training, Debugger concurrently updates the report reflecting the current rules' evaluation status. You can download a complete Debugger report only after the training job has completed.
Important
In the report, plots and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

SageMaker Debugger XGBoost Training Report

For SageMaker XGBoost training jobs, use the Debugger CreateXgboostReport (p. 1977) rule to receive a comprehensive training report of the training progress and results. Following this guide, specify the CreateXgboostReport (p. 1977) rule while constructing an XGBoost estimator, download the report using the Amazon SageMaker Python SDK or the Amazon S3 console, and gain insights into the training results.

Important
In the report, plots and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

Topics
- Construct a SageMaker XGBoost Estimator with the Debugger XGBoost Report Rule (p. 1951)
- Download the Debugger XGBoost Training Report (p. 1952)
- Debugger XGBoost Training Report Walkthrough (p. 1955)

Construct a SageMaker XGBoost Estimator with the Debugger XGBoost Report Rule

The CreateXgboostReport (p. 1977) rule collects the following output tensors from your training job:

- hyperparameters – Saves at the first step.
- metrics – Saves loss and accuracy every 5 steps.
- feature_importance – Saves every 5 steps.
- predictions – Saves every 5 steps.
- labels – Saves every 5 steps.

The output tensors are saved at a default S3 bucket. For example, s3://sagemaker-<region>-<12digit_account_id>/<base-job-name>/debug-output/.

When you construct a SageMaker estimator for an XGBoost training job, specify the rule as shown in the following example code.

Using the SageMaker generic estimator

```python
import boto3
import sagemaker
from sagemaker.estimator import Estimator
from sagemaker import image_uris
from sagemaker.debugger import Rule, rule_configs

rules=[
    Rule.sagemaker(rule_configs.create_xgboost_report())
]

region = boto3.Session().region_name
xgboost_container=sagemaker.image_uris.retrieve("xgboost", region, "1.2-1")

estimator=Estimator(
    role=sagemaker.get_execution_role(),
    image_uri=xgboost_container,
    base_job_name="debugger-xgboost-report-demo",
)```
Use SageMaker Debugger

```python
instance_count=1,
instance_type="ml.m5.2xlarge",

# Add the Debugger XGBoost report rule
rules=rules
)
estimator.fit(wait=False)
```

**Download the Debugger XGBoost Training Report**

Download the Debugger XGBoost training report while your training job is running or after the job has finished using the Amazon SageMaker Python SDK and AWS Command Line Interface (CLI).

**Download using the SageMaker Python SDK and AWS CLI**

1. Check the current job's default S3 output base URI.
   ```
estimator.output_path
   ```

2. Check the current job name.
   ```
estimator.latest_training_job.job_name
   ```

3. The Debugger XGBoost report is stored under `<default-s3-output-base-uri>/ <training-job-name>/rule-output`. Configure the rule output path as follows:
   ```
rule_output_path = estimator.output_path + "" + estimator.latest_training_job.job_name + "/" + "/rule-output"
   ```

4. To check if the report is generated, list directories and files recursively under the `rule_output_path` using `aws s3 ls` with the --recursive option.
   ```
! aws s3 ls {rule_output_path} --recursive
   ```

This should return a complete list of files under autogenerated folders that are named `CreateXgboostReport` and `ProfilerReport-1234567890`. The XGBoost training report is stored in the `CreateXgboostReport`, and the profiling report is stored in the `ProfilerReport-1234567890` folder. To learn more about the profiling report generated by default with the XGBoost training job, see SageMaker Debugger profiling report (p. 2082).

The `xgboost_report.html` is an autogenerated XGBoost training report by Debugger. The `xgboost_report.ipynb` is a Jupyter notebook that's used to aggregate training results into the report. You can download all of the files, browse the HTML report file, and modify the report using the notebook.

5. Download the files recursively using `aws s3 cp`. The following command saves all of the rule output files to the `ProfilerReport-1234567890` folder under the current working directory.

```
aws s3 ls {rule_output_path} --recursive
```

1952
Tip
If you are using a Jupyter notebook server, run `!pwd` to verify the current working directory.

6. Under the `/CreateXgboostReport` directory, open `xgboost_report.html`. If you are using JupyterLab, choose `Trust HTML` to see the autogenerated Debugger training report.

7. Open the `xgboost_report.ipynb` file to explore how the report is generated. You can customize and extend the training report using the Jupyter notebook file.

Download using the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at [https://console.aws.amazon.com/s3/](https://console.aws.amazon.com/s3/).

2. Search for the base S3 bucket. For example, if you haven't specified any base job name, the base S3 bucket name should be in the following format: `sagemaker-<region>-111122223333`. Look up the base S3 bucket through the `Find bucket by name` field.

3. In the base S3 bucket, look up the training job name by entering your job name prefix in `Find objects by prefix` and then choosing the training job name.
4. In the training job’s S3 bucket, choose `rule-output/` subfolder. There must be three subfolders for training data collected by Debugger: `debug-output/`, `profiler-output/`, and `rule-output/`.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Last modified</th>
<th>Size</th>
<th>Storage class</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>debug-output/</code></td>
<td>Folder</td>
<td>-</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td><code>profiler-output/</code></td>
<td>Folder</td>
<td>-</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td><code>rule-output/</code></td>
<td>Folder</td>
<td>-</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>

5. In the `rule-output/` folder, choose the `CreateXgboostReport/` folder. The folder contains `xbgoost_report.html` (the autogenerated report in html) and `xbgoost_report.ipynb` (a Jupyter notebook with scripts that are used for generating the report).

6. Choose the `xbgoost_report.html` file, choose Download actions, and then choose Download.
7. Open the downloaded `xgboost_report.html` file in a web browser.

**Debugger XGBoost Training Report Walkthrough**

This section walks you through the Debugger XGBoost training report. The report is automatically aggregated depending on the output tensor regex, recognizing what type of your training job is among binary classification, multiclass classification, and regression.

**Important**

In the report, plots and and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

**Topics**

- Distribution of True Labels of the Dataset (p. 1956)
- Loss versus Step Graph (p. 1956)
- Feature Importance (p. 1957)
- Confusion Matrix (p. 1958)
- Evaluation of the Confusion Matrix (p. 1959)
- Accuracy Rate of Each Diagonal Element Over Iteration (p. 1960)
- Receiver Operating Characteristic Curve (p. 1961)
- Distribution of Residuals at the Last Saved Step (p. 1962)
- Absolute Validation Error per Label Bin Over Iteration (p. 1963)
Distribution of True Labels of the Dataset

This histogram shows the distribution of labeled classes (for classification) or values (for regression) in your original dataset. Skewness in your dataset could contribute to inaccuracies. This visualization is available for the following model types: binary classification, multiclassification, and regression.

Loss versus Step Graph

This is a line chart that shows the progression of loss on training data and validation data throughout training steps. The loss is what you defined in your objective function, such as mean squared error. You can gauge whether the model is overfit or underfit from this plot. This section also provides insights that you can use to determine how to resolve the overfit and underfit problems. This visualization is available for the following model types: binary classification, multiclassification, and regression.
Feature Importance

There are three different types of feature importance visualizations provided: Weight, Gain and Coverage. We provide detailed definitions for each of the three in the report. Feature importance visualizations help you learn what features in your training dataset contributed to the predictions. Feature importance visualizations are available for the following model types: binary classification, multiclassification, and regression.
Confusion Matrix

This visualization is only applicable to binary and multiclass classification models. Accuracy alone might not be sufficient for evaluating the model performance. For some use cases, such as healthcare and fraud detection, it’s also important to know the false positive rate and false negative rate. A confusion matrix gives you the additional dimensions for evaluating your model performance.
Evaluation of the Confusion Matrix

This section provides you with more insights on the micro, macro, and weighted metrics on precision, recall, and F1-score for your model.
Overall Accuracy

Overall Accuracy: 0.919

Micro Performance Metrics

Performance metrics calculated globally by counting the total true positives, false negatives, and false positive s.

Micro Precision: 0.919
Micro Recall: 0.919
Micro F1-score: 0.919

Macro Performance Metrics

Performance metrics calculated for each label, and find their unweighted mean.
This does not take the class imbalance problem into account.

Macro Precision: 0.919
Macro Recall: 0.918
Macro F1-score: 0.918

Weighted Performance Metrics

Performance metrics calculated for each label and their average weighted by support (the number of true instances for each label).
This extends the macro option to take the class imbalance into account.
It might result in an F-score that is not between precision and recall.

Weighted Precision: 0.92
Weighted Recall: 0.919
Weighted F1-score: 0.919

Classification Report

The summary of the precision, recall, and F1-score for each class.

Accuracy Rate of Each Diagonal Element Over Iteration

This visualization is only applicable to binary classification and multiclass classification models. This is a line chart that plots the diagonal values in the confusion matrix throughout the training steps for each class. This plot shows you how the accuracy of each class progresses throughout the training steps. You can identify the under-performing classes from this plot.
Receiver Operating Characteristic Curve

This visualization is only applicable to binary classification models. The Receiver Operating Characteristic curve is commonly used to evaluate binary classification model performance. The y-axis of the curve is True Positive Rate (TPF) and x-axis is false positive rate (FPR). The plot also displays the value for the area under the curve (AUC). The higher the AUC value, the more predictive your classifier. You can also use the ROC curve to understand the trade-off between TPR and FPR and identify the optimum classification threshold for your use case. The classification threshold can be adjusted to tune the behavior of the model to reduce more of one or another type of error (FP/FN).
Distribution of Residuals at the Last Saved Step

This visualization is a column chart that shows the residual distributions in the last step Debugger captures. In this visualization, you can check whether the residual distribution is close to normal distribution that’s centered at zero. If the residuals are skewed, your features may not be sufficient for predicting the labels.
Absolute Validation Error per Label Bin Over Iteration

This visualization is only applicable to regression models. The actual target values are split into 10 intervals. This visualization shows how validation errors progress for each interval throughout the training steps in line plots. Absolute validation error is the absolute value of difference between prediction and actual during validation. You can identify the underperforming intervals from this visualization.
Action on Amazon SageMaker Debugger Rules

Based on the Debugger rule evaluation status, you can set up automated actions such as stopping a training job and sending notifications using Amazon Simple Notification Service (Amazon SNS). You can also create your own actions using Amazon CloudWatch Events and AWS Lambda. To learn how to set up automated actions based on the Debugger rule evaluation status, see the following topics.

Topics
- Debugger Built-in Actions for Rules (p. 1964)
- Create Actions on Rules Using Amazon CloudWatch and AWS Lambda (p. 1968)

Debugger Built-in Actions for Rules

Use Debugger built-in actions to respond to issues found by Debugger Rule (p. 1976). The Debugger rule_configs class provides tools to configure a list of actions, including automatically stopping training jobs and sending notifications using Amazon Simple Notification Service (Amazon SNS) when the Debugger rules find training issues.

Step 1: Set Up Amazon SNS, Create an SMDebugRules Topic, and Subscribe to the Topic

This section walks you through how to set up an Amazon SNS SMDebugRules topic, subscribe to it, and confirm the subscription to receive notifications from the Debugger rules.

Note
For more information about billing for Amazon SNS, see Amazon SNS pricing and Amazon SNS FAQs.

To create a SMDebugRules topic

2. In the left navigation pane, choose Topics.
3. On the Topics page, choose Create topic.
4. On the Create topic page, in the Details section, do the following:
   a. For Type, choose Standard for topic type.
   b. In Name, enter SMDebugRules.
5. Skip all other optional settings and choose Create topic. If you want to learn more about the optional settings, see Creating an Amazon SNS topic.

To subscribe to the SMDebugRules topic

2. In the left navigation pane, choose Subscriptions.
3. On the Subscriptions page, choose Create subscription.
4. On the Create subscription page, in the Details section, do the following:
   b. For Protocol, choose Email or SMS.
   c. For Endpoint, enter the endpoint value, such as an email address or a phone number that you want to receive notifications.
Note
Make sure you type the correct email address and phone number. Phone numbers must include +, a country code, and phone number, with no special characters or spaces. For example, the phone number +1 (222) 333-4444 is formatted as +12223334444.

5. Skip all other optional settings and choose Create subscription. If you want to learn more about the optional settings, see Subscribing to an Amazon SNS topic.

After you subscribe to the SMDebugRules topic, you receive the following confirmation message in email or by phone:

AWS Notification - Subscription Confirmation

SMDebugRules <no-reply@sns.amazonaws.com>
To:

You have chosen to subscribe to the topic:
arn:aws:sns:us-east-1:1112223333:SMDebugRules

To confirm this subscription, click or visit the link below (If this was in error no action is necessary):
Confirm subscription

Please do not reply directly to this email. If you wish to remove yourself from receiving all future SNS subscription confirmation requests please send an email to sns-set-out

For more information about Amazon SNS, see Mobile text messaging (SMS) and Email notifications in the Amazon SNS Developer Guide.

Step 2: Set Up Your IAM Role to Attach Required Policies

In this step, you add the required policies to your IAM role.

To add the required policies to your IAM role

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose Policies, and choose Create policy.
3. On the Create policy page, do the following to create a new sns-access policy:
   a. Choose the JSON tab.
   b. Paste the JSON strings formatted in bold in the following code into the "Statement", replacing the 12-digit AWS account ID with your AWS account ID.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": [
        "sns:Publish",
        "sns:CreateTopic",
        "sns:Subscribe"
      ],
      "Resource": "arn:aws:sns:::1112223333:SMDebugRules"
    }
  ]
}
```
c. At the bottom of the page, choose **Review policy**.
d. On the **Review policy** page, for **Name**, enter **sns-access**.
e. At the bottom of the page, choose **Create policy**.

4. Go back to the IAM console, and choose **Roles** in the left navigation pane.
5. Look up the IAM role that you use for SageMaker model training and choose that IAM role.
6. On the **Permissions** tab of the **Summary** page, choose **Attach policies**.
7. Search for the **sns-access** policy, select the check box next to the policy, and then choose **Attach policy**.

For more examples of setting up IAM policies for Amazon SNS, see [Example cases for Amazon SNS access control](https://docs.aws.amazon.com/sagemaker/latest/dg/sagemaker-access-control-example-sns.html).

### Step 3: Configure Debugger Rules with the Built-in Actions

After successfully finishing the required settings in the preceding steps, you can configure the Debugger built-in actions for debugging rules as shown in the following example script. You can choose which built-in actions to use while building the actions list object. The `rule_configs` is a helper module that provides high-level tools to configure Debugger built-in rules and actions. The following built-in actions are available for Debugger:

- `rule_configs.StopTraining()` — Stops a training job when the Debugger rule finds an issue.
- `rule_configs.Email("abc@abc.com")` — Sends a notification via email when the Debugger rule finds an issue. Use the email address that you used when you set up your SNS topic subscription.
- `rule_configs.SMS("+1234567890")` — Sends a notification via text message when the Debugger rule finds an issue. Use the phone number that you used when you set up your SNS topic subscription.

**Note**

Make sure you type the correct email address and phone number. Phone numbers must include +, a country code, and a phone number, with no special characters or spaces. For example, the phone number +1 (222) 333-4444 is formatted as +12223334444.

You can use all of the built-in actions or a subset of actions by wrapping up using the `rule_configs.ActionList()` method, which takes the built-in actions and configures a list of actions.

**To add all of the three built-in actions to a single rule**

If you want to assign all of the three built-in actions to a single rule, configure a Debugger built-in action list while constructing an estimator. Use the following template to construct the estimator, and Debugger will stop training jobs and send notifications through email and text for any rules that you use to monitor your training job progress.

```python
from sagemaker.debugger import Rule, rule_configs

# Configure an action list object for Debugger rules
actions = rule_configs.ActionList(
    rule_configs.StopTraining(),
    rule_configs.Email("abc@abc.com"),
    rule_configs.SMS("+1234567890")
)

# Configure rules for debugging with the actions parameter
rules = [
    Rule.sagemaker(
        base_config=rule_configs.built_in_rule(),  # Required
        rule_parameters={"parameter_key": value },  # Optional
        # Other Rule parameters
    )
]
```

1966
To create multiple built-in action objects to assign different actions to a single rule

If you want to assign the built-in actions to be triggered at different threshold values of a single rule, you can create multiple built-in action objects as shown in the following script. To avoid a conflict error by running the same rule, you must submit different rule job names (specify different strings for the rules' name attribute) as shown in the following example script template. This example shows how to set up StalledTrainingRule (p. 1997) to take two different actions: send an email to abc@abc.com when a training job stalls for 60 seconds, and stop the training job if stalling for 120 seconds.

```python
from sagemaker.debugger import Rule, rule_configs
import time

base_job_name_prefix= 'smdebug-stalled-demo-' + str(int(time.time()))

# Configure an action object for StopTraining
action_stop_training = rule_configs.ActionList(
    rule_configs.StopTraining()
)

# Configure an action object for Email
action_email = rule_configs.ActionList(
    rule_configs.Email("abc@abc.com")
)

# Configure a rule with the Email built-in action to trigger if a training job stalls for 60 seconds
stalled_training_job_rule_email = Rule.sagemaker(
    base_config=rule_configs.stalled_training_rule(),
    rule_parameters={
        "threshold": "60",
        "training_job_name_prefix": base_job_name_prefix
    },
    actions=action_email
)

stalled_training_job_rule_email.name="StalledTrainingJobRuleEmail"

# Configure a rule with the StopTraining built-in action to trigger if a training job stalls for 120 seconds
stalled_training_job_rule = Rule.sagemaker(
    base_config=rule_configs.stalled_training_rule(),
    rule_parameters={
        "threshold": "120",
        "training_job_name_prefix": base_job_name_prefix
    },
    actions=action_stop_training
)

stalled_training_job_rule.name="StalledTrainingJobRuleStopTraining"

estimator = Estimator("...
    rules = [stalled_training_job_rule_email, stalled_training_job_rule]
)
While the training job is running, the Debugger built-in action sends notification emails and text messages whenever the rule finds issues with your training job. The following screenshot shows an example of email notification for a training job that has a stalled training job issue.

**SMDebugRule:StalledTrainingRule fired**

![Image of email notification]

Considerations for Using the Debugger Built-in Actions

- To use the Debugger built-in actions, an internet connection is required. This feature is not supported in the network isolation mode provided by Amazon SageMaker or Amazon VPC.
- The built-in actions cannot be used for Profiler rules (p. 2062).
- The built-in actions cannot be used on training jobs with spot training interruptions.
- In email or text notifications, `None` appears at the end of messages. This does not have any meaning, so you can disregard the text `None`.

Create Actions on Rules Using Amazon CloudWatch and AWS Lambda

Amazon CloudWatch collects Amazon SageMaker model training job logs and Amazon SageMaker Debugger rule processing job logs. Configure Debugger with Amazon CloudWatch Events and AWS Lambda to take action based on Debugger rule evaluation status.

CloudWatch Logs for Debugger Rules and Training Jobs

To find training job logs and Debugger rule job logs

2. In the left navigation pane under the Log node, choose Log Groups.
3. In the log groups list, do the following:
Choose `/aws/sagemaker/TrainingJobs` for training job logs.

Choose `/aws/sagemaker/ProcessingJobs` for Debugger rule job logs.

You can use the training and Debugger rule job status in the CloudWatch logs to take further actions when there are training issues.

For more information about monitoring training jobs using CloudWatch, see Monitor Amazon SageMaker.

**Set Up Debugger for Automated Training Job Termination Using CloudWatch and Lambda**

The Debugger rules monitor training job status, and a CloudWatch Events rule watches the Debugger rule training job evaluation status.

**Step 1: Create a Lambda Function**

**To create a Lambda function**

1. Open the AWS Lambda console at https://console.aws.amazon.com/lambda/.
2. In the left navigation pane, choose Functions and then choose Create function.
3. On the Create function page, choose Author from scratch option.
4. In the Basic information section, enter a Function name (for example, `debugger-rule-stop-training-job`).
5. For Runtime, choose Python 3.7.
6. For Permissions, expand the drop down option, and choose Change default execution role.
7. For Execution role, choose Use an existing role and choose the IAM role that you use for training jobs on SageMaker.
   
   **Note**
   
   Make sure you use the execution role with AmazonSageMakerFullAccess and AWSLambdaBasicExecutionRole attached. Otherwise, the Lambda function won't properly react to the Debugger rule status changes of the training job. If you are unsure which execution role is being used, run the following code in a Jupyter notebook cell to retrieve the execution role output:

   ```python
   import sagemaker
   sagemaker.get_execution_role()
   ```

8. At the bottom of the page, choose Create function.

The following figure shows an example of the Create function page with the input fields and selections completed.
Step 2: Configure the Lambda function

To configure the Lambda function

1. In the Function code section of the configuration page, paste the following Python script in the Lambda code editor pane. The `lambda_handler` function monitors the Debugger rule evaluation status collected by CloudWatch and triggers the `StopTrainingJob` API operation. The AWS SDK for Python (Boto3) `client` for SageMaker provides a high-level method, `stop_training_job`, which triggers the `StopTrainingJob` API operation.

```python
import json
import boto3
import logging

logger = logging.getLogger()
logger.setLevel(logging.INFO)

def lambda_handler(event, context):
    training_job_name = event.get("detail").get("TrainingJobName")
    logging.info(f'Evaluating Debugger rules for training job: {training_job_name}')
    stop_training_job(training_job_name)
```

```python
def stop_training_job(training_job_name):
    client = boto3.client('sagemaker')
    response = client.stop_training_job(TrainingJobName=training_job_name)
    print(f'StopTrainingJob API operation triggered: {response}')
```

For more information about the Lambda code editor interface, see Creating functions using the AWS Lambda console editor.

2. Skip all other settings and choose **Save** at the top of the configuration page.

**Step 3: Create a CloudWatch Events Rule and Link to the Lambda Function for Debugger**

To create a CloudWatch Events rule and link to the Lambda function for Debugger

2. In the left navigation pane, choose **Rules** under the **Events** node.
3. Choose **Create rule**.
4. In the **Event Source** section of the **Step 1: Create rule** page, choose **SageMaker** for **Service Name**, and choose **SageMaker Training Job State Change** for **Event Type**. The Event Pattern Preview should look like the following example JSON strings:
5. In the **Targets** section, choose **Add target***, and choose the **debugger-rule-stop-training-job** Lambda function that you created. This step links the CloudWatch Events rule with the Lambda function.

6. Choose **Configure details** and go to the **Step 2: Configure rule details** page.

7. Specify the CloudWatch rule definition name. For example, **debugger-cw-event-rule**.

8. Choose **Create rule** to finish.

9. Go back to the Lambda function configuration page and refresh the page. Confirm that it's configured correctly in the **Designer** panel. The CloudWatch Events rule should be registered as a trigger for the Lambda function. The configuration design should look like the following example:

![CloudWatch Events configuration](image)

**Run Example Notebooks to Test Automated Training Job Termination**

You can run the following example notebooks, which are prepared for experimenting with stopping a training job using Debugger's built-in rules.

- **Amazon SageMaker Debugger - Reacting to CloudWatch Events from Rules**

  This example notebook runs a training job that has a vanishing gradient issue. The Debugger **VanishingGradient** *(p. 1985)* built-in rule is used while constructing the SageMaker TensorFlow estimator. When the Debugger rule detects the issue, the training job is terminated.
• **Detect Stalled Training and Invoke Actions Using SageMaker Debugger Rule**

This example notebook runs a training script with a code line that forces it to sleep for 10 minutes. The Debugger **StalledTrainingRule (p. 1997)** built-in rule invokes issues and stops the training job.

**Disable the CloudWatch Events Rule to Stop Using the Automated Training Job Termination**

If you want to disable the automated training job termination, you need to disable the CloudWatch Events rule. In the Lambda **Designer** panel, choose the **EventBridge (CloudWatch Events)** block linked to the Lambda function. This shows an **EventBridge** panel below the **Designer** panel (for example, see the previous screen shot). Select the check box next to **EventBridge (CloudWatch Events): debugger-cw-event-rule**, and then choose **Disable**. If you want to use the automated termination functionality later, you can enable the CloudWatch Events rule again.

**Visualize Amazon SageMaker Debugger Output Tensors in TensorBoard**

**Important**

This page is deprecated in favor of Amazon SageMaker with TensorBoard, which provides a comprehensive TensorBoard experience integrated with SageMaker Training and the access control functionalities of SageMaker Domain. To learn more, see [Use TensorBoard to debug and analyze training jobs in Amazon SageMaker](p. 1904).

Use SageMaker Debugger to create output tensor files that are compatible with TensorBoard. Load the files to visualize in TensorBoard and analyze your SageMaker training jobs. Debugger automatically generates output tensor files that are compatible with TensorBoard. For any hook configuration you customize for saving output tensors, Debugger has the flexibility to create scalar summaries, distributions, and histograms that you can import to TensorBoard.

You can enable this by passing `DebuggerHookConfig` and `TensorBoardOutputConfig` objects to an estimator.

The following procedure explains how to save scalars, weights, and biases as full tensors, histograms, and distributions that can be visualized with TensorBoard. Debugger saves them to the training container's local path (the default path is `/opt/ml/output/tensors`) and syncs to the Amazon S3 locations passed through the Debugger output configuration objects.

**To save TensorBoard compatible output tensor files using Debugger**

1. Set up a `tensorboard_output_config` configuration object to save TensorBoard output using the Debugger `TensorBoardOutputConfig` class. For the `s3_output_path` parameter, specify the
default S3 bucket of the current SageMaker session or a preferred S3 bucket. This example does not add the container_local_output_path parameter; instead, it is set to the default local path /opt/ml/output/tensors.

```python
import sagemaker
from sagemaker.debugger import TensorBoardOutputConfig

bucket = sagemaker.Session().default_bucket()
tensorboard_output_config = TensorBoardOutputConfig(
    s3_output_path='s3://{}'.format(bucket)
)
```

For additional information, see the Debugger TensorBoardOutputConfig API in the Amazon SageMaker Python SDK.

2. Configure the Debugger hook and customize the hook parameter values. For example, the following code configures a Debugger hook to save all scalar outputs every 100 steps in training phases and 10 steps in validation phases, the weights parameters every 500 steps (the default save_interval value for saving tensor collections is 500), and the bias parameters every 10 global steps until the global step reaches 500.

```python
from sagemaker.debugger import CollectionConfig, DebuggerHookConfig

hook_config = DebuggerHookConfig(
    hook_parameters={
        "train.save_interval": "100",
        "eval.save_interval": "10"
    },
    collection_configs=[
        CollectionConfig("weights"),
        CollectionConfig("biases",
            name="biases",
            parameters={
                "save_interval": "10",
                "end_step": "500",
                "save_histogram": "True"
            }
        )
    ]
)
```

For more information about the Debugger configuration APIs, see the Debugger CollectionConfig and DebuggerHookConfig APIs in the Amazon SageMaker Python SDK.

3. Construct a SageMaker estimator with the Debugger parameters passing the configuration objects. The following example template shows how to create a generic SageMaker estimator. You can replace estimator and Estimator with other SageMaker frameworks' estimator parent classes and estimator classes. Available SageMaker framework estimators for this functionality are TensorFlow, PyTorch, and MXNet.

```python
from sagemaker.estimator import Estimator

estimator = Estimator(
    ...
    # Debugger parameters
default_hook_config=hook_config,
    tensorboard_output_config=tensorboard_output_config
)
estimator.fit()
```
The `estimator.fit()` method starts a training job, and Debugger writes the output tensor files in real-time to the Debugger S3 output path and to the TensorBoard S3 output path. To retrieve the output paths, use the following estimator methods:

- For the Debugger S3 output path, use `estimator.latest_job_debugger_artifacts_path()`.
- For the TensorBoard S3 output path, use `estimator.latest_job_tensorboard_artifacts_path()`.

4. After the training has completed, check the names of saved output tensors:

   ```python
   from smdebug.trials import create_trial
   trial = create_trial(estimator.latest_job_debugger_artifacts_path())
   trial.tensor_names()
   ```

5. Check the TensorBoard output data in Amazon S3:

   ```bash
   tensorboard_output_path=estimator.latest_job_tensorboard_artifacts_path()
   print(tensorboard_output_path)
   !aws s3 ls {tensorboard_output_path}/
   ```

6. Download the TensorBoard output data to your notebook instance. For example, the following AWS CLI command downloads the TensorBoard files to `/logs/fit` under the current working directory of your notebook instance.

   ```bash
   !aws s3 cp --recursive {tensorboard_output_path} ./logs/fit
   ```

7. Compress the file directory to a TAR file to download to your local machine.

   ```bash
   !tar -cf logs.tar logs
   ```

8. Download and extract the Tensorboard TAR file to a directory on your device, launch a Jupyter notebook server, open a new notebook, and run the TensorBoard app.

   ```bash
   !tar -xf logs.tar
   %load_ext tensorboard
   %tensorboard --logdir logs/fit
   ```

### List of Debugger Built-in Rules

Use the Debugger built-in rules provided by Amazon SageMaker Debugger and analyze metrics and tensors collected while training your models. The Debugger built-in rules monitor various common conditions that are critical for the success of a training job. You can call the built-in rules using Amazon SageMaker Python SDK or the low-level SageMaker API operations. There's no additional cost for using the built-in rules. For more information about billing, see the Amazon SageMaker Pricing page.

**Note**
The maximum numbers of built-in rules that you can attach to a training job is 20. SageMaker Debugger fully manages the built-in rules and analyzes your training job synchronously.

**Important**
To use the new Debugger features, you need to upgrade the SageMaker Python SDK and the SMDebug client library. In your iPython kernel, Jupyter notebook, or JupyterLab environment, run the following code to install the latest versions of the libraries and restart the kernel.

```python
import sys
import IPython
```
Use SageMaker Debugger

![sys.executable] -m pip install -U sagemaker smdebug
IPython.Application.instance().kernel.do_shutdown(True)

**Debugger Rule**

The following rules are the Debugger built-in rules that are callable using the `Rule.sagemaker` classmethod.

### Debugger built-in rules for generating training reports

**Scope of Validity** | **Built-in Rules**
--- | ---
Training Report for SageMaker XGboost training job | • `create_xgboost_report (p. 1977)`

### Debugger built-in rules for debugging model training data (output tensors)

**Scope of Validity** | **Built-in Rules**
--- | ---
Deep learning frameworks (TensorFlow, MXNet, and PyTorch) | • `dead_relu (p. 1978)`
• `exploding_tensor (p. 1979)`
• `poor_weight_initialization (p. 1980)`
• `saturated_activation (p. 1982)`
• `vanishing_gradient (p. 1985)`
• `weight_update_ratio (p. 1986)`
Deep learning frameworks (TensorFlow, MXNet, and PyTorch) and the XGBoost algorithm | • `all_zero (p. 1987)`
• `class_imbalance (p. 1988)`
• `loss_not_decreasing (p. 1991)`
• `overfit (p. 1993)`
• `overtraining (p. 1994)`
• `similar_across_runs (p. 1996)`
• `stalled_training_rule (p. 1997)`
• `tensor_variance (p. 1998)`
• `unchanged_tensor (p. 2000)`
Deep learning applications | • `check_input_images (p. 2002)`
• `nlp_sequence_ratio (p. 2003)`
XGBoost algorithm | • `confusion (p. 2004)`
• `feature_importance_overweight (p. 2006)`
• `tree_depth (p. 2008)`

**To use the built-in rules with default parameter values** – use the following configuration format:

```python
from sagemaker.debugger import Rule, ProfilerRule, rule_configs
rules = [
    Rule.sagemaker(rule_configs.built_in_rule_name_1()),
    Rule.sagemaker(rule_configs.built_in_rule_name_2()),
    ...
    Rule.sagemaker(rule_configs.built_in_rule_name_n())
]
```
To use the built-in rules with customizing the parameter values – use the following configuration format:

```python
from sagemaker.debugger import Rule, ProfilerRule, rule_configs

rules = [
    Rule.sagemaker(
        base_config=rule_configs.built_in_rule_name(),
        rule_parameters={
            "key": "value"
        }
    ),
    collections_to_save=[
        CollectionConfig(
            name="tensor_collection_name",
            parameters={
                "key": "value"
            }
        )
    ]
]
```

To find available keys for the `rule_parameters` parameter, see the parameter description tables.

Sample rule configuration codes are provided for each built-in rule below the parameter description tables.

- For a full instruction and examples of using the Debugger built-in rules, see Debugger Built-in Rules Example Code (p. 1947).
- For a full instruction on using the built-in rules with the low-level SageMaker API operations, see Configure Debugger Using Amazon SageMaker API (p. 2014).

**CreateXgboostReport**

The CreateXgboostReport rule collects output tensors from an XGBoost training job and autogenerates a comprehensive training report. You can download a comprehensive profiling report while a training job is running or after the training job is complete, and check progress of training or the final result of the training job. The CreateXgboostReport rule collects the following output tensors by default:

- hyperparameters – Saves at the first step
- metrics – Saves loss and accuracy every 5 steps
- feature_importance – Saves every 5 steps
- predictions – Saves every 5 steps
- labels – Saves every 5 steps

**Parameter Descriptions for the CreateXgboostReport Rule**

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</td>
</tr>
<tr>
<td></td>
<td><strong>Required</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: String</td>
</tr>
</tbody>
</table>
rules=[
    Rule.sagemaker(
        rule_configs.create_xgboost_report()
    )
]

**DeadRelu**

This rule detects when the percentage of rectified linear unit (ReLU) activation functions in a trial are considered dead because their activation activity has dropped below a threshold. If the percent of inactive ReLUs in a layer is greater than the `threshold_layer` value of inactive ReLUs, the rule returns True.

**Parameter Descriptions for the DeadRelu Rule**

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. Required Valid values: String</td>
</tr>
<tr>
<td>tensor_regex</td>
<td>A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched. Optional Valid values: List of strings or a comma-separated string Default value: &quot;.*relu_output&quot;</td>
</tr>
<tr>
<td>threshold_inactivity</td>
<td>Defines a level of activity below which a ReLU is considered to be dead. A ReLU might be active in the beginning of a trial and then slowly die during the training process. If the ReLU is active less than the <code>threshold_inactivity</code>, it is considered to be dead. Optional Valid values: Float Default values: 1.0 (in percentage)</td>
</tr>
<tr>
<td>threshold_layer</td>
<td>Returns True if the percentage of inactive ReLUs in a layer is greater than <code>threshold_layer</code>. Returns False if the percentage of inactive ReLUs in a layer is less than <code>threshold_layer</code>. Optional</td>
</tr>
</tbody>
</table>

1978
Use SageMaker Debugger

Parameter Name | Description
--- | ---
| Valid values: Float
| Default values: 50.0 (in percentage)

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.dead_relu(),
        rule_parameters={
            "tensor_regex": ".*relu_output|.ReLU_output",
            "threshold_inactivity": "1.0",
            "threshold_layer": "50.0"
        },
        collections_to_save=[
            CollectionConfig(
                name="custom_relu_collection",
                parameters={
                    "include_regex": ".*relu_output|.ReLU_output",
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1944).

**Note**

This rule is not available for the XGBoost algorithm.

**ExplodingTensor**

This rule detects whether the tensors emitted during training have non-finite values, either infinite or NaN (not a number). If a non-finite value is detected, the rule returns `True`.

    )
]
```

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1944).

**Note**
This rule is not available for the XGBoost algorithm.

**PoorWeightInitialization**

This rule detects if your model parameters have been poorly initialized.

Good initialization breaks the symmetry of the weights and gradients in a neural network and maintains commensurate activation variances across layers. Otherwise, the neural network doesn't learn effectively. Initializers like Xavier aim to keep variance constant across activations, which is especially relevant for training very deep neural nets. Too small an initialization can lead to vanishing gradients. Too large an initialization can lead to exploding gradients. This rule checks the variance of activation inputs across layers, the distribution of gradients, and the loss convergence for the initial steps to determine if a neural network has been poorly initialized.

</tbody>
</table>

---

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1944).

**Note**
This rule is not available for the XGBoost algorithm.

**SaturatedActivation**

This rule detects if the tanh and sigmoid activation layers are becoming saturated. An activation layer is saturated when the input of the layer is close to the maximum or minimum of the activation function. The minimum and maximum of the tanh and sigmoid activation functions are defined by their respective \texttt{min\_threshold} and \texttt{max\_thresholds} values. If the activity of a node drops below the \texttt{threshold\_inactivity} percentage, it is considered saturated. If more than a \texttt{threshold\_layer} percent of the nodes are saturated, the rule returns True.

### Parameter Name | Description
--- | ---
threshold_sigmoid_max | The minimum and maximum thresholds that define the extremes of the input for a sigmoid activation function, defined as: (min_threshold, max_threshold). The default values are determined based on a vanishing gradient threshold of 0.000001.

**Optional**
Valid values: Float
Default values: 16.99999

threshold_inactivity | The percentage of inactivity below which the activation layer is considered to be saturated. The activation might be active in the beginning of a trial and then slowly become less active during the training process.

**Optional**
Valid values: Float
Default values: 1.0

threshold_layer | Returns True if the number of saturated activations in a layer is greater than the threshold_layer percentage.

Returns False if the number of saturated activations in a layer is less than the threshold_layer percentage.

**Optional**
Valid values: Float
Default values: 50.0

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.saturated_activation(),
        rule_parameters={
            "tensor_regex": ".*tanh_input|.*sigmoid_input",
            "threshold_tanh_min": "-9.4999",
            "threshold_tanh_max": "9.4999",
            "threshold_sigmoid_min": "-23",
            "threshold_sigmoid_max": "16.99999",
            "threshold_inactivity": "1.0",
            "threshold_layer": "50.0"
        },
        collections_to_save=[
            CollectionConfig(
                name="custom_activations_collection",
                parameters={
                    "include_regex": ".*tanh_input|.*sigmoid_input",
                    "save_interval": "500"
                }
            )
        ]
    )
]```
For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1944).

**Note**
This rule is not available for the XGBoost algorithm.

**VanishingGradient**

This rule detects if the gradients in a trial become extremely small or drop to a zero magnitude. If the mean of the absolute values of the gradients drops below a specified threshold, the rule returns True.

**Parameters Descriptions for the VanishingGradient Rule**

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. <strong>Required</strong> Valid values: String</td>
</tr>
<tr>
<td>threshold</td>
<td>The value at which the gradient is determined to be vanishing. <strong>Optional</strong> Valid values: Float Default value: 0.0000001.</td>
</tr>
</tbody>
</table>

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.vanishing_gradient(),
        rule_parameters={
            "threshold": "0.0000001"
        },
        collections_to_save=[
            CollectionConfig(
                name="gradients",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1944).

**Note**
This rule is not available for the XGBoost algorithm.
**WeightUpdateRatio**

This rule keeps track of the ratio of updates to weights during training and detects if that ratio gets too large or too small. If the ratio of updates to weights is larger than the `large_threshold` value or if this ratio is smaller than `small_threshold`, the rule returns True.

Conditions for training are best when the updates are commensurate to gradients. Excessively large updates can push the weights away from optimal values, and very small updates result in very slow convergence. This rule requires weights to be available for two training steps, and `train.save_interval` needs to be set equal to `num_steps`.

**Parameter Descriptions for the WeightUpdateRatio Rule**

<table>
<thead>

            CollectionConfig(
                name="weights",
                parameters={
                    "train.save_interval": "100"
                }
            )
        ]
    )
]
```

For an example of how to configure and deploy a built-in rule, see [Configure Debugger Built-in Rules (p. 1944)].

**Note**
This rule is not available for the XGBoost algorithm.

### AllZero

This rule detects if all or a specified percentage of the tensor values are zero.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the `collection_names` or `tensor_regex` parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.

For an example of how to configure and deploy a built-in rule, see [Configure Debugger Built-in Rules (p. 1944)].

                name="all",  
                parameters={  
                    "save_interval": "500"
                }
            )  
        ]
    )
]
```

**ClassImbalance**

This rule measures sampling imbalances between classes and throws errors if the imbalance exceeds a threshold or if too many mispredictions for underrepresented classes occur as a result of the imbalance.
Classification models require well-balanced classes in the training dataset or a proper weighting/sampling of classes during training. The rule performs the following checks:

- It counts the occurrences per class. If the ratio of number of samples between smallest and largest class is larger than the `threshold_imbalance`, an error is thrown.
- It checks the prediction accuracy per class. If resampling or weighting has not been correctly applied, then the model can reach high accuracy for the class with many training samples, but low accuracy for the classes with few training samples. If a fraction of mispredictions for a certain class is above `threshold_misprediction`, an error is thrown.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1944).

                }
            )
        ]
    )
]```

LossNotDecreasing

This rule detects when the loss is not decreasing in value at an adequate rate. These losses must be scalars.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the collection_names or tensor_regex parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1944).

<tr>
<td>mode</td>
<td>The name of the Debugger mode to query tensor values for rule checking. If this is not passed, the rule checks in order by default for the mode.EVAL, then mode.TRAIN, and then mode.GLOBAL. Optional Valid values: String (EVAL, TRAIN, or GLOBAL) Default value: GLOBAL</td>
</tr>
</tbody>
</table>

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.loss_not_decreasing(),
        rule_parameters={
            "tensor_regex": ".*",
            "use_losses_collection": "True",
            "num_steps": "10",
            "diff_percent": "0.1",
            "increase_threshold_percent": "5",
```
Overfit

This rule detects if your model is being overfit to the training data by comparing the validation and training losses.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1944).

Note
A standard way to prevent overfitting is to regularize your model.

Parameter Descriptions for the Overfit Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</td>
</tr>
<tr>
<td></td>
<td><strong>Required</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: String</td>
</tr>
<tr>
<td>tensor_regex</td>
<td>A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: List of strings or a comma-separated string</td>
</tr>
<tr>
<td></td>
<td>Default value: None</td>
</tr>
<tr>
<td>start_step</td>
<td>The step from which to start comparing the validation and training loss.</td>
</tr>
<tr>

</table>

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.overfit(),
        rule_parameters={
            "tensor_regex": ".*",
            "start_step": "0",
            "patience": "1",
            "ratio_threshold": "0.1"
        },
        collections_to_save=[
            CollectionConfig(
                name="losses",
                parameters={
                    "train.save_interval": "100",
                    "eval.save_interval": "10"
                }
            )
        ]
    )
]
```

### Overtraining

This rule detects if a model is being overtrained. After a number of training iterations on a well-behaved model (both training and validation loss decrease), the model approaches to a minimum of the loss function and does not improve anymore. If the model continues training it can happen that validation loss starts increasing, because the model starts overfitting. This rule sets up thresholds and conditions to determine if the model is not improving, and prevents overfitting problems due to overtraining.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1944).
Note
Overtraining can be avoided by early stopping. For information on early stopping, see Stop Training Jobs Early (p. 1894). For an example that shows how to use spot training with Debugger, see Enable Spot Training with Amazon SageMaker Debugger.

Parameter Descriptions for the Overtraining Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</td>
</tr>
<tr>
<td>patience_train</td>
<td>The number of steps to wait before the training loss is considered to not to be improving anymore.</td>
</tr>
<tr>
<td>patience_validation</td>
<td>The number of steps to wait before the validation loss is considered to not to be improving anymore.</td>

                parameters={
                    "save_interval": "500"
                })
        ]
    )
]
SimilarAcrossRuns

This rule compares tensors gathered from a base trial with tensors from another trial.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1944).

                }
            )
        ]
    )
]

### StalledTrainingRule

StalledTrainingRule detects if there is no progress made on training job, and stops the training job if the rule fires. This rule requires tensors to be periodically saved in a time interval defined by its threshold parameter. This rule keeps on monitoring for new tensors, and if no new tensor has been emitted for threshold interval rule gets fired.

#### Parameter Descriptions for the StalledTrainingRule Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</td>
</tr>
<tr>
<td>threshold</td>
<td>A threshold that defines by how much time in seconds the rule waits for a tensor output until it fires a stalled training issue. Default value is 1800 seconds.</td>
</tr>
<tr>
<td>stop_training_on_fire</td>
<td>If set to True, watches if the base training job outputs tensors in &quot;threshold&quot; seconds.</td>
</tr>
<tr>
<td>training_job_name_prefix</td>
<td>The prefix of base training job name. If stop_training_on_fire is true, the rule searches for SageMaker training jobs with this prefix.</td>
</tr>
</tbody>
</table>
prefix in the same account. If there is an inactivity found, the rule takes a StopTrainingJob action. Note if there are multiple jobs found with same prefix, the rule skips termination. It is important that the prefix is set unique per each training job.

**Optional**

Valid values: String

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.stalled_training_rule(),
        rule_parameters={
            "threshold": "1800",
            "stop_training_on_fire": "True",
            "training_job_name_prefix": "<specify-training-base-job-name>"
        },
        collections_to_save=[
            CollectionConfig(
                name="losses",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

**TensorVariance**

This rule detects if you have tensors with very high or low variances. Very high or low variances in a tensor could lead to neuron saturation, which reduces the learning ability of the neural network. Very high variance in tensors can also eventually lead to exploding tensors. Use this rule to detect such issues early.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the collection_names or tensor_regex parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.

For an example of how to configure and deploy a built-in rule, see [Configure Debugger Built-in Rules](p. 1944).

**Parameter Descriptions for the TensorVariance Rule**

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</td>
</tr>
<tr>
<td></td>
<td><strong>Required</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: String</td>
</tr>
<tr>
<td>collection_names</td>
<td>The list of collection names whose tensors the rule inspects.</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-------------</td>
</tr>
<tr>
<td>tensor_regex</td>
<td>A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched.</td>
</tr>
<tr>
<td>max_threshold</td>
<td>The threshold for the upper bound of tensor variance.</td>
</tr>
<tr>
<td>min_threshold</td>
<td>The threshold for the lower bound of tensor variance.</td>
</tr>
</tbody>
</table>

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.tensor_variance(),
        rule_parameters={
            "collection_names": "weights",
            "max_threshold": "10",
            "min_threshold": "0.00001",
        },
        collections_to_save=[
            CollectionConfig(name="weights",
                            parameters={
                                "save_interval": "500"
                            })
        ]
    )
]```
**UnchangedTensor**

This rule detects whether a tensor is no longer changing across steps.

This rule runs the `numpy.allclose` method to check if the tensor isn't changing.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the `collection_names` or `tensor_regex` parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1944).

**Parameter Descriptions for the UnchangedTensor Rule**

<table>
<thead>
<tr>

</tbody>
</table>

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.unchanged_tensor(),
        rule_parameters={
            "collection_names": "losses",
            "tensor_regex": "",
            "num_steps": "3",
            "rtol": "1e-05",
            "atol": "1e-08",
            "equal_nan": "False"
        },
        collections_to_save=
        [CollectionConfig(name="losses",
                          parameters={
                            "save_interval": "500"
                          })]
    )
]"
```
CheckInputImages

This rule checks if input images have been correctly normalized. Specifically, it detects if the mean of the sample data differs by more than a threshold value from zero. Many computer vision models require that input data has a zero mean and unit variance.

This rule is applicable to deep learning applications.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1944).

Parameter Descriptions for the CheckInputImages Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</td>
</tr>
<tr>
<td>threshold_mean</td>
<td>A threshold that defines by how much mean of the input data can differ from 0.</td>
</tr>
<tr>
<td>threshold_samples</td>
<td>The number of images that have to be sampled before an error can be thrown. If the value is too low, the estimation of the dataset mean will be inaccurate.</td>
</tr>
<tr>
<td>regex</td>
<td>The name of the input data tensor.</td>
</tr>
<tr>
<td>channel</td>
<td>The position of the color channel in the input tensor shape array.</td>
</tr>
</tbody>
</table>
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.check_input_images(),
        rule_parameters={
            "threshold_mean": "0.2",
            "threshold_samples": "500",
            "regex": ".*hybridsequential0_input_0",
            "channel": "1"
        },
        collections_to_save=[
            CollectionConfig(
                name="custom_inputs_collection",
                parameters={
                    "include_regex": ".*hybridsequential0_input_0",
                    "save_interval": "500"
                }]
        )
    )
]

### NLPSequenceRatio

This rule calculates the ratio of specific tokens given the rest of the input sequence that is useful for optimizing performance. For example, you can calculate the percentage of padding end-of-sentence (EOS) tokens in your input sequence. If the number of EOS tokens is too high, an alternate bucketing strategy should be performed. You also can calculate the percentage of unknown tokens in your input sequence. If the number of unknown words is too high, an alternate vocabulary could be used.

This rule is applicable to deep learning applications.

For an example of how to configure and deploy a built-in rule, see [Configure Debugger Built-in Rules](p. 1944).

**Parameter Descriptions for the NLPSequenceRatio Rule**

built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.nlp_sequence_ratio(),
        rule_parameters={
            "tensor_regex": ".*embedding0_input_0",
            "token_values": "0",
            "token_thresholds_percent": "50"
        },
        collections_to_save=[
            CollectionConfig(
                name="custom_inputs_collection",
                parameters={
                    "include_regex": ".*embedding0_input_0"
                }
            )
        ]
    )
]
```

**Confusion**

This rule evaluates the goodness of a confusion matrix for a classification problem.

It creates a matrix of size category_no*category_no and populates it with data coming from (labels, predictions) pairs. For each (labels, predictions) pair, the count in confusion[labels][predictions] is incremented by 1. When the matrix is fully populated, the ratio of data on-diagonal values and off-diagonal values are evaluated as follows:

- For elements on the diagonal: confusion[i][i]/sum_j(confusion[j][j])>=min_diag
- For elements off the diagonal: \( \frac{\text{confusion}[j][i]}{\sum_j(\text{confusion}[j][i])} \leq \text{max\_off\_diag} \)

This rule can be applied to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1944).

### Parameter Descriptions for the Confusion Rule

#### Built-in Rules

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.confusion(),
        rule_parameters={
            "category_no": "10",
            "labels": "labels",
            "predictions": "predictions",
            "labels_collection": "labels",
            "predictions_collection": "predictions",
            "min_diag": "0.9",
            "max_off_diag": "0.1"
        },
        collections_to_save=[
            CollectionConfig(name="labels",
                             parameters={
                                "save_interval": "500"
                             }),
            CollectionConfig(name="predictions",
                             parameters={
                                "include_regex": "500"
                             }
            )
        ]
    )
]
```

**Note**

This rule infers default values for the optional parameters if their values aren't specified.

**FeatureImportanceOverweight**

This rule accumulates the weights of the n largest feature importance values per step and ensures that they do not exceed the threshold. For example, you can set the threshold for the top 3 features to not hold more than 80 percent of the total weights of the model.

This rule is valid only for the XGBoost algorithm.
For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1944).

**Parameter Descriptions for the FeatureImportanceOverweight Rule**

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</td>
</tr>

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.feature_importance_overweight(),
        rule_parameters={
            "threshold": "0.8",
            "nfeatures": "3",
            "tensor_regex": ".*feature_importance/weight"
        },
        collections_to_save=[
            CollectionConfig(
                name="feature_importance",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```
TreeDepth

This rule measures the depth of trees in an XGBoost model. XGBoost rejects splits if they do not improve loss. This regularizes the training. As a result, the tree might not grow as deep as defined by the depth parameter.

This rule is valid only for the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1944).

Parameter Descriptions for the TreeDepth Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. Required</td>
</tr>
<tr>
<td>depth</td>
<td>The depth of the tree. The depth of the tree is obtained by computing the base 2 logarithm of the largest node ID. Optional Valid values: Float Default value: 4</td>
</tr>
</tbody>
</table>

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.tree_depth(),
        rule_parameters={
            "depth": "4"
        },
        collections_to_save=[
            CollectionConfig(
                name="tree",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )

```

Create Debugger Custom Rules for Training Job Analysis

You can create custom rules to monitor your training job using the Debugger Rule APIs and the open source smdebug Python library that provide tools to build your own rule containers.

Topics

- Prerequisites for Creating Debugger Custom Rules (p. 2009)
• **Use the Debugger Client Library smdebug to Create a Custom Rule Python Script (p. 2009)**

• **Use the Debugger APIs to Run Your Own Custom Rules (p. 2009)**

### Prerequisites for Creating Debugger Custom Rules

To create Debugger custom rules, you need the following prerequisites.

- SageMaker Debugger Rule.custom API
- The open source smdebug Python library
- Your own custom rule python script
- Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators (p. 2029)

### Use the Debugger Client Library smdebug to Create a Custom Rule Python Script

The smdebug Rule API provides an interface to set up your own custom rules. The following python script is a sample of how to construct a custom rule, CustomGradientRule. This tutorial custom rule watches if the gradients are getting too large and set the default threshold as 10. The custom rule takes a base trial created by a SageMaker estimator when it initiates training job.

```python
from smdebug.rules.rule import Rule

class CustomGradientRule(Rule):
    def __init__(self, base_trial, threshold=10.0):
        super().__init__(base_trial)
        self.threshold = float(threshold)

    def invoke_at_step(self, step):
        for tname in self.base_trial.tensor_names(collection="gradients"):
            t = self.base_trial.tensor(tname)
            abs_mean = t.reduction_value(step, "mean", abs=True)
            if abs_mean > self.threshold:
                return True
        return False
```

You can add multiple custom rule classes as many as you want in the same python script and deploy them to any training job trials by constructing custom rule objects in the following section.

### Use the Debugger APIs to Run Your Own Custom Rules

The following code sample shows how to configure a custom rule with the Amazon SageMaker Python SDK. This example assumes that the custom rule script you created in the previous step is located at `path/to/my_custom_rule.py`.

```python
from sagemaker.debugger import Rule, CollectionConfig

custom_rule = Rule.custom(
    name='MyCustomRule',
    image_uri='759209512951.dkr.ecr.us-west-2.amazonaws.com/sagemaker-debugger-rule-evaluator:latest',
    instance_type='ml.t3.medium',
    source='path/to/my_custom_rule.py',
    rule_to_invoke='CustomGradientRule',
    collections_to_save=[CollectionConfig("gradients")],
    rule_parameters={"threshold": "20.0"}
)
```
The following list explains the Debugger Rule `custom` API arguments.

- **name (str):** Specify a custom rule name as you want.
- **image_uri (str):** This is the image of the container that has the logic of understanding your custom rule. It sources and evaluates the specified tensor collections you save in the training job. You can find the list of open source SageMaker rule evaluator images from [Amazon SageMaker Debugger Registry](https://docs.aws.amazon.com/sagemaker/latest/dg/using-custom-rules.html). See URLs for Custom Rule Evaluators (p. 2029).
- **instance_type (str):** You need to specify an instance to build a rule docker container. This spins up the instance in parallel with a training container.
- **source (str):** This is the local path or the Amazon S3 URI to your custom rule script.
- **rule_to_invoke (str):** This specifies the particular Rule class implementation in your custom rule script. SageMaker supports only one rule to be evaluated at a time in a rule job.
- **collections_to_save (str):** This specifies which tensor collections you will save for the rule to run.
- **rule_parameters (dictionary):** This accepts parameter inputs in a dictionary format. You can adjust the parameters that you configured in the custom rule script.

After you set up the `custom_rule` object, you can use it for building a SageMaker estimator for any training jobs. Specify the `entry_point` to your training script. You do not need to make any change of your training script.

```python
from sagemaker.tensorflow import TensorFlow
estimator = TensorFlow(
    role=sagemaker.get_execution_role(),
    base_job_name='smdebug-custom-rule-demo-tf-keras',
    entry_point='path/to/your_training_script.py'
    train_instance_type='ml.p2.xlarge'
    ...
    # debugger-specific arguments below
    rules = [custom_rule]
)
estimator.fit()
```

For more variations and advanced examples of using Debugger custom rules, see the following example notebooks.

- Monitor your training job with Amazon SageMaker Debugger custom rules
- PyTorch iterative model pruning of ResNet and AlexNet
- Trigger Amazon CloudWatch Events using Debugger Rules to Take an Action Based on Training Status with TensorFlow

## Use Debugger with Custom Training Containers

Amazon SageMaker Debugger is available for any deep learning models that you bring to Amazon SageMaker. The AWS CLI, SageMaker Estimator API, and the Debugger APIs enable you to use any Docker base images to build and customize containers to train your models. To use Debugger with customized containers, you need to make a minimal change to your training script to implement the Debugger hook callback and retrieve tensors from training jobs.

You need the following resources to build a customized container with Debugger.

- Amazon SageMaker Python SDK
- The SMDebug open source client library
• A Docker base image of your choice
• Your training script with a Debugger hook registered – For more information about registering a Debugger hook to your training script, see Register Debugger Hook to Your Training Script (p. 2011).

For an end-to-end example of using Debugger with a custom training container, see the following example notebook.

• Build a Custom Training Container and Debug Training Jobs with Debugger

Tip
This custom container with Debugger guide is an extension of the Adapting your own training container (p. 3299) guide which walks you thorough how to build and push your custom training container to Amazon ECR.

Prepare to Build a Custom Training Container

To build a docker container, the basic structure of files should look like the following:

<table>
<thead>
<tr>
<th></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>debugger_custom_container_test_notebook.ipynb</td>
<td>a notebook to run python snippet codes</td>
</tr>
<tr>
<td>debugger_custom_container_test_folder</td>
<td>this is a docker folder</td>
</tr>
<tr>
<td>your-training-script.py</td>
<td>your training script with Debugger hook</td>
</tr>
<tr>
<td>Dockerfile</td>
<td>a Dockerfile to build your own container</td>
</tr>
</tbody>
</table>

Register Debugger Hook to Your Training Script

To debug your model training, you need to add a Debugger hook to your training script.

Note
This step is required to collect model parameters (output tensors) for debugging your model training. If you only want to monitor and profile, you can skip this hook registration step and exclude the debugger_hook_config parameter when constructing an estimator.

The following example code shows the structure of a training script using the Keras ResNet50 model and how to pass the Debugger hook as a Keras callback for debugging. To find a complete training script, see TensorFlow training script with SageMaker Debugger hook.

```python
# An example of training script (your-training-script.py)
import tensorflow.compat.v2 as tf
from tensorflow.keras.applications.resnet50 import ResNet50
import smdebug.tensorflow as smd
def train(batch_size, epoch, model, hook):
    ...
    model.fit(X_train, Y_train,
              batch_size=batch_size,
              epochs=epoch,
              validation_data=(X_valid, Y_valid),
              shuffle=True,
              callbacks=[# smdebug modification: Pass the Debugger hook in the main() as a Keras callback
tensorflow共振Void])
def main():

2011
parser=argparse.ArgumentParser(description="Train resnet50 cifar10")

# hyperparameter settings
parser.add_argument(...)  
args = parser.parse_args()

model=ResNet50(weights=None, input_shape=(32,32,3), classes=10)

# Add the following line to register the Debugger hook for Keras.
hook=smd.KerasHook.create_from_json_file()

# Start the training.
train(args.batch_size, args.epoch, model, hook)

if __name__ == '__main__':
    main()

For more information about registering the Debugger hook for the supported frameworks and algorithm, see the following links in the SMDebug client library:

- SMDebug TensorFlow hook
- SMDebug PyTorch hook
- SMDebug MXNet hook
- SMDebug XGBoost hook

In the following example notebooks' training scripts, you can find more examples about how to add the Debugger hooks to training scripts and collect output tensors in detail:

- Debugger in script mode with the TensorFlow 2.1 framework

To see the difference between using Debugger in a Deep Learning Container and in script mode, open this notebook and put it and the previous Debugger in a Deep Learning Container TensorFlow v2.1 notebook example side by side.

In script mode, the hook configuration part is removed from the script in which you set the estimator. Instead, the Debugger hook feature is merged into the training script, TensorFlow Keras ResNet training script in script mode. The training script imports the smdebug library in the required TensorFlow Keras environment to communicate with the TensorFlow ResNet50 algorithm. It also manually implements the smdebug hook functionality by adding the callbacks=[hook] argument inside the train function (in line 49), and by adding the manual hook configuration (in line 89) provided through SageMaker Python SDK.

This script mode example runs the training job in the TF 2.1 framework for direct comparison with the zero script change in the TF 2.1 example. The benefit of setting up Debugger in script mode is the flexibility to choose framework versions not covered by AWS Deep Learning Containers.

- Using Amazon SageMaker Debugger in a PyTorch Container in Script Mode

This notebook enables Debugger in script mode in PyTorch v1.3.1 framework. PyTorch v1.3.1 is supported by SageMaker containers, and this example shows details of how to modify a training script.

The SageMaker PyTorch estimator is already in script mode by default. In the notebook, the line to activate script_mode is not included in the estimator configuration.

This notebook shows detailed steps to change the original PyTorch training script to a modified version to enable Debugger. Additionally, this example shows how you can use Debugger built-in rules to detect training issues such as the vanishing gradients problem, and the Debugger trial features to call and analyze the saved tensors.
Create and Configure a Dockerfile

Open your SageMaker JupyterLab and create a new folder, `debugger_custom_container_test_folder` in this example, to save your training script and Dockerfile. The following code example is a Dockerfile that includes essential docker build commands. Paste the following code into the Dockerfile text file and save it. Upload your training script to the same folder.

```dockerfile
# Specify a docker base image
FROM tensorflow/tensorflow:2.2.0rc2-gpu-py3
RUN /usr/bin/python3 -m pip install --upgrade pip
RUN pip install --upgrade protobuf

# Install required packages to enable the SageMaker Python SDK and the smdebug library
RUN pip install sagemaker-training
RUN pip install smdebug

CMD ["bin/bash"]
```

If you want to use a pre-built AWS Deep Learning Container image, see Available AWS Deep Learning Containers Images.

Build and Push the Custom Training Container to Amazon ECR

Create a test notebook, `debugger_custom_container_test_notebook.ipynb`, and run the following code in the notebook cell. This will access the `debugger_byoc_test_docker` directory, build the docker with the specified `algorithm_name`, and push the docker container to your Amazon ECR.

```python
import boto3

account_id = boto3.client('sts').get_caller_identity().get('Account')
ecr_repository = 'sagemaker-debugger-mnist-byoc-tf2'
tag = ':latest'

region = boto3.session.Session().region_name
uri_suffix = 'amazonaws.com'
if region in ['cn-north-1', 'cn-northwest-1']:
    uri_suffix = 'amazonaws.com.cn'
byoc_image_uri = '{}/{}@{}'.format(account_id, region, uri_suffix, ecr_repository + tag)

!docker build -t $ecr_repository docker
!$(aws ecr get-login --region $region --registry-ids $account_id --no-include-email)
!aws ecr create-repository --repository-name $ecr_repository
!docker tag $ecr_repository + tag $byoc_image_uri
!docker push $byoc_image_uri
```

Tip
If you use one of the AWS Deep Learning Container base images, run the following code to log in to Amazon ECR and access to the Deep Learning Container image repository.

```bash
! aws ecr get-login-password --region {region} | docker login --username AWS --password-stdin {763104351884.dkr.ecr.us-east-1.amazonaws.com}
```

Run and Debug Training Jobs Using the Custom Training Container

After you build and push your docker container to Amazon ECR, configure a SageMaker estimator with your training script and the Debugger-specific parameters. After you execute the `estimator.fit()`, Debugger will collect output tensors, monitor them, and detect training issues. Using the saved tensors,
Amazon SageMaker Developer Guide
Use SageMaker Debugger

you can further analyze the training job by using the smdebug core features and tools. Conﬁguring a
workﬂow of Debugger rule monitoring process with Amazon CloudWatch Events and AWS Lambda, you
can automate a stopping training job process whenever the Debugger rules spots training issues.
import sagemaker
from sagemaker.estimator import Estimator
from sagemaker.debugger import Rule, DebuggerHookConfig, CollectionConfig, rule_configs
profiler_config=ProfilerConfig(...)
debugger_hook_config=DebuggerHookConfig(...)
rules=[
Rule.sagemaker(rule_configs.built_in_rule()),
ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]
estimator=Estimator(
image_uri=byoc_image_uri,
entry_point="./debugger_custom_container_test_folder/your-training-script.py"
role=sagemaker.get_execution_role(),
base_job_name='debugger-custom-container-test',
instance_count=1,
instance_type='ml.p3.2xlarge',

)

# Debugger-specific parameters
profiler_config=profiler_config,
debugger_hook_config=debugger_hook_config,
rules=rules

# start training
estimator.fit()

Conﬁgure Debugger Using Amazon SageMaker API
The preceding topics focus on using Debugger through Amazon SageMaker Python SDK, which is a
wrapper around AWS SDK for Python (Boto3) and SageMaker API operations. This oﬀers a high-level
experience of accessing the Amazon SageMaker API operations. In case you need to manually conﬁgure
the SageMaker API operations using AWS Boto3 or AWS Command Line Interface (CLI) for other SDKs,
such as Java, Go, and C++, this section covers how to conﬁgure the following low-level API operations.
Topics
• JSON (AWS CLI) (p. 2014)
• AWS Boto3 (p. 2019)

JSON (AWS CLI)
Amazon SageMaker Debugger built-in rules can be conﬁgured for a training job using the
DebugHookConﬁg, DebugRuleConﬁguration, ProﬁlerConﬁg, and ProﬁlerRuleConﬁguration objects
through the SageMaker CreateTrainingJob API operation. You need to specify the right image URI in the
RuleEvaluatorImage parameter, and the following examples walk you through how to set up the
JSON strings to request CreateTrainingJob.
The following code shows a complete JSON template to run a training job with required settings and
Debugger conﬁgurations. Save the template as a JSON ﬁle in your working directory and run the training
job using AWS CLI. For example, save the following code as debugger-training-job-cli.json.

Note

Ensure that you use the correct Docker container images. To ﬁnd AWS Deep Learning Container
images, see Available Deep Learning Containers Images. To ﬁnd a complete list of available

2014


Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 2028).

```json
{

                "RuleParameters": {"rule_to_invoke": "ProfilerReport"}
            }
        ],
        "ResourceConfig": {
```
After saving the JSON file, run the following command in your terminal. (Use ! at the beginning of the line if you use a Jupyter notebook.)

```
aws sagemaker create-training-job --cli-input-json file://debugger-training-job-cli.json
```

To configure a Debugger rule for debugging model parameters

The following code samples show how to configure a built-in VanishingGradient rule using this SageMaker API.

To enable Debugger to collect output tensors

Specify the Debugger hook configuration as follows:

```json
"DebugHookConfig": {
    "S3OutputPath": "s3://<default-bucket>/<training-job-name>/debug-output",
    "CollectionConfigurations": [
        {
            "CollectionName": "gradients",
            "CollectionParameters": {
                "save_interval": "500"
            }
        }
    ]
}
```

This will make the training job save the tensor collection, gradients, every save_interval of 500 steps. To find available CollectionName values, see Debugger Built-in Collections in the SMDebug client library documentation. To find available CollectionParameters parameter keys and values, see the sagemaker.debugger.CollectionConfig class in the SageMaker Python SDK documentation.

To enable Debugger rules for debugging the output tensors

The following DebugRuleConfigurations API example shows how to run the built-in VanishingGradient rule on the saved gradients collection.

```json
"DebugRuleConfigurations": [
    {
        "RuleConfigurationName": "VanishingGradient",
        "RuleEvaluatorImage": "503895931360.dkr.ecr.us-east-1.amazonaws.com/sagemaker-debugger-rules:latest",
        "RuleParameters": {
            "rule_to_invoke": "VanishingGradient",
            "threshold": "20.0"
        }
    }
]
```

With a configuration like the one in this sample, Debugger starts a rule evaluation job for your training job using the VanishingGradient rule on the collection of gradients tensor. To find a complete list...
of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 2028). To find the key-value pairs for RuleParameters, see List of Debugger Built-in Rules (p. 1975).

To configure a Debugger built-in rule for profiling system and framework metrics

The following example code shows how to specify the ProfilerConfig API operation to enable collecting system and framework metrics.

To enable Debugger profiling to collect system and framework metrics

Target Step

```
"ProfilerConfig": {
    // Optional. Path to an S3 bucket to save profiling outputs
    "S3OutputPath": "s3://<default-bucket>/<training-job-name>/profiler-output",
    // Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.
    "ProfilingIntervalInMilliseconds": 500,
    "ProfilerParameters": {
        "DataloaderProfilingConfig": "{"\"StartStep\": 5, \"NumSteps\": 3, \"MetricsRegex\": ".*" }",
        "DetailedProfilingConfig": "{"\"StartStep\": 5, \"NumSteps\": 3 }",
        // For PythonProfilingConfig,
        // available ProfilerName options: cProfile, Pyinstrument
        // available cProfileTimer options only when using cProfile: cpu, off_cpu, total_time
        "PythonProfilingConfig": "{"\"StartTimeInSecSinceEpoch\": 12345567789, \"DurationInSeconds\": 10, \"MetricsRegex\": ".*" }",
        "DetailedProfilingConfig": "{"\"StartTimeInSecSinceEpoch\": 12345567789, \"DurationInSeconds\": 10 }",
        // For PythonProfilingConfig,
        // available ProfilerName options: cProfile, Pyinstrument
        // available cProfileTimer options only when using cProfile: cpu, off_cpu, total_time
        "PythonProfilingConfig": "{"\"StartTimeInSecSinceEpoch\": 12345567789, \"DurationInSeconds\": 10, \"ProfilerName\": \"cProfile\", \"cProfileTimer\": \"total_time\" }",
        // Optional. Local path for profiling outputs
        "LocalPath": "/opt/ml/output/profiler/"
    }
}
```

Target Time Duration

```
"ProfilerConfig": {
    // Optional. Path to an S3 bucket to save profiling outputs
    "S3OutputPath": "s3://<default-bucket>/<training-job-name>/profiler-output",
    // Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.
    "ProfilingIntervalInMilliseconds": 500,
    "ProfilerParameters": {
        "DataloaderProfilingConfig": "{"\"StartTimeInSecSinceEpoch\": 12345567789, \"DurationInSeconds\": 10, \"MetricsRegex\": ".*" }",
        "DetailedProfilingConfig": "{"\"StartTimeInSecSinceEpoch\": 12345567789, \"DurationInSeconds\": 10 }",
        // For PythonProfilingConfig,
        // available ProfilerName options: cProfile, Pyinstrument
        // available cProfileTimer options only when using cProfile: cpu, off_cpu, total_time
        "PythonProfilingConfig": "{"\"StartTimeInSecSinceEpoch\": 12345567789, \"DurationInSeconds\": 10, \"ProfilerName\": \"cProfile\", \"cProfileTimer\": \"total_time\" }",
        // Optional. Local path for profiling outputs
        "LocalPath": "/opt/ml/output/profiler/"
    }
}
```

To enable Debugger rules for profiling the metrics

The following example code shows how to configure the ProfilerReport rule.
"ProfilerRuleConfigurations": [
  {
    "RuleConfigurationName": "ProfilerReport",
    "RuleParameters": {
      "rule_to_invoke": "ProfilerReport",
      "CPUBottleneck_cpu_threshold": "90",
      "IOBottleneck_threshold": "90"
    }
  }
]

To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 2028). To find the key-value pairs for RuleParameters, see List of Debugger Built-in Rules (p. 1975).

**Update Debugger Profiling Configuration Using the UpdateTrainingJob API Operation**

Debugger profiling configuration can be updated while your training job is running by using the UpdateTrainingJob API operation. Configure new ProfilerConfig and ProfilerRuleConfiguration objects, and specify the training job name to the TrainingJobName parameter.

```
{
  "ProfilerConfig": {
    "DisableProfiler": boolean,
    "ProfilingIntervalInMilliseconds": number,
    "ProfilingParameters": {
      "string": "string"
    }
  },
  "ProfilerRuleConfigurations": [
    {
      "RuleConfigurationName": "string",
      "RuleEvaluatorImage": "string",
      "RuleParameters": {
        "string": "string"
      }
    }
  ],
  "TrainingJobName": "your-training-job-name-YYYY-MM-DD-HH-MM-SS-SSS"
}
```

**Add Debugger Custom Rule Configuration to the CreateTrainingJob API Operation**

A custom rule can be configured for a training job using the DebugHookConfig and DebugRuleConfiguration objects in the CreateTrainingJob API operation. The following code sample shows how to configure a custom ImproperActivation rule written with the smdebug library using this SageMaker API operation. This example assumes that you've written the custom rule in custom_rules.py file and uploaded it to an Amazon S3 bucket. The example provides pre-built Docker images that you can use to run your custom rules. These are listed at Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators (p. 2029). You specify the URL registry address for the pre-built Docker image in the RuleEvaluatorImage parameter.

```
"DebugHookConfig": {
  "S3OutputPath": "s3://<default-bucket>/<training-job-name>/debug-output",
  "CollectionConfigurations": [
    {
      "CollectionName": "relu_activations",
      "CollectionParameters": {
        "string": "string"
      }
    }
  ]
}
```
To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 2028). To find the key-value pairs for RuleParameters, see List of Debugger Built-in Rules (p. 1975).

AWS Boto3

Amazon SageMaker Debugger built-in rules can be configured for a training job using the create_training_job() function of the AWS Boto3 SageMaker client. You need to specify the right image URI in the RuleEvaluatorImage parameter, and the following examples walk you through how to set up the request body for the create_training_job() function.

The following code shows a complete example of how to configure Debugger for the create_training_job() request body and start a training job in us-west-2, assuming that a training script entry_point/train.py is prepared using TensorFlow. To find an end-to-end example notebook, see Profiling TensorFlow Multi GPU Multi Node Training Job with Amazon SageMaker Debugger (Boto3).

Note

Ensure that you use the correct Docker container images. To find available AWS Deep Learning Container images, see Available Deep Learning Containers Images. To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 2028).

```python
import sagemaker, boto3
import datetime, tarfile

# Start setting up a SageMaker session and a Boto3 SageMaker client
session = sagemaker.Session()
region = session.boto_region_name
bucket = session.default_bucket()

# Upload a training script to a default Amazon S3 bucket of the current SageMaker session
source = 'source.tar.gz'
project = 'debugger-boto3-test'

# Specify the directory and name of your training script
source = 'entry_point/train.py'
tar.add(source)

# Start the training job
s3 = boto3.client('s3')
s3.upload_file(source, bucket, source)
```
s3.upload_file(source, bucket, project+'/'+source)

# Set up a Boto3 session client for SageMaker
sm = boto3.Session(region_name=region).client("sagemaker")

# Start a training job
sm.create_training_job(
    TrainingJobName='debugger-boto3-+'+datetime.datetime.now().strftime('%Y-%m-%d-%H-%M-%S'),
    HyperParameters={
        'sagemaker_submit_directory': 's3://'+bucket+'/'+project+'/'+source,
        'sagemaker_program': '/entry_point/train.py' # training script file location and
                                                         # name under the sagemaker_submit_directory
    },
    AlgorithmSpecification={
        # Specify a training Docker container image URI (Deep Learning Container or your
        # own training container) to TrainingImage.
        'TrainingImage': '763104351884.dkr.ecr.us-west-2.amazonaws.com/tensorflow-
                        training:2.4.1-gpu-py37-cu110-ubuntu18.04',
        'TrainingInputMode': 'File',
        'EnableSageMakerMetricsTimeSeries': False
    },
    RoleArn='arn:aws:iam::111122223333:role/service-role/AmazonSageMaker-
            ExecutionRole-202010014T161125',
    OutputDataConfig={'S3OutputPath': 's3://'+bucket+'/'+project+'/output'},
    ResourceConfig={
        'InstanceType': 'ml.p3.8xlarge',
        'InstanceCount': 1,
        'VolumeSizeInGB': 30
    },
    StoppingCondition={
        'MaxRuntimeInSeconds': 86400
    },
    DebugHookConfig={
        'S3OutputPath': 's3://'+bucket+'/'+project+'/debug-output',
        'CollectionConfigurations': [
            {
                'CollectionName': 'losses',
                'CollectionParameters': {
                    'train.save_interval': '500',
                    'eval.save_interval': '50'
                }
            }
        ],
    DebugRuleConfigurations=[
        {
            'RuleConfigurationName': 'LossNotDecreasing',
            'RuleEvaluatorImage': '895741380848.dkr.ecr.us-west-2.amazonaws.com/sagemaker-
                                    debugger-rules:latest',
            'RuleParameters': {'rule_to_invoke': 'LossNotDecreasing'}
        }
    ],
    ProfilerConfig={
        'S3OutputPath': 's3://'+bucket+'/'+project+'/profiler-output',
        'ProfilingIntervalInMilliseconds': 500,
        'ProfilingParameters': {
            'DataloaderProfilingConfig': '{"StartStep": 5, "NumSteps": 3, "MetricsRegex":
                                     ".*", }',
            'DetailedProfilingConfig': '{"StartStep": 5, "NumSteps": 3, }',
            'PythonProfilingConfig': '{"StartStep": 5, "NumSteps": 3, "ProfilerName":
                                      "cprofile", "cProfileTimer": "total_time"},
            'LocalPath': '/opt/ml/output/profiler/' # Optional. Local path for profiling
                                  # outputs
        }
    }
)
To configure a Debugger rule for debugging model parameters

The following code samples show how to configure a built-in VanishingGradient rule using this SageMaker API.

To enable Debugger to collect output tensors

Specify the Debugger hook configuration as follows:

```python
DebugHookConfig={
    'S3OutputPath': 's3://<default-bucket>/<training-job-name>/debug-output',
    'CollectionConfigurations': [
        {
            'CollectionName': 'gradients',
            'CollectionParameters':{
                'train.save_interval': '500',
                'eval.save_interval': '50'
            }
        }
    ]
}
```

This will make the training job save a tensor collection, gradients, every save_interval of 500 steps. To find available CollectionName values, see Debugger Built-in Collections in the SMDebug client library documentation. To find available CollectionParameters parameter keys and values, see the `sagemaker.debugger.CollectionConfig` class in the SageMaker Python SDK documentation.

To enable Debugger rules for debugging the output tensors

The following DebugRuleConfigurations API example shows how to run the built-in VanishingGradient rule on the saved gradients collection.

```python
DebugRuleConfigurations=[
    {
        'RuleConfigurationName': 'VanishingGradient',
        'RuleParameters': { 'rule_to_invoke': 'VanishingGradient',
            'threshold': '20.0'
        }
    }
]
```

With a configuration like the one in this sample, Debugger starts a rule evaluation job for your training job using the VanishingGradient rule on the collection of gradients tensor. To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 2028). To find the key-value pairs for RuleParameters, see List of Debugger Built-in Rules (p. 1975).
To configure a Debugger built-in rule for profiling system and framework metrics

The following example code shows how to specify the ProfilerConfig API operation to enable collecting system and framework metrics.

To enable Debugger profiling to collect system and framework metrics

Target Step

```json
ProfilerConfig=
  {'S3OutputPath': 's3://<default-bucket>/<training-job-name>/profiler-output', # Optional. Path to an S3 bucket to save profiling outputs
    # Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.
    'ProfilingIntervalInMilliseconds': 500,
    'ProfilingParameters': {
      'DataloaderProfilingConfig': {
        'StartTimeInSecSinceEpoch': 123456789,
        'DurationInSeconds': 10,
        'MetricsRegex': ".*"
      },
      'DetailedProfilingConfig': {
        'StartTimeInSecSinceEpoch': 123456789,
        'DurationInSeconds': 10
      },
      'PythonProfilingConfig': {
        'StartTimeInSecSinceEpoch': 123456789,
        'DurationInSeconds': 10,
        'ProfilerName': "cprofile",  # Available options: cprofile, pyinstrument
        "cProfileTimer": "total_time"  # Include only when using cprofile.
        Available options: cpu, off_cpu, total_time
      }
    }
  }
```

Target Time Duration

```json
ProfilerConfig=
  {'S3OutputPath': 's3://<default-bucket>/<training-job-name>/profiler-output', # Optional. Path to an S3 bucket to save profiling outputs
    # Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.
    'ProfilingIntervalInMilliseconds': 500,
    'ProfilingParameters': {
      'DataloaderProfilingConfig': {
        'StartTimeInSecSinceEpoch': 123456789,
        'DurationInSeconds': 10,
        'MetricsRegex': ".*"
      },
      'DetailedProfilingConfig': {
        'StartTimeInSecSinceEpoch': 123456789,
        'DurationInSeconds': 10
      },
      'PythonProfilingConfig': {
        'StartTimeInSecSinceEpoch': 123456789,
        'DurationInSeconds': 10,
        'ProfilerName': "cprofile",  # Available options: cprofile, pyinstrument
        "cProfileTimer": "total_time"  # Include only when using cprofile.
        Available options: cpu, off_cpu, total_time
      }
    }
  }
```

2022
To enable Debugger rules for profiling the metrics

The following example code shows how to configure the ProfilerReport rule.

```python
ProfilerRuleConfigurations=[
    {
        'RuleConfigurationName': 'ProfilerReport',
        'RuleParameters': {
            'rule_to_invoke': 'ProfilerReport',
            'CPUBottleneck_cpu_threshold': '90',
            'IOBottleneck_threshold': '90'
        }
    }
]
```

To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 2028). To find the key-value pairs for RuleParameters, see List of Debugger Built-in Rules (p. 1975).

Update Debugger Profiling Configuration Using the UpdateTrainingJob API Operation

Debugger profiling configuration can be updated while your training job is running by using the `update_training_job()` function of the AWS Boto3 SageMaker client. Configure new `ProfilerConfig` and `ProfilerRuleConfiguration` objects, and specify the training job name to the `TrainingJobName` parameter.

```python
ProfilerConfig={
    'DisableProfiler': boolean,
    'ProfilingIntervalInMilliseconds': number,
    'ProfilingParameters': {
        'string' : 'string'
    }
},
ProfilerRuleConfigurations=[
    {
        'RuleConfigurationName': 'string',
        'RuleEvaluatorImage': 'string',
        'RuleParameters': {
            'string' : 'string'
        }
    }
]
TrainingJobName='your-training-job-name-YYYY-MM-DD-HH-MM-SS-SSS'
```

Add Debugger Custom Rule Configuration to the CreateTrainingJob API Operation

A custom rule can be configured for a training job using the `DebugHookConfig` and `DebugRuleConfiguration` objects using the AWS Boto3 SageMaker client's `create_training_job()` function. The following code sample shows how to configure a custom ImproperActivation rule written with the `smdebug` library using this SageMaker API operation. This example assumes that you’ve written the custom rule in `custom_rules.py` file and uploaded it to an Amazon S3 bucket. The example provides pre-built Docker images that you can use to run your custom rules. These are listed at Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators (p. 2029). You specify the URL registry address for the pre-built Docker image in the `RuleEvaluatorImage` parameter.
DebugHookConfig={
    'S3OutputPath': 's3://<default-bucket>/<training-job-name>/debug-output',
    'CollectionConfigurations': [
        {
            'CollectionName': 'relu_activations',
            'CollectionParameters': {
                'include_regex': 'relu',
                'save_interval': '500',
                'end_step': '5000'
            }
        }
    ],
},
DebugRulesConfigurations=[
    {
        'RuleConfigurationName': 'improper_activation_job',
        'InstanceType': 'ml.c4.xlarge',
        'VolumeSizeInGB': 400,
        'RuleParameters': {
            'source_s3_uri': 's3://bucket/custom_rules.py',
            'rule_to_invoke': 'ImproperActivation',
            'collection_names': 'relu_activations'
        }
    }
]

To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 2028). To find the key-value pairs for RuleParameters, see List of Debugger Built-in Rules (p. 1975).

Best Practices for Amazon SageMaker Debugger

Use the following guidelines when you run training jobs with Debugger.

Topics
- Choose a Machine Learning Framework (p. 2024)
- Use Studio Debugger Insights Dashboard (p. 2025)
- Download Debugger Reports and Gain More Insights (p. 2025)
- Capture Data from Your Training Job and Save Data to Amazon S3 (p. 2025)
- Analyze the Data with a Fleet of Debugger Built-in Rules (p. 2025)
- Take Actions Based on the Built-in Rule Status (p. 2025)
- Dive Deep into the Data Using the SMDebug Client Library (p. 2025)
- Monitor and Analyze Training Job Metrics (p. 2026)
- Monitoring System Utilization and Detect Bottlenecks (p. 2026)
- Profiling Framework Operations (p. 2026)
- Debugging Model Output Tensors (p. 2027)

Choose a Machine Learning Framework

You can choose a machine learning framework and use SageMaker pre-built training containers or your own containers. Use Debugger to detect training and performance issues, and analyze training progress of your training job in SageMaker. SageMaker provides you options to use pre-built containers that are prepared for a number of machine learning framework environments to train your model on Amazon
EC2. Any training job can be adapted to run in AWS Deep Learning Containers, SageMaker training containers, and custom containers.

Use Studio Debugger Insights Dashboard

With Studio Debugger insights dashboard, you are in control of your training jobs. Use the Studio Debugger dashboards to keep your model performance on Amazon EC2 instances in control and optimized. For any SageMaker training jobs running on Amazon EC2 instance, Debugger monitors resource utilization and basic model output data (loss and accuracy values). Through the Studio Debugger dashboards, gain insights into your training jobs and improve your model training performance. To learn more, see Amazon SageMaker Debugger UI in Amazon SageMaker Studio Experiments (p. 2073).

Download Debugger Reports and Gain More Insights

You can view aggregated results and gain insights in Debugger reports. Debugger aggregates training and profiling results collected from the built-in rule analysis into a report per training job. You can find more detailed information about your training results through the Debugger reports. To learn more, see SageMaker Debugger interactive report (p. 2082).

Capture Data from Your Training Job and Save Data to Amazon S3

You can use a Debugger hook to save output tensors. After you choose a container and a framework that fit your training script, use a Debugger hook to configure which tensors to save and to which directory to save them, such as a Amazon S3 bucket. A Debugger hook helps you to build the configuration and to keep it in your account to use in subsequent analyses, where it is secured for use with the most privacy-sensitive applications. To learn more, see Configure SageMaker Debugger to Save Tensors (p. 1938).

Analyze the Data with a Fleet of Debugger Built-in Rules

You can use Debugger built-in rules to inspect tensors in parallel with a training job. To analyze the training performance data, Debugger provides built-in rules that watch for abnormal training process behaviors. For example, a Debugger rule detects issues when the training process suffers from system bottleneck issues or training issues, such as vanishing gradients, exploding tensors, overfitting, or overtraining. If necessary, you can also build customized rules by creating a rule definition with your own criteria to define a training issue. To learn more about the Debugger rules, see Configure Debugger Built-in Rules (p. 1944) for detailed instructions of using the Amazon SageMaker Python SDK. For a full list of the Debugger built-in rules, see List of Debugger Built-in Rules (p. 1975). If you want to create a custom rule, see Create Debugger Custom Rules for Training Job Analysis (p. 2008).

Take Actions Based on the Built-in Rule Status

You can use Debugger with Amazon CloudWatch Events and AWS Lambda. You can automate actions based on the rule status, such as stopping training jobs early and setting up notifications through email or text. When the Debugger rules detect problems and triggers an "IssuesFound" evaluation status, CloudWatch Events detects the rule status changes and invokes the Lambda function to take actions. To configure automated actions to your training issues, see Create Actions on Rules Using Amazon CloudWatch and AWS Lambda (p. 1968).

Dive Deep into the Data Using the SMDebug Client Library

You can use the SMDebug tools to access and analyze training data collected by Debugger. The TrainingJob and create_trial classes load the metrics and tensors saved by Debugger. These classes provide extended class methods to analyze the data in real time or after the training has finished. The SMDebug library also provides visualization tools: merge timelines of framework metrics to aggregate different profiling, line charts and heatmap to track the system utilization, and histograms to
find step duration outliers. To learn more about the SMDebug library tools, see Analyze data using the Debugger Python client library (p. 2093).

**Monitor and Analyze Training Job Metrics**

Amazon CloudWatch supports high-resolution custom metrics, and its finest resolution is 1 second. However, the finer the resolution, the shorter the lifespan of the CloudWatch metrics. For the 1-second frequency resolution, the CloudWatch metrics are available for 3 hours. For more information about the resolution and the lifespan of the CloudWatch metrics, see GetMetricStatistics in the Amazon CloudWatch API Reference.

If you want to profile your training job with a finer resolution down to 100-millisecond (0.1 second) granularity and store the training metrics indefinitely in Amazon S3 for custom analysis at any time, consider using Amazon SageMaker Debugger. SageMaker Debugger provides built-in rules to automatically detect common training issues; it detects hardware resource utilization issues (such as CPU, GPU, and I/O bottlenecks) and non-converging model issues (such as overfit, vanishing gradients, and exploding tensors).

SageMaker Debugger also provides visualizations through Studio and its profiling report. Unlike CloudWatch metrics, which accumulates resource utilization rates of CPU and GPU cores and averages those out across multiple instances, Debugger tracks the utilization rate of each core. This enables you to identify unbalanced usage of hardware resources as you scale up to larger compute clusters. To explore the Debugger visualizations, see SageMaker Debugger Insights Dashboard Walkthrough, Debugger Profiling Report Walkthrough, and Analyze Data Using the SMDebug Client Library.

**Monitoring System Utilization and Detect Bottlenecks**

With Amazon SageMaker Debugger monitoring, you can measure hardware system resource utilization of Amazon EC2 instances. Monitoring is available for any SageMaker training job constructed with the SageMaker framework estimators (TensorFlow, PyTorch, and MXNet) and the generic SageMaker estimator (SageMaker built-in algorithms and your own custom containers). Debugger built-in rules for monitoring detect system bottleneck issues and notify you when they detect the bottleneck issues.

To learn how to enable Debugger system monitoring, see Configure an estimator with parameters for basic profiling using the Amazon SageMaker Debugger Python modules (p. 2051) and then Configure settings for basic profiling of system resource utilization (p. 2055).

For a full list of available built-in rules for monitoring, see Debugger built-in rules for profiling hardware system resource utilization (system metrics) (p. 2062).

**Profiling Framework Operations**

With Amazon SageMaker Debugger profiling you can profile deep learning frameworks operations. You can profile your model training with the SageMaker TensorFlow training containers, the SageMaker PyTorch framework containers, and your own training containers. Using the profiling feature of Debugger, you can drill down into the Python operators and functions that are executed to perform the training job. Debugger supports detailed profiling, Python profiling, data loader profiling, and Horovod distributed training profiling. You can merge the profiled timelines to correlate with the system bottlenecks. Debugger built-in rules for profiling watch framework operation related issues, including excessive training initialization time due to data downloading before training starts and step duration outliers in training loops.

To learn how to configure Debugger for framework profiling, see Configure an estimator with parameters for basic profiling using the Amazon SageMaker Debugger Python modules (p. 2051) and then Configure for framework profiling (p. 2055).

For a complete list of available built-in rules for profiling, see Debugger built-in rules for profiling framework metrics (p. 2062).
**Debugging Model Output Tensors**

Debugging is available for deep learning frameworks using AWS Deep Learning Containers and the SageMaker training containers. For fully supported framework versions (see the versions at Supported Frameworks and Algorithms (p. 1917)), Debugger automatically registers hooks to collect output tensors, and you can directly run your training script. For the versions with one asterisk sign, you need to manually register the hooks to collect tensors. Debugger provides preconfigured tensor collections with generalized names that you can utilize across the different frameworks. If you want to customize output tensor configuration, you can also use the CollectionConfig and DebuggerHookConfig API operations and the Amazon SageMaker Python SDK to configure your own tensor collections. Debugger built-in rules for debugging analyze the output tensors and identifies model optimization problems that blocks your model from minimizing the loss function. For example, the rules identify overfitting, overtraining, loss not decreasing, exploding tensors, and vanishing gradients.

To learn how to configure Debugger for debugging output tensors, see Step 2: Launch and Debug Training Jobs Using SageMaker Python SDK (p. 1935) and then Configure SageMaker Debugger to Save Tensors (p. 1938).

For a full list of available built-in rules for debugging, see Debugger built-in rules for debugging model training data (output tensors) (p. 1976).

**Amazon SageMaker Debugger Advanced Topics and Reference Documentation**

The following sections contain advanced topics, reference documentation for the API operations, exceptions, and known limitations for Debugger.

**Topics**

- Amazon SageMaker Debugger API Operations (p. 2027)
- Use Debugger Docker Images for Built-in or Custom Rules (p. 2028)
- Amazon SageMaker Debugger Exceptions (p. 2030)
- Considerations for Amazon SageMaker Debugger (p. 2031)
- Amazon SageMaker Debugger Usage Statistics (p. 2033)

**Amazon SageMaker Debugger API Operations**

Amazon SageMaker Debugger has API operations in several locations that are used to implement its monitoring and analysis of model training.

Amazon SageMaker Debugger also provides the open source sagemaker-debugger Python SDK that is used to configure built-in rules, define custom rules, and register hooks to collect output tensor data from training jobs.

The Amazon SageMaker Python SDK is a high-level SDK focused on machine learning experimentation. The SDK can be used to deploy built-in or custom rules defined with the SMDebug Python library to monitor and analyze these tensors using SageMaker estimators.

Debugger has added operations and types to the Amazon SageMaker API that enable the platform to use Debugger when training a model and to manage the configuration of inputs and outputs.

- CreateTrainingJob and UpdateTrainingJob use the following Debugger APIs to configure tensor collections, rules, rule images, and profiling options:
  - CollectionConfiguration
  - DebugHookConfig
• **DebugRuleConfiguration**
• **TensorBoardOutputConfig**
• **ProfilerConfig**
• **ProfilerRuleConfiguration**

**DescribeTrainingJob** provides a full description of a training job, including the following Debugger configurations and rule evaluation statuses:
• **DebugHookConfig**
• **DebugRuleConfiguration**
• **DebugRuleEvaluationStatus**
• **ProfilerConfig**
• **ProfilerRuleConfiguration**
• **ProfilerRuleEvaluationStatus**

The rule configuration API operations use the SageMaker Processing functionality when analyzing a model training. For more information about SageMaker Processing, see Process data (p. 1399).

**Use Debugger Docker Images for Built-in or Custom Rules**

Amazon SageMaker provides two sets of Docker images for rules: one set for evaluating rules provided by SageMaker (built-in rules) and one set for evaluating custom rules provided in Python source files.

If you use the [Amazon SageMaker Python SDK](https://docs.aws.amazon.com/sagemaker/latest/dg/python-sdk.html), you can simply use SageMaker high-level Debugger API operations with SageMaker Estimator API operations, without having to manually retrieve the Debugger Docker images and configure the ConfigureTrainingJob API.

If you are not using the SageMaker Python SDK, you have to retrieve a relevant pre-built container base image for the Debugger rules. Amazon SageMaker Debugger provides pre-built Docker images for built-in and custom rules, and the images are stored in Amazon Elastic Container Registry (Amazon ECR). To pull an image from an Amazon ECR repository (or to push an image to one), use the full name registry URL of the image using the CreateTrainingJob API. SageMaker uses the following URL patterns for the Debugger rule container image registry address.

```
<account_id>.dkr.ecr.<Region>.amazonaws.com/<ECR repository name>:<tag>
```

For the account ID in each AWS Region, Amazon ECR repository name, and tag value, see the following topics.

Amazon SageMaker Debugger Exceptions

Amazon SageMaker Debugger is designed to be aware that tensors required to execute a rule might not be available at every step. As a result, it raises a few exceptions, which enable you to control what happens when a tensor is missing. These exceptions are available in the `smdebug.exceptions` module. You can import them as follows:

```python
from smdebug.exceptions import *
```

The following exceptions are available:
• **TensorUnavailableForStep** – The tensor requested is not available for the step. This might mean that this step might not be saved at all by the hook, or that this step might have saved some tensors but the requested tensor is not part of them. Note that when you see this exception, it means that this tensor can never become available for this step in the future. If the tensor has reductions saved for the step, it notifies you they can be queried.

• **TensorUnavailable** – This tensor is not being saved or has not been saved by the smdebug API. This means that this tensor is never seen for any step in smdebug.

• **StepUnavailable** – The step was not saved and Debugger has no data from the step.

• **StepNotYetAvailable** – The step has not yet been seen by smdebug. It might be available in the future if the training is still going on. Debugger automatically loads new data as it becomes available.

• **NoMoreData** – Raised when the training ends. Once you see this, you know that there are no more steps and no more tensors to be saved.

• **IndexReaderException** – The index reader is not valid.

• **InvalidWorker** – A worker was invoked that was not valid.

• **RuleEvaluationConditionMet** – Evaluation of the rule at the step resulted in the condition being met.

• **InsufficientInformationForRuleInvocation** – Insufficient information was provided to invoke the rule.

### Considerations for Amazon SageMaker Debugger

Consider the following when using Amazon SageMaker Debugger.

### Considerations for Distributed Training

The following list shows the scope of validity and considerations for using Debugger on training jobs with deep learning frameworks and various distributed training options.

- **Horovod**

  **Scope of validity of using Debugger for training jobs with Horovod**

<table>
<thead>
<tr>

<td>Yes</td>
</tr>
<tr>
<td>Debugging model output tensors</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

* Debugger does not support framework profiling for TensorFlow 2.x.

** SageMaker distributed data parallel does not support TensorFlow 2.x with Keras implementation.

- **SageMaker distributed model parallel** – Debugger does not support SageMaker distributed model parallel training.
- **Distributed training with SageMaker checkpoints** – Debugger is not available for training jobs when both the distributed training option and SageMaker checkpoints are enabled. You might see an error that looks like the following:

```
SMDebug Does Not Currently Support Distributed Training Jobs With Checkpointing Enabled
```

To use Debugger for training jobs with distributed training options, you need to disable SageMaker checkpointing and add manual checkpointing functions to your training script. For more information about using Debugger with distributed training options and checkpoints, see [*Using SageMaker Distributed Data Parallel with Amazon SageMaker Debugger and Checkpoints*](#) and [*Saving Checkpoints*](#).

- **Parameter Server** – Debugger does not support parameter server-based distributed training.
- **Profiling distributed training framework operations**, such as the `AllReduced` operation of SageMaker distributed data parallel and **Horovod operations**, is not available.

Considerations for Monitoring System Bottlenecks and Profiling Framework Operations

- For AWS TensorFlow, data loader metrics cannot be collected using the default `local_path` setting of the `FrameworkProfile` class. The path has to be manually configured and end in "/". For example:

```
FrameworkProfile(local_path="/opt/ml/output/profiler/")
```

- For AWS TensorFlow, the data loader profiling configuration cannot be updated while a training job is running.
- For AWS TensorFlow, a `NoneType` error might occur when you use analysis tools and notebook examples with TensorFlow 2.3 training jobs and the detailed profiling option.
- Python profiling and detailed profiling are only supported for Keras API.
- To access the deep profiling feature for TensorFlow and PyTorch, currently you must specify the latest AWS deep learning container images with CUDA 11. For example, you must specify the specific image URI in the TensorFlow and PyTorch estimator as follows:

```
• For TensorFlow
```
image_uri = f"763104351884.dkr.ecr.{region}.amazonaws.com/tensorflow-training:2.3.1-gpu-py37-cu110-ubuntu18.04"

- For PyTorch

image_uri = f"763104351884.dkr.ecr.{region}.amazonaws.com/pytorch-training:1.6.0-gpu-py36-cu110-ubuntu18.04"

Considerations for Debugging Model Output Tensors

- Avoid using functional API operations. Debugger cannot collect model output tensors from PyTorch and MXNet training scripts composed of functional API operations.
- Debugger cannot collect model output tensors from the `torch.nn.functional` API operations. When you write a PyTorch training script, it is recommended to use the `torch.nn` modules instead.
- Debugger cannot collect model output tensors from MXNet functional objects in hybrid blocks. For example, the ReLu activation (`F.relu`) outputs cannot be collected from the following example of `mxnet.gluon.HybridBlock` with `F` in the `hybrid_forward` function.

```python
import mxnet as mx
from mxnet.gluon import HybridBlock, nn

class Model(HybridBlock):
    def __init__(self, **kwargs):
        super(Model, self).__init__(**kwargs)
        # use name_scope to give child Blocks appropriate names.
        with self.name_scope():
            self.dense0 = nn.Dense(20)
            self.dense1 = nn.Dense(20)

    def hybrid_forward(self, F, x):
        x = F.relu(self.dense0(x))
        return F.relu(self.dense1(x))

model = Model()
model.initialize(ctx=mx.cpu(0))
model.hybridize()
model(mx.nd.zeros((10, 10), ctx=mx.cpu(0)))
```

Amazon SageMaker Debugger Usage Statistics

Consider the following when using autogenerated reports by Amazon SageMaker Debugger.

Debug Profiling Report Usage

For all SageMaker training jobs, Amazon SageMaker Debugger runs the `ProfilerReport (p. 2063)` rule and autogenerates a `SageMaker Debugger profiling report (p. 2082)`. The `ProfilerReport` rule provides a Jupyter notebook file (`profiler-report.ipynb`) that generates a corresponding HTML file (`profiler-report.html`).

Debugger collects profiling report usage statistics by including code in the Jupyter notebook that collects the unique `ProfilerReport` rule's processing job ARN if the user opens the final `profiler-report.html` file.

Debugger only collects information about whether a user opens the final HTML report. It **DOES NOT** collect any information from training jobs, training data, training scripts, processing jobs, logs, or the content of the profiling report itself.
You can opt out of the collection of usage statistics using either of the following options.

(Recommended) Option 1: Opt Out before Running a Training Job

To opt out, you need to add the following Debugger ProfilerReport rule configuration to your training job request.

SageMaker Python SDK

```python
estimator=sagemaker.estimator.Estimator(
    ...
    rules=ProfilerRule.sagemaker(
        base_config=rule_configs.ProfilerReport()
        rule_parameters={"opt_out_telemetry": "True"}
    )
)
```

AWS CLI

```
"ProfilerRuleConfigurations": [
    {
        "RuleConfigurationName": "ProfilerReport-1234567890",
        "RuleParameters": {
            "rule_to_invoke": "ProfilerReport",
            "opt_out_telemetry": "True"
        }
    }
]
```

AWS SDK for Python (Boto3)

```python
ProfilerRuleConfigurations=[
    {
        'RuleConfigurationName': 'ProfilerReport-1234567890',
        'RuleParameters': {
            'rule_to_invoke': 'ProfilerReport',
            'opt_out_telemetry': 'True'
        }
    }
]
```

Option 2: Opt Out after a Training Job Has Completed

To opt out after training has completed, you need to modify the profiler-report.ipynb file.

Note

HTML reports autogenerated without Option 1 already added to your training job request still report the usage statistics even after you opt out using Option 2.

1. Follow the instructions on downloading the Debugger profiling report files in the [Download the SageMaker Debugger profiling report](p. 2083) page.
2. In the `/ProfilerReport-1234567890/profiler-output` directory, open `profiler-report.ipynb`.
3. Add `opt_out=True` to the `setup_profiler_report()` function in the fifth code cell as shown in the following example code:
```python
setup_profiler_report(processing_job_arn, opt_out=True)
```

4. Run the code cell to finish opting out.

## Release notes for debugging capabilities of Amazon SageMaker

See the following release notes to track the latest updates for debugging capabilities of Amazon SageMaker.

### September 7, 2023

#### New features

Added a new utility module `sagemaker.interactive_apps.tensorboard.TensorBoardApp` that provides a function called `get_app_url()`. The `get_app_url()` function generates unsigned or presigned URLs to open the TensorBoard application in any environment in SageMaker or Amazon EC2. This is to provide a unified experience for both Studio and non-Studio users. For the Studio environment, you can open TensorBoard by running the `get_app_url()` function as is, or you can also specify a job name to start tracking as the TensorBoard application opens. For non-Studio environments, you can open TensorBoard by providing your Domain information to the utility function. With this functionality, regardless of where or how you run training code and launch training jobs, you can directly access TensorBoard by running the `get_app_url` function in your Jupyter notebook or terminal. This functionality is available in the SageMaker Python SDK v2.184.0 and later. For more information, see the section called “How to access TensorBoard on SageMaker” (p. 1907).

### April 4, 2023

#### New features

Released SageMaker with TensorBoard, a capability that hosts TensorBoard on SageMaker. TensorBoard is available as an application through SageMaker Domain, and the SageMaker Training platform supports TensorBoard output data collection to S3 and loading them automatically to the hosted TensorBoard on SageMaker. With this capability, you can run training jobs set up with TensorBoard summary writers in SageMaker, save the TensorBoard output files in Amazon S3, open the TensorBoard application directly from the SageMaker console, and load the output files using SageMaker Data Manager plugin implemented to the hosted TensorBoard interface. You don't need to install TensorBoard manually and host locally on the SageMaker IDEs or local machine. To learn more, see the section called “Use TensorBoard” (p. 1904).

### March 16, 2023

#### Deprecation notes

SageMaker Debugger deprecates the framework profiling feature starting from TensorFlow 2.11 and PyTorch 2.0. You can still use the feature in the previous versions of the frameworks and SDKs as follows.

- SageMaker Python SDK <= v2.130.0
- PyTorch >= v1.6.0, < v2.0
- TensorFlow >= v2.3.1, < v2.11

With the deprecation, SageMaker Debugger also discontinues support for the following three ProfilerRules for framework profiling.
Profile and optimize computational performance

When training state-of-the-art deep learning models that rapidly grow in size, scaling the training job of such models to a large GPU cluster and identifying computational performance issues from billions and trillions of operations and communications in every iteration of the gradient descent process become a challenge.

SageMaker provides profiling tools to visualize and diagnose such complex computation issues arising from running training jobs on AWS cloud computing resources. There are two profiling options that SageMaker offers: Amazon SageMaker Profiler and a resource utilization monitor in Amazon SageMaker Studio. See the following introductions of the two functionalities to gain quick insights and learn which one to use depending on your needs.

Amazon SageMaker Profiler

Amazon SageMaker Profiler is a profiling capability of SageMaker with which you can deep dive into compute resources provisioned while training deep learning models, and gain visibility into operation-level details. SageMaker Profiler provides Python modules for adding annotations throughout PyTorch or TensorFlow training scripts and activating SageMaker Profiler. You can access the modules through the SageMaker Python SDK and AWS Deep Learning Containers.

With SageMaker Profiler, you can track all activities on CPUs and GPUs, such as CPU and GPU utilizations, kernel runs on GPUs, kernel launches on CPUs, sync operations, memory operations across CPUs and GPUs, latencies between kernel launches and corresponding runs, and data transfer between CPUs and GPUs.

SageMaker Profiler also offers a user interface (UI) that visualizes the profile, a statistical summary of profiled events, and the timeline of a training job for tracking and understanding the time relationship of the events between GPUs and CPUs.

Other changes

- The XGBoost report tab has been removed from the SageMaker Debugger's profiler dashboard. You can still access the XGBoost report by downloading it as a Jupyter notebook or a HTML file. For more information, see [SageMaker Debugger XGBoost Training Report](#).
- Starting from this release, the built-in profiler rules are not activated by default. To use the SageMaker Debugger profiler rules to detect certain computational problems, you need to add the rules when you configure a SageMaker training job launcher.

December 1, 2020

Amazon SageMaker Debugger launched deep profiling features at re:Invent 2020.

December 3, 2019

Amazon SageMaker Debugger initially launched at re:Invent 2019.
To learn more about SageMaker Profiler, see the section called “Use SageMaker Profiler” (p. 2037).

Monitoring AWS compute resources in Amazon SageMaker Studio

SageMaker also provides a user interface in Studio for monitoring resource utilization at high level, but with more granularity compared to the default utilization metrics collected from SageMaker to CloudWatch.

For any training job you run in SageMaker using the SageMaker Python SDK, SageMaker starts profiling basic resource utilization metrics, such as CPU utilization, GPU utilization, GPU memory utilization, network, and I/O wait time. It collects these resource utilization metrics every 500 milliseconds.

Compared to Amazon CloudWatch metrics, which collect metrics at intervals of 1 second, the monitoring functionality of SageMaker provides finer granularity into the resource utilization metrics down to 100-millisecond (0.1 second) intervals, so you can dive deep into the metrics at the level of an operation or a step.

To access the dashboard for monitoring the resource utilization metrics of a training job, see the SageMaker Debugger UI in SageMaker Studio Experiments.

Topics
- Use Amazon SageMaker Profiler to profile activities on AWS compute resources (p. 2037)
- Monitor AWS compute resource utilization in Amazon SageMaker Studio (p. 2050)
- Release notes for profiling capabilities of Amazon SageMaker (p. 2101)

Use Amazon SageMaker Profiler to profile activities on AWS compute resources

Amazon SageMaker Profiler is currently in preview release and available at no cost in supported AWS Regions. The generally available version of Amazon SageMaker Profiler (if any) may include features and pricing that are different than those offered in preview.

Amazon SageMaker Profiler is a capability of Amazon SageMaker that provides a detailed view into the AWS compute resources provisioned during training deep learning models on SageMaker. It focuses on profiling the CPU and GPU usage, kernel runs on GPUs, kernel launches on CPUs, sync operations, memory operations across CPUs and GPUs, latencies between kernel launches and corresponding runs, and data transfer between CPUs and GPUs. SageMaker Profiler also offers a user interface (UI) that visualizes the profile, a statistical summary of profiled events, and the timeline of a training job for tracking and understanding the time relationship of the events between GPUs and CPUs.

**Note**

SageMaker Profiler supports PyTorch and TensorFlow and is available in AWS Deep Learning Containers for SageMaker. To learn more, see the section called “Supported frameworks, AWS Regions, and instance types” (p. 2038).

For data scientists

Training deep learning models on a large compute cluster often has computational optimization problems, such as bottlenecks, kernel launch latencies, memory limit, and low resource utilization.

To identify such computational performance issues, you need to profile deeper into the compute resources to understand which kernels introduce latencies and which operations cause bottlenecks. Data scientists can take the benefit from using the SageMaker Profiler UI for visualizing the detailed profile.
of training jobs. The UI provides a dashboard furnished with summary charts and a timeline interface to track every event on the compute resources. Data scientists can also add custom annotations to track certain parts of the training job using the SageMaker Profiler Python modules.

For administrators

Through the Profiler landing page in the SageMaker console or SageMaker Domain, you can manage the Profiler application users if you are an administrator of an AWS account or SageMaker Domain. Each Domain user can access their own Profiler application given the granted permissions. As a SageMaker Domain administrator and Domain user, you can create and delete the Profiler application given the permission level you have.

Supported frameworks, AWS Regions, and instance types

This feature supports the following machine learning frameworks and AWS Regions.

**Note**

To use this feature, be sure to have at least version 2.180.0 of the SageMaker Python SDK installed.

Supported frameworks

SageMaker Profiler is available in the following AWS Deep Learning Containers for SageMaker.

**PyTorch**

<table>
<thead>
<tr>
<th>PyTorch versions</th>
<th>AWS DLC image URI</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.0.0</td>
<td>763104351884.dkr.ecr.&lt;region&gt;.amazonaws.com/pytorch-training:2.0.0-gpu-py310-cu118-ubuntu20.04-sagemaker</td>
</tr>
</tbody>
</table>

**TensorFlow**

<table>
<thead>
<tr>
<th>TensorFlow versions</th>
<th>AWS DLC image URI</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.12.0</td>
<td>763104351884.dkr.ecr.&lt;region&gt;.amazonaws.com/tensorflow-training:2.12.0-gpu-py310-cu118-ubuntu20.04-sagemaker</td>
</tr>
<tr>
<td>2.11.0</td>
<td>763104351884.dkr.ecr.&lt;region&gt;.amazonaws.com/tensorflow-training:2.11.0-gpu-py39-cu112-ubuntu20.04-sagemaker</td>
</tr>
</tbody>
</table>

**Supported AWS Regions**

SageMaker Profiler is available in the following AWS Regions.

- US East (N. Virginia) (us-east-1)
- US East (Ohio) (us-east-2)
- US West (Oregon) (us-west-2)
Supported instance types

SageMaker Profiler is available in the following instance types for training workloads.

- ml.p4de.24xlarge
- ml.p4d.24xlarge
- ml.p3dn.24xlarge
- ml.g4dn.12xlarge

Prerequisites

The following list shows the prerequisites to start using SageMaker Profiler.

- A SageMaker Domain set up with Amazon VPC in your AWS account.
  
  For instructions on setting up a Domain, see [Onboard to Amazon SageMaker Domain using quick setup](#). You also need to add Domain user profiles for individual users to access the Profiler UI application. For more information, see [Add and remove SageMaker Domain user profiles](#).
- The following list is the minimum set of permissions for using the Profiler UI application.
  
  - sagemaker:CreateApp
  - sagemaker:DeleteApp
  - sagemaker:DescribeTrainingJob
  - sagemaker:Search
  - s3:GetObject
  - s3:ListBucket

Prepare and run a training job with SageMaker Profiler

Setting up to running a training job with the SageMaker Profiler consists of two steps: adapting the training script and configuring the SageMaker training job launcher.

Step 1: Adapt your training script using the SageMaker Profiler Python modules

To start capturing kernel runs on GPUs while the training job is running, modify your training script using the SageMaker Profiler Python modules. Import the library and add the `start_profiling()` and `stop_profiling()` methods to define the beginning and the end of profiling. You can also use optional custom annotations to add markers in the training script to visualize hardware activities during particular operations in each step.

Note that the annotators extract operations from GPUs. For profiling operations in CPUs, you don’t need to add any additional annotations. CPU profiling is also activated when you specify the profiling configuration, which you’ll practice in [the section called “Step 2: Create a SageMaker framework estimator and activate SageMaker Profiler”](#).

Note

Profiling an entire training job is not the most efficient use of resources. We recommend profiling at most 300 steps of a training job.

Approach 1. Use the context manager `smppy.annotate` to annotate full functions
You can wrap full functions with by the `smppy.annotate()` context manager. This wrapper is recommended if you want to profile by functions instead of code lines. The following example script shows how to implement the context manager to wrap the training loop and full functions in each iteration.

```python
import smppy

SMProf = smppy.SMProfiler.instance()
config = smppy.Config()
config.profiler = {
    "EnableCuda": "1",
}
SMProf.configure(config)
SMProf.start_profiling()

for epoch in range(args.epochs):
    if world_size > 1:
        sampler.set_epoch(epoch)
    tstart = time.perf_counter()
    for i, data in enumerate(trainloader, 0):
        with smppy.annotate("step_\{\d\}"
                           "step_\{\d\}"
        inputs, labels = data
        inputs = inputs.to("cuda", non_blocking=True)
        labels = labels.to("cuda", non_blocking=True)
        optimizer.zero_grad()
        with smppy.annotate("Forward"):
            outputs = net(inputs)
        with smppy.annotate("Loss"):
            loss = criterion(outputs, labels)
        with smppy.annotate("Backward"):
            loss.backward()
        with smppy.annotate("Optimizer"):
            optimizer.step()
    SMProf.stop_profiling()

Approach 2. Use `smppy.annotation_begin()` and `smppy.annotation_end()` to annotate specific code line in functions

You can also define annotations to profile specific code lines. You can set the exact starting point and end point of profiling at the level of individual code lines, not by the functions. For example, in the following script, the `step_annotator` is defined at the beginning of each iteration and ends at the end of the iteration. Meanwhile, other detailed annotators for each operations are defined and wrap around the target operations throughout each iteration.

```python
import smppy

SMProf = smppy.SMProfiler.instance()
config = smppy.Config()
config.profiler = {
    "EnableCuda": "1",
}
SMProf.configure(config)
SMProf.start_profiling()

for epoch in range(args.epochs):
    if world_size > 1:
        sampler.set_epoch(epoch)
    tstart = time.perf_counter()
    for i, data in enumerate(trainloader, 0):
        step_annotator = smppy.annotation_begin("step_" + str(i))
        inputs, labels = data
        inputs = inputs.to("cuda", non_blocking=True)
        labels = labels.to("cuda", non_blocking=True)
        optimizer.zero_grad()
        with smppy.annotate("Forward"):
            outputs = net(inputs)
        with smppy.annotate("Loss"):
            loss = criterion(outputs, labels)
        with smppy.annotate("Backward"):
            loss.backward()
        with smppy.annotate("Optimizer"):
            optimizer.step()
    SMProf.stop_profiling()
```
inputs, labels = data
inputs = inputs.to("cuda", non_blocking=True)
labels = labels.to("cuda", non_blocking=True)
optimizer.zero_grad()

forward_annotator = smppy.annotation_begin("Forward")
outputs = net(inputs)
smppy.annotation_end(forward_annotator)

loss_annotator = smppy.annotation_begin("Loss")
loss = criterion(outputs, labels)
smppy.annotation_end(loss_annotator)

backward_annotator = smppy.annotation_begin("Backward")
loss.backward()
smppy.annotation_end(backward_annotator)

optimizer_annotator = smppy.annotation_begin("Optimizer")
optimizer.step()
smppy.annotation_end(optimizer_annotator)

SMProf.stop_profiling()

After annotating and setting up the profiler initiation modules, save the script to submit using a SageMaker training job launcher in the following Step 2. The sample launcher assumes that the training script is named train_with_profiler_demo.py.

**Step 2: Create a SageMaker framework estimator and activate SageMaker Profiler**

The following procedure shows how to prepare a SageMaker framework estimator for training using the SageMaker Python SDK.

1. Set up a profiler_config object using the ProfilerConfig and Profiler modules as follows.

```python
from sagemaker import ProfilerConfig, Profiler
profiler_config = ProfilerConfig(
    profile_params = Profiler(cpu_profiling_duration=3600)
)
```

The following is the description of the Profiler module and its argument.
- **Profiler**: The module for activating SageMaker Profiler with the training job.
- **cpu_profiling_duration (int)**: Specify the time duration in seconds for profiling on CPUs. Default is 3600 seconds.

2. Create a SageMaker estimator with the profiler_config object created in the previous step. The following code shows an example of creating a PyTorch estimator. If you want to create a TensorFlow estimator, import sagemaker.tensorflow.TensorFlow instead, and specify one of the TensorFlow version supported by SageMaker Profiler. For more information about supported frameworks and instance types, see the section called "Supported frameworks" (p. 2038).

```python
import sagemaker
from sagemaker.pytorch import PyTorch

estimator = PyTorch(
    framework_version="2.0.0",
    role=sagemaker.get_execution_role(),
    entry_point="train_with_profiler_demo.py", # your training job entry point
)```
source_dir=source_dir, # source dir for your training script
goal=goal, # goal you want your training script to achieve
output_path=output_path,
base_job_name="sagemaker-profiler-demo",
hyperparameters=hyperparameters, # if any
instance_count=1, # Recommended to test with < 8
instance_type=ml.p4d.24xlarge,
profiler_config=profiler_config
)

3. Start the training job by running the fit method. With wait=False, you can silence the training job logs and let it run in the background.

```python
estimator.fit(wait=False)
```

While running the training job or after the job has completed, you can go to the next topic at the section called “Open the SageMaker Profiler UI application” (p. 2042) and start exploring and visualizing the saved profiles.

If you want to directly access the profile data saved in the Amazon S3 bucket, use the following script to retrieve the S3 URI.

```python
import os
# This is an ad-hoc function to get the S3 URI
def get_detailed_profiler_output_uri(estimator):
    config_name = None
    for processing in estimator.profiler_rule_configs:
        params = processing.get("RuleParameters", dict())
        rule = config_name = params.get("rule_to_invoke", "")
        if rule == "DetailedProfilerProcessing"
            config_name = processing.get("RuleConfigurationName")
            break
    return os.path.join(
        estimator.output_path,
        estimator.latest_training_job.name,
        "rule-output",
        config_name,
    )

print(f"Profiler output S3 bucket: ",
    get_detailed_profiler_output_uri(estimator)
)
```

**Open the SageMaker Profiler UI application**

You can access the SageMaker Profiler UI application through the SageMaker Profiler landing page in the SageMaker console, or through the SageMaker Domain.

**Topics**

- **Option 1: Launch the SageMaker Profiler UI from the Domain details page** (p. 2042)
- **Option 2: Launch the SageMaker Profiler UI application from the SageMaker Profiler landing page in the SageMaker console** (p. 2043)

**Option 1: Launch the SageMaker Profiler UI from the Domain details page**

Navigate to the Domain details page
The following procedure shows how to navigate to the Domain details page.

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. On the left navigation pane, choose Domains.
3. From the list of Domains, select the Domain in which you want to launch the SageMaker Profiler application.

**Launch the SageMaker Profiler UI application**

The following procedure shows how to launch the SageMaker Profiler application that is scoped to a user profile.

1. On the Domain details page, choose the User profiles tab.
2. Identify the user profile for which you want to launch the SageMaker Profiler UI application.
3. Choose Launch for the selected user profile, and choose Profiler.

**Option 2: Launch the SageMaker Profiler UI application from the SageMaker Profiler landing page in the SageMaker console**

The following procedure describes how to launch a SageMaker Profiler UI application from the SageMaker Profiler landing page.

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. On the left navigation pane, choose Profiler.
3. Under Get started, select the Domain in which you want to launch the Studio application. If your user profile only belongs to one Domain, you do not see the option for selecting a Domain.
4. Select the user profile for which you want to launch the SageMaker Profiler UI application. If there is no user profile in the Domain, choose Create user profile. For more information about creating a new user profile, see Add and Remove User Profiles.
5. Choose Open Profiler.

**Explore the profile output data visualized in the SageMaker Profiler UI**

This section walks through the SageMaker Profiler UI and provides tips for how to use and gain insights from it.

**Load profile**

When you open the SageMaker Profiler UI, the Load profile page opens up. To load and generate the Dashboard and Timeline, go through the following procedure.

**To load the profile of a training job**

1. From the List of training jobs section, use the check box to choose the training job for which you want to load the profile.
2. Choose Load. The job name should appear in the Loaded profile section at the top.
3. Choose the radio button on the left of the Job name to generate the Dashboard and Timeline. Note that when you choose the radio button, the UI automatically opens the Dashboard. Note also that if you generate the visualizations while the job status and loading status still appear to be in progress, the SageMaker Profiler UI generates Dashboard plots and a Timeline up to the most recent profile data collected from the ongoing training job or the partially loaded profile data.
Tip
You can load and visualize one profile at a time. To load another profile, you must first unload the previously loaded profile. To unload a profile, use the trash bin icon on the right end of the profile in the Loaded profile section.

Dashboard
After you finish loading and selecting the training job, the UI opens the Dashboard page furnished with the following panels by default.

- **GPU active time** – This pie chart shows the percentage of GPU active time versus GPU idle time. You can check if your GPUs are more active than idle throughout the entire training job. GPU active time is based on the profile data points with a utilization rate greater than 0%, whereas GPU idle time is the profiled data points with 0% utilization.

- **GPU utilization over time** – This timeline graph shows the average GPU utilization rate over time per node, aggregating all of the nodes in a single chart. You can check if the GPUs have an unbalanced workload, under-utilization issues, bottlenecks, or idle issues during certain time intervals. To track the utilization rate at the individual GPU level and related kernel runs, use the the section called “Timeline interface” (p. 2047). Note that the GPU activity collection starts from where you added the profiler starter function SMProf.start_profiling() in your training script, and stops at SMProf.stop_profiling().

- **CPU active time** – This pie chart shows the percentage of CPU active time versus CPU idle time. You can check if your CPUs are more active than idle throughout the entire training job. CPU active time is based on the profiled data points with a utilization rate greater than 0%, whereas CPU idle time is the profiled data points with 0% utilization.

- **CPU utilization over time** – This timeline graph shows the average CPU utilization rate over time per node, aggregating all of the nodes in a single chart. You can check if the CPUs are bottlenecked or underutilized during certain time intervals. To track the utilization rate of the CPUs aligned with the individual GPU utilization and kernel runs, use the the section called “Timeline interface” (p. 2047). Note that the utilization metrics start from the start of the job initialization.
• **Time spent by all GPU kernels** – This pie chart shows all GPU kernels operated throughout the training job. It shows the top 15 GPU kernels by default as individual sectors and all other kernels in one sector. Hover over the sectors to see more detailed information. The value shows the total time of the GPU kernels operated in seconds, and the percentage is based on the entire time of the profile.

• **Time spent by top 15 GPU kernels** – This pie chart shows all GPU kernels operated throughout the training job. It shows the top 15 GPU kernels as individual sectors. Hover over the sectors to see more detailed information. The value shows the total time of the GPU kernels operated in seconds, and the percentage is based on the entire time of the profile.

• **Launch counts of all GPU kernels** – This pie chart shows the number of counts for every GPU kernel launched throughout the training job. It shows the top 15 GPU kernels as individual sectors and all other kernels in one sector. Hover over the sectors to see more detailed information. The value shows the total count of the launched GPU kernels, and the percentage is based on the entire count of all kernels.

• **Launch counts of top 15 GPU kernels** – This pie chart shows the number of counts of every GPU kernel launched throughout the training job. It shows the top 15 GPU kernels. Hover over the sectors to see more detailed information. The value shows the total count of the launched GPU kernels, and the percentage is based on the entire count of all kernels.

• **Step time distribution** – This histogram shows the distribution of step durations on GPUs. This plot is generated only after you add the step annotator in your training script.

• **Kernel precision distribution** – This pie chart shows the percentage of time spent on running kernels in different data types such as FP32, FP16, INT32, and INT8.

• **GPU activity distribution** – This pie chart shows the percentage of time spent on GPU activities, such as running kernels, memory (memcpy and memset), and synchronization (sync).

• **GPU memory operations distribution** – This pie chart shows the percentage of time spent on GPU memory operations. This visualizes the memcpy activities and helps identify if your training job is spending excessive time on certain memory operations.

• **Create a new histogram** – Create a new diagram of a custom metric you annotated manually during the section called “Step 1: Adapt your training script using the SageMaker Profiler Python modules” (p. 2039). When adding a custom annotation to a new histogram, select or type the name of the annotation you added in the training script. For example, in the demo training script in Step 1, step, Forward, Backward, Optimize, and Loss are the custom annotations. While creating a new histogram, these annotation names should appear in the dropdown menu for metric selection. If you choose Backward, the UI adds the histogram of the time spent on backward passes throughout the profiled time to the Dashboard. This type of histogram is useful for checking if there are outliers taking abnormally longer time and causing bottleneck problems.

The following screenshots show the GPU and CPU active time ratio and the average GPU and CPU utilization rate with respect to time per compute node.
The following screenshot shows an example of pie charts for comparing how many times the GPU kernels are launched and measuring the time spent on running them. In the **Time spent by all GPU kernels** and **Launch counts of all GPU kernels** panels, you can also specify an integer to the input field for $k$ to adjust the number of legend to show in the plots. For example, if you specify 10, the plots show the top 10 most run and launched kernels respectively.

The following screenshot shows an example of step time duration histogram, and pie charts for the kernel precision distribution, GPU activity distribution, and GPU memory operation distribution.
Timeline interface

To gain a detailed view into the compute resources at the level of operations and kernels scheduled on the CPUs and run on the GPUs, use the **Timeline** interface.

You can zoom in and out and pan left or right in the timeline interface using your mouse, the `[w, a, s, d]` keys, or the four arrow keys on the keyboard.

**Tip**
For more tips on the keyboard shortcuts to interact with the **Timeline** interface, choose **Keyboard shortcuts** in the left pane.

The timeline tracks are organized in a tree structure, giving you information from the host level to the device level. For example, if you run $N$ instances with eight GPUs in each, the timeline structure of each instance would be as follows.

- **algo-i_node** – This is what SageMaker tags to assign jobs to provisioned instances. The digit $i_{node}$ is randomly assigned. For example, if you use 4 instances, this section expands from **algo-1** to **algo-4**.
- **CPU** – In this section, you can check the average CPU utilization rate and performance counters.
- **GPUs** – In this section, you can check the average GPU utilization rate, individual GPU utilization rate, and kernels.
- **SUM Utilization** – The average GPU utilization rates per instance.
- **HOST-0 PID-123** – A unique name assigned to each process track. The acronym PID is the process ID, and the number appended to it is the process ID number that's recorded during data capture from the process. This section shows the following information from the process.
  - **GPU-i_{num_gpus} utilization** – The utilization rate of the $i_{num_gpus}$-th GPU over time.
  - **GPU-i_{num_gpus} device** – The kernel runs on the $i_{num_gpus}$-th GPU device.
    - **stream i_{cuda_stream}** – CUDA streams showing kernel runs on the GPU device. To learn more about CUDA streams, see the slides in PDF at [CUDA C/C++ Streams and Concurrency](https://docs.nvidia.com/cuda/cuda-c-plus-plus-programming-guide/index.html) provided by NVIDIA.
    - **GPU-i_{num_gpus} host** – The kernel launches on the $i_{num_gpus}$-th GPU host.

The following several screenshots show the **Timeline** of the profile of a training job run on ml.p4d.24xlarge instances, which are equipped with 8 NVIDIA A100 Tensor Core GPUs in each.
The following is a zoomed-out view of the profile, printing a dozen of steps including an intermittent data loader between step_232 and step_233 for fetching the next data batch.

For each CPU, you can track the CPU utilization and performance counters, such as "clk_unhalted_ref.tsc" and "itlb_misses.miss-causes-a.walk", which are indicative of instructions run on the CPU.

For each GPU, you can see a host timeline and a device timeline. Kernel launches are on the host timeline and kernel runs are on the device timeline. You can also see annotations (such as forward, backward, and optimize) if you have added in training script in the GPU host timeline.

In the timeline view, you can also track kernel launch-and-run pairs. This helps you understand how a kernel launch scheduled on a host (CPU) is run on the corresponding GPU device.

**Tip**
Press the f key to zoom into the selected kernel.

The following screenshot is a zoomed-in view into step_233 and step_234 from the previous screenshot. The timeline interval selected in the following screenshot is the AllReduce operation, an essential communication and synchronization step in distributed training, run on the GPU-0 device. In the screenshot, note that the kernel launch in the GPU-0 host connects to the kernel run in the GPU-0 device stream 1, indicated with the arrow in cyan color.
Also two information tabs appear in the bottom pane of the UI when you select a timeline interval, as shown in the previous screenshot. The **Current Selection** tab shows the details of the selected kernel and the connected kernel launch from the host. The connection direction is always from host (CPU) to device (GPU) since each GPU kernel is always called from a CPU. The **Connections** tab shows the chosen kernel launch and run pair. You can select either of them to move it to the center of the **Timeline** view.

The following screenshot zooms in further into the **AllReduce** operation launch and run pair.

### Information

In **Information**, you can access information about the loaded training job, such as the instance type, Amazon Resource Names (ARNs) of compute resources provisioned for the job, node names, and hyperparameters.
**Settings**

The SageMaker Profiler UI application instance is configured to shut down after 2 hours of idle time by default. In **Settings**, use the following settings to adjust the auto shutdown timer.

- **Enable app auto shutdown** – Choose and set to **Enabled** to let the application automatically shut down after the specified number of hours of idle time. To turn off the auto-shutdown functionality, choose **Disabled**.

- **Auto shutdown threshold in hours** – If you choose **Enabled** for **Enable app auto shutdown**, you can set the threshold time in hours for the application to shut down automatically. This is set to 2 by default.

**Considerations**

Consider the following when using SageMaker Profiler.

- SageMaker Profiler is not compatible with [SageMaker managed warm pools](https://aws.amazon.com/sagemaker/managed-warm-pools/).

**Monitor AWS compute resource utilization in Amazon SageMaker Studio**

To track compute resource utilization of your training job, use the monitoring tools offered by Amazon SageMaker Debugger.

For any training job you run in SageMaker using the SageMaker Python SDK, Debugger collects basic resource utilization metrics, such as CPU utilization, GPU utilization, GPU memory utilization, network, and I/O wait time every 500 milliseconds. To see the dashboard of the resource utilization metrics of your training job, simply use the [SageMaker Debugger UI in SageMaker Studio Experiments](https://aws.amazon.com/sagemaker/).  

Deep learning operations and steps might operate in intervals of milliseconds. Compared to Amazon CloudWatch metrics, which collect metrics at intervals of 1 second, Debugger provides finer granularity into the resource utilization metrics down to 100-millisecond (0.1 second) intervals so you can dive deep into the metrics at the level of an operation or a step.

If you want to change the metric collection time interval, you can add a paramter for profiling configuration to your training job launcher. For example, if you're using the SageMaker Python SDK, you need to pass the `profiler_config` parameter when you create an estimator object. To learn how to adjust the resource utilization metric collection interval, see the section called “[Code template for configuring a SageMaker estimator object with the SageMaker Debugger Python modules in the SageMaker Python SDK](https://docs.aws.amazon.com/sagemaker/latest/dg/aws-sagemaker-debugger.html)” (p. 2051) and then the section called “[Configure settings for basic profiling of system resource utilization](https://docs.aws.amazon.com/sagemaker/latest/dg/aws-sagemaker-debugger.html)” (p. 2055).

Additionally, you can add issue detecting tools called [built-in profiling rules](https://aws.amazon.com/sagemaker/controlled-profiling/) provided by SageMaker Debugger. The built-in profiling rules run analysis against the resource utilization metrics and detect computational performance issues. For more information, see the section called “[Configure built-in profiler rules](https://docs.aws.amazon.com/sagemaker/latest/dg/aws-sagemaker-debugger.html)” (p. 2060). You can receive rule analysis results through the [SageMaker Debugger UI in SageMaker Studio Experiments](https://aws.amazon.com/sagemaker/) or the [SageMaker Debugger Profiling Report](https://aws.amazon.com/sagemaker/). You can also create custom profiling rules using the SageMaker Python SDK.

To learn more about monitoring functionalities provided by SageMaker Debugger, see the following topics.

**Topics**

- [Configure an estimator with parameters for basic profiling using the Amazon SageMaker Debugger Python modules](https://docs.aws.amazon.com/sagemaker/latest/dg/aws-sagemaker-debugger.html) (p. 2051)
Configure an estimator with parameters for basic profiling using the Amazon SageMaker Debugger Python modules

By default, SageMaker Debugger basic profiling is on by default and monitors resource utilization metrics, such as CPU utilization, GPU utilization, GPU memory utilization, Network, and I/O wait time, of all SageMaker training jobs submitted using the Amazon SageMaker Python SDK. SageMaker Debugger collects these resource utilization metrics every 500 milliseconds. You don't need to make any additional changes in your code, training script, or the job launcher for tracking basic resource utilization. If you want to access the resource utilization metrics dashboard of your training job in SageMaker Studio, you can jump onto the Amazon SageMaker Debugger UI in Amazon SageMaker Studio Experiments.

If you want to change the metric collection interval for basic profiling, you can specify Debugger-specific parameters while creating a SageMaker training job launcher using the SageMaker Python SDK, AWS SDK for Python (Boto3), or AWS Command Line Interface (CLI). In this guide, we focus on how to change profiling options using the Amazon SageMaker Python SDK.

If you want to activate the rules that detect system resource utilization problems automatically, you can add the `rules` parameter in the estimator object for activating the rules.

**Important**
To use the latest SageMaker Debugger features, you need to upgrade the SageMaker Python SDK and the SMDebug client library. In your iPython kernel, Jupyter Notebook, or JupyterLab environment, run the following code to install the latest versions of the libraries and restart the kernel.

```python
import sys
import IPython
!{sys.executable} -m pip install -U sagemaker smdebug
IPython.Application.instance().kernel.do_shutdown(True)
```

**Code template for configuring a SageMaker estimator object with the SageMaker Debugger Python modules in the SageMaker Python SDK**

To adjust the basic profiling configuration (`profiler_config`) or add the profiler rules (`rules`), choose one of the tabs to get the template for setting up a SageMaker estimator. In the subsequent pages, you can find more information about how to configure the two parameters.

**Note**
The following code examples are not directly executable. Proceed to the next sections to learn how to configure each parameter.

**PyTorch**

```python
# An example of constructing a SageMaker PyTorch estimator
import boto3
import sagemaker
from sagemaker.pytorch import PyTorch
```
from sagemaker.debugger import ProfilerConfig, ProfilerRule, rule_configs

session=boto3.session.Session()
region=session.region_name

profiler_config=ProfilerConfig(...)
rules=[
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=PyTorch(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-profiling-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="1.12.0",
    py_version="py37",
    # SageMaker Debugger parameters
    profiler_config=profiler_config,
    rules=rules
)

estimator.fit(wait=False)

TensorFlow

# An example of constructing a SageMaker TensorFlow estimator
import boto3
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import ProfilerConfig, ProfilerRule, rule_configs

session=boto3.session.Session()
region=session.region_name

profiler_config=ProfilerConfig(...)
rules=[
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=TensorFlow(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-profiling-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="2.8.0",
    py_version="py37",
    # SageMaker Debugger parameters
    profiler_config=profiler_config,
    rules=rules
)

estimator.fit(wait=False)

MXNet

# An example of constructing a SageMaker MXNet estimator
import sagemaker
from sagemaker.mxnet import MXNet
from sagemaker.debugger import ProfilerConfig, ProfilerRule, rule_configs
```
profiler_config=ProfilerConfig(...)  
rules=[
        ProfilerRule.sagemaker(rule_configs.BuiltInRule())
    ]

estimator=MXNet(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-profiling-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="1.7.0",
    py_version="py37",

    # SageMaker Debugger parameters
    profiler_config=profiler_config,
    rules=rules
)

estimator.fit(wait=False)
```

**Note**

For MXNet, when configuring the `profiler_config` parameter, you can only configure for system monitoring. Profiling framework metrics is not supported for MXNet.

**XGBoost**

```
# An example of constructing a SageMaker XGBoost estimator
import sagemaker
from sagemaker.xgboost.estimator import XGBoost
from sagemaker.debugger import ProfilerConfig, ProfilerRule, rule_configs

profiler_config=ProfilerConfig(...)  
rules=[
        ProfilerRule.sagemaker(rule_configs.BuiltInRule())
    ]

estimator=XGBoost(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-profiling-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="1.5-1",

    # Debugger-specific parameters
    profiler_config=profiler_config,
    rules=rules
)

estimator.fit(wait=False)
```

**Note**

For XGBoost, when configuring the `profiler_config` parameter, you can only configure for system monitoring. Profiling framework metrics is not supported for XGBoost.

**Generic estimator**

```
# An example of constructing a SageMaker generic estimator using the XGBoost algorithm
base image
import boto3
import sagemaker
from sagemaker.estimator import Estimator
```

2053
from sagemaker import image_uris
from sagemaker.debugger import ProfilerConfig, DebuggerHookConfig, Rule, ProfilerRule, rule_configs

profiler_config=ProfilerConfig(...)  
rules=[
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

region=boto3.Session().region_name
xgboost_container=sagemaker.image_uris.retrieve("xgboost", region, "1.5-1")

estimator=Estimator(
    role=sagemaker.get_execution_role(),
    image_uri=xgboost_container,
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.m5.2xlarge",

    # Debugger-specific parameters
    profiler_config=profiler_config,
    rules=rules
)

estimator.fit(wait=False)

The following provides brief descriptions of the parameters.

- **profiler_config** – Configure Debugger to collect system metrics and framework metrics from your training job and save into your secured S3 bucket URI or local machine. You can set how frequently or loosely collect the system metrics. To learn how to configure the profiler_config parameter, see Configure settings for basic profiling of system resource utilization (p. 2055) and Configure for framework profiling (p. 2055).

- **rules** – Configure this parameter to activate SageMaker Debugger built-in rules that you want to run in parallel. Make sure that your training job has access to this S3 bucket. The rules runs on processing containers and automatically analyze your training job to find computational and operational performance issues. The ProfilerReport (p. 2063) rule is the most integrated rule that runs all built-in profiling rules and saves the profiling results as a report into your secured S3 bucket. To learn how to configure the rules parameter, see Configure built-in profiler rules managed by Amazon SageMaker Debugger (p. 2060).

**Note**

Debugger securely saves output data in subfolders of your default S3 bucket. For example, the format of the default S3 bucket URI is s3://sagemaker-<region>-<12digit_account_id>/<base-job-name>/<debugger-subfolders>/. There are three subfolders created by Debugger: debug-output, profiler-output, and rule-output. You can also retrieve the default S3 bucket URIs using the SageMaker estimator classmethods (p. 1949).

See the following topics to find out how to configure the Debugger-specific parameters in detail.

**Topics**

- Configure settings for basic profiling of system resource utilization (p. 2055)
- Configure for framework profiling (p. 2055)
- Updating Debugger system monitoring and framework profiling configuration while a training job is running (p. 2059)
- Turn off Debugger (p. 2059)
Configure settings for basic profiling of system resource utilization

To adjust the time interval for collecting the utilization metrics, use the ProfilerConfig API operation to create a parameter object while constructing a SageMaker framework or generic estimator depending on your preference.

**Note**
By default, for all SageMaker training jobs, Debugger collects resource utilization metrics from Amazon EC2 instances every 500 milliseconds for system monitoring, without any Debugger-specific parameters specified in SageMaker estimators. Debugger saves the system metrics in the default S3 bucket. The format of the default S3 bucket URI is s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/profiler-output/.

The following code example shows how to set up the profiler_config parameter with a system monitoring time interval of 1000 milliseconds.

```python
from sagemaker.debugger import ProfilerConfig

profiler_config=ProfilerConfig(
    system_monitor_interval_millis=1000
)
```

- **system_monitor_interval_millis** (int) – Specify the monitoring intervals in milliseconds to record system metrics. Available values are 100, 200, 500, 1000 (1 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds. The default value is 500 milliseconds.

To see the progress of system monitoring, see [Open the Amazon SageMaker Debugger Insights dashboard](p. 2074).

Configure for framework profiling

**Warning**
In favor of Amazon SageMaker Profiler (p. 2037), SageMaker Debugger deprecates the framework profiling feature starting from TensorFlow 2.11 and PyTorch 2.0. You can still use the feature in the previous versions of the frameworks and SDKs as follows.

- SageMaker Python SDK <= v2.130.0
- PyTorch >= v1.6.0, < v2.0
- TensorFlow >= v2.3.1, < v2.11

See also [March 16, 2023](p. 2035).

To enable Debugger framework profiling, configure the framework_profile_params parameter when you construct an estimator. Debugger framework profiling collects framework metrics, such as data from initialization stage, data loader processes, Python operators of deep learning frameworks and training scripts, detailed profiling within and between steps, with cProfile or Pyinstrument options. Using the FrameworkProfile class, you can configure custom framework profiling options.

**Note**
Before getting started with Debugger framework profiling, verify that the framework used to build your model is supported by Debugger for framework profiling. For more information, see [Supported Frameworks and Algorithms](p. 1917).

Debugger saves the framework metrics in a default S3 bucket. The format of the default S3 bucket URI is s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/profiler-output/.
Start a training job with the default framework profiling

The following example code is the simplest profiler_config parameter setting to start the default system monitoring and the default framework profiling. The FrameworkProfile class in the following example code initiates the default framework profiling when a training job starts. Debugger framework profiling includes the following options: detailed profiling, data loader profiling, and Python profiling.

```python
from sagemaker.debugger import ProfilerConfig, FrameworkProfile
profiler_config=ProfilerConfig(
    framework_profile_params=FrameworkProfile()
)
```

With this profiler_config parameter configuration, Debugger calls the default settings of monitoring and profiling. Debugger monitors system metrics every 500 milliseconds; profiles the fifth step with the detailed profiling option; the seventh step with the data loader profiling option; and the ninth, tenth, and eleventh steps with the Python profiling option.

To find available profiling configuration options, the default parameter settings, and examples of how to configure them, see Start a training job with the default system monitoring and customized framework profiling with different profiling options (p. 2057) and SageMaker Debugger APIs – FrameworkProfile in the Amazon SageMaker Python SDK.

If you want to change the system monitoring interval and enable the default framework profiling, you can specify the system_monitor_interval_millis parameter explicitly with the framework_profile_params parameter. For example, to monitor every 1000 milliseconds and enable the default framework profiling, use the following example code.

```python
from sagemaker.debugger import ProfilerConfig, FrameworkProfile
profiler_config=ProfilerConfig(
    system_monitor_interval_millis=1000,
    framework_profile_params=FrameworkProfile()
)
```

For more information about the FrameworkProfile class, see SageMaker Debugger APIs – FrameworkProfile in the Amazon SageMaker Python SDK.

Start a training job with the default system monitoring and customized framework profiling for target steps or a target time range

If you want to specify target steps or target time intervals to profile your training job, you need to specify parameters for the FrameworkProfile class. The following code examples show how to specify the target ranges for profiling along with system monitoring.

- **For a target step range**

  With the following example configuration, Debugger monitors the entire training job every 500 milliseconds (the default monitoring) and profiles a target step range from step 5 to step 15 (for 10 steps).

  ```python
  from sagemaker.debugger import ProfilerConfig, FrameworkProfile
  profiler_config=ProfilerConfig(
      framework_profile_params=FrameworkProfile(start_step=5, num_steps=10)
  )
  ```

  With the following example configuration, Debugger monitors the entire training job every 1000 milliseconds and profiles a target step range from step 5 to step 15 (for 10 steps).
Monitor AWS compute resource utilization in SageMaker Studio from sagemaker.debugger import ProfilerConfig, FrameworkProfile

from sagemaker.debugger import ProfilerConfig, FrameworkProfile
profiler_config=ProfilerConfig(
    system_monitor_interval_millis=1000,
    framework_profile_params=FrameworkProfile(start_step=5, num_steps=10)
)

• For a target time range

With the following example configuration, Debugger monitors the entire training job every 500 milliseconds (the default monitoring) and profiles a target time range from the current Unix time for 600 seconds.

import time
from sagemaker.debugger import ProfilerConfig, FrameworkProfile

profiler_config=ProfilerConfig(
    framework_profile_params=FrameworkProfile(start_unix_time=int(time.time()), duration=600)
)

With the following example configuration, Debugger monitors the entire training job every 1000 milliseconds and profiles a target time range from the current Unix time for 600 seconds.

import time
from sagemaker.debugger import ProfilerConfig, FrameworkProfile

profiler_config=ProfilerConfig(
    system_monitor_interval_millis=1000,
    framework_profile_params=FrameworkProfile(start_unix_time=int(time.time()), duration=600)
)

The framework profiling is performed for all of the profiling options at the target step or time range.

To find more information about available profiling options, see SageMaker Debugger APIs – FrameworkProfile in the Amazon SageMaker Python SDK.

The next section shows you how to script the available profiling options.

Start a training job with the default system monitoring and customized framework profiling with different profiling options

You can use the following profiling configuration classes to manage the framework profiling options:

• DetailedProfilingConfig – Specify a target step or time range to profile framework operations using the native framework profilers (TensorFlow profiler and PyTorch profiler). For example, if using TensorFlow, the Debugger hooks enable the TensorFlow profiler to collect TensorFlow-specific framework metrics. Detailed profiling enables you to profile all framework operators at a pre-step (before the first step), within steps, and between steps of a training job.

  **Note**
  Detailed profiling might significantly increase GPU memory consumption. We do not recommend enabling detailed profiling for more than a couple of steps.

• DataloaderProfilingConfig – Specify a target step or time range to profile deep learning framework data loader processes. Debugger collects every data loader event of the frameworks.
Note
Data loader profiling might lower the training performance while collecting information from
data loaders. We don't recommend enabling data loader profiling for more than a couple of
steps.
Debugger is preconfigured to annotate data loader processes only for the AWS deep learning
containers. Debugger cannot profile data loader processes from any other custom or external
training containers.

- **PythonProfilingConfig** – Specify a target step or time range to profile Python functions. You can also
  choose between two Python profilers: cProfile and Pyinstrument.

  - **cProfile** – The standard Python profiler. cProfile collects information for every Python operator
called during training. With cProfile, Debugger saves cumulative time and annotation for each
function call, providing complete detail about Python functions. In deep learning, for example, the
most frequently called functions might be the convolutional filters and backward pass operators,
and cProfile profiles every single of them. For the cProfile option, you can further select a timer
option: total time, CPU time, and off-CPU time. While you can profile every function call executing
on processors (both CPU and GPU) in CPU time, you can also identify I/O or network bottlenecks
with the off-CPU time option. The default is total time, and Debugger profiles both CPU and off-CPU
time. With cProfile, you are able to drill down to every single functions when analyzing the profile
data.

  - **Pyinstrument** – Pyinstrument is a low-overhead Python profiler that works based on sampling.
With the Pyinstrument option, Debugger samples profiling events every millisecond. Because
Pyinstrument measures elapsed wall-clock time instead of CPU time, the Pyinstrument option
 can be a better choice over the cProfile option for reducing profiling noise (filtering out irrelevant
function calls that are cumulatively fast) and capturing operators that are actually compute
intensive (cumulatively slow) for training your model. With Pyinstrument, you are able to see a tree
of function calls and better understand the structure and root cause of the slowness.

Note
Enabling Python profiling might slow down the overall training time. cProfile profiles the
most frequently called Python operators at every call, so the processing time on profiling
increases with respect to the number of calls. For Pyinstrument, the cumulative profiling time
increases with respect to time because of its sampling mechanism.

The following example configuration shows the full structure when you use the different profiling
options with specified values.

```python
import time
from sagemaker.debugger import (ProfilerConfig,
                                FrameworkProfile,
                                DetailedProfilingConfig,
                                DataloaderProfilingConfig,
                                PythonProfilingConfig,
                                PythonProfiler, cProfileTimer)

profiler_config=ProfilerConfig(
    system_monitor_interval_millis=500,
    framework_profile_params=FrameworkProfile(
        detailed_profiling_config=DetailedProfilingConfig(
            start_step=5,
            num_steps=1
        ),
        dataloader_profiling_config=DataloaderProfilingConfig(
            start_step=7,
            num_steps=1
        ),
        python_profiling_config=PythonProfilingConfig(
            start_step=9,
            num_steps=1,
```
Monitor AWS compute resource utilization in SageMaker Studio

```python
pythonProfiler=PythonProfiler.CPROFILE,
cprofile_timer=cProfileTimer.TOTAL_TIME
)
)
```

For more information about available profiling options, see `DetailedProfilingConfig`, `DataloaderProfilingConfig`, and `PythonProfilingConfig` in the Amazon SageMaker Python SDK.

### Updating Debugger system monitoring and framework profiling configuration while a training job is running

If you want to activate or update the Debugger monitoring configuration for a training job that is currently running, use the following SageMaker estimator extension methods:

- To activate Debugger system monitoring for a running training job and receive a Debugger profiling report, use the following:

  ```python
  estimator.enable_default_profiling()
  ```

  When you use the `enable_default_profiling` method, Debugger initiates the default system monitoring and the `ProfileReport` built-in rule, which generates a comprehensive profiling report at the end of the training job. This method can be called only if the current training job is running without both Debugger monitoring and profiling.

  For more information, see `estimator.enable_default_profiling` in the Amazon SageMaker Python SDK.

- To update system monitoring configuration, use the following:

  ```python
  estimator.update_profiler(
    system_monitor_interval_millis=500
  )
  ```

  For more information, see `estimator.update_profiler` in the Amazon SageMaker Python SDK.

### Turn off Debugger

If you want to completely turn off Debugger, do one of the following:

- Before starting a training job, do the following:

  To turn off profiling, include the `disable_profiler` parameter to your estimator and set it to `True`.

    **Warning**
    If you disable it, you won't be able to view the comprehensive Studio Debugger insights dashboard and the autogenerated profiling report.

  To turn off debugging, set the `debugger_hook_config` parameter to `False`.

    **Warning**
    If you disable it, you won't be able to collect output tensors and cannot debug your model parameters.

  ```python
  estimator=Estimator(
    ...
    disable_profiler=True
    debugger_hook_config=False
  )
  ```
For more information about the Debugger-specific parameters, see SageMaker Estimator in the Amazon SageMaker Python SDK.

- While a training job is running, do the following:

  To disable both monitoring and profiling while your training job is running, use the following estimator classmethod:

  ```python
  estimator.disable_profiling()
  ```

  To disable framework profiling only and keep system monitoring, use the `update_profiler` method:

  ```python
  estimator.update_profiler(disable_framework_metrics=true)
  ```

  For more information about the estimator extension methods, see the `estimator.disable_profiling` and `estimator.update_profiler` classmethods in the Amazon SageMaker Python SDK documentation.

### Configure built-in profiler rules managed by Amazon SageMaker Debugger

The Amazon SageMaker Debugger built-in profiler rules analyze system metrics and framework operations collected during the training of a model. Debugger offers the `ProfilerRule` API operation that helps configure the rules to monitor training compute resources and operations and to detect anomalies. For example, the profiling rules can help you detect whether there are computational problems such as CPU bottlenecks, excessive I/O wait time, imbalanced workload across GPU workers, and compute resource underutilization. To see a full list of available built-in profiling rules, see [List of Debugger built-in profiler rules](#).

**Note**

The built-in rules are provided through Amazon SageMaker processing containers and fully managed by SageMaker Debugger at no additional cost. For more information about billing, see the [Amazon SageMaker Pricing](#) page.

In the following topics, learn how to use the Debugger built-in rules.

**Topics**

- [Use SageMaker Debugger built-in profiler rules with their default parameter settings](#)
- [Use Debugger built-in profiler rules with custom parameter values](#)

### Use SageMaker Debugger built-in profiler rules with their default parameter settings

To add SageMaker Debugger built-in rules in your estimator, you need to configure a `rules` list object. The following example code shows the basic structure of listing the SageMaker Debugger built-in rules.

```python
from sagemaker.debugger import Rule, ProfilerRule, rule_configs
rules=[
    ProfilerRule.sagemaker(rule_configs.BuiltInProfilerRuleName_1()),
    ProfilerRule.sagemaker(rule_configs.BuiltInProfilerRuleName_2()),
    ...
    ProfilerRule.sagemaker(rule_configs.BuiltInProfilerRuleName_n()),
    ... # You can also append more debugging rules in the Rule.sagemaker(rule_configs.*()) format.
]
```
Monitor AWS compute resource utilization in SageMaker Studio

```python
estimator=Estimator(
    ...
    rules=rules
)
```

For a complete list of available built-in rules, see List of Debugger built-in profiler rules (p. 2062).

To use the profiling rules and inspect the computational performance and progress of your training job, add the `ProfilerReport` rule of SageMaker Debugger. This rule activates all built-in rules under the Debugger ProfilerRule ProfilerRule family. Furthermore, this rule generates an aggregated profiling report. For more information, see Profiling Report Generated Using SageMaker Debugger. You can use the following code to add the profiling report rule to your training estimator.

```python
from sagemaker.debugger import Rule, rule_configs

rules=[
    ProfilerRule.sagemaker(rule_configs.ProfilerReport())
]
```

When you start the training job with the `ProfilerReport` rule, Debugger collects resource utilization data every 500 milliseconds. Debugger analyzes the resource utilization to identify if your model is having bottleneck problems. If the rules detect training anomalies, the rule evaluation status changes to `IssueFound`. You can set up automated actions, such as notifying training issues and stopping training jobs using Amazon CloudWatch Events and AWS Lambda. For more information, see Action on Amazon SageMaker Debugger Rules (p. 1964).

**Use Debugger built-in profiler rules with custom parameter values**

If you want to adjust the built-in rule parameter values and customize tensor collection regex, configure the `base_config` and `rule_parameters` parameters for the `ProfilerRule.sagemaker` and `Rule.sagemaker` class methods. In case of the `Rule.sagemaker` class methods, you can also customize tensor collections through the `collections_to_save` parameter. For instruction on how to use the `CollectionConfig` class, see Configure Tensor Collections Using the `CollectionConfig API` (p. 1939).

Use the following configuration template for built-in rules to customize parameter values. By changing the rule parameters as you want, you can adjust the sensitivity of the rules to be initiated.

- The `base_config` argument is where you call the built-in rule methods.
- The `rule_parameters` argument is to adjust the default key values of the built-in rules listed in List of Debugger built-in profiler rules (p. 2062).

For more information about the Debugger rule class, methods, and parameters, see SageMaker Debugger Rule class in the Amazon SageMaker Python SDK.

```python
from sagemaker.debugger import Rule, ProfilerRule, rule_configs, CollectionConfig

rules=[
    ProfilerRule.sagemaker(
        base_config=rule_configs.BuiltinProfilerRuleName(),
        rule_parameters={
            "key": "value"
        }
    )
]
```

The parameter descriptions and value customization examples are provided for each rule at List of Debugger built-in profiler rules (p. 2062).
For a low-level JSON configuration of the Debugger built-in rules using the CreateTrainingJob API, see Configure Debugger Using Amazon SageMaker API (p. 2014).

**List of Debugger built-in profiler rules**

Use the Debugger built-in profiler rules provided by Amazon SageMaker Debugger and analyze metrics collected while training your models. The Debugger built-in rules monitor various common conditions that are critical for the success of running a performant training job. You can call the built-in profiler rules using Amazon SageMaker Python SDK or the low-level SageMaker API operations. There's no additional cost for using the built-in rules. For more information about billing, see the Amazon SageMaker Pricing page.

**Note**
The maximum numbers of built-in profiler rules that you can attach to a training job is 20. SageMaker Debugger fully manages the built-in rules and analyzes your training job synchronously.

**Important**
To use the new Debugger features, you need to upgrade the SageMaker Python SDK and the SMDebug client library. In your iPython kernel, Jupyter notebook, or JupyterLab environment, run the following code to install the latest versions of the libraries and restart the kernel.

```python
import sys
import IPython
!{sys.executable} -m pip install -U sagemaker smdebug
IPython.Application.instance().kernel.do_shutdown(True)
```

**Profiler rules**

The following rules are the Debugger built-in rules that are callable using the ProfilerRule.sagemaker classmethod.

### Debugger built-in rule for generating the profiling report

<table>
<thead>
<tr>

</tbody>
</table>
Monitor AWS compute resource utilization in SageMaker Studio

### Scope of Validity

#### Built-in Rules

- **OverallFrameworkMetrics** (p. 2072)
- **StepOutlier** (p. 2072)

### Warning

In favor of *Amazon SageMaker Profiler* (p. 2037), SageMaker Debugger deprecates the framework profiling feature starting from TensorFlow 2.11 and PyTorch 2.0. You can still use the feature in the previous versions of the frameworks and SDKs as follows.

- SageMaker Python SDK <= v2.130.0
- PyTorch >= v1.6.0, < v2.0
- TensorFlow >= v2.3.1, < v2.11

See also *March 16, 2023* (p. 2035).

**To use the built-in rules with default parameter values** – use the following configuration format:

```python
from sagemaker.debugger import Rule, ProfilerRule, rule_configs
rules = [
    ProfilerRule.sagemaker(rule_configs.BuiltInRuleName_1()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRuleName_2()),
    ...
    ProfilerRule.sagemaker(rule_configs.BuiltInRuleName_n())
]
```

**To use the built-in rules with customizing the parameter values** – use the following configuration format:

```python
from sagemaker.debugger import Rule, ProfilerRule, rule_configs
rules = [
    ProfilerRule.sagemaker(
        base_config=rule_configs.BuiltInRuleName(),
        rule_parameters={
            "key": "value"
        }
    )
]
```

To find available keys for the `rule_parameters` parameter, see the parameter description tables.

Sample rule configuration codes are provided for each built-in rule below the parameter description tables.

- For a full instruction and examples of using the Debugger built-in rules, see *Debugger Built-in Rules Example Code* (p. 1947).
- For a full instruction on using the built-in rules with the low-level SageMaker API operations, see *Configure Debugger Using Amazon SageMaker API* (p. 2014).

### ProfilerReport

The ProfilerReport rule invokes all of the built-in rules for monitoring and profiling. It creates a profiling report and updates when the individual rules are triggered. You can download a comprehensive profiling report while a training job is running or after the training job is complete. You can adjust the rule
parameter values to customize sensitivity of the built-in monitoring and profiling rules. The following example code shows the basic format to adjust the built-in rule parameters through the ProfilerReport rule.

```python
rules=[
    ProfilerRule.sagemaker(
        rule_configs.ProfilerReport(
            <BuiltInRuleName>_<parameter_name> = value
        )
    )
]
```

If you trigger this ProfilerReport rule without any customized parameter as shown in the following example code, then the ProfilerReport rule triggers all of the built-in rules for monitoring and profiling with their default parameter values.

```python
rules=[ProfilerRule.sagemaker(rule_configs.ProfilerReport())]
```

The following example code shows how to specify and adjust the CPUBottleneck rule's cpu_threshold parameter and the IOBottleneck rule's threshold parameter.

```python
rules=[
    ProfilerRule.sagemaker(
        rule_configs.ProfilerReport(
            CPUBottleneck_cpu_threshold = 90,
            IOBottleneck_threshold = 90
        )
    )
]
```

To explore what's in the profiler report, see SageMaker Debugger Profiling Report. Also, because this rule activates all of the profiling rules, you can also check the rule analysis status using the SageMaker Debugger UI in SageMaker Studio Experiments.

**Parameter Descriptions for the OverallSystemUsage Rule**

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</td>
</tr>
<tr>
<td></td>
<td><strong>Required</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: String</td>
</tr>
<tr>
<td>&lt;BuiltInRuleName&gt;_&lt;parameter_name&gt;</td>
<td>Customizable parameter to adjust thresholds of other built-in monitoring and profiling rules.</td>
</tr>
<tr>
<td></td>
<td>Default value: None</td>
</tr>
</tbody>
</table>

**BatchSize**

The BatchSize rule helps detect if GPU is underutilized due to a small batch size. To detect this issue, this rule monitors the average CPU utilization, GPU utilization, and GPU memory utilization. If utilization on
CPU, GPU, and GPU memory is low on average, it may indicate that the training job can either run on a smaller instance type or can run with a bigger batch size. This analysis does not work for frameworks that heavily overallocate memory. However, increasing the batch size can lead to processing or data loading bottlenecks because more data preprocessing time is required in each iteration.

## Parameter Descriptions for the BatchSize Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>

**LowGPUUtilization**

The LowGPUUtilization rule helps detect if GPU utilization is low or suffers from fluctuations. This is checked for each GPU on each worker. Rule returns True if 95th quantile is below \( \text{threshold}_p95 \) which indicates underutilization. Rule returns true if 95th quantile is above \( \text{threshold}_p95 \) and 5th quantile is below \( \text{threshold}_p5 \) which indicates fluctuations.

**Parameter Descriptions for the LowGPUUtilization Rule**

Amazon SageMaker Debugger UI in Amazon SageMaker Studio Experiments

Use the Amazon SageMaker Debugger Insights dashboard in Amazon SageMaker Studio Experiments to analyze your model performance and system bottlenecks while running training jobs on Amazon Elastic Compute Cloud (Amazon EC2) instances. Gain insights into your training jobs and improve your model training performance and accuracy with the Debugger dashboards. By default, Debugger monitors system metrics (CPU, GPU, GPU memory, network, and data I/O) every 500 milliseconds and basic
output tensors (loss and accuracy) every 500 iterations for training jobs. You can also further customize Debugger configuration parameter values and adjust the saving intervals through the Studio UI or using the Amazon SageMaker Python SDK.

Important
If you're using an existing Studio app, delete the app and restart to use the latest Studio features. For instructions on how to restart and update your Studio environment, see Update Amazon SageMaker Studio.

Topics
• Open the Amazon SageMaker Debugger Insights dashboard (p. 2074)
• Amazon SageMaker Debugger Insights dashboard controller (p. 2075)
• Explore the Amazon SageMaker Debugger Insights dashboard (p. 2076)
• Shut down the Amazon SageMaker Debugger Insights instance (p. 2081)

Open the Amazon SageMaker Debugger Insights dashboard

In the SageMaker Debugger Insights dashboard in Studio, you can see the compute resource utilization, resource utilization, and system bottleneck information of your training job that runs on Amazon EC2 instances in real time and after trainings

Note
The SageMaker Debugger Insights dashboard runs a Studio application on an ml.m5.4xlarge instance to process and render the visualizations. Each SageMaker Debugger Insights tab runs one Studio kernel session. Multiple kernel sessions for multiple SageMaker Debugger Insights tabs run on the single instance. When you close a SageMaker Debugger Insights tab, the corresponding kernel session is also closed. The Studio application remains active and accrues charges for the ml.m5.4xlarge instance usage. For information about pricing, see the Amazon SageMaker Pricing page.

Important
When you are done using the SageMaker Debugger Insights dashboard, you must shut down the ml.m5.4xlarge instance to avoid accruing charges. For instructions on how to shut down the instance, see Shut down the Amazon SageMaker Debugger Insights instance (p. 2081).

To open the SageMaker Debugger Insights dashboard

1. On the Studio Home page, choose Experiments in the left navigation pane.
2. Search your training job in the Experiments page. If your training job is set up with an Experiments run, the job should appear in the Experiments tab; if you didn't set up an Experiments run, the job should appear in the Unassigned runs tab.
3. Choose (click) the link of the training job name to see the job details.
4. Under the OVERVIEW menu, choose Debugger. This should show the following two sections.
   • In the Debugger rules section, you can browse the status of the Debugger built-in rules associated with the training job.
   • In the Debugger insights section, you can find links to open SageMaker Debugger Insights on the dashboard.
5. In the SageMaker Debugger Insights section, choose the link of the training job name to open the SageMaker Debugger Insights dashboard. This opens a Debug [your-training-job-name] window. In this window, Debugger provides an overview of the computational performance of your training job on Amazon EC2 instances and helps you identify issues in compute resource utilization.

You can also download an aggregated profiling report by adding the built-in ProfilerReport rule of SageMaker Debugger. For more information, see Configure Built-in Profiler Rules and Profiling Report Generated Using SageMaker Debugger.
Amazon SageMaker Debugger Insights dashboard controller

There are different components of the Debugger controller for monitoring and profiling. In this guide, you learn about the Debugger controller components.

**Note**
The SageMaker Debugger Insights dashboard runs a Studio app on an ml.m5.4xlarge instance to process and render the visualizations. Each SageMaker Debugger Insights tab runs one Studio kernel session. Multiple kernel sessions for multiple SageMaker Debugger Insights tabs run on the single instance. When you close a SageMaker Debugger Insights tab, the corresponding kernel session is also closed. The Studio app remains active and accrues charges for the ml.m5.4xlarge instance usage. For information about pricing, see the Amazon SageMaker Pricing page.

**Important**
When you are done using the SageMaker Debugger Insights dashboard, shut down the ml.m5.4xlarge instance to avoid accruing charges. For instructions on how to shut down the instance, see Shut down the Amazon SageMaker Debugger Insights instance (p. 2081).

SageMaker Debugger Insights controller UI

Using the Debugger controller located at the upper-left corner of the Insights dashboard, you can refresh the dashboard, configure or update Debugger settings for monitoring system metrics, stop a training job, and download a Debugger profiling report.

- If you want to manually refresh the dashboard, choose the refresh button (the round arrow at the upper-left corner) as shown in the preceding screenshot.
- The Monitoring toggle button is on by default for any SageMaker training job initiated using the SageMaker Python SDK. If not activated, you can use the toggle button to start monitoring. During monitoring, Debugger only collects resource utilization metrics to detect computational problems such as CPU bottlenecks and GPU underutilization. For a complete list of resource utilization problems that Debugger monitors, see Debugger built-in rules for profiling hardware system resource utilization (system metrics) (p. 2062).
- The Configure monitoring button opens a pop-up window that you can use to set or update the data collection frequency and the S3 path to save the data.
You can specify values for the following fields.

- **S3 bucket URI**: Specify the base S3 bucket URI.

- **Collect monitoring data every**: Select a time interval to collect system metrics. You can choose one of the monitoring intervals from the dropdown list. Available intervals are 100 milliseconds, 200 milliseconds, 500 milliseconds (default), 1 second, 5 seconds, and 1 minute.

  **Note**  
  If you choose one of the lower time intervals, you increase the granularity of resource utilization metrics, so you can capture spikes and anomalies with a higher time resolution. However, higher the resolution, larger the size of system metrics to process. This might introduce additional overhead and impact the overall training and processing time.

- Using the **Stop training** button, you can stop the training job when you find anomalies in resource utilization.

- Using the **Download report** button, you can download an aggregated profiling report by using the built-in `ProfilerReport` rule of SageMaker Debugger. The button is activated when you add the built-in `ProfilerReport` rule to the estimator. For more information, see Configure Built-in Profiler Rules and Profiling Report Generated Using SageMaker Debugger.

**Explore the Amazon SageMaker Debugger Insights dashboard**

When you initiate a SageMaker training job, SageMaker Debugger starts monitoring the resource utilization of the Amazon EC2 instances by default. You can track the system utilization rates, statistics overview, and built-in rule analysis through the Insights dashboard. This guide walks you through the content of the SageMaker Debugger Insights dashboard under the following tabs: System Metrics and Rules.

  **Note**  
  The SageMaker Debugger Insights dashboard runs a Studio application on an ml.m5.4xlarge instance to process and render the visualizations. Each SageMaker Debugger Insights tab
runs one Studio kernel session. Multiple kernel sessions for multiple SageMaker Debugger Insights tabs run on the single instance. When you close a SageMaker Debugger Insights tab, the corresponding kernel session is also closed. The Studio application remains active and accrues charges for the ml.m5.4xlarge instance usage. For information about pricing, see the Amazon SageMaker Pricing page.

Important
When you are done using the SageMaker Debugger Insights dashboard, shut down the ml.m5.4xlarge instance to avoid accruing charges. For instructions on how to shut down the instance, see Shut down the Amazon SageMaker Debugger Insights instance (p. 2081).

Important
In the reports, plots and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

Topics
- System metrics (p. 2077)
- Rules (p. 2080)

System metrics
In the System Metrics tab, you can use the summary table and timeseries plots to understand resource utilization.

Resource utilization summary
This summary table shows the statistics of compute resource utilization metrics of all nodes (denoted as algo-n). The resource utilization metrics include the total CPU utilization, the total GPU utilization, the total CPU memory utilization, the total GPU memory utilization, the total I/O wait time, and the total network in bytes. The table shows the minimum and the maximum values, and p99, p90, and p50 percentiles.

Resource utilization time series plots
Use the time series graphs to see more details of resource utilization and identify at what time interval each instance shows any undesired utilization rate, such as low GPU utilization and CPU bottlenecks that can cause a waste of the expensive instance.
The time series graph controller UI

The following screenshot shows the UI controller for adjusting the time series graphs.

- **algo-1**: Use this dropdown menu to choose the node that you want to look into.
- **Zoom In**: Use this button to zoom in the time series graphs and view shorter time intervals.
- **Zoom Out**: Use this button to zoom out the time series graphs and view wider time intervals.
- **Pan Left**: Move the time series graphs to an earlier time interval.
- **Pan Right**: Move the time series graphs to a later time interval.
- **Fix Timeframe**: Use this check box to fix or bring back the time series graphs to show the whole view from the first data point to the last data point.

CPU utilization and I/O wait time

The first two graphs show CPU utilization and I/O wait time over time. By default, the graphs show the average of CPU utilization rate and I/O wait time spent on the CPU cores. You can select one or more CPU cores by selecting the labels to graph them on single chart and compare utilization across cores. You can drag and zoom in and out to have a closer look at specific time intervals.

GPU utilization and GPU memory utilization

The following graphs show GPU utilization and GPU memory utilization over time. By default, the graphs show the mean utilization rate over time. You can select the GPU core labels to see the utilization rate of each core. Taking the mean of utilization rate over the total number of GPU cores shows the mean utilization of the entire hardware system resource. By looking at the mean utilization rate, you can check the overall system resource usage of an Amazon EC2 instance. The following figure shows an example.
training job on an `ml.p3.16xlarge` instance with 8 GPU cores. You can monitor if the training job is well distributed, fully utilizing all GPUs.

Overall system utilization over time

The following heatmap shows an example of the entire system utilization of an `ml.p3.16xlarge` instance over time, projected onto the two-dimensional plot. Every CPU and GPU core is listed in the vertical axis, and the utilization is recorded over time with a color scheme, where the bright colors represent low utilization and the darker colors represent high utilization. See the labeled color bar on the right side of the plot to find out which color level corresponds to which utilization rate.
Rules

Use the Rules tab to find a summary of the profiling rule analysis on your training job. If the profiling rule is activated with the training job, the text appears highlighted with the solid white text. Inactive rules are dimmed in gray text. To activate these rules, follow instructions at the section called “Configure built-in profiler rules” (p. 2060).
Shut down the Amazon SageMaker Debugger Insights instance

When you are not using the SageMaker Debugger Insights dashboard, you should shut down the app instance to avoid incurring additional fees.

To shut down the SageMaker Debugger Insights app instance in Studio

2081
1. In Studio, select the **Running Instances and Kernels** icon ( ).

2. Under the **RUNNING APPS** list, look for the **sagemaker-debugger-1.0** app. Select the shutdown icon ( ) next to the app. The SageMaker Debugger Insights dashboards run on an ml.m5.4xlarge instance. This instance also disappears from the **RUNNING INSTANCES** when you shut down the **sagemaker-debugger-1.0** app.

**SageMaker Debugger interactive report**

Receive profiling reports autogenerated by Debugger. The Debugger report provide insights into your training jobs and suggest recommendations to improve your model performance. The following screenshot shows a collage of the Debugger profiling report. To learn more, see [SageMaker Debugger profiling report](p. 2082).

**Note**

You can download a Debugger reports while your training job is running or after the job has finished. During training, Debugger concurrently updates the report reflecting the current rules' evaluation status. You can download a complete Debugger report only after the training job has completed.

**Important**

In the reports, plots and and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

**SageMaker Debugger profiling report**

For any SageMaker training jobs, the SageMaker Debugger [ProfilerReport](p. 2063) rule invokes all of the [monitoring and profiling rules](p. 2062) and aggregates the rule analysis into a comprehensive report. Following this guide, download the report using the [Amazon SageMaker Python SDK](https://aws.amazon.com/sagemaker/) or the S3 console, and learn what you can interpret from the profiling results.
Important
In the report, plots and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

Download the SageMaker Debugger profiling report

Download the SageMaker Debugger profiling report while your training job is running or after the job has finished using the Amazon SageMaker Python SDK and AWS Command Line Interface (CLI).

Note
To get the profiling report generated by SageMaker Debugger, you must use the built-in ProfilerReport rule offered by SageMaker Debugger. To activate the rule with your training job, see Configure Built-in Profiler Rules.

Tip
You can also download the report with a single click in the SageMaker Studio Debugger insights dashboard. This doesn't require any additional scripting to download the report. To find out how to download the report from Studio, see Open the Amazon SageMaker Debugger Insights dashboard (p. 2074).

Download using SageMaker Python SDK and AWS CLI

1. Check the current job's default S3 output base URI.

   ```python
   estimator.output_path
   ```

2. Check the current job name.

   ```python
   estimator.latest_training_job.job_name
   ```

3. The Debugger profiling report is stored under `<default-s3-output-base-uri>/ <training-job-name>/rule-output`. Configure the rule output path as follows:

   ```python
   rule_output_path = estimator.output_path + estimator.latest_training_job.job_name + "/rule-output"
   ```

4. To check if the report is generated, list directories and files recursively under the `rule_output_path` using `aws s3 ls` with the `--recursive` option.

   ```bash
   ! aws s3 ls {rule_output_path} --recursive
   ```

   This should return a complete list of files under an autogenerated folder that's named as ProfilerReport-1234567890. The folder name is a combination of strings: ProfilerReport and a unique 10-digit tag based on the Unix timestamp when the ProfilerReport rule is initiated.

The `profiler-report.html` is an autogenerated profiling report by Debugger. The remaining files are the built-in rule analysis components stored in JSON and a Jupyter notebook that are used to aggregate them into the report.

5. Download the files recursively using `aws s3 cp`. The following command saves all of the rule output files to the ProfilerReport-1234567890 folder under the current working directory.
Monitor AWS compute resource utilization in SageMaker Studio

```
! aws s3 cp {rule_output_path} ./ --recursive
```

**Tip**
If using a Jupyter notebook server, run `!pwd` to double check the current working directory.

6. Under the `/ProfilerReport-1234567890/profiler-output` directory, open `profiler-report.html`. If using JupyterLab, choose **Trust HTML** to see the autogenerated Debugger profiling report.

7. Open the `profiler-report.ipynb` file to explore how the report is generated. You can also customize and extend the profiling report using the Jupyter notebook file.

**Download using Amazon S3 Console**

1. Sign in to the AWS Management Console and open the Amazon S3 console at [https://console.aws.amazon.com/s3/](https://console.aws.amazon.com/s3/).

2. Search for the base S3 bucket. For example, if you haven't specified any base job name, the base S3 bucket name should be in the following format: `sagemaker-<region>-111122223333`. Look up the base S3 bucket through the **Find bucket by name** field.

3. In the base S3 bucket, look up the training job name by specifying your job name prefix into the **Find objects by prefix** input field. Choose the training job name.
4. In the training job's S3 bucket, there must be three subfolders for training data collected by Debugger: `debug-output/`, `profiler-output/`, and `rule-output/`. Choose `rule-output/`.

5. In the `rule-output/` folder, choose `ProfilerReport-1234567890`, and choose `profiler-output/` folder. The `profiler-output/` folder contains `profiler-report.html` (the autogenerated profiling report in html), `profiler-report.ipynb` (a Jupyter notebook with scripts that are used for generating the report), and a `profiler-report/` folder (contains rule analysis JSON files that are used as components of the report).

6. Select the `profiler-report.html` file, choose Actions, and Download.

7. Open the downloaded `profiler-report.html` file in a web browser.

Note
If you started your training job without configuring the Debugger-specific parameters, Debugger generates the report based only on the system monitoring rules because the Debugger parameters are not configured to save framework metrics. To enable framework metrics
profiling and receive an extended Debugger profiling report, configure the profiler_config parameter when constructing or updating SageMaker estimators.
To learn how to configure the profiler_config parameter before starting a training job, see Configure for framework profiling (p. 2055).
To update the current training job and enable framework metrics profiling, see Update Debugger Framework Profiling Configuration (p. 2059).

Debugger profiling report walkthrough
This section walks you through the Debugger profiling report section by section. The profiling report is generated based on the built-in rules for monitoring and profiling. The report shows result plots only for the rules that found issues.

Important
In the report, plots and and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

Topics
- Training job summary (p. 2086)
- System usage statistics (p. 2087)
- Framework metrics summary (p. 2088)
- Rules summary (p. 2089)
- Analyzing the training loop – step durations (p. 2090)
- GPU utilization analysis (p. 2090)
- Batch size (p. 2090)
- CPU bottlenecks (p. 2091)
- I/O bottlenecks (p. 2092)
- Load balancing in multi-GPU training (p. 2092)
- GPU memory analysis (p. 2092)

Training job summary
At the beginning of the report, Debugger provides a summary of your training job. In this section, you can overview the time durations and timestamps at different training phases.

Training job summary

The following table gives a summary about the training job. The table includes information about when the training job started and ended, how much time initialization, training loop and finalization took. Your training job started on 11/29/2020 at 23:12:42 and ran for 737 seconds.

<table>
<thead>
<tr>
<th></th>
<th>Job Statistics</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Start time 23:12:42 11/29/2020</td>
</tr>
<tr>
<td>1</td>
<td>End time 23:24:59 11/29/2020</td>
</tr>
<tr>
<td>2</td>
<td>Job duration 737 seconds</td>
</tr>
<tr>
<td>3</td>
<td>Training loop start 23:17:31 11/29/2020</td>
</tr>
<tr>
<td>4</td>
<td>Training loop end 23:24:59 11/29/2020</td>
</tr>
<tr>
<td>5</td>
<td>Training loop duration 448 seconds</td>
</tr>
<tr>
<td>6</td>
<td>Initialization time 288 seconds</td>
</tr>
<tr>
<td>7</td>
<td>Finalization time 0 seconds</td>
</tr>
<tr>
<td>8</td>
<td>Initialization 39 %</td>
</tr>
<tr>
<td>9</td>
<td>Training loop 60 %</td>
</tr>
<tr>
<td>10</td>
<td>Finalization 0 %</td>
</tr>
</tbody>
</table>
The summary table contains the following information:

- **start_time** – The exact time when the training job started.
- **end_time** – The exact time when the training job finished.
- **job_duration_in_seconds** – The total training time from the start_time to the end_time.
- **training_loop_start** – The exact time when the first step of the first epoch has started.
- **training_loop_end** – The exact time when the last step of the last epoch has finished.
- **training_loop_duration_in_seconds** – The total time between the training loop start time and the training loop end time.
- **initialization_in_seconds** – Time spent on initializing the training job. The initialization phase covers the period from the start_time to the training_loop_start time. The initialization time is spent on compiling the training script, starting the training script, creating and initializing the model, initiating EC2 instances, and downloading training data.
- **finalization_in_seconds** – Time spent on finalizing the training job, such as finishing the model training, updating the model artifacts, and closing the EC2 instances. The finalization phase covers the period from the training_loop_end time to the end_time.
- **initialization (%)** – The percentage of time spent on initialization over the total job_duration_in_seconds.
- **training loop (%)** – The percentage of time spent on training loop over the total job_duration_in_seconds.
- **finalization (%)** – The percentage of time spent on finalization over the total job_duration_in_seconds.

**System usage statistics**

In this section, you can see an overview of system utilization statistics.

**System usage statistics**

The 99th quantile of the total GPU utilization on node algo-2 is 74%. GPUs on node algo-2 are well utilized.

The following table shows usage statistics per worker node such as total CPU and GPU utilization, total CPU and memory footprint. The table also include total IO wait time and total sent/received bytes. The table shows min and max values as well as p99, p90 and p50 percentiles.

<table>
<thead>
<tr>

<td>3.778288125</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

The Debugger profiling report includes the following information:

- **node** – Lists the name of nodes. If using distributed training on multi nodes (multiple EC2 instances), the node names are in format of algo-n.
- **metric** – The system metrics collected by Debugger: CPU, GPU, CPU memory, GPU memory, I/O, and Network metrics.
- **unit** – The unit of the system metrics.
- **max** – The maximum value of each system metric.
- **p99** – The 99th percentile of each system utilization.
- **p95** – The 95th percentile of each system utilization.
- **p50** – The 50th percentile (median) of each system utilization.
- **min** – The minimum value of each system metric.

**Framework metrics summary**

In this section, the following pie charts show the breakdown of framework operations on CPUs and GPUs.

Each of the pie charts analyzes the collected framework metrics in various aspects as follows:

- **Ratio between TRAIN/EVAL phase and others** – Shows the ratio between time durations spent on different training phases.
- **Ratio between forward and backward pass** – Shows the ratio between time durations spent on forward and backward pass in the training loop.
- **Ratio between CPU/GPU operators** – Shows the ratio between time spent on operators running on CPU or GPU, such as convolutional operators.
- **General metrics recorded in framework** – Shows the ratio between time spent on major framework metrics, such as data loading, forward and backward pass.
Overview: CPU Operators

This section provides information of the CPU operators in detail. The table shows the percentage of the time and the absolute cumulative time spent on the most frequently called CPU operators.

<table>
<thead>
<tr>
<th>#</th>
<th>Percentage</th>

Rules summary

In this section, Debugger aggregates all of the rule evaluation results, analysis, rule descriptions, and suggestions.
Monitor AWS compute resource utilization in SageMaker Studio

Analyzing the training loop – step durations

In this section, you can find a detailed statistics of step durations on each GPU core of each node. Debugger evaluates mean, maximum, p99, p95, p50, and minimum values of step durations, and evaluate step outliers. The following histogram shows the step durations captured on different worker nodes and GPUs. You can enable or disable the histogram of each worker by choosing the legends on the right side. You can check if there is a particular GPU that’s causing step duration outliers.

GPU utilization analysis

This section shows the detailed statistics about GPU core utilization based on LowGPUUtilization rule. It also summarizes the GPU utilization statistics, mean, p95, and p5 to determine if the training job is underutilizing GPUs.

Batch size

This section shows the detailed statistics of total CPU utilization, individual GPU utilizations, and GPU memory footprints. The BatchSize rule determines if you need to change the batch size to better utilize
the GPUs. You can check whether the batch size is too small resulting in underutilization or too large causing overutilization and out of memory issues. In the plot, the boxes show the p25 and p75 percentile ranges (filled with dark purple and bright yellow respectively) from the median (p50), and the error bars show the 5th percentile for the lower bound and 95th percentile for the upper bound.

**CPU bottlenecks**

In this section, you can drill down into the CPU bottlenecks that the CPUBottleneck rule detected from your training job. The rule checks if the CPU utilization is above \( \text{cpu\_threshold} \) (90% by default) and also if the GPU utilization is below \( \text{gpu\_threshold} \) (10% by default).

The pie charts show the following information:

- **Low GPU usage caused by CPU bottlenecks** – Shows the ratio of data points between the ones with GPU utilization above and below the threshold and the ones that matches the CPU bottleneck criteria.
- **Ratio between TRAIN/EVAL phase and others** – Shows the ratio between time durations spent on different training phases.
- **Ratio between forward and backward pass** – Shows the ratio between time durations spent on forward and backward pass in the training loop.
- **Ratio between CPU/GPU operators** – Shows the ratio between time durations spent on GPUs and CPUs by Python operators, such as data loader processes and forward and backward pass operators.
- **General metrics recorded in framework** – Shows major framework metrics and the ratio between time durations spent on the metrics.

**I/O bottlenecks**

In this section, you can find a summary of I/O bottlenecks. The rule evaluates the I/O wait time and GPU utilization rates and monitors if the time spent on the I/O requests exceeds a threshold percent of the total training time. It might indicate I/O bottlenecks where GPUs are waiting for data to arrive from storage.

**Load balancing in multi-GPU training**

In this section, you can identify workload balancing issue across GPUs.

**GPU memory analysis**

In this section, you can analyze the GPU memory utilization collected by the GPUMemoryIncrease rule. In the plot, the boxes show the p25 and p75 percentile ranges (filled with dark purple and bright yellow respectively) from the median (p50), and the error bars show the 5th percentile for the lower bound and 95th percentile for the upper bound.
Analyze data using the Debugger Python client library

While your training job is running or after it has completed, you can access the training data collected by Debugger using the Amazon SageMaker Python SDK and the SMDebug client library. The Debugger Python client library provides analysis and visualization tools that enable you to drill down into your training job data.

To install the library and use its analysis tools (in a JupyterLab notebook or an iPython kernel)

```
! pip install -U smdebug
```

The following topics walk you through how to use the Debugger Python tools to visualize and analyze the training data collected by Debugger.

**Analyze system and framework metrics**

- Access the profile data (p. 2093)
- Plot the system metrics and framework metrics data (p. 2094)
- Access the profiling data using the pandas data parsing tool (p. 2096)
- Access the Python profiling stats data (p. 2096)
- Merge timelines of multiple profile trace files (p. 2098)
- Profiling data loaders (p. 2100)

**Access the profile data**

The SMDebug TrainingJob class reads data from the S3 bucket where the system and framework metrics are saved.

**To set up a TrainingJob object and retrieve profiling event files of a training job**

```python
from smdebug.profiler.analysis.notebook_utils.training_job import TrainingJob

tj = TrainingJob(training_job_name, region)
```

**Tip**

You need to specify the `training_job_name` and `region` parameters to log to a training job. There are two ways to specify the training job information:

- Use the SageMaker Python SDK while the estimator is still attached to the training job.
import sagemaker
training_job_name=estimator.latest_training_job.job_name
region=sagemaker.Session().boto_region_name

• Pass strings directly.

training_job_name="your-training-job-name-YYYY-MM-DD-HH-MM-SS-SSS"
region="us-west-2"

**Note**

By default, SageMaker Debugger collects system metrics to monitor hardware resource utilization and system bottlenecks. Running the following functions, you might receive error messages regarding unavailability of framework metrics. To retrieve framework profiling data and gain insights into framework operations, you must enable framework profiling.

• If you use SageMaker Python SDK to manipulate your training job request, pass the `framework_profile_params` to the `profiler_config` argument of your estimator. To learn more, see [Configure SageMaker Debugger Framework Profiling](#).
• If you use Studio, turn on profiling using the **Profiling** toggle button in the Debugger insights dashboard. To learn more, see [SageMaker Debugger Insights Dashboard Controller](#).

To retrieve a description of the training job description and the S3 bucket URI where the metric data are saved

tj.describe_training_job()
tj.get_config_and_profiler_s3_output_path()

To check if the system and framework metrics are available from the S3 URI

tj.wait_for_sys_profiling_data_to_be_available()
tj.wait_for_framework_profiling_data_to_be_available()

To create system and framework reader objects after the metric data become available

```
system_metrics_reader = tj.get_systems_metrics_reader()
framework_metrics_reader = tj.get_framework_metrics_reader()
```

To refresh and retrieve the latest training event files

The reader objects have an extended method, `refresh_event_file_list()`, to retrieve the latest training event files.

```
system_metrics_reader.refresh_event_file_list()
framework_metrics_reader.refresh_event_file_list()
```

**Plot the system metrics and framework metrics data**

You can use the system and algorithm metrics objects for the following visualization classes to plot timeline graphs and histograms.

**Note**

To visualize the data with narrowed-down metrics in the following visualization object plot methods, specify `select_dimensions` and `select_events` parameters. For example, if
you specify select_dimensions=["GPU"], the plot methods filter the metrics that include the "GPU" keyword. If you specify select_events=["total"], the plot methods filter the metrics that include the "total" event tags at the end of the metric names. If you enable these parameters and give the keyword strings, the visualization classes return the charts with filtered metrics.

• The MetricsHistogram class

```python
from smdebug.profiler.analysis.notebook_utils.metrics_histogram import MetricsHistogram
metrics_histogram = MetricsHistogram(system_metrics_reader)
metrics_histogram.plot(
    starttime=0,
    endtime=system_metrics_reader.get_timestamp_of_latest_available_file(),
    select_dimensions=["CPU", "GPU", "I/O"], # optional
    select_events=["total"]                         # optional
)
```

• The StepTimelineChart class

```python
from smdebug.profiler.analysis.notebook_utils.step_timeline_chart import StepTimelineChart
view_step_timeline_chart = StepTimelineChart(framework_metrics_reader)
```

• The StepHistogram class

```python
from smdebug.profiler.analysis.notebook_utils.step_histogram import StepHistogram
step_histogram = StepHistogram(framework_metrics_reader)
step_histogram.plot(
    starttime=step_histogram.last_timestamp - 5 * 1000 * 1000,
    endtime=step_histogram.last_timestamp,
    show_workers=True
)
```

• The TimelineCharts class

```python
from smdebug.profiler.analysis.notebook_utils.timeline_charts import TimelineCharts
view_timeline_charts = TimelineCharts(
    system_metrics_reader,
    framework_metrics_reader,
    select_dimensions=["CPU", "GPU", "I/O"], # optional
    select_events=["total"]                         # optional
)
view_timeline_charts.plot_detailed_profiler_data([700,710])
```

• The Heatmap class

```python
from smdebug.profiler.analysis.notebook_utils.heatmap import Heatmap
view_heatmap = Heatmap(
    system_metrics_reader,
    framework_metrics_reader,
    select_dimensions=["CPU", "GPU", "I/O"], # optional
    select_events=["total"],                         # optional
    plot_height=450
)```
Access the profiling data using the pandas data parsing tool

The following PandasFrame class provides tools to convert the collected profiling data to Pandas data frame.

```python
from smdebug.profiler.analysis.utils.profiler_data_to_pandas import PandasFrame

The PandasFrame class takes the tj object's S3 bucket output path, and its methods
get_all_system_metrics() get_all_framework_metrics() return system metrics and
framework metrics in the Pandas data format.

```pf = PandasFrame(tj.profiler_s3_output_path)
system_metrics_df = pf.get_all_system_metrics()
framework_metrics_df = pf.get_all_framework_metrics(
    selected_framework_metrics=[
        'Step:ModeKeys.TRAIN',
        'Step:ModeKeys.GLOBAL'
    ]
)
```

Access the Python profiling stats data

The Python profiling provides framework metrics related to Python functions and operators in your
training scripts and the SageMaker deep learning frameworks.

Training Modes and Phases for Python Profiling

To profile specific intervals during training to partition statistics for each of these intervals, Debugger
provides tools to set modes and phases.

For training modes, use the following PythonProfileModes class:

```python
from smdebug.profiler.python_profile_utils import PythonProfileModes

This class provides the following options:

- PythonProfileModes.TRAIN – Use if you want to profile the target steps in the training phase. This
  mode option available only for TensorFlow.
- PythonProfileModes.EVAL – Use if you want to profile the target steps in the evaluation phase.
  This mode option available only for TensorFlow.
- PythonProfileModes.PREDICT – Use if you want to profile the target steps in the prediction phase.
  This mode option available only for PyTorch.
- PythonProfileModes.GLOBAL – Use if you want to profile the target steps in the global phase,
  which includes the previous three phases. This mode option available only for PyTorch.
- PythonProfileModes.PRE_STEP_ZERO – Use if you want to profile the target steps in the
  initialization stage before the first training step of the first epoch starts. This phase includes the initial
  job submission, uploading the training scripts to EC2 instances, preparing the EC2 instances, and
  downloading input data. This mode option available for both TensorFlow and PyTorch.
- PythonProfileModes.POST_HOOK_CLOSE – Use if you want to profile the target steps in the
  finalization stage after the training job has done and the Debugger hook is closed. This phase includes
  profiling data while the training jobs are finalized and completed. This mode option available for both
  TensorFlow and PyTorch.

For training phases, use the following StepPhase class:
This class provides the following options:

- **StepPhase.START** – Use to specify the start point of the initialization phase.
- **StepPhase.STEP_START** – Use to specify the start step of the training phase.
- **StepPhase.FORWARD_PASS_END** – Use to specify the steps where the forward pass ends. This option is available only for PyTorch.
- **StepPhase.STEP_END** – Use to specify the end steps in the training phase. This option is available only for TensorFlow.
- **StepPhase.END** – Use to specify the ending point of the finalization (post-hook-close) phase. If the callback hook is not closed, the finalization phase profiling does not occur.

**Python Profiling Analysis Tools**

Debugger supports the Python profiling with two profiling tools:

- **cProfile** – The standard python profiler. cProfile collects framework metrics on CPU time for every function called when profiling was enabled.
- **Pyinstrument** – This is a low overhead Python profiler sampling profiling events every milliseconds.

To learn more about the Python profiling options and what's collected, see Start a training job with the default system monitoring and customized framework profiling with different profiling options (p. 2057).

The following methods of the PythonProfileAnalysis, cProfileAnalysis, PyinstrumentAnalysis classes are provided to fetch and analyze the Python profiling data. Each function loads the latest data from the default S3 URI.

```
from smdebug.profiler.analysis.python_profile_analysis import PythonProfileAnalysis, cProfileAnalysis, PyinstrumentAnalysis
```

To set Python profiling objects for analysis, use the cProfileAnalysis or PyinstrumentAnalysis classes as shown in the following example code. It shows how to set a cProfileAnalysis object, and if you want to use PyinstrumentAnalysis, replace the class name.

```
python_analysis = cProfileAnalysis(
    local_profile_dir=tf_python_stats_dir,
    s3_path=tj.profiler_s3_output_path
)
```

The following methods are available for the cProfileAnalysis and PyinstrumentAnalysis classes to fetch the Python profiling stats data:

- **python_analysis.fetch_python_profile_stats_by_time(start_time_since_epoch_in_secs, end_time_since_epoch_in_secs)** – Takes in a start time and end time, and returns the function stats of step stats whose start or end times overlap with the provided interval.
- **python_analysis.fetch_python_profile_stats_by_step(start_step, end_step, mode, start_phase, end_phase)** – Takes in a start step and end step and returns the function stats of all step stats whose profiled step satisfies start_step <= step < end_step.
- **start_step and end_step (str)** – Specify the start step and end step to fetch the Python profiling stats data.
Monitor AWS compute resource utilization in SageMaker Studio

- **mode (str)** – Specify the mode of training job using the PythonProfileModes enumerator class. The default is PythonProfileModes.TRAIN. Available options are provided in the Training Modes and Phases for Python Profiling (p. 2096) section.

- **start_phase (str)** – Specify the start phase in the target step(s) using the StepPhase enumerator class. This parameter enables profiling between different phases of training. The default is StepPhase.STEP_START. Available options are provided in the Training Modes and Phases for Python Profiling (p. 2096) section.

- **end_phase (str)** – Specify the end phase in the target step(s) using the StepPhase enumerator class. This parameter sets up the end phase of training. Available options are as same as the ones for the start_phase parameter. The default is StepPhase.STEP_END. Available options are provided in the Training Modes and Phases for Python Profiling (p. 2096) section.

- **python_analysis.fetch_profile_stats_between_modes(start_mode, end_mode)** – Fetches stats from the Python profiling between the start and end modes.

- **python_analysis.fetch_pre_step_zero_profile_stats()** – Fetches the stats from the Python profiling until step 0.

- **python_analysis.fetch_post_hook_close_profile_stats()** – Fetches stats from the Python profiling after the hook is closed.

- **python_analysis.list_profile_stats()** – Returns a DataFrame of the Python profiling stats.

- **python_analysis.list_available_node_ids()** – Returns a list the available node IDs for the Python profiling stats.

The cProfileAnalysis class specific methods:

- **fetch_profile_stats_by_training_phase()** – Fetches and aggregates the Python profiling stats for every possible combination of start and end modes. For example, if a training and validation phases are done while detailed profiling is enabled, the combinations are (PRE_STEP_ZERO, TRAIN), (TRAIN, TRAIN), (TRAIN, EVAL), (EVAL, EVAL), and (EVAL, POST_HOOK_CLOSE). All stats files within each of these combinations are aggregated.

- **fetch_profile_stats_by_job_phase()** – Fetches and aggregates the Python profiling stats by job phase. The job phases are initialization (profiling until step 0), training_loop (training and validation), and finalization (profiling after the hook is closed).

**Merge timelines of multiple profile trace files**

The SMDebug client library provide profiling analysis and visualization tools for merging timelines of system metrics, framework metrics, and Python profiling data collected by Debugger.

**Tip**

Before proceeding, you need to set a TrainingJob object that will be utilized throughout the examples in this page. For more information about setting up a TrainingJob object, see Access the profile data (p. 2093).

The MergedTimeline class provides tools to integrate and correlate different profiling information in a single timeline. After Debugger captures profiling data and annotations from different phases of a training job, JSON files of trace events are saved in a default tracefolder directory.

- For annotations in the Python layers, the trace files are saved in *pythontimeline.json.
- For annotations in the TensorFlow C++ layers, the trace files are saved in *model_timeline.json.
- Tensorflow profiler saves events in a *trace.json.gz file.
Tip
If you want to list all of the JSON trace files, use the following AWS CLI command:

```
! aws s3 ls {tj.profiler_s3_output_path} --recursive | grep '\.json$'
```

As shown in the following animated screenshot, putting and aligning the trace events captured from the different profiling sources in a single plot can provide an overview of the entire events occurring in different phases of the training job.

Tip
To interact with the merged timeline on the tracing app using a keyboard, use the W key for zooming in, the A key for shifting to the left, the S key for zooming out, and the D key for shifting to the right.

The multiple event trace JSON files can be merged into one trace event JSON file using the following MergedTimeline API operation and class method from the smdebug.profiler.analysis.utils.merge_timelines module.

```python
from smdebug.profiler.analysis.utils.merge_timelines import MergedTimeline

combined_timeline = MergedTimeline(path, file_suffix_filter, output_directory)
combined_timeline.merge_timeline(start, end, unit)
```

The MergedTimeline API operation passes the following parameters:

- **path** (str) – Specify a root folder ("/profiler-output") that contains system and framework profiling trace files. You can locate the profiler-output using the SageMaker estimator classmethod or the TrainingJob object. For example, estimator.latest_job_profiler_artifacts_path() or tj.profiler_s3_output_path.
- **file_suffix_filter** (list) – Specify a list of file suffix filters to merge timelines. Available suffix filters are ["model_timeline.json", "pythontimeline.json", "trace.json.gz"]. If this parameter is not manually specified, all of the trace files are merged by default.
Monitor AWS compute resource utilization in SageMaker Studio

- output_directory (str) – Specify a path to save the merged timeline JSON file. The default is to the directory specified for the path parameter.

The merge_timeline() classmethod passes the following parameters to execute the merging process:

- start (int) – Specify start time (in microseconds and in Unix time format) or start step to merge timelines.
- end (int) – Specify end time (in microseconds and in Unix time format) or end step to merge timelines.
- unit (str) – Choose between "time" and "step". The default is "time".

Using the following example codes, execute the merge_timeline() method and download the merged JSON file.

- Merge timeline with the "time" unit option. The following example code merges all available trace files between the Unix start time (the absolute zero Unix time) and the current Unix time, which means that you can merge the timelines for the entire training duration.

```python
import time
from smdebug.profiler.analysis.utils.merge_timelines import MergedTimeline
from smdebug.profiler.profiler_constants import CONVERT_TO_MICROSECS
combined_timeline = MergedTimeline(tj.profiler_s3_output_path, output_directory="/"
combined_timeline.merge_timeline(0, int(time.time() * CONVERT_TO_MICROSECS))
```

- Merge timeline with the "step" unit option. The following example code merges all available timelines between step 3 and step 9.

```python
from smdebug.profiler.analysis.utils.merge_timelines import MergedTimeline
combined_timeline = MergedTimeline(tj.profiler_s3_output_path, output_directory="/"
combined_timeline.merge_timeline(3, 9, unit="step")
```

Open the Chrome tracing app at chrome://tracing on a Chrome browser, and open the JSON file. You can explore the output to plot the merged timeline.

Profiling data loaders

In PyTorch, data loader iterators, such as SingleProcessingDataLoaderIter and MultiProcessingDataLoaderIter, are initiated at the beginning of every iteration over a dataset. During the initialization phase, PyTorch turns on worker processes depending on the configured number of workers, establishes data queue to fetch data and pin_memory threads.

To use the PyTorch data loader profiling analysis tool, import the following PT_dataloader_analysis class:

```python
from smdebug.profiler.analysis.utils.pytorch_dataloader_analysis import PT_dataloader_analysis
```

Pass the profiling data retrieved as a Pandas frame data object in the Access the profiling data using the pandas data parsing tool (p. 2096) section:

```python
pt_analysis = PT_dataloader_analysis(pf)
```

The following functions are available for the pt_analysis object:
The SMDebug S3SystemMetricsReader class reads the system metrics from the S3 bucket specified to the s3_trial_path parameter.

- `pt_analysis.analyze_dataloaderIter_initialization()`
  
  The analysis outputs the median and maximum duration for these initializations. If there are outliers, (i.e. duration is greater than 2 * median), the function prints the start and end times for those durations. These can be used to inspect system metrics during those time intervals.
  
  The following list shows what analysis is available from this class method:
  - Which type of data loader iterators were initialized.
  - The number of workers per iterator.
  - Inspect whether the iterator was initialized with or without pin_memory.
  - Number of times the iterators were initialized during training.

- `pt_analysis.analyze_dataloaderWorkers()`
  
  The following list shows what analysis is available from this class method:
  - The number of worker processes that were spun off during the entire training.
  - Median and maximum duration for the worker processes.
  - Start and end time for the worker processes that are outliers.

- `pt_analysis.analyze_dataloader_getnext()`
  
  The following list shows what analysis is available from this class method:
  - Number of GetNext calls made during the training.
  - Median and maximum duration in microseconds for GetNext calls.
  - Start time, End time, duration and worker id for the outlier GetNext call duration.

- `pt_analysis.analyze_batchtime(start_timestamp, end_timestamp, select_events=[".*"], select_dimensions=[".*"])`
  
  Debugger collects the start and end times of all the GetNext calls. You can find the amount of time spent by the training script on one batch of data. Within the specified time window, you can identify the calls that are not directly contributing to the training. These calls can be from the following operations: computing the accuracy, adding the losses for debugging or logging purposes, and printing the debugging information. Operations like these can be compute intensive or time consuming. We can identify such operations by correlating the Python profiler, system metrics, and framework metrics.
  
  The following list shows what analysis is available from this class method:
  - Profile time spent on each data batch, BatchTime_in_seconds, by finding the difference between start times of current and subsequent GetNext calls.
  - Find the outliers in BatchTime_in_seconds and start and end time for those outliers.
  - Obtain the system and framework metrics during those BatchTime_in_seconds timestamps. This indicates where the time was spent.

- `pt_analysis.plot_the_window()`
  
  Plots a timeline charts between a start timestamp and the end timestamp.

---

Release notes for profiling capabilities of Amazon SageMaker

See the following release notes to track the latest updates for profiling capabilities of Amazon SageMaker.
August 24, 2023

New features

Released Amazon SageMaker Profiler, a profiling and visualization capability of SageMaker to deep dive into compute resources provisioned while training deep learning models and gain visibility into operation-level details. SageMaker Profiler provides Python modules for adding annotations throughout PyTorch or TensorFlow training scripts and activating SageMaker Profiler. You can access the modules through the SageMaker Python SDK and AWS Deep Learning Containers. For any jobs run with the SageMaker Profiler Python modules, you can load the profile data in the SageMaker Profiler UI application that provides a summary dashboard and a detailed timeline. To learn more, see Use Amazon SageMaker Profiler to profile activities on AWS compute resources (p. 2037).

Distributed training in Amazon SageMaker

SageMaker provides distributed training libraries and supports various distributed training options for deep learning tasks such as computer vision (CV) and natural language processing (NLP). With SageMaker’s distributed training libraries, you can run highly scalable and cost-effective custom data parallel and model parallel deep learning training jobs. You can also use other distributed training frameworks and packages such as PyTorch DistributedDataParallel (DDP), torchrun, MPI (mpirun), and parameter server. Throughout the documentation, instructions and examples focus on how to set up the distributed training options for deep learning tasks using the SageMaker Python SDK.

Tip
To learn best practices for distributed computing of machine learning (ML) training and processing jobs in general, see Distributed computing with SageMaker best practices (p. 2225).

Before you get started

SageMaker Training supports distributed training on a single instance as well as multiple instances, so you can run any size of training at scale. We recommend you to use the framework estimator classes such as PyTorch and TensorFlow in the SageMaker Python SDK, which are the training job launchers with various distributed training options. When you create an estimator object, the object sets up distributed training infrastructure, runs the CreateTrainingJob API in the backend, finds the Region where your current sessions is running, and pulls one of the pre-built AWS deep learning container prepackaged with a number of libraries including deep learning frameworks, distributed training frameworks, and the EFA driver. If you want to mount an FSx file system to the training instances, you need to pass your VPC subnet and security group ID to the estimator. Before running your distributed training job in SageMaker, read the following general guidance on the basic infrastructure setup.

Availability zones and network backplane

When using multiple instances (also called nodes), it’s important to understand the network that connects the instances, how they read the training data, and how they share information between themselves. For example, when you run a distributed data-parallel training job, a number of factors, such as communication between the nodes of a compute cluster for running the AllReduce operation and data transfer between the nodes and data storage in Amazon Simple Storage Service or Amazon FSx for Lustre, play a crucial role to achieve an optimal use of compute resources and a faster training speed. To reduce communication overhead, make sure that you configure instances, VPC subnet, and data storage in the same AWS Region and Availability Zone.

GPU instances with faster network and high-throughput storage

You can technically use any instances for distributed training. For cases where you need to run multi-node distributed training jobs for training large models, such as large language models (LLMs) and diffusion models, which require faster inter-node commutation, we recommend EFA-enabled GPU.
instances supported by SageMaker. Especially, to achieve the most performant distributed training job in SageMaker, we recommend P4d and P4de instances equipped with NVIDIA A100 GPUs. These are also equipped with high-throughput low-latency local instance storage and faster intra-node network. For data storage, we recommend Amazon FSx for Lustre that provides high throughput for storing training datasets and model checkpoints.

Get started with distributed training in Amazon SageMaker

If you're already familiar with distributed training, choose one of the following options that matches your preferred strategy or framework to get started. If you want to learn about distributed training in general, see the section called "Basic distributed training concepts" (p. 2105).

The SageMaker distributed training libraries are optimized for the SageMaker training environment, help adapt your distributed training jobs to SageMaker, and improve training speed and throughput. The libraries offer both data parallel and model parallel training strategies. They combine software and hardware technologies to improve inter-GPU and inter-node communications, and extend SageMaker’s training capabilities with built-in options that require minimal code changes to your training scripts.

Use the SageMaker data parallelism library (SMDDP)

To use SageMaker's data parallelism library, configure the distribution parameter of the SageMaker framework estimators. Supported framework estimators are PyTorch and TensorFlow. The following code example shows how to set a framework estimator for distributed training with the data parallelism library on two ml.p4d.24xlarge instances.

```python
from sagemaker.framework import Framework

estimator = Framework(
    ...
    instance_count=2,
    instance_type="ml.p4d.24xlarge",
    distribution="smdistributed": {"dataparallel": {"enabled": True}}
)
```

To learn how to prepare your training script and launch a distributed data-parallel training job, see SageMaker's data parallelism library (p. 2112) (see also Distributed Training APIs in the SageMaker Python SDK documentation).

Use the SageMaker model parallelism library (SMP)

SageMaker provides the SMP library and supports various distributed training techniques, such as sharded data parallelism, pipelining, tensor parallelism, optimizer state sharding, and more. To learn more about what the SMP library offers, see the section called "Core Features" (p. 2156).

To use SageMaker's model parallelism library, configure the distribution parameter of the SageMaker framework estimators. Supported framework estimators are PyTorch and TensorFlow. The following code example shows how to construct a framework estimator for distributed training with the model parallelism library on two ml.p4d.24xlarge instances.

```python
from sagemaker.framework import Framework
distribution={
    "smdistributed": {
        "modelparallel": {
            "enabled": True,
            "parameters": {
                ...  # enter parameter key-value pairs here
            }
        }
    }
}
```
Get started with distributed training in Amazon SageMaker

To learn how to adapt your training script, configure distribution parameters in the estimator class, and launch a distributed training job, see SageMaker’s model parallelism library (p. 2145) (see also Distributed Training APIs in the SageMaker Python SDK documentation).

Use open source distributed training frameworks

SageMaker also supports the following options to operate mpirun and torchrun in the backend.

- **To use PyTorch DistributedDataParallel (DDP) in SageMaker with the mpirun backend, add**
  distribution={"pytorchddp": {"enabled": True}} to your PyTorch estimator. For more information, see also PyTorch Distributed Training and SageMaker PyTorch Estimator’s distribution argument in the SageMaker Python SDK documentation.
  
  **Note**
  This option is available for PyTorch 1.12.0 and later.

```
from sagemaker.pytorch import PyTorch

estimator = PyTorch(
    ...
    instance_count=2,
    instance_type="ml.p4d.24xlarge",
    distribution={"pytorchddp": {"enabled": True}}  # runs mpirun in the backend
)
```

- **SageMaker supports the PyTorch torchrun launcher for distributed training on GPU-based Amazon EC2 instances, such as P3 and P4, as well as Trn1 powered by the AWS Trainium device.**

  To use PyTorch DistributedDataParallel (DDP) in SageMaker with the torchrun backend, add
  distribution={"torch_distributed": {"enabled": True}} to the PyTorch estimator.
  
  **Note**
  This option is available for PyTorch 1.13.0 and later.

The following code snippet shows an example of constructing a SageMaker PyTorch estimator to run distributed training on two ml.p4d.24xlarge instances with the torch_distributed distribution option.

```
from sagemaker.pytorch import PyTorch

estimator = PyTorch(
    ...
    instance_count=2,
    instance_type="ml.p4d.24xlarge",
    distribution={"torch_distributed": {"enabled": True}}  # runs torchrun in the backend
)
```
Basic distributed training concepts

SageMaker’s distributed training libraries use the following distributed training terms and features.

Datasets and Batches

- **Training Dataset**: All of the data you use to train the model.
- **Global batch size**: The number of records selected from the training dataset in each iteration to send to the GPUs in the cluster. This is the number of records over which the gradient is computed at each iteration. If data parallelism is used, it is equal to the total number of model replicas multiplied by the per-replica batch size: \( \text{global batch size} = (\text{the number of model replicas}) \times (\text{per-replica batch size}) \). A single batch of global batch size is often referred to as the mini-batch in machine learning literature.

- **Per-replica batch size**: When data parallelism is used, this is the number of records sent to each model replica. Each model replica performs a forward and backward pass with this batch to calculate weight updates. The resulting weight updates are synchronized (averaged) across all replicas before the next set of per-replica batches are processed.

- **Micro-batch**: A subset of the mini-batch or, if hybrid model and data parallelism is used, it is a subset of the per-replica sized batch. When you use SageMaker’s distributed model parallelism library, each micro-batch is fed into the training pipeline one-by-one and follows an execution schedule defined by the library’s runtime.

**Training**

- **Epoch**: One training cycle through the entire dataset. It is common to have multiple iterations per an epoch. The number of epochs you use in training is unique on your model and use case.

- **Iteration**: A single forward and backward pass performed using a global batch sized batch (a mini-batch) of training data. The number of iterations performed during training is determined by the number of epochs used for training. For example, if a dataset includes 5,000 samples, and you use a global batch size of 500, it will take 10 iterations to complete a single epoch.

- **Learning rate**: A variable that influences the amount that weights are changed in response to the calculated error of the model. The learning rate plays an important role in the model’s ability to converge as well as the speed and optimality of convergence.

**Instances and GPUs**

- **Instances**: An AWS machine learning compute instance. These are also referred to as nodes.

- **Cluster size**: When using SageMaker’s distributed training library, this is the number of instances multiplied by the number of GPUs in each instance. For example, if you use two ml.p3.8xlarge instances in a training job, which have 4 GPUs each, the cluster size is 8. While increasing cluster size can lead to faster training times, communication between instances must be optimized; Otherwise, communication between the nodes can add overhead and lead to slower training times. The SageMaker distributed training library is designed to optimize communication between Amazon EC2 ML compute instances, leading to higher device utilization and faster training times.

**Distributed Training Solutions**

- **Data parallelism**: A strategy in distributed training where a training dataset is split up across multiple GPUs in a compute cluster, which consists of multiple Amazon EC2 ML Instances. Each GPU contains a replica of the model, receives different batches of training data, performs a forward and backward pass, and shares weight updates with the other nodes for synchronization before moving on to the next batch and ultimately another epoch.

- **Model parallelism**: A strategy in distributed training where the model partitioned across multiple GPUs in a compute cluster, which consists of multiple Amazon EC2 ML Instances. The model might be complex and have a large number of hidden layers and weights, making it unable to fit in the memory of a single instance. Each GPU carries a subset of the model, through which the data flows and the transformations are shared and compiled. The efficiency of model parallelism, in terms of GPU utilization and training time, is heavily dependent on how the model is partitioned and the execution schedule used to perform forward and backward passes.

- **Pipeline Execution Schedule (Pipelining)**: The pipeline execution schedule determines the order in which computations (micro-batches) are made and data is processed across devices during model
Pipelining is a technique to achieve true parallelization in model parallelism and overcome the performance loss due to sequential computation by having the GPUs compute simultaneously on different data samples. To learn more, see Pipeline Execution Schedule.

Advanced concepts

Machine Learning (ML) practitioners commonly face two scaling challenges when training models: scaling model size and scaling training data. While model size and complexity can result in better accuracy, there is a limit to the model size you can fit into a single CPU or GPU. Furthermore, scaling model size may result in more computations and longer training times.

Not all models handle training data scaling equally well because they need to ingest all the training data in memory for training. They only scale vertically, and to bigger and bigger instance types. In most cases, scaling training data results in longer training times.

Deep Learning (DL) is a specific family of ML algorithms consisting of several layers of artificial neural networks. The most common training method is with mini-batch Stochastic Gradient Descent (SGD). In mini-batch SGD, the model is trained by conducting small iterative changes of its coefficients in the direction that reduces its error. Those iterations are conducted on equally sized subsamples of the training dataset called mini-batches. For each mini-batch, the model is run in each record of the mini-batch, its error measured and the gradient of the error estimated. Then the average gradient is measured across all the records of the mini-batch and provides an update direction for each model coefficient. One full pass over the training dataset is called an epoch. Model trainings commonly consist of dozens to hundreds of epochs. Mini-batch SGD has several benefits: First, its iterative design makes training time theoretically linear of dataset size. Second, in a given mini-batch each record is processed individually by the model without need for inter-record communication other than the final gradient average. The processing of a mini-batch is consequently particularly suitable for parallelization and distribution.

Parallelizing SGD training by distributing the records of a mini-batch over different computing devices is called data parallel distributed training, and is the most commonly used DL distribution paradigm. Data parallel training is a relevant distribution strategy to scale the mini-batch size and process each mini-batch faster. However, data parallel training comes with the extra complexity of having to compute the mini-batch gradient average with gradients coming from all the workers and communicating it to all the workers, a step called allreduce that can represent a growing overhead, as the training cluster is scaled, and that can also drastically penalize training time if improperly implemented or implemented over improper hardware substracts.

Data parallel SGD still requires developers to be able to fit at least the model and a single record in a computing device, such as a single CPU or GPU. When training very large models such as large transformers in Natural Language Processing (NLP), or segmentation models over high-resolution images, there may be situations in which this is not feasible. An alternative way to break up the workload is to partition the model over multiple computing devices, an approach called model-parallel distributed training.

Strategies

Distributed training is usually split by two approaches: data parallel and model parallel. Data parallel is the most common approach to distributed training: You have a lot of data, batch it up, and send blocks of data to multiple CPUs or GPUs (nodes) to be processed by the neural network or ML algorithm, then combine the results. The neural network is the same on each node. A model parallel approach is used with large models that won’t fit in a node’s memory in one piece; it breaks up the model and places different parts on different nodes. In this situation, you need to send your batches of data out to each node so that the data is processed on all parts of the model.

The terms network and model are often used interchangeably: A large model is really a large network with many layers and parameters. Training with a large network produces a large model, and loading
the model back onto the network with all your pre-trained parameters and their weights loads a large
model into memory. When you break apart a model to split it across nodes, you're also breaking apart
the underlying network. A network consists of layers, and to split up the network, you put layers on
different compute devices.

A common pitfall of naively splitting layers across devices is severe GPU under-utilization. Training is
inherently sequential in both forward and backward passes, and at a given time, only one GPU can
actively compute, while the others wait on the activations to be sent. Modern model parallel libraries
solve this problem by using pipeline execution schedules to improve device utilization. However, only
the Amazon SageMaker's distributed model parallel library includes automatic model splitting. The two
core features of the library, automatic model splitting and pipeline execution scheduling, simplifies the
process of implementing model parallelism by making automated decisions that lead to efficient device
utilization.

Train with data parallel and model parallel

If you are training with a large dataset, start with a data parallel approach. If you run out of memory
during training, you may want to switch to a model parallel approach, or try hybrid model and data
parallelism. You can also try the following to improve performance with data parallel:

- Change your model's hyperparameters.
- Reduce the batch size.
- Keep reducing the batch size until it fits. If you reduce batch size to 1, and still run out of memory,
then you should try model-parallel training.

Try gradient compression (FP16, INT8):

- On NVIDIA TensorCore-equipped hardware, using mixed precision training creates both speed-up and
memory consumption reduction.
- SageMaker's distributed data parallelism library supports Automatic Mixed Precision (AMP) out of the
box. No extra action is needed to enable AMP other than the framework-level modifications to your
training script. If gradients are in FP16, the SageMaker data parallelism library runs its AllReduce
operation in FP16. For more information about implementing AMP APIs to your training script, see the
following resources:
  - Frameworks - PyTorch in the NVIDIA Deep Learning Performance documentation
  - Frameworks - TensorFlow in the NVIDIA Deep Learning Performance documentation
  - Automatic Mixed Precision for Deep Learning in the NVIDIA Developer Docs
  - Introducing native PyTorch automatic mixed precision for faster training on NVIDIA GPUs in the
    PyTorch Blog
  - TensorFlow mixed precision APIs in the TensorFlow documentation

Try reducing the input size:

- Reduce the NLP sequence length if you increase the sequence link, need to adjust the batch size down,
or adjust the GPUs up to spread the batch.
- Reduce image resolution.

Check if you use batch normalization, since this can impact convergence. When you use distributed
training, your batch is split across GPUs and the effect of a much lower batch size can be a higher error
rate thereby disrupting the model from converging. For example, if you prototyped your network on a
single GPU with a batch size of 64, then scaled up to using four p3dn.24xlarge, you now have 32 GPUs
and your per-GPU batch size drops from 64 to 2. This will likely break the convergence you saw with a
single node.

Start with model-parallel training when:
• Your model does not fit on a single device.
• Due to your model size, you're facing limitations in choosing larger batch sizes, such as if your model weights take up most of your GPU memory and you are forced to choose a smaller, suboptimal batch size.

To learn more about the SageMaker distributed libraries, see the following:

• SageMaker's Data Parallelism Library (p. 2112)
• SageMaker's Model Parallelism Library (p. 2145)

Optimize distributed training

Customize hyperparameters for your use case and your data to get the best scaling efficiency. In the following discussion, we highlight some of the most impactful training variables and provide references to state-of-the-art implementations so you can learn more about your options. Also, we recommend that you refer to your preferred framework's distributed training documentation.

• Apache MXNet distributed training
• PyTorch distributed training
• TensorFlow distributed training

Batch Size

SageMaker distributed toolkits generally allow you to train on bigger batches. For example, if a model fits within a single device but can only be trained with a small batch size, using either model-parallel training or data parallel training enables you to experiment with larger batch sizes.

Be aware that batch size directly influences model accuracy by controlling the amount of noise in the model update at each iteration. Increasing batch size reduces the amount of noise in the gradient estimation, which can be beneficial when increasing from very small batches sizes, but can result in degraded model accuracy as the batch size increases to large values.

**Tip**
Adjust your hyperparameters to ensure that your model trains to a satisfying convergence as you increase its batch size.

A number of techniques have been developed to maintain good model convergence when batch is increased.

Mini-batch size

In SGD, the mini-batch size quantifies the amount of noise present in the gradient estimation. A small mini-batch results in a very noisy mini-batch gradient, which is not representative of the true gradient over the dataset. A large mini-batch results in a mini-batch gradient close to the true gradient over the dataset and potentially not noisy enough—likely to stay locked in irrelevant minima.

To learn more about these techniques, see the following papers:

• Accurate, Large Minibatch SGD:Training ImageNet in 1 Hour, Goya et al.
• PowerAI DDL, Cho et al.
• Scale Out for Large Minibatch SGD: Residual Network Training on ImageNet-1K with Improved Accuracy and Reduced Time to Train, Codreanu et al.
• ImageNet Training in Minutes, You et al.

2109
Scenarios

The following sections cover scenarios in which you may want to scale up training, and how you can do so using AWS resources.

Scaling from a Single GPU to Many GPUs

The amount of data or the size of the model used in machine learning can create situations in which the time to train a model is longer that you are willing to wait. Sometimes, the training doesn't work at all because the model or the training data is too large. One solution is to increase the number of GPUs you use for training. On an instance with multiple GPUs, like a p3.16xlarge that has eight GPUs, the data and processing is split across the eight GPUs. When you use distributed training libraries, this can result in a near-linear speedup in the time it takes to train your model. It takes slightly over 1/8 the time it would have taken on p3.2xlarge with one GPU.

<table>
<thead>
<tr>
<th>Instance type</th>
<th>GPUs</th>
</tr>
</thead>
<tbody>
<tr>
<td>p3.2xlarge</td>
<td>1</td>
</tr>
<tr>
<td>p3.8xlarge</td>
<td>4</td>
</tr>
<tr>
<td>p3.16xlarge</td>
<td>8</td>
</tr>
<tr>
<td>p3dn.24xlarge</td>
<td>8</td>
</tr>
</tbody>
</table>

**Note**

The ml instance types used by SageMaker training have the same number of GPUs as the corresponding p3 instance types. For example, ml.p3.8xlarge has the same number of GPUs as p3.8xlarge - 4.

Scaling from a single instance to multiple instances

If you want to scale your training even further, you can use more instances. However, you should choose a larger instance type before you add more instances. Review the previous table to see how many GPUs are in each p3 instance type.

If you have made the jump from a single GPU on a p3.2xlarge to four GPUs on a p3.8xlarge, but decide that you require more processing power, you may see better performance and incur lower costs if you choose a p3.16xlarge before trying to increase instance count. Depending on the libraries you use, when you keep your training on a single instance, performance is better and costs are lower than a scenario where you use multiple instances.

When you are ready to scale the number of instances, you can do this with SageMaker Python SDK estimator function by setting your instance_count. For example, you can set instance_type = p3.16xlarge and instance_count = 2. Instead of the eight GPUs on a single p3.16xlarge, you have 16 GPUs across two identical instances. The following chart shows scaling and throughput starting with eight GPUs on a single instance and increasing to 64 instances for a total of 256 GPUs.
Custom training scripts

While SageMaker makes it simple to deploy and scale the number of instances and GPUs, depending on your framework of choice, managing the data and results can be very challenging, which is why external supporting libraries are often used. This most basic form of distributed training requires modification of your training script to manage the data distribution.

SageMaker also supports Horovod and implementations of distributed training native to each major deep learning framework. If you choose to use examples from these frameworks, you can follow SageMaker’s container guide for Deep Learning Containers, and various example notebooks that demonstrate implementations.

SageMaker's Data Parallelism Library

The SageMaker data parallelism library extends SageMaker training capabilities on deep learning models with near-linear scaling efficiency, achieving fast time-to-train with minimal code changes.

When training a model on a large amount of data, machine learning practitioners often turn to distributed training to reduce the time to train. In some cases, where time is of the essence, the business requirement is to finish training as quickly as possible or at least within a constrained time period. Then, distributed training is scaled to use a cluster of multiple nodes—not just multiple GPUs in a computing instance, but multiple instances with multiple GPUs. As the cluster size increases, so does the significant drop in performance. This drop in performance is primarily caused by the communications overhead between nodes in a cluster.

To resolve such overhead problems, SageMaker offers two distributed training options: SageMaker model parallelism and SageMaker data parallelism. This guide focuses on how to train models using the SageMaker data parallelism library.

- The library optimizes your training job for AWS network infrastructure and Amazon EC2 instance topology.
- The library takes advantage of gradient updates to communicate between nodes with a custom AllReduce algorithm.

To track the latest updates of the library, see the SageMaker Distributed Data Parallel Release Notes in the SageMaker Python SDK documentation.

For more information about training with a model-parallel strategy, see SageMaker's Model Parallelism Library (p. 2145).

Introduction to SageMaker's Distributed Data Parallel Library

Why Use SageMaker Distributed Data Parallel Library?

SageMaker's distributed data parallel library addresses communications overhead in two ways:
1. The library performs AllReduce, a key operation during distributed training that is responsible for a large portion of communication overhead.

2. The library performs optimized node-to-node communication by fully utilizing AWS's network infrastructure and Amazon EC2 instance topology.

Use this data parallel library to increase speed by up to 25% in training models such as BERT. While implementations like Horovod offer sub-linear performance at scale, this library offers near-linear performance at scale. This means that you get a faster training time and a lower cost to train a model.

**Note**
The SageMaker distributed training libraries are available only through the AWS deep learning containers for the TensorFlow, PyTorch, and HuggingFace frameworks within the SageMaker training platform. To use the libraries, you must use the SageMaker Python SDK or the SageMaker APIs through SDK for Python (Boto3) or AWS Command Line Interface. Throughout the documentation, instructions and examples focus on how to use the distributed training libraries with the SageMaker Python SDK.

**Optimal Bandwidth Use with Balanced Fusion Buffer**

SageMaker's distributed data parallel library uses a communication pattern similar to parameter servers to reduce the amount of data transferred and the number of steps involved in averaging gradients from multiple GPUs. It also uses a new technique called balanced fusion buffers to make optimal use of the bandwidth available across all nodes in the cluster.

One key disadvantage of traditional parameter servers is their suboptimal use of available network bandwidth. Parameter servers treat variables as atomic units and place each variable on one server. Since gradients become available sequentially during the backward pass, at any given instant, there is imbalance in the volume of data being sent and received from different servers. Some servers are receiving and sending more data, some less, and some none. This problem becomes worse as the number of parameter servers increases.

The library addresses these problems by introducing balanced fusion buffers. A balanced fusion buffer is a buffer in the GPU that holds the gradients until the size of the buffer exceeds a threshold. In a setup with N parameter servers, when the buffer exceeds the threshold, the balanced fusion buffer is copied to CPU memory, sharded into N parts, and the ith part is sent to the ith parameter server. Each server receives exactly the same number of bytes from a balanced fusion buffer. The ith server receives the ith partition of the balanced fusion buffer from all workers, sums them up, and sends the results back to all workers. Since all the servers participate equally in averaging each balanced fusion buffer, server bandwidth is efficiently utilized.

**Optimal GPU Usage with Efficient AllReduce Overlapping with a Backward Pass**

SageMaker's distributed data parallel library achieves optimal overlapping of the AllReduce operation with the backward pass, significantly improving the GPU utilization, and achieves near-linear scaling efficiency and faster time to train by optimizing tasks between CPUs and GPUs. The library performs AllReduce in parallel while GPU is computing gradients without taking away additional GPU cycles, which makes the library faster.

- **Leverages CPUs**: The library uses CPUs to AllReduce gradients, offloading this task from the GPUs.
- **Improved GPU usage**: The cluster's GPUs focus on computing gradients, improving their utilization throughout training.
SageMaker Distributed Data Parallel Architecture

The library supports larger compute instances that have 8 GPUs per node: `ml.p3.16xlarge`, `ml.p3dn.24xlarge`, and `ml.p4d.24xlarge`. The high-level workflow of the SageMaker distributed data parallel library is as following:

1. The library assigns ranks to GPUs (workers).
2. At each iteration, the library divides each global batch by the total number of workers (world size) and assigns small batches (batch shards) to the workers.
   - The size of the global batch is `(number of nodes in a cluster) * (number of GPUs per node) * (per batch shard)`.
   - A batch shard (small batch) is a subset of dataset assigned to each GPU (worker) per iteration.
3. The library launches a training script on each worker.
4. The library manages copies of model weights and gradients from the workers at the end of every iteration.
5. The library synchronizes model weights and gradients across the workers to aggregate a single trained model.

The following architecture diagram shows an example of how the library sets up data parallelism for a cluster of 3 nodes.

To start using the SageMaker distributed data parallel library, see Step 2: Launch a SageMaker Distributed Training Job Using the SageMaker Python SDK (p. 2127) to set up a SageMaker estimator through Amazon SageMaker Python SDK, and Run a SageMaker Distributed Training Job with Data Parallelism (p. 2119) to adapt your training script using the SageMaker distributed data parallel library.
Supported Frameworks, AWS Regions, and Instances Types

Before using the SageMaker data parallelism library, check what are the supported ML frameworks and instance types and if there are enough quotas in your AWS account and AWS Region.

Supported Frameworks

The following tables show the deep learning frameworks and their versions that SageMaker and the SageMaker data parallelism library support. The SageMaker data parallelism library is available in AWS Deep Learning Containers (DLC) or downloadable as a binary file.

Note

To check the latest updates and release notes of the library, see also the SageMaker Data Parallel Release Notes in the SageMaker Python SDK documentation.

</tr>
</tbody>
</table>
**Note**  
The SageMaker data parallelism library v1.4.0 and later works as a backend of PyTorch distributed. In accordance with the change, the following `smdistributed APIs` for the PyTorch distributed package are deprecated.

- `smdistributed.dataparallel.torch.distributed` is deprecated. Use the `torch.distributed` package instead.
- `smdistributed.dataparallel.torch.parallel.DistributedDataParallel` is deprecated. Use the `torch.nn.parallel.DistributedDataParallel` API instead.

If you need to use the previous versions of the library (v1.3.0 or before), see the archived SageMaker data parallelism library documentation in the SageMaker Python SDK documentation.

**The URLs of the binary files are for installing the SageMaker data parallelism library in custom containers. For more information, see Create Your Own Docker Container with the SageMaker Distributed Data Parallel Library (p. 2130).**

**PyTorch Lightning**

<table>

| 1.6.4                     |                  |                                            | \lambda-\lambda-\lambda-\lambda-\lambda-\lambda-\lambda-
| 1.6.3                     |                  |                                            | \lambda-\lambda-\lambda-\lambda-\lambda-\lambda-\lambda-
| 1.5.10                    |                  |                                            | \lambda-\lambda-\lambda-\lambda-\lambda-\lambda-\lambda-

**Note**  
PyTorch Lightning and its utility libraries such as Lightning Bolts are not preinstalled in the PyTorch DLCs. When you construct a SageMaker PyTorch estimator and submit a training job request in Step 2, you need to provide `requirements.txt` to install `pytorch-lightning` and `lightning-bolts` in the SageMaker PyTorch training container.

```
# requirements.txt
pytorch-lightning
lightning-bolts
```

For more information about specifying the source directory to place the `requirements.txt` file along with your training script and a job submission, see Using third-party libraries in the Amazon SageMaker Python SDK documentation.

Run a SageMaker Distributed Training Job with Data Parallelism

SageMaker's distributed data parallel library APIs are designed for ease of use and to provide seamless integration with existing distributed training toolkits.

- **SageMaker Python SDK with the library API** – In most cases, all you have to change in your training script is the data parallel library import statements. Swap these out with the SageMaker data parallel library equivalents.
- **Focus on your model training without infrastructure management** – When training a deep learning model with the library on SageMaker, you can focus on writing your training script and model training. You can run a training job using estimator classes provided by the SageMaker Python SDK. The estimator classes help prepare ML instances, load datasets from specified data resources, submit the training job using your training script, and shut down the instances after the training job is completed.

To begin, you need to adapt TensorFlow or PyTorch training scripts to use the library. The following topics provide instructions on how to modify your training script.

**Topics**
- [Step 1: Modify Your Own Training Script (p. 2119)](#)
- [Step 2: Launch a SageMaker Distributed Training Job Using the SageMaker Python SDK (p. 2127)](#)

**Step 1: Modify Your Own Training Script**

Use this section to learn how to customize your training script to use the core features of the Amazon SageMaker distributed data parallel library. To use the library-specific API functions and parameters, we recommend you use this documentation alongside the [SageMaker data parallel library APIs](#) in the [SageMaker Python SDK documentation](#).

The training script examples provided in these sections are simplified and designed to highlight the required changes you must make to use the library. For end-to-end, runnable notebook examples that demonstrate how to use a TensorFlow or PyTorch training script with the SageMaker distributed data parallel library, see [Amazon SageMaker Distributed Training Notebook Examples (p. 2223)](#).

**Topics**
- [Modify a TensorFlow Training Script (p. 2120)](#)
Modify a TensorFlow Training Script

The following steps show you how to modify a TensorFlow training script to utilize SageMaker's distributed data parallel library.

The library APIs are designed to be similar to Horovod APIs. For additional details on each API that the library offers for TensorFlow, see the SageMaker distributed data parallel TensorFlow API documentation.

**Note**
SageMaker distributed data parallel is adaptable to TensorFlow training scripts composed of tf core modules except tf.keras modules. SageMaker distributed data parallel does not support TensorFlow with Keras implementation.

**Note**
SageMaker's distributed data parallelism library supports Automatic Mixed Precision (AMP) out of the box. No extra action is needed to enable AMP other than the framework-level modifications to your training script. If gradients are in FP16, the SageMaker data parallelism library runs its AllReduce operation in FP16. For more information about implementing AMP APIs to your training script, see the following resources:

- Frameworks - TensorFlow in the NVIDIA Deep Learning Performance documentation
- Automatic Mixed Precision for Deep Learning in the NVIDIA Developer Docs
- TensorFlow mixed precision APIs in the TensorFlow documentation

1. Import the library's TensorFlow client and initialize it.

```python
import smdistributed.dataparallel.tensorflow as sdp
sdp.init()
```

2. Pin each GPU to a single `smdistributed.dataparallel` process with `local_rank`—this refers to the relative rank of the process within a given node. The `sdp.tensorflow.local_rank()` API provides you the local rank of the device. The leader node is rank 0, and the worker nodes are rank 1, 2, 3, and so on. This is invoked in the following code block as `sdp.local_rank()`.

```python
gpus = tf.config.experimental.list_physical_devices('GPU')
for gpu in gpus:
    tf.config.experimental.set_memory_growth(gpu, True)
if gpus:
    tf.config.experimental.set_visible_devices(gpus[sdp.local_rank()], 'GPU')
```

3. Scale the learning rate by the number of workers. The `sdp.tensorflow.size()` API provides you the number of workers in the cluster. This is invoked in the following code block as `sdp.size()`.

```python
learning_rate = learning_rate * sdp.size()
```

4. Use the library's `DistributedGradientTape` to optimize AllReduce operations during training. This wraps `tf.GradientTape`.

```python
with tf.GradientTape() as tape:
    output = model(input)
    loss_value = loss(label, output)
```
# SageMaker data parallel: Wrap tf.GradientTape with the library's DistributedGradientTape
tape = sdp.DistributedGradientTape(tape)

5. Broadcast the initial model variables from the leader node (rank 0) to all the worker nodes (ranks 1 through n). This is needed to ensure a consistent initialization across all the worker ranks. Use the sdp.tensorflow.broadcast_variables API after the model and optimizer variables are initialized. This is invoked in the following code block as sdp.broadcast_variables().

```
sdp.broadcast_variables(model.variables, root_rank=0)
sdp.broadcast_variables(opt.variables(), root_rank=0)
```

6. Finally, modify your script to save checkpoints only on the leader node. The leader node has a synchronized model. This also avoids worker nodes overwriting the checkpoints and possibly corrupting the checkpoints.

```
if sdp.rank() == 0:
    checkpoint.save(checkpoint_dir)
```

The following is an example TensorFlow training script for distributed training with the library.

```python
import tensorflow as tf
import smdistributed.dataparallel.tensorflow as sdp

# SageMaker data parallel: Initialize the library
sdp.init()

gpus = tf.config.experimental.list_physical_devices('GPU')
for gpu in gpus:
    tf.config.experimental.set_memory_growth(gpu, True)
if gpus:
    # SageMaker data parallel: Pin GPUs to a single library process
    tf.config.experimental.set_visible_devices(gpus[sdp.local_rank()], 'GPU')

# Prepare Dataset
dataset = tf.data.Dataset.from_tensor_slices(...)

# Define Model
mnist_model = tf.keras.Sequential(...)
loss = tf.losses.SparseCategoricalCrossentropy()

# SageMaker data parallel: Scale Learning Rate
# LR for 8 node run : 0.000125
# LR for single node run : 0.001
opt = tf.optimizers.Adam(0.000125 * sdp.size())

@tf.function
def training_step(images, labels, first_batch):
    with tf.GradientTape() as tape:
        probs = mnist_model(images, training=True)
        loss_value = loss(labels, probs)

        # SageMaker data parallel: Wrap tf.GradientTape with the library's DistributedGradientTape
tape = sdp.DistributedGradientTape(tape)
        grads = tape.gradient(loss_value, mnist_model.trainable_variables)
        opt.apply_gradients(zip(grads, mnist_model.trainable_variables))
```
if first_batch:
    # SageMaker data parallel: Broadcast model and optimizer variables
    sdp.broadcast_variables(mnist_model.variables, root_rank=0)
    sdp.broadcast_variables(opt.variables(), root_rank=0)

    return loss_value
...

# SageMaker data parallel: Save checkpoints only from master node.
if sdp.rank() == 0:
    checkpoint.save(checkpoint_dir)

After you have completed adapting your training script, move on to Step 2: Launch a SageMaker Distributed Training Job Using the SageMaker Python SDK (p. 2127).

Modify a PyTorch Training Script

In the SageMaker data parallel library v1.4.0 and later, the library is available as a backend option for the PyTorch distributed package. You only need to import the library once at the top of your training script and set it as the PyTorch distributed backend during initialization. With the single line of backend specification, you can keep your PyTorch training script unchanged and directly use the PyTorch distributed modules. To find the latest API documentation for the library, see the SageMaker distributed data parallel APIs for PyTorch in the SageMaker Python SDK documentation. To learn more about the PyTorch distributed package and backend options, see Distributed communication package - torch.distributed.

Important
Because the SageMaker distributed data parallelism library v1.4.0 and later works as a backend of PyTorch distributed, the following smdistributed APIs for the PyTorch distributed package are deprecated.

- smdistributed.dataparallel.torch.distributed is deprecated. Use the torch.distributed package instead.
- smdistributed.dataparallel.torch.parallel.DistributedDataParallel is deprecated. Use the torch.nn.parallel.DistributedDataParallel API instead.

If you need to use the previous versions of the library (v1.3.0 or before), see the archived SageMaker distributed data parallel library documentation in the SageMaker Python SDK documentation.

Use the SageMaker Distributed Data Parallel Library as the Backend of torch.distributed

To use the SageMaker distributed data parallel library, the only thing you need to do is to import the SageMaker distributed data parallel library's PyTorch client (smdistributed.dataparallel.torch.torch_smdp). The client registers smdp as a backend for PyTorch. When you initialize the PyTorch distributed process group using the torch.distributed.init_process_group API, make sure you specify 'smdp' to the backend argument.

```python
import smdistributed.dataparallel.torch.torch_smdp
import torch.distributed as dist

dist.init_process_group(backend='smdp')
```

Note
The smdp backend currently does not support creating subprocess groups with the torch.distributed.new_group() API. You cannot use the smdp backend concurrently with other process group backends such as NCCL and Gloo.
If you already have a working PyTorch script and only need to add the backend specification, you can proceed to Using the SageMaker Framework Estimators For PyTorch and TensorFlow (p. 2128) in the Step 2: Launch a SageMaker Distributed Training Job Using the SageMaker Python SDK (p. 2127) topic.

If you still need to modify your training script to properly use the PyTorch distributed package, follow the rest of the procedures on this page.

Preparing a PyTorch Training Script for Distributed Training

The following steps provide additional tips on how to prepare your training script to successfully run a distributed training job using PyTorch.

**Note**
In v1.4.0, the SageMaker distributed data parallel library supports the following collective primitive data types of the `torch.distributed` interface: `all_reduce`, `broadcast`, `reduce`, `all_gather`, and `barrier`.

1. Import the PyTorch distributed modules.

   ```python
   import torch
   import torch.distributed as dist
   from torch.nn.parallel import DistributedDataParallel as DDP
   ```

2. After parsing arguments and defining a batch size parameter (for example, `batch_size=args.batch_size`), add two lines of code to resize the batch size per worker (GPU). PyTorch's DataLoader operation does not automatically handle the batch resizing for distributed training.

   ```python
   batch_size //= dist.get_world_size()
   batch_size = max(batch_size, 1)
   ```

3. Pin each GPU to a single SageMaker data parallel library process with `local_rank`—this refers to the relative rank of the process within a given node.

   You can retrieve the rank of the process from the LOCAL_RANK environment variable.

   ```python
   import os
   local_rank = os.environ['LOCAL_RANK']
   torch.cuda.set_device(local_rank)
   ```

4. After defining a model, wrap it with the PyTorch `DistributedDataParallel` API.

   ```python
   model = ...
   # Wrap the model with the PyTorch DistributedDataParallel API
   model = DDP(model)
   ```

5. When you call the `torch.utils.data.distributed.DistributedSampler` API, specify the total number of processes (GPUs) participating in training across all the nodes in the cluster. This is called `world_size`, and you can retrieve the number from the `torch.distributed.get_world_size()` API. Also, specify the rank of each process among all processes using the `torch.distributed.get_rank()` API.

   ```python
   from torch.utils.data.distributed import DistributedSampler
   train_sampler = DistributedSampler(
       train_dataset,
       num_replicas = dist.get_world_size(),
       rank = dist.get_rank())
   ```
6. Modify your script to save checkpoints only on the leader process (rank 0). The leader process has a synchronized model. This also avoids other processes overwriting the checkpoints and possibly corrupting the checkpoints.

```python
if dist.get_rank() == 0:
    torch.save(...)
```

The following example code shows the structure of a PyTorch training script with smddp as the backend.

```python
import os
import torch

# SageMaker data parallel: Import the library PyTorch API
import smdistributed.dataparallel.torch.torch_smddp

# SageMaker data parallel: Import PyTorch's distributed API
import torch.distributed as dist
from torch.nn.parallel import DistributedDataParallel as DDP

# SageMaker data parallel: Initialize the process group
dist.init_process_group(backend='smddp')

class Net(nn.Module):
    ...
    # Define model

def train(...):
    ...
    # Model training

def test(...):
    ...
    # Model evaluation

def main():
    # SageMaker data parallel: Scale batch size by world size
    batch_size //= dist.get_world_size()
    batch_size = max(batch_size, 1)
    # Prepare dataset
    train_dataset = torchvision.datasets.MNIST(...)
    
    # SageMaker data parallel: Set num_replicas and rank in DistributedSampler
    train_sampler = torch.utils.data.distributed.DistributedSampler(
        train_dataset,
        num_replicas=dist.get_world_size(),
        rank=dist.get_rank())

    train_loader = torch.utils.data.DataLoader(..)
    # SageMaker data parallel: Wrap the PyTorch model with the library's DDP
    model = DDP(Net().to(device))
    # SageMaker data parallel: Pin each GPU to a single library process.
    local_rank = os.environ["LOCAL_RANK"]
    torch.cuda.set_device(local_rank)
    model.cuda(local_rank)
    # Train
```
optimizer = optim.Adadelta(...)  
scheduler = StepLR(...)  
for epoch in range(1, args.epochs + 1):  
    train(...)  
    if rank == 0:  
        test(...)  
    scheduler.step()  

    # SageMaker data parallel: Save model on master node.  
    if dist.get_rank() == 0:  
        torch.save(...)  

if __name__ == '__main__':  
    main()  

After you have completed adapting your training script, proceed to Step 2: Launch a SageMaker Distributed Training Job Using the SageMaker Python SDK (p. 2127).

Modify a PyTorch Lightning Script

If you want to bring your PyTorch Lightning training script and run a distributed data parallel training job in SageMaker, you can run the training job with minimal changes in your training script. The necessary changes include the following: import the smdistributed.dataparallel library's PyTorch modules, set up the environment variables for PyTorch Lightning to accept the SageMaker environment variables that are preset by the SageMaker training toolkit, and activate the SageMaker data parallel library by setting the process group backend to "smddp". To learn more, walk through the following instructions that break down the steps with code examples.

Note
The PyTorch Lightning support is available in the SageMaker data parallel library v1.5.0 and later.

1. Import the pytorch_lightning library and the smdistributed.dataparallel.torch modules.

```python
import pytorch_lightning as pl
import smdistributed.dataparallel.torch.torch_smddp
```

2. Set the world size and the rank for the LightningEnvironment class object. When launching a training job in SageMaker, the SageMaker training toolkit sets up the environment variables "RANK", "LOCAL_RANK", and "WORLD_SIZE". These environment variables represent the processes' global ranks, their local ranks, and the world size, respectively. Use these SageMaker environment variables to configure the LightningEnvironment.

```python
import os
from pytorch_lightning.plugins.environments.lightning_environment \ import LightningEnvironment

e = LightningEnvironment()

e.world_size = lambda: int(os.environ['WORLD_SIZE'])

e.global_rank = lambda: int(os.environ['RANK'])
```

3. Set distributed training strategy using the PyTorch Lightning DDPStrategy module, create a PyTorch Lightning Trainer object, and adapt them to use the SageMaker data parallel library.

(Recommended) For PyTorch Lightning v1.6.0 and later

Create an object (ddp in the following code example) of the DDPStrategy class, and specify "smddp" to the process_group_backend parameter. When configuring a PyTorch Lightning Trainer object, use the SageMaker environment variables to specify the scale of the GPU cluster and the ddp object to set up the distributed training strategy.
Note
We recommend that you check the versions of PyTorch Lightning tested for compatibility with the SageMaker data parallel library in the the section called “Supported Frameworks and AWS Regions” (p. 2153) page.

```python
from pytorch_lightning.strategies import DDPStrategy
ddp = DDPStrategy(
    cluster_environment=env,
    process_group_backend="smddp",
    accelerator="gpu"
)

world_size = int(os.environ["WORLD_SIZE"])
num_gpus = int(os.environ["SM_NUM_GPUS"])
num_nodes = int(world_size/num_gpus)

trainer = pl.Trainer(
    devices=num_gpus,
    num_nodes=num_nodes,
    max_epochs=10,
    strategy=ddp
)
```

(Optional) For PyTorch Lightning v1.5.10

If you are using DDPPlugin, which is a deprecated functionality, set the distributed strategy as shown in the following code example.

```python
from pytorch_lightning.plugins.training_type.ddp import DDPPlugin
os.environ["PL_TORCH_DISTRIBUTED_BACKEND"] = "smddp"

ddp = DDPPlugin(
    parallel_devices=[torch.device("cuda", d) for d in range(num_gpus)],
    cluster_environment=env
)

world_size = int(os.environ["WORLD_SIZE"])
num_gpus = int(os.environ["SM_NUM_GPUS"])
num_nodes = int(world_size/num_gpus)

trainer = pl.Trainer(
    gpus=num_gpus,
    num_nodes=num_nodes,
    max_epochs=10,
    strategy=ddp
)
```

4. Run `trainer.fit` to start the training job of a PyTorch model. The following code example shows a PyTorch model object wrapped by the PyTorch Lightning MNIST data module.

```python
from pl_bolts.datamodules import MNISTDataModule
trainer.fit(model, datamodule=MNISTDataModule(batch_size=32))
```

After you have completed adapting your training script, proceed to Step 2: Launch a SageMaker Distributed Training Job Using the SageMaker Python SDK (p. 2127).
Note
When you construct a SageMaker PyTorch estimator and submit a training job request in Step 2, you need to provide requirements.txt to install pytorch-lightning and lightning-bolts in the SageMaker PyTorch training container.

```
# requirements.txt
pytorch-lightning
lightning-bolts
```

For more information about specifying the source directory to place the requirements.txt file along with your training script and a job submission, see Using third-party libraries in the Amazon SageMaker Python SDK documentation.

Step 2: Launch a SageMaker Distributed Training Job Using the SageMaker Python SDK

To run your adapted script in Step 1: Modify Your Own Training Script (p. 2119), start with creating a SageMaker framework or generic estimator object with the prepared training script and the distributed training configuration parameter. You can use the library in any kind of SageMaker environment and web IDEs, such as SageMaker notebook instance and SageMaker Studio.

Use the high-level SageMaker Python SDK to do one of the following:

- If you want to achieve a quick adoption of your distributed training job in SageMaker, configure a SageMaker PyTorch or TensorFlow framework estimator class. The framework estimator picks up your training script and automatically matches the right image URI of the pre-built PyTorch or TensorFlow Deep Learning Containers (DLC), given the value specified to the framework_version parameter.

- If you want to extend one of the pre-built containers or build a custom container to create your own ML environment with SageMaker, use the SageMaker generic Estimator class and specify the image URI of the custom Docker container hosted in your Amazon Elastic Container Registry (Amazon ECR).

Your training datasets should be stored in Amazon S3 or Amazon FSx for Lustre in the AWS Region in which you are launching your training job. If you use Jupyter notebooks, you should have a SageMaker notebook instance or a SageMaker Studio app running in the same AWS Region. For more information about storing your training data, see the SageMaker Python SDK data inputs documentation.

Tip
We highly recommend that you use Amazon FSx for Lustre instead of Amazon S3 to increase training performance. Amazon FSx has higher throughput and lower latency than Amazon S3.

Choose one of the following topics for instructions on how to run your TensorFlow or PyTorch training scripts. After you launch a training job, you can monitor system utilization and model performance using Use Amazon SageMaker Debugger to debug and improve model performance (p. 1916) or Amazon CloudWatch.

While you follow instructions in the following topics to learn more about technical details, we also recommend that you try the Amazon SageMaker Distributed Training Notebook Examples (p. 2223) to get started.

Topics
- Using the SageMaker Framework Estimators For PyTorch and TensorFlow (p. 2128)
- Using the SageMaker Generic Estimator to Extend Prebuilt Containers (p. 2129)
- Create Your Own Docker Container with the SageMaker Distributed Data Parallel Library (p. 2130)
Using the SageMaker Framework Estimators For PyTorch and TensorFlow

You can activate the SageMaker distributed data parallel library by specifying it as the distribution strategy in the SageMaker framework estimator class.

SageMaker PyTorch

```python
from sagemaker.pytorch import PyTorch

pt_estimator = PyTorch(
    base_job_name="training_job_name_prefix",
    source_dir="sub-folder-for-your-code",
    entry_point="adapted-training-script.py",
    role="SageMakerRole",
    py_version="py38",
    framework_version="1.12.0",

    # For running a multi-node distributed training job, specify a value greater than 1
    # Example: 2,3,4,..8
    instance_count=2,

    # Instance types supported by the SageMaker data parallel library:
    # ml.p4d.24xlarge, ml.p3dn.24xlarge, and ml.p3.16xlarge
    instance_type="ml.p3.16xlarge",

    # Training using the SageMaker data parallel distributed training strategy
    distribution={ "smdistributed": { "dataparallel": { "enabled": True } } }
)

pt_estimator.fit("s3://bucket/path/to/training/data")
```

Note

PyTorch Lightning and its utility libraries such as Lightning Bolts are not preinstalled in the SageMaker PyTorch DLCs. Create the following requirements.txt file and save in the source directory where you save the training script.

```
# requirements.txt
pytorch-lightning
lightning-bolts
```

For example, the tree-structured directory should look like the following.

```
### pytorch_training_launcher_jupyter_notebook.ipynb
### sub-folder-for-your-code
    ### adapted-training-script.py
    ### requirements.txt
```

For more information about specifying the source directory to place the requirements.txt file along with your training script and a job submission, see Using third-party libraries in the Amazon SageMaker Python SDK documentation.

SageMaker TensorFlow

```python
from sagemaker.tensorflow import TensorFlow

tf_estimator = TensorFlow(
    base_job_name = "training_job_name_prefix",
    entry_point="adapted-training-script.py",
    role="SageMakerRole",
    framework_version="2.9.1",
```

2128
The following two parameters of the SageMaker framework estimator are required to activate the SageMaker data parallelism.

**distribution** (dict): A dictionary with information on how to run distributed training (default: None).

- To use `smdistributed.dataparallel` as a distribution strategy, configure a dictionary as shown in the following code:

```python
distribution = { "smdistributed": { "dataparallel": { "enabled": True } } }
```

**custom_mpi_options** (str)(optional): Custom MPI options. The following is an example of how you can use this parameter when defining `distribution`. To learn more, see Custom MPI Options (p. 2139).

```python
distribution = { "smdistributed": { "dataparallel": { "enabled": True, 
"custom_mpi_options": "-verbose -x NCCL_DEBUG=VERSION" 
} } }
```

**instance_type** (str): A type of Amazon EC2 instance to use.

- If using the `smdistributed` with `dataparallel` distribution strategy, you must use one of the following instance types: `ml.p4d.24xlarge`, `ml.p3dn.24xlarge`, and `ml.p3.16xlarge`. For best performance, we recommend that you use an EFA-enabled instance, which are `ml.p3dn.24xlarge` and `ml.p4d.24xlarge`.

Using the SageMaker Generic Estimator to Extend Prebuilt Containers

You can customize SageMaker prebuilt containers or extend them to handle any additional functional requirements for your algorithm or model that the prebuilt SageMaker Docker image doesn't support. For an example of how you can extend a pre-built container, see Extend a Prebuilt Container.

To extend a prebuilt container or adapt your own container to use the library, you must use one of the images listed in Supported Frameworks (p. 2115).
**Important**

From TensorFlow 2.4.1 and PyTorch 1.8.1, the framework DLCs supports EFA-enabled instance types (ml.p3dn.24xlarge, ml.p4d.24xlarge). We recommend that you use the DLC images that contain TensorFlow 2.4.1 or later and PyTorch 1.8.1 or later.

For example, if you use PyTorch, your Dockerfile should contain a FROM statement similar to the following:

```bash
# SageMaker PyTorch image
FROM 763104351884.dkr.ecr.<aws-region>.amazonaws.com/pytorch-training:<image-tag>

ENV PATH="/opt/ml/code:${PATH}"
# this environment variable is used by the SageMaker PyTorch container to determine our
# user code directory.
ENV SAGEMAKER_SUBMIT_DIRECTORY /opt/ml/code

# /opt/ml and all subdirectories are utilized by SageMaker, use the /code subdirectory to
# store your user code.
COPY cifar10.py /opt/ml/code/cifar10.py

# Defines cifar10.py as script entrypoint
ENV SAGEMAKER_PROGRAM cifar10.py
```

You can further customize your own Docker container to work with SageMaker using the SageMaker Training toolkit and the binary file of the SageMaker distributed data parallel library. To learn more, see the instructions in the following section.

**Create Your Own Docker Container with the SageMaker Distributed Data Parallel Library**

To build your own Docker container for training and use the SageMaker data parallel library, you must include the correct dependencies and the binary files of the SageMaker distributed parallel libraries in your Dockerfile. This section provides instructions on how to create a complete Dockerfile with the minimum set of dependencies for distributed training in SageMaker using the data parallel library.

**Note**

This custom Docker option with the SageMaker data parallel library as a binary is available only for PyTorch.

**To create a Dockerfile with the SageMaker training toolkit and the data parallel library**

1. Start with a Docker image from NVIDIA CUDA. Use the cuDNN developer versions that contain CUDA runtime and development tools (headers and libraries) to build from the PyTorch source code.

   ```bash
   FROM nvidia/cuda:11.3.1-cudnn8-devel-ubuntu20.04
   ```

   **Tip**
   The official AWS Deep Learning Container (DLC) images are built from the NVIDIA CUDA base images. If you want to use the prebuilt DLC images as references while following the rest of the instructions, see the AWS Deep Learning Containers for PyTorch Dockerfiles.

2. Add the following arguments to specify versions of PyTorch and other packages. Also, indicate the Amazon S3 bucket paths to the SageMaker data parallel library and other software to use AWS resources, such as the Amazon S3 plug-in.

   ```bash
   Tip
   The official AWS Deep Learning Container (DLC) images are built from the NVIDIA CUDA base images. If you want to use the prebuilt DLC images as references while following the rest of the instructions, see the AWS Deep Learning Containers for PyTorch Dockerfiles.

   2. Add the following arguments to specify versions of PyTorch and other packages. Also, indicate the Amazon S3 bucket paths to the SageMaker data parallel library and other software to use AWS resources, such as the Amazon S3 plug-in.

   ```bash
   FROM nvidia/cuda:11.3.1-cudnn8-devel-ubuntu20.04
   ```

   **Tip**
   The official AWS Deep Learning Container (DLC) images are built from the NVIDIA CUDA base images. If you want to use the prebuilt DLC images as references while following the rest of the instructions, see the AWS Deep Learning Containers for PyTorch Dockerfiles.

   2. Add the following arguments to specify versions of PyTorch and other packages. Also, indicate the Amazon S3 bucket paths to the SageMaker data parallel library and other software to use AWS resources, such as the Amazon S3 plug-in.

   ```bash
   Tip
   The official AWS Deep Learning Container (DLC) images are built from the NVIDIA CUDA base images. If you want to use the prebuilt DLC images as references while following the rest of the instructions, see the AWS Deep Learning Containers for PyTorch Dockerfiles.

   2. Add the following arguments to specify versions of PyTorch and other packages. Also, indicate the Amazon S3 bucket paths to the SageMaker data parallel library and other software to use AWS resources, such as the Amazon S3 plug-in.

   ```bash
   ```

   **To use versions of the third party libraries other than the ones provided in the following code example, we recommend you look into the official Dockerfiles of AWS Deep Learning Container for PyTorch to find versions that are tested, compatible, and suitable for your application.

   **To find URLs for the SMDATAPARALLEL_BINARY argument, see the look up tables at Supported Frameworks (p. 2115).**
3. Set the following environment variables to properly build SageMaker training components and run the data parallel library. You use these variables for the components in the subsequent steps.

```bash
# Set ENV variables required to build PyTorch
ENV TORCH_CUDA_ARCH_LIST="7.0+PTX 8.0"
ENV TORCH_NVCC_FLAGS="-Xfatbin -compress-all"
ENV NCCL_VERSION=2.10.3

# Add OpenMPI to the path.
ENV PATH /opt/amazon/openmpi/bin:$PATH

# Add Conda to path
ENV PATH $CONDA_PREFIX/bin:$PATH

# Set this environment variable for SageMaker to launch SMDDP correctly.
ENV SAGEMAKER_TRAINING_MODULE=sagemaker_pytorch_container.training:main

# Add environment variable for processes to be able to call fork()
ENV RDMAV_FORK_SAFE=1

# Indicate the container type
ENV DLC_CONTAINER_TYPE=training

# Add EFA and SMDDP to LD library path
ENV LD_LIBRARY_PATH="/opt/conda/lib/python${PYTHON_SHORT_VERSION}/site-packages/smdistributed/dataparallel/lib:$LD_LIBRARY_PATH"
ENV LD_LIBRARY_PATH=/opt/amazon/efa/lib/:$LD_LIBRARY_PATH
```

4. Install or update `curl`, `wget`, and `git` to download and build packages in the subsequent steps.

```bash
RUN --mount=type=cache,id=apt-final,target=/var/cache/apt \
    apt-get update && apt-get install -y --no-install-recommends \
    curl \ 
    wget \ 
    git \ 
    && rm -rf /var/lib/apt/lists/*
```

```bash
RUN DEBIAN_FRONTEND=noninteractive apt-get update
RUN mkdir /tmp/efa \ 
    && cd /tmp/efa \ 
    && curl --silent -O https://efa-installer.amazonaws.com/aws-efa-installer-$(EFA_VERSION).tar.gz \ 
    && tar -xf aws-efa-installer-$(EFA_VERSION).tar.gz \ 
    && cd aws-efa-installer \ 
    && ./efa_installer.sh -y --skip-kmod -g \ 
    && rm -rf /tmp/efa
```

6. Install [Conda](https://conda.io/) to handle package management.
7. Get, build, and install PyTorch and its dependencies. We build PyTorch from the source code because we need to have control of the NCCL version to guarantee compatibility with the AWS OFI NCCL plug-in.

a. Following the steps in the PyTorch official dockerfile, install build dependencies and set up ccache to speed up recompilation.

```bash
RUN DEBIAN_FRONTEND=noninteractive \  
    apt-get install -y --no-install-recommends \ 
    build-essential \ 
    ca-certificates \ 
    ccache \ 
    cmake \ 
    git \ 
    libjpeg-dev \ 
    libpng-dev \ 
    && rm -rf /var/lib/apt/lists/*
# Setup ccache
RUN /usr/sbin/update-ccache-symlinks
RUN mkdir /opt/ccache && ccache --set-config=cache_dir=/opt/ccache
```

b. Install PyTorch's common and Linux dependencies.

```bash
# Common dependencies for PyTorch
RUN conda install astunparse numpy ninja pyyaml mkl mkl-include setuptools cmake cffi typing_extensions future six requests dataclasses
# Linux specific dependency for PyTorch
RUN conda install -c pytorch magma-cuda113
```

c. Clone the PyTorch GitHub repository.

```bash
RUN --mount=type=cache,target=/opt/ccache \  
    cd / \ 
    && git clone --recursive https://github.com/pytorch/pytorch -b v${PYTORCH_VERSION}
```

d. Install and build a specific NCCL version. To do this, replace the content in the PyTorch's default NCCL folder (/pytorch/third_party/nccl) with the specific NCCL version from the NVIDIA repository. The NCCL version was set in the step 3 of this guide.

```bash
RUN cd /pytorch/third_party/nccl \  
    && rm -rf nccl \ 
    && git clone https://github.com/NVIDIA/nccl.git -b v${NCCL_VERSION}-1 \ 
    && cd nccl \ 
    && make -j64 src.build CUDA_HOME=/usr/local/cuda NVCC_GENCODE="-gencode=arch=compute_70,code=sm_70 -gencode=arch=compute_80,code=sm_80" \ 
    && make pkg.txz.build \ 
    && tar -xvf build/pkg/txz/nccl_*_.txz -C $CONDA_PREFIX --strip-components=1
```

e. Build and install PyTorch. This process usually takes slightly more than one hour to complete. It is built using the NCCL version downloaded in a previous step.
8. Build and install AWS OFI NCCL plugin. This enables libfabric support for the SageMaker data parallel library.

```bash
RUN DEBIAN_FRONTEND=noninteractive apt-get update \
    && apt-get install -y --no-install-recommends  \
        autoconf \
        automake \
        libtool \
RUN mkdir /tmp/efa-ofi-nccl \
    && cd /tmp/efa-ofi-nccl \
    && git clone https://github.com/aws/aws-ofi-nccl.git -b v${BRANCH_OFI} \
    && cd aws-ofi-nccl \
    && ./autogen.sh \
    && ./configure --with-libfabric=/opt/amazon/efa \
        --with-mpi=/opt/amazon/openmpi \
        --with-cuda=/usr/local/cuda \
        --with-nccl=$CONDA_PREFIX \
    && make \
    && make install \
    && rm -rf /tmp/efa-ofi-nccl
```

```bash
RUN pip install --no-cache-dir -U \
    packaging \
    mpi4py==3.0.3 \
RUN cd /tmp \
    && git clone https://github.com/pytorch/vision.git -b v0.9.1 \
    && cd vision \
    && BUILD_VERSION="0.9.1+cu111" python setup.py install \
    && cd /tmp \
    && rm -rf vision
```

10. Install and configure OpenSSH. OpenSSH is required for MPI to communicate between containers. Allow OpenSSH to talk to containers without asking for confirmation.

```bash
RUN apt-get update \
    && apt-get install -y --allow-downgrades --allow-change-held-packages --no-install-recommends  \
        && apt-get install -y --no-install-recommends openssh-client openssh-server \
    && mkdir -p /var/run/sshd \
    && cat /etc/ssh/ssh_config | grep -v StrictHostKeyChecking > /etc/ssh/ssh_config.new \
    && echo "    StrictHostKeyChecking no" >> /etc/ssh/ssh_config.new \
    && mv /etc/ssh/ssh_config.new /etc/ssh/ssh_config \
    && rm -rf /var/lib/apt/lists/*
    # Configure OpenSSH so that nodes can communicate with each other 
RUN mkdir -p /var/run/sshd && 
    sed 's@session\s*required\s*pam_loginuid.so@session optional pam_loginuid.so@g' -i /etc/pam.d/sshd 
RUN rm -rf /root/.ssh/ && 
    mkdir -p /root/.ssh/ && 
    ssh-keygen -q -t rsa -N '' -f /root/.ssh/id_rsa && 
    cp /root/.ssh/id_rsa.pub /root/.ssh/authorized_keys \
    && printf "Host *
    StrictHostKeyChecking no\n" >> /root/.ssh/config
```

2133
11. Install the PT S3 plug-in to efficiently access datasets in Amazon S3.

```bash
RUN pip install --no-cache-dir -U ${PT_S3_WHL_GPU}
RUN mkdir -p /etc/pki/tls/certs && cp /etc/ssl/certs/ca-certificates.crt /etc/pki/tls/certs/ca-bundle.crt
```

12. Install the `libboost` library. This package is needed for networking the asynchronous IO functionality of the SageMaker data parallel library.

```bash
WORKDIR /
RUN wget https://sourceforge.net/projects/boost/files/boost/1.73.0/boost_1_73_0.tar.gz/ download -O boost_1_73_0.tar.gz \
   && tar -xzf boost_1_73_0.tar.gz \
   && cd boost_1_73_0 \
   && ./bootstrap.sh \
   && ./b2 threading=multi --prefix=${CONDA_PREFIX} -j 64 cxxflags=-fPIC cflags=-fPIC install || true \
   && cd .. \
   && rm -rf boost_1_73_0.tar.gz \
   && rm -rf boost_1_73_0 \
   && cd ${CONDA_PREFIX}/include/boost
```

13. Install the following SageMaker tools for PyTorch training.

```bash
WORKDIR /root
RUN pip install --no-cache-dir -U \
   smclarify \
   "sagemaker>=2,<3" \
   sagemaker-experiments==0.* \
   sagemaker-pytorch-training
```

14. Finally, install the SageMaker data parallel binary and the remaining dependencies.

```bash
RUN --mount=type=cache,id=apt-final,target=/var/cache/apt \
    apt-get update && apt-get install -y --no-install-recommends \
    jq \
    libhwloc-dev \
    libnuma1 \
    libnuma-dev \
    libssl1.1 \
    libtool \
    hwloc \
    && rm -rf /var/lib/apt/lists/*
RUN SMDATAPARALLEL_PT=1 pip install --no-cache-dir ${SMDATAPARALLEL_BINARY}
```

15. After you finish creating the Dockerfile, see Adapting Your Own Training Container to learn how to build the Docker container, host it in Amazon ECR, and run a training job using the SageMaker Python SDK.

The following example code shows a complete Dockerfile after combining all the previous code blocks.

```bash
# This file creates a docker image with minimum dependencies to run SageMaker data parallel training
FROM nvidia/cuda:11.3.1-cudnn8-devel-ubuntu20.04

Tip
For more general information about creating a custom Dockerfile for training in SageMaker, see
Use Your Own Training Algorithms.

Tip
If you want to extend the custom Dockerfile to incorporate the SageMaker model parallel
library, see Create Your Own Docker Container with the SageMaker Distributed Model Parallel
Library (p. 2206).

SageMaker Distributed Data Parallel Configuration Tips and Pitfalls

Review the following tips and pitfalls before using SageMaker's distributed data parallel library. This list includes tips that are applicable across frameworks.

Topics
- Data Preprocessing (p. 2138)
- Single Versus Multiple Nodes (p. 2138)
- Debug Scaling Efficiency with Debugger (p. 2138)
- Batch Size (p. 2139)
- Custom MPI Options (p. 2139)
- Use Amazon FSx and set up an optimal storage and throughput capacity (p. 2139)

Data Preprocessing

If you preprocess data during training using an external library that utilizes the CPU, you may run into a CPU bottleneck because SageMaker distributed data parallel uses the CPU for AllReduce operations. You may be able to improve training time by moving preprocessing steps to a library that uses GPUs or by completing all preprocessing before training.

Single Versus Multiple Nodes

We recommend that you use this library with multiple nodes. The library can be used with a single-host, multi-device setup (for example, a single ML compute instance with multiple GPUs); however, when you use two or more nodes, the library's AllReduce operation gives you significant performance improvement. Also, on a single host, NVLink already contributes to in-node AllReduce efficiency.

Debug Scaling Efficiency with Debugger

You can use Amazon SageMaker Debugger to monitor and visualize CPU and GPU utilization and other metrics of interest during training. You can use Debugger built-in rules to monitor computational
performance issues, such as CPU Bottleneck, Load Balancing, and Low GPU Utilization. You can specify these rules with Debugger configurations when you define an Amazon SageMaker Python SDK estimator. If you use AWS CLI and AWS Boto3 for training on SageMaker, you can enable Debugger as shown in Configure Debugger Using Amazon SageMaker API.

To see an example using Debugger in a SageMaker training job, you can reference one of the notebook examples in the SageMaker Notebook Examples GitHub repository. To learn more about Debugger, see Amazon SageMaker Debugger.

Batch Size

In distributed training, as more nodes are added, batch sizes should increase proportionally. To improve convergence speed as you add more nodes to your training job and increase the global batch size, increase the learning rate.

One way to achieve this is by using a gradual learning rate warmup where the learning rate is ramped up from a small to a large value as the training job progresses. This ramp avoids a sudden increase of the learning rate, allowing healthy convergence at the start of training. For example, you can use a Linear Scaling Rule where each time the mini-batch size is multiplied by k, the learning rate is also multiplied by k. To learn more about this technique, see the research paper, Accurate, Large Minibatch SGD: Training ImageNet in 1 Hour, Sections 2 and 3.

Custom MPI Options

The SageMaker distributed data parallel library employs Message Passing Interface (MPI), a popular standard for managing communication between nodes in a high-performance cluster, and uses NVIDIA's NCCL library for GPU-level communication. When you use the data parallel library with a TensorFlow or PyTorch Estimator, the respective container sets up the MPI environment and executes the mpirun command to start jobs on the cluster nodes.

You can set custom MPI operations using the custom_mpi_options parameter in the Estimator. Any mpirun flags passed in this field are added to the mpirun command and executed by SageMaker for training. For example, you may define the distribution parameter of an Estimator using the following to use the NCCL_DEBUG variable to print the NCCL version at the start of the program:

```
distribution = {'smdistributed':{'dataparallel':{'enabled': True, "custom_mpi_options": "-verbose -x NCCL_DEBUG=VERSION"}}}
```

Use Amazon FSx and set up an optimal storage and throughput capacity

When training a model on multiple nodes with distributed data parallelism, it is highly recommended to use FSx for Lustre. Amazon FSx is a scalable and high-performance storage service that supports shared file storage with a faster throughput. Using Amazon FSx storage at scale, you can achieve a faster data loading speed across the compute nodes.

Typically, with distributed data parallelism, you would expect that the total training throughput scales near-linearly with the number of GPUs. However, if you use suboptimal Amazon FSx storage, the training performance might slow down due to a low Amazon FSx throughput.

For example, if you use the SCRATCH_2 deployment type of Amazon FSx file system with the minimum 1.2 TiB storage capacity, the I/O throughput capacity is 240 MB/s. Amazon FSx storage works in a way that you can assign physical storage devices, and the more devices assigned, the larger throughput you get. The smallest storage increment for the SCRATCH_2 type is 1.2 TiB, and the corresponding throughput gain is 240 MB/s.

Assume that you have a model to train on a 4-node cluster over a 100 GB data set. With a given batch size that's optimized to the cluster, assume that the model can complete one epoch in about 30 seconds.
In this case, the minimum required I/O speed is approximately 3 GB/s (100 GB / 30 s). This is apparently a much higher throughput requirement than 240 MB/s. With such a limited Amazon FSx capacity, scaling your distributed training job up to larger clusters might aggravate I/O bottleneck problems; model training throughput might improve in later epochs as cache builds up, but Amazon FSx throughput can still be a bottleneck.

To alleviate such I/O bottleneck problems, you should increase the Amazon FSx storage size to obtain a higher throughput capacity. Typically, to find an optimal I/O throughput, you may experiment with different Amazon FSx throughput capacities, assigning an equal to or slightly lower throughput than your estimate, until you find that it is sufficient to resolve the I/O bottleneck problems. In case of the aforementioned example, Amazon FSx storage with 2.4 GB/s throughput and 67 GB RAM cache would be sufficient. If the file system has an optimal throughput, the model training throughput should reach maximum either immediately or after the first epoch as cache has built up.

To learn more about how to increase Amazon FSx storage and deployment types, see the following pages in the Amazon FSx for Lustre documentation:

- How to increase storage capacity
- Aggregate file system performance

Amazon SageMaker Data Parallel Library FAQ

Use the following to find answers to commonly asked questions about SageMaker's data parallelism library.

**Q: When using the library, how are the allreduce-supporting CPU instances managed? Do I have to create heterogeneous CPU-GPU clusters, or does the SageMaker service create extra C5s for jobs that use the library?**

The library uses the CPUs available with GPU instances. No additional C5 or CPU instances are launched; if your SageMaker training job is 8-node `ml.p3dn.24xlarge` clusters, only `ml.p3dn.24xlarge` instances are used. No additional instances are provisioned.

**Q: I have a training job taking 5 days on a single `ml.p3.24xlarge` instance with a set of hyperparameters H1 (learning rate, batch size, optimizer, etc). Is using SageMaker's data parallelism library and a five-time bigger cluster enough to achieve an approximate five-time speedup? Or do I have to revisit its training hyperparameters after activating the library?**

The library changes the overall batch size. The new overall batch size is scaled linearly with the number of training instances used. As a result of this, hyperparameters, such as learning rate, have to be changed to ensure convergence.

**Q: Does the library support Spot?**

Yes. You can use managed spot training. You specify the path to the checkpoint file in the SageMaker training job. You save and restore checkpoints in their training script as mentioned in the last steps of the section called "TensorFlow" (p. 2120) and the section called "PyTorch" (p. 2122).

**Q: Is the library relevant in a single-host, multi-device setup?**

The library can be used in single-host multi-device training but the library offers performance improvements only in multi-host training.

**Q: Where should the training dataset be stored?**

The training dataset can be stored in an Amazon S3 bucket or on an Amazon FSx drive. See this document for various supported input file systems for a training job.
Q: When using the library, is it mandatory to have training data in FSx for Lustre? Can Amazon EFS and Amazon S3 be used?

We generally recommend you use Amazon FSx because of its lower latency and higher throughput. If you prefer, you can use Amazon EFS or Amazon S3.

Q: Can the library be used with CPU nodes?

No. The library supports ml.p3.16xlarge, ml.p3dn.24xlarge, and ml.p4d.24xlarge instances at this time.

Q: What frameworks and framework versions are currently supported by the library at launch?

The library currently supports PyTorch v1.6.0 or later and TensorFlow v2.3.0 or later. It doesn't support TensorFlow 1.x. For more information about which version of the library is packaged within AWS deep learning containers, see Release Notes for Deep Learning Containers.

Q: Does the library support AMP?

Yes, SageMaker's distributed data parallelism library supports Automatic Mixed Precision (AMP) out of the box. No extra action is needed to use AMP other than the framework-level modifications to your training script. If gradients are in FP16, the SageMaker data parallelism library runs its AllReduce operation in FP16. For more information about implementing AMP APIs to your training script, see the following resources:

- Frameworks - PyTorch in the NVIDIA Deep Learning Performance documentation
- Frameworks - TensorFlow in the NVIDIA Deep Learning Performance documentation
- Automatic Mixed Precision for Deep Learning in the NVIDIA Developer Docs
- Introducing native PyTorch automatic mixed precision for faster training on NVIDIA GPUs in the PyTorch Blog
- TensorFlow mixed precision APIs in the TensorFlow documentation

Q: How do I identify if my distributed training job is slowed down due to I/O bottleneck?

With a larger cluster, the training job requires more I/O throughput, and therefore the training throughput might take longer (more epochs) to ramp up to the maximum performance. This indicates that I/O is being bottlenecked and cache is harder to build up as you scale nodes up (higher throughput requirement and more complex network topology). For more information about monitoring the Amazon FSx throughput on CloudWatch, see Monitoring FSx for Lustre in the FSx for Lustre User Guide.

Q: How do I resolve I/O bottlenecks when running a distributed training job with data parallelism?

We highly recommend that you use Amazon FSx as your data channel if you are using Amazon S3. If you are already using Amazon FSx but still having I/O bottleneck problems, you might have set up your Amazon FSx file system with a low I/O throughput and a small storage capacity. For more information about how to estimate and choose the right size of I/O throughput capacity, see Use Amazon FSx and set up an optimal storage and throughput capacity (p. 2139).

Q: (For the library v1.4.0 or later) How do I resolve the Invalid backend error while initializing process group.

If you encounter the error message ValueError: Invalid backend: 'smddp' when calling init_process_group, this is due to the breaking change in the library v1.4.0 and later. You must import the PyTorch client of the library, smdistributed.dataparallel.torch.torch_smddp, which registers smddp as a backend for PyTorch. To learn more, see Use the SageMaker Distributed Data Parallel Library as the Backend of torch.distributed (p. 2122).

Q: (For the library v1.4.0 or later) I would like to call the collective primitives of the torch.distributed interface. Which primitives does the smddp backend support?
In v1.4.0, the library supports `all_reduce`, `broadcast`, `reduce`, `all_gather`, and `barrier`.

**Q:** (For the library v1.4.0 or later) Does this new API work with other custom DDP classes or libraries like Apex DDP?

The SageMaker data parallel library is tested with other third-party distributed data parallel libraries and framework implementations that use the `torch.distributed` modules. Using the SageMaker data parallel library with custom DDP classes works as long as the collectives used by the custom DDP classes are supported by the library. See the preceding question for a list of supported collectives. If you have these use cases and need further support, reach out to the SageMaker team through the [AWS Support Center](https://aws.amazon.com/support) or [AWS Developer Forums for Amazon SageMaker](https://aws.amazon.com/sagemaker/developer-forums).

**Q:** Does the library support the bring-your-own-container (BYOC) option? If so, how do I install the library and run a distributed training job by writing a custom Dockerfile?

If you want to integrate the SageMaker data parallel library and its minimum dependencies in your own Docker container, BYOC is the right approach. You can build your own container using the binary file of the library. The recommended process is to write a custom Dockerfile with the library and its dependencies, build the Docker container, host it in Amazon ECR, and use the ECR image URI to launch a training job using the SageMaker generic estimator class. For more instructions on how to prepare a custom Dockerfile for distributed training in SageMaker with the SageMaker data parallel library, see [Create Your Own Docker Container with the SageMaker Distributed Data Parallel Library](https://docs.aws.amazon.com/sagemaker/latest/dg/developing-python-sdk-data-parallelism.html) (p. 2130).

**Data Parallel Troubleshooting**

If you have problems in running a training job when you use the library, use the following list to try to troubleshoot. If you need further support, reach out to the SageMaker team through [AWS Support Center](https://aws.amazon.com/support) or [AWS Developer Forums for Amazon SageMaker](https://aws.amazon.com/sagemaker/developer-forums).

**Topics**
- Using SageMaker Distributed Data Parallel with Amazon SageMaker Debugger and Checkpoints (p. 2142)
- An Unexpected Prefix Attached to Model Parameter Keys (p. 2143)

**Using SageMaker Distributed Data Parallel with Amazon SageMaker Debugger and Checkpoints**

To monitor system bottlenecks, profile framework operations, and debug model output tensors for training jobs with SageMaker distributed data parallel, use Amazon SageMaker Debugger. However, when you use SageMaker Debugger, SageMaker distributed data parallel, and SageMaker checkpoints, you might see an error that looks like the following example.

```
SMDebug Does Not Currently Support Distributed Training Jobs With Checkpointing Enabled
```

This is due to an internal error between Debugger and checkpoints, which occurs when you enable SageMaker distributed data parallel.

- If you enable all three features, SageMaker Python SDK automatically turns off Debugger by passing `debugger_hook_config=False`, which is equivalent to the following framework `estimator` example.
bucket=sagemaker.Session().default_bucket()
base_job_name="sagemaker-checkpoint-test"
checkpoint_in_bucket="checkpoints"

# The S3 URI to store the checkpoints
checkpoint_s3_bucket="s3://{}/{}/{}".format(bucket, base_job_name, checkpoint_in_bucket)
estimator = TensorFlow(  
  distribution={"smdistributed": {"dataparallel": { "enabled": True }},
  checkpoint_s3_uri=checkpoint_s3_bucket,
  checkpoint_local_path="/opt/ml/checkpoints",
  debugger_hook_config=False
}

• If you want to keep using both SageMaker distributed data parallel and SageMaker Debugger, a workaround is manually adding checkpointing functions to your training script instead of specifying the checkpoint_s3_uri and checkpoint_local_path parameters from the estimator.

For more information about setting up manual checkpointing in a training script, see Saving Checkpoints (p. 2220).

An Unexpected Prefix Attached to Model Parameter Keys

For PyTorch distributed training jobs, an unexpected prefix (model for example) might be attached to state_dict keys (model parameters). The SageMaker data parallel library does not directly alter or prepend any model parameter names when PyTorch training jobs save model artifacts. The PyTorch's distributed training changes the names in the state_dict to go over the network, prepending the prefix. If you encounter any model failure problem due to different parameter names while you are using the SageMaker data parallel library and checkpointing for PyTorch training, adapt the following example code to remove the prefix at the step you load checkpoints in your training script.

```
state_dict = {k.partition('model.')[2]:state_dict[k] for k in state_dict.keys()}
```

This takes each state_dict key as a string value, separates the string at the first occurrence of 'model.', and takes the third list item (with index 2) of the partitioned string.

For more information about the prefix issue, see a discussion thread at Prefix parameter names in saved model if trained by multi-GPU? in the PyTorch discussion forum.

For more information about the PyTorch methods for saving and loading models, see Saving & Loading Model Across Devices in the PyTorch documentation.

SageMaker Distributed Training Job Stalling During Initialization

If your SageMaker distributed data parallel training job stalls during initialization when using EFA-enabled instances (ml.p3dn.24xlarge and ml.p4d.24xlarge), this might be due to a misconfiguration in the security group of the VPC subnet that's used for the training job. EFA requires a proper security group configuration to enable traffic between the nodes.

To configure inbound and outbound rules for the security group

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc/
2. Choose Security Groups in the left navigation pane.
3. Select the security group that's tied to the VPC subnet you use for training.
4. In the Details section, copy the Security group ID.
6. On the Edit inbound rules page, do the following:
   a. Choose Add rule.
   b. For Type, choose All traffic.
   c. For Source, choose Custom, paste the security group ID into the search box, and select the security group that pops up.
7. Choose Save rules to finish configuring the inbound rule for the security group.
9. Repeat the step 6 and 7 to add the same rule as an outbound rule.

After you complete the preceding steps for configuring the security group with the inbound and outbound rules, rerun the training job and verify if the stalling issue is resolved.

For more information about configuring security groups for VPC and EFA, see Security groups for your VPC and Elastic Fabric Adapter.

SageMaker Distributed Training Job Stalling at the End of Training

One of the root causes of stalling issues at the end of training is a mismatch in the number of batches that are processed per epoch across different ranks. All workers (GPUs) synchronize their local gradients in the backward pass to ensure they all have the same copy of the model at the end of the batch iteration. If the batch sizes are unevenly assigned to different worker groups during the final epoch of training, the training job stalls. For example, while a group of workers (group A) finishes processing all batches and exits the training loop, another group of workers (group B) starts processing another batch and still expects communication from group A to synchronize the gradients. This causes group B to wait for group A, which already completed training and does not have any gradients to synchronize.

Therefore, when setting up your training dataset, it is important that each worker gets the same number of data samples so that each worker goes through the same number of batches while training. Make sure each rank gets the same number of batches to avoid this stalling issue.

Observing Scaling Efficiency Degradation Due to Amazon FSx Throughput Bottlenecks

One potential cause of lowered scaling efficiency is the FSx throughput limit. If you observe a sudden drop in scaling efficiency when you switch to a larger training cluster, try using a larger FSx for Lustre file system with a higher throughput limit. For more information, see Aggregate file system performance and Managing storage and throughput capacity in the Amazon FSx for Lustre User Guide.

SageMaker Distributed Training Job with PyTorch Returns Deprecation Warnings

Since v1.4.0, the SageMaker distributed data parallelism library works as a backend of PyTorch distributed. Because of the breaking change of using the library with PyTorch, you might encounter a warning message that the smdistributed APIs for the PyTorch distributed package are deprecated. The warning message should be similar to the following:

```
smdistributed.dataparallel.torch.dist is deprecated in the SageMaker distributed data parallel library v1.4.0+.
Please use torch.distributed and specify 'smddp' as a backend when initializing process group as follows:
torch.distributed.init_process_group(backend='smddp')
For more information, see the library's API documentation at https://docs.aws.amazon.com/sagemaker/latest/dg/data-parallel-modify-sdp-tp.html
```
In v1.4.0 and later, the library only needs to be imported once at the top of your training script and set as the backend during the PyTorch distributed initialization. With the single line of backend specification, you can keep your PyTorch training script unchanged and directly use the PyTorch distributed modules. See Modify a PyTorch Training Script (p. 2122) to learn about the breaking changes and the new way to use the library with PyTorch.

**SageMaker's Model Parallelism Library**

Use Amazon SageMaker's model parallel library to train large deep learning (DL) models that are difficult to train due to GPU memory limitations. The library automatically and efficiently splits a model across multiple GPUs and instances. Using the library, you can achieve a target prediction accuracy faster by efficiently training larger DL models with billions or trillions of parameters.

You can use the library to automatically partition your own TensorFlow and PyTorch models across multiple GPUs and multiple nodes with minimal code changes. You can access the library's API through the SageMaker Python SDK.

Use the following sections to learn more about model parallelism and the SageMaker model parallel library. This library's API documentation is located at Distributed Training APIs in the SageMaker Python SDK documentation.

To track the latest updates of the library, see the SageMaker Model Parallel Release Notes in the SageMaker Python SDK documentation.

**Introduction to Model Parallelism**

Model parallelism is a distributed training method in which the deep learning model is partitioned across multiple devices, within or across instances. This introduction page provides a high-level overview about model parallelism, a description of how it can help overcome issues that arise when training DL models that are typically very large in size, and examples of what the SageMaker model parallel library offers to help manage model parallel strategies as well as memory consumption.

**What is Model Parallelism?**

Increasing the size of deep learning models (layers and parameters) yields better accuracy for complex tasks such as computer vision and natural language processing. However, there is a limit to the maximum model size you can fit in the memory of a single GPU. When training DL models, GPU memory limitations can be bottlenecks in the following ways:

- They limit the size of the model you can train, since the memory footprint of a model scales proportionally to the number of parameters.
- They limit the per-GPU batch size during training, driving down GPU utilization and training efficiency.
To overcome the limitations associated with training a model on a single GPU, SageMaker provides the model parallel library to help distribute and train DL models efficiently on multiple compute nodes. Furthermore, with the library, you can achieve most optimized distributed training using EFA-supported devices, which enhance the performance of inter-node communication with low latency, high throughput, and OS bypass.

**Estimate Memory Requirements Before Using Model Parallelism**

Before you use the SageMaker model parallel library, consider the following to get a sense of the memory requirements of training large DL models.

For a training job that uses AMP (FP16) and Adam optimizers, the required GPU memory per parameter is about 20 bytes, which we can break down as follows:

- An FP16 parameter ~ 2 bytes
- An FP16 gradient ~ 2 bytes
- An FP32 optimizer state ~ 8 bytes based on the Adam optimizers
- An FP32 copy of parameter ~ 4 bytes (needed for the optimizer apply (OA) operation)
- An FP32 copy of gradient ~ 4 bytes (needed for the OA operation)

Even for a relatively small DL model with 10 billion parameters, it can require at least 200GB of memory, which is much larger than the typical GPU memory (for example, NVIDIA A100 with 40GB/80GB memory and V100 with 16/32 GB) available on a single GPU. Note that on top of the memory requirements for model and optimizer states, there are other memory consumers such as activations generated in the forward pass. The memory required can be a lot greater than 200GB.

For distributed training, we recommend that you use Amazon EC2 P3 and P4 instances that have NVIDIA V100 and A100 Tensor Core GPUs respectively. For more details about specifications such as CPU cores, RAM, attached storage volume, and network bandwidth, see the Accelerated Computing section in the Amazon EC2 Instance Types page.

Even with the accelerated computing instances, it is obvious that models with about 10 billion parameters such as Megatron-LM and T5 and even larger models with hundreds of billions of parameters such as GPT-3 cannot fit model replicas in each GPU device.

**How the Library Employs Model Parallelism and Memory Saving Techniques**

The library consists of various types of model parallelism features and memory-saving features such as optimizer state sharding, activation checkpointing, and activation offloading. All these techniques can be combined to efficiently train large models that consist of hundreds of billions of parameters.

**Topics**

- Sharded data parallelism (available for PyTorch) (p. 2146)
- Pipeline parallelism (available for PyTorch and TensorFlow) (p. 2147)
- Tensor parallelism (available for PyTorch) (p. 2148)

- Choosing the right techniques for your model (p. 2153)

**Sharded data parallelism (available for PyTorch)**

*Sharded data parallelism* is a memory-saving distributed training technique that splits the state of a model (model parameters, gradients, and optimizer states) across GPUs within a data-parallel group.
SageMaker implements sharded data parallelism through the implementation of MiCS, which is a library that minimizes communication scale and discussed in the blog post [Near-linear scaling of gigantic-model training on AWS](https://aws.amazon.com/blogs/machine-learning/near-linear-scaling-of-gigantic-model-training-on-aws/).

You can apply sharded data parallelism to your model as a stand-alone strategy. Furthermore, if you are using the most performant GPU instances equipped with NVIDIA A100 Tensor Core GPUs, `ml.p4d.24xlarge`, you can take the advantage of improved training speed from the AllGather operation offered by SMDDP Collectives.

To dive deep into sharded data parallelism and learn how to set it up or use a combination of sharded data parallelism with other techniques like tensor parallelism and FP16 training, see the section called “Sharded Data Parallelism” (p. 2157).

**Pipeline parallelism (available for PyTorch and TensorFlow)**

Pipeline parallelism partitions the set of layers or operations across the set of devices, leaving each operation intact. When you specify a value for the number of model partitions (pipeline_parallel_degree), the total number of GPUs (processes_per_host) must be divisible by the number of the model partitions. To set this up properly, you have to specify the correct values for the pipeline_parallel_degree and processes_per_host parameters. The simple math is as follows:

\[
\text{pipeline_parallel_degree} \times \text{data_parallel_degree} = \text{processes_per_host}
\]

The library takes care of calculating the number of model replicas (also called data_parallel_degree) given the two input parameters you provide.

For example, if you set "pipeline_parallel_degree": 2 and "processes_per_host": 8 to use an ML instance with eight GPU workers such as `ml.p3.16xlarge`, the library automatically sets up the distributed model across the GPUs and four-way data parallelism. The following image illustrates how a model is distributed across the eight GPUs achieving four-way data parallelism and two-way pipeline parallelism. Each model replica, where we define it as a pipeline parallel group and label it as PP_GROUP, is partitioned across two GPUs. Each partition of the model is assigned to four GPUs, where the four partition replicas are in a data parallel group and labeled as DP_GROUP. Without tensor parallelism, the pipeline parallel group is essentially the model parallel group.
Tensor parallelism (available for PyTorch)

Tensor parallelism splits individual layers, or nn.Modules, across devices, to be run in parallel. The following figure shows the simplest example of how the library splits a model with four layers to achieve two-way tensor parallelism ("tensor_parallel_degree": 2). The layers of each model replica are bisected and distributed into two GPUs. In this example case, the model parallel configuration also

To dive deep into pipeline parallelism, see Core Features of the SageMaker Model Parallelism Library (p. 2156).

To get started with running your model using pipeline parallelism, see Run a SageMaker Distributed Training Job with the SageMaker Model Parallel Library.
SageMaker's Model Parallelism Library includes "pipeline_parallel_degree": 1 and "ddp": True (uses PyTorch DistributedDataParallel package in the background), so the degree of data parallelism becomes eight. The library manages communication across the tensor-distributed model replicas.
The usefulness of this feature is in the fact that you can select specific layers or a subset of layers to apply tensor parallelism. To dive deep into tensor parallelism and other memory-saving features for PyTorch, and to learn how to set a combination of pipeline and tensor parallelism, see Tensor Parallelism (p. 2171).

**Optimizer state sharding (available for PyTorch)**

To understand how the library performs optimizer state sharding, consider a simple example model with four layers. The key idea in optimizing state sharding is you don't need to replicate your optimizer state in all of your GPUs. Instead, a single replica of the optimizer state is sharded across data-parallel ranks, with no redundancy across devices. For example, GPU 0 holds the optimizer state for layer one, the next GPU 1 holds the optimizer state for L2, and so on. The following animated figure shows a backward propagation with the optimizer state sharding technique. At the end of the backward propagation, there's compute and network time for the optimizer apply (OA) operation to update optimizer states and the all-gather (AG) operation to update the model parameters for the next iteration. Most importantly, the reduce operation can overlap with the compute on GPU 0, resulting in a more memory-efficient and faster backward propagation. In the current implementation, AG and OA operations do not overlap with compute. It can result in an extended computation during the AG operation, so there might be a tradeoff.
Sample model with:

Optimizer State for L1

L1  L2  L3  L4

GPU 0
For more information about how to use this feature, see Optimizer State Sharding.

Activation offloading and checkpointing (available for PyTorch)

To save GPU memory, the library supports activation checkpointing to avoid storing internal activations in the GPU memory for user-specified modules during the forward pass. The library recomputes these activations during the backward pass. In addition, the activation offloading feature offloads the stored activations to CPU memory and fetches back to GPU during the backward pass to further reduce activation memory footprint. For more information about how to use these features, see Activation Checkpointing and Activation Offloading.

Choosing the right techniques for your model

For more information about choosing the right techniques and configurations, see SageMaker Distributed Model Parallel Best Practices and Configuration Tips and Pitfalls.

Supported Frameworks and AWS Regions

Before using the SageMaker model parallelism library, check the supported frameworks and instance types, and determine if there are enough quotas in your AWS account and AWS Region.

Note
To check the latest updates and release notes of the library, see the SageMaker Model Parallel Release Notes in the SageMaker Python SDK documentation.

Supported Frameworks

The SageMaker model parallelism library supports the following deep learning frameworks and is available in AWS Deep Learning Containers (DLC) or downloadable as a binary file.

PyTorch versions supported by SageMaker and the SageMaker model parallelism library

**Hugging Face Transformers versions supported by SageMaker and the SageMaker distributed data parallel library**

The AWS Deep Learning Containers for Hugging Face use the SageMaker Training Containers for PyTorch and TensorFlow as their base images. To look up the Hugging Face Transformers library versions and paired PyTorch and TensorFlow versions, see the latest Hugging Face Containers and the Prior Hugging Face Container Versions.

**AWS Regions**

The SageMaker data parallel library is available in all of the AWS Regions where the AWS Deep Learning Containers for SageMaker are in service. For more information, see Available Deep Learning Containers Images.

**Supported Instance Types**

The SageMaker model parallelism library requires one of the following ML instance types.

<table>
<thead>
<tr>
<th>Instance type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ml.g4dn.12xlarge</td>
</tr>
<tr>
<td>ml.p3.16xlarge</td>
</tr>
<tr>

</tr>
<tr>
<td>ml.p4de.24xlarge</td>
</tr>
</tbody>
</table>

For specs of the instance types, see the Accelerated Computing section in the Amazon EC2 Instance Types page. For information about instance pricing, see Amazon SageMaker Pricing.
If you encountered an error message similar to the following, follow the instructions at Request a service quota increase for SageMaker resources.

ResourceLimitExceeded: An error occurred (ResourceLimitExceeded) when calling the CreateTrainingJob operation: The account-level service limit 'ml.p3dn.24xlarge for training job usage' is 0 Instances, with current utilization of 0 Instances and a request delta of 1 Instances. Please contact AWS support to request an increase for this limit.

Core Features of the SageMaker Model Parallelism Library

Amazon SageMaker's model parallelism library offers distribution strategies and memory-saving techniques, such as sharded data parallelism, tensor parallelism, model partitioning by layers for pipeline scheduling, and checkpointing. The model parallelism strategies and techniques help distribute large models across multiple devices while optimizing training speed and memory consumption. The library also provides Python helper functions, context managers, and wrapper functions to adapt your training script for automated or manual partitioning of your model.

When you implement model parallelism to your training job, you keep the same two-step workflow shown in the Run a SageMaker Distributed Training Job with Model Parallelism section. For adapting your training script, you'll add zero or few additional code lines to your training script. For launching a training job of the adapted training script, you'll need to set the distribution configuration parameters to activate the memory-saving features or to pass values for the degree of parallelism.

To get started with examples, see the following Jupyter notebooks that demonstrate how to use the SageMaker model parallelism library.

- PyTorch example notebooks
- TensorFlow example notebooks

To dive deep into the core features of the library, see the following topics.

Note
The SageMaker distributed training libraries are available through the AWS deep learning containers for PyTorch, Hugging Face, and TensorFlow within the SageMaker Training platform. To utilize the features of the distributed training libraries, we recommend that you use the SageMaker Python SDK. You can also manually configure in JSON request syntax if you use SageMaker APIs through SDK for Python (Boto3) or AWS Command Line Interface. Throughout the documentation, instructions and examples focus on how to use the distributed training libraries with the SageMaker Python SDK.

Important
The SageMaker model parallelism library supports all the core features for PyTorch, and supports pipeline parallelism for TensorFlow.

Sharded Data Parallelism

*Sharded data parallelism* is a memory-saving distributed training technique that splits the state of a model (model parameters, gradients, and optimizer states) across GPUs in a data parallel group.

**Note**

Sharded data parallelism is available for PyTorch in the SageMaker model parallelism library v1.11.0 and later.

When scaling up your training job to a large GPU cluster, you can reduce the per-GPU memory footprint of the model by sharding the training state of the model over multiple GPUs. This returns two benefits: you can fit larger models, which would otherwise run out of memory with standard data parallelism, or you can increase the batch size using the freed-up GPU memory.

The standard data parallelism technique replicates the training states across the GPUs in the data parallel group, and performs gradient aggregation based on the `AllReduce` operation. Sharded data parallelism modifies the standard data-parallel distributed training procedure to account for the sharded nature of the optimizer states. A group of ranks over which the model and optimizer states are sharded is called a *sharding group*. The sharded data parallelism technique shards the trainable parameters of a model and corresponding gradients and optimizer states across the GPUs in the *sharding group*.

SageMaker achieves sharded data parallelism through the implementation of MiCS, which is discussed in the AWS blog post [*Near-linear scaling of gigantic-model training on AWS*](https://aws.amazon.com/blogs/machine-learning/near-linear-scaling-of-gigantic-model-training-on-aws/). In this implementation, you can set the sharding degree as a configurable parameter, which must be less than the data parallelism degree. During each forward and backward pass, MiCS temporarily recombines the model parameters in all GPUs through the `AllGather` operation. After the forward or backward pass of each layer, MiCS shards the parameters again to save GPU memory. During the backward pass, MiCS reduces gradients and simultaneously shards them across GPUs through the `ReduceScatter` operation. Finally, MiCS applies the local reduced and sharded gradients to their corresponding local parameter shards, using the local shards of optimizer states. To bring down communication overhead, the SageMaker model parallelism library prefetches the upcoming layers in the forward or backward pass, and overlaps the network communication with the computation.

The training state of the model is replicated across the sharding groups. This means that before gradients are applied to the parameters, the `AllReduce` operation must take place across the sharding groups, in addition to the `ReduceScatter` operation that takes place within the sharding group.

In effect, sharded data parallelism introduces a tradeoff between the communication overhead and GPU memory efficiency. Using sharded data parallelism increases the communication cost, but the memory footprint per GPU (excluding the memory usage due to activations) is divided by the sharded data parallelism degree, thus larger models can be fit in the GPU cluster.

**Selecting the degree of sharded data parallelism**

When you select a value for the degree of sharded data parallelism, the value must evenly divide the degree of data parallelism. For example, for an 8-way data parallelism job, choose 2, 4, or 8 for the sharded data parallelism degree. While choosing the sharded data parallelism degree, we recommend that you start with a small number, and gradually increase it until the model fits in the memory together with the desired batch size.

**Selecting the batch size**

After setting up sharded data parallelism, make sure you find the most optimal training configuration that can successfully run on the GPU cluster. For training large language models (LLM), start from the batch size 1, and gradually increase it until you reach the point to receive the out-of-memory (OOM) error. If you encounter the OOM error even with the smallest batch size, apply a higher degree of sharded data parallelism or a combination of sharded data parallelism and tensor parallelism.

**Topics**
How to apply sharded data parallelism to your training job

To get started with sharded data parallelism, apply required modifications to your training script, and set up the SageMaker PyTorch estimator with the sharded-data-parallelism-specific parameters. Also consider to take reference values and example notebooks as a starting point.

Adapt your PyTorch training script

Follow the instructions at Step 1: Modify a PyTorch Training Script (p. 2196) to wrap the model and optimizer objects with the smdistributed.modelparallel.torch wrappers of the torch.nn.parallel and torch.distributed modules.

(Optional) Additional modification to register external model parameters

If your model is built with torch.nn.Module and uses parameters that is not defined within the module class, you should register them to the module manually for SMP to gather the full parameters while. To register parameters to a module, use smp.register_parameter(module, parameter).

```python
class Module(torch.nn.Module):
    def __init__(self, *args):
        super().__init__(self, *args)
        self.layer1 = Layer1()
        self.layer2 = Layer2()
        smp.register_parameter(self, self.layer1.weight)

    def forward(self, input):
        x = self.layer1(input)
        # self.layer1.weight is required by self.layer2.forward
        y = self.layer2(x, self.layer1.weight)
        return y
```

Set up the SageMaker PyTorch estimator

When configuring a SageMaker PyTorch estimator in the section called "Step 2: Launch a Training Job" (p. 2202), add the parameters for sharded data parallelism.

To turn on sharded data parallelism, add the sharded_data_parallel_degree parameter to the SageMaker PyTorch Estimator. This parameter specifies the number of GPUs over which the training state is sharded. The value for sharded_data_parallel_degree must be an integer between one and the data parallelism degree and must evenly divide the data parallelism degree. Note that the library automatically detects the number of GPUs so thus the data parallel degree. The following additional parameters are available for configuring sharded data parallelism.

- "sdp_reduce_bucket_size" (int, default: 5e8) – Specifies the size of PyTorch DDP gradient buckets in number of elements of the default dtype.
- "sdp_param_persistence_threshold" (int, default: 1e6) – Specifies the size of a parameter tensor in number of elements that can persist at each GPU. Sharded data parallelism splits each parameter tensor across GPUs of a data parallel group. If the number of elements in the parameter tensor is smaller than this threshold, the parameter tensor is not split; this helps reduce communication overhead because the parameter tensor is replicated across data-parallel GPUs.
• "sdp_max_live_parameters" (int, default: 1e9) – Specifies the maximum number of parameters that can simultaneously be in a recombined training state during the forward and backward pass. Parameter fetching with the AllGather operation pauses when the number of active parameters reaches the given threshold. Note that increasing this parameter increases the memory footprint.

• "sdp_hierarchical_allgather" (bool, default: True) – If set to True, the AllGather operation runs hierarchically: it runs within each node first, and then runs across nodes. For multi-node distributed training jobs, the hierarchical AllGather operation is automatically activated.

• "sdp_gradient_clipping" (float, default: 1.0) – Specifies a threshold for gradient clipping the L2 norm of the gradients before propagating them backward through the model parameters. When sharded data parallelism is activated, gradient clipping is also activated. The default threshold is 1.0. Adjust this parameter if you have the exploding gradients problem.

The following code shows an example of how to configure sharded data parallelism.

```python
import sagemaker
from sagemaker.pytorch import PyTorch

smp_options = {
    "enabled": True,
    "parameters": {
        "sharded_data_parallel_degree": 2,  # Add this to activate sharded data parallelism
        "sdp_reduce_bucket_size": int(5e8),  # Optional
        "sdp_param_persistence_threshold": int(1e6),  # Optional
        "sdp_max_live_parameters": int(1e9),  # Optional
        "sdp_hierarchical_allgather": True,  # Optional
        "sdp_gradient_clipping": 1.0  # Optional
    }
}

mpi_options = {
    "enabled" : True,                      # Required
    "processes_per_host" : 8               # Required
}

smp_estimator = PyTorch(
    entry_point="your_training_script.py",  # Specify your train script
    role=sagemaker.get_execution_role(),
    instance_count=1,
    instance_type='ml.p3.16xlarge',
    framework_version='1.13.1',
    py_version='py3',
    distribution={
        "smdistributed": {"modelparallel": smp_options},
        "mpi": mpi_options
    },
    base_job_name="sharded-data-parallel-job"
)

smp_estimator.fit('s3://my_bucket/my_training_data/')
```

Reference configurations

The SageMaker distributed training team provides the following reference configurations that you can use as a starting point. You can extrapolate from the following configurations to experiment and estimate the GPU memory usage for your model configuration.
Sharded data parallelism with SMDDP Collectives

<table>
<thead>
<tr>
<th>Model/the number of parameters</th>
<th>Num instances</th>
<th>Instance type</th>
<th>Sequence length</th>
<th>Global batch size</th>
<th>Mini batch size</th>
<th>Sharded data parallel degree</th>
</tr>
</thead>
<tbody>
<tr>
<td>GPT-NEOX-20B</td>
<td>2</td>
<td>ml.p4d.24xlarge048</td>
<td>64</td>
<td>4</td>
<td>16</td>
<td></td>
</tr>
<tr>
<td>GPT-NEOX-20B</td>
<td>8</td>
<td>ml.p4d.24xlarge048</td>
<td>768</td>
<td>12</td>
<td>32</td>
<td></td>
</tr>
</tbody>
</table>

For example, if you increase the sequence length for a 20-billion-parameter model or increase the size of the model to 65 billion parameters, you need to try reducing the batch size first. If the model still doesn’t fit with the smallest batch size (the batch size of 1), try increasing the degree of model parallelism.

The combined usage of sharded data parallelism and tensor parallelism is useful when you want to fit a large language model (LLM) into a large-scale cluster while using text data with a longer sequence length, which leads to using a smaller batch size, and consequently handling the GPU memory usage to train LLMs against longer text sequences. To learn more, see the section called “Sharded data parallelism with tensor parallelism” (p. 2164).

For case studies, benchmarks, and more configuration examples, see the blog post New performance improvements in Amazon SageMaker model parallel library.

Sharded data parallelism with SMDDP Collectives

The SageMaker data parallelism library offers collective communication primitives (SMDDP collectives) optimized for the AWS infrastructure. It achieves optimization by adopting an all-to-all-type communication pattern by making use of Elastic Fabric Adapter (EFA), resulting in high-throughput and less latency-sensitive collectives, offloading the communication-related processing to the CPU, and freeing up GPU cycles for computation. On large clusters, SMDDP Collectives can offer improvements in distributed training performance by up to 40% compared to NCCL. For case studies and benchmark results, see the blog New performance improvements in the Amazon SageMaker model parallelism library.

Note

Sharded data parallelism with SMDDP Collectives is available in the SageMaker model parallelism library v1.13.0 and later, and the SageMaker data parallelism library v1.6.0 and later. See also Supported configurations (p. 2161) to use sharded data parallelism with SMDDP Collectives.
In sharded data parallelism, which is a commonly used technique in large-scale distributed training, the AllGather collective is used to reconstitute the sharded layer parameters for forward and backward pass computations, in parallel with GPU computation. For large models, performing the AllGather operation efficiently is critical to avoid GPU bottleneck problems and slowing down training speed. When sharded data parallelism is activated, SMDDP Collectives drops into these performance-critical AllGather collectives, improving training throughput.

**Train with SMDDP Collectives**

When your training job has sharded data parallelism activated and meets the Supported configurations (p. 2161), SMDDP Collectives are automatically activated. Internally, SMDDP Collectives optimize the AllGather collective to be performant on the AWS infrastructure and falls back to NCCL for all other collectives. Furthermore, under unsupported configurations, all collectives, including AllGather, automatically use the NCCL backend.

Since the SageMaker model parallelism library version 1.13.0, the "ddp_dist_backend" parameter is added to the modelparallel options. The default value for this configuration parameter is "auto", which uses SMDDP Collectives whenever possible, and falls back to NCCL otherwise. To force the library to always use NCCL, specify "nccl" to the "ddp_dist_backend" configuration parameter.

The following code example shows how to set up a PyTorch estimator using the sharded data parallelism with the "ddp_dist_backend" parameter, which is set to "auto" by default and, therefore, optional to add.

```python
import sagemaker
from sagemaker.pytorch import PyTorch

smp_options = {
    "enabled":True,
    "parameters": {
        "partitions": 1,
        "ddp": True,
        "sharded_data_parallel_degree": 64
        "bf16": True,
        "ddp_dist_backend": "auto"  # Specify "nccl" to force to use NCCL.
    }
}

mpi_options = {
    "enabled" : True,                      # Required
    "processes_per_host" : 8               # Required
}

smd_mp_estimator = PyTorch(
    entry_point="your_training_script.py", # Specify your train script
    source_dir="location_to_your_script",
    role=sagemaker.get_execution_role(),
    instance_count=8,
    instance_type='ml.p4d.24xlarge',
    framework_version='1.13.1',
    py_version='py3',
    distribution={
        "smdistributed": {"modelparallel": smp_options},
        "mpi": mpi_options
    },
    base_job_name="sharded-data-parallel-demo",
)

smd_mp_estimator.fit('s3://my_bucket/my_training_data/')
```

**Supported configurations**
The `AllGather` operation with SMDDP Collectives are activated in training jobs when all the following configuration requirements are met.

- The sharded data parallelism degree greater than 1
- `Instance_count` greater than 1
- `Instance_type` equal to `ml.p4d.24xlarge`
- SageMaker training container for PyTorch v1.12.1 or later
- The SageMaker data parallelism library v1.6.0 or later
- The SageMaker model parallelism library v1.13.0 or later

**Performance and memory tuning**

SMDDP Collectives utilize additional GPU memory. There are two environment variables to configure the GPU memory usage depending on different model training use cases.

- `SMDDP_AG_SCRATCH_BUFFER_SIZE_BYTES` – During the SMDDP `AllGather` operation, the `AllGather` input buffer is copied into a temporary buffer for inter-node communication. The `SMDDP_AG_SCRATCH_BUFFER_SIZE_BYTES` variable controls the size (in bytes) of this temporary buffer. If the size of the temporary buffer is smaller than the `AllGather` input buffer size, the `AllGather` collective falls back to use NCCL.
  - Default value: 16 * 1024 * 1024 (16 MB)
  - Acceptable values: any multiple of 8192

- `SMDDP_AG_SORT_BUFFER_SIZE_BYTES` – The `SMDDP_AG_SORT_BUFFER_SIZE_BYTES` variable is to size the temporary buffer (in bytes) to hold data gathered from inter-node communication. If the size of this temporary buffer is smaller than `1/8 * sharded_data_parallel_degree * AllGather input size`, the `AllGather` collective falls back to use NCCL.
  - Default value: 128 * 1024 * 1024 (128 MB)
  - Acceptable values: any multiple of 8192

**Tuning guidance on the buffer size variables**

The default values for the environment variables should work well for most use cases. We recommend tuning these variables only if training runs into the out-of-memory (OOM) error.

The following list discusses some tuning tips to reduce the GPU memory footprint of SMDDP Collectives while retaining the performance gain from them.

- Tuning `SMDDP_AG_SCRATCH_BUFFER_SIZE_BYTES`
  - The `AllGather` input buffer size is smaller for smaller models. Hence, the required size for `SMDDP_AG_SCRATCH_BUFFER_SIZE_BYTES` can be smaller for models with fewer parameters.
  - The `AllGather` input buffer size decreases as `sharded_data_parallel_degree` increases, because the model gets sharded across more GPUs. Hence, the required size for `SMDDP_AG_SCRATCH_BUFFER_SIZE_BYTES` can be smaller for training jobs with large values for `sharded_data_parallel_degree`.

- Tuning `SMDDP_AG_SORT_BUFFER_SIZE_BYTES`
  - The amount of data gathered from inter-node communication is less for models with fewer parameters. Hence, the required size for `SMDDP_AG_SORT_BUFFER_SIZE_BYTES` can be smaller for such models with fewer number of parameters.

Some collectives might fall back to use NCCL; hence, you might not get the performance gain from the optimized SMDDP collectives. If additional GPU memory is available for use, you can consider increasing
the values of SMDDP_AG_SCRATCH_BUFFER_SIZE_BYTES and SMDDP_AG_SORT_BUFFER_SIZE_BYTES to benefit from the performance gain.

The following code shows how you can configure the environment variables by appending them to mpi_options in the distribution parameter for the PyTorch estimator.

```python
import sagemaker
from sagemaker.pytorch import PyTorch

smp_options = {
    .... # All modelparallel configuration options go here
}

mpi_options = {
    "enabled": True,                      # Required
    "processes_per_host": 8               # Required
}

# Use the following two lines to tune values of the environment variables for buffer
mpioptions += " -x SMDDP_AG_SCRATCH_BUFFER_SIZE_BYTES=8192"
mpioptions += " -x SMDDP_AG_SORT_BUFFER_SIZE_BYTES=8192"

smd_mp_estimator = PyTorch(
    entry_point="your_training_script.py", # Specify your train script
    source_dir="location_to_your_script",
    role=sagemaker.get_execution_role(),
    instance_count=8,
    instance_type='ml.p4d.24xlarge',
    framework_version='1.13.1',
    py_version='py3',
    distribution={
        "smdistributed": {"modelparallel": smp_options},
        "mpi": mpi_options
    },
    base_job_name="sharded-data-parallel-demo-with-tuning",
)

smd_mp_estimator.fit('s3://my_bucket/my_training_data/')
```

Mixed precision training with sharded data parallelism

To further save GPU memory with half-precision floating point numbers and sharded data parallelism, you can activate 16-bit floating point format (FP16) or Brain floating point format (BF16) by adding one additional parameter to the distributed training configuration.

**Note**
Mixed precision training with sharded data parallelism is available in the SageMaker model parallelism library v1.11.0 and later.

For FP16 Training with Sharded Data Parallelism

To run FP16 training with sharded data parallelism, add "fp16": True to the smp_options configuration dictionary. In your training script, you can choose between the static and dynamic loss scaling options through the smp.DistributedOptimizer module. For more information, see the section called “FP16 Training with Model Parallelism” (p. 2185).

```python
smp_options = {
    "enabled": True,
    "parameters": {
        "ddp": True,
        "sharded_data_parallel_degree": 2,
    }
}
```
"fp16": True
}
}

For BF16 Training with Sharded Data Parallelism

The sharded data parallelism feature of SageMaker supports training in BF16 data type. The BF16 data type uses 8 bits to represent the exponent of a floating point number, while the FP16 data type uses 5 bits. Preserving the 8 bits for the exponent allows to keep the same representation of the exponent of a 32-bit single precision floating point (FP32) number. This makes the conversion between FP32 and BF16 simpler and significantly less prone to cause overflow and underflow issues that arise often in FP16 training, especially when training larger models. While both data types use 16 bits in total, this increased representation range for the exponent in the BF16 format comes at the expense of reduced precision. For training large models, this reduced precision is often considered an acceptable trade-off for the range and training stability.

**Note**
Currently, BF16 training works only when sharded data parallelism is activated.

To run BF16 training with sharded data parallelism, add "bf16": True to the `smp_options` configuration dictionary.

```python
smp_options = {
    "enabled": True,
    "parameters": {
        "ddp": True,
        "sharded_data_parallel_degree": 2,
        "bf16": True
    }
}
```

Sharded data parallelism with tensor parallelism

If you use sharded data parallelism and also need to reduce the global batch size, consider using tensor parallelism with sharded data parallelism. When training a large model with sharded data parallelism on a very large compute cluster (typically 128 nodes or beyond), even a small batch size per GPU results in a very large global batch size. It might lead to convergence issues or low computational performance issues. Reducing the batch size per GPU sometimes is not possible with sharded data parallelism alone when a single batch is already large and cannot be reduced further. In such cases, using sharded data parallelism in combination with tensor parallelism helps reduce the global batch size.

Choosing the optimal sharded data parallel and tensor parallel degrees depends on the scale of the model, the instance type, and the global batch size that is reasonable for the model to converge. We recommend that you start from a low tensor parallel degree to fit the global batch size into the compute cluster to resolve CUDA out-of-memory errors and achieve the best performance. See the following two example cases to learn how the combination of tensor parallelism and sharded data parallelism helps you adjust the global batch size by grouping GPUs for model parallelism, resulting in a lower number of model replicas and a smaller global batch size.

**Note**
This feature is available from the SageMaker model parallelism library v1.15, and supports PyTorch v1.13.1.

**Note**
This feature is available for the supported models by the tensor parallelism functionality of the library. To find the list of the supported models, see [Support for Hugging Face Transformer Models](#). Also note that you need to pass `tensor.parallelism=True` to the `smp.model_creation` argument while modifying your training script. To learn more, see the training script `train_gpt_simple.py` in the [SageMaker Examples GitHub repository](#).
Example 1

Assume that we want to train a model over a cluster of 1536 GPUs (192 nodes with 8 GPUs in each), setting the degree of sharded data parallelism to 32 (sharded_data_parallel_degree=32) and the batch size per GPU to 1, where each batch has a sequence length of 4096 tokens. In this case, there are 1536 model replicas, the global batch size becomes 1536, and each global batch contains about 6 million tokens.

$$\text{(1536 GPUs)} \times (1 \text{ batch per GPU}) = (1536 \text{ global batches})$$
$$\text{(1536 batches)} \times (4096 \text{ tokens per batch}) = (6,291,456 \text{ tokens})$$

Adding tensor parallelism to it can lower the global batch size. One configuration example can be setting the tensor parallel degree to 8 and the batch size per GPU to 4. This forms 192 tensor parallel groups or 192 model replicas, where each model replica is distributed across 8 GPUs. The batch size of 4 is the amount of training data per iteration and per tensor parallel group; that is, each model replica consumes 4 batches per iteration. In this case, the global batch size becomes 768, and each global batch contains about 3 million tokens. Hence, the global batch size is reduced by half compared to the previous case with sharded data parallelism only.

$$\text{(1536 GPUs)} / (8 \text{ tensor parallel degree}) = (192 \text{ tensor parallelism groups})$$
$$\text{(192 tensor parallelism groups)} \times (4 \text{ batches per tensor parallelism group}) = (768 \text{ global batches})$$
$$\text{(768 batches)} \times (4096 \text{ tokens per batch}) = (3,145,728 \text{ tokens})$$

Example 2

When both sharded data parallelism and tensor parallelism are activated, the library first applies tensor parallelism and shards the model across this dimension. For each tensor parallel rank, the data parallelism is applied as per sharded_data_parallel_degree.

For example, assume that we want to set 32 GPUs with a tensor parallel degree of 4 (forming groups of 4 GPUs), a sharded data parallel degree of 4, ending up with a replication degree of 2. The assignment creates eight GPU groups based on the tensor parallel degree as follows:

$$\text{(0, 1, 2, 3), (4, 5, 6, 7), (8, 9, 10, 11), (12, 13, 14, 15), (16, 17, 18, 19), (20, 21, 22, 23), (24, 25, 26, 27), (28, 29, 30, 31).}$$

That is, four GPUs form one tensor parallel group. In this case, the reduced data parallel group for the 0th rank GPUs of the tensor parallel groups would be $$\text{(0, 4, 8, 12, 16, 20, 24, 28).}$$ The reduced data parallel group is shards based on the sharded data parallel degree of 4, resulting in two replication groups for data parallelism. GPUs $$\text{(0, 4, 8, 12)}$$ form one sharding group, which collectively hold a complete copy of all parameters for the 0th tensor parallel rank, and GPUs $$\text{(16, 20, 24, 28)}$$ form another such group. Other tensor parallel ranks also have similar sharding and replication groups.

![Figure 1: Tensor parallelism groups for (nodes, sharded data parallel degree, tensor parallel degree) = (4, 4, 4), where each rectangle represents a GPU with indices from 0 to 31. The GPUs form tensor parallelism](image_url)
groups from TPG\textsubscript{0} to TPG\textsubscript{7}. Replication groups are \{(TPG\textsubscript{0}, TPG\textsubscript{4}), \{TPG\textsubscript{1}, TPG\textsubscript{5}\}, \{TPG\textsubscript{2}, TPG\textsubscript{6}\} and \{TPG\textsubscript{3}, TPG\textsubscript{7}\}); each replication group pair shares the same color but filled differently.

Figure 2: Sharded data parallelism groups for (nodes, sharded data parallel degree, tensor parallel degree) = (4, 4, 4), where each rectangle represents a GPU with indices from 0 to 31. The GPUs form sharded data parallelism groups from SDPG\textsubscript{0} to SDPG\textsubscript{7}. Replication groups are \{(SDPG\textsubscript{0}, SDPG\textsubscript{4}), \{SDPG\textsubscript{1}, SDPG\textsubscript{5}\}, \{SDPG\textsubscript{2}, SDPG\textsubscript{6}\} and \{SDPG\textsubscript{3}, SDPG\textsubscript{7}\}); each replication group pair shares the same color but filled differently.

**How to activate sharded data parallelism with tensor parallelism**

To use sharded data parallelism with tensor parallelism, you need to set both `sharded_data_parallel_degree` and `tensor_parallel_degree` in the configuration for distribution while creating an object of the SageMaker PyTorch estimator class.

You also need to activate `prescaled_batch`. This means that, instead of each GPU reading its own batch of data, each tensor parallel group collectively reads a combined batch of the chosen batch size. Effectively, instead of dividing the dataset into parts equal to the number of GPUs (or data parallel size, `smp.dp_size()`), it divides into parts equal to the number of GPUs divided by `tensor_parallel_degree` (also called reduced data parallel size, `smp.rdp_size()`). For more details on prescaled batch, see Prescaled Batch in the *SageMaker Python SDK documentation*. See also the example training script `train_gpt_simple.py` for GPT-2 in the *SageMaker Examples GitHub repository*.

The following code snippet shows an example of creating a PyTorch estimator object based on the aforementioned scenario in the section called "Example 2" (p. 2165).

```python
mpi_options = "-verbose --mca orte_base_help_aggregate 0 ">
smp_parameters = {
    "ddp": True,
    "fp16": True,
    "prescaled_batch": True,
    "sharded_data_parallel_degree": 4,
    "tensor_parallel_degree": 4
}

pytorch_estimator = PyTorch(
    entry_point="your_training_script.py",
    role=role,
    instance_type="ml.p4d.24xlarge",
    volume_size=200,
    instance_count=4,
    sagemaker_session=sagemaker_session,
    py_version="py3",
    framework_version="1.13.1",
    distribution=
    "smdistributed": {
        "modelparallel": {
```
Tips and considerations for using sharded data parallelism

Consider the following when using the SageMaker model parallelism library's sharded data parallelism.

- Sharded data parallelism is compatible with FP16 training. To run FP16 training, see the section called “FP16 Training with Model Parallelism” (p. 2185) section.
- Sharded data parallelism is compatible with tensor parallelism. The following items are what you might need to consider for using sharded data parallelism with tensor parallelism.
  - When using sharded data parallelism with tensor parallelism, the embedding layers are also automatically distributed across the tensor parallel group. In other words, the distribute_embedding parameter is automatically set to True. For more information about tensor parallelism, see the section called “Tensor Parallelism” (p. 2171).
  - Note that sharded data parallelism with tensor parallelism currently uses the NCCL collectives as the backend of the distributed training strategy.
- Sharded data parallelism currently is not compatible with pipeline parallelism (p. 2147) or optimizer state sharding (p. 2182). To activate sharded data parallelism, turn off optimizer state sharding and set the pipeline parallel degree to 1.
- The activation checkpointing (p. 2183) and activation offloading (p. 2184) features are compatible with sharded data parallelism.
- To use sharded data parallelism with gradient accumulation, set the backward_passes_per_step argument to the number of accumulation steps while wrapping your model with the smdistributed.modelparallel.torch.DistributedModel module. This ensures that the gradient AllReduce operation across the model replication groups (sharding groups) takes place at the boundary of gradient accumulation.
- You can checkpoint your models trained with sharded data parallelism using the library's checkpointing APIs, smp.save_checkpoint and smp.resume_from_checkpoint. For more information, see the section called “Checkpointing a distributed PyTorch model (for the SageMaker model parallelism library v1.10.0 and later)” (p. 2208).
- The behavior of the delayed_parameter_initialization configuration parameter changes under sharded data parallelism. When these two features are simultaneously turned on, parameters are immediately initialized upon model creation in a sharded manner instead of delaying the parameter initialization, so that each rank initializes and stores its own shard of parameters.
- When sharded data parallelism is activated, the library performs gradient clipping internally when the optimizer.step() call runs. You don't need to use utility APIs for gradient clipping, such as torch.nn.utils.clip_grad_norm(). To adjust the threshold value for gradient clipping, you can set it through the sdp_gradient_clipping parameter for the distribution parameter configuration when you construct the SageMaker PyTorch estimator, as shown in the section called “How to apply sharded data parallelism to your training job” (p. 2158) section.
Pipelining a Model

One of the core features of SageMaker's model parallelism library is **pipeline parallelism**, which determines the order in which computations are made and data is processed across devices during model training. Pipelining is a technique to achieve true parallelization in model parallelism, by having the GPUs compute simultaneously on different data samples, and to overcome the performance loss due to sequential computation. When you use pipeline parallelism, training job is executed in a pipelined fashion over microbatches to maximize GPU usage.

**Note**

Pipeline parallelism, also called model partitioning, is available for both PyTorch and TensorFlow. For supported versions of the frameworks, see the section called “Supported Frameworks and AWS Regions” (p. 2153).

Pipeline Execution Schedule

Pipelining is based on splitting a mini-batch into microbatches, which are fed into the training pipeline one-by-one and follow an execution schedule defined by the library runtime. A **microbatch** is a smaller subset of a given training mini-batch. The pipeline schedule determines which microbatch is executed by which device for every time slot.

For example, depending on the pipeline schedule and the model partition, GPU i might perform (forward or backward) computation on microbatch b while GPU i+1 performs computation on microbatch b+1, thereby keeping both GPUs active at the same time. During a single forward or backward pass, execution flow for a single microbatch might visit the same device multiple times, depending on the partitioning decision. For instance, an operation that is at the beginning of the model might be placed on the same device as an operation at the end of the model, while the operations in between are on different devices, which means this device is visited twice.

The library offers two different pipeline schedules, **simple** and **interleaved**, which can be configured using the `pipeline` parameter in the SageMaker Python SDK. In most cases, interleaved pipeline can achieve better performance by utilizing the GPUs more efficiently.

**Interleaved Pipeline**

In an interleaved pipeline, backward execution of the microbatches is prioritized whenever possible. This allows quicker release of the memory used for activations, using memory more efficiently. It also allows for scaling the number of microbatches higher, reducing the idle time of the GPUs. At steady-state, each device alternates between running forward and backward passes. This means that the backward pass of one microbatch may run before the forward pass of another microbatch finishes.

The preceding figure illustrates an example execution schedule for the interleaved pipeline over 2 GPUs. In the figure, F0 represents the forward pass for microbatch 0, and B1 represents the backward pass for microbatch 1. **Update** represents the optimizer update of the parameters. GPU0 always prioritizes backward passes whenever possible (for instance, executes B0 before F2), which allows for clearing of the memory used for activations earlier.

**Simple Pipeline**

A simple pipeline, by contrast, finishes running the forward pass for each microbatch before starting the backward pass. This means that it only pipelines the forward pass and backward pass stages within themselves. The following figure illustrates an example of how this works, over 2 GPUs.
Pipelining Execution in Specific Frameworks

Use the following sections to learn about the framework-specific pipeline scheduling decisions SageMaker's model parallelism library makes for TensorFlow and PyTorch.

Pipeline Execution with TensorFlow

The following image is an example of a TensorFlow graph partitioned by the model parallelism library, using automated model splitting. When a graph is split, each resulting subgraph is replicated B times (except for the variables), where B is the number of microbatches. In this figure, each subgraph is replicated 2 times (B=2). An SMPInput operation is inserted at each input of a subgraph, and an SMPOutput operation is inserted at each output. These operations communicate with the library backend to transfer tensors to and from each other.

The following image is an example of 2 subgraphs split with B=2 with gradient operations added. The gradient of a SMPInput op is a SMPOutput op, and vice versa. This enables the gradients to flow backwards during back-propagation.
This GIF demonstrates an example interleaved pipeline execution schedule with $B=2$ microbatches and 2 subgraphs. Each device sequentially executes one of the subgraph replicas to improve GPU utilization. As $B$ grows larger, the fraction of idle time slots goes to zero. Whenever it is time to do (forward or backward) computation on a specific subgraph replica, the pipeline layer signals to the corresponding blue SMPInput operations to start executing.

Once the gradients from all microbatches in a single mini-batch are computed, the library combines the gradients across microbatches, which can then be applied to the parameters.

**Pipeline Execution with PyTorch**

Conceptually, pipelining follows a similar idea in PyTorch. However, since PyTorch does not involve static graphs and so the model parallelism library's PyTorch feature uses a more dynamic pipelining paradigm.

As in TensorFlow, each batch is split into a number of microbatches, which are executed one at a time on each device. However, the execution schedule is handled via execution servers launched on each device. Whenever the output of a submodule that is placed on another device is needed on the current device, an execution request is sent to the execution server of the remote device along with the input tensors to the submodule. The server then executes this module with the given inputs and returns the response to the current device.

Since the current device is idle during the remote submodule execution, the local execution for the current microbatch pauses, and the library runtime switches execution to another microbatch which the current device can actively work on. The prioritization of microbatches is determined by the chosen...
pipeline schedule. For an interleaved pipeline schedule, microbatches that are in the backward stage of the computation are prioritized whenever possible.

Tensor Parallelism

Tensor parallelism is a type of model parallelism in which specific model weights, gradients, and optimizer states are split across devices. In contrast to pipeline parallelism, which keeps individual weights intact but partitions the set of weights, tensor parallelism splits individual weights. This typically involves distributed computation of specific operations, modules, or layers of the model.

Tensor parallelism is required in cases in which a single parameter consumes most of the GPU memory (such as large embedding tables with a large vocabulary size or a large softmax layer with a large number of classes). In this case, treating this large tensor or operation as an atomic unit is inefficient and impedes balance of the memory load.

Tensor parallelism is also useful for extremely large models in which a pure pipelining is simply not enough. For example, with GPT-3-scale models that require partitioning over tens of instances, a pure microbatch pipelining is inefficient because the pipeline depth becomes too high and the overhead becomes prohibitively large.

Note
Tensor parallelism is available for PyTorch in the SageMaker model parallelism library v1.6.0 and later.

- Ranking Mechanism when Using a Combination of Pipeline Parallelism and Tensor Parallelism (p. 2180)

How Tensor Parallelism Works

Tensor parallelism takes place at the level of nn.Module; it partitions specific modules in the model across tensor parallel ranks. This is in addition to the existing partition of the set of modules used in pipeline parallelism.

When a module is partitioned through tensor parallelism, its forward and backward propagation are distributed. The library handles the necessary communication across devices to implement the distributed execution of these modules. The modules are partitioned across multiple data parallel ranks. Contrary to the traditional distribution of workloads, each data parallel rank does not have the complete model replica when the library's tensor parallelism is used. Instead, each data parallel rank may have only a portion of the distributed modules, in addition to the entirety of the modules that are not distributed.

Example: Consider tensor parallelism across data parallel ranks, where the degree of data parallelism is 4 and the degree of tensor parallelism is 2. Assume that you have a data parallel group that holds the following module tree, after partitioning the set of modules.

```
A
### B
   ### E
   ### F
### C
### D
   ### G
   ### H
```
Assume that tensor parallelism is supported for the modules B, G, and H. One possible outcome of tensor parallel partition of this model could be:

<table>
<thead>
<tr>
<th>dp_rank 0 (tensor parallel rank 0)</th>
<th>dp_rank 1 (tensor parallel rank 1)</th>
<th>dp_rank 2 (tensor parallel rank 0)</th>
<th>dp_rank 3 (tensor parallel rank 1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>A, B:0, C, D, G:0, H</td>
<td>A, B:1, C, D, G:1, H</td>
<td>A, B:0, C, D, G:0, H</td>
<td>A, B:1, C, D, G:1, H</td>
</tr>
</tbody>
</table>

Each line represents the set of modules stored in that dp_rank, and the notation X:y represents the yth fraction of the module X. Note the following:

1. Partitioning takes place across subsets of data parallel ranks, which we call TP_GROUP, not the entire DP_GROUP, so that the exact model partition is replicated across dp_rank 0 and dp_rank 2, and similarly across dp_rank 1 and dp_rank 3.

2. The modules E and F are no longer part of the model, since their parent module B is partitioned, and any execution that is normally a part of E and F takes place within the (partitioned) B module.

3. Even though H is supported for tensor parallelism, in this example it is not partitioned, which highlights that whether to partition a module depends on user input. The fact that a module is supported for tensor parallelism does not necessarily mean it is partitioned.

How the library adapts tensor parallelism to PyTorch nn.Linear module

When tensor parallelism is performed over data parallel ranks, a subset of the parameters, gradients, and optimizer states are partitioned across the tensor parallel devices for the modules that are partitioned. For the rest of the modules, the tensor parallel devices operate in a regular data parallel manner. To execute the partitioned module, a device first collects the necessary parts of all data samples across peer devices in the same tensor parallelism group. The device then runs the local fraction of the module on all these data samples, followed by another round of synchronization which both combines the parts of the output for each data sample and returns the combined data samples to the GPUs from which the data sample first originated. The following figure shows an example of this process over a partitioned nn.Linear module.
The first figure shows a small model with a large `nn.Linear` module with data parallelism over the two tensor parallelism ranks. The `nn.Linear` module is replicated into the two parallel ranks.

The second figure shows tensor parallelism applied on a larger model while splitting the `nn.Linear` module. Each `tp_rank` holds half the linear module, and the entirety of the rest of the operations. While the linear module runs, each `tp_rank` collects the relevant half of all data samples and passes it through their half of the `nn.Linear` module. The result needs to be reduce-scattered (with summation as the reduction operation) so that each rank has the final linear output for their own data samples. The rest of the model runs in the typical data parallel manner.

Run a SageMaker Distributed Model Parallel Training Job with Tensor Parallelism

In this section, you learn:

- How to configure a SageMaker PyTorch estimator and the SageMaker model parallelism option to use tensor parallelism.
- How to adapt your training script using the extended `smdistributed.modelparallel` modules for tensor parallelism.

To learn more about the `smdistributed.modelparallel` modules, see the SageMaker model parallel APIs in the SageMaker Python SDK documentation.

Topics

- [Tensor parallelism alone](#) (p. 2174)
- [Tensor parallelism combined with pipeline parallelism](#) (p. 2176)
Tensor parallelism alone

The following is an example of a distributed training option to activate tensor parallelism alone, without pipeline parallelism. Configure the `mpi_options` and `smp_options` dictionaries to specify distributed training options to the SageMaker PyTorch estimator.

**Note**

Extended memory-saving features are available through Deep Learning Containers for PyTorch, which implements the SageMaker model parallelism library v1.6.0 or later.

Configure a SageMaker PyTorch estimator

```python
mpi_options = {
    "enabled": True,
    "processes_per_host": 8, # 8 processes
    "custom_mpi_options": "--mca btl_vader_single_copy_mechanism none"
}

smp_options = {
    "enabled": True,
    "parameters": {
        "pipeline_parallel_degree": 1, # alias for "partitions"
        "placement_strategy": "cluster",
        "tensor_parallel_degree": 4, # tp over 4 devices
        "ddp": True
    }
}

smp_estimator = PyTorch(  
    entry_point='your_training_script.py', # Specify
    role=role,  
    instance_type='ml.p3.16xlarge',      
    sagemaker_session=sagemaker_session,  
    framework_version='1.13.1',  
    py_version='py36',  
    instance_count=1,  
    distribution={  
        "smdistributed": {"modelparallel": smp_options},  
        "mpi": mpi_options
    },  
    base_job_name="SMD-MP-demo",
)

smp_estimator.fit('s3://my_bucket/my_training_data/')
```

**Tip**

To find a complete list of parameters for `distribution`, see Configuration Parameters for Model Parallelism in the SageMaker Python SDK documentation.

Adapt your PyTorch training script

The following example training script shows how to adapt the SageMaker model parallelism library to a training script. In this example, it is assumed that the script is named `your_training_script.py`.

```python
import torch
import torch.nn as nn
import torch.nn.functional as F
import torch.optim as optim
from torchnet.dataset import SplitDataset
from torchvision import datasets
import smdistributed.modelparallel.torch as smp
```

2174
class Net(nn.Module):
    def __init__(self):
        super(Net, self).__init__()
        self.conv1 = nn.Conv2d(1, 32, 3, 1)
        self.conv2 = nn.Conv2d(32, 64, 3, 1)
        self.fc1 = nn.Linear(9216, 128)
        self.fc2 = nn.Linear(128, 10)

    def forward(self, x):
        x = self.conv1(x)
        x = F.relu(x)
        x = self.conv2(x)
        x = F.relu(x)
        x = F.max_pool2d(x, 2)
        x = torch.flatten(x, 1)
        x = self.fc1(x)
        x = F.relu(x)
        x = self.fc2(x)
        return F.log_softmax(x, 1)

def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        # smdistributed: Move input tensors to the GPU ID used by
        # the current process, based on the set_device call.
        data, target = data.to(device), target.to(device)
        optimizer.zero_grad()
        output = model(data)
        loss = F.nll_loss(output, target, reduction="mean")
        loss.backward()
        optimizer.step()

    # smdistributed: Initialize the backend
    smp.init()

    # smdistributed: Set the device to the GPU ID used by the current process.
    # Input tensors should be transferred to this device.
    device = torch.device("cuda")

    # smdistributed: Download only on a single process per instance.
    # When this is not present, the file is corrupted by multiple processes trying
    # to download and extract at the same time
    if smp.local_rank() == 0:
        dataset = datasets.MNIST("../data", train=True, download=False)
        smp.barrier()

    # smdistributed: Shard the dataset based on data parallel ranks
    if smp.dp_size() > 1:
        partitions_dict = {f"{i}": 1 / smp.dp_size() for i in range(smp.dp_size())}
        dataset = SplitDataset(dataset, partitions=partitions_dict)
        dataset.select(f"{smp.dp_rank()}")

    train_loader = torch.utils.data.DataLoader(dataset, batch_size=64)

    # smdistributed: Enable tensor parallelism for all supported modules in the model
    # i.e., nn.Linear in this case. Alternatively, we can use
    # smp.set_tensor_parallelism(model.fc1, True)
    # to enable it only for model.fc1
    with smp.tensor_parallelism():
        model = Net()

    # smdistributed: Use the DistributedModel wrapper to distribute the
    # modules for which tensor parallelism is enabled
    model = smp.DistributedModel(model)
optimizer = optim.Adam(model.parameters(), lr=4.0)
optimizer = smp.DistributedOptimizer(optimizer)
train(model, device, train_loader, optimizer)

**Tensor parallelism combined with pipeline parallelism**

The following is an example of a distributed training option that enables tensor parallelism combined with pipeline parallelism. Set up the `mpi_options` and `smp_options` parameters to specify model parallel options with tensor parallelism when you configure a SageMaker PyTorch estimator.

**Note**
Extended memory-saving features are available through Deep Learning Containers for PyTorch, which implements the SageMaker model parallelism library v1.6.0 or later.

**Configure a SageMaker PyTorch estimator**

```python
mpi_options = {
    "enabled": True,
    "processes_per_host": 8,  # 8 processes
    "custom_mpi_options": "--mca btl_vader_single_copy_mechanism none"
}

smp_options = {
    "enabled": True,
    "parameters": {
        "microbatches": 4,
        "pipeline_parallel_degree": 2,  # alias for "partitions"
        "placement_strategy": "cluster",
        "tensor_parallel_degree": 2,  # tp over 2 devices
        "ddp": True
    }
}

smp_estimator = PyTorch(
    entry_point='your_training_script.py',  # Specify
    role=role,
    instance_type='ml.p3.16xlarge',
    sagemaker_session=sagemaker_session,
    framework_version='1.13.1',
    py_version='py36',
    instance_count=1,
    distribution={
        "smdistributed": {"modelparallel": smp_options},
        "mpi": mpi_options
    },
    base_job_name="SMD-MP-demo",
)

smp_estimator.fit('s3://my_bucket/my_training_data/')</code>

**Adapt your PyTorch training script**

The following example training script shows how to adapt the SageMaker model parallelism library to a training script. Note that the training script now includes the `smp.step` decorator:

```python
import torch
import torch.nn as nn
import torch.nn.functional as F
import torch.optim as optim
from torchtext.dataset import import SplitDataset
```
from torchvision import datasets
import smdistributed.modelparallel.torch as smp

class Net(nn.Module):
    def __init__(self):
        super(Net, self).__init__()
        self.conv1 = nn.Conv2d(1, 32, 3, 1)
        self.conv2 = nn.Conv2d(32, 64, 3, 1)
        self.fc1 = nn.Linear(9216, 128)
        self.fc2 = nn.Linear(128, 10)

    def forward(self, x):
        x = self.conv1(x)
        x = F.relu(x)
        x = self.conv2(x)
        x = F.relu(x)
        x = F.max_pool2d(x, 2)
        x = torch.flatten(x, 1)
        x = self.fc1(x)
        x = F.relu(x)
        x = self.fc2(x)
        return F.log_softmax(x, 1)

@smp.step
def train_step(model, data, target):
    output = model(data)
    loss = F.nll_loss(output, target, reduction="mean")
    model.backward(loss)
    return output, loss

def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        # smdistributed: Move input tensors to the GPU ID used by
        # the current process, based on the set_device call.
        data, target = data.to(device), target.to(device)
        optimizer.zero_grad()
        # Return value, loss_mb is a StepOutput object
        _, loss_mb = train_step(model, data, target)
        # smdistributed: Average the loss across microbatches.
        loss = loss_mb.reduce_mean()
        optimizer.step()

    # smdistributed: Initialize the backend
    smp.init()

    # smdistributed: Set the device to the GPU ID used by the current process.
    # Input tensors should be transferred to this device.
    torch.cuda.set_device(smp.local_rank())
    device = torch.device("cuda")

    # smdistributed: Download only on a single process per instance.
    # When this is not present, the file is corrupted by multiple processes trying
    # to download and extract at the same time
    if smp.local_rank() == 0:
        dataset = datasets.MNIST("../data", train=True, download=False)
    smp.barrier()

    # smdistributed: Shard the dataset based on data parallel ranks
    if smp.dp_size() > 1:
        partitions_dict = {f"{i}": 1 / smp.dp_size() for i in range(smp.dp_size())}
Support for Hugging Face Transformer Models

The SageMaker model parallelism library's tensor parallelism offers out-of-the-box support for the following Hugging Face Transformer models:

- GPT-2, BERT, and RoBERTa (Available in the SageMaker model parallelism library v1.7.0 and later)
- GPT-J (Available in the SageMaker model parallelism library v1.8.0 and later)
- GPT-Neo (Available in the SageMaker model parallelism library v1.10.0 and later)

**Note**
For any other Transformers models, you need to use the [smdistributed.modelparallel.torch.tp_register_with_module()](https://smdistributed.readthedocs.io/en/latest/smdistributed.modelparallel.torch.html#smdistributed.modelparallel.torch.tp_register_with_module) API to apply tensor parallelism.

**Note**
To use tensor parallelism for training Hugging Face Transformer models, make sure you use Hugging Face Deep Learning Containers for PyTorch that has the SageMaker model parallelism library v1.7.0 and later. For more information, see the [SageMaker model parallelism library release notes](https://sagemaker.readthedocs.io/en/latest/sagemaker_model_parallelism.html).

Supported Models Out of the Box

For the Hugging Face Transformer models supported by the library out of the box, you don't need to manually implement hooks to translate Transformer APIs to smdistributed transformer layers. You can activate tensor parallelism by using the context manager [smdistributed.modelparallel.torch.tensor_parallelism()](https://smdistributed.readthedocs.io/en/latest/smdistributed.modelparallel.torch.html#smdistributed.modelparallel.torch.tensor_parallelism) and wrapping the model by [smdistributed.modelparallel.torch.DistributedModel()](https://smdistributed.readthedocs.io/en/latest/smdistributed.modelparallel.torch.html#smdistributed.modelparallel.torch.DistributedModel). You don't need to manually register hooks for tensor parallelism using the `smp.tp_register` API.

The `state_dict` translation functions between Hugging Face Transformers and smdistributed.modelparallel can be accessed as follows.

- `smdistributed.modelparallel.torch.nn.huggingface.gpt2.translate_state_dict_to_hf_gpt2(state_dict, max_seq_len=None)`
- `smdistributed.modelparallel.torch.nn.huggingface.gpt2.translate_hf_state_dict_to_smdistributed_gpt2(state_dict)`
- `smdistributed.modelparallel.torch.nn.huggingface.bert.translate_state_dict_to_hf_bert(state_dict, max_seq_len=None)`
- `smdistributed.modelparallel.torch.nn.huggingface.bert.translate_hf_state_dict_to_smdistributed_bert(state_dict, max_seq_len=None)`
• `smdistributed.modelparallel.torch.nn.huggingface.bert.translate_hf_state_dict_to_smdistributed_bert(state_dict)`
• `smdistributed.modelparallel.torch.nn.huggingface.roberta.translate_state_dict_to_hf_roberta(state_dict, max_seq_len=None)` (Available in the SageMaker model parallelism library v1.8.0 and later)
• `smdistributed.modelparallel.torch.nn.huggingface.roberta.translate_hf_state_dict_to_smdistributed_roberta(state_dict)` (Available in the SageMaker model parallelism library v1.10.0 and later)
• `smdistributed.modelparallel.torch.nn.huggingface.gptj.translate_state_dict_to_hf_gptj(state_dict, max_seq_len=None)` (Available in the SageMaker model parallelism library v1.8.0 and later)
• `smdistributed.modelparallel.torch.nn.huggingface.gptneo.translate_state_dict_to_hf_gptneo(state_dict, max_seq_len=None)` (Available in the SageMaker model parallelism library v1.10.0 and later)
• `smdistributed.modelparallel.torch.nn.huggingface.gptneo.translate_hf_state_dict_to_smdistributed_gptneo(state_dict)` (Available in the SageMaker model parallelism library v1.10.0 and later)

**Example usage of the GPT-2 translation function**

Start with wrapping the model as shown in the following code.

```python
from transformers import AutoModelForCausalLM
with smp.tensor_parallelism():
    model = AutoModelForCausalLM.from_config(hf_gpt2_config)
model = smp.DistributedModel(model)
```

Given a `state_dict` from the `DistributedModel` object, you can load the weights into the original Hugging Face GPT-2 model using the `translate_state_dict_to_hf_gpt2` function as shown in the following code.

```python
from smdistributed.modelparallel.torch.nn.huggingface.gpt2 import translate_state_dict_to_hf_gpt2
max_seq_len = 1024
# [... code block for training ...]
if smp.xp_rank() == 0:
    state_dict = dist_model.state_dict()
    hf_state_dict = translate_state_dict_to_hf_gpt2(state_dict, max_seq_len)
    # can now call model.load_state_dict(hf_state_dict) to the original HF model
```

**Example usage of the RoBERTa translation function**

Similarly, given a supported HuggingFace model `state_dict`, you can use the `translate_hf_state_dict_to_smdistributed` function to convert it to a format readable by `smp.DistributedModel`. This can be useful in transfer learning use cases, where a pre-trained model is loaded into a `smp.DistributedModel` for model-parallel fine-tuning:

```python
from smdistributed.modelparallel.torch.nn.huggingface.roberta import translate_state_dict_to_smdistributed
model = AutoModelForMaskedLM.from_config(roberta_config)
model = smp.DistributedModel(model)
pretrained_model = AutoModelForMaskedLM.from_pretrained("roberta-large")
translated_state_dict =
```
translate_state_dict_to_smdistributed(pretrained_model.state_dict())

# load the translated pretrained weights into the smp.DistributedModel
model.load_state_dict(translated_state_dict)

# start fine-tuning...

**Ranking Mechanism when Using a Combination of Pipeline Parallelism and Tensor Parallelism**

This section explains how the ranking mechanism of model parallelism works with tensor parallelism. This is extended from the Ranking Basics for Core Features of the SageMaker Model Parallelism Library (p. 2156). With tensor parallelism, the library introduces three types of ranking and process group APIs: `smp.tp_rank()` for tensor parallel rank, `smp.pp_rank()` for pipeline parallel rank, and `smp.rdp_rank()` for reduced-data parallel rank. The corresponding communication process groups are tensor parallel group (TP_GROUP), pipeline parallel group (PP_GROUP), and reduced-data parallel group (RDP_GROUP). These groups are defined as follows:

- **A tensor parallel group** (TP_GROUP) is an evenly divisible subset of the data parallel group, over which tensor parallel distribution of modules takes place. When the degree of pipeline parallelism is 1, TP_GROUP is the same as model parallel group (MP_GROUP).

- **A pipeline parallel group** (PP_GROUP) is the group of processes over which pipeline parallelism takes place. When the tensor parallelism degree is 1, PP_GROUP is the same as MP_GROUP.

- **A reduced-data parallel group** (RDP_GROUP) is a set of processes that hold both the same pipeline parallelism partitions and the same tensor parallel partitions, and perform data parallelism among themselves. This is called the reduced data parallel group because it is a subset of the entire data parallelism group, DP_GROUP. For the model parameters that are distributed within the TP_GROUP, the gradient allreduce operation is performed only for reduced-data parallel group, while for the parameters that are not distributed, the gradient allreduce takes place over the entire DP_GROUP.

- **A model parallel group** (MP_GROUP) refers to a group of processes that collectively store the entire model. It consists of the union of the PP_GROUPs of all the ranks that are in the TP_GROUP of the current process. When the degree of tensor parallelism is 1, MP_GROUP is equivalent to PP_GROUP. It is also consistent with the existing definition of MP_GROUP from previous smdistributed releases. Note that the current TP_GROUP is a subset of both the current DP_GROUP and the current MP_GROUP.

To learn more about the communication process APIs in the SageMaker model parallelism library, see the Common API and the PyTorch-specific APIs in the SageMaker Python SDK documentation.
This figure shows ranking mechanism, parameter distribution, and associated AllReduce operations of tensor parallelism.

For example, consider process groups for a single node with 8 GPUs, where the degree of tensor parallelism is 2, the degree of pipeline parallelism is 2, and the degree of data parallelism is 4. The upper center part of the preceding figure shows an example of a model with 4 layers. The lower left and lower right parts of figure illustrate the 4-layer model distributed across 4 GPUs using both pipeline parallelism and tensor parallelism, where tensor parallelism is used for the middle two layers. These two lower figures are simple copies to illustrate different group boundary lines. The partitioned model is replicated for data parallelism across GPUs 0-3 and 4-7. The lower left figure shows the definitions of MP_GROUP, PP_GROUP, and TP_GROUP. The lower right figure shows RDP_GROUP, DP_GROUP, and WORLD over the same set of GPUs. The gradients for the layers and layer slices that have the same color are allreduced together for data parallelism. For example, the first layer (light blue) gets the allreduce operations across DP_GROUP, whereas the dark orange slice in the second layer only gets the allreduce operations within the RDP_GROUP of its process. The bold dark red arrows represent tensors with the batch of its entire TP_GROUP.

| GPU0: pp_rank 0, tp_rank 0, rdp_rank 0, dp_rank 0, mp_rank 0 |
| GPU1: pp_rank 1, tp_rank 0, rdp_rank 0, dp_rank 0, mp_rank 1 |
| GPU2: pp_rank 0, tp_rank 1, rdp_rank 0, dp_rank 1, mp_rank 2 |
| GPU3: pp_rank 1, tp_rank 1, rdp_rank 0, dp_rank 1, mp_rank 3 |
| GPU4: pp_rank 0, tp_rank 0, rdp_rank 1, dp_rank 2, mp_rank 0 |
| GPU5: pp_rank 1, tp_rank 0, rdp_rank 1, dp_rank 2, mp_rank 1 |
| GPU6: pp_rank 0, tp_rank 1, rdp_rank 1, dp_rank 3, mp_rank 2 |
| GPU7: pp_rank 1, tp_rank 1, rdp_rank 1, dp_rank 3, mp_rank 3 |
In this example, pipeline parallelism occurs across the GPU pairs (0,1); (2,3); (4,5) and (6,7). In addition, data parallelism (allreduce) takes place across GPUs 0, 2, 4, 6, and independently over GPUs 1, 3, 5, 7. Tensor parallelism happens over subsets of DP_GROUPS, across the GPU pairs (0,2); (1,3); (4,6) and (5,7).

**Optimizer State Sharding**

*Optimizer state sharding* is a useful memory-saving technique that shards the optimizer state (the set of weights that describes the state of optimizer) across data parallel device groups. You can use optimizer state sharding whenever you use a stateful optimizer (such as Adam) or an FP16 optimizer (which stores both FP16 and FP32 copies of the parameters).

**Note**

Optimizer state sharding is available for PyTorch in the SageMaker model parallelism library v1.6.0 and later.

**How to Use Optimizer State Sharding**

You can turn on *optimizer state sharding* by setting "shard_optimizer_state": True in the modelparallel configuration.

When this feature is turned on, the library partitions the set of model parameters based on the data parallelism degree. The gradients corresponding to the ith partition get reduced only at the ith data parallel rank. At the end of the first call to an smp.step decorator function, the optimizer wrapped by smp.DistributedOptimizer redefines its parameters to be only limited to those parameters corresponding to the partition of the current data parallel rank. The redefined parameters are called *virtual parameters* and share underlying storage with the original parameters. During the first call to optimizer.step, the optimizer states are created based on these redefined parameters, which are sharded because of the original partition. After the optimizer update, the AllGather operation (as part of the optimizer.step call) runs across the data parallel ranks to achieve consistent parameter states.

**Tip**

Optimizer state sharding can be useful when the degree of data parallelism is greater than 1 and the model has more than a billion parameters.

The degree of data parallelism is calculated by (processes_per_host * instance_count / pipeline_parallel_degree), and the smp.dp_size() function handles the sizing in the background.

**Configure a SageMaker PyTorch estimator**

```python
mpi_options = {
    "enabled": True,
    "processes_per_host": 8,               # 8 processes
    "custom_mpi_options": "--mca btl_vader_single_copy_mechanism none "
}

smp_options = {
    "enabled": True,
    "parameters": {
        "microbatches": 4,
        "pipeline_parallel_degree": 2,       # alias for "partitions"
        "placement_strategy": "cluster",
        "tensor_parallel_degree": 2,        # tp over 2 devices
        "ddp": True,
        "shard_optimizer_state": True
    }
}
```

**Adapt your PyTorch training script**

See Adapt your PyTorch training script (p. 2176) in the Tensor parallelism combined with pipeline parallelism section. There's no additional modification required for the script.
Activation Checkpointing

Activation checkpointing (or gradient checkpointing) is a technique to reduce memory usage by clearing activations of certain layers and recomputing them during a backward pass. Effectively, this trades extra computation time for reduced memory usage. If a module is checkpointed, at the end of a forward pass, the inputs to and outputs from the module stay in memory. Any intermediate tensors that would have been part of the computation inside that module are freed up during the forward pass. During the backward pass of checkpointed modules, these tensors are recomputed. At this point, the layers beyond this checkpointed module have finished their backward pass, so the peak memory usage with checkpointing can be lower.

**Note**
This feature is available for PyTorch in the SageMaker model parallelism library v1.6.0 and later.

How to Use Activation Checkpointing

With `smdistributed.modelparallel`, you can use activation checkpointing at the granularity of a module. For all `torch.nn` modules except `torch.nn.Sequential`, you can only checkpoint a module tree if it lies within one partition from the perspective of pipeline parallelism. In case of the `torch.nn.Sequential` module, each module tree inside the sequential module must lie completely within one partition for activation checkpointing to work. When you use manual partitioning, be aware of these restrictions.

When you use automated model partitioning, you can find the partitioning assignment logs starting with `Partition assignments:` in the training job logs. If a module is partitioned across multiple ranks (for example, with one descendant on one rank and another descendant on a different rank), the library ignores the attempt to checkpoint the module and raises a warning message that the module won't be checkpointed.

**Note**
The SageMaker model parallelism library supports both overlapping and non-overlapping allreduce operation in combination with checkpointing.

**Note**
PyTorch's native checkpointing API is not compatible with `smdistributed.modelparallel`.

**Example 1:** The following sample code shows how to use activation checkpointing when you have a model definition in your script.

```python
import torch.nn as nn
import torch.nn.functional as F
from smdistributed.modelparallel.torch.patches.checkpoint import checkpoint

class Net(nn.Module):
    def __init__(self):
        super(Net, self).__init__()
        self.conv1 = nn.Conv2d(1, 32, 3, 1)
        self.conv2 = nn.Conv2d(32, 64, 3, 1)
        self.fc1 = nn.Linear(9216, 128)
        self.fc2 = nn.Linear(128, 10)

    def forward(self, x):
        x = self.conv1(x)
        x = self.conv2(x)
        x = F.max_pool2d(x, 2)
        x = torch.flatten(x, 1)
        # This call of fc1 will be checkpointed
        x = checkpoint(self.fc1, x)
        x = self.fc2(x)
        return F.log_softmax(x, 1)
```
Example 2: The following sample code shows how to use activation checkpointing when you have a sequential model in your script.

```python
import torch.nn as nn
from smdistributed.modelparallel.torch.patches.checkpoint import checkpoint_sequential

class Net(nn.Module):
    def __init__(self):
        super(Net, self).__init__()
        self.seq = nn.Sequential(
            nn.Conv2d(1,20,5),
            nn.ReLU(),
            nn.Conv2d(20,64,5),
            nn.ReLU()
        )

    def forward(self, x):
        # This call of self.seq will be checkpointed
        x = checkpoint_sequential(self.seq, x)
        return F.log_softmax(x, 1)
```

Example 3: The following sample code shows how to use activation checkpointing when you import a prebuilt model from a library, such as PyTorch and Hugging Face Transformers. Whether you checkpoint sequential modules or not, do the following:

1. Wrap the model by `smp.DistributedModel()`.
2. Define an object for sequential layers.
3. Wrap the sequential layer object by `smp.set_activation_checkpointing()`.

```python
import smdistributed.modelparallel.torch as smp
from transformers import AutoModelForCausalLM

smp.init()
model = AutoModelForCausalLM(*args, **kwargs)
model = smp.DistributedModel(model)

# Call set_activation_checkpointing API
transformer_layers = model.module.module.module.transformer.seq_layers
smp.set_activation_checkpointing(transformer_layers, pack_args_as_tuple=True, strategy='each')
```

Activation Offloading

When activation checkpointing and pipeline parallelism are turned on and the number of microbatches is greater than one, *activation offloading* is an additional feature that can further reduce memory usage. Activation offloading asynchronously moves the checkpointed activations corresponding to their microbatches that are not currently running in the CPU. Right before the GPU needs the activations for the microbatch’s backward pass, this functionality prefetches the offloaded activations back from the CPU.

**Note**

This feature is available for PyTorch in the SageMaker model parallelism library v1.6.0 and later.

How to Use Activation Offloading

Use activation offloading to reduce memory usage when the number of microbatches is greater than 1, and activation checkpointing is turned on (see Activation Checkpointing (p. 2183)). When the activation checkpointing is not used, activation offloading has no effect. When it is used with only one microbatch, it does not save memory.
To use activation offloading, set "offload_activations": True in the modelparallel configuration.

Activation offloading moves the checkpointed activations in `nn.Sequential` modules to CPU asynchronously. The data transfer over the PCIe link overlaps with GPU computation. The offloading happens immediately, as soon as the forward pass for a particular checkpointed layer is computed. The activations are loaded back to the GPU shortly before they are needed for the backward pass of a particular microbatch. The CPU-GPU transfer similarly overlaps with computation.

To adjust how early the activations are loaded back into the GPU, you can use the configuration parameter "activation_loading_horizon" (default is set to 4, must be int larger than 0). A larger activation loading horizon would cause the activations to be loaded back to the GPU earlier. If the horizon is too large, the memory-saving impact of activation offloading might be diminished. If the horizon is too small, the activations may not be loaded back in time, reducing the amount of overlap and degrading performance.

**Tip**
Activation offloading can be useful for large models with over a hundred billion parameters.

**Configure a SageMaker PyTorch estimator**

```python
mpi_options = {
    "enabled" : True,
    "processes_per_host" : 8,               # 8 processes
    "custom_mpi_options" : "--mca btl_vader_single_copy_mechanism none "
}

smp_options = {
    "enabled":True,
    "parameters": {
        "microbatches": 4,
        "pipeline_parallel_degree": 2,       # alias for "partitions"
        "placement_strategy": "cluster",
        "tensor_parallel_degree": 2,        # tp over 2 devices
        "ddp": True,
        "offload_activations": True,
        "activation_loading_horizon": 4      # optional. default is 4.
    }
}
```

**FP16 Training with Model Parallelism**

For FP16 training, apply the following modifications to your training script and estimator.

**Note**
This feature is available for PyTorch in the SageMaker model parallelism library v1.10.0 and later.

**Adapt your PyTorch training script**

1. Wrap your model using the `smdistributed.modelparallel.torch.model_creation()` context manager.

```python
# fp16_training_script.py
import torch
import smdistributed.modelparallel.torch as smp

with smp.model_creation(
    dtype=torch.float16 if args.fp16 else torch.get_default_dtype()
):
    model = ...
```
**Tip**
If you are using tensor parallelism, add `tensor_parallelism=smp.tp_size() > 1` to the `smp.model_creation` context manager. Adding this line also helps automatically detect whether tensor parallelism is activated or not.

```python
with smp.model_creation(
    ..., 
    tensor_parallelism=smp.tp_size() > 1
):
    model = ...
```

2. When you wrap the optimizer with `smdistributed.modelparallel.torch.DistributedOptimizer`, set either the `static_loss_scaling` or `dynamic_loss_scaling` argument. By default, `static_loss_scaling` is set to 1.0, and `dynamic_loss_scaling` is set to False. If you set `dynamic_loss_scale=True`, you can feed dynamic loss scaling options as a dictionary through the `dynamic_loss_args` argument. For more information, options, and examples of the optimizer wrapper function, see the `smdistributed.modelparallel.torch.DistributedOptimizer` API.

The following code is an example of wrapping an Adadelta optimizer object with dynamic loss scaling for FP16 training.

```python
optimizer = torch.optim.Adadelta(...)  
optimizer = smp.DistributedOptimizer(  
    optimizer,  
    static_loss_scale=None,  
    dynamic_loss_scale=True,  
    dynamic_loss_args={  
        "scale_window": 1000,  
        "min_scale": 1,  
        "delayed_shift": 2  
    }  
)
```

**Configure a SageMaker PyTorch estimator**

Add the FP16 parameter ("fp16") to the distribution configuration for model parallelism when creating a SageMaker PyTorch estimator object. For a complete list of the configuration parameters for model parallelism, see `Parameters for smdistributed`.

```python
from sagemaker.pytorch import PyTorch  
smp_options = {  
    "enabled": True,  
    "parameters": {  
        "microbatches": 4,  
        "pipeline_parallel_degree": 2,  
        "tensor_parallel_degree": 2,  
        ...  
        "fp16": True  
    }  
}  
fp16_estimator = PyTorch(  
    entry_point="fp16_training_script.py",  # Specify your train script  
...  
)"
When FP16 training starts, the model and the optimizer are wrapped by FP16_Module and FP16_Optimizer respectively, which are modified smdistributed versions of the Apex utils. FP16_Module converts the model to FP16 dtype and deals with the forward pass in FP16.

**Tip**
You can apply gradient clipping by calling `clip_master_grads` before `optimizer.step`.

```python
optimizer.clip_master_grads(max_norm)  # max_norm(float or int): max norm of the gradients
```

**Tip**
When using `torch.optim.lr_scheduler` and FP16 training, you need to pass `optimizer.optimizer` to the LR scheduler rather than the optimizer. See the following example code.

```python
from torch.optim.lr_scheduler import StepLR

scheduler = StepLR(
    optimizer.optimizer if smp.state.cfg.fp16 else optimizer,
    step_size=1,
    gamma=args.gamma
)
```

### Support for FlashAttention

Support for FlashAttention is a feature of the library only applicable for the distributed transformer model, which is a Transformer model wrapped by `smp.DistributedModel()` for model-parallel training. This feature is also compatible with the section called "Tensor Parallelism" (p. 2171).

The FlashAttention library only supports models when `attention_head_size` is set to a value that's a multiple of 8 and less than 128. Therefore, when you train a distributed transformer and make sure that FlashAttention works properly, you should adjust parameters to make the attention head size comply the requirements. For more information, see also Installation and features in the FlashAttention GitHub repository.

For example, assume that you configure a Transformer model with `hidden_width=864` and `num_heads=48`. The head size of FlashAttention is calculated as `attention_head_size = hidden_width / num_heads = 864 / 48 = 18`. To enable FlashAttention, you need to adjust the `num_heads` parameter to 54, so that `attention_head_size = hidden_width / num_heads = 864 / 54 = 16`, which is a multiple of 8.

### Run a SageMaker Distributed Training Job with Model Parallelism

Learn how to run a model-parallel training job of your own training script using the SageMaker Python SDK with the SageMaker model parallelism library.

There are three use-case scenarios for running a SageMaker training job.
1. You can use one of the pre-built AWS Deep Learning Container for TensorFlow and PyTorch. This option is recommended if it is the first time for you to use the model parallel library. To find a tutorial for how to run a SageMaker model parallel training job, see the example notebooks at PyTorch training with Amazon SageMaker's model parallelism library.

2. You can extend the pre-built containers to handle any additional functional requirements for your algorithm or model that the pre-built SageMaker Docker image doesn't support. To find an example of how you can extend a pre-built container, see Extend a Pre-built Container (p. 3289).

3. You can adapt your own Docker container to work with SageMaker using the SageMaker Training toolkit. For an example, see Adapting Your Own Training Container.

For options 2 and 3 in the preceding list, refer to Extend a Pre-built Docker Container that Contains SageMaker’s Distributed Model Parallel Library (p. 2205) to learn how to install the model parallel library in an extended or customized Docker container.

In all cases, you launch your training job configuring a SageMaker TensorFlow or PyTorch estimator to activate the library. To learn more, see the following topics.

Topics
- Step 1: Modify Your Own Training Script Using SageMaker's Distributed Model Parallel Library (p. 2188)
- Step 2: Launch a Training Job Using the SageMaker Python SDK (p. 2202)

Step 1: Modify Your Own Training Script Using SageMaker's Distributed Model Parallel Library

Use this section to learn how to customize your training script to use the core features of the Amazon SageMaker model parallelism library. To use the library-specific API functions and parameters, we recommend you use this documentation alongside the SageMaker model parallel library APIs in the SageMaker Python SDK documentation.

The training script examples provided in these sections are simplified and designed to highlight the required changes you must make to use the library. For end-to-end, runnable notebook examples that demonstrate how to use a TensorFlow or PyTorch training script with the SageMaker model parallelism library, see Amazon SageMaker Distributed Training Notebook Examples (p. 2223).

Topics
- Split the model of your training script using the SageMaker model parallelism library (p. 2188)
- Modify a TensorFlow training script (p. 2190)
- Modify a PyTorch Training Script (p. 2196)

Split the model of your training script using the SageMaker model parallelism library

There are two ways to modify your training script to set up model splitting: automated splitting or manual splitting.

Automated model splitting

When you use SageMaker's model parallelism library, you can take advantage of automated model splitting, also referred to as automated model partitioning. The library uses a partitioning algorithm that balances memory, minimizes communication between devices, and optimizes performance. You can configure the automated partitioning algorithm to optimize for speed or memory.

Alternatively, you can use manual model splitting. We recommend automated model splitting, unless you are very familiar with the model architecture and have a good idea of how to efficiently partition your model.
How it works

Auto-partitioning occurs during the first training step, when the `smp.step`-decorated function is first called. During this call, the library first constructs a version of the model on the CPU RAM (to avoid GPU memory limitations), and then analyzes the model graph and makes a partitioning decision. Based on this decision, each model partition is loaded on a GPU, and only then the first step is executed. Because of these analysis and partitioning steps, the first training step might take longer.

In either framework, the library manages the communication between devices through its own backend, which is optimized for AWS infrastructure.

The auto-partition design adapts to the characteristics of the framework, and the library does the partitioning at the granularity level that is more natural in each framework. For instance, in TensorFlow, each specific operation can be assigned to a different device, whereas in PyTorch, the assignment is done at the module level, where each module consists of multiple operations. The follow section reviews the specifics of the design in each framework.

Automated model splitting with PyTorch

During the first training step, the model parallelism library internally runs a tracing step that is meant to construct the model graph and determine the tensor and parameter shapes. After this tracing step, the library constructs a tree, which consists of the nested `nn.Module` objects in the model, as well as additional data gathered from tracing, such as the amount of stored `nn.Parameter`s, and execution time for each `nn.Module`.

Next, the library traverses this tree from the root and runs a partitioning algorithm that assigns each `nn.Module` to a device, which balances computational load (measured by module execution time) and memory use (measured by the total stored `nn.Parameter` size and activations). If multiple `nn.Modules` share the same `nn.Parameter`, then these modules are placed on the same device to avoid maintaining multiple versions of the same parameter. Once the partitioning decision is made, the assigned modules and weights are loaded to their devices.

For instructions on how to register the `smp.step` decorator to your PyTorch training script, see the section called “Automated splitting with PyTorch” (p. 2196).

Automated model splitting with TensorFlow

The model parallelism library analyzes the sizes of the trainable variables and the graph structure, and internally uses a graph partitioning algorithm. This algorithm comes up with a device assignment for each operation, with the objective of minimizing the amount of communication needed across devices, subject to two constraints:

- Balancing the number of variables stored in each device
- Balancing the number of operations executed in each device

If you specify `speed` for `optimize` (in the model parallelism parameters in the Python SDK), the library tries to balance the number of operations and `tf.Variable` objects in each device. Otherwise, it tries to balance the total size of `tf.Variables`.

Once the partitioning decision is made, the library creates a serialized representation of the subgraph that each device needs to execute and imports them onto each device. While partitioning, the library places operations that consume the same `tf.Variable` and operations that are part of the same Keras layer onto the same device. It also respects the colocation constraints imposed by TensorFlow. This means that, for example, if there are two Keras layers that share a `tf.Variable`, then all operations that are part of these layers are placed on a single device.

For instructions on how to register the `smp.step` decorator to your PyTorch training script, see the section called “Automated splitting with TensorFlow” (p. 2191).
Comparison of automated model splitting between frameworks

In TensorFlow, the fundamental unit of computation is a `tf.Operation`, and TensorFlow represents the model as a directed acyclic graph (DAG) of `tf.Operation`s, and therefore the model parallelism library partitions this DAG so that each node goes to one device. Crucially, `tf.Operation` objects are sufficiently rich with customizable attributes, and they are universal in the sense that every model is guaranteed to consist of a graph of such objects.

PyTorch on the other hand, does not have an equivalent notion of operation that is sufficiently rich and universal. The closest unit of computation in PyTorch that has these characteristics is an `nn.Module`, which is at a much higher granularity level, and this is why the library does partitioning at this level in PyTorch.

Manual Model Splitting

If you want to manually specify how to partition your model across devices, use the `smp.partition` context manager. For instructions on how to set the context manager for manual partitioning, see the following pages.

- the section called “Manual splitting with TensorFlow” (p. 2194)
- the section called "Manual splitting with PyTorch" (p. 2198)

To use this option after making modifications, in Step 2, you'll need to set `auto_partition` to False, and define a `default_partition` in the framework estimator class of the SageMaker Python SDK. Any operation that is not explicitly placed on a partition through the `smp.partition` context manager is executed on the `default_partition`. In this case, the automated splitting logic is bypassed, and each operation is placed based on your specification. Based on the resulting graph structure, the model parallelism library creates a pipelined execution schedule automatically.

Modify a TensorFlow training script

In this section, you learn how to modify TensorFlow training scripts to configure the SageMaker model parallelism library for auto-partitioning and manual partitioning. This selection of examples also includes an example integrated with Horovod for hybrid model and data parallelism.

Note

To find which TensorFlow versions are supported by the library, see the section called “Supported Frameworks and AWS Regions” (p. 2155).

The required modifications you must make to your training script to use the library are listed in Automated splitting with TensorFlow (p. 2191).

To learn how to modify your training script to use hybrid model and data parallelism with Horovod, see Automated splitting with TensorFlow and Horovod for hybrid model and data parallelism (p. 2192).

If you want to use manual partitioning, also review Manual splitting with TensorFlow (p. 2194).

Tip

For end-to-end notebook examples that demonstrate how to use a TensorFlow training script with the SageMaker model parallelism library, see TensorFlow Examples (p. 2224).

The following topics show examples of training scripts that you can use to configure SageMaker's model parallelism library for auto-partitioning and manual partitioning TensorFlow models.

Note

Auto-partitioning is enabled by default. Unless otherwise specified, the example scripts use auto-partitioning.

Topics
Automated splitting with TensorFlow (p. 2191)
Automated splitting with TensorFlow and Horovod for hybrid model and data parallelism (p. 2192)
Manual splitting with TensorFlow (p. 2194)
Unsupported framework features (p. 2195)

Automated splitting with TensorFlow

The following training script changes are required to run a TensorFlow model with SageMaker's model parallelism library:

1. Import and initialize the library with `smp.init()`.
2. Define a Keras model by inheriting from `smp.DistributedModel` instead of the Keras Model class. Return the model outputs from the call method of the `smp.DistributedModel` object. Be mindful that any tensors returned from the call method will be broadcast across model-parallel devices, incurring communication overhead, so any tensors that are not needed outside the call method (such as intermediate activations) should not be returned.
3. Set `drop_remainder=True` in `tf.Dataset.batch()` method. This is to ensure that the batch size is always divisible by the number of microbatches.
4. Seed the random operations in the data pipeline using `smp.dp_rank()`, e.g., `shuffle(ds, seed=smp.dp_rank())` to ensure consistency of data samples across GPUs that hold different model partitions.
5. Put the forward and backward logic in a step function and decorate it with `smp.step`.
6. Perform post-processing on the outputs across microbatches using `StepOutput` methods such as `reduce_mean`. The `smp.step` function must have a return value that depends on the output of `smp.DistributedModel`.
7. If there is an evaluation step, similarly place the forward logic inside an `smp.step`-decorated function and post-process the outputs using `StepOutput API`.

To learn more about the SageMaker's model parallelism library API, refer to the API documentation.

The following Python script is an example of a training script after the changes are made.

```python
import tensorflow as tf
# smdistributed: Import TF2.x API
import smdistributed.modelparallel.tensorflow as smp

# smdistributed: Initialize
smp.init()

# Download and load MNIST dataset.
(x_train, y_train), (x_test, y_test) = tf.keras.datasets.mnist.load_data(
    "MNIST-data-%d" % smp.rank()
)
x_train, x_test = x_train / 255.0, x_test / 255.0

# Add a channels dimension
x_train = x_train[..., tf.newaxis]
x_test = x_test[..., tf.newaxis]

# smdistributed: If needed, seed the shuffle with smp.dp_rank(), and drop_remainder
# in batching to make sure batch size is always divisible by number of microbatches
train_ds = (tf.data.Dataset.from_tensor_slices((x_train, y_train))
    .shuffle(10000, seed=smp.dp_rank()))
```

2191
.batch(256, drop_remainder=True)
)

# smdistributed: Define smp.DistributedModel the same way as Keras sub-classing API
class MyModel(smp.DistributedModel):
    def __init__(self):
        super(MyModel, self).__init__()
        # define layers
        def call(self, x, training=None):
            # define forward pass and return the model output
            model = MyModel()
            loss_object = tf.keras.losses.SparseCategoricalCrossentropy(from_logits=True)
            optimizer = tf.keras.optimizers.Adam()
            train_accuracy = tf.keras.metrics.SparseCategoricalAccuracy(name="train_accuracy")
            # smdistributed: Define smp.step. Return any tensors needed outside
            @smp.step
            def get_grads(images, labels):
                predictions = model(images, training=True)
                loss = loss_object(labels, predictions)
                grads = optimizer.get_gradients(loss, model.trainable_variables)
                return grads, loss, predictions
            @tf.function
            def train_step(images, labels):
                gradients, loss, predictions = get_grads(images, labels)
                # smdistributed: Accumulate the gradients across microbatches
                gradients = [g.accumulate() for g in gradients]
                optimizer.apply_gradients(zip(gradients, model.trainable_variables))
                # smdistributed: Merge predictions and average losses across microbatches
                train_accuracy(labels, predictions.merge())
                return loss.reduce_mean()
            for epoch in range(5):
                # Reset the metrics at the start of the next epoch
                train_accuracy.reset_states()
                for images, labels in train_ds:
                    loss = train_step(images, labels)
                    accuracy = train_accuracy.result()

If you are done preparing your training script, proceed to Step 2: Launch a Training Job Using the SageMaker Python SDK (p. 2202). If you want to run a hybrid model and data parallel training job, continue to the next section.

Automated splitting with TensorFlow and Horovod for hybrid model and data parallelism

You can use the SageMaker model parallelism library with Horovod for hybrid model and data parallelism. To read more about how the library splits a model for hybrid parallelism, see Pipeline parallelism (available for PyTorch and TensorFlow) (p. 2147).

In this step, we focus on how to modify your training script to adapt the SageMaker model parallelism library.

To properly set up your training script to pick up the hybrid parallelism configuration that you'll set in Step 2: Launch a Training Job Using the SageMaker Python SDK (p. 2202), use the library's helper
functions, `smp.dp_rank()` and `smp.mp_rank()`, which automatically detect the data parallel rank and model parallel rank respectively.

To find all MPI primitives the library supports, see [MPI Basics](#) in the SageMaker Python SDK documentation.

The required changes needed in the script are:

- Adding `hvd.allreduce`
- Broadcasting variables after the first batch, as required by Horovod
- Seeding shuffling and/or sharding operations in the data pipeline with `smp.dp_rank()`.

**Note**

When you use Horovod, you must not directly call `hvd.init` in your training script. Instead, you'll have to set `"horovod"` to `True` in the SageMaker Python SDK model parallel parameters in Step 2: Launch a Training Job Using the SageMaker Python SDK (p. 2202). This allows the library to internally initialize Horovod based on the device assignments of model partitions. Calling `hvd.init()` directly in your training script can cause problems.

**Note**

Using the `hvd.DistributedOptimizer` API directly in your training script might result in a poor training performance and speed, because the API implicitly places the AllReduce operation inside `smp.step`. We recommend you to use the model parallelism library with Horovod by directly calling `hvd.allreduce` after calling `accumulate()` or `reduce_mean()` on the gradients returned from `smp.step`, as will be shown in the following example.

To learn more about the SageMaker's model parallelism library API, refer to the [API documentation](#).

```python
import tensorflow as tf
import horovod.tensorflow as hvd
import smpdistrbuted.modelparallel.tensorflow as smp

# smdistributed: Import TF2.x API
import smpdistrbuted.modelparallel.tensorflow as smp

# smdistributed: Initialize
smp.init()

# Download and load MNIST dataset.
(x_train, y_train), (x_test, y_test) = tf.keras.datasets.mnist.load_data(
    "MNIST-data-%d" % smp.rank()
)
x_train, x_test = x_train / 255.0, x_test / 255.0

# Add a channels dimension
x_train = x_train[..., tf.newaxis]
x_test = x_test[..., tf.newaxis]

# smdistributed: Seed the shuffle with smp.dp_rank(), and drop_remainder
# in batching to make sure batch size is always divisible by number of microbatches
train_ds = (tf.data.Dataset.from_tensor_slices((x_train, y_train)).shuffle(10000, seed=smp.dp_rank()).batch(256, drop_remainder=True))

# smdistributed: Define smp.DistributedModel the same way as Keras sub-classing API
class MyModel(smp.DistributedModel):
    def __init__(self):
        super(MyModel, self).__init__()
        # define layers
```
def call(self, x, training=None):
    # define forward pass and return model outputs

model = MyModel()

loss_object = tf.keras.losses.SparseCategoricalCrossentropy(from_logits=True)
optimizer = tf.keras.optimizers.Adam()
train_accuracy = tf.keras.metrics.SparseCategoricalAccuracy(name="train_accuracy")

# smdistributed: Define smp.step. Return any tensors needed outside
@smp.step
def get_grads(images, labels):
    predictions = model(images, training=True)
    loss = loss_object(labels, predictions)

    grads = optimizer.get_gradients(loss, model.trainable_variables)
    return grads, loss, predictions

@tf.function
def train_step(images, labels, first_batch):
    gradients, loss, predictions = get_grads(images, labels)

    # smdistributed: Accumulate the gradients across microbatches
    # Horovod: AllReduce the accumulated gradients
    gradients = [hvd.allreduce(g.accumulate()) for g in gradients]
    optimizer.apply_gradients(zip(gradients, model.trainable_variables))

    # Horovod: Broadcast the variables after first batch
    if first_batch:
        hvd.broadcast_variables(model.variables, root_rank=0)
        hvd.broadcast_variables(optimizer.variables(), root_rank=0)

    # smdistributed: Merge predictions across microbatches
    train_accuracy(labels, predictions.merge())
    return loss.reduce_mean()

for epoch in range(5):
    # Reset the metrics at the start of the next epoch
    train_accuracy.reset_states()

    for batch, (images, labels) in enumerate(train_ds):
        loss = train_step(images, labels, tf.constant(batch == 0))

Manual splitting with TensorFlow

Use smp.partition context managers to place operations in specific partition. Any operation not
placed in any smp.partition contexts is placed in the default_partition. To learn more about the
SageMaker's model parallelism library API, refer to the API documentation.

import tensorflow as tf
# smdistributed: Import TF2.x API.
import smdistributed.modelparallel.tensorflow as smp
# smdistributed: Initialize
smp.init()
x_train, x_test = x_train / 255.0, x_test / 255.0

# Add a channels dimension
x_train = x_train[..., tf.newaxis]
x_test = x_test[..., tf.newaxis]

# smdistributed: If needed, seed the shuffle with smp.dp_rank(), and drop_remainder
# in batching to make sure batch size is always divisible by number of microbatches.
train_ds = {
    tf.data.Dataset.from_tensor_slices((x_train, y_train))
    .shuffle(10000, seed=smp.dp_rank())
    .batch(256, drop_remainder=True)
}

# smdistributed: Define smp.DistributedModel the same way as Keras sub-classing API.
class MyModel(smp.DistributedModel):
    def __init__(self):
        # define layers
        def call(self, x):
            with smp.partition(0):
                x = self.layer0(x)
            with smp.partition(1):
                return self.layer1(x)

model = MyModel()

loss_object = tf.keras.losses.SparseCategoricalCrossentropy(from_logits=True)
optimizer = tf.keras.optimizers.Adam()
train_accuracy = tf.keras.metrics.SparseCategoricalAccuracy(name="train_accuracy")

# smdistributed: Define smp.step. Return any tensors needed outside @smp.step
@tf.function
def get_grads(images, labels):
    predictions = model(images, training=True)
    loss = loss_object(labels, predictions)
    grads = optimizer.get_gradients(loss, model.trainable_variables)
    return grads, loss, predictions

@tf.function
def train_step(images, labels):
    gradients, loss, predictions = get_grads(images, labels)

    # smdistributed: Accumulate the gradients across microbatches
    gradients = [g.accumulate() for g in gradients]
    optimizer.apply_gradients(zip(gradients, model.trainable_variables))

    # smdistributed: Merge predictions and average losses across microbatches
    train_accuracy(labels, predictions.merge())
    return loss.reduce_mean()

for epoch in range(5):
    # Reset the metrics at the start of the next epoch
    train_accuracy.reset_states()
    for images, labels in train_ds:
        loss = train_step(images, labels)
    accuracy = train_accuracy.result()
• `tf.GradientTape()` is currently not supported. You can use `Optimizer.get_gradients()` or `Optimizer.compute_gradients()` instead to compute gradients.

• The `tf.train.Checkpoint.restore()` API is currently not supported. For checkpointing, use `smp.CheckpointManager` instead, which provides the same API and functionality. Note that checkpoint restores with `smp.CheckpointManager` should take place after the first step.

### Modify a PyTorch Training Script

In this section, you learn how to modify PyTorch training scripts to configure the SageMaker model parallelism library for auto-partitioning and manual partitioning.

**Note**
To find which PyTorch versions are supported by the library, see [the section called “Supported Frameworks and AWS Regions”](#page-2153).

**Tip**
For end-to-end notebook examples that demonstrate how to use a PyTorch training script with the SageMaker model parallelism library, see [PyTorch Examples](#page-2223).

Note that auto-partitioning is enabled by default. Unless otherwise specified, the following scripts use auto-partitioning.

**Topics**
- Automated splitting with PyTorch (p. 2196)
- Manual splitting with PyTorch (p. 2198)
- Considerations (p. 2199)
- Unsupported framework features (p. 2201)

### Automated splitting with PyTorch

The following training script changes are required to run a PyTorch training script with SageMaker's model parallelism library:

1. Import and initialize the library with `smdistributed.modelparallel.torch.init()`.
2. Wrap the model with `smdistributed.modelparallel.torch.DistributedModel`. Be mindful that any tensors returned from the forward method of the underlying `nn.Module` object will be broadcast across model-parallel devices, incurring communication overhead, so any tensors that are not needed outside the call method (such as intermediate activations) should not be returned.

   **Note**
   For FP16 training, you need to use the `smdistributed.modelparallel.torch.model_creation()` context manager to wrap the model. For more information, see [FP16 Training with Model Parallelism](#page-2185).

3. Wrap the optimizer with `smdistributed.modelparallel.torch.DistributedOptimizer`.

   **Note**
   For FP16 training, you need to set up static or dynamic loss scaling. For more information, see [FP16 Training with Model Parallelism](#page-2185).

4. Use the returned `DistributedModel` object instead of a user model.
5. Put the forward and backward logic in a step function and decorate it with `smdistributed.modelparallel.torch.step`.
6. Restrict each process to its own device through `torch.cuda.set_device(smp.local_rank())`.
7. Move the input tensors to the GPU using the `.to()` API before the `smp.step` call (see example below).

9. Perform post-processing on the outputs across microbatches using `StepOutput` methods such as `reduce_mean`.

10. If there is an evaluation step, similarly place the forward logic inside an `smp.step`-decorated function and post-process the outputs using `StepOutput API`.

11. Set `drop_last=True` in `DataLoader`. Alternatively, manually skip a batch in the training loop if the batch size is not divisible by the number of microbatches.

To learn more about the SageMaker's model parallelism library API, refer to the [API documentation](#).

```python
import torch
import torch.nn as nn
import torch.nn.functional as F
import torch.optim as optim
from torchtext.datasets import SplitDataset
from torchvision import datasets
import smdistributed.modelparallel.torch as smp

class GroupedNet(nn.Module):
    def __init__(self):
        super(GroupedNet, self).__init__()
        # define layers
        def forward(self, x):
            # define forward pass and return model outputs

        @smp.step
        def train_step(model, data, target):
            output = model(data)
            loss = F.nll_loss(output, target, reduction="mean")
            model.backward(loss)
            return output, loss

    def train(model, device, train_loader, optimizer):
        model.train()
        for batch_idx, (data, target) in enumerate(train_loader):
            # smdistributed: Move input tensors to the GPU ID used by the current process,
            # based on the set_device call.
            data, target = data.to(device), target.to(device)
            optimizer.zero_grad()
            # Return value, loss_mb is a StepOutput object
            _, loss_mb = train_step(model, data, target)
            # smdistributed: Average the loss across microbatches.
            loss = loss_mb.reduce_mean()
            optimizer.step()

        # smdistributed: initialize the backend
        smp.init()

        # smdistributed: Set the device to the GPU ID used by the current process.
        # Input tensors should be transferred to this device.
        torch.cuda.set_device(smp.local_rank())
        device = torch.device("cuda")
        # smdistributed: Download only on a single process per instance.
```
# When this is not present, the file is corrupted by multiple processes trying to download and extract at the same time.

dataset = datasets.MNIST("../data", train=True, download=False)

# smdistributed: Shard the dataset based on data-parallel ranks
if smp.dp_size() > 1:
    partitions_dict = {f"{i}": 1 / smp.dp_size() for i in range(smp.dp_size())}
    dataset = SplitDataset(dataset, partitions=partitions_dict)
    dataset.select(f"{smp.dp_rank()}")

# smdistributed: Set drop_last=True to ensure that batch size is always divisible by the number of microbatches.
train_loader = torch.utils.data.DataLoader(dataset, batch_size=64, drop_last=True)

model = GroupedNet()
optimizer = optim.Adadelta(model.parameters(), lr=4.0)

# smdistributed: Use the DistributedModel container to provide the model to be partitioned across different ranks. For the rest of the script, the returned DistributedModel object should be used in place of the model provided for DistributedModel class instantiation.
model = smp.DistributedModel(model)
optimizer = smp.DistributedOptimizer(optimizer)

train(model, device, train_loader, optimizer)

Manual splitting with PyTorch

Use smpartition context managers to place modules in specific devices. Any module not placed in any sm.partition contexts is placed in the default_partition. The default_partition needs to be provided if auto_partition is set to False. The modules that are created within a specific sm.partition context are placed on the corresponding partition.

To learn more about the SageMaker's model parallelism library API, refer to the API documentation.

```python
import torch
import torch.nn as nn
import torch.nn.functional as F
import torch.optim as optim
from torchnet.dataset import SplitDataset
from torchvision import datasets
import smdistributed.modelparallel.torch as smp

class GroupedNet(nn.Module):
    def __init__(self):
        super(GroupedNet, self).__init__()
        with smp.partition(0):
            # define child modules on device 0
        with smp.partition(1):
            # define child modules on device 1

    def forward(self, x):
        # define forward pass and return model outputs

    @smp.step
    def train_step(model, data, target):
        output = model(data)
        loss = F.nll_loss(output, target, reduction="mean")
        model.backward(loss)
        return output, loss
```
```python
def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        # smdistributed: Move input tensors to the GPU ID used by the current process,
        # based on the set_device call.
        data, target = data.to(device), target.to(device)
        optimizer.zero_grad()
        # Return value, loss_mb is a StepOutput object
        _, loss_mb = train_step(model, data, target)
        # smdistributed: Average the loss across microbatches.
        loss = loss_mb.reduce_mean()
        optimizer.step()

    smp.init()

    torch.cuda.set_device(smp.local_rank())
    device = torch.device("cuda")

    dataset = datasets.MNIST("../data", train=True, download=False)

    if smp.dp_size() > 1:
        partitions_dict = {f"{i}": 1 / smp.dp_size() for i in range(smp.dp_size())}
        dataset = SplitDataset(dataset, partitions=partitions_dict)
        dataset.select(f"{smp.dp_rank()}"

    train_loader = torch.utils.data.DataLoader(dataset, batch_size=64, drop_last=True)

    model = GroupedNet()
    optimizer = optim.Adadelta(model.parameters(), lr=4.0)

    model = smp.DistributedModel(model)
    optimizer = smp.DistributedOptimizer(optimizer)

    train(model, device, train_loader, optimizer)
```

**Considerations**

When you configure a PyTorch training script using SageMaker's model parallelism library, you should be aware of the following:

- If you are using an optimization technique that relies on global gradient norms, for example gradient norm from the entire model, such as some variants of LAMB optimizer or global gradient clipping, you need to gather all the norms across the model partitions for correctness. You can use the library's communication basic data types to do this.
- All `torch.Tensor` arguments to the forward methods of the `nn.Module` in your model must be used in the computation of the module output. In other words, the library does not support the case where there is a `torch.Tensor` argument to a module on which the module output does not depend.
- The argument to the smp.DistributedModel.backward() call must depend on all model outputs. In other words, there cannot be an output from the smp.DistributedModel.forward call that is not used in the computation of the tensor that is fed into the smp.DistributedModel.backward call.

- If there are torch.cuda.synchronize() calls in your code, you might need to call torch.cuda.set_device(smp.local_rank()) immediately before the synchronize call. Otherwise unnecessary CUDA contexts might be created in device 0, which will needlessly consume memory.

- Since the library places nn.Modules on different devices, the modules in the model must not depend on any global state that is modified inside smp.step. Any state that remains fixed throughout training, or that is modified outside smp.step in a way that is visible to all processes, is allowed.

- You don't need to move the model to GPU (for example, using model.to(device)) when using the library. If you try to move the model to GPU before the model is partitioned (before the first smp.step call), the move call is ignored. The library automatically moves the part of the model assigned to a rank to its GPU. Once training with the library starts, don't move the model to CPU and use it, as it won't have correct parameters for modules not assigned to the partition held by the process. If you want to retrain a model or use it for inference without the library after it was trained using the model parallelism library, the recommended way is to save the full model using our checkpointing API and load it back to a regular PyTorch Module.

- If you have a list of modules such that output of one feeds into another, replacing that list with nn.Sequential can significantly improve performance.

- The weight update (optimizer.step()) needs to happen outside of smp.step because that is when the entire backward pass is done and gradients are ready. When using a hybrid model with model and data parallelism, at this point, AllReduce of gradients is also guaranteed to finish.

- When using the library in combination with data parallelism, make sure that the number of batches on all data parallel ranks is the same so that AllReduce does not hang waiting for a rank which is not participating in the step.

- If you launch a training job using an ml.p4d instance type (such as ml.p4d.24xlarge), you must set the data loader variable num_workers=0. For example, you may define your DataLoader as follows:

```python
dataloader = torch.utils.data.DataLoader(  
    data,  
    batch_size=batch_size,  
    num_workers=0,  
    pin_memory=True,  
    drop_last=True,  
    shuffle=shuffle,  
)
```

- The inputs to smp.step must be the model inputs generated by DataLoader. This is because smp.step internally splits the input tensors along the batch dimension and pipelines them. This means that passing DataLoader itself to the smp.step function to generate the model inputs inside does not work.

For example, if you define a DataLoader as follows:

```python
train_loader = torch.utils.data.DataLoader(dataset, batch_size=64, drop_last=True)
```

You should access the model inputs generated by train_loader and pass those to an smp.step decorated function. Do not pass train_loader directly to the smp.step function.

```python
def train(model, device, train_loader, optimizer):
    model.train()  
    for batch_idx, (data, target) in enumerate(train_loader):
        ...
```
The input tensors to `smp.step` must be moved to the current device using `.to()` API, which must take place after the `torch.cuda.set_device(local rank())` call.

For example, you may define the `train` function as follows. This function adds data and target to the current device using `.to()` API before using those input tensors to call `train_step`.

```python
def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        # smdistributed: Move input tensors to the GPU ID used by the current process,
        # based on the set_device call.
        data, target = data.to(device), target.to(device)
        optimizer.zero_grad()
        # Return value, loss_mb is a StepOutput object
        _, loss_mb = train_step(model, data, target)
        # smdistributed: Average the loss across microbatches.
        loss = loss_mb.reduce_mean()
        optimizer.step()
```

The input tensors to this `smp.set` decorated function have been moved to the current device in the `train` function above. The model does *not* need to be moved to the current device. The library automatically moves the part of the model assigned to a rank to its GPU.

```python
@smp.step
def train_step(model, data, target):
    output = model(data)
    loss = F.nll_loss(output, target, reduction="mean")
    model.backward(loss)
    return output, loss
```

## Unsupported framework features

The following PyTorch features are unsupported by SageMaker’s model parallelism library:

- If you use data parallelism with the native PyTorch DDP, the `torch.nn.parallel.DistributedDataParallel` wrapper module is not supported by the library. The library internally manages integrating with PyTorch DDP, including parameter broadcast and gradient AllReduce. When using the library, module buffers are only broadcast once at the start of training. If your model has module buffers that need to be synchronized across data parallel groups at each step, you can do so through the `torch.distributed` API, using the process group that can be obtained via `smp.get_dp_process_group()`.
- For mixed precision training, the `apex.amp` module is not supported. The recommended way to use the library with automatic mixed-precision is to use `torch.cuda.amp`, with the exception of using `smp.amp.GradScaler` instead of the implementation in torch.
- `torch.jit.ScriptModules` or `ScriptFunctions` are not supported by `smp.DistributedModel`.
- `apex : FusedLayerNorm, FusedAdam, FusedLAMB, and FusedNovoGrad` from apex are not supported. You can use the library implementations of these through `smp.optimizers` and `smp.nn APIs` instead.
Step 2: Launch a Training Job Using the SageMaker Python SDK

The SageMaker Python SDK supports managed training of models with ML frameworks such as TensorFlow and PyTorch. To launch a training job using one of these frameworks, you define a SageMaker TensorFlow estimator, a SageMaker PyTorch estimator, or a SageMaker generic Estimator to use the modified training script and model parallelism configuration.

Topics
- Using the SageMaker TensorFlow and PyTorch Estimators (p. 2202)
- Extend a Pre-built Docker Container that Contains SageMaker's Distributed Model Parallel Library (p. 2205)
- Create Your Own Docker Container with the SageMaker Distributed Model Parallel Library (p. 2206)

Using the SageMaker TensorFlow and PyTorch Estimators

The TensorFlow and PyTorch estimator classes contain the distribution parameter, which you can use to specify configuration parameters for using distributed training frameworks. The SageMaker model parallel library internally uses MPI for hybrid data and model parallelism, so you must use the MPI option with the library.

The following template of a TensorFlow or PyTorch estimator shows how to configure the distribution parameter for using the SageMaker model parallel library with MPI.

Using the SageMaker TensorFlow estimator

```python
import sagemaker
from sagemaker.tensorflow import TensorFlow

smp_options = {
    "enabled":True,  # Required
    "parameters": {
        "partitions": 2,       # Required
        "microbatches": 4,
        "placement_strategy": "spread",
        "pipeline": "interleaved",
        "optimize": "speed",
        "horovod": True,       # Use this for hybrid model and data parallelism
    }
}

mpi_options = {
    "enabled": True,  # Required
    "processes_per_host": 8,  # Required
    "custom_mpi_options": "--mca btl_vader_single_copy_mechanism none"
}

smd_mp_estimator = TensorFlow(
    entry_point="your_training_script.py",  # Specify your train script
    source_dir="location_to_your_script",
    role=sagemaker.get_execution_role(),
    instance_count=1,
    instance_type='ml.p3.16xlarge',
    framework_version='2.6.3',
    py_version='py38',
    distribution={
        "smdistributed": {"modelparallel": smp_options},
        "mpi": mpi_options
    },
    base_job_name="SMD-MP-demo",
)
```

2202
smd_mp_estimator.fit('s3://my_bucket/my_training_data/')

Using the SageMaker PyTorch estimator

```python
import sagemaker
from sagemaker.pytorch import PyTorch

smp_options = {
    "enabled": True,
    "parameters": {
        "pipeline_parallel_degree": 2,  # Required
        "microbatches": 4,
        "placement_strategy": "spread",
        "pipeline": "interleaved",
        "optimize": "speed",
        "ddp": True,
    }
}

mpi_options = {
    "enabled": True,  # Required
    "processes_per_host": 8,  # Required
    # "custom_mpi_options": "--mca btl_vader_single_copy_mechanism none"
}

smd_mp_estimator = PyTorch(
    entry_point="your_training_script.py",  # Specify your train script
    source_dir=location_to_your_script,
    role=sagemaker.get_execution_role(),
    instance_count=1,
    instance_type='ml.p3.16xlarge',
    framework_version='1.13.1',
    py_version='py38',
    distribution={
        "smdistributed": {"modelparallel": smp_options},
        "mpi": mpi_options
    },
    base_job_name="SMD-MP-demo",
)

smd_mp_estimator.fit('s3://my_bucket/my_training_data/')
```

To enable the library, you need to pass configuration dictionaries to the "smdistributed" and "mpi" keys through the distribution argument of the SageMaker estimator constructors.

**Configuration parameters for SageMaker model parallelism**

- For the "smdistributed" key, pass a dictionary with the "modelparallel" key and the following inner dictionaries.

  **Note**
  Using "modelparallel" and "dataparallel" in one training job is not supported.

  - "enabled" – Required. To enable model parallelism, set "enabled": True.
  - "parameters" – Required. Specify a set of parameters for SageMaker model parallelism.
  - For a complete list of common parameters, see Parameters for smdistributed in the SageMaker Python SDK documentation.

    For TensorFlow, see TensorFlow-specific Parameters.

    For PyTorch, see PyTorch-specific Parameters.
• "pipeline_parallel_degree" (or "partitions" in `smdistributed-modelparallel<v1.6.0`) – Required. Among the parameters for `smdistributed`, this parameter is required to specify how many model partitions you want to split into.

**Important**
There is a breaking change in the parameter name. The "pipeline_parallel_degree" parameter replaces the "partitions" since `smdistributed-modelparallel v1.6.0`. For more information, see Common Parameters for SageMaker model parallelism configuration and SageMaker Distributed Model Parallel Release Notes in the SageMaker Python SDK documentation.

• For the "mpi" key, pass a dictionary that contains the following:
  • "enabled" – Required. Set True to launch the distributed training job with MPI.
  • "processes_per_host" – Required. Specify the number of processes MPI should launch on each host. In SageMaker, a host is a single Amazon EC2 ML instance. The SageMaker Python SDK maintains a one-to-one mapping between processes and GPUs across model and data parallelism. This means that SageMaker schedules each process on a single, separate GPU and no GPU contains more than one process. If you are using PyTorch, you must restrict each process to its own device through `torch.cuda.set_device(smp.local_rank())`. To learn more, see Automated splitting with PyTorch (p. 2196).

**Important**
`process_per_host` must not be greater than the number of GPUs per instance and typically will be equal to the number of GPUs per instance.

• "custom_mpi_options" (optional) – Use this key to pass any custom MPI options you might need. If you do not pass any MPI custom options to the key, the MPI option is set by default to the following flag.

```
--mca btl_vader_single_copy_mechanism none
```

**Note**
You do not need to explicitly specify this default flag to the key. If you explicitly specify it, your distributed model parallel training job might fail with the following error:

```
The following MCA parameter has been listed multiple times on the command line:
MCA param: btl_vader_single_copy_mechanism MCA parameters can only be listed once
on a command line to ensure there is no ambiguity as to its value.
Please correct the situation and try again.
```

**Tip**
If you launch a training job using an EFA-enabled instance type, such as ml.p4d.24xlarge and ml.p3dn.24xlarge, use the following flag for best performance:

```
-x FI_EFA_USEDEVICE_RDMA=1 -x FI_PROVIDER=efa -x RDMAV_FORK_SAFE=1
```

To launch the training job using the estimator and your SageMaker model parallel configured training script, run the estimator.fit() function.

Use the following resources to learn more about using the model parallelism features in the SageMaker Python SDK:

• Use TensorFlow with the SageMaker Python SDK
• Use PyTorch with the SageMaker Python SDK
We recommend you use a SageMaker notebook instance if you are new users. To see an example of how you can launch a training job using a SageMaker notebook instance, see Amazon SageMaker Distributed Training Notebook Examples (p. 2223).

You can also submit a distributed training job from your machine using AWS CLI. To set up AWS CLI on your machine, see set up your AWS credentials and Region for development.

Extend a Pre-built Docker Container that Contains SageMaker’s Distributed Model Parallel Library

To extend a pre-built container and use SageMaker’s model parallelism library, you must use one of the available AWS Deep Learning Containers (DLC) images for PyTorch or TensorFlow. The SageMaker model parallelism library is included in the TensorFlow (2.3.0 and later) and PyTorch (1.6.0 and later) DLC images with CUDA (cudxyz). For a complete list of DLC images, see Available Deep Learning Containers Images in the AWS Deep Learning Containers GitHub repository.

Tip
We recommend that you use the image that contains the latest version of TensorFlow or PyTorch to access the most up-to-date version of the SageMaker model parallelism library.

For example, your Dockerfile should contain a FROM statement similar to the following:

```
# Use the SageMaker DLC image URI for TensorFlow or PyTorch
FROM aws-dlc-account-id.dkr.ecr.aws-region.amazonaws.com/framework-training:{framework-version-tag}

# Add your dependencies here
RUN ...

ENV PATH="/opt/ml/code:$PATH"

# this environment variable is used by the SageMaker container to determine our user code directory.
ENV SAGEMAKER_SUBMIT_DIRECTORY /opt/ml/code
```

Additionally, when you define a PyTorch or TensorFlow estimator, you must specify that the entry_point for your training script. This should be the same path identified with ENV SAGEMAKER_SUBMIT_DIRECTORY in your Dockerfile.

Tip
You must push this Docker container to Amazon Elastic Container Registry (Amazon ECR) and use the image URI (image_uri) to define a SageMaker estimator for training. For more information, see Extend a Pre-built Container (p. 3289).

After you finish hosting the Docker container and retrieving the image URI of the container, create a SageMaker PyTorch estimator object as follows. This example assumes that you have already defined smp_options and mpi_options.

```
smd_mp_estimator = Estimator(
    entry_point="your_training_script.py",
    role=sagemaker.get_execution_role(),
    instance_type='ml.p3.16xlarge',
    sagemaker_session=sagemaker_session,
    image_uri='your_aws_account_id.dkr.ecr.region.amazonaws.com/name:tag'
    instance_count=1,
    distribution=
        "smdistributed": smp_options,
        "mpi": mpi_options
    ),
    base_job_name="SMD-MP-demo",
```

2205
Create Your Own Docker Container with the SageMaker Distributed Model Parallel Library

To build your own Docker container for training and use the SageMaker model parallel library, you must include the correct dependencies and the binary files of the SageMaker distributed parallel libraries in your Dockerfile. This section provides the minimum set of code blocks you must include to properly prepare a SageMaker training environment and the model parallel library in your own Docker container.

Note
This custom Docker option with the SageMaker model parallel library as a binary is available only for PyTorch.

To create a Dockerfile with the SageMaker training toolkit and the model parallel library

1. Start with one of the NVIDIA CUDA base images.

```
FROM <cuda-cudnn-base-image>
```

Tip
The official AWS Deep Learning Container (DLC) images are built from the NVIDIA CUDA base images. We recommend you look into the official Dockerfiles of AWS Deep Learning Container for PyTorch to find which versions of the libraries you need to install and how to configure them. The official Dockerfiles are complete, benchmark tested, and managed by the SageMaker and Deep Learning Container service teams. In the provided link, choose the PyTorch version you use, choose the CUDA (cuxyz) folder, and choose the Dockerfile ending with .gpu or .sagemaker.gpu.

2. To set up a distributed training environment, you need to install software for communication and network devices, such as Elastic Fabric Adapter (EFA), NVIDIA Collective Communications Library (NCCL), and Open MPI. Depending on the PyTorch and CUDA versions you choose, you must install compatible versions of the libraries.

Important
Because the SageMaker model parallel library requires the SageMaker data parallel library in the subsequent steps, we highly recommend that you follow the instructions at Create Your Own Docker Container with the SageMaker Distributed Data Parallel Library (p. 2130) to properly set up a SageMaker training environment for distributed training.

For more information about setting up EFA with NCCL and Open MPI, see Get started with EFA and MPI and Get started with EFA and NCCL.

3. Add the following arguments to specify the URLs of the SageMaker distributed training packages for PyTorch. The SageMaker model parallel library requires the SageMaker data parallel library to use the cross-node Remote Direct Memory Access (RDMA).

```
ARG SMDATAPARALLEL_BINARY=https://smdataparallel.s3.amazonaws.com/binary/pytorch/1.10.2/cu113/2022-02-18/smdistributed_dataparallel-1.4.0-cp38-cp38-linux_x86_64.whl
```

4. Install dependencies that the SageMaker model parallel library requires.

a. Install the METIS library.

```
ARG METIS=metis-5.1.0
```
b. Install the **RAPIDS Memory Manager library**. This requires **CMake** 3.14 or later.

```bash
ARG RMM_VERSION=0.15.0
RUN wget -nv https://github.com/rapidsai/rmm/archive/v${RMM_VERSION}.tar.gz \\
    && tar -xvf v${RMM_VERSION}.tar.gz \\
    && cd rmm-${RMM_VERSION} \\
    && INSTALL_PREFIX=/usr/local ./build.sh librmm \\
    && cd .. \\
    && rm -rf v${RMM_VERSION}.tar* \\
    && rm -rf rmm-${RMM_VERSION}
```

5. Install the SageMaker model parallel library.

```bash
RUN pip install --no-cache-dir -U ${SMD_MODEL_PARALLEL_URL}
```

6. Install the SageMaker data parallel library.

```bash
RUN SMDATAPARALLEL_PT=1 pip install --no-cache-dir ${SMDATAPARALLEL_BINARY}
```

7. Install the **sagemaker-training toolkit**. The toolkit contains the common functionality that's necessary to create a container compatible with the SageMaker training platform and the SageMaker Python SDK.

```bash
RUN pip install sagemaker-training
```

8. After you finish creating the Dockerfile, see **Adapting Your Own Training Container** to learn how to build the Docker container and host it in Amazon ECR.

**Tip**
For more general information about creating a custom Dockerfile for training in SageMaker, see **Use Your Own Training Algorithms**.

### Checkpointing and Fine-Tuning a Model with Model Parallelism

The SageMaker model parallelism library provides checkpointing APIs to save the model state and the optimizer state split by the various model parallelism strategies, and to load checkpoints for continuous training from where you want to restart training and fine-tune. The APIs also support options to save the model and optimizer states partially or fully.

**Topics**
- Checkpointing a distributed model (p. 2208)
- Fine-tuning a distributed model (p. 2212)
Checkpointing a distributed model

Choose one of the following topics depending on the framework between PyTorch and TensorFlow and the version of the SageMaker model parallelism library you use.

Topics

- Checkpointing a distributed PyTorch model (for the SageMaker model parallelism library v1.10.0 and later) (p. 2208)
- Checkpointing a distributed PyTorch model (for the SageMaker model parallelism library between v1.6.0 and v1.9.0) (p. 2210)
- Checkpointing a distributed TensorFlow model (p. 2211)

Checkpointing a distributed PyTorch model (for the SageMaker model parallelism library v1.10.0 and later)

The SageMaker model parallelism library provides checkpoint APIs to save and load full or partial checkpoints of the distributed model state and its optimizer state.

**Note**

This checkpointing method is recommended if you use PyTorch and the SageMaker model parallelism library v1.10.0 or later.

Partial checkpointing

To save checkpoints of a model trained with model parallelism, use the `smdistributed.modelparallel.torch.save_checkpoint` API with the partial checkpointing option set to true (`partial=True`). This saves each model partition individually. In addition to the model and the optimizer state, you can also save any additional custom data through the `user_content` argument. The checkpointed model, optimizer, and user content are saved as separate files. The `save_checkpoint` API call creates checkpoint folders in the following structure.

```
- path
  - ${tag}_partial (folder for partial checkpoints)
    - model_rankinfo.pt
    - optimizer_rankinfo.pt
    - fp16_states_rankinfo.pt
    - user_content.pt
  - $tag (checkpoint file for full checkpoints)
  - user_content_$tag (user_content file for full checkpoints)
  - newest (a file that indicates the newest checkpoint)
```

To resume training from partial checkpoints, use the `smdistributed.modelparallel.torch.resume_from_checkpoint` API with `partial=True`, and specify the checkpoint directory and the tag used while saving the partial checkpoints. Note that the actual loading of model weights happens after model partitioning, during the first run of the `smdistributed.modelparallel.torch.step`-decorated training step function.

When saving a partial checkpoint, the library also saves the model partition decision as files with .pt file extension. Conversely, when resuming from the partial checkpoint, the library loads the partition decision files together. Once the partition decision is loaded, you can't change the partition.

The following code snippet shows how to set the checkpoint APIs in a PyTorch training script.

```python
import smdistributed.modelparallel.torch as smp
model = ...
```
model = smp.DistributedModel(model)
optimizer = ...
optimizer = smp.DistributedOptimizer(optimizer)
user_content = ...       # additional custom data
checkpoint_path = "/opt/ml/checkpoint/model_parallel"

# Save a checkpoint.
smp.save_checkpoint(
    path=checkpoint_path,
    tag=f"total_steps{total_steps}",
    partial=True,
    model=model,
    optimizer=optimizer,
    user_content=user_content
    num_kept_partial_checkpoints=5
)

# Load a checkpoint.
# This automatically loads the most recently saved checkpoint.
smp_checkpoint = smp.resume_from_checkpoint(
    path=checkpoint_path,
    partial=True
)

Full checkpointing

To save the final model artifact for inference purposes, use the smdistributed.modelparallel.torch.save_checkpoint API with partial=False, which combines the model partitions to create a single model artifact. Note that this does not combine the optimizer states.

To initialize training with particular weights, given a full model checkpoint, you can use the smdistributed.modelparallel.torch.resume_from_checkpoint API with partial=False. Note that this does not load optimizer states.

Note

With tensor parallelism, in general, the state_dict must be translated between the original model implementation and the DistributedModel implementation. Optionally, you can provide the state_dict translation function as an argument to the smdistributed.modelparallel.torch.resume_from_checkpoint. However, for the section called “Supported Models Out of the Box” (p. 2178), the library takes care of this translation automatically.

The following code shows an example of how to use the checkpoint APIs for fully checkpointing a PyTorch model trained with model parallelism.

```python
import smdistributed.modelparallel.torch as smp

model = ...
model = smp.DistributedModel(model)
optimizer = ...
optimizer = smp.DistributedOptimizer(optimizer)
user_content = ...       # additional custom data
checkpoint_path = "/opt/ml/checkpoint/model_parallel"

# Save a checkpoint.
smp.save_checkpoint(
    path=checkpoint_path,
    tag=f"total_steps{total_steps}",
    partial=False,
    model=model,
    optimizer=optimizer,
```
Checkpointing a distributed PyTorch model (for the SageMaker model parallelism library between v1.6.0 and v1.9.0)

The SageMaker model parallelism library provides Python functions for saving partial or full checkpoints for training jobs with tensor parallelism. The following procedure shows how to use `smp.save()` and `smp.load()` to save and load a checkpoint when you use tensor parallelism.

**Note**
This checkpointing method is recommended if you use PyTorch, the section called “Tensor Parallelism” (p. 2171), and the SageMaker model parallelism library between v1.6.0 and v1.9.0.

1. Prepare a model object and wrap it with the library's wrapper function `smp.DistributedModel()`.

```python
model = MyModel(...)  
model = smp.DistributedModel(model)
```

2. Prepare an optimizer for the model. A set of model parameters is an iterable argument required by optimizer functions. To prepare a set of model parameters, you must process `model.parameters()` to assign unique IDs to individual model parameters.

If there are parameters with duplicated IDs in the model parameter iterable, loading the checkpointed optimizer state fails. To create an iterable of model parameters with unique IDs for your optimizer, see the following:

```python
unique_params = []
unique_params_set = set()
for p in model.parameters():
    if p not in unique_params_set:
        unique_params.append(p)
        unique_params_set.add(p)
del unique_params_set
optimizer = MyOpt(unique_params, ...)
```

3. Wrap the optimizer using the library's wrapper function `smp.DistributedOptimizer()`.

```python
optimizer = smp.DistributedOptimizer(optimizer)
```

4. Save the model and the optimizer state using `smp.save()`. Depending on how you want to save checkpoints, choose one of the following two options:

   - **Option 1**: Save a partial model on each `mp_rank` for a single `MP_GROUP`.

```python
model_dict = model.local_state_dict() # save a partial model
opt_dict = optimizer.local_state_dict() # save a partial optimizer state
# Save the dictionaries at rdp_rank 0 as a checkpoint
if smp.rdp_rank() == 0:
    smp.save(
        "model_state_dict": model_dict, "optimizer_state_dict": opt_dict),
        f"/checkpoint.pt",
```
With tensor parallelism, the library saves checkpointed files named in the following format:

class.pt_{pp_rank}_{tp_rank}.

Note

With tensor parallelism, make sure you set the if statement as if smp.rdp_rank() == 0 instead of if smp.dp_rank() == 0. When the optimizer state is sharded with tensor parallelism, all reduced-data parallel ranks must save their own partition of the optimizer state. Using a wrong if statement for checkpointing might result in a stalling training job. For more information about using if smp.dp_rank() == 0 without tensor parallelism, see General Instruction for Saving and Loading in the SageMaker Python SDK documentation.

• Option 2: Save the full model.

```python
if smp.rdp_rank() == 0:
    model_dict = model.state_dict(gather_to_rank0=True) # save the full model
if smp.rank() == 0:
    smp.save(
        "model_state_dict": model_dict,
        "/checkpoint.pt",
        partial=False,
    )
```

Note

Consider the following for full checkpointing:

- If you set gather_to_rank0=True, all ranks other than 0 return empty dictionaries.
- For full checkpointing, you can only checkpoint the model. Full checkpointing of optimizer states is currently not supported.
- The full model only needs to be saved at smp.rank() == 0.

5. Load the checkpoints using smp.load(). Depending on how you checkpointed in the previous step, choose one of the following two options:

• Option 1: Load the partial checkpoints.

```python
checkpoint = smp.load("/checkpoint.pt", partial=True)
model.load_state_dict(checkpoint["model_state_dict"], same_partition_load=False)
optimizer.load_state_dict(checkpoint["optimizer_state_dict"])
```

You can set same_partition_load=True in model.load_state_dict() for a faster load, if you know that the partition will not change.

• Option 2: Load the full checkpoints.

```python
if smp.rdp_rank() == 0:
    checkpoint = smp.load("/checkpoint.pt", partial=False)
    model.load_state_dict(checkpoint["model_state_dict"])
```

The if smp.rdp_rank() == 0 condition is not required, but it can help avoid redundant loading among different MPGROUPs. Full checkpointing optimizer state dict is currently not supported with tensor parallelism.

Checkpointing a distributed TensorFlow model

To save a TensorFlow model while training with model parallelism, use the following functions provided by the SageMaker model parallelism library.
Fine-tuning a distributed model

The fine-tuning needs to be configured in your training script. The following code snippet shows an example structure of a training script using the `AutoModelForCausalLM` class of Hugging Face Transformers with modifications for registering the `smdistributed.model.parallel.torch` modules and settings for fine-tuning.

```python
import argparse
from transformers import AutoModelForCausalLM
import smdistributed.modelparallel
import smdistributed.modelparallel.torch as smp

def parse_args():
    parser = argparse.ArgumentParser()
    # set an arg group for model
    model_grp = parser.add_argument_group(
        title="model", description="arguments to describe model configuration"
    )
    ...
    # set up numerous args to parse from the configuration dictionary to the script for training
    # add arg for activating fine-tuning
    model_grp.add_argument(
        "--fine_tune",
        type=int,
        default=0,
        help="Fine-tune model from checkpoint or pretrained model",
    )

def main():
    """Main function to train GPT."""
    args = parse_args()
    ...
    # parse numerous args
    if args.fine_tune > 0 and args.delayed_param > 0 and smp.rank() == 0:
        pretrained_model = AutoModelForCausalLM.from_pretrained(
            args.model_name or args.model_dir
        )
        model_state_dict = pretrained_model.state_dict()
        path = os.path.join(args.model_dir, "fullmodel.pt")
        torch.save(model_state_dict, path)

        # create a Transformer model and wrap by smp.model_creation()
        # with options to configure model parallelism parameters offered by SageMaker
        with smp.model_creation(
            tensor_parallelism=smp.tp_size() > 1 or args.use_distributed_transformer > 0,
            zero_init=args.use_distributed_transformer == 0,
            dtype=dtype,
```
SageMaker's Model Parallelism Library

distribute_embedding=args.sharded_data_parallel_degree > 1 and smp.tp_size() > 1,
use_alibi=args.alibi > 0,
attention_in_fp32=args.attention_in_fp32 > 0,
fp32_residual_addition=args.residual_addition_in_fp32 > 0,
query_key_layer_scaling=args.query_key_layer_scaling > 0 and args.bf16 < 1,
fused_softmax=args.fused_softmax > 0,
fused_dropout=args.fused_dropout > 0,
fused_bias_gelu=args.fused_bias_gelu > 0,
flash_attention=args.flash_attention > 0,
)
if args.fine_tune > 0 and args.delayed_param == 0:
    model = AutoModelForCausalLM.from_pretrained(
        args.model_name or args.model_dir
    )
else:
    model = AutoModelForCausalLM.from_config(model_config)

# wrap the model by smp.DistributedModel() to apply SageMaker model parallelism
model = smp.DistributedModel(
    model, trace_device="gpu", backward_passes_per_step=args.gradient_accumulation
)

# wrap the optimizer by smp.DistributedOptimizer() to apply SageMaker model parallelism
optimizer = smp.DistributedOptimizer(
    optimizer,
    static_loss_scale=None,
    dynamic_loss_scale=True,
    dynamic_loss_args={"scale_window": 1000, "min_scale": 1, "delayed_shift": 2},
)

# for fine-tuning, use smp.resume_from_checkpoint() to load a pre-trained model
if args.fine_tune > 0 and args.delayed_param > 0:
    smp.resume_from_checkpoint(args.model_dir, tag="fullmodel.pt", partial=False)

For a complete example of training scripts and Jupyter notebooks, see the GPT-2 examples for PyTorch in the SageMaker Examples GitHub repository.

SageMaker Distributed Model Parallelism Best Practices

Use the following guidelines when you run a distributed training job with the SageMaker model parallel library.

Setting Up the Right Configuration for a Given Model

When scaling up a model, we recommend you to go over the following list in order. Each list item discusses the advantage of using the library's techniques along with the tradeoffs that might arise.

Tip
If a model can fit well using a subset of the library's features, adding more model parallelism or memory saving features does not usually improve performance.

Using large GPU instance types

- In the realm of model parallelism, it is best to use powerful instances with large GPU memories to handle overhead from model parallelism operations such as partitioning models across multiple GPUs. We recommend using ml.p4d or ml.p3dn instances for training large DL models. These instances are also equipped with Elastic Fabric Adapter (EFA), which provides higher network bandwidth and enables large-scale training with model parallelism.
Sharding optimizer state

- The impact of sharding optimizer state depends on the number of data parallel ranks. Typically, a higher degree of data parallelism (proportional to the size of compute node) can improve the efficiency of memory usage.

When you want to downsize a cluster, make sure you check the optimizer state sharding configuration. For example, a large DL model with optimizer state sharding that fits on a compute cluster with 16 GPUs (for example, two P4d or P4de instances) might not always fit on a node with 8 GPUs (for example, a single P4d or P4de instance). This is because the combined memory of 8 GPUs is lower than the combined memory of 16 GPUs, and the required memory per GPU for sharding over 8 GPUs is also higher than the memory per GPU for sharding over the 16-GPU scenario. As a result, the increased memory requirement might not fit into the smaller cluster.

For more information, see Optimizer State Sharding (p. 2182).

Activation checkpointing

- Memory efficiency can be improved by using activation checkpointing for a group of modules. The more you group the modules, the more efficient the memory usage. When checkpointing sequential modules for layers, the strategy argument of the smp.set_activation_checkpointing function groups the layers together for checkpointing. For example, grouping two or more layers together for checkpointing is more memory efficient than checkpointing one layer at a time, and this trades extra computation time for reduced memory usage.

For more information, see Activation Checkpointing (p. 2183).

Tensor parallelism

- The degree of tensor parallelism should be a power of two (2, 4, 8, ..., 2^n), where the maximum degree must be equal to the number of GPUs per node. For example, if you use a node with 8 GPUs, possible numbers for the degree of tensor parallelism are 2, 4, and 8. We don't recommend arbitrary numbers (such as 3, 5, 6, and 7) for the degree of tensor parallelism. When you use multiple nodes, misconfiguring the degree of tensor parallelism might result in running tensor parallelism across the nodes; this adds significant overhead from communication of activations across the nodes and can become computationally expensive.

For more information, see Tensor Parallelism (p. 2171).

Pipeline parallelism across nodes

- You can run pipeline parallelism both within a single node and across multiple nodes. When you use pipeline parallelism in combination with tensor parallelism, we recommend running pipeline parallelism across multiple nodes and keeping tensor parallelism within individual nodes.

- Pipeline parallelism comes with the following three knobs: microbatches, active_microbatches, and prescaled_batch.

- When you use tensor parallelism with pipeline parallelism, we recommend activating prescaled_batch so that the batch size per model parallel group can be increased for efficient pipelining. With prescaled_batch activated, the batch size set in the training script becomes tp_size times the batch size set for each rank without prescaled_batch.

- Increasing the number of microbatches helps achieve efficient pipelining and better performance. Note that the effective microbatch size is the batch size divided by number of microbatches. If you increase the number of microbatches while keeping batch size constant, each microbatch processes fewer samples.
• The number of active microbatches is the maximum number of microbatches that are simultaneously in process during pipelining. For each active microbatch in process, its activations and gradients take up GPU memory. Therefore, increasing active microbatches takes up more GPU memory.

• If both GPU and GPU memory are underutilized, increase active microbatches for better parallelization during pipelining.

• For more information about how to use tensor parallelism with pipeline parallelism, see Tensor parallelism combined with pipeline parallelism (p. 2176).

• To find descriptions of the aforementioned parameters, see Parameters for smdistributed in the SageMaker Python SDK documentation.

Offloading activations to CPU

• Make sure that this is used in combination with activation checkpointing and pipeline parallelism. To ensure that the offloading and preloading happen in the background, specify a value greater than 1 to the microbatches parameter.

• When offloading activations, you might be able to increase active microbatches and sometimes match with the total number of microbatches. This depends on which modules are checkpointed and how the model is partitioned.

For more information, see Activation Offloading (p. 2184).

Reference configurations

The SageMaker model parallelism training team provides the following reference points based on experiments with the GPT-2 model, the sequence length of 512, and the vocabulary size of 50,000.

<table>
<thead>
<tr>
<th>The number of model parameters</th>
<th>Instance type</th>
<th>Pipeline parallelism</th>
<th>Tensor parallelism</th>
<th>Optimizer state sharding</th>
<th>Activation checkpointing</th>
<th>Prescaled batch</th>
<th>Batch size</th>
</tr>
</thead>
<tbody>
<tr>
<td>10 billion</td>
<td>ml.p4d.24xlarge</td>
<td>1</td>
<td>4</td>
<td>True</td>
<td>Each transformer layer</td>
<td>True</td>
<td>batch_size=40</td>
</tr>
<tr>
<td>30 billion</td>
<td>ml.p4d.24xlarge</td>
<td>1</td>
<td>8</td>
<td>True</td>
<td>Each transformer layer</td>
<td>True</td>
<td>batch_size=32</td>
</tr>
<tr>
<td>60 billion</td>
<td>ml.p4d.24xlarge</td>
<td>2</td>
<td>8</td>
<td>True</td>
<td>Each transformer layer</td>
<td>True</td>
<td>batch_size=56, microbatches=4, active_microbatches=2</td>
</tr>
</tbody>
</table>

You can extrapolate from the preceding configurations to estimate GPU memory usage for your model configuration. For example, if you increase the sequence length for a 10-billion-parameter model or increase the size of the model to 20 billion, you might want to lower batch size first. If the model still doesn't fit, try increasing the degree of tensor parallelism.

Modifying Your Training Script

• Before you use the SageMaker model parallel library's features in your training script, review The SageMaker Distributed Model Parallelism Library Configuration Tips and Pitfalls (p. 2216).
• To launch a training job faster, use the SageMaker local mode. This helps you quickly run a training job locally on a SageMaker notebook instance. Depending on the scale of the ML instance on which your SageMaker notebook instance is running, you might need to adjust the size of your model by changing the model configurations, such as the hidden width, number of transformer layers, and attention heads. Validate if the reduced model runs well on the notebook instance before using a large cluster for training the full model.

**Monitoring and Logging a Training Job Using the SageMaker Console and Amazon CloudWatch**

To monitor system-level metrics such as CPU memory utilization, GPU memory utilization, and GPU utilization, use visualization provided through the SageMaker console.

1. In the left navigation pane, choose Training.
2. Choose Training jobs.
3. In the main pane, choose the training job name for which you want to see more details.
4. Browse the main pane and find the Monitor section to see the automated visualization.
5. To see training job logs, choose View logs in the Monitor section. You can access the distributed training job logs of the training job in CloudWatch. If you launched multi-node distributed training, you should see multiple log streams with tags in the format of algo-n-1234567890. The algo-1 log stream tracks training logs from the main (0th) node.

For more information, see [Monitor and Analyze Training Jobs Using Amazon CloudWatch Metrics](p. 2315).

**Permissions**

To run a SageMaker training job with model parallelism or the SageMaker distributed training example notebooks, make sure you have the right permissions in your IAM role, such as the following:

• To use FSx for Lustre, add AmazonFSxFullAccess.
• To use Amazon S3 as a data channel, add AmazonS3FullAccess.
• To use Docker, build your own container, and push it to Amazon ECR, add AmazonEC2ContainerRegistryFullAccess.
• To have a full access to use the entire suite of SageMaker features, add AmazonSageMakerFullAccess.

**The SageMaker Distributed Model Parallelism Library**

**Configuration Tips and Pitfalls**

Review the following tips and pitfalls before using Amazon SageMaker's model parallelism library. This list includes tips that are applicable across frameworks. For TensorFlow and PyTorch specific tips, see [Modify a TensorFlow training script](p. 2190) and [Modify a PyTorch Training Script](p. 2196), respectively.

**Batch Size and Number of Microbatches**

• The library is most efficient when the batch size is increased. For use cases where the model fits within a single device, but can only be trained with a small batch size, batch size can and should be increased after the library is integrated. Model parallelism saves memory for large models, enabling you to train using batch sizes that previously did not fit in memory.
• Choosing a number of microbatches that is too small or too large can lower performance. The library executes each microbatch sequentially in each device, so microbatch size (batch size divided by
number of microbatches) must be large enough to fully utilize each GPU. At the same time, pipeline efficiency increases with the number of microbatches, so striking the right balance is important. Typically, a good starting point is to try 2 or 4 microbatches, increasing the batch size to the memory limit, and then experiment with larger batch sizes and numbers of microbatches. As the number of microbatches is increased, larger batch sizes might become feasible if an interleaved pipeline is used.

- Your batch size must be always divisible by the number of microbatches. Note that depending on the size of the dataset, sometimes the last batch of every epoch can be of a smaller size than the rest, and this smaller batch needs to be divisible by the number of microbatches as well. If it is not, you can set `drop_remainder=True` in the `tf.Dataset.batch()` call (in TensorFlow), or set `drop_last=True` in `DataLoader` (in PyTorch), so that this last, small batch is not used. If you are using a different API for the data pipeline, you might need to manually skip the last batch whenever it is not divisible by the number of microbatches.

**Manual Partitioning**

- If you use manual partitioning, be mindful of the parameters that are consumed by multiple operations and modules in your model, such as the embedding table in transformer architectures. Modules that share the same parameter must be placed in the same device for correctness. When auto-partitioning is used, the library automatically enforces this constraint.

**Data Preparation**

- If the model takes multiple inputs, make sure you seed the random operations in your data pipeline (e.g., shuffling) with `smp.dp_rank()`. If the dataset is being deterministically sharded across data parallel devices, make sure that the shard is indexed by `smp.dp_rank()`. This is to make sure that the order of the data seen on all ranks that form a model partition is consistent.

**Returning Tensors from `smp.DistributedModel`**

- Any tensor that is returned from the `smp.DistributedModel.call` (for TensorFlow) or `smp.DistributedModel.forward` (for PyTorch) function is broadcast to all other ranks, from the rank that computed that particular tensor. As a result, any tensor that is not needed outside the call and forward methods (intermediate activations, for example) should not be returned, as this causes needless communication and memory overhead and hurts performance.

**The `@smp.step` Decorator**

- If an `smp.step`-decorated function has a tensor argument that does not have a batch dimension, the argument name must be provided in the `non_split_inputs` list when calling `smp.step`. This prevents the library from attempting to split the tensor into microbatches. For more information see `smp.step` in the API documentation.

**Delaying Parameter Initialization**

For very large models over 100 billion parameters, weight initialization through the CPU memory might result in an out-of-memory error. To get around this, the library offers `smp.delay_param_initialization` context manager. This delays the physical allocation of parameters until they move to GPU during the first execution of a `smp.step`-decorated function. This avoids unnecessary memory usage of the CPU during the initialization of training. Use the context manager when you create a model object as shown in the following code.

```python
with smp.delay_param_initialization(enabled=True):
```
Tensor Parallelism for PyTorch

- If you are using a seed for deterministic results, set the seed based on `smp.dp_rank()` (for example, `torch.manual_seed(42 + smp.dp_rank())`). If you do not do this, different partitions of an `nn.Parameter` are initialized in the same way, impacting convergence.

- SageMaker's model parallelism library uses NCCL to implement collectives needed for the distribution of the modules. Especially for smaller models, if too many NCCL calls are scheduled on the GPU at the same time, memory usage might increase because of additional space used by NCCL. To counteract this, `smp` throttles the NCCL calls so that the number of ongoing NCCL operations at any given time is less than or equal to a given limit. The default limit is 8, but this can be adjusted using the environment variable `SMP_NCCL_THROTTLE_LIMIT`. If you observe more memory usage than you expect while using tensor parallelism, you can try reducing this limit. However, choosing a limit that is too small might cause throughput loss. To disable throttling altogether, you can set `SMP_NCCL_THROTTLE_LIMIT=-1`.

- The following identity, which holds when the degree of tensor parallelism is 1, does not hold when the degree of tensor parallelism is greater than 1: `smp.mp_size() * smp.dp_size() == smp.size()`. This is because the tensor parallel group is part of both the model parallelism group and the data parallelism group. If your code has existing references to `mp_rank`, `mp_size`, `MP_GROUP`, and so on, and if you want to work with only the pipeline parallel group, you might need to replace the references with `smp.pp_size()`. The following identities are always true:
  - `smp.mp_size() * smp.rdp_size() == smp.size()`  
  - `smp.pp_size() * smp.dp_size() == smp.size()`  
  - `smp.pp_size() * smp.tp_size() * smp.rdp_size() == smp.size()`  

- Since the `smp.DistributedModel` wrapper modifies the model parameters when tensor parallelism is enabled, the optimizer should be created after calling `smp.DistributedModel`, with the distributed parameters. For example, the following does not work:
  ```python
  ## WRONG
  model = MyModel()
  optimizer = SomeOptimizer(model.parameters())
  model = smp.DistributedModel(model)  # optimizer now has outdated parameters!
  ```

  Instead, the optimizer should be created with the parameters of the `smp.DistributedModel` as follows:
  ```python
  ## CORRECT
  model = smp.DistributedModel(MyModel())
  optimizer = SomeOptimizer(model.optimizers())
  ```

- When a module is replaced with its distributed counterpart through tensor parallelism, the distributed module does not inherit its weights from the original module, and initializes new weights. This means that, for instance, if the weights need to be initialized in a particular call (for example, through a `load_state_dict` call), this needs to happen after the `smp.DistributedModel` call, once the module distribution takes place.

- When accessing the parameters of distributed modules directly, note that the weight does not have the same shape as the original module. For instance,
  ```python
  with smp.tensor_parallelism():
      linear = nn.Linear(60, 60)
  # will pass
  assert tuple(linear.weight.shape) == (60, 60)
  ```
Using `torch.utils.data.distributed.DistributedSampler` is strongly recommended for tensor parallelism. This ensures that every data parallel rank receives the same number of data samples, which prevents hangs that might result from different `dp_ranks` taking a different number of steps.

If you use the `join` API of PyTorch's `DistributedDataParallel` class to handle cases in which different data parallel ranks have different numbers of batches, you still need to make sure that ranks that are in the same `TP_GROUP` have the same number of batches; otherwise the communication collectives used in distributed execution of modules may hang. Ranks that are in different `TP_GROUP` can have different numbers of batches, as long as `join` API is used.

If you want to checkpoint your model and use tensor parallelism, consider the following:

- To avoid stalling and race conditions while saving and loading models when you use tensor parallelism, make sure you call appropriate functions from the following model and optimizer states inside a reduced-data parallelism rank.

- If you are transitioning an existing pipeline parallel script and enabling tensor parallel for the script, ensure that you modify any `if smp.dp_rank() == 0` block used for saving and loading with `if smp.rdp_rank() == 0` blocks. Otherwise, it might cause your training job to stall.

For more information about checkpointing a model with tensor parallelism, see the section called “Checkpointing a distributed model” (p. 2208).

## Model Parallel Troubleshooting

If you run into an error, you can use the following list to try to troubleshoot your training job. If the problem persists, contact AWS Support.

### Topics

- Considerations for Using SageMaker Debugger with the SageMaker Model Parallelism Library (p. 2219)
- Saving Checkpoints (p. 2220)
- Convergence Using Model Parallel and TensorFlow (p. 2221)
- Stalling or Crashing Distributed Training Jobs (p. 2221)
- Receiving NCCL Error for a PyTorch Training Job (p. 2222)
- Receiving RecursionError for a PyTorch Training Job (p. 2223)

### Considerations for Using SageMaker Debugger with the SageMaker Model Parallelism Library

SageMaker Debugger is not available for the SageMaker model parallelism library. Debugger is enabled by default for all SageMaker TensorFlow and PyTorch training jobs, and you might see an error that looks like the following:

```python
FileNotFoundError: [Errno 2] No such file or directory: '/opt/ml/checkpoints/metadata.json.sagemaker-uploading
```

To fix this issue, disable Debugger by passing `debugger_hook_config=False` when creating a framework estimator as shown in the following example.
bucket=sagemaker.Session().default_bucket()
base_job_name="sagemaker-checkpoint-test"
checkpoint_in_bucket="checkpoints"

# The S3 URI to store the checkpoints
checkpoint_s3_bucket="s3://{}/{}/{}".format(bucket, base_job_name, checkpoint_in_bucket)
estimator = TensorFlow(
    ...
    distribution="smdistributed": {"modelparallel": { "enabled": True }},
    checkpoint_s3_uri=checkpoint_s3_bucket,
    checkpoint_local_path="/opt/ml/checkpoints",
    debugger_hook_config=False
)

**Saving Checkpoints**

You might run into the following error when saving checkpoints of a large model on SageMaker:

```
InternalServerError: We encountered an internal error. Please try again
```

This could be caused by a SageMaker limitation while uploading the local checkpoint to Amazon S3 during training. To disable checkpointing in SageMaker, use the following example to explicitly upload the checkpoints.

If you run into the preceding error, do not use `checkpoint_s3_uri` with the SageMaker `estimator` call. While saving checkpoints for larger models, we recommend saving checkpoints to a custom directory and passing the same to the helper function (as a `local_path` argument).

```python
import os
def aws_s3_sync(source, destination):
    """aws s3 sync in quiet mode and time profile""
    import time, subprocess
    cmd = ['aws', 's3', 'sync', '--quiet', source, destination]
    print(f"Syncing files from {source} to {destination}"
    start_time = time.time()
    p = subprocess.Popen(cmd, stdout=subprocess.PIPE, stderr=subprocess.PIPE)
    p.wait()
    end_time = time.time()
    print(f"Time Taken to Sync: ", (end_time-start_time))
    return

def sync_local_checkpoints_to_s3(local_path="/opt/ml/checkpoints",
s3_uri=os.path.dirname(os.path.dirname(os.getenv('SM_MODULE_DIR', '')))+'/checkpoints'): ""
    sample function to sync checkpoints from local path to s3"
    import boto3
    #check if local path exists
    if not os.path.exists(local_path):
        raise RuntimeError("Provided local path {local_path} does not exist. Please check")
    #check if s3 bucket exists
    s3 = boto3.resource('s3')
    if not s3_uri.startswith("s3://"):
        raise ValueError(f"Provided s3 uri {s3_uri} is not valid.
    s3_bucket = s3_uri.replace("s3://", '').split('/')[0]
    print(f"S3 Bucket: {s3_bucket}")
    try:
```
s3.meta.client.head_bucket(Bucket=s3_bucket)
except Exception as e:
    raise e
aws_s3_sync(local_path, s3_uri)
return

def sync_s3_checkpoints_to_local(local_path="/opt/ml/checkpoints",
s3_uri=os.path.dirname(os.path.dirname(os.getenv('SM_MODULE_DIR', '')))+'/checkpoints':
    """sample function to sync checkpoints from s3 to local path """
import boto3
#try to create local path if it does not exist
if not os.path.exists(local_path):
    print(f"Provided local path {local_path} does not exist. Creating...")
    try:
        os.makedirs(local_path)
    except Exception as e:
        raise RuntimeError(f"Failed to create {local_path}")

#check if s3 bucket exists
s3 = boto3.resource('s3')
if not s3_uri.startswith("s3://"):
    raise ValueError(f"Provided s3 uri {s3_uri} is not valid.")
s3_bucket = s3_uri.replace('s3://','').split('/')[0]
print(f"S3 Bucket: {s3_bucket}")
try:
    s3.meta.client.head_bucket(Bucket=s3_bucket)
except Exception as e:
    raise e
aws_s3_sync(s3_uri, local_path)
return

Usage of helper functions:

#base_s3_uri - user input s3 uri or save to model directory (default)
#curr_host - to save checkpoints of current host
#iteration - current step/epoch during which checkpoint is saved

# save checkpoints on every node using local_rank
if smp.local_rank() == 0:
    base_s3_uri = os.path.dirname(os.path.dirname(os.getenv('SM_MODULE_DIR', '')))
curr_host = os.environ['SM_CURRENT_HOST']
full_s3_uri = f'{base_s3_uri}/checkpoints/{curr_host}/iteration'
sync_local_checkpoints_to_s3(local_path=checkpoint_dir, s3_uri=full_s3_uri)

Convergence Using Model Parallel and TensorFlow

When you use SageMaker multi-node training with TensorFlow and the model parallelism library, the loss may not converge as expected because the order of training input files may be different on each node. This may cause different ranks in the same model parallel group to work on different input files, causing inconsistencies. To prevent this, ensure the input files are ordered the same way in all the ranks before they get converted to TensorFlow datasets. One way to achieve this is to sort the input file names in the training script.

Stalling or Crashing Distributed Training Jobs

If your training job has stalling, crashing, or not responding issues, read the following troubleshooting items to identify what's the cause of the issue. If you need any further support, reach out to the SageMaker distributed training team through [AWS Support](https://aws.amazon.com/support/contact/).

- If you see a distributed training job stalling at the NCCL initialization step, consider the following:
• If you are using one of the EFA-enabled instances (ml.p4d or ml.p3dn instances) with a custom VPC and its subnet, ensure that the security group used has inbound and outbound connections for all ports to and from the same SG. You also generally need outbound connections to any IP as a separate rule (for internet access). To find instructions on how to add inbound and outbound rules for EFA communication, refer to SageMaker Distributed Training Job Stalling During Initialization (p. 2143).

• If you see a distributed training job stalling when checkpointing the full model, this might be because the state_dict() call on the model or optimizer was not made on all ranks with rdp_rank()==0 (when using tensor parallelism) or dp_rank()==0 (when using only pipeline parallelism). These ranks need to communicate to construct the checkpoint to be saved. Similar stalling issues can also happen when checkpointing partial optimizer if shard_optimizer_state is enabled.

For more information about checkpointing a model with model parallelism, see General Instruction for Saving and Loading and Checkpointing a distributed PyTorch model (for the SageMaker model parallelism library between v1.6.0 and v1.9.0) (p. 2210).

• If the training job crashes with a CUDA Out of Memory error, this means that the distributed training configuration needs to be adjusted to fit the model on the GPU cluster. For more information and best practices, see Setting Up the Right Configuration for a Given Model (p. 2213).

• If the training job crashes with an uncorrectable ECC error, this means that one of the GPUs in the cluster has gone bad. If you need technical support, share the job ARN with the AWS team and restart your training job from a checkpoint if possible.

• In rare cases, a job configuration that worked previously but is close to the limits of GPU memory might fail later with a different cluster due to a CUDA Out of Memory error. This could be because some GPU has lower available memory than usual due to ECC errors.

• Network timeout crash might happen when running a multinode job which doesn’t use all GPUs in the node. To get around this, use all GPUs on the node by ensuring that the processes_per_host parameter is set to the number of GPUs in each instance. For example, this is processes_per_host=8 for ml.p3.16xlarge, ml.p3dn.24xlarge, and ml.p4d.24xlarge instances.

• If you find that your training job takes a long time during the data downloading stage, make sure the Amazon S3 path you provided to checkpoint_s3_uri for the SageMaker Estimator class is unique for the current training job. If this path is reused across multiple training jobs running simultaneously, all those checkpoints are uploaded and downloaded to the same Amazon S3 path and might significantly increase checkpoint loading time.

• Use FSx for Lustre when you deal with large data and models.
  • If your dataset is large and fetching it takes a long time, we recommend keeping your dataset in FSx for Lustre.
  • When training models are beyond 10 billion parameters, we recommend using FSx for Lustre for checkpointing.
  • After you create a file system, make sure to wait for the status to become available before starting a training job using it.

Receiving NCCL Error for a PyTorch Training Job

If you encountered the following error, it might be due to a process running out of GPU memory.

```
NCCL error in: ../torch/lib/c10d/ProcessGroupNCCL.cpp:825, unhandled system error, NCCL version 2.7.8
ncclSystemError: System call (socket, malloc, munmap, etc) failed.
```

You can resolve this by reducing the batch size or active_microbatches. If auto partitioning is not resulting in a well-balanced partitioning, you might have to consider manual partitioning. For more information, see Pipeline parallelism across nodes (p. 2214).
Receiving `RecursionError` for a PyTorch Training Job

The library does not support calling `super.forward()` inside a module's forward call. If you use `super.forward()`, you might receive the following error message.

```
RecursionError: maximum recursion depth exceeded
```

To fix the error, instead of calling `super.forward()`, you should call `super()._orig_forward()`.

Amazon SageMaker Distributed Training Notebook Examples

The following case studies and notebooks provide examples of implementing the SageMaker distributed training libraries for the supported deep learning frameworks (PyTorch, TensorFlow, and HuggingFace) and models, such as CNN and MaskRCNN for vision, and BERT for natural language processing.

These notebooks are provided in the [SageMaker examples GitHub repository](https://github.com/aws-sagemaker). You can also browse them on the [SageMaker examples website](https://console.aws.amazon.com/spot/home?region=us-west-2&service=sagemaker).

Blogs and Case Studies

The following blogs discuss case studies about using the SageMaker distributed training libraries.

**How to Access or Download the SageMaker Distributed Training Notebook Examples**

Follow instructions to access or download the SageMaker distributed training example notebooks.
Option 1: Use a SageMaker notebook instance

To use the aforementioned examples, we recommend that you use an Amazon SageMaker notebook instance. A notebook instance runs Jupyter Notebook and JupyterServer apps on Amazon EC2 instances, which are optimized for machine learning. If you do not have an active notebook instance, follow the instructions in Create a Notebook Instance (p. 319) in the SageMaker developer guide to create one.

After you have created an instance, in the Notebook instances page of the SageMaker console, do the following:

1. Open JupyterLab.
2. Select the examples icon ( ) in the left tray.
3. Browse the examples for Training and look for notebooks titled Distributed Data Parallel or Distributed Model Parallel.

Option 2: Clone the SageMaker example repository to SageMaker Studio or notebook instance

To download and use the aforementioned example notebooks, do the following to clone the example GitHub repositories:

1. Open a terminal.
2. In the command line, navigate to the SageMaker folder.
   
   ```
   cd SageMaker
   ```
3. Clone the SageMaker examples GitHub repository.
   
   ```
   git clone https://github.com/aws/amazon-sagemaker-examples.git
   ```

   **Note**
   To download the HuggingFace example notebooks (p. 2224), clone the HuggingFace notebooks GitHub repository:
   
   ```
   git clone https://github.com/huggingface/notebooks huggingface-notebooks
   ```
4. In the JupyterLab interface, navigate into the amazon-sagemaker-examples folder.
5. In the training/distributed_training folder, there are folders for frameworks, and in each of these, there are folders for data_parallel and model_parallel. Choose the example of your choice and follow the instructions to launch distributed training with an SageMaker distributed training library.

Distributed computing with SageMaker best practices

This best practices page presents various flavors of distributed computing for machine learning (ML) jobs in general. The term distributed computing in this page encompasses distributed training for machine learning tasks and parallel computing for data processing, data generation, feature engineering, and reinforcement learning. In this page, we discuss about common challenges in distributed computing, and available options in SageMaker Training and SageMaker Processing. For additional reading materials about distributed computing, see What Is Distributed Computing?.

You can configure ML tasks to run in a distributed manner across multiple nodes (instances), accelerators (NVIDIA GPUs, AWS Trainium chips), and vCPU cores. By running distributed computation, you can
achieve a variety of goals such as computing operations faster, handling large datasets, or training large
ML models.

The following list covers common challenges that you might face when you run an ML training job at
scale.

- You need to make decisions on how to distribute computation depending on ML tasks, software
  libraries you want to use, and compute resources.
- Not all ML tasks are straightforward to distribute. Also, not all ML libraries support distributed
  computation.
- Distributed computation might not always result in a linear increase in compute efficiency. In
  particular, you need to identify if data I/O and inter-GPU communication have bottlenecks or cause
  overhead.
- Distributed computation might disturb numerical processes and change model accuracy. Specifically
to data-parallel neural network training, when you change the global batch size while scaling up to a
larger compute cluster, you also need to adjust the learning rate accordingly.

SageMaker provides distributed training solutions to ease such challenges for various use cases. Choose
one of the following options that best fits your use case.

Topics
- Option 1: Use a SageMaker built-in algorithm that supports distributed training (p. 2226)
- Option 2: Run a custom ML code in the SageMaker managed training or processing
  environment (p. 2226)
- Option 3: Write your own custom distributed training code (p. 2228)
- Option 4: Launch multiple jobs in parallel or sequentially (p. 2228)

Option 1: Use a SageMaker built-in algorithm that supports distributed training

SageMaker provides built-in algorithms that you can use out of the box through the SageMaker console
or the SageMaker Python SDK. Using the built-in algorithms, you don't need to spend time for code
customization, understanding science behind the models, or running Docker on provisioned Amazon EC2
instances.

A subset of the SageMaker built-in algorithms support distributed training. To check if the algorithm
of your choice supports distributed training, see the Parallelizable column in the Common Information
About Built-in Algorithms table. Some of the algorithms support multi-instance distributed training,
while the rest of the parallelizable algorithms support parallelization across multiple GPUs in a single
instance, as indicated in the Parallelizable column.

Option 2: Run a custom ML code in the SageMaker managed training or processing environment

SageMaker jobs can instantiate distributed training environment for specific use cases and frameworks.
This environment acts as a ready-to-use whiteboard, where you can bring and run your own ML code.

If your ML code uses a deep learning framework

You can launch distributed training jobs using the Deep Learning Containers (DLC) for SageMaker
Training, which you can orchestrate either through the dedicated Python modules in the SageMaker
Python SDK, or through the SageMaker APIs with AWS CLI, AWS SDK for Python (Boto3). SageMaker
provides training containers for machine learning frameworks, including PyTorch, TensorFlow, Hugging Face Transformers, and Apache MXNet. You have two options to write deep learning code for distributed training.

- **The SageMaker distributed training libraries**

  The SageMaker distributed training libraries propose AWS-managed code for neural network data parallelism and model parallelism. SageMaker distributed training also comes with launcher clients built into the SageMaker Python SDK, and you don't need to author parallel launch code. To learn more, see SageMaker's data parallelism library and SageMaker's model parallelism library.

- **Open-source distributed training libraries**

  Open source frameworks have their own distribution mechanisms such as DistributedDataParallelism (DDP) in PyTorch or tf.distribute modules in TensorFlow. You can choose to run these distributed training frameworks in the SageMaker-managed framework containers. For example, the sample code for training MaskRCNN in SageMaker shows how to use both PyTorch DDP in the SageMaker PyTorch framework container and Horovod in the SageMaker TensorFlow framework container.

SageMaker ML containers also come with MPI preinstalled, so you can parallelize your entry point script using mpi4py. Using the MPI integrated training containers is a great option when you launch a third-party distributed training launcher or write ad-hoc parallel code in the SageMaker managed training environment.

**Notes for data-parallel neural network training on GPUs**

- **Scale to multi-GPU and multi-machine parallelism when appropriate**

  We often run neural network training jobs on multiple-CPU or multiple-GPU instances. Each GPU-based instance usually contains multiple GPU devices. Consequently, distributed GPU computing can happen either within a single GPU instance with multiple GPUs (single-node multi-GPU training), or across multiple GPU instances with multiple GPU cores in each (multi-node multi-GPU training). Single-instance training is easier to write code and debug, and the intra-node GPU-to-GPU throughput is usually faster than the inter-node GPU-to-GPU throughput. Therefore, it is a good idea to scale data parallelism vertically first (use one GPU instance with multiple GPUs) and expand to multiple GPU instances if needed. This might not apply to cases where the CPU budget is high (for example, a massive workload for data pre-processing) and when the CPU-to-GPU ratio of a multi-GPU instance is too low. In all cases, you need to experiment with different combinations of instance types based on your own ML training needs and workload.

- **Monitor the quality of convergence**

  When training a neural network with data parallelism, increasing the number of GPUs while keeping the mini-batch size per GPU constant leads to increasing the size of global mini-batch for the mini-batch stochastic gradient descent (MSGD) process. The size of mini-batches for MSGD is known to impact the descent noise and convergence. For properly scaling while preserving accuracy, you need to adjust other hyperparameters such as the learning rate [Goyal et al. (2017)].

- **Monitor I/O bottlenecks**

  As you increase the number of GPUs, the throughput for reading and writing storage should also increase. Make sure that your data source and pipeline don't become bottlenecks.

- **Modify your training script as needed**

  Training scripts written for single-GPU training must be modified for multi-node multi-GPU training. In most data parallelism libraries, script modification is required to do the following.
  - Assign batches of training data to each GPU.
  - Use an optimizer that can deal with gradient computation and parameter updates across multiple GPUs.
• Assign responsibility of checkpointing to a specific host and GPU.

**If your ML code involves tabular data processing**

PySpark is a Python frontend of Apache Spark, which is an open-source distributed computing framework. PySpark has been widely adopted for distributed tabular data processing for large-scale production workloads. If you want to run tabular data processing code, consider using the SageMaker Processing PySpark containers and running parallel jobs. You can also run data processing jobs in parallel using SageMaker Training and SageMaker Processing APIs in Amazon SageMaker Studio, which is integrated with Amazon EMR and AWS Glue.

**Option 3: Write your own custom distributed training code**

When you submit a training or processing job to SageMaker, SageMaker Training and SageMaker Processing APIs launch Amazon EC2 compute instances. You can customize training and processing environment in the instances by running your own Docker container or installing additional libraries in the AWS managed containers. For more information about Docker with SageMaker Training, see Adapting your own Docker container to work with SageMaker and Create a container with your own algorithms and models. For more information about Docker with SageMaker Processing, see Use Your Own Processing Code.

Every SageMaker training job environment contains a configuration file at `/opt/ml/input/config/resourceconfig.json`, and every SageMaker processing job environment contains a similar configuration file at `/opt/ml/config/resourceconfig.json`. Your code can read this file to find hostnames and establish inter-node communications. To learn more, including the schema of the JSON file, see Distributed Training Configuration and How Amazon SageMaker Processing Configures Your Processing Container. You can also install and use third-party distributed computing libraries such as Ray or DeepSpeed in SageMaker.

You can also use SageMaker Training and SageMaker Processing to run custom distributed computations that do not require inter-worker communication. In the computing literature, those tasks are often described as *embarrassingly parallel* or *share-nothing*. Examples include parallel processing of data files, training models in parallel on different configurations, or running batch inference on a collection of records. You can trivially parallelize such share-nothing use cases with Amazon SageMaker. When you launch a SageMaker Training or SageMaker Processing job on a cluster with multiple nodes, SageMaker by default replicates and launches your training code (in Python or Docker) on all the nodes. Tasks requiring random spread of input data across such multiple nodes can be facilitated by setting `S3DataDistributionType=ShardedByS3Key` in the data input configuration of the SageMaker TrainingInput API.

**Option 4: Launch multiple jobs in parallel or sequentially**

You can also distribute an ML compute workflow into smaller parallel or sequential compute tasks, each represented by its own SageMaker Training or SageMaker Processing job. Splitting a task into multiple jobs can be beneficial for the following situations or tasks:

• When you have specific data channels and metadata entries (such as hyperparameters, model configuration, or instance types) for each sub-tasks.

• When you implement retry steps at a sub-task level.

• When you vary the configuration of the sub-tasks over the course of the workload, such as when training on increasing batch sizes.

• When you need to run an ML task that takes longer than the maximum training time allowed for a single training job (28 days maximum).

• When different steps of a compute workflow require different instance types.
For the specific case of hyperparameter search, use SageMaker Automated Model Tuning. SageMaker Automated Model Tuning is a serverless parameter search orchestrator that launches multiple training jobs on your behalf, according to a search logic that can be random, Bayesian, or HyperBand.

Additionally, to orchestrate multiple training jobs, you can also consider workflow orchestration tools, such as SageMaker Pipelines, AWS Step Functions, and Apache Airflow supported by Amazon Managed Workflows for Apache Airflow (MWAA) and SageMaker Workflows.

Amazon SageMaker Training Compiler

Use Amazon SageMaker Training Compiler to train deep learning (DL) models faster on scalable GPU instances managed by SageMaker.

What Is SageMaker Training Compiler?

State-of-the-art deep learning (DL) models consist of complex multi-layered neural networks with billions of parameters that can take thousands of GPU hours to train. Optimizing such models on training infrastructure requires extensive knowledge of DL and systems engineering; this is challenging even for narrow use cases. Although there are open-source implementations of compilers that optimize the DL training process, they can lack the flexibility to integrate DL frameworks with some hardware such as GPU instances.

SageMaker Training Compiler is a capability of SageMaker that makes these hard-to-implement optimizations to reduce training time on GPU instances. The compiler optimizes DL models to accelerate training by more efficiently using SageMaker machine learning (ML) GPU instances. SageMaker Training Compiler is available at no additional charge within SageMaker and can help reduce total billable time as it accelerates training.

SageMaker Training Compiler is integrated into the AWS Deep Learning Containers (DLCs). Using the SageMaker Training Compiler–enabled AWS DLCs, you can compile and optimize training jobs on GPU instances with minimal changes to your code. Bring your deep learning models to SageMaker and enable SageMaker Training Compiler to accelerate the speed of your training job on SageMaker ML instances for accelerated computing.

How It Works

SageMaker Training Compiler converts DL models from their high-level language representation to hardware-optimized instructions. Specifically, SageMaker Training Compiler applies graph-level optimizations, dataflow-level optimizations, and backend optimizations to produce an optimized model that efficiently uses hardware resources. As a result, you can train your models faster than when you train them without compilation.
It is a two-step process to activate SageMaker Training Compiler for your training job:

1. Bring your own DL script and, if needed, adapt to compile and train with SageMaker Training Compiler. To learn more, see Bring Your Own Deep Learning Model (p. 2248).
2. Create a SageMaker estimator object with the compiler configuration parameter using the SageMaker Python SDK.
   a. Turn on SageMaker Training Compiler by adding `compiler_config=TrainingCompilerConfig()` to the SageMaker estimator class.
   b. Adjust hyperparameters (batch_size and learning_rate) to maximize the benefit that SageMaker Training Compiler provides.

Compilation through SageMaker Training Compiler changes the memory footprint of the model. Most commonly, this manifests as a reduction in memory utilization and a consequent increase in the largest batch size that can fit on the GPU. In some cases, the compiler intelligently promotes caching which leads to a decrease in the largest batch size that can fit on the GPU. Note that if you want to change the batch size, you must adjust the learning rate appropriately.

For a reference for batch_size tested for popular models, see Tested Models (p. 2233).

When you adjust the batch size, you also have to adjust the learning_rate appropriately. For best practices for adjusting the learning rate along with the change in batch size, see the section called “Best Practices and Considerations” (p. 2270).

   c. By running the `estimator.fit()` class method, SageMaker compiles your model and starts the training job.

   For instructions on how to launch a training job, see Enable SageMaker Training Compiler (p. 2256).

SageMaker Training Compiler does not alter the final trained model, while allowing you to accelerate the training job by more efficiently using the GPU memory and fitting a larger batch size per iteration. The final trained model from the compiler-accelerated training job is identical to the one from the ordinary training job.

**Tip**
SageMaker Training Compiler only compiles DL models for training on supported GPU instances managed by SageMaker. To compile your model for inference and deploy it to run anywhere in the cloud and at the edge, use SageMaker Neo compiler.

**Supported Frameworks, AWS Regions, Instance Types, and Tested Models**

Before using SageMaker Training Compiler, check if your framework of choice is supported, the instance types are available in your AWS account, and your AWS account is in one of the supported AWS Regions.
Note
SageMaker Training Compiler is available in the SageMaker Python SDK v2.70.0 or later.

Supported Frameworks

SageMaker Training Compiler supports the following deep learning frameworks and is available through AWS Deep Learning Containers.

Topics
• PyTorch (p. 2231)
• TensorFlow (p. 2232)

For more information, see [Available Images](#) in the AWS Deep Learning Containers GitHub repository.

### AWS Regions

The SageMaker Training Compiler Containers are available in the AWS Regions where AWS Deep Learning Containers are in service except the China regions.

### Supported Instance Types

SageMaker Training Compiler is tested on and supports the following ML instance types.

- P4 instances
- P3 instances
- G4dn instances
• G5 instances

For specs of the instance types, see the Accelerated Computing section in the Amazon EC2 Instance Types page. For information about instance pricing, see Amazon SageMaker Pricing.

If you encountered an error message similar to the following, follow the instructions at Request a service quota increase for SageMaker resources.

```
ResourceLimitExceeded: An error occurred (ResourceLimitExceeded) when calling the CreateTrainingJob operation: The account-level service limit 'ml.p3dn.24xlarge for training job usage' is 0 Instances, with current utilization of 0 Instances and a request delta of 1 Instances. Please contact AWS support to request an increase for this limit.
```

Tested Models

The following table includes a list of the models that have been tested with SageMaker Training Compiler. For reference, the largest batch size that is able to fit into memory is also included alongside other training parameters. SageMaker Training Compiler can change the memory footprint of the model training process; as a result, a larger batch size can often be used during the training process, further decreasing total training time. In some cases, SageMaker Training Compiler intelligently promotes caching which leads to a decrease in the largest batch size that can fit on the GPU. You must retune your model hyperparameters and find an optimal batch size for your case. To save time, use the following reference tables to look up a batch size that can be a good starting point for your use case.

**Note**
The batch sizes are local batch size that fit into each individual GPU in the respective instance type. You should also adjust the learning rate when changing the batch size.

**PyTorch 1.13.1**

**Natural language processing (NLP) models**

The following models are tested for training jobs for all combinations of single-node and multi-node with single or multi GPU cores and Automatic Mixed Precision (AMP) as indicated.

Transformers 4.11.0 with TensorFlow 2.5.1

Tested with Sequence Len=128 and Automatic Mixed Precision (AMP).
### Bring Your Own Deep Learning Model

This guide walks you through how to adapt your training script for a compiler-accelerated training job. The preparation of your training script depends on the following:

- Training settings such as single-core or distributed training.
- Frameworks and libraries that you use to create the training script.

Choose one of the following topics depending on the framework you use.
Topics

- **PyTorch (p. 2249)**
- **TensorFlow (p. 2254)**

Note

After you finish preparing your training script, you can run a SageMaker training job using the SageMaker framework estimator classes. For more information, see the previous topic at [Enable SageMaker Training Compiler (p. 2256)].

PyTorch

Bring your own PyTorch model to SageMaker, and run the training job with SageMaker Training Compiler.

Topics

- **PyTorch Models with Hugging Face Transformers (p. 2249)**

PyTorch Models with Hugging Face Transformers

PyTorch models with Hugging Face Transformers are based on PyTorch's `torch.nn.Module` API. Hugging Face Transformers also provides Trainer and pretrained model classes for PyTorch to help reduce the effort for configuring natural language processing (NLP) models. After preparing your training script, you can launch a training job using the SageMaker PyTorch or HuggingFace estimator with the SageMaker Training Compiler configuration when you'll proceed to the next topic at [Enable SageMaker Training Compiler (p. 2256)].

Tip

When you create a tokenizer for an NLP model using Transformers in your training script, make sure that you use a static input tensor shape by specifying `padding='max_length'`. Do not use `padding='longest'` because padding to the longest sequence in the batch can change the tensor shape for each training batch. The dynamic input shape can trigger recompilation of the model and might increase total training time. For more information about padding options of the Transformers tokenizers, see [Padding and truncation](https://huggingface.co/transformers/main_classes/tokenizer.html) in the Hugging Face Transformers documentation.

Topics

- **Large Language Models Using the Hugging Face Transformers Trainer Class (p. 2249)**
- **Large Language Models Using PyTorch Directly (without the Hugging Face Transformers Trainer API) (p. 2250)**

Large Language Models Using the Hugging Face Transformers Trainer Class

If you use the transformers library's Trainer class, you don't need to make any additional changes to your training script. SageMaker Training Compiler automatically compiles your Trainer model if you enable it through the estimator class. The following code shows the basic form of a PyTorch training script with Hugging Face Trainer API.

```python
from transformers import Trainer, TrainingArguments

training_args=TrainingArguments(**kwargs)
trainer=Trainer(args=training_args, **kwargs)
```

Topics

- **For single GPU training (p. 2250)**
- **For distributed training (p. 2250)**
For single GPU training

You don't need to change your code when you use the `transformers.Trainer` class.

For distributed training

**PyTorch v1.11.0 and later**

To run distributed training with SageMaker Training Compiler, you must add the following `_mp_fn()` function in your training script and wrap the `main()` function. It redirects the `_mp_fn(index)` function calls from the SageMaker distributed runtime for PyTorch (pytorchxla) to the `main()` function of your training script.

```python
def _mp_fn(index):
    main()
```

This function accepts the `index` argument to indicate the rank of the current GPU in the cluster for distributed training. To find more example scripts, see the [Hugging Face Transformers language modeling example scripts](https://huggingface.co/transformers/script/). **For Transformers v4.17 and before with PyTorch v1.10.2 and before**

SageMaker Training Compiler uses an alternate mechanism for launching a distributed training job, and you don't need to make any modification in your training script. Instead, SageMaker Training Compiler requires you to pass a SageMaker distributed training launcher script to the `entry_point` argument and pass your training script to the `hyperparameters` argument in the SageMaker Hugging Face estimator.

**Best Practices to Use SageMaker Training Compiler with Trainer**

- Make sure that you use SyncFree optimizers by setting the `optim` argument to `adamw_torch_xla` while setting up `transformers.TrainingArguments`. See also `Optimizer` in the [Hugging Face Transformers documentation](https://huggingface.co/transformers/script/).
- Ensure that the throughput of the data processing pipeline is higher than the training throughput. You can tweak the `dataloader_num_workers` and `preprocessing_num_workers` arguments of the `transformers.TrainingArguments` class to achieve this. Typically, these need to be greater than or equal to the number of GPUs but less than the number of CPUs.

After you have completed adapting your training script, proceed to the section called “Run PyTorch Training Jobs with Training Compiler” (p. 2257).

**Large Language Models Using PyTorch Directly (without the Hugging Face Transformers Trainer API)**

If you have a training script that uses PyTorch directly, you need to make additional changes to your PyTorch training script to implement PyTorch/XLA. Follow the instructions to modify your script to properly set up the PyTorch/XLA primitives.

**Topics**

- [For single GPU training (p. 2250)]
- [For distributed training (p. 2251)]
- [Best Practices to Use SageMaker Training Compiler with PyTorch/XLA (p. 2253)]

**For single GPU training**

1. Import the optimization libraries.
import torch_xla
import torch_xla.core.xla_model as xm

2. Change the target device to be XLA instead of `torch.device("cuda")`

```
device=xm.xla_device()
```

3. If you're using PyTorch's **Automatic Mixed Precision** (AMP), do the following:
   a. Replace `torch.cuda.amp` with the following:

```
import torch_xla.amp
```
   b. Replace `torch.optim.SGD` and `torch.optim.Adam` with the following:

```
import torch_xla.amp.syncfree.Adam as adam
import torch_xla.amp.syncfree.SGD as SGD
```
   c. Replace `torch.cuda.amp.GradScaler` with the following:

```
import torch_xla.amp.GradScaler as grad_scaler
```

4. If you're not using AMP, replace `optimizer.step()` with the following:

```
xm.optimizer_step(optimizer)
```

5. If you're using a distributed dataloader, wrap your dataloader in the PyTorch/XLA's `ParallelLoader` class:

```
import torch_xla.distributed.parallel_loader as pl
parallel_loader=pl.ParallelLoader(dataloader, [device]).per_device_loader(device)
```

6. Add `mark_step` at the end of the training loop when you're not using `parallel_loader`:

```
xm.mark_step()
```

7. To checkpoint your training, use the PyTorch/XLA's model checkpoint method:

```
xm.save(model.state_dict(), path_to_save)
```

After you have completed adapting your training script, proceed to the section called “Run PyTorch Training Jobs with Training Compiler” (p. 2257).

For distributed training

In addition to the changes listed in the previous For single GPU training (p. 2250) section, add the following changes to properly distribute workload across GPUs.

1. If you're using AMP, add `all_reduce` after `scaler.scale(loss).backward()`:

```
gradients=xm._fetch_gradients(optimizer)
xm.all_reduce('sum', gradients, scale=1.0/xm.xrt_world_size())
```

2. If you need to set variables for `local_ranks` and `world_size`, use similar code to the following:

```
local_rank=xm.get_local_ordinal()
```
3. For any `world_size` (num_gpus_per_node*num_nodes) greater than 1, you must define a train sampler which should look similar to the following:

```python
import torch_xla.core.xla_model as xm

if xm.xrt_world_size() > 1:
    train_sampler = torch.utils.data.distributed.DistributedSampler(
        train_dataset,
        num_replicas=xm.xrt_world_size(),
        rank=xm.get_ordinal(),
        shuffle=True
    )

train_loader = torch.utils.data.DataLoader(
    train_dataset,
    batch_size=args.batch_size,
    sampler=train_sampler,
    drop_last=args.drop_last,
    shuffle=False if train_sampler else True,
    num_workers=args.num_workers
)
```

4. Make the following changes to make sure you use the parallel_loader provided by the `torch_xla` distributed module.

```python
import torch_xla.distributed.parallel_loader as pl
train_device_loader = pl.MpDeviceLoader(train_loader, device)
```

The `train_device_loader` functions like a regular PyTorch loader as follows:

```python
for step, (data, target) in enumerate(train_device_loader):
    optimizer.zero_grad()
    output = model(data)
    loss = torch.nn.NLLLoss(output, target)
    loss.backward()
```

With all of these changes, you should be able to launch distributed training with any PyTorch model without the Transformer Trainer API. Note that these instructions can be used for both single-node multi-GPU and multi-node multi-GPU.

5. **For PyTorch v1.11.0 and later**

   To run distributed training with SageMaker Training Compiler, you must add the following `_mp_fn()` function in your training script and wrap the `main()` function. It redirects the `_mp_fn(index)` function calls from the SageMaker distributed runtime for PyTorch (pytorchxla) to the `main()` function of your training script.

```python
def _mp_fn(index):
    main()
```

This function accepts the `index` argument to indicate the rank of the current GPU in the cluster for distributed training. To find more example scripts, see the Hugging Face Transformers language modeling example scripts.

**For Transformers v4.17 and before with PyTorch v1.10.2 and before**
SageMaker Training Compiler uses an alternate mechanism for launching a distributed training job and requires you to pass a SageMaker distributed training launcher script to the entry_point argument and pass your training script to the hyperparameters argument in the SageMaker Hugging Face estimator.

After you have completed adapting your training script, proceed to the section called “Run PyTorch Training Jobs with Training Compiler” (p. 2257).

Best Practices to Use SageMaker Training Compiler with PyTorch/XLA

If you want to leverage the SageMaker Training Compiler on your native PyTorch training script, you may want to first get familiar with PyTorch on XLA devices. The following sections list some best practices to enable XLA for PyTorch.

**Note**
This section for best practices assumes that you use the following PyTorch/XLA modules:

```python
import torch_xla.core.xla_model as xm
import torch_xla.distributed.parallel_loader as pl
```

**Understand the lazy mode in PyTorch/XLA**

One significant difference between PyTorch/XLA and native PyTorch is that the PyTorch/XLA system runs in lazy mode while the native PyTorch runs in eager mode. Tensors in lazy mode are placeholders for building the computational graph until they are materialized after the compilation and evaluation are complete. The PyTorch/XLA system builds the computational graph on the fly when you call PyTorch APIs to build the computation using tensors and operators. The computational graph gets compiled and executed when `xm.mark_step()` is called explicitly or implicitly by `pl.ParallelLoader`. During training, you might want to examine some intermediate results such as loss values. In such case, the printing of lazy tensors should be wrapped using `xm.add_step_closure()` to avoid unnecessary compilation-and-executions.

**Minimize the number of compilation-and-executions using pl.ParallelLoader and xm.step_closure**

For best performance, you should keep in mind the possible ways to initiate compilation-and-executions as described in Understand the lazy mode in PyTorch/XLA (p. 2253) and should try to minimize the number of compilation-and-executions. Ideally, only one compilation-and-execution is necessary per training iteration and is initiated automatically by `pl.ParallelLoader`. The `ParallelLoader` is optimized for XLA and should always be used if possible for best performance.

**Use AMP and syncfree optimizers**

Training in Automatic Mixed Precision (AMP) mode significantly accelerates your training speed by leveraging the Tensor cores of NVIDIA GPUs. SageMaker Training Compiler provides syncfree optimizers that are optimized for XLA to improve AMP performance. Currently, the following three syncfree optimizers are available and should be used if possible for best performance.

```python
torch_xla.amp.syncfree.SGD
torch_xla.amp.syncfree.Adam
torch_xla.amp.syncfree.AdamW
```

These syncfree optimizers should be paired with `torch_xla.amp.GradScaler` for gradient scaling/ unscaling.
Tip
Starting PyTorch 1.13.1, SageMaker Training Compiler improves performance by letting PyTorch/XLA to automatically override the optimizers (such as SGD, Adam, AdamW) in `torch.optim` or `transformers.optimization` with the syncfree versions of them in `torch_xla.amp.syncfree` (such as `torch_xla.amp.syncfree.SGD`, `torch_xla.amp.syncfree.Adam`, `torch_xla.amp.syncfree.AdamW`). You don't need to change those code lines where you define optimizers in your training script.

TensorFlow

Bring your own TensorFlow model to SageMaker, and run the training job with SageMaker Training Compiler.

TensorFlow Models

SageMaker Training Compiler automatically optimizes model training workloads that are built on top of the native TensorFlow API or the high-level Keras API.

Tip
For preprocessing your input dataset, ensure that you use a static input shape. Dynamic input shape can initiate recompilation of the model and might increase total training time.

Using Keras (Recommended)

For the best compiler acceleration, we recommend using models that are subclasses of TensorFlow Keras (`tf.keras.Model`).

For single GPU training

There's no additional change you need to make in the training script.

Without Keras

SageMaker Training Compiler does not support eager execution in TensorFlow. Accordingly, you should wrap your model and training loops with the TensorFlow function decorator (`@tf.function`) to leverage compiler acceleration.

SageMaker Training Compiler performs a graph-level optimization, and uses the decorator to make sure your TensorFlow functions are set to run in graph mode.

For single GPU training

TensorFlow 2.0 or later has the eager execution on by default, so you should add the `@tf.function` decorator in front of every function that you use for constructing a TensorFlow model.

TensorFlow Models with Hugging Face Transformers

TensorFlow models with Hugging Face Transformers are based on TensorFlow's `tf.keras.Model` API. Hugging Face Transformers also provides pretrained model classes for TensorFlow to help reduce the effort for configuring natural language processing (NLP) models. After creating your own training script using the Transformers library, you can run the training script using the SageMaker HuggingFace estimator with the SageMaker Training Compiler configuration class as shown in the previous topic at Run TensorFlow Training Jobs with SageMaker Training Compiler (p. 2264).

SageMaker Training Compiler automatically optimizes model training workloads that are built on top of the native TensorFlow API or the high-level Keras API, such as the TensorFlow transformer models.

Tip
When you create a tokenizer for an NLP model using Transformers in your training script, make sure that you use a static input tensor shape by specifying `padding='max_length'`. Do not
use padding='longest' because padding to the longest sequence in the batch can change the tensor shape for each training batch. The dynamic input shape can initiate recompilation of the model and might increase total training time. For more information about padding options of the Transformers tokenizers, see Padding and truncation in the Hugging Face Transformers documentation.

Topics
- Using Keras (p. 2255)
- Without Keras (p. 2256)

Using Keras

For the best compiler acceleration, we recommend using models that are subclasses of TensorFlow Keras (tf.keras.Model). As noted in the Quick tour page in the Hugging Face Transformers documentation, you can use the models as regular TensorFlow Keras models.

For single GPU training

There's no additional change you need to make in the training script.

For distributed training

SageMaker Training Compiler acceleration works transparently for multi-GPU workloads when the model is constructed and trained using Keras APIs within the scope of tf.distribute.Strategy.scope() call.

1. Choose the right distributed training strategy.
   a. For single-node multi-GPU, use tf.distribute.MirroredStrategy to set the strategy.

   ```python
   strategy = tf.distribute.MirroredStrategy()
   ```

   b. For multi-node multi-GPU, add the following code to properly set the TensorFlow distributed training configuration before creating the strategy.

   ```python
def set_sm_dist_config():
    DEFAULT_PORT = '8890'
    DEFAULT_CONFIG_FILE = '/opt/ml/input/config/resourceconfig.json'
    with open(DEFAULT_CONFIG_FILE) as f:
        config = json.loads(f.read())
        current_host = config['current_host']
    tf_config = {
        'cluster': {
            'worker': []
        },
        'task': {'type': 'worker', 'index': -1}
    }
    for i, host in enumerate(config['hosts']):
        tf_config['cluster']['worker'].append("%s:%s" % (host, DEFAULT_PORT))
        if current_host == host:
            tf_config['task']['index'] = i
            os.environ['TF_CONFIG'] = json.dumps(tf_config)
    set_sm_dist_config()

   Use tf.distribute.MultiWorkerMirroredStrategy to set the strategy.

   ```python
   strategy = tf.distribute.MultiWorkerMirroredStrategy()
   ```
2. Using the strategy of your choice, wrap the model.

```python
with strategy.scope():
    # create a model and do fit
```

### Without Keras

If you want to bring custom models with custom training loops using TensorFlow without Keras, you should wrap the model and the training loop with the TensorFlow function decorator (@tf.function) to leverage compiler acceleration.

SageMaker Training Compiler performs a graph-level optimization, and uses the decorator to make sure your TensorFlow functions are set to run in graph mode.

#### For single GPU training

TensorFlow 2.0 or later has the eager execution on by default, so you should add the @tf.function decorator in front of every function that you use for constructing a TensorFlow model.

#### For distributed training

In addition to the changes needed for Using Keras for distributed training, you need to ensure that functions to be run on each GPU are annotated with @tf.function, while cross-GPU communication functions are not annotated. An example training code should look like the following:

```python
@tf.function()
def compiled_step(inputs, outputs):
    with tf.GradientTape() as tape:
        pred=model(inputs, training=True)
        total_loss=loss_object(outputs, pred)/args.batch_size
        gradients=tape.gradient(total_loss, model.trainable_variables)
    return total_loss, pred, gradients

def train_step(inputs, outputs):
    total_loss, pred, gradients=compiled_step(inputs, outputs)
    if args.weight_decay > 0.:
        gradients=[g+v*args.weight_decay for g,v in zip(gradients, model.trainable_variables)]
    optimizer.apply_gradients(zip(gradients, model.trainable_variables))
    train_loss.update_state(total_loss)
    train_accuracy.update_state(outputs, pred)

@tf.function()
def train_step_dist(inputs, outputs):
    strategy.run(train_step, args= (inputs, outputs))
```

Note that this instruction can be used for both single-node multi-GPU and multi-node multi-GPU.

### Enable SageMaker Training Compiler

SageMaker Training Compiler is built into the SageMaker Python SDK and AWS Deep Learning Containers so that you don’t need to change your workflows to enable Training Compiler. Choose one of the following topics that matches with your use case.

### Topics
Run PyTorch Training Jobs with SageMaker Training Compiler

You can use any of the SageMaker interfaces to run a training job with SageMaker Training Compiler: Amazon SageMaker Studio, Amazon SageMaker notebook instances, AWS SDK for Python (Boto3), and AWS Command Line Interface.

Topics

- Using the SageMaker Python SDK (p. 2257)
- Using the SageMaker CreateTrainingJob API Operation (p. 2264)

Using the SageMaker Python SDK

SageMaker Training Compiler for PyTorch is available through the SageMaker PyTorch and HuggingFace framework estimator classes. To turn on SageMaker Training Compiler, add the compiler_config parameter to the SageMaker estimators. Import the TrainingCompilerConfig class and pass an instance of it to the compiler_config parameter. The following code examples show the structure of SageMaker estimator classes with SageMaker Training Compiler turned on.

Tip
To get started with prebuilt models provided by PyTorch or Transformers, try using the batch sizes provided in the reference table at Tested Models (p. 2233).

Note
The native PyTorch support is available in the SageMaker Python SDK v2.121.0 and later. Make sure that you update the SageMaker Python SDK accordingly.

Note
Starting PyTorch v1.12.0, SageMaker Training Compiler containers for PyTorch are available. Note that the SageMaker Training Compiler containers for PyTorch are not prepackaged with Hugging Face Transformers. If you need to install the library in the container, make sure that you add the requirements.txt file under the source directory when submitting a training job. For PyTorch v1.11.0 and before, use the previous versions of the SageMaker Training Compiler containers for Hugging Face and PyTorch.
For a complete list of framework versions and corresponding container information, see the section called “Supported Frameworks” (p. 2231).

For information that fits your use case, see one of the following options.

For single GPU training

PyTorch v1.12.0 and later

To compile and train a PyTorch model, configure a SageMaker PyTorch estimator with SageMaker Training Compiler as shown in the following code example.

```python
from sagemaker.pytorch import PyTorch, TrainingCompilerConfig

# the original max batch size that can fit into GPU memory without compiler
batch_size_native=12
```
Enable Training Compiler

```python
learning_rate_native=float('5e-5')

# an updated max batch size that can fit into GPU memory with compiler
batch_size=64

# update learning rate
learning_rate=learning_rate_native/batch_size_native*batch_size

hyperparameters={
    "n_gpus": 1,
    "batch_size": batch_size,
    "learning_rate": learning_rate
}

pytorch_estimator=PyTorch(
    entry_point='train.py',
    source_dir='path-to-requirements-file', # Optional. Add this if need to install additional packages.
    instance_count=1,
    instance_type='ml.p3.2xlarge',
    framework_version='1.13.1',
    py_version='py3',
    hyperparameters=hyperparameters,
    compiler_config=TrainingCompilerConfig(),
    disable_profiler=True,
    debugger_hook_config=False
)

pytorch_estimator.fit()
```

Hugging Face Transformers with PyTorch v1.11.0 and before

To compile and train a transformer model with PyTorch, configure a SageMaker Hugging Face estimator with SageMaker Training Compiler as shown in the following code example.

```python
from sagemaker.huggingface import HuggingFace, TrainingCompilerConfig

# the original max batch size that can fit into GPU memory without compiler
batch_size_native=12
learning_rate_native=float('5e-5')

# an updated max batch size that can fit into GPU memory with compiler
batch_size=64

# update learning rate
learning_rate=learning_rate_native/batch_size_native*batch_size

hyperparameters={
    "n_gpus": 1,
    "batch_size": batch_size,
    "learning_rate": learning_rate
}

pytorch_huggingface_estimator=HuggingFace(
    entry_point='train.py',
    instance_count=1,
    instance_type='ml.p3.2xlarge',
    transformers_version='4.21.1',
    pytorch_version='1.11.0',
    hyperparameters=hyperparameters,
    compiler_config=TrainingCompilerConfig(),
    disable_profiler=True,
    debugger_hook_config=False
)
```

2258
Enable Training Compiler

pytorch_huggingface_estimator.fit()

To prepare your training script, see the following pages.

- **For single GPU training (p. 2250)** of a PyTorch model using Hugging Face Transformers' Trainer API
- **For single GPU training (p. 2250)** of a PyTorch model without Hugging Face Transformers' Trainer API

To find end-to-end examples, see the following notebooks:

- Compile and Train a Hugging Face Transformers Trainer Model for Question and Answering with the SQuAD dataset
- Compile and Train a Hugging Face Transformer BERT Model with the SST Dataset using SageMaker Training Compiler
- Compile and Train a Binary Classification Trainer Model with the SST2 Dataset for Single-Node Single-GPU Training

**For distributed training**

**PyTorch v1.12**

For PyTorch v1.12, you can run distributed training with SageMaker Training Compiler by adding the `pytorch_xla` option specified to the `distribution` parameter of the SageMaker PyTorch estimator class.

**Note**
This native PyTorch support is available in the SageMaker Python SDK v2.121.0 and later. Make sure that you update the SageMaker Python SDK.

```python
from sagemaker.pytorch import PyTorch, TrainingCompilerConfig

# choose an instance type, specify the number of instances you want to use, # and set the num_gpus variable the number of GPUs per instance.
instance_count=1
instance_type='ml.p3.8xlarge'
num_gpus=4

# the original max batch size that can fit to GPU memory without compiler
batch_size_native=16
learning_rate_native=float('5e-5')

# an updated max batch size that can fit to GPU memory with compiler
batch_size=26

# update learning rate
learning_rate=learning_rate_native/batch_size_native*batch_size*num_gpus*instance_count

hyperparameters={
    "n_gpus": num_gpus,
    "batch_size": batch_size,
    "learning_rate": learning_rate
}

pytorch_estimator=PyTorch(
    entry_point='your_training_script.py', # Optional. Add this if need to install additional packages.
    source_dir='path-to-requirements-file',
    instance_count=instance_count,
)```
instance_type=instance_type,  
framework_version='1.13.1',  
py_version='py3',  
hyperparameters=hyperparameters,  
compiler_config=TrainingCompilerConfig(),  
distribution ={'pytorchxla' : { 'enabled': True }},  
disable_profiler=True,  
debugger_hook_config=False)
)

pytorch_estimator.fit()

Tip

To prepare your training script, see PyTorch (p. 2249)

Transformers v4.21 with PyTorch v1.11

For PyTorch v1.11 and later, SageMaker Training Compiler is available for distributed training with the pytorch_xla option specified to the distribution parameter.

from sagemaker.huggingface import HuggingFace, TrainingCompilerConfig

# choose an instance type, specify the number of instances you want to use,  
# and set the num_gpus variable the number of GPUs per instance.  
instance_count=1  
instance_type='ml.p3.8xlarge'  
num_gpus=4

# the original max batch size that can fit to GPU memory without compiler  
batch_size_native=16  
learning_rate_native=float('5e-5')

# an updated max batch size that can fit to GPU memory with compiler  
batch_size=26

# update learning rate  
learning_rate=learning_rate_native/batch_size_native*batch_size*num_gpus*instance_count

hyperparameters={
    "n_gpus": num_gpus,  
    "batch_size": batch_size,  
    "learning_rate": learning_rate
}

pytorch_huggingface_estimator=HuggingFace(  
    entry_point='your_training_script.py',  
    instance_count=instance_count,  
    instance_type=instance_type,  
    transformers_version='4.21.1',  
    pytorch_version='1.11.0',  
    hyperparameters=hyperparameters,  
    compiler_config=TrainingCompilerConfig(),  
    distribution ={'pytorchxla' : { 'enabled': True }},  
    disable_profiler=True,  
    debugger_hook_config=False)
)

pytorch_huggingface_estimator.fit()

Tip

To prepare your training script, see the following pages.

- For distributed training (p. 2250) of a PyTorch model using Hugging Face Transformers' Trainer API
- For distributed training (p. 2251) of a PyTorch model without Hugging Face Transformers' Trainer API

Transformers v4.17 with PyTorch v1.10.2 and before

For the supported version of PyTorch v1.10.2 and before, SageMaker Training Compiler requires an alternate mechanism for launching a distributed training job. To run distributed training, SageMaker Training Compiler requires you to pass a SageMaker distributed training launcher script to the entry_point argument, and pass your training script to the hyperparameters argument. The following code example shows how to configure a SageMaker Hugging Face estimator applying the required changes.

```python
from sagemaker.huggingface import HuggingFace, TrainingCompilerConfig

# choose an instance type, specify the number of instances you want to use, # and set the num_gpus variable the number of GPUs per instance.
instance_count=1
instance_type='ml.p3.8xlarge'
num_gpus=4

# the original max batch size that can fit to GPU memory without compiler
batch_size_native=16
learning_rate_native=float('5e-5')

# an updated max batch size that can fit to GPU memory with compiler
batch_size=26

# update learning rate
learning_rate=learning_rate_native/batch_size_native*batch_size*num_gpus*instance_count

training_script="your_training_script.py"

hyperparameters={
    "n_gpus": num_gpus,
    "batch_size": batch_size,
    "learning_rate": learning_rate,
    "training_script": training_script  # Specify the file name of your training script.
}

pytorch_huggingface_estimator=HuggingFace(
    entry_point='distributed_training_launcher.py',    # Specify the distributed training launcher script.
    instance_count=instance_count,                   # Specify the number of instances you want to use.
    instance_type=instance_type,                     # Specify the instance type.
    transformers_version='4.17.0',                   # Specify the supported version of Transformers.
    pytorch_version='1.10.2',                         # Specify the supported version of PyTorch.
    hyperparameters=hyperparameters,                 # Specify the hyperparameters.
    compiler_config=TrainingCompilerConfig(),        # Specify the configuration for the compiler.
    disable_profiler=True,                           # Disable the profiler.
    debugger_hook_config=False                       # Disable the debugger hook.
)

pytorch_huggingface_estimator.fit()
```

The launcher script should look like the following. It wraps your training script and configures the distributed training environment depending on the size of the training instance of your choice.

```python
# distributed_training_launcher.py
#!/bin/python
```
import subprocess
import sys

if __name__ == "__main__":
    arguments_command = " ".join([arg for arg in sys.argv[1:]])
    
    subprocess.check_call("python -m torch_xla.distributed.sm_dist " + arguments_command, shell=True)

Tip
To prepare your training script, see the following pages.

- For distributed training (p. 2250) of a PyTorch model using Hugging Face Transformers' Trainer API
- For distributed training (p. 2251) of a PyTorch model without Hugging Face Transformers' Trainer API

Tip
To find end-to-end examples, see the following notebooks:

- Compile and Train the GPT2 Model using the Transformers Trainer API with the SST2 Dataset for Single-Node Multi-GPU Training
- Compile and Train the GPT2 Model using the Transformers Trainer API with the SST2 Dataset for Multi-Node Multi-GPU Training

The following list is the minimal set of parameters required to run a SageMaker training job with the compiler.

Note
When using the SageMaker Hugging Face estimator, you must specify the transformers_version, pytorch_version, hyperparameters, and compiler_config parameters to enable SageMaker Training Compiler. You cannot use image_uri to manually specify the Training Compiler integrated Deep Learning Containers that are listed at Supported Frameworks (p. 2231).

- **entry_point** (str) – Required. Specify the file name of your training script.

  Note
  To run a distributed training with SageMaker Training Compiler and PyTorch v1.10.2 and before, specify the file name of a launcher script to this parameter. The launcher script should be prepared to wrap your training script and configure the distributed training environment. For more information, see the following example notebooks:
  - Compile and Train the GPT2 Model using the Transformers Trainer API with the SST2 Dataset for Single-Node Multi-GPU Training
  - Compile and Train the GPT2 Model using the Transformers Trainer API with the SST2 Dataset for Multi-Node Multi-GPU Training

- **source_dir** (str) – Optional. Add this if need to install additional packages. To install packages, you need to prepare a requirements.txt file under this directory.

- **instance_count** (int) – Required. Specify the number of instances.

- **instance_type** (str) – Required. Specify the instance type.

- **transformers_version** (str) – Required only when using the SageMaker Hugging Face estimator. Specify the Hugging Face Transformers library version supported by SageMaker Training Compiler. To find available versions, see Supported Frameworks (p. 2231).
Enable Training Compiler

- **framework_version or pytorch_version (str)** – Required. Specify the PyTorch version supported by SageMaker Training Compiler. To find available versions, see [Supported Frameworks](p. 2231).

  **Note**
  When using the SageMaker Hugging Face estimator, you must specify both `transformers_version` and `pytorch_version`.

- **hyperparameters (dict)** – Optional. Specify hyperparameters for the training job, such as `n_gpus`, `batch_size`, and `learning_rate`. When you enable SageMaker Training Compiler, try larger batch sizes and adjust the learning rate accordingly. To find case studies of using the compiler and adjusted batch sizes to improve training speed, see the section called "Tested Models" (p. 2233) and [SageMaker Training Compiler Example Notebooks and Blogs](p. 2270).

  **Note**
  To run a distributed training with SageMaker Training Compiler and PyTorch v1.10.2 and before, you need to add an additional parameter, "training_script", to specify your training script, as shown in the preceding code example.

- **compiler_config (TrainingCompilerConfig object)** – Required to activate SageMaker Training Compiler. Include this parameter to turn on SageMaker Training Compiler. The following are parameters for the `TrainingCompilerConfig` class.
  - **enabled (bool)** – Optional. Specify True or False to turn on or turn off SageMaker Training Compiler. The default value is True.
  - **debug (bool)** – Optional. To receive more detailed training logs from your compiler-accelerated training jobs, change it to True. However, the additional logging might add overhead and slow down the compiled training job. The default value is False.
  - **distribution (dict)** – Optional. To run a distributed training job with SageMaker Training Compiler, add `distribution = { 'pytorchxla' : { 'enabled': True }}`.

  **Warning**
  If you turn on SageMaker Debugger, it might impact the performance of SageMaker Training Compiler. We recommend that you turn off Debugger when running SageMaker Training Compiler to make sure there's no impact on performance. For more information, see the section called "Considerations" (p. 2271). To turn the Debugger functionalities off, add the following two arguments to the estimator:

  ```
  disable_profiler=True,
  debugger_hook_config=False
  ```

  If the training job with the compiler is launched successfully, you receive the following logs during the job initialization phase:

  - **With TrainingCompilerConfig(debug=False)**
    ```
    Found configuration for Training Compiler
    Configuring SM Training Compiler...
    ```
  
  - **With TrainingCompilerConfig(debug=True)**
    ```
    Found configuration for Training Compiler
    Configuring SM Training Compiler...
    Training Compiler set to debug mode
    ```
Using the SageMaker CreateTrainingJob API Operation

SageMaker Training Compiler configuration options must be specified through the AlgorithmSpecification and HyperParameters field in the request syntax for the CreateTrainingJob API operation.

```json
"AlgorithmSpecification": {
    "TrainingImage": "<sagemaker-training-compiler-enabled-dlc-image>",
},
"HyperParameters": {
    "sagemaker_training_compiler_enabled": "true",
    "sagemaker_training_compiler_debug_mode": "false",
    "sagemaker_pytorch_xla_multi_worker_enabled": "false" // set to "true" for distributed training
}
```

To find a complete list of deep learning container image URIs that have SageMaker Training Compiler implemented, see Supported Frameworks (p. 2231).

Run TensorFlow Training Jobs with SageMaker Training Compiler

You can use any of the SageMaker interfaces to run a training job with SageMaker Training Compiler: Amazon SageMaker Studio, Amazon SageMaker notebook instances, AWS SDK for Python (Boto3), and AWS Command Line Interface.

Topics
- Using the SageMaker Python SDK (p. 2264)
- Using the SageMaker Python SDK and Extending SageMaker Framework Deep Learning Containers (p. 2268)
- Enable SageMaker Training Compiler Using the SageMaker CreateTrainingJob API Operation (p. 2270)

Using the SageMaker Python SDK

To turn on SageMaker Training Compiler, add the compiler_config parameter to the SageMaker TensorFlow or Hugging Face estimator. Import the TrainingCompilerConfig class and pass an instance of it to the compiler_config parameter. The following code examples show the structure of the SageMaker estimator classes with SageMaker Training Compiler turned on.

**Tip**
To get started with prebuilt models provided by the TensorFlow and Transformers libraries, try using the batch sizes provided in the reference table at Tested Models (p. 2233).

**Note**
SageMaker Training Compiler for TensorFlow is available through the SageMaker TensorFlow and Hugging Face framework estimators.

For information that fits your use case, see one of the following options.

For single GPU training

```python
from sagemaker.tensorflow import TensorFlow, TrainingCompilerConfig
```
# the original max batch size that can fit into GPU memory without compiler
batch_size_native=12
learning_rate_native=float('5e-5')

# an updated max batch size that can fit into GPU memory with compiler
batch_size=64

# update the global learning rate
learning_rate=learning_rate_native/batch_size_native*batch_size

hyperparameters={
    "n_gpus": 1,
    "batch_size": batch_size,
    "learning_rate": learning_rate
}

tensorflow_estimator=TensorFlow(
    entry_point='train.py',
    instance_count=1,
    instance_type='ml.p3.2xlarge',
    framework_version='2.9.1',
    hyperparameters=hyperparameters,
    compiler_config=TrainingCompilerConfig(),
    disable_profiler=True,
    debugger_hook_config=False
)

tensorflow_estimator.fit()

To prepare your training script, see the following pages.

- For single GPU training (p. 2254) of a model constructed using TensorFlow Keras (tf.keras.*).
- For single GPU training (p. 2254) of a model constructed using TensorFlow modules (tf.* excluding the TensorFlow Keras modules).

Hugging Face Estimator with TensorFlow

from sagemaker.huggingface import HuggingFace, TrainingCompilerConfig

# the original max batch size that can fit into GPU memory without compiler
batch_size_native=12
learning_rate_native=float('5e-5')

# an updated max batch size that can fit into GPU memory with compiler
batch_size=64

# update the global learning rate
learning_rate=learning_rate_native/batch_size_native*batch_size

hyperparameters={
    "n_gpus": 1,
    "batch_size": batch_size,
    "learning_rate": learning_rate

```python
disable_profiler=True,
debugger_hook_config=False
```

If the training job with the compiler is launched successfully, you receive the following logs during the job initialization phase:

- With TrainingCompilerConfig(debug=False)

```
Found configuration for Training Compiler
Configuring SM Training Compiler...
```
With `TrainingCompilerConfig(debug=True)`

```python
    Found configuration for Training Compiler
    Configuring SM Training Compiler...
    Training Compiler set to debug mode
```

**Using the SageMaker Python SDK and Extending SageMaker Framework Deep Learning Containers**

AWS Deep Learning Containers (DLC) for TensorFlow use adapted versions of TensorFlow that include changes on top of the open-source TensorFlow framework. The [SageMaker Framework Deep Learning Containers](https://docs.aws.amazon.com/sagemaker/latest/dg/sagemaker-reusable-container.html) are optimized for the underlying AWS infrastructure and Amazon SageMaker. With the advantage of using the DLCs, SageMaker Training Compiler integration adds more performance improvements over the native TensorFlow. Furthermore, you can create a custom training container by extending the DLC image.

**Note**

This Docker customization feature is currently available only for TensorFlow.

To extend and customize the SageMaker TensorFlow DLCs for your use-case, use the following instructions.

**Create a Dockerfile**

Use the following Dockerfile template to extend the SageMaker TensorFlow DLC. You must use the SageMaker TensorFlow DLC image as the base image of your Docker container. To find the SageMaker TensorFlow DLC image URIs, see [Supported Frameworks](https://docs.aws.amazon.com/sagemaker/latest/dg/compatibility.html).

```bash
# SageMaker TensorFlow Deep Learning Container image
FROM 763104351884.dkr.ecr.<aws-region>.amazonaws.com/tensorflow-training:<image-tag>

ENV PATH="/opt/ml/code:${PATH}"
# This environment variable is used by the SageMaker container
# to determine user code directory.
ENV SAGEMAKER_SUBMIT_DIRECTORY /opt/ml/code

# Add more code lines to customize for your use-case
...
```

For more information, see [Step 2: Create and upload the Dockerfile and Python training scripts](https://docs.aws.amazon.com/sagemaker/latest/dg/step-2-dockerfile.html).

Consider the following pitfalls when extending SageMaker Framework DLCs:

- Do not explicitly uninstall or change the version of TensorFlow packages in SageMaker containers. Doing so causes the AWS optimized TensorFlow packages to be overwritten by open-source TensorFlow packages, which might result in performance degradation.

- Watch out for packages that have a particular TensorFlow version or flavor as a dependency. These packages might implicitly uninstall the AWS optimized TensorFlow and install open-source TensorFlow packages.

For example, there’s a known issue that the `tensorflow/models` and `tensorflow/text` libraries always attempt to reinstall open source TensorFlow. If you need to install these libraries to choose a specific version for your use case, we recommend that you look into the SageMaker TensorFlow DLC Dockerfiles for v2.9 or later. The paths to the Dockerfiles are typically in the following format: `tensorflow/training/docker/<tensorflow-version>/py3/<cuda-version>/Dockerfile.gpu`. In the
Dockerfiles, you should find the code lines to reinstall AWS managed TensorFlow binary (specified to the TF_URL environment variable) and other dependencies in order. The reinstallation section should look like the following example:

```
# tf-models does not respect existing installations of TensorFlow
# and always installs open source TensorFlow
RUN pip3 install --no-cache-dir -U \
    tf-models-official==x.y.z

RUN pip3 uninstall -y tensorflow tensorflow-gpu \
    ; pip3 install --no-cache-dir -U \
    ${TF_URL} \
    tensorflow-io==x.y.z \n    tensorflow-datasets==x.y.z
```

### Build and push to ECR

To build and push your Docker container to Amazon ECR, follow the instructions in the following links:

- **Step 3: Build the container**
- **Step 4: Test the container**
- **Step 5: Push the container to Amazon ECR**

### Run using the SageMaker Python SDK Estimator

Use the SageMaker TensorFlow framework estimator as usual. You must specify image_uri to use the new container you hosted in Amazon ECR.

```
import sagemaker, boto3
from sagemaker import get_execution_role
from sagemaker.tensorflow import TensorFlow, TrainingCompilerConfig

account_id = boto3.client('sts').get_caller_identity().get('Account')
ecr_repository = 'tf-custom-container-test'
tag = ':latest'
region = boto3.Session().region_name
uri_suffix = 'amazonaws.com'
byoc_image_uri = '{}.dkr.ecr.{}.{}/{}'.format(  
    account_id, region, uri_suffix, ecr_repository + tag
)

# This should return something like
# 111122223333.dkr.ecr.us-east-2.amazonaws.com/tf-custom-container-test:latest

estimator = TensorFlow(  
    image_uri=image_uri,  
    role=get_execution_role(),  
    base_job_name='tf-custom-container-test-job',  
    instance_count=1,  
    instance_type='ml.p3.8xlarge'  
    compiler_config=TrainingCompilerConfig(),  
    disable_profiler=True,  
    debugger_hook_config=False
)

# Start training
```
estimator.fit()

**Enable SageMaker Training Compiler Using the SageMaker CreateTrainingJob API Operation**

SageMaker Training Compiler configuration options must be specified through the `AlgorithmSpecification` and `HyperParameters` field in the request syntax for the `CreateTrainingJob` API operation.

```json
"AlgorithmSpecification": {
    "TrainingImage": "<sagemaker-training-compiler-enabled-dlc-image>",

    "HyperParameters": {
        "sagemaker_training_compiler_enabled": "true",
        "sagemaker_training_compiler_debug_mode": "false"
    }
}
```

To find a complete list of deep learning container image URIs that have SageMaker Training Compiler implemented, see [Supported Frameworks](p. 2231).

**SageMaker Training Compiler Example Notebooks and Blogs**

The following blogs, case studies, and notebooks provide examples of how to implement SageMaker Training Compiler.

Example notebooks are provided in the [SageMaker examples GitHub repository](https://github.com/aws/sagemaker-examples) and you can also browse them on the [SageMaker examples website](https://aws.amazon.com/sagemaker/).

**Blogs and Case Studies**

The following blogs discuss case studies about using SageMaker Training Compiler.

- [Hugging Face Transformers BERT fine-tuning using Amazon SageMaker Training Compiler](https://aws.amazon.com/blogs/machine-learning/hugging-face-transformers-bert-fine-tuning-using-amazon-sagemaker-training-compiler/)
- [Speed up Hugging Face Training Jobs on AWS by Up to 50% with SageMaker Training Compiler](https://aws.amazon.com/blogs/machine-learning/speed-up-hugging-face-training-jobs-on-aws-by-up-to-50-with-sagemaker-training-compiler/)

**Examples Notebooks**

To find examples of using SageMaker Training Compiler, see the [Training Compiler page](https://docs.aws.amazon.com/sagemaker/latest/dg/compiling-training-estimators.html) in the [Amazon SageMaker Example Read the Docs website](https://sagemaker-examples.readthedocs.io/en/latest/).

**SageMaker Training Compiler Best Practices and Considerations**

Review the following best practices and considerations when using SageMaker Training Compiler.

**Best Practices**

Use the following guidelines to achieve the best results when you run training jobs with SageMaker Training Compiler.
General Best Practices

• Make sure that you use one of the Supported Instance Types (p. 2232) and Tested Models (p. 2233).

• When you create a tokenizer for an NLP model using the Hugging Face Transformers library in your training script, make sure that you use a static input tensor shape by specifying padding='max_length'. Do not use padding='longest' because padding to the longest sequence in the batch can change the tensor shape for each training batch. The dynamic input shape can initiate recompilation of the model and might increase total training time. For more information about padding options of the Transformers tokenizers, see Padding and truncation in the Hugging Face Transformers documentation.

• Measure GPU memory utilization to make sure that you use the maximum batch size that can fit into the GPU memory. Amazon SageMaker Training Compiler reduces the memory footprint of your model during training, which typically allows you to fit a larger batch_size in the GPU memory. Using a larger batch_size results in a better GPU utilization and reduces the total training time.

When you adjust the batch size, you also have to adjust the learning_rate appropriately. For example, if you increased the batch size by a factor of k, you need to adjust learning_rate linearly (simple multiplication by k) or multiply by the square root of k. This is to achieve the same or similar convergence behavior in the reduced training time. For reference of batch_size tested for popular models, see Tested Models (p. 2233).

• To debug the compiler-accelerated training job, enable the debug flag in the compiler_config parameter. This enables SageMaker to put the debugging logs into SageMaker training job logs.

huggingface_estimator=HuggingFace(
    ...
    compiler_config=TrainingCompilerConfig(debug=True)
)

Note that if you enable full debugging of the training job with the compiler, this might add some overhead.

Best Practices for PyTorch

• If you bring a PyTorch model and want to checkpoint it, make sure you use PyTorch/XLA's model save function to properly checkpoint your model. For more information about the function, see torch_xla.core.xla_model.save in the PyTorch on XLA Devices documentation.

To learn how to add the modifications to your PyTorch script, see Large Language Models Using PyTorch Directly (without the Hugging Face Transformers Trainer API) (p. 2250).

For more information about the actual application of using the model save function, see Checkpoint Writing and Loading in the Hugging Face on PyTorch/XLA TPUs: Faster and cheaper training blog.

• To achieve the most optimal training time for distributed training, consider the following.

  • Use instances with multiple GPUs instead of using single-gpu instances. For example, a single ml.p3dn.24xlarge instance has faster training time compared to 8 x ml.p3.2xlarge instances.

  • Use instances with EFA support such as ml.p3dn.24xlarge and ml.p4d.24xlarge. These instance types have accelerated networking speed and reduce training time.

  • Tune the preprocessing_num_workers parameter for datasets, so that model training is not delayed by slow preprocessing.

Considerations

Consider the following when using SageMaker Training Compiler.
Performance degradation due to logging, checkpointing, and profiling

- Avoid logging, checkpointing, and profiling model tensors that lead to explicit evaluations. To understand what an explicit evaluation is, consider the following code compiling example.

```
a = b+c
e = a+d
```

A compiler interprets the code as follows and reduces the memory footprint for the variable `a`:

```
e = b+c+d
```

Now consider the following case in which the code is changed to add a print function for the variable `a`.

```
a = b+c
e = a+d
print(a)
```

The compiler makes an explicit evaluation of the variable `a` as follows.

```
e = b+c+d
a = b+c      # Explicit evaluation
print(a)
```

In PyTorch, for example, avoid using `torch.tensor.items()`, which might introduce explicit evaluations. In deep learning, such explicit evaluations can cause overhead because they break fused operations in a compilation graph of a model and lead to recomputation of the tensors.

If you still want to periodically evaluate the model during training while using SageMaker Training Compiler, we recommend logging and checkpointing at a lower frequency to reduce overhead due to explicit evaluations. For example, log every 10 epochs instead of every epoch.

- Graph compilation runs during the first few steps of training. As a result, the first few steps are expected to be exceptionally slow. However, this is a one-time compilation cost and can be amortized by training for a longer duration because compilation makes future steps much faster. The initial compilation overhead depends on the size of the model, the size of the input tensors, and the distribution of input tensor shapes.

Incorrect use of the PyTorch/XLA APIs when using PyTorch directly

PyTorch/XLA defines a set of APIs to replace some of the existing PyTorch training APIs. Failing to use them properly leads PyTorch training to fail.

- One of the most typical errors when compiling a PyTorch model is due to a wrong device type for operators and tensors. To properly compile a PyTorch model, make sure you use XLA devices (`xm.xla_device()`) instead of using CUDA or mixing CUDA devices and XLA devices.
- `mark_step()` is a barrier just for XLA. Failing to set it correctly causes a training job to stall.
- PyTorch/XLA provides additional distributed training APIs. Failing to program the APIs properly causes gradients to be collected incorrectly, which causes a training convergence failure.

To properly set up your PyTorch script and avoid the aforementioned incorrect API uses, see Large Language Models Using PyTorch Directly (without the Hugging Face Transformers Trainer API) (p. 2250).
SageMaker Training Compiler FAQ

Use the following FAQ items to find answers to commonly asked questions about SageMaker Training Compiler.

Q. How do I know SageMaker Training Compiler is working?

If you successfully launched your training job with SageMaker Training Compiler, you receive the following log messages:

- With `TrainingCompilerConfig(debug=False)`

```
Found configuration for Training Compiler
Configuring SM Training Compiler...
```

- With `TrainingCompilerConfig(debug=True)`

```
Found configuration for Training Compiler
Configuring SM Training Compiler...
Training Compiler set to debug mode
```

Q. Which models does SageMaker Training Compiler accelerate?

SageMaker Training Compiler supports the most popular deep learning models from the Hugging Face transformers library. With most of the operators that the compiler supports, these models can be trained faster with SageMaker Training Compiler. Compilable models include but are not limited to the following: bert-base-cased, bert-base-chinese, bert-base-uncased, distilbert-base-uncased, distilbert-base-uncased-finetuned-sst-2-english, gpt2, roberta-base, roberta-large, t5-base, and xlm-roberta-base. The compiler works with most DL operators and data structures and can accelerate many other DL models beyond those that have been tested.

Q. What happens if I enable SageMaker Training Compiler with a model that isn't tested?

For an untested model, you might need to first modify the training script to be compatible with SageMaker Training Compiler. For more information, see Bring Your Own Deep Learning Model (p. 2248) and follow the instructions on how to prepare your training script.

Once you have updated your training script, you can start the training job. The compiler proceeds to compile the model. However, training speed may not increase and might even decrease relative to the baseline with an untested model. You might need to retune training parameters such as `batch_size` and `learning_rate` to achieve any speedup benefits.

If compilation of the untested model fails, the compiler returns an error. See SageMaker Training Compiler Troubleshooting (p. 2274) for detailed information about the failure types and error messages.

Q. Will I always get a faster training job with SageMaker Training Compiler?

No, not necessarily. First, SageMaker Training Compiler adds some compilation overhead before the ongoing training process can be accelerated. The optimized training job must run sufficiently long to amortize and make up for this incremental compilation overhead at the beginning of the training job.

Additionally, as with any model training process, training with suboptimal parameters can increase training time. SageMaker Training Compiler can change the characteristics of the training job by, for example, changing the memory footprint of the job. Because of these differences, you might need to retune your training job parameters to speed up training. A reference table specifying the best performing parameters for training jobs with different instance types and models can be found at Tested Models (p. 2233).
Finally, some code in a training script might add additional overhead or disrupt the compiled computation graph and slow training. If working with a customized or untested model, see the instructions at Best Practices to Use SageMaker Training Compiler with PyTorch/XLA (p. 2253).

Q. Can I always use a larger batch size with SageMaker Training Compiler?

Batch size increases in most, but not all, cases. The optimizations made by SageMaker Training Compiler can change the characteristics of your training job, such as the memory footprint. Typically, a Training Compiler job occupies less memory than an uncompiled training job with the native framework, which allows for a larger batch size during training. A larger batch size, and a corresponding adjustment to the learning rate, increases training throughput and can decrease total training time.

However, there could be cases where SageMaker Training Compiler might actually increase memory footprint based on its optimization scheme. The compiler uses an analytical cost model to predict the execution schedule with the lowest cost of execution for any compute-intensive operator. This model could find an optimal schedule that increases memory use. In this case, you won’t be able to increase batch sizes, but your sample throughput is still higher.

Q. Does SageMaker Training Compiler work with other SageMaker training features, such as the SageMaker distributed training libraries and SageMaker Debugger?

SageMaker Training Compiler is currently not compatible with SageMaker’s distributed training libraries.

SageMaker Training Compiler is compatible with SageMaker Debugger, but Debugger might degrade computational performance by adding overhead.

Q. Does SageMaker Training Compiler support custom containers (bring your own container)?

SageMaker Training Compiler is provided through AWS Deep Learning Containers, and you can extend a subset of the containers to customize for your use-case. Containers that are extended from AWS DLCs are supported by SageMaker Training Compiler. For more information, see Supported Frameworks and Using the SageMaker Python SDK and Extending SageMaker Framework Deep Learning Containers (p. 2268). If you need further support, reach out to the SageMaker team through AWS Support or AWS Developer Forums for Amazon SageMaker.

SageMaker Training Compiler Troubleshooting

If you run into an error, you can use the following list to try to troubleshoot your training job. If you need further support, reach out to the SageMaker team through AWS Support or AWS Developer Forums for Amazon SageMaker.

Training job is not converging as expected when compared to the native framework training job

Convergence issues range from “the model is not learning when SageMaker Training Compiler is turned on” to “the model is learning but slower than the native framework”. In this troubleshooting guide, we assume your convergence is fine without SageMaker Training Compiler (in the native framework) and consider this the baseline.

When faced with such convergence issues, the first step is to identify if the issue is limited to distributed training or stems from single-GPU training. Distributed training with SageMaker Training Compiler is an extension of single-GPU training with additional steps.

1. Set up a cluster with multiple instances or GPUs.
2. Distribute input data to all workers.
3. Synchronize the model updates from all workers.
Therefore, any convergence issue in single-GPU training propagates to distributed training with multiple workers.
A flow chart to troubleshoot convergence issues in training jobs when using SageMaker Training Compiler. Descriptions are in the following sections.

**Convergence issues occurring in single-GPU training**

If your convergence issue stems from single-GPU training, this is likely due to improper settings for hyperparameters or the `torch_xla` APIs.

**Check the hyperparameters**

Training with SageMaker Training Compiler leads to change in the memory footprint of a model. The compiler intelligently arbitrates between re-use and re-compute leading to a corresponding increase or decrease in memory consumption. To leverage this, it is essential to re-tune the batch size and associated hyperparameters when migrating a training job to SageMaker Training Compiler. However, incorrect hyperparameter settings often cause oscillation in training loss and possibly a slower convergence as a result. In rare cases, aggressive hyperparameters might result in the model not learning (the training loss metric doesn’t decrease or returns NaN). To identify if the convergence issue is due to the hyperparameters, do a side-by-side test of two training jobs with and without SageMaker Training Compiler while keeping all the hyperparameters the same.

**Check if the `torch_xla` APIs are properly set up for single-GPU training**

If the convergence issue persists with the baseline hyperparameters, you need to check if there’s any improper usage of the `torch_xla` APIs, specifically the ones for updating the model. Fundamentally, `torch_xla` continues to accumulate instructions (deferring execution) in the form of graph until it is explicitly instructed to run the accumulated graph. The `torch_xla.core.xla_model.mark_step()` function facilitates the execution of the accumulated graph. The graph execution should be synchronized using this function *after each model update* and *before printing and logging any variables*. If it lacks the synchronization step, the model might use stale values from memory during prints, logs, and the subsequent forward passes, instead of using the most recent values that have to be synchronized after every iteration and model update.

It can be more complicated when using SageMaker Training Compiler with gradient scaling (possibly from the use of AMP) or gradient clipping techniques. The appropriate order of gradient computation with AMP is as follows.

1. Gradient computation with scaling
2. Gradient un-scaling, gradient clipping, and then scaling
3. Model update
4. Synchronizing the graph execution with `mark_step()`

To find the right APIs for the operations mentioned in the list, see the guide for [migrating your training script to SageMaker Training Compiler](#).

**Consider using Automatic Model Tuning**

If the convergence issue arises when re-tuning the batch size and associated hyperparameters such as the learning rate while using SageMaker Training Compiler, consider using [Automatic Model Tuning](#) to tune your hyperparameters. You can refer to the [example notebook on tuning hyperparameters with SageMaker Training Compiler](#).

**Convergence issues occurring in distributed training**

If your convergence issue persists in distributed training, this is likely due to improper settings for weight initialization or the `torch_xla` APIs.

**Check weight initialization across the workers**
If the convergence issue arises when running a distributed training job with multiple workers, ensure there is a uniform deterministic behavior across all workers by setting a constant seed where applicable. Beware of techniques such as weight initialization, which involves randomization. Each worker might end up training a different model in the absence of a constant seed.

**Check if the torch_xla APIs are properly set up for distributed training**

If the issue still persists, this is likely due to improper use of the torch_xla APIs for distributed training. Make sure that you add the following in your estimator to set up a cluster for distributed training with SageMaker Training Compiler.

```python
distribution={'torchxla': {'enabled': True}}
```

This should be accompanied by a function `mp_fn(index)` in your training script, which is invoked once per worker. Without the `mp_fn(index)` function, you might end up letting each of the workers train the model independently without sharing model updates.

Next, make sure that you use the `torch_xla.distributed.parallel_loader.MpDeviceLoader` API along with the distributed data sampler, as guided in the documentation about migrating your training script to SageMaker Training Compiler, as in the following example.

```python
torch.utils.data.distributed.DistributedSampler()
```

This ensures that the input data is properly distributed across all workers.

Finally, to synchronize model updates from all workers, use `torch_xla.core.xla_model._fetch_gradients` to gather gradients from all workers and `torch_xla.core.xla_model.all_reduce` to combine all the gathered gradients into a single update.

It can be more complicated when using SageMaker Training Compiler with gradient scaling (possibly from use of AMP) or gradient clipping techniques. The appropriate order of gradient computation with AMP is as follows.

1. Gradient computation with scaling
2. Gradient synchronization across all workers
3. Gradient un-scaling, gradient clipping, and then gradient scaling
4. Model update
5. Synchronizing the graph execution with `mark_step()`

Note that this checklist has an additional item for synchronizing all workers, compared to the checklist for single-GPU training.

**Training job fails due to missing PyTorcl/XLA configuration**

If a training job fails with the `Missing XLA configuration` error message, it might be due to a misconfiguration in the number of GPUs per instance that you use.

XLA requires additional environment variables to compile the training job. The most common missing environment variable is `GPU_NUM_DEVICES`. For the compiler to work properly, you must set this environment variable equal to the number of GPUs per instance.

There are three approaches to set the `GPU_NUM_DEVICES` environment variable:
• **Approach 1** – Use the environment argument of the SageMaker estimator class. For example, if you use an `ml.p3.8xlarge` instance that has four GPUs, do the following:

```
# Using the SageMaker Python SDK's HuggingFace estimator
hf_estimator=HuggingFace(  
    ...  
    instance_type="ml.p3.8xlarge",  
    hyperparameters={...},  
    environment={  
    ...  
    "GPU_NUM_DEVICES": "4"  
    # corresponds to number of GPUs on the specified instance  
    },  
)
```

• **Approach 2** – Use the hyperparameters argument of the SageMaker estimator class and parse it in your training script.

1. To specify the number of GPUs, add a key-value pair to the hyperparameters argument.

   For example, if you use an `ml.p3.8xlarge` instance that has four GPUs, do the following:

   ```
   # Using the SageMaker Python SDK's HuggingFace estimator
   hf_estimator=HuggingFace(  
    entry_point = "train.py"  
    instance_type= "ml.p3.8xlarge",  
    hyperparameters = {  
    ...  
    "n_gpus": 4  
    # corresponds to number of GPUs on specified instance  
    }  
   
   hf_estimator.fit()  
   ```

2. In your training script, parse the `n_gpus` hyperparameter and specify it as an input for the `GPU_NUM_DEVICES` environment variable.

   ```
   # train.py
   import os, argparse
   
   if __name__ == '__main__':
       parser = argparse.ArgumentParser()  
       ...  
       # Data, model, and output directories
       parser.add_argument("--output_data_dir", type=str,  
       default=os.environ["SM_OUTPUT_DATA_DIR"])
       parser.add_argument("--model_dir", type=str, default=os.environ["SM_MODEL_DIR"])
       parser.add_argument("--training_dir", type=str,  
       default=os.environ["SM_CHANNEL_TRAIN"])
       parser.add_argument("--test_dir", type=str, default=os.environ["SM_CHANNEL_TEST"])
       parser.add_argument("--n_gpus", type=str, default=os.environ["SM_NUM_GPUS"])
       
       args, _ = parser.parse_known_args()  
       os.environ["GPU_NUM_DEVICES"] = args.n_gpus  
   ```

• **Approach 3** – Hard-code the `GPU_NUM_DEVICES` environment variable in your training script. For example, add the following to your script if you use an instance that has four GPUs.

   ```
   # train.py
   import os  
   ```
os.environ["GPU_NUM_DEVICES"] = 4

Tip
To find the number of GPU devices on machine learning instances that you want to use, see Accelerated Computing in the Amazon EC2 Instance Types page.

SageMaker Training Compiler doesn't reduce the total training time

If the total training time does not decrease with SageMaker Training Compiler, we highly recommend you to go over the SageMaker Training Compiler Best Practices and Considerations (p. 2270) page to check your training configuration, padding strategy for the input tensor shape, and hyperparameters.

Amazon SageMaker Training Compiler Release Notes

See the following release notes to track the latest updates for Amazon SageMaker Training Compiler.

SageMaker Training Compiler Release Notes: February 13, 2023

Currency Updates

• Added support for PyTorch v1.13.1

Bug Fixes

• Fixed a race condition issue on GPU which was causing NAN loss in some models like vision transformer (ViT) models.

Other Changes

• SageMaker Training Compiler improves performance by letting PyTorch/XLA to automatically override the optimizers (such as SGD, Adam, AdamW) in torch.optim or transformers.optimization with the syncfree versions of them in torch_xla.amp.syncfree (such as torch_xla.amp.syncfree.SGD, torch_xla.amp.syncfree.Adam, torch_xla.amp.syncfree.AdamW). You don't need to change those code lines where you define optimizers in your training script.

Migration to AWS Deep Learning Containers

This release passed benchmark testing and is migrated to the following AWS Deep Learning Container:

• PyTorch v1.13.1

To find a complete list of the prebuilt containers with Amazon SageMaker Training Compiler, see Supported Frameworks, AWS Regions, Instance Types, and Tested Models (p. 2230).

SageMaker Training Compiler Release Notes: January 9, 2023

Breaking Changes
• `tf.keras.optimizers.Optimizer` points to a new optimizer in TensorFlow 2.11.0 and later. The old optimizers are moved to `tf.keras.optimizers.legacy`. You might encounter job failure due to the breaking change when you do the following.
  • Load checkpoints from an old optimizer. We recommend you to switch to use the legacy optimizers.
  • Use TensorFlow v1. We recommend you to migrate to TensorFlow v2, or switch to the legacy optimizers if you need to continue using TensorFlow v1.

For more detailed list of breaking changes from the optimizer changes, see the [official TensorFlow v2.11.0 release notes](https://www.tensorflow.org/releasenotes/v2.11.0) in the TensorFlow GitHub repository.

### Migration to AWS Deep Learning Containers

This release passed benchmark testing and is migrated to the following AWS Deep Learning Container:

• TensorFlow v2.11.0

```
763104351884.dkr.ecr.<region>.amazonaws.com/tensorflow-training:2.11.0-gpu-py39-cu112-ubuntu20.04-sagemaker
```

To find a complete list of the prebuilt containers with Amazon SageMaker Training Compiler, see [Supported Frameworks, AWS Regions, Instance Types, and Tested Models](https://docs.aws.amazon.com/sagemaker/latest/dg/training-compute.html) (p. 2230).

### SageMaker Training Compiler Release Notes: December 8, 2022

#### Bug Fixes

• Fixed the seed for PyTorch training jobs starting PyTorch v1.12 to ensure that there is no discrepancy in model initialization across different processes. See also [PyTorch Reproducibility](https).

• Fixed the issue causing PyTorch distributed training jobs on G4dn and G5 instances to not default to communication through `PCIe`.

#### Known Issues

• Improper use of PyTorch/XLA APIs in Hugging Face's vision transformers might lead to convergence issues.

#### Other Changes

• When using the Hugging Face Transformers `Trainer` class, make sure that you use SyncFree optimizers by setting the `optim` argument to `adamw_torch_xla`. For more information, see [Large Language Models Using the Hugging Face Transformers Trainer Class](https://huggingface.dev/blog/large-language-models-training) (p. 2249). See also [Optimizer](https://huggingface.dev/blog/large-language-models-training) in the [Hugging Face Transformers documentation](https).

### Migration to AWS Deep Learning Containers

This release passed benchmark testing and is migrated to the following AWS Deep Learning Container:

• PyTorch v1.12.0

```
```
SageMaker Training Compiler Release Notes: October 4, 2022

Currency Updates

• Added support for TensorFlow v2.10.0.

Other Changes

• Added Hugging Face NLP models using the Transformers library to TensorFlow framework tests. To find the tested Transformer models, see the section called “Tested Models” (p. 2233).

Migration to AWS Deep Learning Containers

This release passed benchmark testing and is migrated to the following AWS Deep Learning Container:

• TensorFlow v2.10.0

763104351884.dkr.ecr.<region>.amazonaws.com/tensorflow-training:2.10.0-gpu-py39-cu112-ubuntu20.04-sagemaker

SageMaker Training Compiler Release Notes: September 1, 2022

Currency Updates

• Added support for Hugging Face Transformers v4.21.1 with PyTorch v1.11.0.

Improvements

• Implemented a new distributed training launcher mechanism to activate SageMaker Training Compiler for Hugging Face Transformer models with PyTorch. To learn more, see Run PyTorch Training Jobs with SageMaker Training Compiler for Distributed Training (p. 2259).

• Integrated with EFA to improve the collective communication in distributed training.

• Added support for G5 instances for PyTorch training jobs. For more information, see the section called “Supported Frameworks, AWS Regions, Instance Types, and Tested Models” (p. 2230).

Migration to AWS Deep Learning Containers

This release passed benchmark testing and is migrated to the following AWS Deep Learning Container:

• HuggingFace v4.21.1 with PyTorch v1.11.0

To find a complete list of the prebuilt containers with Amazon SageMaker Training Compiler, see Supported Frameworks, AWS Regions, Instance Types, and Tested Models (p. 2230).

SageMaker Training Compiler Release Notes: June 14, 2022

**New Features**

- Added support for custom containers created by extending AWS Deep Learning Containers for TensorFlow. For more information, see Enable SageMaker Training Compiler Using the SageMaker Python SDK and Extending SageMaker Framework Deep Learning Containers (p. 2268).
- Added support for G5 instances for TensorFlow training jobs.

**Migration to AWS Deep Learning Containers**

This release passed benchmark testing and is migrated to the following AWS Deep Learning Container:

- TensorFlow 2.9.1

```
763104351884.dkr.ecr.<region>.amazonaws.com/tensorflow-training:2.9.1-gpu-py39-cu112-ubuntu20.04-sagemaker
```

To find a complete list of the pre-built containers with Amazon SageMaker Training Compiler, see Supported Frameworks, AWS Regions, Instance Types, and Tested Models (p. 2230).

SageMaker Training Compiler Release Notes: April 26, 2022

**Improvements**

- Added support for all of the AWS Regions where AWS Deep Learning Containers are in service except the China regions.

SageMaker Training Compiler Release Notes: April 12, 2022

**Currency Updates**

- Added support for Hugging Face Transformers v4.17.0 with TensorFlow v2.6.3 and PyTorch v1.10.2.

SageMaker Training Compiler Release Notes: February 21, 2022

**Improvements**

- Completed benchmark test and confirmed training speed-ups on the `ml.g4dn` instance types. To find a complete list of tested `ml` instances, see Supported Instance Types (p. 2232).
SageMaker Training Compiler Release Notes: December 01, 2021

New Features

• Launched Amazon SageMaker Training Compiler at AWS re:Invent 2021.

Migration to AWS Deep Learning Containers

• Amazon SageMaker Training Compiler passed benchmark testing and is migrated to AWS Deep Learning Containers. To find a complete list of the prebuilt containers with Amazon SageMaker Training Compiler, see Supported Frameworks, AWS Regions, Instance Types, and Tested Models (p. 2230).

Access Training Data

When you create a training job, you specify the location of a training dataset and an input mode for accessing the dataset. For data location, Amazon SageMaker supports Amazon Simple Storage Service (Amazon S3), Amazon Elastic File System (Amazon EFS), and Amazon FSx for Lustre. The input modes determine whether to stream data files of the dataset in real time or download the whole dataset at the start of the training job.

Note
Your input dataset must be in the same AWS Region as your training job.

SageMaker Input Modes and AWS Cloud Storage

This section summarizes SageMaker input modes for Amazon S3 and file systems in Amazon EFS and Amazon FSx for Lustre.
• **File mode** presents a file system view of the dataset to the training container. This is the default input mode if you don't explicitly specify one of the other two options. If you use file mode, SageMaker downloads the training data from the storage location to a local directory in the Docker container. Training starts after the full dataset has been downloaded. In file mode, the training instance must have enough storage space to fit the entire dataset. File mode download speed depends on the size of dataset, the average size of files, and the number of files. You can configure the dataset for file mode by providing either an Amazon S3 prefix, manifest file, or augmented manifest file. You should use an S3 prefix when all your dataset files are located within a common S3 prefix. File mode is compatible with SageMaker local mode (starting a SageMaker training container interactively in seconds). For distributed training, you can shard the dataset across multiple instances with the `ShardedByS3Key` option.

• **Fast file mode** provides file system access to an Amazon S3 data source while leveraging the performance advantage of pipe mode. At the start of training, fast file mode identifies the data files but does not download them. Training can start without waiting for the entire dataset to download. This means that the training startup takes less time when there are fewer files in the Amazon S3 prefix provided.

In contrast to pipe mode, fast file mode works with random access to the data. However, it works best when data is read sequentially. Fast file mode doesn't support augmented manifest files.

Fast file mode exposes S3 objects using a POSIX-compliant file system interface, as if the files are available on the local disk of your training instance. It streams S3 content on demand as your training script consumes data. This means that your dataset no longer needs to fit into the training instance storage space as a whole, and you don't need to wait for the entire dataset to be downloaded to the training instance before training starts. Fast file mode exposes S3 prefixes only (it does not support manifest and augmented manifest). Fast file mode is compatible with SageMaker local mode.

• **Pipe mode** streams data directly from an Amazon S3 data source. Streaming can provide faster start times and better throughput than file mode.

When you stream the data directly, you can reduce the size of the Amazon EBS volumes used by the training instance. Pipe mode needs only enough disk space to store the final model artifacts.

It is another streaming mode that is largely replaced by the newer and simpler-to-use fast file mode. In pipe mode, data is pre-fetched from Amazon S3 at high concurrency and throughput, and streamed into a named pipe, which also known as a First-In-First-Out (FIFO) pipe for its behavior. Each pipe may only be read by a single process. A SageMaker specific extension to TensorFlow conveniently integrates Pipe mode into the native TensorFlow data loader for streaming text, TFRecords, or RecordIO file formats. Pipe mode also supports managed sharding and shuffling of data.

• **Amazon FSx for Lustre** – FSx for Lustre can scale to hundreds of gigabytes of throughput and millions of IOPS with low-latency file retrieval. When starting a training job, SageMaker mounts the FSx for Lustre file system to the training instance file system, then starts your training script. Mounting itself is a relatively fast operation that doesn't depend on the size of the dataset stored in FSx for Lustre.

To access FSx for Lustre, your training job must connect to an Amazon Virtual Private Cloud (VPC), which requires DevOps setup and involvement. To avoid data transfer costs, the file system uses a single Availability Zone, and you need to specify a VPC subnet which maps to this Availability Zone ID when running the training job.

• **Amazon EFS** – To use Amazon EFS as a data source, the data must already reside in Amazon EFS prior to training. SageMaker mounts the specified Amazon EFS file system to the training instance, then starts your training script. Your training job must connect to a VPC to access Amazon EFS.

**Tip**
To learn more about how to specify your VPC configuration to SageMaker estimators, see Use File Systems as Training Inputs in the SageMaker Python SDK documentation.
Choosing Data Input Mode Using the SageMaker Python SDK

SageMaker Python SDK provides the generic `Estimator class` and its `variations for ML frameworks` for launching training jobs. You can specify one of the data input modes while configuring the SageMaker `Estimator class` or the `Estimator.fit` method. The following code templates show the two ways to specify input modes.

**To specify the input mode using the Estimator class**

```python
from sagemaker.estimator import Estimator
from sagemaker.inputs import TrainingInput

estimator = Estimator(
    checkpoint_s3_uri='s3://my-bucket/checkpoint-destination/',
    output_path='s3://my-bucket/output-path/',
    base_job_name='job-name',
    input_mode='File'  # Available options: File | Pipe | FastFile
)

# Run the training job
estimator.fit(
    inputs=TrainingInput(s3_data="s3://my-bucket/my-data/train")
)
```

For more information, see the `sagemaker.estimator.Estimator` class in the `SageMaker Python SDK documentation`.

**To specify the input mode through the Estimator fit method**

```python
from sagemaker.estimator import Estimator
from sagemaker.inputs import TrainingInput

estimator = Estimator(
    checkpoint_s3_uri='s3://my-bucket/checkpoint-destination/',
    output_path='s3://my-bucket/output-path/',
    base_job_name='job-name',
)

# Run the training job
estimator.fit(
    inputs=TrainingInput(
        s3_data="s3://my-bucket/my-data/train",
        input_mode='File'  # Available options: File | Pipe | FastFile
    )
)
```

For more information, see the `sagemaker.estimator.Estimator.fit` class method and the `sagemaker.inputs.TrainingInput` class in the `SageMaker Python SDK documentation`.

**Tip**

To learn more about how to configure Amazon FSx for Lustre or Amazon EFS with your VPC configuration using the SageMaker Python SDK estimators, see `Use File Systems as Training Inputs` in the `SageMaker Python SDK documentation`.

**Tip**

The data input mode integrations with Amazon S3, Amazon EFS, and FSx for Lustre are recommended ways to optimally configure data source for the best practices. You can
strategically improve data loading performance using the SageMaker managed storage options and input modes, but it's not strictly constrained. You can write your own data reading logic directly in your training container. For example, you can set to read from a different data source, write your own S3 data loader class, or use third-party frameworks' data loading functions within your training script. However, you must make sure that you specify the right paths that SageMaker can recognize.

**Tip**
If you use a custom training container, make sure you install the [SageMaker training toolkit](https://docs.aws.amazon.com/sagemaker/latest/dg/sagemaker-toolkit-container.html) that helps set up the environment for SageMaker training jobs. Otherwise, you must specify the environment variables explicitly in your Dockerfile. For more information, see the [Create a container with your own algorithms and models](https://docs.aws.amazon.com/sagemaker/latest/dg/containers-create-training-container.html).

For more information about how to set the data input modes using the low-level SageMaker APIs, see [How Amazon SageMaker Provides Training Information](https://docs.aws.amazon.com/sagemaker/latest/dg/how-amazon-sagemaker-provides-training-information.html), the `CreateTrainingJob` API, and the `TrainingInputMode` in the `AlgorithmSpecification`.

### Configure Data Input Channel to Use Amazon FSx for Lustre

Learn how to use Amazon FSx for Lustre as your data source for higher throughput and faster training by reducing the time for data loading.

### Sync Amazon S3 and Amazon FSx for Lustre

To link your Amazon S3 to Amazon FSx for Lustre and upload your training datasets, do the following.

1. Prepare your dataset and upload to an Amazon S3 bucket. For example, assume that the Amazon S3 paths for a train dataset and a test dataset are in the following format.

```
 s3://my-bucket/data/train
 s3://my-bucket/data/test
```

2. To create an FSx for Lustre file system linked with the Amazon S3 bucket with the training data, follow the steps at the [Linking your file system to an Amazon S3 bucket](https://docs.aws.amazon.com/fsx-lustre/latest/ug/fsx-lustre-link-s3-bucket.html) in the [Amazon FSx for Lustre User Guide](https://docs.aws.amazon.com/fsx-lustre/latest/ug/). Make sure that you add an endpoint to your VPC allowing Amazon S3 access. For more information, see the section called "Create an Amazon S3 VPC Endpoint" (p. 3543). When you specify **Data repository path**, provide the Amazon S3 bucket URI of the folder that contains your datasets. For example, based on the example S3 paths in step 1, the data repository path should be the following.

```
 s3://my-bucket/data
```

3. After the FSx for Lustre file system is created, check the configuration information by running the following commands.

```
 aws fsx describe-file-systems && \\
 aws fsx describe-data-repository-association
```

These commands return `FileSystemId`, `MountName`, `FileSystemPath`, and `DataRepositoryPath`. For example, the outputs should look like the following.

```
# Output of aws fsx describe-file-systems
"FileSystemId": "fs-0123456789abcdef0"
"MountName": "1234abcd"

# Output of aws fsx describe-data-repository-association
```

2288
Configure Data Input Channel to Use Amazon FSx for Lustre

"FileSystemPath": "/ns1",
"DataRepositoryPath": "s3://my-bucket/data/"

After the sync between Amazon S3 and Amazon FSx has completed, your datasets are saved in Amazon FSx in the following directories.

/ns1/train  # synced with s3://my-bucket/data/train
/ns1/test   # synced with s3://my-bucket/data/test

Set the Amazon FSx file system path as the data input channel for SageMaker training

The following procedures walk you through the process of setting the Amazon FSx file system as the data source for SageMaker training jobs.

Using the SageMaker Python SDK

To properly set the Amazon FSx file system as the data source, configure the SageMaker estimator classes and FileSystemInput using the following instruction.

1. Configure a FileSystemInput class object.

```python
from sagemaker.inputs import FileSystemInput

train_fs = FileSystemInput(
    file_system_id="fs-0123456789abcdef0",
    file_system_type="FSxLustre",
    directory_path="/1234abcd/ns1/",
    file_system_access_mode="ro",
)
```

**Tip**

When you specify directory_path, make sure that you provide the Amazon FSx file system path starting with MountName.

2. Configure a SageMaker estimator with the VPC configuration used for the Amazon FSx file system.

```python
from sagemaker.estimator import Estimator

estimator = Estimator(
    ...,
    role="your-iam-role-with-access-to-your-fsx",
    subnets=["subnet-id"],  # Should be the same as the subnet used for Amazon FSx
    security_group_ids="security-group-id"
)
```

3. Launch the training job by running the estimator.fit method with the Amazon FSx file system.

```python
estimator.fit(train_fs)
```

To find more code examples, see Use File Systems as Training Inputs in the SageMaker Python SDK documentation.

Using the SageMaker CreateTrainingJob API

As part of the CreateTrainingJob request JSON, configure InputDataConfig as follows.
"InputDataConfig": [  
  {  
    "ChannelName": "string",  
    "DataSource": {  
      "FileSystemDataSource": {  
        "DirectoryPath": "/1234abcd/ns1/",  
        "FileSystemAccessMode": "ro",  
        "FileSystemId": "fs-0123456789abcdef0",  
        "FileSystemType": "FSxLustre"  
      }  
    }  
  }  
],

**Tip**

When you specify DirectoryPath, make sure that you provide the Amazon FSx file system path starting with MountName.

**Tips and Considerations When Configuring FSx for Lustre**

1. When you use EFA-enabled instances such as P4d and P3dn, make sure that you set appropriate inbound and output rules in the security group. Specially, opening up these ports is necessary for SageMaker to access the Amazon FSx file system in the training job. To learn more, see [File System Access Control with Amazon VPC](#).
2. Make sure the IAM Role used to launch the SageMaker training job has access to Amazon FSx.

**Best Practices for Choosing Data Source and Input Mode**

The best data source for your training job depends on workload characteristics such as the size of the dataset, the file format, the average size of files, the training duration, a sequential or random data loader read pattern, and how fast your model can consume the training data. The following best practices provide guidelines to get started with the most suitable input mode and data storage for your use case.
Flowchart:

1. Start
2. Where is the dataset stored?
   - EFS
     - Try Amazon EFS
     - Good enough performance?
       - Yes
         - How big are your files?
           - Less than 50MB
             - Try Amazon FSx for Lustre
           - More than 50MB
             - How big is the dataset?
               - Less than 50GB-100GB
                 - Try File mode
               - More than 50GB-100GB
                 - Try FastFile mode
       - No
         - How big is the dataset?
           - Less than 50GB-100GB
             - Try File mode
           - More than 50GB-100GB
             - Try FastFile mode
3. End
This flowchart summarizes and visualizes best practices of choosing the best storage as the data source and input file mode. All of the cases in the flowchart are described in the following sections.

**When to use Amazon EFS**

If your dataset is stored in Amazon Elastic File System, you might have a preprocessing or annotations application that uses Amazon EFS for storage. You can run a training job configured with a data channel that points to the Amazon EFS file system. For more information, see Speed up training on Amazon SageMaker using Amazon FSx for Lustre and Amazon EFS file systems. If you cannot achieve better performance, check your optimization options following the Amazon Elastic File System performance guide or consider using different input modes or data storage.

**Use file mode for small datasets**

If the dataset is stored in Amazon Simple Storage Service and its overall volume is relatively small (for example, less than 50-100 GB), try using file mode. The overhead of downloading a 50 GB dataset can vary based on the total number of files. For example, it takes about 5 minutes if a dataset is chunked into 100 MB shards. Whether this startup overhead is acceptable primarily depends on the overall duration of your training job, because a longer training phase means a proportionally smaller download phase.

**Serializing many small files**

If your dataset size is small (less than 50-100 GB), but is made up of many small files (less than 50 MB per file), the file mode download overhead grows, because each file needs to be downloaded individually from Amazon Simple Storage Service to the training instance volume. To reduce this overhead and data traversal time in general, consider serializing groups of such small files into fewer larger file containers (such as 150 MB per file) by using file formats, such as TFRecord for TensorFlow, WebDataset for PyTorch, and RecordIO for MXNet.

**When to use fast file mode**

For larger datasets with larger files (more than 50 MB per file), the first option is to try fast file mode, which is more straightforward to use than FSx for Lustre because it doesn't require creating a file system, or connecting to a VPC. Fast file mode is ideal for large file containers (more than 150 MB), and might also do well with files more than 50 MB. Because fast file mode provides a POSIX interface, it supports random reads (reading non-sequential byte-ranges). However, this is not the ideal use case, and your throughput might be lower than with the sequential reads. However, if you have a relatively large and computationally intensive ML model, fast file mode might still be able to saturate the effective bandwidth of the training pipeline and not result in an IO bottleneck. You'll need to experiment and see. To switch from file mode to fast file mode (and back), just add (or remove) the input_mode='FastFile' parameter while defining your input channel using the SageMaker Python SDK:

```python
sagemaker.inputs.TrainingInput(S3_INPUT_FOLDER, input_mode = 'FastFile')
```

**When to use Amazon FSx for Lustre**

If your dataset is too large for file mode, has many small files that you can't serialize easily, or uses a random read access pattern, FSx for Lustre is a good option to consider. Its file system scales to hundreds of gigabytes per second (GB/s) of throughput and millions of IOPS, which is ideal when you have many small files. However, note that there might be the cold start issue due to lazy loading and the overhead of setting up and initializing the FSx for Lustre file system.
Tip
To learn more, see Choose the best data source for your Amazon SageMaker training job. This AWS machine learning blog further discusses case studies and performance benchmark of data sources and input modes.

Train Using a Heterogeneous Cluster

Using the heterogeneous cluster feature of SageMaker Training, you can run a training job with multiple types of ML instances for a better resource scaling and utilization for different ML training tasks and purposes. For example, if your training job on a cluster with GPU instances suffers low GPU utilization and CPU bottleneck problems due to CPU-intensive tasks, using a heterogeneous cluster can help offload CPU-intensive tasks by adding more cost-efficient CPU instance groups, resolve such bottleneck problems, and achieve a better GPU utilization.

Note
This feature is available in the SageMaker Python SDK v2.98.0 and later.

Note
This feature is available through the SageMaker PyTorch and TensorFlow framework estimator classes. Supported frameworks are PyTorch v1.10 or later and TensorFlow v2.6 or later.

Topics
- How to Configure a Heterogeneous Cluster (p. 2293)
- Distributed Training with a Heterogeneous Cluster (p. 2296)
- Modify Your Training Script to Assign Instance Groups (p. 2298)
- Considerations (p. 2300)
- Examples, Blogs, and Case Studies (p. 2300)

How to Configure a Heterogeneous Cluster

This section provides instructions on how to run a training job using a heterogeneous cluster that consists of multiple instance types.

Topics
- Using the SageMaker Python SDK (p. 2293)
- Using the Low-Level SageMaker APIs (p. 2296)

Using the SageMaker Python SDK

Follow instructions on how to configure instance groups for a heterogeneous cluster using the SageMaker Python SDK.

1. To configure instance groups of a heterogeneous cluster for a training job, use the sagemaker.instance_group.InstanceGroup class. You can specify a custom name for each instance group, the instance type, and the number of instances for each instance group. For more information, see sagemaker.instance_group.InstanceGroup in the SageMaker Python SDK documentation.

   Note
   For more information about available instance types and the maximum number of instance groups that you can configure in a heterogeneous cluster, see the InstanceGroup API reference.
The following code example shows how to set up two instance groups that consists of two ml.c5.18xlarge CPU-only instances named `instance_group_1` and one ml.p3dn.24xlarge GPU instance named `instance_group_2`, as shown in the following diagram.

```python
from sagemaker.instance_group import InstanceGroup

instance_group_1 = InstanceGroup(
    "instance_group_1", "ml.c5.18xlarge", 2
)

instance_group_2 = InstanceGroup(
    "instance_group_2", "ml.p3dn.24xlarge", 1
)
```

The preceding diagram shows a conceptual example of how pre-training processes, such as data preprocessing, can be assigned to the CPU instance group and stream the preprocessed data to the GPU instance group.
2. Using the instance group objects, set up training input channels and assign instance groups to the channels through the instance_group_names argument of the `sagemaker.inputs.TrainingInput` class. The instance_group_names argument accepts a list of strings of instance group names.

The following example shows how to set two training input channels and assign the instance groups created in the example of the previous step. You can also specify Amazon S3 bucket paths to the `s3_data` argument for the instance groups to process data for your usage purposes.

```python
from sagemaker.inputs import TrainingInput

training_input_channel_1 = TrainingInput(
    s3_data_type='S3Prefix', # Available Options: S3Prefix | ManifestFile | AugmentedManifestFile
    s3_data='s3://your-training-data-storage/folder1',
    distribution='FullyReplicated', # Available Options: FullyReplicated | ShardedByS3Key
    input_mode='File', # Available Options: File | Pipe | FastFile
    instance_groups=['instance_group_1']
)

training_input_channel_2 = TrainingInput(
    s3_data_type='S3Prefix',
    s3_data='s3://your-training-data-storage/folder2',
    distribution='FullyReplicated',
    input_mode='File',
    instance_groups=['instance_group_2']
)
```

For more information about the arguments of `TrainingInput`, see the following links.
- The `sagemaker.inputs.TrainingInput` class in the SageMaker Python SDK documentation
- The `S3DataSource` API in the SageMaker API Reference

3. Configure a SageMaker estimator with the `instance_groups` argument as shown in the following code example. The `instance_groups` argument accepts a list of `InstanceGroup` objects.

**PyTorch**

```python
from sagemaker.pytorch import PyTorch

estimator = PyTorch(
    ...
    entry_point='my-training-script.py',
    framework_version='x.y.z', # 1.10.0 or later
    py_version='pyxy',
    job_name='my-training-job-with-heterogeneous-cluster',
    instance_groups=['instance_group_1', 'instance_group_2']
)
```

**TensorFlow**

```python
from sagemaker.tensorflow import TensorFlow

estimator = TensorFlow(
    ...
    entry_point='my-training-script.py',
    framework_version='x.y.z', # 2.6.0 or later
    py_version='pyxy',
    job_name='my-training-job-with-heterogeneous-cluster',
    instance_groups=['instance_group_1', 'instance_group_2']
)
```
Note
The instance_type and instance_count argument pair and the instance_groups argument of the SageMaker estimator class are mutually exclusive. For homogeneous cluster training, use the instance_type and instance_count argument pair. For heterogeneous cluster training, use instance_groups.

Note
To find a complete list of available framework containers, framework versions, and Python versions, see SageMaker Framework Containers in the AWS Deep Learning Container GitHub repository.

4. Configure the estimator.fit method with the training input channels configured with the instance groups and start the training job.

```python
estimator.fit(
    inputs={
        'training': training_input_channel_1,
        'dummy-input-channel': training_input_channel_2
    }
)
```

Using the Low-Level SageMaker APIs

If you use the AWS Command Line Interface or AWS SDK for Python (Boto3) and want to use low-level SageMaker APIs for submitting a training job request with a heterogeneous cluster, see the following API references.

- CreateTrainingJob
- ResourceConfig
- InstanceGroup
- S3DataSource

Distributed Training with a Heterogeneous Cluster

Through the distribution argument of the SageMaker estimator class, you can assign a specific instance group to run distributed training. For example, assume that you have the following two instance groups and want to run multi-GPU training on one of them.

```python
from sagemaker.instance_group import InstanceGroup

instance_group_1 = InstanceGroup("instance_group_1", "ml.c5.18xlarge", 1)
instance_group_2 = InstanceGroup("instance_group_2", "ml.p3dn.24xlarge", 2)
```

You can set the distributed training configuration for one of the instance groups. For example, the following code examples show how to assign training_group_2 with two ml.p3dn.24xlarge instances to the distributed training configuration.

Note
Currently, only one instance group of a heterogeneous cluster can be specified to the distribution configuration.

With MPI

PyTorch

```python
from sagemaker.pytorch import PyTorch
```
estimator = PyTorch(
    ...
    instance_groups=[instance_group_1, instance_group_2],
    distribution={
        "mpi": {
            "enabled": True, "processes_per_host": 8
        },
        "instance_groups": [instance_group_2]
    }
)

## TensorFlow

from sagemaker.tensorflow import TensorFlow

estimator = TensorFlow(
    ...
    instance_groups=[instance_group_1, instance_group_2],
    distribution={
        "mpi": {
            "enabled": True, "processes_per_host": 8
        },
        "instance_groups": [instance_group_2]
    }
)

### With the SageMaker data parallel library

**PyTorch**

from sagemaker.pytorch import PyTorch

estimator = PyTorch(
    ...
    instance_groups=[instance_group_1, instance_group_2],
    distribution={
        "smdistributed": {
            "dataparallel": {
                "enabled": True
            },
            "instance_groups": [instance_group_2]
        }
    }
)

**TensorFlow**

from sagemaker.tensorflow import TensorFlow

estimator = TensorFlow(
    ...
    instance_groups=[instance_group_1, instance_group_2],
    distribution={
        "smdistributed": {
            "dataparallel": {
                "enabled": True
            },
            "instance_groups": [instance_group_2]
        }
    }
)
Modify Your Training Script to Assign Instance Groups

With the heterogeneous cluster configuration in the previous sections, you have prepared the SageMaker training environment and instances for your training job. To further assign the instance groups to certain training and data processing tasks, the next step is to modify your training script. By default, the training

```python
from sagemaker.pytorch import PyTorch

estimator = PyTorch(
    ...
    instance_groups=[instance_group_1, instance_group_2],
    distribution={
        "smdistributed": {
            "modelparallel": {
                "enabled": True,
                "parameters": {
                    ...  # SageMaker model parallel parameters
                }
            }
        },
        "instance_groups": [instance_group_2]
    }
)
```

```python
from sagemaker.tensorflow import TensorFlow

estimator = TensorFlow(
    ...
    instance_groups=[instance_group_1, instance_group_2],
    distribution={
        "smdistributed": {
            "modelparallel": {
                "enabled": True,
                "parameters": {
                    ...  # SageMaker model parallel parameters
                }
            }
        },
        "instance_groups": [instance_group_2]
    }
)
```

For more information about the SageMaker model parallel library, see SageMaker Model Parallel Training.

Modify Your Training Script to Assign Instance Groups

With the heterogeneous cluster configuration in the previous sections, you have prepared the SageMaker training environment and instances for your training job. To further assign the instance groups to certain training and data processing tasks, the next step is to modify your training script. By default, the training

```python
from sagemaker.pytorch import PyTorch

estimator = PyTorch(
    ...
    instance_groups=[instance_group_1, instance_group_2],
    distribution={
        "smdistributed": {
            "modelparallel": {
                "enabled": True,
                "parameters": {
                    ...  # SageMaker model parallel parameters
                }
            }
        },
        "instance_groups": [instance_group_2]
    }
)
```

```python
from sagemaker.tensorflow import TensorFlow

estimator = TensorFlow(
    ...
    instance_groups=[instance_group_1, instance_group_2],
    distribution={
        "smdistributed": {
            "modelparallel": {
                "enabled": True,
                "parameters": {
                    ...  # SageMaker model parallel parameters
                }
            }
        },
        "instance_groups": [instance_group_2]
    }
)
```

For more information about the SageMaker model parallel library, see SageMaker Model Parallel Training.
job simply makes training script replicas for all nodes regardless the size of the instance, and this might lead to performance loss.

For example, if you mix CPU instances and GPU instances in a heterogeneous cluster while passing a deep neural network training script to the `entry_point` argument of the SageMaker estimator, the `entry_point` script is replicated to each instance. This means that, without proper task assignments, CPU instances also run the entire script and start the training job that’s designed for distributed training on GPU instances. Therefore, you must make changes in specific processing functions that you want to offload and run on the CPU instances. You can use the SageMaker environment variables to retrieve the information of the heterogeneous cluster and let specific processes to run accordingly.

### Query instance group information during the initialization phase of a SageMaker training job

When your training job starts, your training script reads SageMaker training environment information that includes heterogeneous cluster configuration. The configuration contains information such as the current instance groups, the current hosts in each group, and in which group the current host resides.

You can retrieve instance group information in the following ways.

**(Recommended) Reading instance group information with the SageMaker training toolkit**

Use the environment Python module that the [SageMaker training toolkit library](https://github.com/aws/sagemaker-training-toolkit) provides. The toolkit library is preinstalled in the [SageMaker framework containers](https://github.com/aws/sagemaker-fpm) for TensorFlow and PyTorch, so you don’t need an additional installation step when using the prebuilt containers. This is the recommended way to retrieve the SageMaker environment variables with fewer code changes in your training script.

```python
from sagemaker_training import environment
env = environment.Environment()
```

Environment variables related to general SageMaker training and heterogeneous clusters:

- `env.is_hetero` – Returns a Boolean result whether a heterogeneous cluster is configured or not.
- `env.current_host` – Returns the current host.
- `env.current_instance_type` – Returns the type of instance of the current host.
- `env.current_instance_group` – Returns the name of the current instance group.
- `env.current_instance_group_hosts` – Returns a list of hosts in current instance group.
- `env.instance_groups` – Returns a list of instance group names used for training.
- `env.instance_groups_dict` – Returns the entire heterogeneous cluster configuration of the training job.
- `env.distribution_instance_groups` – Returns a list of instance groups assigned to the distribution parameter of the SageMaker estimator class.
- `env.distribution_hosts` – Returns a list of hosts belonging to the instance groups assigned to the distribution parameter of the SageMaker estimator class.

For example, consider the following example of a heterogeneous cluster that consists of two instance groups.

```python
from sagemaker.instance_group import InstanceGroup
instance_group_1 = InstanceGroup()
```
"instance_group_1", "ml.c5.18xlarge", 1)
instance_group_2 = InstanceGroup(
    "instance_group_2", "ml.p3dn.24xlarge", 2)

The output of env.instance_groups_dict of the example heterogeneous cluster should be similar to the following.

```json
{
    "instance_group_1": {
        "hosts": ["algo-2"],
        "instance_group_name": "instance_group_1",
        "instance_type": "ml.c5.18xlarge"
    },
    "instance_group_2": {
        "hosts": ["algo-3", "algo-1"],
        "instance_group_name": "instance_group_2",
        "instance_type": "ml.p3dn.24xlarge"
    }
}
```

(Optional) Reading instance group information from the resource configuration JSON file

If you prefer to retrieve the environment variables in JSON format, you can directly use the resource configuration JSON file. The JSON file in a SageMaker training instance is located at /opt/ml/input/config/resourceconfig.json by default.

```python
file_path = '/opt/ml/input/config/resourceconfig.json'
config = read_file_as_json(file_path)
print(json.dumps(config, indent=4, sort_keys=True))
```

Considerations

Consider the following items when using the heterogeneous cluster feature.

- All instance groups share the same Docker image and training script. Therefore, your training script should be modified to detect which instance group it belongs to and fork execution accordingly.
- The heterogeneous cluster feature is not supported in SageMaker local mode.
- The Amazon CloudWatch log streams of a heterogeneous cluster training job are not grouped by instance groups. You need to figure out from the logs which nodes are in which group.
- The heterogeneous cluster feature is available through the SageMaker PyTorch and TensorFlow framework estimator classes. Supported frameworks are PyTorch v1.10 or later and TensorFlow v2.6 or later. To find a complete list of available framework containers, framework versions, and Python versions, see SageMaker Framework Containers in the AWS Deep Learning Container GitHub repository.
- A distributed training strategy can be applied only to one instance group.

Examples, Blogs, and Case Studies

The following blog discusses case studies about using the SageMaker heterogeneous cluster training.
Use Incremental Training in Amazon SageMaker

Over time, you might find that a model generates inference that are not as good as they were in the past. With incremental training, you can use the artifacts from an existing model and use an expanded dataset to train a new model. Incremental training saves both time and resources.

Use incremental training to:

• Train a new model using an expanded dataset that contains an underlying pattern that was not accounted for in the previous training and which resulted in poor model performance.
• Use the model artifacts or a portion of the model artifacts from a popular publicly available model in a training job. You don’t need to train a new model from scratch.
• Resume a training job that was stopped.
• Train several variants of a model, either with different hyperparameter settings or using different datasets.

For more information about training jobs, see Train a Model with Amazon SageMaker (p. 1521).

You can train incrementally using the SageMaker console or the Amazon SageMaker Python SDK.

Important
Only three built-in algorithms currently support incremental training: Object Detection - MXNet (p. 1778), Image Classification - MXNet (p. 1754), and Semantic Segmentation Algorithm (p. 1797).

Topics
• Perform Incremental Training (Console) (p. 2301)
• Perform Incremental Training (API) (p. 2303)

Perform Incremental Training (Console)

To complete this procedure, you need:

• The Amazon Simple Storage Service (Amazon S3) bucket URI where you’ve stored the training data.
• The S3 bucket URI where you want to store the output of the job.
• The Amazon Elastic Container Registry path where the training code is stored. For more information, see Docker Registry Paths and Example Code.
• The URL of the S3 bucket where you’ve stored the model artifacts that you want to use in incremental training. To find the URL for the model artifacts, see the details page of the training job used to create the model. To find the details page, in the SageMaker console, choose Inference, choose Models, and then choose the model.

To restart a stopped training job, use the URL to the model artifacts that are stored in the details page as you would with a model or a completed training job.

To perform incremental training (console)

2. In the navigation pane, choose Training, then choose Training jobs.
3. Choose Create training job.
4. Provide a name for the training job. The name must be unique within an AWS Region in an AWS account. The training job name must have 1 to 63 characters. Valid characters: a-z, A-Z, 0-9, and . : + = @ _ % - (hyphen).
5. Choose the algorithm that you want to use. For information about algorithms, see Use Amazon SageMaker Built-in Algorithms or Pre-trained Models (p. 1528).
6. (Optional) For Resource configuration, either leave the default values or increase the resource consumption to reduce computation time.
   a. (Optional) For Instance type, choose the ML compute instance type that you want to use. In most cases, ml.m4.xlarge is sufficient.
   b. For Instance count, use the default, 1.
   c. (Optional) For Additional volume per instance (GB), choose the size of the ML storage volume that you want to provision. In most cases, you can use the default, 1. If you are using a large dataset, use a larger size.
7. Provide information about the input data for the training dataset.
   a. For Channel name, either leave the default (train) or enter a more meaningful name for the training dataset, such as expanded-training-dataset.
   b. For InputMode, choose File. For incremental training, you need to use file input mode.
   c. For S3 data distribution type, choose FullyReplicated. This causes each ML compute instance to use a full replicate of the expanded dataset when training incrementally.
   d. If the expanded dataset is uncompressed, set the Compression type to None. If the expanded dataset is compressed using Gzip, set it to Gzip.
   e. (Optional) If you are using File input mode, leave Content type empty. For Pipe input mode, specify the appropriate MIME type. Content type is the multipurpose internet mail extension (MIME) type of the data.
   f. For Record wrapper, if the dataset is saved in RecordIO format, choose RecordIO. If your dataset is not saved as a RecordIO formatted file, choose None.
   g. For S3 data type, if the dataset is stored as a single file, choose S3Prefix. If the dataset is stored as several files in a folder, choose Manifest.
   h. For S3 location, provide the URL to the path where you stored the expanded dataset.
   i. Choose Done.
8. To use model artifacts in a training job, you need to add a new channel and provide the needed information about the model artifacts.
   a. For Input data configuration, choose Add channel.
   b. For Channel name, enter model to identify this channel as the source of the model artifacts.
   c. For InputMode, choose File. Model artifacts are stored as files.
   d. For S3 data distribution type, choose FullyReplicated. This indicates that each ML compute instance should use all of the model artifacts for training.
   e. Leave Compression type empty because we are using a model for the channel.
   f. Leave Content type empty. Content type is the multipurpose internet mail extension (MIME) type of the data. For model artifacts, we leave it empty.
   g. Set Record wrapper to None because model artifacts are not stored in RecordIO format.
   h. For S3 data type, if you are using a built-in algorithm or an algorithm that stores the model as a single file, choose S3Prefix. If you are using an algorithm that stores the model as several files, choose Manifest.
   i. For S3 location, provide the URL to the path where you stored the model artifacts. Typically, the model is stored with the name model.tar.gz. To find the URL for the model artifacts, in
the navigation pane, choose **Inference**, then choose **Models**. From the list of models, choose a model to display its details page. The URL for the model artifacts is listed under **Primary container**.

j. Choose **Done**.

9. For **Output data configuration**, provide the following information:

a. For **S3 location**, type the path to the S3 bucket where you want to store the output data.

b. (Optional) For **Encryption key**, you can add your AWS Key Management Service (AWS KMS) encryption key to encrypt the output data at rest. Provide the key ID or its Amazon Resource Number (ARN). For more information, see [KMS-Managed Encryption Keys](#).

10. (Optional) For **Tags**, add one or more tags to the training job. A **tag** is metadata that you can define and assign to AWS resources. In this case, you can use tags to help you manage your training jobs. A tag consists of a key and a value, which you define. For example, you might want to create a tag with **Project** as a key and a value referring to a project that is related to the training job, such as **Home value forecasts**.

11. Choose **Create training job**. SageMaker creates and runs training job.

After the training job has completed, the newly trained model artifacts are stored under the **S3 output path** that you provided in the **Output data configuration** field. To deploy the model to get predictions, see [Step 5: Deploy the Model to Amazon EC2](p. 310).

### Perform Incremental Training (API)

This example shows how to use SageMaker APIs to train a model using the SageMaker image classification algorithm and the Caltech 256 Image Dataset, then train a new model using the first one. It uses Amazon S3 for input and output sources. Please see the [incremental training sample notebook](#) for more details on using incremental training.

**Note**

In this example we used the original datasets in the incremental training, however you can use different datasets, such as ones that contain newly added samples. Upload the new datasets to S3 and make adjustments to the `data_channels` variable used to train the new model.

Get an AWS Identity and Access Management (IAM) role that grants required permissions and initialize environment variables:

```python
import sagemaker
from sagemaker import get_execution_role

role = get_execution_role()
print(role)

sess = sagemaker.Session()

bucket = sess.default_bucket()
print(bucket)

prefix = 'ic-incr-training'
```

Get the training image for the image classification algorithm:

```python
from sagemaker.amazon.amazon_estimator import get_image_uri

training_image = get_image_uri(sess.boto_region_name, 'image-classification', repo_version="latest")

# Display the training image
print(training_image)
```
Download the training and validation datasets, then upload them to Amazon Simple Storage Service (Amazon S3):

```python
import os
import urllib.request
import boto3

# Define a download function
def download(url):
    filename = url.split('/')[-1]
    if not os.path.exists(filename):
        urllib.request.urlretrieve(url, filename)

# Download the caltech-256 training and validation datasets
download('http://data.mxnet.io/data/caltech-256/caltech-256-60-train.rec')
download('http://data.mxnet.io/data/caltech-256/caltech-256-60-val.rec')

# Create four channels: train, validation, train_lst, and validation_lst
s3train = 's3://{}/{}train/'.format(bucket, prefix)
s3validation = 's3://{}/{}validation/'.format(bucket, prefix)

# Upload the first files to the train and validation channels
!aws s3 cp caltech-256-60-train.rec $s3train --quiet
!aws s3 cp caltech-256-60-val.rec $s3validation --quiet
```

Define the training hyperparameters:

```python
# Define hyperparameters for the estimator
hyperparams = {
    "num_layers": "18",
    "resize": "32",
    "num_training_samples": "50000",
    "num_classes": "10",
    "image_shape": "3,28,28",
    "mini_batch_size": "128",
    "epochs": "3",
    "learning_rate": "0.1",
    "lr_scheduler_step": "2,3",
    "lr_scheduler_factor": "0.1",
    "augmentation_type": "crop_color",
    "optimizer": "sgd",
    "momentum": "0.9",
    "weight_decay": "0.0001",
    "beta_1": "0.9",
    "beta_2": "0.999",
    "gamma": "0.9",
    "eps": "1e-8",
    "top_k": "5",
    "checkpoint_frequency": "1",
    "use_pretrained_model": "0",
    "model_prefix": ""}
```

Create an estimator object and train the first model using the training and validation datasets:

```python
# Fit the base estimator
s3_output_location = 's3://{}/{}output'.format(bucket, prefix)
ic = sagemaker.estimator.Estimator(training_image,
    role,
    instance_count=1,
    instance_type='ml.p2.xlarge',
    volume_size=50,
    max_run=360000,
    input_mode='File',
)```
To use the model to incrementally train another model, create a new estimator object and use the model artifacts (ic.model_data, in this example) for the model_uri input argument:

```python
# Given the base estimator, create a new one for incremental training
incr_ic = sagemaker.estimator.Estimator(training_image,
    role,
    instance_count=1,
    instance_type='ml.p2.xlarge',
    volume_size=50,
    max_run=360000,
    input_mode='File',
    output_path=s3_output_location,
    sagemaker_session=sess,
    hyperparameters=hyperparams,
    model_uri=ic.model_data)  # This parameter will
ingest the previous job's model as a new channel
incr_ic.fit(inputs=data_channels, logs=True)
```

After the training job has completed, the newly trained model artifacts are stored under the S3 output path that you provided in `Output_path`. To deploy the model to get predictions, see Step 5: Deploy the Model to Amazon EC2 (p. 310).

## Use Managed Spot Training in Amazon SageMaker

Amazon SageMaker makes it easy to train machine learning models using managed Amazon EC2 Spot instances. Managed spot training can optimize the cost of training models up to 90% over on-demand instances. SageMaker manages the Spot interruptions on your behalf.

Managed Spot Training uses Amazon EC2 Spot instance to run training jobs instead of on-demand instances. You can specify which training jobs use spot instances and a stopping condition that specifies how long SageMaker waits for a job to run using Amazon EC2 Spot instances. Metrics and logs generated during training runs are available in CloudWatch.

Amazon SageMaker automatic model tuning, also known as hyperparameter tuning, can use managed spot training. For more information on automatic model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1863).

Spot instances can be interrupted, causing jobs to take longer to start or finish. You can configure your managed spot training job to use checkpoints. SageMaker copies checkpoint data from a local path to Amazon S3. When the job is restarted, SageMaker copies the data from Amazon S3 back into the local path. The training job can then resume from the last checkpoint instead of restarting. For more information about checkpointing, see Use Checkpoints in Amazon SageMaker (p. 2330).
Note
Unless your training job will complete quickly, we recommend you use checkpointing with managed spot training. SageMaker built-in algorithms and marketplace algorithms that do not checkpoint are currently limited to a MaxWaitTimeInSeconds of 3600 seconds (60 minutes).

Topics
- Using Managed Spot Training (p. 2306)
- Managed Spot Training Lifecycle (p. 2306)

Using Managed Spot Training

To use managed spot training, create a training job. Set `EnableManagedSpotTraining` to `True` and specify the `MaxWaitTimeInSeconds`. `MaxWaitTimeInSeconds` must be larger than `MaxRuntimeInSeconds`. For more information about creating a training job, see `DescribeTrainingJob`.

You can calculate the savings from using managed spot training using the formula 

\[
(1 - \frac{\text{BillableTimeInSeconds}}{\text{TrainingTimeInSeconds}}) \times 100
\]

For example, if `BillableTimeInSeconds` is 100 and `TrainingTimeInSeconds` is 500, this means that your training job ran for 500 seconds, but you were billed for only 100 seconds. Your savings is \((1 - (100 / 500)) \times 100 = 80\%\).

To learn how to run training jobs on Amazon SageMaker spot instances and how managed spot training works and reduces the billable time, see the following example notebooks:

- Managed Spot Training with TensorFlow
- Managed Spot Training with XGBoost
- Managed Spot Training with MXNet
- Amazon SageMaker Managed Spot Training Examples GitHub repository

Managed Spot Training Lifecycle

You can monitor a training job using `TrainingJobStatus` and `SecondaryStatus` returned by `DescribeTrainingJob`. The list below shows how `TrainingJobStatus` and `SecondaryStatus` values change depending on the training scenario:

- **Spot instances acquired with no interruption during training**
  1. InProgress: Starting → Downloading → Training → Uploading

- **Spot instances interrupted once. Later, enough spot instances were acquired to finish the training job.**
  1. InProgress: Starting → Downloading → Training → Interrupted → Starting → Downloading → Training → Uploading

- **Spot instances interrupted twice and MaxWaitTimeInSeconds exceeded.**
  1. InProgress: Starting → Downloading → Training → Interrupted → Starting → Downloading → Training → Interrupted → Downloading → Training
  2. Stopping: Stopping
  3. Stopped: MaxWaitTimeExceeded

- **Spot instances were never launched.**
  1. InProgress: Starting
  2. Stopping: Stopping
  3. Stopped: MaxWaitTimeExceeded
Train Using SageMaker Managed Warm Pools

SageMaker managed warm pools let you retain and reuse provisioned infrastructure after the completion of a training job to reduce latency for repetitive workloads, such as iterative experimentation or running many jobs consecutively. Subsequent training jobs that match specified parameters run on the retained warm pool infrastructure, which speeds up start times by reducing the time spent provisioning resources.

**Important**
SageMaker managed warm pools are a billable resource. For more information, see [Billing](p. 2310).

**Topics**
- How it works (p. 2307)
- Warm pool resource limits (p. 2310)
- How to use SageMaker managed warm pools (p. 2311)
- Considerations (p. 2315)

**How it works**

To use SageMaker managed warm pools and reduce latency between similar consecutive training jobs, create a training job that specifies a `KeepAlivePeriodInSeconds` value in its `ResourceConfig`. This value represents the duration of time in seconds to retain configured resources in a warm pool for subsequent training jobs. If you need to run several training jobs using similar configurations, you can further reduce latency and billable time by using a dedicated persistent cache directory to store and re-use your information in a different job.

**Topics**
- Warm pool lifecycle (p. 2307)
- Warm pool creation (p. 2308)
- Matching training jobs (p. 2308)
- Maximum warm pool duration (p. 2308)
- Using persistent cache (p. 2309)
- Billing (p. 2310)

**Warm pool lifecycle**

1. Create an initial training job with a `KeepAlivePeriodInSeconds` value greater than 0. When you run this first training job, this “cold-starts” a cluster with typical startup times.

2. When the first training job completes, the provisioned resources are kept alive in a warm pool for the period specified in the `KeepAlivePeriodInSeconds` value. As long as the cluster is healthy and the warm pool is within the specified `KeepAlivePeriodInSeconds`, then the warm pool status is `Available`.

3. The warm pool stays `Available` until it either identifies a matching training job for reuse or it exceeds the specified `KeepAlivePeriodInSeconds` and is terminated. The maximum length of time allowed for the `KeepAlivePeriodInSeconds` is 3600 seconds (60 minutes). If the warm pool status is `Terminated`, then this is the end of the warm pool lifecycle.

4. If the warm pool identifies a second training job with matching specifications such as instance count or instance type, then the warm pool moves from the first training job to the second training job for reuse. The status of the first training job warm pool becomes `Reused`. This is the end of the warm pool lifecycle for the first training job.
5. The status of the second training job that reused the warm pool becomes InUse. After the second training job completes, the warm pool is Available for the KeepAlivePeriodInSeconds duration specified in the second training job. A warm pool can continue moving to subsequent matching training jobs for a maximum of 28 days.

6. If the warm pool is no longer available to reuse, the warm pool status is Terminated. Warm pools are no longer available if they are terminated by a user, for a patch update, or for exceeding the specified KeepAlivePeriodInSeconds.

For more information on warm pool status options, see `WarmPoolStatus` in the Amazon SageMaker API Reference.

**Warm pool creation**

If an initial training job successfully completes and has a KeepAlivePeriodInSeconds value greater than 0, this creates a warm pool. If you stop a training job after a cluster is already launched, a warm pool is still retained. If the training job fails due to an algorithm or client error, a warm pool is still retained. If the training job fails for any other reason that might compromise the health of the cluster, then the warm pool is not created.

To verify successful warm pool creation, check the warm pool status of your training job. If a warm pool successfully provisions, the warm pool status is Available. If a warm pool fails to provision, the warm pool status is Terminated.

**Matching training jobs**

For a warm pool to persist, it must find a matching training job within the time specified in the KeepAlivePeriodInSeconds value. The next training job is a match if the following values are identical:

- RoleArn
- ResourceConfig values:
  - InstanceCount
  - InstanceType
  - VolumeKmsKeyId
  - VolumeSizeInGB
  - VpcConfig values:
    - SecurityGroupIds
    - Subnets
    - EnableInterContainerTrafficEncryption
    - EnableNetworkIsolation

All of these values must be the same for a warm pool to move to a subsequent training job for reuse.

**Maximum warm pool duration**

The maximum KeepAlivePeriodInSeconds for a single training job is 3600 seconds (60 minutes) and the maximum length of time that a warm pool cluster can continue running consecutive training jobs is 28 days.

Each subsequent training job must also specify a KeepAlivePeriodInSeconds value. When the warm pool moves to the next training job, it inherits the new KeepAlivePeriodInSeconds value specified in that training job's ResourceConfig. In this way, you can keep a warm pool moving from training job to training job for a maximum of 28 days.
If no `KeepAlivePeriodInSeconds` is specified, then the warm pool spins down after the training job completes.

**Using persistent cache**

When you create a warm pool, SageMaker mounts a special directory on the volume that will persist throughout the lifecycle of the warm pool. This directory can also be used to store information that you want to re-use in another job.

Using persistent cache can reduce latency and billable time over using warm pools alone for jobs that require the following:

- multiple interactions with similar configurations
- incremental training jobs
- hyperparameter optimization

For example, you can avoid downloading the same Python dependencies on repeated runs by setting up a pip cache directory inside the persistent cache directory. You are fully responsible for managing the contents of this directory. The following are examples of types of information that you can put in your persistent cache to help reduce your latency and billable time.

- Dependencies managed by pip.
- Dependencies managed by conda.
- **Checkpoint information.**
- Any additional information generated during training.

The location of the persistent cache is `/opt/ml/sagemaker/warmpoolcache`. The environment variable `SAGEMAKER_MANAGED_WARMPOOL_CACHE_DIRECTORY` points to the location of the persistent cache directory.

The following code example shows you how to set up a warm pool and use persistent cache to store your pip dependencies for use in a subsequent job. The subsequent job must run within the time frame given by the parameter `keep_alive_period_in_seconds`.

```python
import sagemaker
from sagemaker import get_execution_role
from sagemaker.tensorflow import TensorFlow

# Creates a SageMaker session and gets execution role
session = sagemaker.Session()
role = get_execution_role()

# Creates an example estimator
estimator = TensorFlow(
    entry_point='my-training-script.py',
    source_dir='code',
    role=role,
    model_dir='model_dir',
    framework_version='2.2',
    py_version='py37',
    job_name='my-training-job-1',
    instance_type='ml.g4dn.xlarge',
    instance_count=1,
    volume_size=250,
    hyperparameters={
        "batch-size": 512,
        "epochs": 1,
        "learning-rate": 1e-3,
        "beta_1": 0.9,
        "beta_2": 0.999,
```
import os
import shutil
if __name__ == '__main__':
    PERSISTED_DIR = os.environ['SAGEMAKER_MANAGED_WARMPOOL_CACHE_DIRECTORY']
    # create a file to be persisted
    open(os.path.join(PERSISTED_DIR, "test.txt"), 'a').close()
    # create a directory to be persisted
    os.mkdir(os.path.join(PERSISTED_DIR, "test_dir"))
    # Move a file to be persisted
    shutil.move("path/of/your/file.txt", PERSISTED_DIR)
1. Open the [AWS Service Quotas console](https://console.aws.amazon.com/servicequotas/home).
2. On the left-hand navigation panel, choose **AWS services**.
3. Search for and choose **Amazon SageMaker**.
4. Search for the keyword **warm pool** to see all available warm pool service quotas.
5. Find the instance type for which you want to increase your warm pool quota, select the warm pool service quota for that instance type, and choose **Request quota increase**.
6. Enter your requested instance limit number under **Change quota value**. The new value must be greater than the current **Applied quota value**.
7. Choose **Request**.

There is a limit on the number of instances that you can retain for each account, which is determined by instance type. You can check your resource limits in the [AWS Service Quotas console](https://console.aws.amazon.com/servicequotas/home) or directly using the `list-service-quotas` AWS CLI command. For more information on AWS Service Quotas, see [Requesting a quota increase](https://docs.aws.amazon.com/service-quotas/latest/userguide/service-quotas-request-assign.html) in the **Service Quotas User Guide**.

You can also use [AWS Support Center](https://console.aws.amazon.com/support/home) to request a warm pool quota increase. For a list of available instance types according to Region, see [Amazon SageMaker Pricing](https://aws.amazon.com/sagemaker-pricing/) and choose **Training** in the **On-Demand Pricing** table.

### How to use SageMaker managed warm pools

You can use SageMaker managed warm pools through the SageMaker Python SDK, the Amazon SageMaker console, or through the low-level APIs. Administrators can optionally use the `sagemaker:KeepAlivePeriod` condition key to further restrict the `KeepAlivePeriodInSeconds` limits for certain users or groups.

**Topics**
- [Using the SageMaker Python SDK](https://docs.aws.amazon.com/sagemaker/latest/dg/how-to-managed-warm-pool-sdk.html) (p. 2311)

### Using the SageMaker Python SDK

Create, update, or terminate warm pools using the SageMaker Python SDK.

**Note**
This feature is available in the SageMaker Python SDK v2.110.0 and later.

**Topics**
- [Create a warm pool](https://docs.aws.amazon.com/sagemaker/latest/dg/how-to-managed-warm-pool-sdk.html) (p. 2311)
- [Update a warm pool](https://docs.aws.amazon.com/sagemaker/latest/dg/how-to-managed-warm-pool-sdk.html) (p. 2313)
- [Terminate a warm pool](https://docs.aws.amazon.com/sagemaker/latest/dg/how-to-managed-warm-pool-sdk.html) (p. 2313)

### Create a warm pool

To create a warm pool, use the SageMaker Python SDK to create an estimator with a `keep_alive_period_in_seconds` value greater than 0 and call `fit()`. When the training job completes, a warm pool is retained. For more information on training scripts and estimators, see [Train a Model with the SageMaker Python SDK](https://docs.aws.amazon.com/sagemaker/latest/dg/how-to-managed-warm-pool-sdk.html). If your script does not create a warm pool, see [Warm pool creation](https://docs.aws.amazon.com/sagemaker/latest/dg/how-to-managed-warm-pool-sdk.html) for possible explanations.
import sagemaker
from sagemaker import get_execution_role
from sagemaker.tensorflow import TensorFlow

# Creates a SageMaker session and gets execution role
session = sagemaker.Session()
role = get_execution_role()

# Creates an example estimator
estimator = TensorFlow(
    ...,
    entry_point='my-training-script.py',
    source_dir='code',
    role=role,
    model_dir='model_dir',
    framework_version='2.2',
    py_version='py37',
    job_name='my-training-job-1',
    instance_type='ml.g4dn.xlarge',
    instance_count=1,
    volume_size=250,
    hyperparameters={
        "batch-size": 512,
        "epochs": 1,
        "learning-rate": 1e-3,
        "beta_1": 0.9,
        "beta_2": 0.999,
        },
    keep_alive_period_in_seconds=1800,
    )

# Starts a SageMaker training job and waits until completion
estimator.fit('s3://my_bucket/my_training_data/)

Next, create a second matching training job. In this example, we create `my-training-job-2`, which has all of the necessary attributes to match with `my-training-job-1`, but has a different hyperparameter for experimentation. The second training job reuses the warm pool and starts up faster than the first training job. The following code example uses a Tensorflow estimator. The warm pool feature can be used with any training algorithm that runs on Amazon SageMaker. For more information on which attributes need to match, see Matching training jobs (p. 2308).

# Creates an example estimator
estimator = TensorFlow(
    ...,
    entry_point='my-training-script.py',
    source_dir='code',
    role=role,
    model_dir='model_dir',
    framework_version='py37',
    py_version='py37',
    job_name='my-training-job-2',
    instance_type='ml.g4dn.xlarge',
    instance_count=1,
    volume_size=250,
    hyperparameters={
        "batch-size": 512,
        "epochs": 2,
        "learning-rate": 1e-3,
        "beta_1": 0.9,
        "beta_2": 0.999,
        },
    keep_alive_period_in_seconds=1800,
    )
Amazon SageMaker Developer Guide
How to use SageMaker managed warm pools

# Starts a SageMaker training job and waits until completion
estimator.fit('s3://my_bucket/my_training_data/')

Check the warm pool status of both training jobs to conﬁrm that the warm pool is Reused for mytraining-job-1 and InUse for my-training-job-2.

Note

Training job names have date/time suﬃxes. The example training job names my-trainingjob-1 and my-training-job-2 should be replaced with actual training job names. You can
use the estimator.latest_training_job.job_name command to fetch the actual training
job name.
session.describe_training_job('my-training-job-1')
session.describe_training_job('my-training-job-2')

The result of describe_training_job provides all details about a given training job. Find the
WarmPoolStatus attribute to check information about a training job’s warm pool. Your output should
look similar to the following example:
# Warm pool status for training-job-1
...
'WarmPoolStatus': {'Status': 'Reused',
'ResourceRetainedBillableTimeInSeconds': 1000,
'ReusedByName': my-training-job-2}
...
# Warm pool status for training-job-2
...
'WarmPoolStatus': {'Status': 'InUse'}
...

Update a warm pool
When the training job is complete and the warm pool status is Available, then you can update the
KeepAlivePeriodInSeconds value.
session.update_training_job(job_name, resource_config={"KeepAlivePeriodInSeconds":3600})

Terminate a warm pool
To manually terminate a warm pool, set the KeepAlivePeriodInSeconds value to 0.
session.update_training_job(job_name, resource_config={"KeepAlivePeriodInSeconds":0})

The warm pool automatically terminates when it exceeds the designated KeepAlivePeriodInSeconds
value or if there is a patch update for the cluster.

Using the Amazon SageMaker console
Through the console, you can create a warm pool, release a warm pool, or check the warm pool status
and billable time of speciﬁc training jobs. You can also see which matching training job reused a warm
pool.
1.

Open the Amazon SageMaker console and choose Training jobs from the navigation pane. If
applicable, the warm pool status of each training job is visible in the Warm pool status column and
the time left for an active warm pool is visible in the Time left column.

2313


2. To create a training job that uses a warm pool from the console, choose **Create training job**. Then, be sure to specify a value for the **Keep alive period** field when configuring your training job resources. This value must be an integer between 1 and 3600, which represents duration of time in seconds.

3. To release a warm pool from the console, select a specific training job and choose **Release cluster** from the **Actions** dropdown menu.

4. To see more information about a warm pool, choose a training job name. In the job details page, scroll down to the **Warm pool status** section to find the warm pool status, the time left if the warm pool status is **Available**, the warm pool billable seconds, and the name of the training job that reused the warm pool if the warm pool status is **Reused**.

**Using the low-level SageMaker APIs**

Use SageMaker managed warm pools with either the SageMaker API or the AWS CLI.

**SageMaker API**

Set up SageMaker managed warm pools using the SageMaker API with the following commands:

- CreateTrainingJob
- UpdateTrainingJob
- ListTrainingJobs
- DescribeTrainingJob

**AWS CLI**

Set up SageMaker managed warm pools using the AWS CLI with the following commands:

- create-training-job
- update-training-job
- list-training-jobs
- describe-training-job

**IAM condition key**

Administrators can optionally use the `sagemaker:KeepAlivePeriod` condition key to further restrict the `KeepAlivePeriodInSeconds` limits for certain users or groups. SageMaker managed warm pools are limited to a `KeepAlivePeriodInSeconds` value of 3600 seconds (60 minutes), but administrators can lower this limit if needed.

```json
{
    "Version": "2012-10-17",
    "Statement": [
    {
       "Sid": "EnforceKeepAlivePeriodLimit",
       "Effect": "Allow",
       "Action": [
       "sagemaker:CreateTrainingJob"
       ],
       "Resource": "*",
       "Condition": {
       "NumericLessThanIfExists": {
       2314
       }
       }
    }
    ]
}
```
"sagemaker:KeepAlivePeriod": 1800
}
]
}
]
}
]
}

For more information, see Condition keys for Amazon SageMaker in the Service Authorization Reference.

Considerations

Consider the following items when using SageMaker managed warm pools.

• SageMaker managed warm pools cannot be used with heterogeneous cluster training.
• SageMaker managed warm pools cannot be used with spot instances.
• SageMaker managed warm pools are limited to a KeepAlivePeriodInSeconds value of 3600 seconds (60 minutes).
• If a warm pool continues to successfully match training jobs within the specified KeepAlivePeriodInSeconds value, the cluster can only continue running for a maximum of 28 days.

Monitor and Analyze Training Jobs Using Amazon CloudWatch Metrics

An Amazon SageMaker training job is an iterative process that teaches a model to make predictions by presenting examples from a training dataset. Typically, a training algorithm computes several metrics, such as training error and prediction accuracy. These metrics help diagnose whether the model is learning well and will generalize well for making predictions on unseen data. The training algorithm writes the values of these metrics to logs, which SageMaker monitors and sends to Amazon CloudWatch in real time. To analyze the performance of your training job, you can view graphs of these metrics in CloudWatch. When a training job has completed, you can also get a list of the metric values that it computes in its final iteration by calling the DescribeTrainingJob operation.

Note
Amazon CloudWatch supports high-resolution custom metrics, and its finest resolution is 1 second. However, the finer the resolution, the shorter the lifespan of the CloudWatch metrics. For the 1-second frequency resolution, the CloudWatch metrics are available for 3 hours. For more information about the resolution and the lifespan of the CloudWatch metrics, see GetMetricStatistics in the Amazon CloudWatch API Reference.

Tip
If you want to profile your training job with a finer resolution down to 100-millisecond (0.1 second) granularity and store the training metrics indefinitely in Amazon S3 for custom analysis at any time, consider using Amazon SageMaker Debugger. SageMaker Debugger provides built-in rules to automatically detect common training issues; it detects hardware resource utilization issues (such as CPU, GPU, and I/O bottlenecks) and non-converging model issues (such as overfit, vanishing gradients, and exploding tensors). SageMaker Debugger also provides visualizations through Studio and its profiling report. To explore the Debugger visualizations, see SageMaker Debugger Insights Dashboard Walkthrough, Debugger Profiling Report Walkthrough, and Analyze Data Using the SMDebug Client Library.

Topics

• Defining Training Metrics (p. 2316)
Defining Training Metrics

SageMaker automatically parses training job logs and sends training metrics to CloudWatch. By default, SageMaker sends system resource utilization metrics listed in SageMaker Jobs and Endpoint Metrics. If you want SageMaker to parse logs and send custom metrics from a training job of your own algorithm to CloudWatch, you need to specify metrics definitions by passing the name of metrics and regular expressions when you configure a SageMaker training job request.

You can specify the metrics that you want to track using the SageMaker console, the SageMaker Python SDK, or the low-level SageMaker API.

If you are using your own algorithm, do the following:

- Make sure that the algorithm writes the metrics that you want to capture to logs.
- Define a regular expression that accurately searches the logs to capture the values of the metrics that you want to send to CloudWatch.

For example, suppose your algorithm emits the following metrics for training error and validation error:

```
Train_error=0.138318; Valid_error=0.324557;
```

If you want to monitor both of those metrics in CloudWatch, the dictionary for the metric definitions should look like the following example:

```
[
  {
    "Name": "train:error",
    "Regex": "Train_error=(.*?);"
  },
  {
    "Name": "validation:error",
    "Regex": "Valid_error=(.*?);"
  }
]
```

In the regex for the train:error metric defined in the preceding example, the first part of the regex finds the exact text "Train_error=", and the expression (.*?); captures any characters until the first semicolon character appears. In this expression, the parenthesis tell the regex to capture what is inside them, . means any character, * means zero or more, and ? means capture only until the first instance of the ; character.

Define Metrics Using the SageMaker Python SDK

Define the metrics that you want to send to CloudWatch by specifying a list of metric names and regular expressions as the metric_definitions argument when you initialize an Estimator object. For example, if you want to monitor both the train:error and validation:error metrics in CloudWatch, your Estimator initialization would look like the following example:

```
import sagemaker
```

```
from sagemaker.estimator import Estimator

estimator = Estimator(
    image_uri="your-own-image-uri",
    role=sagemaker.get_execution_role(),
    sagemaker_session=sagemaker.Session(),
    instance_count=1,
    instance_type='ml.c4.xlarge',
    metric_definitions=[
        {'Name': 'train:error', 'Regex': 'Train_error=(.*?);'},
        {'Name': 'validation:error', 'Regex': 'Valid_error=(.*?);'}
    ]
)

For more information about training by using Amazon SageMaker Python SDK estimators, see Sagemaker Python SDK on GitHub.

Define Metrics Using the SageMaker Console

If you choose the Your own algorithm container in ECR option as your algorithm source in the SageMaker console when you create a training job, add the metric definitions in the Metrics section. The following screenshot shows how it should look after you add the example metric names and the corresponding regular expressions.

Algorithm options
Use an Amazon SageMaker built-in algorithm, your own algorithm, or a third-party algorithm from AWS Marketplace.

- Amazon SageMaker built-in algorithm
- Your own algorithm resource
- Your own algorithm container in ECR
- An algorithm subscription from AWS Marketplace

Provide container ECR path

The registry path where the training image is stored in Amazon ECR.

Input mode
You can provide your training data as a file or pipe.

File

Metrics
Define the metrics you want to emit to CloudWatch metrics.

Metric name | Regex
---|---
train:error | Train_error=(.*?);
validation:error | Valid_error=(.*?);

Add metric

Define Metrics Using the Low-level SageMaker API

Define the metrics that you want to send to CloudWatch by specifying a list of metric names and regular expressions in the MetricDefinitions field of the AlgorithmSpecification input parameter.
that you pass to the `CreateTrainingJob` operation. For example, if you want to monitor both the `train:error` and `validation:error` metrics in CloudWatch, your `AlgorithmSpecification` would look like the following example:

```
"AlgorithmSpecification": {
   "TrainingImage": "your-own-image-uri",
   "TrainingInputMode": "File",
   "MetricDefinitions": [
      {
         "Name": "train:error",
         "Regex": "Train_error=(.*?);"
      },
      {
         "Name": "validation:error",
         "Regex": "Valid_error=(.*?);"
      }
   ]
}
```

For more information about defining and running a training job by using the low-level SageMaker API, see `CreateTrainingJob`.

**Monitoring Training Job Metrics (CloudWatch Console)**

You can monitor the metrics that a training job emits in real time in the CloudWatch console.

**To monitor training job metrics (CloudWatch console)**

2. Choose `Metrics`, then choose `/aws/sagemaker/TrainingJobs`.
3. Choose `TrainingJobName`.
4. On the `All metrics` tab, choose the names of the training metrics that you want to monitor.
5. On the `Graphed metrics` tab, configure the graph options. For more information about using CloudWatch graphs, see `Graph Metrics` in the `Amazon CloudWatch User Guide`.

**Monitoring Training Job Metrics (SageMaker Console)**

You can monitor the metrics that a training job emits in real time by using the SageMaker console.

**To monitor training job metrics (SageMaker console)**

2. Choose `Training jobs`, then choose the training job whose metrics you want to see.
3. Choose `TrainingJobName`.
4. In the `Monitor` section, you can review the graphs of instance utilization and algorithm metrics.
Example: Viewing a Training and Validation Curve

Typically, you split the data on which you train your model into training and validation datasets. You use the training set to train the model parameters that are used to make predictions on the training dataset. Then you test how well the model makes predictions by calculating predictions for the validation set. To analyze the performance of a training job, you commonly plot a training curve against a validation curve.

Viewing a graph that shows the accuracy for both the training and validation sets over time can help you to improve the performance of your model. For example, if training accuracy continues to increase over time, but, at some point, validation accuracy starts to decrease, you are likely overfitting your model. To address this, you can make adjustments to your model, such as increasing regularization.

For this example, you can use the Image-classification-full-training example in the Example notebooks section of your SageMaker notebook instance. If you don't have a SageMaker notebook instance, create one by following the instructions at Step 1: Create an Amazon SageMaker Notebook Instance (p. 299). If you prefer, you can follow along with the End-to-End Multiclass Image Classification Example in the example notebook on GitHub. You also need an Amazon S3 bucket to store the training data and for the model output.

To view training and validation error curves

2. Choose Notebooks, and then choose Notebook instances.
3. Choose the notebook instance that you want to use, and then choose Open.
4. On the dashboard for your notebook instance, choose SageMaker Examples.
5. Expand the Introduction to Amazon Algorithms section, and then choose Use next to Image-classification-fulltraining.ipynb.
7. Run all of the cells in the notebook up to the Inference section. You don't need to deploy an endpoint or get inference for this example.
8. After the training job starts, open the CloudWatch console at https://console.aws.amazon.com/cloudwatch.
9. Choose Metrics, then choose /aws/sagemaker/TrainingJobs.
10. Choose TrainingJobName.
11. On the All metrics tab, choose the train:accuracy and validation:accuracy metrics for the training job that you created in the notebook.
12. On the graph, choose an area that the metric's values to zoom in. You should see something like the following example.
Use Amazon SageMaker Training Storage Paths for Training Datasets, Checkpoints, Model Artifacts, and Outputs

This page provides a high-level summary of how the SageMaker training platform manages storage paths for training datasets, model artifacts, checkpoints, and outputs between AWS cloud storage and training jobs in SageMaker. Throughout this guide, you learn to identify the default paths set by the SageMaker platform and how the data channels can be streamlined with your data sources in Amazon
Simple Storage Service (Amazon S3), FSx for Lustre, and Amazon EFS. For more information about various data channel input modes and storage options, see Access Training Data (p. 2284).

Topics

- Overview (p. 2322)
- Uncompressed model output (p. 2324)
- Tips and Considerations for Setting Up Storage Paths (p. 2324)
- SageMaker Environment Variables and Default Paths for Training Storage Locations (p. 2325)

Overview

The following diagram shows the simplest example of how SageMaker manages input and output paths when you run a training job using the SageMaker Python SDK Estimator class and its fit method. It's based on using file mode as the data access strategy and Amazon S3 as the data source for the training input channels.
s3://bucket-data1/
This figure shows an overview of how SageMaker pairs storage paths between an Amazon S3 bucket as the data source and the SageMaker training instance based on how the paths are specified in a SageMaker estimator class. More information about the paths, how they read from or write to the paths, and purposes of the paths are described in the following section the section called “SageMaker Environment Variables and Default Paths for Training Storage Locations” (p. 2325).

You can use OutputDataConfig in the CreateTrainingJob API to find where your S3 bucket is located. Use the ModelArtifacts API to find the S3 location that contains your model artifacts. See the abalone_build_train_deploy notebook for an example of output paths and how they are used in API calls.

For more information and examples of how SageMaker manages data source, input modes, and local paths in SageMaker training instances, see Access Training Data.

### Uncompressed model output

SageMaker stores your model in /opt/ml/model and your data in /opt/ml/output/data. After the model and data are written to those locations, they're uploaded to your Amazon S3 bucket as compressed files by default.

You can save time on large data file compression by uploading model and data outputs to your S3 bucket as uncompressed files. To do this, create a training job in uncompressed upload mode by using either the AWS Command Line Interface (AWS CLI) or the SageMaker Python SDK.

The following code example shows how to create a training job in uncompressed upload mode when using the AWS CLI. To enable uncompressed upload mode, set CompressionType field in the OutputDataConfig API to NONE.

```json
{
    "TrainingJobName": "uncompressed_model_upload",
    "OutputDataConfig": {
        "S3OutputPath": "s3://DOC-EXAMPLE-BUCKET/uncompressed_upload/output",
        "CompressionType": "NONE"
    }
}
```

The following code example shows you how to create a training job in uncompressed upload mode using the SageMaker Python SDK.

```python
import sagemaker
from sagemaker.estimator import Estimator

estimator = Estimator(
    image_uri="your-own-image-uri",
    role=sagemaker.get_execution_role(),
    sagemaker_session=sagemaker.Session(),
    instance_count=1,
    instance_type='ml.c4.xlarge',
    disable_output_compression=True
)
```

### Tips and Considerations for Setting Up Storage Paths

Consider the following items when setting up storage paths for training jobs in SageMaker.

- If you want to store training artifacts for distributed training in the /opt/ml/output/data directory, you must properly append subdirectories or use unique file names for the artifacts through your model definition or training script. If the subdirectories and file names are not properly configured, all
of the distributed training workers might write outputs to the same file name in the same output path in Amazon S3.

- If you use a custom training container, make sure you install the SageMaker Training Toolkit that helps set up the environment for SageMaker training jobs. Otherwise, you must specify the environment variables explicitly in your Dockerfile. For more information, see Create a container with your own algorithms and models.

- When using an ML instance with NVMe SSD volumes, SageMaker doesn’t provision Amazon EBS gp2 storage. Available storage is fixed to the NVMe-type instance's storage capacity. SageMaker configures storage paths for training datasets, checkpoints, model artifacts, and outputs to use the entire capacity of the instance storage. For example, ML instance families with the NVMe-type instance storage include ml.p4d, ml.g4dn, and ml.g5. When using an ML instance with the EBS-only storage option and without instance storage, you must define the size of EBS volume through the volume_size parameter in the SageMaker estimator class (or VolumeSizeInGB if you are using the ResourceConfig API). For example, ML instance families that use EBS volumes include ml.c5 and ml.p2. To look up instance types and their instance storage types and volumes, see Amazon EC2 Instance Types.

- The default paths for SageMaker training jobs are mounted to Amazon EBS volumes or NVMe SSD volumes of the ML instance. When you adapt your training script to SageMaker, make sure that you use the default paths listed in the previous topic about the section called “SageMaker Environment Variables and Default Paths for Training Storage Locations” (p. 2325). We recommend that you use the /tmp directory as a scratch space for temporarily storing any large objects during training. This means that you must not use directories that are mounted to small disk space allocated for system, such as /user and /home, to avoid out-of-space errors.

To learn more, see the AWS machine learning blog Choose the best data source for your Amazon SageMaker training job that further discusses case studies and performance benchmarks of data sources and input modes.

## SageMaker Environment Variables and Default Paths for Training Storage Locations

The following table summarizes input and output paths for training datasets, checkpoints, model artifacts, and outputs, managed by the SageMaker training platform.

<table>
<thead>
<tr>
<th>Local path in SageMaker training instance</th>
<th>SageMaker environment variable</th>
<th>Purpose</th>
<th>Read from S3 during start</th>
<th>Read from S3 during Spot-restart</th>
<th>Writes to S3 during training</th>
<th>Writes to S3 when job is terminated</th>
</tr>
</thead>
<tbody>
<tr>
<td>/opt/ml/input/data/channel_name$^1$</td>
<td>SM_CHANNEL$^1$</td>
<td>Reading training data from the input channels specified through the SageMaker Python SDK Estimator class or the CreateTrainingJob API operation. For more information about how to specify it in your training script using the SageMaker Python SDK, see Prepare a Training script.</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>
### Local path in SageMaker training instance | SageMaker environment variable | Purpose | Read from S3 during start | Read from S3 during Spot-restart | Writes to S3 during training | Writes to S3 when job is terminated
---|---|---|---|---|---|---
``/opt/ml/output/data`` | SM_OUTPUT_DIR | Saving outputs such as loss, accuracy, intermediate layers, weights, gradients, bias, and TensorBoard-compatible outputs. You can also save any arbitrary output you’d like using this path. Note that this is a different path from the one for storing the final model artifact `/opt/ml/model/`. | No | No | No | Yes
``/opt/ml/model`` | SM_MODEL_DIR | Storing the final model artifact. This is also the path from where the model artifact is deployed for Real-time inference in SageMaker Hosting. | No | No | No | Yes
``/opt/ml/checkpoints`` | SM_MODELCheckpoint_DIR | Saving model checkpoints (the state of model) to resume training from a certain point, and recover from unexpected or Managed Spot Training interruptions. | Yes | Yes | Yes | No
``/opt/ml/code`` | SAGEMAKER_SUBMIT_DIRECTORY | Copying training scripts, additional libraries, and dependencies. | Yes | | No | No
``/tmp`` | - | Reading or writing to `/tmp` as a scratch space. | No | No | No | No

1. `channel_name` is the place to specify user-defined channel names for training data inputs. Each training job can contain several data input channels. You can specify up to 20 training input channels per training job. Note that the data downloading time from the data channels is counted to the billable time. For more information about data input paths, see [How Amazon SageMaker Provides Training Information](https://docs.aws.amazon.com/sagemaker/latest/dg/how-training-provides-training-information.html). Also, there are three types of data input modes that SageMaker supports: file, FastFile, and pipe mode. To learn more about the data input modes for training in SageMaker, see [Access Training Data](https://docs.aws.amazon.com/sagemaker/latest/dg/how-training-provides-training-data.html).

2. SageMaker compresses and writes training artifacts to TAR files (`tar.gz`). Compression and uploading time is counted to the billable time. For more information, see [How Amazon SageMaker Processes Training Output](https://docs.aws.amazon.com/sagemaker/latest/dg/how-training-proceses-training-output.html).
SageMaker compresses and writes the final model artifact to a TAR file (tar.gz). Compression and uploading time is counted to the billable time. For more information, see How Amazon SageMaker Processes Training Output.

Sync with Amazon S3 during training. Write as is without compressing to TAR files. For more information, see Use Checkpoints in Amazon SageMaker.

Provide Dataset Metadata to Training Jobs with an Augmented Manifest File

To include metadata with your dataset in a training job, use an augmented manifest file. When using an augmented manifest file, your dataset must be stored in Amazon Simple Storage Service (Amazon S3), and you must configure your training job to use the dataset stored there. You specify the location and format of this dataset for one or more Channel. Augmented manifests can only support Pipe input mode. See the section, InputMode in Channel to learn more about pipe input mode.

When specifying a channel's parameters, you specify a path to the file, called a S3Uri. Amazon SageMaker interprets this URI based on the specified S3DataType in S3DataSource. The AugmentedManifestFile option defines a manifest format that includes metadata with the input data. Using an augmented manifest file is an alternative to preprocessing when you have labeled data. For training jobs using labeled data, you typically need to preprocess the dataset to combine input data with metadata before training. If your training dataset is large, preprocessing can be time consuming and expensive.

Augmented Manifest File Format

An augmented manifest file must be formatted in JSON Lines format. In JSON Lines format, each line in the file is a complete JSON object followed by a newline separator.

During training, SageMaker parses each JSON line and sends some or all of its attributes on to the training algorithm. You specify which attribute contents to pass and the order in which to pass them with the AttributeNames parameter of the CreateTrainingJob API. The AttributeNames parameter is an ordered list of attribute names that SageMaker looks for in the JSON object to use as training input.

For example, if you list ["line", "book"] for AttributeNames, the input data must include the attribute names of line and book in the specified order. For this example, the following augmented manifest file content is valid:

```json
{"author": "Herman Melville", "line": "Call me Ishmael", "book": "Moby Dick"}
{"line": "It was love at first sight.", "author": "Joseph Heller", "book": "Catch-22"}
```

SageMaker ignores unlisted attribute names even if they precede, follow, or are in between listed attributes.

When using augmented manifest files, observe the following guidelines:

- The order of the attributes listed in the AttributeNames parameter determines the order of the attributes passed to the algorithm in the training job.
- The listed AttributeNames can be a subset of all of the attributes in the JSON line. SageMaker ignores unlisted attributes in the file.
- You can specify any type of data allowed by the JSON format in AttributeNames, including text, numerical, data arrays, or objects.
- To include an S3 URI as an attribute name, add the suffix -ref to it.
If an attribute name contains the suffix -ref, the attribute's value must be an S3 URI to a data file that is accessible to the training job. For example, if AttributeNames contains ["image-ref", "is-a-cat"], the following example shows a valid augmented manifest file:

```
{"image-ref": "s3://mybucket/sample01/image1.jpg", "is-a-cat": 1}
{"image-ref": "s3://mybucket/sample02/image2.jpg", "is-a-cat": 0}
```

In case of the first JSON line of this manifest file, SageMaker retrieves the image1.jpg file from s3://mybucket/sample01/ and the string representation of the is-a-cat attribute "1" for image classification.

**Tip**
To create an augmented manifest file, use Amazon SageMaker Ground Truth and create a labeling job. For more information about the output from a labeling job, see Output Data (p. 890).

## Stream Augmented Manifest File Data

Augmented manifest format enables you to do training in Pipe mode using files without needing to create RecordIO files. You need to specify both train and validation channels as values for the InputDataConfig parameter of the CreateTrainingJob request. Augmented manifest files are supported only for channels using Pipe input mode. For each channel, the data is extracted from its augmented manifest file and streamed (in order) to the algorithm through the channel's named pipe. Pipe mode uses the first in first out (FIFO) method, so records are processed in the order in which they are queued. For information about Pipe input mode, see Input Mode.

Attribute names with a "-ref" suffix point to preformatted binary data. In some cases, the algorithm knows how to parse the data. In other cases, you might need to wrap the data so that records are delimited for the algorithm. If the algorithm is compatible with RecordIO-formatted data, specifying RecordIO for RecordWrapperType solves this issue. If the algorithm is not compatible with RecordIO format, specify None for RecordWrapperType and make sure that your data is parsed correctly for your algorithm.

Using the ["image-ref", "is-a-cat"] example, if you use RecordIO wrapping, the following stream of data is sent to the queue:

```
recordio_formatted(s3://mybucket/foo/image1.jpg)recordio_formatted("1")recordio_formatted(s3://mybucket/bar/image2.jpg)recordio_formatted("0")
```

Images that are not wrapped with RecordIO format, are streamed with the corresponding is-a-cat attribute value as one record. This can cause a problem because the algorithm might not delimit the images and attributes correctly. For more information about using augmented manifest files for image classification, see Train with Augmented Manifest Image Format.

With augmented manifest files and Pipe mode in general, size limits of the EBS volume do not apply. This includes settings that otherwise must be within the EBS volume size limit such as S3DataDistributionType. For more information about Pipe mode and how to use it, see Using Your Own Training Algorithms - Input Data Configuration.

## Use an Augmented Manifest File (Console)

To complete this procedure, you need:

- The URL of the S3 bucket where you've stored the augmented manifest file.
- To store the data that is listed in the augmented manifest file in an S3 bucket.
- The URL of the S3 bucket where you want to store the output of the job.
To use an augmented manifest file in a training job (console)

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose Training, then choose Training jobs.
3. Choose Create training job.
4. Provide a name for the training job. The name must be unique within an AWS Region in an AWS account. It can have 1 to 63 characters. Valid characters: a-z, A-Z, 0-9, and : + @ _ % - (hyphen).
5. Choose the algorithm that you want to use. For information about supported built-in algorithms, see Use Amazon SageMaker Built-in Algorithms or Pre-trained Models (p. 1528). If you want to use a custom algorithm, make sure that it is compatible with Pipe mode.
6. (Optional) For Resource configuration, either accept the default values or, to reduce computation time, increase the resource consumption.
   a. (Optional) For Instance type, choose the ML compute instance type that you want to use. In most cases, ml.m4.xlarge is sufficient.
   b. For Instance count, use the default, 1.
   c. (Optional) For Additional volume per instance (GB), choose the size of the ML storage volume that you want to provision. In most cases, you can use the default, 1. If you are using a large dataset, use a larger size.
7. Provide information about the input data for the training dataset.
   a. For Channel name, either accept the default (train) or enter a more meaningful name, such as training-augmented-manifest-file.
   b. For InputMode, choose Pipe.
   c. For S3 data distribution type, choose FullyReplicated. When training incrementally, fully replicating causes each ML compute instance to use a complete copy of the expanded dataset. For neural-based algorithms, such as Neural Topic Model (NTM) Algorithm (p. 1663), choose ShardedByS3Key.
   d. If the data specified in the augmented manifest file is uncompressed, set the Compression type to None. If the data is compressed using gzip, set it to Gzip.
   e. (Optional) For Content type, specify the appropriate MIME type. Content type is the multipurpose internet mail extension (MIME) type of the data.
   f. For Record wrapper, if the dataset specified in the augmented manifest file is saved in RecordIO format, choose RecordIO. If your dataset is not saved as a RecordIO-formatted file, choose None.
   g. For S3 data type, choose AugmentedManifestFile.
   h. For S3 location, provide the path to the bucket where you stored the augmented manifest file.
   i. For AugmentedManifestFile attribute names, specify the name of an attribute that you want to use. The attribute name must be present within the augmented manifest file, and is case-sensitive.
   j. (Optional) To add more attribute names, choose Add row and specify another attribute name for each attribute.
   k. (Optional) To adjust the order of attribute names, choose the up or down buttons next to the names. When using an augmented manifest file, the order of the specified attribute names is important.
   l. Choose Done.
8. For Output data configuration, provide the following information:
   a. For S3 location, type the path to the S3 bucket where you want to store the output data.
   b. (Optional) You can use your AWS Key Management Service (AWS KMS) encryption key to encrypt the output data at rest. For Encryption key, provide the key ID or its Amazon Resource Number (ARN). For more information, see KMS-Managed Encryption Keys.
9. **(Optional) For Tags**, add one or more tags to the training job. A *tag* is metadata that you can define and assign to AWS resources. In this case, you can use tags to help you manage your training jobs. A tag consists of a key and a value, which you define. For example, you might want to create a tag with *Project* as a key and a value that refers to a project that is related to the training job, such as **Home value forecasts**.

10. Choose **Create training job**. SageMaker creates and runs the training job.

   After the training job has finished, SageMaker stores the model artifacts in the bucket whose path you provided for **S3 output path** in the **Output data configuration** field. To deploy the model to get predictions, see **Step 5: Deploy the Model to Amazon EC2** (p. 310).

### Use an Augmented Manifest File (API)

The following shows how to train a model with an augmented manifest file using the SageMaker high-level Python library:

```python
import sagemaker

# Create a model object set to using "Pipe" mode.
model = sagemaker.estimator.Estimator(
    training_image,
    role,
    instance_count=1,
    instance_type='ml.p3.2xlarge',
    volume_size = 50,
    max_run = 360000,
    input_mode = 'Pipe',
    output_path=s3_output_location,
    sagemaker_session=session
)

# Create a train data channel with S3_data_type as 'AugmentedManifestFile' and attribute names.
train_data = sagemaker.inputs.TrainingInput(
    your_augmented_manifest_file,
    distribution='FullyReplicated',
    content_type='application/x-recordio',
    s3_data_type='AugmentedManifestFile',
    attribute_names=['source-ref', 'annotations'],
    input_mode='Pipe',
    record_wrapper='RecordIO'
)

data_channels = {'train': train_data}

# Train a model.
model.fit(inputs=data_channels, logs=True)
```

After the training job has finished, SageMaker stores the model artifacts in the bucket whose path you provided for **S3 output path** in the **Output data configuration** field. To deploy the model to get predictions, see **Step 5: Deploy the Model to Amazon EC2** (p. 310).

### Use Checkpoints in Amazon SageMaker

Use checkpoints in Amazon SageMaker to save the state of machine learning (ML) models during training. Checkpoints are snapshots of the model and can be configured by the callback functions of ML frameworks. You can use the saved checkpoints to restart a training job from the last saved checkpoint.
The SageMaker training mechanism uses training containers on Amazon EC2 instances, and the checkpoint files are saved under a local directory of the containers (the default is /opt/ml/checkpoints). SageMaker provides the functionality to copy the checkpoints from the local path to Amazon S3 and automatically syncs the checkpoints in that directory with Amazon S3. Existing checkpoints in S3 are written to the SageMaker container at the start of the job, enabling jobs to resume from a checkpoint. Checkpoints added to the S3 folder after the job has started are not copied to the training container. SageMaker also writes new checkpoints from the container to S3 during training. If a checkpoint is deleted in the SageMaker container, it will also be deleted in the S3 folder.

Using checkpoints, you can do the following:

- Save your model snapshots under training due to an unexpected interruption to the training job or instance.
- Resume training the model in the future from a checkpoint.
- Analyze the model at intermediate stages of training.
- Use checkpoints with SageMaker managed spot training to save on training costs.

If you are using checkpoints with SageMaker managed spot training, SageMaker manages checkpointing your model training on a spot instance and resuming the training job on the next spot instance. With SageMaker managed spot training, you can significantly reduce the billable time for training ML models. For more information, see Use Managed Spot Training in Amazon SageMaker (p. 2305).

**Checkpoints for Frameworks and Algorithms in SageMaker**

Use checkpoints to save snapshots of ML models built on your preferred frameworks within SageMaker.

**SageMaker frameworks and algorithms that support checkpointing**

SageMaker supports checkpointing for AWS Deep Learning Containers and a subset of built-in algorithms without requiring training script changes. SageMaker saves the checkpoints to the default local path '/opt/ml/checkpoints' and copies them to Amazon S3.

- **Deep Learning Containers:** TensorFlow, PyTorch, MXNet, and HuggingFace

  **Note**
  If you are using the HuggingFace framework estimator, you need to specify a checkpoint output path through hyperparameters. For more information, see Run training on Amazon SageMaker in the HuggingFace documentation.

- **Built-in algorithms:** Image Classification, Object Detection, Semantic Segmentation, and XGBoost (0.90-1 or later)

  **Note**
  If you are using the XGBoost algorithm in framework mode (script mode), you need to bring an XGBoost training script with checkpointing that's manually configured. For more information about the XGBoost training methods to save model snapshots, see Training XGBoost in the XGBoost Python SDK documentation.
If a pre-built algorithm that does not support checkpointing is used in a managed spot training job, SageMaker does not allow a maximum wait time greater than an hour for the job in order to limit wasted training time from interrupts.

**For custom training containers and other frameworks**

If you are using your own training containers, training scripts, or other frameworks not listed in the previous section, you must properly set up your training script using callbacks or training APIs to save checkpoints to the local path (`'/opt/ml/checkpoints'`) and load from the local path in your training script. SageMaker estimators can sync up with the local path and save the checkpoints to Amazon S3.

### Enable Checkpointing

After you enable checkpointing, SageMaker saves checkpoints to Amazon S3 and syncs your training job with the checkpoint S3 bucket.

![Diagram: Enable Checkpointing](image)

The following example shows how to configure checkpoint paths when you construct a SageMaker estimator. To enable checkpointing, add the `checkpoint_s3_uri` and `checkpoint_local_path` parameters to your estimator.

The following example template shows how to create a generic SageMaker estimator and enable checkpointing. You can use this template for the supported algorithms by specifying the `image_uri` parameter. To find Docker image URIs for algorithms with checkpointing supported by SageMaker, see [Docker Registry Paths and Example Code](#). You can also replace `estimator` and `Estimator` with other SageMaker frameworks' estimator parent classes and estimator classes, such as [TensorFlow](#), [PyTorch](#), [MXNet](#), [HuggingFace](#) and [XGBoost](#).

```python
import sagemaker
from sagemaker.estimator import Estimator

bucket=sagemaker.Session().default_bucket()
base_job_name="sagemaker-checkpoint-test"
checkpoint_in_bucket="checkpoints"

# The S3 URI to store the checkpoints
checkpoint_s3_bucket="s3://{}//{}//{}".format(bucket, base_job_name, checkpoint_in_bucket)

# The local path where the model will save its checkpoints in the training container
checkpoint_local_path="/opt/ml/checkpoints"

estimator = Estimator(
    ...
    image_uri="<ecr_path>/<algorithm-name>:<tag>" # Specify to use built-in algorithms
    output_path=bucket,
    base_job_name=base_job_name,
    checkpoint_s3_uri=checkpoint_s3_bucket,
    checkpoint_local_path=checkpoint_local_path,
)
```

2332
The following two parameters specify paths for checkpointing:

- **checkpoint_local_path** – Specify the local path where the model saves the checkpoints periodically in a training container. The default path is set to '/opt/ml/checkpoints'. If you are using other frameworks or bringing your own training container, ensure that your training script's checkpoint configuration specifies the path to '/opt/ml/checkpoints'.

  **Note**
  We recommend specifying the local paths as '/opt/ml/checkpoints' to be consistent with the default SageMaker checkpoint settings. If you prefer to specify your own local path, make sure you match the checkpoint saving path in your training script and the checkpoint_local_path parameter of the SageMaker estimators.

- **checkpoint_s3_uri** – The URI to an S3 bucket where the checkpoints are stored in real time.

To find a complete list of SageMaker estimator parameters, see the **Estimator API** in the *Amazon SageMaker Python SDK* documentation.

**Browse Checkpoint Files**

Locate checkpoint files using the SageMaker Python SDK and the Amazon S3 console.

**To find the checkpoint files programmatically**

To retrieve the S3 bucket URI where the checkpoints are saved, check the following estimator attribute:

```
estimator.checkpoint_s3_uri
```

This returns the Amazon S3 output path for checkpoints configured while requesting the CreateTrainingJob request. To find the saved checkpoint files using the Amazon S3 console, use the following procedure.

**To find the checkpoint files from the Amazon S3 console**

2. In the left navigation pane, choose **Training jobs**.
3. Choose the link to the training job with checkpointing enabled to open **Job settings**.
4. On the **Job settings** page of the training job, locate the **Checkpoint configuration** section.

<table>
<thead>
<tr>
<th>S3 output path</th>
<th>Local path</th>
</tr>
</thead>
<tbody>
<tr>
<td>s3://path-to-your-checkpoint</td>
<td>/opt/ml/checkpoints/</td>
</tr>
</tbody>
</table>

5. Use the link to the S3 bucket to access the checkpoint files.
Resume Training From a Checkpoint

To resume a training job from a checkpoint, run a new estimator with the same `checkpoint_s3_uri` that you created in the Enable Checkpointing (p. 2332) section. Once the training has resumed, the checkpoints from this S3 bucket are restored to `checkpoint_local_path` in each instance of the new training job. Ensure that the S3 bucket is in the same Region as that of the current SageMaker session.

Considerations for Checkpointing

Consider the following when using checkpoints in SageMaker.

- To avoid overwrites in distributed training with multiple instances, you must manually configure the checkpoint file names and paths in your training script. The high-level SageMaker checkpoint configuration specifies a single Amazon S3 location without additional suffixes or prefixes to tag checkpoints from multiple instances.
- The SageMaker Python SDK does not support high-level configuration for checkpointing frequency. To control the checkpointing frequency, modify your training script using the framework's model save functions or checkpoint callbacks.
- If you use SageMaker checkpoints with SageMaker Debugger and SageMaker distributed and are facing issues, see the following pages for troubleshooting and considerations.
  - Considerations for Amazon SageMaker Debugger (p. 2031)
  - Data Parallel Troubleshooting (p. 2142)
  - Model Parallel Troubleshooting (p. 2219)
Deploy models for inference

With Amazon SageMaker, you can deploy your machine learning (ML) models to make predictions, also known as inference. SageMaker provides a broad selection of ML infrastructure and model deployment options to help meet all your ML inference needs. It is a fully managed service and integrates with MLOps tools, so you can scale your model deployment, reduce inference costs, manage models more effectively in production, and reduce operational burden.

After you've built and trained a machine learning model, you can use SageMaker Inference to start getting predictions, or inferences, from your model. With SageMaker Inference, you can either set up an endpoint that returns inferences or run batch inferences from your model.

To get started with SageMaker Inference, see the following sections and review the Inference options (p. 2336) to determine which feature best fits your use case.

You can refer to the Resources (p. 2792) section for more troubleshooting and reference information, blogs and examples to help you get started, and common FAQs.

Topics
- Before you begin (p. 2335)
- Steps for model deployment (p. 2335)
- Inference options (p. 2336)
- Advanced endpoint options (p. 2337)
- Bring your own model (p. 2337)
- Next steps (p. 2338)

Before you begin

These topics assume that you have built and trained one or more machine learning models and are ready to deploy them. You don't need to train your model in SageMaker in order to deploy your model in SageMaker and get inferences. If you don't have your own model, you can also use SageMaker's built-in algorithms or pre-trained models.

If you are new to SageMaker and haven't picked out a model to deploy, work through the steps in the Get Started with Amazon SageMaker tutorial to familiarize yourself with an example of how SageMaker manages the data science process and how it handles model deployment. For more information about training a model, see Train Models.

For additional information, reference, and examples, see the Resources (p. 2792).

Steps for model deployment

For inference endpoints, the general workflow consists of the following:

- Create a model in SageMaker Inference by pointing to model artifacts stored in Amazon S3 and a container image.
- Select an inference option. For more information, see Inference options (p. 2336).
- Create a SageMaker Inference endpoint configuration by choosing the instance type and number of instances you need behind the endpoint. You can use Amazon SageMaker Inference Recommender to get recommendations for instance types. For Serverless Inference, you only need to provide the memory configuration you need based on your model size.
Inference options

- Create a SageMaker Inference endpoint.
- Invoke your endpoint to receive an inference as a response.

The following diagram shows the preceding workflow.

You can perform these actions using the AWS console, the AWS SDKs, the SageMaker Python SDK, AWS CloudFormation or the AWS CLI.

For batch inference with batch transform, point to your model artifacts and input data and create a batch inference job. Instead of hosting an endpoint for inference, SageMaker outputs your inferences to an Amazon S3 location of your choice.

Inference options

SageMaker provides multiple inference options so that you can pick the option that best suits your workload:

- **Real-Time Inference**: *Real-time inference* is ideal for online inferences that have low latency or high throughput requirements. Use real-time inference for a persistent and fully managed endpoint (REST API) that can handle sustained traffic, backed by the instance type of your choice. Real-time inference can support payload sizes up to 6 MB and processing times of 60 seconds.

- **Serverless Inference**: *Serverless inference* is ideal when you have intermittent or unpredictable traffic patterns. SageMaker manages all of the underlying infrastructure, so there's no need to manage instances or scaling policies. You pay only for what you use and not for idle time. It can support payload sizes up to 4 MB and processing times up to 60 seconds.

- **Batch Transform**: *Batch transform* is suitable for offline processing when large amounts of data are available upfront and you don't need a persistent endpoint. You can also use batch transform for pre-processing datasets. It can support large datasets that are GBs in size and processing times of days.

- **Asynchronous Inference**: *Asynchronous inference* is ideal when you want to queue requests and have large payloads with long processing times. Asynchronous Inference can support payloads up to 1 GB and long processing times up to one hour. You can also scale down your endpoint to 0 when there are no requests to process.
Advanced endpoint options

With real-time inference, you can further optimize for performance and cost with the following advanced inference options:

- If you have multiple models that use the same framework and can share a container, then use **Host multiple models in one container behind one endpoint** (p. 2399). This option helps you optimize costs by improving endpoint utilization and reducing deployment overhead.

- If you have multiple models that use different frameworks and require their own containers, then use **Host multiple models which use different containers behind one endpoint** (p. 2426). With this option, you get many of the benefits of Multi-Model Endpoints and can deploy a variety of frameworks and models.

- If you want to host models with pre-processing and post-processing logic behind an endpoint, then use **Serial Inference Pipelines**. Inference pipelines are fully managed by SageMaker and provide lower latency because all of the containers are hosted on the same Amazon EC2 instances.

Bring your own model

To use an existing Docker container in SageMaker, see **Adapting your own Docker container to work with SageMaker** (p. 3297).

To create a new Docker container and receive more advanced guidance on how to run your own inference code, see the following links.

- To run your own inference code hosting services, see **Use Your Own Inference Code with Hosting Services** (p. 3327).
- To run your own inference code for batch inference, see **Use Your Own Inference Code with Batch Transform** (p. 3335).
After you have an endpoint and understand the general inference workflow, you can use the following features within SageMaker Inference to improve your inference workflow.

**Monitoring**

To track your model over time through metrics such as model accuracy and drift, you can use Model Monitor. With Model Monitor, you can set alerts that notify you when there are deviations in your model's quality. To learn more, see the Model Monitor documentation. To learn more about tools that can be used to monitor model deployments and events that change your endpoint, see Monitor Amazon SageMaker. For example, you can monitor your endpoint's health through metrics such as invocation errors and model latency using Amazon CloudWatch metrics. The SageMaker endpoint invocation metrics can provide you with valuable information about your endpoint's performance.

**CI/CD for model deployment**

To put together machine learning solutions in SageMaker, you can use SageMaker MLOps. You can use this feature to automate the steps in your machine learning workflow and practice CI/CD. You can use MLOps Project Templates to help with the setup and implementation of SageMaker MLOps projects. SageMaker also supports using your own third-party Git repo for creating a CI/CD system.

For your ML pipelines, use Model Registry to manage your model versions and the deployment and automation of your models.

**Deployment guardrails**

If you want to update your model while it's in production without impacting production, you can use deployment guardrails. Deployment guardrails are a set of model deployment options in SageMaker Inference to update your machine learning models in production. Using the fully managed deployment options, you can control the switch from the current model in production to a new one. Traffic shifting modes give you granular control over the traffic shifting process, and built-in safeguards like auto-rollbacks help you catch issues early on. To learn more about deployment guardrails, see the deployment guardrails documentation.

**Inferentia**

If you need to run large scale machine learning and deep learning applications for use cases such as image or speech recognition, natural language processing (NLP), personalization, forecasting, or fraud detection, you can use an Inf1 instance with a real-time endpoint. Inf1 instances are built to support machine learning inference applications and feature the AWS Inferentia chips. Inf1 instances provide higher throughput and lower cost per inference than GPU-based instances.

To deploy a model on Inf1 instances, compile your model with SageMaker Neo and choose an Inf1 instance for your deployment option. To learn more, see Optimize model performance using SageMaker Neo.

**Optimize model performance**

SageMaker provides features to manage resources and optimize inference performance when deploying machine learning models. You can use SageMaker's built-in algorithms and pre-built models, as well as...
Autoscaling

If you have varying amounts of traffic to your endpoints, you might want to try autoscaling. For example, during peak hours, you might require more instances to process requests, but during periods of low traffic, you might want to reduce your use of computing resources. To dynamically adjust the number of instances provisioned in response to changes in your workload, see *Automatically Scale Amazon SageMaker Models* (p. 2447).

If you have unpredictable traffic patterns or don’t want to set up scaling policies, you can also use Serverless Inference for an endpoint where SageMaker manages autoscaling for you. During periods of low traffic, SageMaker scales down your endpoint, and if traffic increases, then SageMaker scales your endpoint up. For more information, see the *Serverless Inference* (p. 2496) documentation.

Deploy a Model in Amazon SageMaker

After you train your machine learning model, you can deploy it using Amazon SageMaker to get predictions in any of the following ways, depending on your use case:

- For persistent, real-time endpoints that make one prediction at a time, use SageMaker real-time hosting services. See *Real-time inference* (p. 2388).
- Workloads that have idle periods between traffic spurts and can tolerate cold starts, use Serverless Inference. See *Serverless Inference* (p. 2496).
- Requests with large payload sizes up to 1GB, long processing times, and near real-time latency requirements, use Amazon SageMaker Asynchronous Inference. See *Asynchronous inference* (p. 2522).
- To get predictions for an entire dataset, use SageMaker batch transform. See *Use Batch Transform* (p. 2545).

SageMaker also provides features to manage resources and optimize inference performance when deploying machine learning models:

- To manage models on edge devices so that you can optimize, secure, monitor, and maintain machine learning models on fleets of edge devices such as smart cameras, robots, personal computers, and mobile devices, see *Deploy models at the edge with SageMaker Edge Manager* (p. 2641).
- To optimize Gluon, Keras, MXNet, PyTorch, TensorFlow, TensorFlow-Lite, and ONNX models for inference on Android, Linux, and Windows machines based on processors from Ambarella, ARM, Intel, Nvidia, NXP, Qualcomm, Texas Instruments, and Xilinx, see *Optimize model performance using Neo* (p. 2693).

For more information about all deployment options, see *Deploy models for inference* (p. 2335).

Validate a Machine Learning Model

After training a model, evaluate it to determine whether its performance and accuracy enable you to achieve your business goals. You might generate multiple models using different methods and evaluate each. For example, you could apply different business rules for each model, and then apply various
measures to determine each model's suitability. You might consider whether your model needs to be more sensitive than specific (or vice versa).

You can evaluate your model using historical data (offline) or live data:

- **Offline testing**—Use historical, not live, data to send requests to the model for inferences.

  Deploy your trained model to an alpha endpoint, and use historical data to send inference requests to it. To send the requests, use a Jupyter notebook in your Amazon SageMaker notebook instance and either the AWS SDK for Python (Boto) or the high-level Python library provided by SageMaker.

- **Online testing with live data**—SageMaker supports A/B testing for models in production by using production variants. Production variants are models that use the same inference code and are deployed on the same SageMaker endpoint. You configure the production variants so that a small portion of the live traffic goes to the model that you want to validate. For example, you might choose to send 10% of the traffic to a model variant for evaluation. After you are satisfied with the model's performance, you can route 100% traffic to the updated model. For an example of testing models in production, see [Production variants](p. 2464).

For more information, see articles and books about how to evaluate models, for example, *Evaluating Machine Learning Models*.

Options for offline model evaluation include:

- **Validating using a holdout set**—Machine learning practitioners often set aside a part of the data as a "holdout set." They don't use this data for model training.

  With this approach, you evaluate how well your model provides inferences on the holdout set. You then assess how effectively the model generalizes what it learned in the initial training, as opposed to using model memory. This approach to validation gives you an idea of how often the model is able to infer the correct answer.

  In some ways, this approach is similar to teaching elementary school students. First, you provide them with a set of examples to learn, and then test their ability to generalize from their learning. With homework and tests, you pose problems that were not included in the initial learning and determine whether they are able to generalize effectively. Students with perfect memories could memorize the problems, instead of learning the rules.

  Typically, the holdout dataset is of 20-30% of the training data.

- **k-fold validation**—In this validation approach, you split the example dataset into $k$ parts. You treat each of these parts as a holdout set for $k$ training runs, and use the other $k-1$ parts as the training set for that run. You produce $k$ models using a similar process, and aggregate the models to generate your final model. The value $k$ is typically in the range of 5-10.

---

**Amazon SageMaker Inference Recommender**

Amazon SageMaker Inference Recommender is a capability of Amazon SageMaker that reduces the time required to get machine learning (ML) models in production by automating load testing and model tuning across SageMaker ML instances. You can use Inference Recommender to deploy your model to a real-time or serverless inference endpoint that delivers the best performance at the lowest cost.
Inference Recommender helps you select the best instance type and configuration (such as instance count, container parameters, and model optimizations) or serverless configuration (such as max concurrency and memory size) for your ML models and workloads.

Amazon SageMaker Inference Recommender only charges you for the instances used while your jobs are executing.

How it Works

To use Amazon SageMaker Inference Recommender, you can either create a SageMaker model or register a model to the SageMaker model registry with your model artifacts. Use the AWS SDK for Python (Boto3) or the SageMaker console to run benchmarking jobs for different SageMaker endpoint configurations. Inference Recommender jobs help you collect and visualize metrics across performance and resource utilization to help you decide on which endpoint type and configuration to choose.

How to Get Started

If you are a first-time user of Amazon SageMaker Inference Recommender, we recommend that you do the following:

1. Read through the Prerequisites section to make sure you have satisfied the requirements to use Amazon SageMaker Inference Recommender.
2. Read through the Recommendation jobs section to launch your first Inference Recommender recommendation jobs.
3. Explore the introductory Amazon SageMaker Inference Recommender Jupyter notebook example, or review the example notebooks in the following section.

Example notebooks

The following example Jupyter notebooks can help you with the workflows for multiple use cases in Inference Recommender:

- If you want an introductory notebook that benchmarks a TensorFlow model, see the SageMaker Inference Recommender TensorFlow notebook.
- If you want to benchmark a HuggingFace model, see the SageMaker Inference Recommender for HuggingFace notebook.
- If you want to benchmark an XGBoost model, see the SageMaker Inference Recommender XGBoost notebook.
- If you want to review CloudWatch metrics for your Inference Recommender jobs, see the SageMaker Inference Recommender CloudWatch metrics notebook.

Prerequisites

To use Amazon SageMaker Inference Recommender, first make sure you have met the prerequisites listed below. As an example, we show how to use a PyTorch (v1.7.1) ResNet-18 pre-trained model for both types of Amazon SageMaker Inference Recommender recommendation jobs.

Note

- The following code examples use Python. Remove the ! prefix character if you run any of the following code samples in your terminal or AWS CLI.
This example uses the conda_pytorch_p36_latest kernel within a Amazon SageMaker Notebook instance. This kernel is provided by SageMaker and uses Python 3.6 and PyTorch 1.7.1. For more information about SageMaker Notebooks, see Amazon SageMaker Notebook Instances (p. 298).

1. **Create an IAM role for Amazon SageMaker.**

   Create an IAM Role for Amazon SageMaker that has the AmazonSageMakerFullAccess IAM managed policy attached.

2. **(Optional) Review existing models benchmarked by Inference Recommender.**

   Inference Recommender benchmarks models from popular model zoos. Inference Recommender supports your model even if it is not already benchmarked.

   Use `ListModelMetadata` to get a response object that lists the domain, framework, task, and model name of machine learning models found in common model zoos.

   You use the domain, framework, framework version, task, and model name in later steps to both select an inference Docker image and register your model with SageMaker Model Registry. The following demonstrates how to list model metadata with SDK for Python (Boto3):

   ```python
   import boto3
   aws_region = '<INSERT>'
   sagemaker_client = boto3.client('sagemaker', aws_region)
   list_model_metadata_response = sagemaker_client.list_model_metadata()
   ```

   The output includes model summaries (`ModelMetadataSummaries`) and response metadata (`ResponseMetadata`) similar to the following:

   ```json
   {
       'ModelMetadataSummaries': [{
           'Domain': 'NATURAL_LANGUAGE_PROCESSING',
           'Framework': 'PYTORCH:1.6.0',
           'Model': 'bert-base-cased',
           'Task': 'FILL_MASK'
       },
       {
           'Domain': 'NATURAL_LANGUAGE_PROCESSING',
           'Framework': 'PYTORCH:1.6.0',
           'Model': 'bert-base-uncased',
           'Task': 'FILL_MASK'
       },
       {
           'Domain': 'COMPUTER_VISION',
           'Framework': 'MXNET:1.8.0',
           'Model': 'resnet18v2-gluon',
           'Task': 'IMAGE_CLASSIFICATION'
       },
       {
           'Domain': 'COMPUTER_VISION',
           'Framework': 'PYTORCH:1.6.0',
           'Model': 'resnet152',
           'Task': 'IMAGE_CLASSIFICATION'
       }],
       'ResponseMetadata': {
           'HTTPHeaders': {
               'content-length': '2345',
               'content-type': 'application/x-amz-json-1.1',
               'date': 'Tue, 19 Oct 2021 20:52:03 GMT'
           }
       }
   }
   ```
For this demo, we use a PyTorch (v1.7.1) ResNet-18 model to perform image classification. The following Python code sample stores the framework, framework version, domain, and task into variables for later use:

```python
# ML framework details
framework = 'PYTORCH'
framework_version = '1.7.1'

# ML model details
ml_domain = 'COMPUTER_VISION'
ml_task = 'IMAGE_CLASSIFICATION'
```

### 3. Upload your machine learning model to Amazon S3.

Use this PyTorch (v1.7.1) ResNet-18 model if you do not have a pre-trained machine learning model:

```python
# Optional: Download a sample PyTorch model
import torch
from torchvision import models, transforms, datasets

# Create an example input for tracing
image = torch.zeros([1, 3, 256, 256], dtype=torch.float32)

# Load a pretrained resnet18 model from TorchHub
model = models.resnet18(pretrained=True)

# Tell the model we are using it for evaluation (not training). Note this is required for Inferentia compilation.
model.eval()
model_trace = torch.jit.trace(model, image)

# Save your traced model
model_trace.save('model.pth')
```

Download a sample inference script `inference.py`. Create a code directory and move the inference script to the code directory:

```bash
# Download the inference script

# move it into a code/ directory
!mkdir code
!mv inference.py code/
```

Amazon SageMaker requires pre-trained machine learning models be packaged as a compressed TAR file (`*.tar.gz`). Compress your model to satisfy this requirement:

```bash
!tar -czf test.tar.gz model.pth resnet18.py
```

When your endpoint is provisioned, the files in the archive are extracted to `/opt/ml/model/` on the endpoint.
After you compress your model and model artifacts as a .tar.gz file, upload them to your Amazon S3 bucket. The following demonstrates how to upload your model to Amazon S3 using the AWS CLI:

```bash
!aws s3 cp test.tar.gz s3://{your-bucket}/models/
```

4. **Select a prebuilt Docker inference image or create your own Inference Docker Image.**

SageMaker provides containers for its built-in algorithms and prebuilt Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. For a full list of the available SageMaker images, see [Available Deep Learning Containers Images](#).

If none of the existing SageMaker containers meet your needs and you don't have an existing container of your own, create a new Docker image. See [Use your own inference code](#) for information about how to create your Docker image.

The following demonstrates how to retrieve a PyTorch version 1.7.1 inference image using the SageMaker Python SDK:

```python
from sagemaker import image_uris

aws_region="<aws_region>"

## Uncomment and replace with your own values if you did not define
## these variables a previous step.
#framework = 'PYTORCH'
#framework_version = '1.7.1'

# Note: you can use any CPU-based instance here,
# this is just to set the arch as CPU for the Docker image
instance_type = 'ml.m5.2xlarge'

image_uri = image_uris.retrieve(framework,
                                region=aws_region,
                                version=framework_version,
                                py_version='py3',
                                instance_type=instance_type,
                                image_scope='inference')
```

For a list of available SageMaker Instances, see [Amazon SageMaker Pricing](#).

5. **Create a sample payload archive.**

Create an archive that contains individual files that the load testing tool can send to your SageMaker endpoints. Your inference code must be able to read the file formats from the sample payload.

The following downloads a .jpg image that this example uses in a later step for the ResNet-18 model.

```bash
!wget https://cdn.pixabay.com/photo/2020/12/18/05/56/flowers-5841251_1280.jpg
```

Compress the sample payload as a tarball:

```bash
!tar -cvzf payload.tar.gz flowers-5841251_1280.jpg
```

Upload the sample payload to Amazon S3 and note the Amazon S3 URI:
You need the Amazon S3 URI in a later step, so store it in a variable:

```python
bucket_prefix='models'
bucket = '<your-bucket-name>' # Provide the name of your S3 bucket
payload_s3_key = f'{bucket_prefix}/payload.tar.gz'
sample_payload_url = f's3://{bucket}/{payload_s3_key}'
```

6. **Prepare your model input for the recommendations job**

For the last prerequisite, you have two options to prepare your model input. You can either register your model with SageMaker Model Registry, which you can use to catalog models for production, or you can create a SageMaker model and specify it in the `ContainerConfig` field when creating a recommendations job. The first option is best if you want to take advantage of the features that Model Registry provides, such as managing model versions and automating model deployment. The second option is ideal if you want to get started quickly. For the first option, go to step 7. For the second option, skip step 7 and go to step 8.

7. **Option 1: Register your model in the model registry**

With SageMaker Model Registry, you can catalog models for production, manage model versions, associate metadata (such as training metrics) with a model, manage the approval status of a model, deploy models to production, and automate model deployment with CI/CD.

When you use SageMaker Model Registry to track and manage your models, they are represented as a versioned model package within model package groups. Unversioned model packages are not part of a model group. Model package groups hold multiple versions or iterations of a model. Though it is not required to create them for every model in the registry, they help organize various models that all have the same purpose and provide automatic versioning.

To use Amazon SageMaker Inference Recommender, you must have a versioned model package. You can create a versioned model package programmatically with the AWS SDK for Python (Boto3) or with Amazon SageMaker Studio. To create a versioned model package programmatically, first create a model package group with the `CreateModelPackageGroup` API. Next, create a model package using the `CreateModelPackage` API. Calling this method makes a versioned model package.

See [Create a Model Group](p. 2990) and [Register a Model Version](p. 2992) for detailed instructions about how to programmatically and interactively create a model package group and how to create a versioned model package, respectively, with the AWS SDK for Python (Boto3) and Amazon SageMaker Studio.

The following code sample demonstrates how to create a versioned model package using the AWS SDK for Python (Boto3).

**Note**

You do not need to approve the model package to create an Inference Recommender job.

a. **Create a model package group**

Create a model package group with the `CreateModelPackageGroup` API. Provide a name to the model package group for the `ModelPackageGroupName` and optionally provide a description of the model package in the `ModelPackageGroupDescription` field.

```python
model_package_group_name = '<INSERT>'
model_package_group_description = '<INSERT>'
model_package_group_input_dict = {
```
Create a Model Package by specifying a Docker image that runs your inference code and the Amazon S3 location of your model artifacts and provide values for `InferenceSpecification`. `InferenceSpecification` should contain information about inference jobs that can be run with models based on this Model Package, including the following:

- The Amazon ECR paths of images that run your inference code.
- (Optional) The instance types that the Model Package supports for transform jobs and real-time endpoints used for inference.
- The input and output content formats that the Model Package supports for inference.

In addition, you must specify the following parameters when you create a model package:

- **Domain**: The machine learning domain of your model package and its components. Common machine learning domains include computer vision and natural language processing.
- **Task**: The machine learning task your model package accomplishes. Common machine learning tasks include object detection and image classification. Specify "OTHER" if none of the tasks listed in the API Reference Guide satisfy your use case. See the Task API field descriptions for a list of supported machine learning tasks.
- **SamplePayloadUrl**: The Amazon Simple Storage Service (Amazon S3) path where the sample payload are stored. This path must point to a single gzip compressed tar archive (.tar.gz suffix).
- **Framework**: The machine learning framework of the model package container image.
- **FrameworkVersion**: The framework version of the Model Package Container Image.

If you provide an allow list of instance types to use to generate inferences in real-time for the `SupportedRealtimeInferencelInstanceTypes`, Inference Recommender will limit the search space for instance types during a Default job. Use this parameter if you have budget constraints or know there's a specific set of instance types that can support your model and container image.

In a previous step we downloaded a pre-trained ResNet18 model and stored it in an Amazon S3 bucket in a directory called `models`. We retrieved a PyTorch (v1.7.1) Deep Learning Container inference image and stored the URI in a variable called `image_uri`. We use those variables in the following code sample where we define a dictionary used as input to the `CreateModelPackage` API.

```python
# Provide the Amazon S3 URI of your compressed tarfile
# so that Model Registry knows where to find your model artifacts
bucket_prefix='models'
bucket = f'<your-bucket-name>' # Provide the name of your S3 bucket
model_s3_key = f'{bucket_prefix}/test.tar.gz'
model_url= f's3://{bucket}/{model_s3_key}'

# Similar open source model to the packaged model
# The name of the ML model as standardized by common model zoos
nearest_model_name = 'resnet18'
```

See the Amazon SageMaker API Reference Guide for a full list of optional and required arguments you can pass to `CreateModelPackageGroup`. 

```python
model_package_group_response =
    sagemaker_client.create_model_package_group(**model_package_group_input_dict)
```
# The supported MIME types for input and output data. In this example, we are using images as input.
input_content_type='image/jpeg'

# Optional - provide a description of your model.
model_package_description = '<INSERT>'

## Uncomment if you did not store the domain and task in an earlier step
# ml_domain = 'COMPUTER_VISION'
# ml_task = 'IMAGE_CLASSIFICATION'

## Uncomment if you did not store the framework and framework version in a previous step.
# framework = 'PYTORCH'
# framework_version = '1.7.1'

# Optional: Used for optimizing your model using SageMaker Neo
# PyTorch uses NCHW format for images
data_input_configuration = "[[1,3,256,256]]"

# Create a dictionary to use as input for creating a model package group
model_package_input_dict = {
    "ModelPackageGroupName" : model_package_group_name,
    "ModelPackageDescription" : model_package_description,
    "Domain": ml_domain,
    "Task": ml_task,
    "SamplePayloadUrl": sample_payload_url,
    "InferenceSpecification": {
        "Containers": [
            {
                "Image": image_uri,
                "ModelDataUrl": model_url,
                "Framework": framework.upper(),
                "FrameworkVersion": framework_version,
                "NearestModelName": nearest_model_name,
                "ModelInput": {"DataInputConfig": data_input_configuration}
            }
        ],
        "SupportedContentTypes": [input_content_type]
    }
}

b. **Create a Model Package**

Use the `CreateModelPackage` API to create a Model Package. Pass the input dictionary defined in the previous step:

```python
model_package_response = 
sagemaker_client.create_model_package(**model_package_input_dict)
```

You need the model package ARN to use Amazon SageMaker Inference Recommender. Note the ARN of the model package or store it in a variable:

```python
model_package_arn = model_package_response["ModelPackageArn"]
print('ModelPackage Version ARN : {}'.format(model_package_arn))
```

8. **Option 2: Create a model and configure the ContainerConfig field**
Use this option if you want to start an inference recommendations job and don't need to register your model in the Model Registry. In the following steps, you create a model in SageMaker and configure the ContainerConfig field as input for the recommendations job.

a. **Create a model**

Create a model with the `CreateModel` API. For an example that calls this method when deploying a model to SageMaker Hosting, see [Create a Model (AWS SDK for Python (Boto3))](https://boto3.amazonaws.com/v1/documentation/api/latest/reference/services/sagemaker.html#SageMaker.Client.create_model).

In a previous step, we downloaded a pre-trained ResNet18 model and stored it in an Amazon S3 bucket in a directory called models. We retrieved a PyTorch (v1.7.1) Deep Learning Container inference image and stored the URI in a variable called `image_uri`. We use those variables in the following code example where we define a dictionary used as input to the `CreateModel` API.

```python
model_name = '<name_of_the_model>'
# Role to give SageMaker permission to access AWS services.
sagemaker_role = 'arn:aws:iam::<region>::<account>:role/*'  
# Provide the Amazon S3 URI of your compressed tarfile
# so that Model Registry knows where to find your model artifacts
bucket_prefix='models'
bucket = '<your-bucket-name>'  
model_s3_key = f'{bucket_prefix}/test.tar.gz'
model_url = f's3://{bucket}/{model_s3_key}'

#Create model
create_model_response = sagemaker_client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = sagemaker_role,
    PrimaryContainer = {
        'Image': image_uri,
        'ModelDataUrl': model_url,
    })
```

b. **Configure the ContainerConfig field**

Next, you must configure the `ContainerConfig` field with the model you just created and specify the following parameters in it:

- **Domain**: The machine learning domain of the model and its components, such as computer vision or natural language processing.
- **Task**: The machine learning task that the model accomplishes, such as image classification or object detection.
- **PayloadConfig**: The configuration for the payload for a recommendation job. For more information about the subfields, see [RecommendationJobPayloadConfig](https://docs.aws.amazon.com/sagemaker/latest/dg/algorithm-concepts.html#sagemaker-payload).
- **Framework**: The machine learning framework of the container image, such as PyTorch.
- **FrameworkVersion**: The framework version of the container image.
- **(Optional) SupportedInstanceTypes**: A list of the instance types that are used to generate inferences in real-time.

If you use the `SupportedInstanceTypes` parameter, Inference Recommender limits the search space for instance types during a Default job. Use this parameter if you have budget constraints or know there's a specific set of instance types that can support your model and container image.
In the following code example, we use the previously defined parameters, along with NearestModelName, to define a dictionary used as input to the CreateInferenceRecommendationsJob API.

```python
## Uncomment if you did not store the domain and task in a previous step
#ml_domain = 'COMPUTER_VISION'
#ml_task = 'IMAGE_CLASSIFICATION'

## Uncomment if you did not store the framework and framework version in a previous step
#framework = 'PYTORCH'
#framework_version = '1.7.1'

# The name of the ML model as standardized by common model zoos
nearest_model_name = 'resnet18'

# The supported MIME types for input and output data. In this example,
# we are using images as input
input_content_type = 'image/jpeg'

data_input_configuration = "[[1,3,256,256]]"

# Create a dictionary to use as input for creating an inference recommendation job
container_config = {
    "Domain": ml_domain,
    "Framework": framework.upper(),
    "FrameworkVersion": framework_version,
    "NearestModelName": nearest_model_name,
    "PayloadConfig": {
        "SamplePayloadUrl": sample_payload_url,
        "SupportedContentTypes": [input_content_type]
    },
    "DataInputConfig": data_input_configuration
    "Task": ml_task,
}
```

### Recommendation jobs

Amazon SageMaker Inference Recommender can make two types of recommendations:

1. **Inference recommendations** *(Default job type)* run a set of load tests on the recommended instance types. You can also load test for a serverless endpoint. You only need to provide a model package Amazon Resource Name (ARN) to launch this type of recommendation job. Inference recommendation jobs complete within 45 minutes.

2. **Endpoint recommendations** *(Advanced job type)* are based on a custom load test where you select your desired ML instances or a serverless endpoint, provide a custom traffic pattern, and provide requirements for latency and throughput based on your production requirements. This job takes an average of 2 hours to complete depending on the job duration set and the total number of inference configurations tested.

Both types of recommendations use the same APIs to create, describe, and stop jobs. The output is a list of instance configuration recommendations with associated environment variables, cost, throughput, and latency metrics. Recommendation jobs also provide an initial instance count which you can use to configure an autoscaling policy. To differentiate between the two types of jobs, when you’re creating a
job through either the SageMaker console or the APIs, specify Default to create preliminary endpoint recommendations and Advanced for custom load testing and endpoint recommendations.

**Note**
You do not need to do both types of recommendation jobs in your own workflow. You can do either independently of each other.

Inference Recommender can also provide you with a list of prospective instances, or the top five instance types that are optimized for cost, throughput and latency for model deployment, along with a confidence score. You can choose these instances when deploying your model. Inference Recommender automatically performs benchmarking against your model for you to provide the prospective instances. Since these are preliminary recommendations, we recommend that you run further instance recommendation jobs to get more accurate results. To view the prospective instances, go to your SageMaker model details page. For more information, see [Get instant prospective instances](p. 2350).

**Topics**
- [Get instant prospective instances](p. 2350)
- [Get an inference recommendation](p. 2351)
- [Get an inference recommendation for an existing endpoint](p. 2363)
- [Get compiled recommendations with Neo](p. 2366)
- [Interpret recommendation results](p. 2368)
- [Get autoscaling policy recommendations](p. 2370)
- [Run a custom load test](p. 2372)
- [Troubleshoot Inference Recommender errors](p. 2386)

**Get instant prospective instances**

Inference Recommender can also provide you with a list of prospective instances, or instance types that might be suitable for your model, on your SageMaker model details page. Inference Recommender automatically performs preliminary benchmarking against your model for you to provide the top five prospective instances. Since these are preliminary recommendations, we recommend that you run further instance recommendation jobs to get more accurate results.

You can view a list of prospective instances for your model either programatically by using the DescribeModel API, the SageMaker Python SDK, or the SageMaker console.

**Note**
You won’t get prospective instances for models that you created in SageMaker before this feature became available.

To view the prospective instances for your model through the console, do the following:

2. In the left navigation pane, choose **Inference**, and then choose **Models**.
3. From the list of models, choose your model.

On the details page for your model, go to the **Prospective instances to deploy model** section. The following screenshot shows this section.
In this section, you can view the prospective instances that are optimized for cost, throughput, and latency for model deployment, along with additional information for each instance type such as the memory size, CPU and GPU count, and cost per hour.

If you decide that you want to benchmark a sample payload and run a full inference recommendation job for your model, you can start a default inference recommendation job from this page. To start a default job through the console, do the following:

1. On your model details page in the **Prospective instances to deploy model** section, choose **Run Inference recommender job**.

2. In the dialog box that pops up, for **S3 bucket for benchmarking payload**, enter the Amazon S3 location where you've stored a sample payload for your model.

3. For **Payload content type**, enter the MIME types for your payload data.

4. (Optional) In the **Model compilation using SageMaker Neo** section, for the **Data input configuration**, enter a data shape in dictionary format.

5. Choose **Run job**.

Inference Recommender starts the job, and you can view the job and its results from the **Inference recommender** list page in the SageMaker console.

If you want to run an advanced job and perform custom load tests, or if you want to configure additional settings and parameters for your job, see **Run a custom load test (p. 2372)**.

### Get an inference recommendation

Inference recommendation jobs run a set of load tests on recommended instance types or a serverless endpoint. Inference recommendation jobs use performance metrics that are based on load tests using the sample data you provided during model version registration.

**Note**

Before you create an Inference Recommender recommendation job, make sure you have satisfied the **Prerequisites (p. 2341)**.

The following demonstrates how to use Amazon SageMaker Inference Recommender to create an inference recommendation based on your model type using the AWS SDK for Python (Boto3), AWS CLI, and Amazon SageMaker Studio, and the SageMaker console.

### Create an inference recommendation

Create an inference recommendation programmatically using the AWS SDK for Python (Boto3) or the AWS CLI, or interactively using Studio or the SageMaker console. Specify a job name for your inference recommendation, an AWS IAM role ARN, an input configuration, and either a model package ARN when you registered your model with the model registry, or your model name and a `ContainerConfig` dictionary from when you created your model in the **Prerequisites** section.
AWS SDK for Python (Boto3)

Use the `CreateInferenceRecommendationsJob` API to start an inference recommendation job. Set the `JobType` field to 'Default' for inference recommendation jobs. In addition, provide the following:

- The Amazon Resource Name (ARN) of an IAM role that enables Inference Recommender to perform tasks on your behalf. Define this for the `RoleArn` field.
- A model package ARN or model name. Inference Recommender supports either one model package ARN or a model name as input. Specify one of the following:
  - The ARN of the versioned model package you created when you registered your model with the model registry. Define this for `ModelPackageVersionArn` in the `InputConfig` field.
  - The name of the model you created. Define this for `ModelName` in the `InputConfig` field. Also, provide the `ContainerConfig` dictionary, which includes the required fields that need to be provided with the model name. Define this for `ContainerConfig` in the `InputConfig` field. In the `ContainerConfig`, you can also optionally specify the `SupportedEndpointType` field as either `RealTime` or `Serverless`. If you specify this field, Inference Recommender returns recommendations for only that endpoint type. If you don't specify this field, Inference Recommender returns recommendations for both endpoint types.
- A name for your Inference Recommender recommendation job for the `JobName` field. The Inference Recommender job name must be unique within the AWS Region and within your AWS account.

Import the AWS SDK for Python (Boto3) package and create a SageMaker client object using the client class. If you followed the steps in the Prerequisites section, only specify one of the following:

- Option 1: If you would like to create an inference recommendations job with a model package ARN, then store the model package group ARN in a variable named `model_package_arn`.
- Option 2: If you would like to create an inference recommendations job with a model name and `ContainerConfig`, store the model name in a variable named `model_name` and the `ContainerConfig` dictionary in a variable named `container_config`.

```python
# Create a low-level SageMaker service client.
import boto3
aws_region = '<INSERT>'
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Provide only one of model package ARN or model name, not both.
# Provide your model package ARN that was created when you registered your model with Model Registry
model_package_arn = '<INSERT>'

## Uncomment if you would like to create an inference recommendations job with a model name instead of a model package ARN, and comment out model_package_arn above
## Provide your model name
# model_name = '<INSERT>'

## Provide your container config
# container_config = '<INSERT>'

# Provide a unique job name for SageMaker Inference Recommender job
job_name = '<INSERT>'

# Inference Recommender job type. Set to Default to get an initial recommendation
job_type = 'Default'

# Provide an IAM Role that gives SageMaker Inference Recommender permission to access AWS services
role_arn = 'arn:aws:iam::<account>::role/*'
```
sagemaker_client.create_inference_recommendations_job(
    JobName = job_name,
    JobType = job_type,
    RoleArn = role_arn,
    # Provide only one of model package ARN or model name, not both.
    # If you would like to create an inference recommendations job with a model name,
    # uncomment ModelName and ContainerConfig, and comment out ModelPackageVersionArn.
    InputConfig = {
        'ModelPackageVersionArn': model_package_arn
        # 'ModelName': model_name,
        # 'ContainerConfig': container_config
    }
)

See the Amazon SageMaker API Reference Guide for a full list of optional and required arguments you can pass to CreateInferenceRecommendationsJob.

AWS CLI

Use the create-inference-recommendations-job API to start an inference recommendation job. Set the job-type field to 'Default' for inference recommendation jobs. In addition, provide the following:

- The Amazon Resource Name (ARN) of an IAM role that enables Amazon SageMaker Inference Recommender to perform tasks on your behalf. Define this for the role-arn field.
- A model package ARN or model name. Inference Recommender supports either one model package ARN or a model name as input. Specify one of the following
  - The ARN of the versioned model package you created when you registered your model with Model Registry. Define this for ModelPackageVersionArn in the input-config field.
  - The name of the model you created. Define this for ModelName in the input-config field. Also, provide the ContainerConfig dictionary which includes the required fields that need to be provided with the model name. Define this for ContainerConfig in the input-config field. In the ContainerConfig dictionary, you can also optionally specify the SupportedEndpointType field as either RealTime or Serverless. If you specify this field, Inference Recommender returns recommendations for only that endpoint type. If you don't specify this field, Inference Recommender returns recommendations for both endpoint types.
- A name for your Inference Recommender recommendation job for the job-name field. The Inference Recommender job name must be unique within the AWS Region and within your AWS account.

To create an inference recommendation jobs with a model package ARN, use the following example:

```
aws sagemaker create-inference-recommendations-job
    --region <region>\n    --job-name <job_name>\n    --job-type Default\n    --role-arn arn:aws:iam::<account:role/*>\n    --input-config "{
        "ModelPackageVersionArn": "arn:aws:sagemaker::<region:account:role/*>",
    }"
```

To create an inference recommendation jobs with a model name and ContainerConfig, use the following example. The example uses the SupportedEndpointType field to specify that we only want to return real-time inference recommendations:

```
aws sagemaker create-inference-recommendations-job
    --region <region>\n    --job-name <job_name>\n```
Recommendation jobs

```
--job-type Default
--role-arn arn:aws:iam::<account:role/>/*
--input-config "{
    "ModelName": "model-name",
    "ContainerConfig": {
        "Domain": "COMPUTER_VISION",
        "Framework": "PYTORCH",
        "FrameworkVersion": "1.7.1",
        "NearestModelName": "resnet18",
        "PayloadConfig": {
            "SamplePayloadUrl": "s3://{bucket}/{payload_s3_key}",
            "SupportedContentTypes": ["image/jpeg"]
        },
        "SupportedEndpointType": "RealTime",
        "DataInputConfig": "[[1,3,256,256]]",
        "Task": "IMAGE_CLASSIFICATION"
    }
}
```

Amazon SageMaker Studio

Create an inference recommendation job in Studio.

1. In your Studio application, choose the home icon (🏠).
2. In the left sidebar of Studio, choose Models.
3. Choose Model Registry from the dropdown list to display models you have registered with the model registry.

   The left panel displays a list of model groups. The list includes all the model groups registered with the model registry in your account, including models registered outside of Studio.
4. Select the name of your model group. When you select your model group, the right pane of Studio displays column heads such as Versions and Setting.

   If you have one or more model packages within your model group, you will see a list of those model packages within the Versions column.
5. Choose the Inference recommender column.
6. Choose an IAM role that grants Inference Recommender permission to access AWS services. You can create a role and attach the AmazonSageMakerFullAccess IAM managed policy to accomplish this. Or you can let Studio create a role for you.
7. Choose Get recommendations.

   The inference recommendation can take up to 45 minutes.

   Warning
   Do not close this tab. If you close this tab, you cancel the instance recommendation job.

SageMaker console

Create an instance recommendation job through the SageMaker console by doing the following:

2. In the left navigation pane, choose Inference, and then choose Inference recommender.
3. On the Inference recommender jobs page, choose Create job.
4. For Step 1: Model configuration, do the following:
   a. For Job type, choose Default recommender job.
b. If you're using a model registered in the SageMaker model registry, then turn on the Choose a model from the model registry toggle and do the following:
   i. From the Model group dropdown list, choose the model group in SageMaker model registry where your model is located.
   ii. From the Model version dropdown list, choose the desired version of your model.

c. If you're using a model that you've created in SageMaker, then turn off the Choose a model from the model registry toggle and do the following:
   • For the Model name field, enter the name of your SageMaker model.

d. From the IAM role dropdown list, you can select an existing AWS IAM role that has the necessary permissions to create an instance recommendation job. Alternatively, if you don't have an existing role, you can choose Create a new role to open the role creation pop-up, and SageMaker adds the necessary permissions to the new role that you create.

e. For S3 bucket for benchmarking payload, enter the Amazon S3 path to your sample payload archive, which should contain sample payload files that Inference Recommender uses to benchmark your model on different instance types.

f. For Payload content type, enter the MIME types of your sample payload data.

g. (Optional) If you turned off the Choose a model from the model registry toggle and specified a SageMaker model, then for Container configuration, do the following:
   i. For the Domain dropdown list, select the machine learning domain of the model, such as computer vision, natural language processing, or machine learning.
   ii. For the Framework dropdown list, select the framework of your container, such as TensorFlow or XGBoost.
   iii. For Framework version, enter the framework version of your container image.
   iv. For the Nearest model name dropdown list, select the pre-trained model that mostly closely matches your own.
   v. For the Task dropdown list, select the machine learning task that the model accomplishes, such as image classification or regression.

h. (Optional) For Model compilation using SageMaker Neo, you can configure the recommendation job for a model that you've compiled using SageMaker Neo. For Data input configuration, enter the correct input data shape for your model in a format similar to `{'input': [1, 1024, 1024, 3]}`.

   i. Choose Next.

5. For Step 2: Instances and environment parameters, do the following:
   a. (Optional) For Select instances for benchmarking, you can select up to 8 instance types that you want to benchmark. If you don't select any instances, Inference Recommender considers all instance types.

   b. Choose Next.

6. For Step 3: Job parameters, do the following:
   a. (Optional) For the Job name field, enter a name for your instance recommendation job. When you create the job, SageMaker appends a timestamp to the end of this name.
   b. (Optional) For the Job description field, enter a description for the job.
   c. (Optional) For the Encryption key dropdown list, choose an AWS KMS key by name or enter its ARN to encrypt your data.
   d. (Optional) For Max test duration (s), enter the maximum number of seconds you want each test to run for.
   e. (Optional) For Max invocations per minute, enter the maximum number of requests per minute the endpoint can reach before stopping the recommendation job. After reaching this limit, SageMaker ends the job.
f. (Optional) For **P99 Model latency threshold (ms)**, enter the model latency percentile in milliseconds.

g. Choose **Next**.

7. For **Step 4: Review job**, review your configurations and then choose **Submit**.

### Get your inference recommendation job results

Collect the results of your inference recommendation job programmatically with AWS SDK for Python (Boto3), the AWS CLI, Studio, or the SageMaker console.

**AWS SDK for Python (Boto3)**

Once an inference recommendation is complete, you can use `DescribeInferenceRecommendationsJob` to get the job details and recommendations. Provide the job name that you used when you created the inference recommendation job.

```python
job_name='<INSERT>'
response = sagemaker_client.describe_inference_recommendations_job(
    JobName=job_name)
```

Print the response object. The previous code sample stored the response in a variable name `response`.

```python
print(response['Status'])
```

This returns a JSON response similar to the following example. Note that this example shows the recommended instance types for real-time inference (for an example showing serverless inference recommendations, see the example after this one).

```json
{
  'JobName': 'job-name',
  'JobDescription': 'job-description',
  'JobType': 'Default',
  'Status': 'COMPLETED',
  'CreationTime': datetime.datetime(2021, 10, 26, 20, 4, 57, 627000, tzinfo=tzlocal()),
  'LastModifiedTime': datetime.datetime(2021, 10, 26, 20, 25, 1, 997000, tzinfo=tzlocal()),
  'InputConfig': {
    'JobDurationIn_SECONDS': 0
  },
  'InferenceRecommendations': [{
    'Metrics': {
      'CostPerHour': 0.20399999618530273,
      'CostPerInference': 5.246913588052848e-06,
      'MaximumInvocations': 648,
      'ModelLatency': 263596
    },
    'EndpointConfiguration': {
      'EndpointName': 'endpoint-name',
      'VariantName': 'variant-name',
      'InstanceType': 'ml.c5.xlarge',
      'InitialInstanceCount': 1
    }
  }],
  'ModelConfiguration': {
```

2356
The first few lines provide information about the inference recommendation job itself. This includes the job name, role ARN, and creation and deletion times.

The `InferenceRecommendations` dictionary contains a list of Inference Recommender inference recommendations.

The `EndpointConfiguration` nested dictionary contains the instance type (`InstanceType`) recommendation along with the endpoint and variant name (a deployed AWS machine learning model) that was used during the recommendation job. You can use the endpoint and variant name for monitoring in Amazon CloudWatch Events. See Monitor Amazon SageMaker with Amazon CloudWatch (p. 3577) for more information.
The Metrics nested dictionary contains information about the estimated cost per hour (CostPerHour) for your real-time endpoint in US dollars, the estimated cost per inference (CostPerInference) in US dollars for your real-time endpoint, the expected maximum number of InvokeEndpoint requests per minute sent to the endpoint (MaxInvocations), and the model latency (ModelLatency), which is the interval of time (in microseconds) that your model took to respond to SageMaker. The model latency includes the local communication times taken to send the request and to fetch the response from the container of a model and the time taken to complete the inference in the container.

The following example shows the InferenceRecommendations part of the response for an inference recommendations job configured to return serverless inference recommendations:

```
"InferenceRecommendations": [
  {
    "EndpointConfiguration": {
      "EndpointName": "value",
      "InitialInstanceCount": value,
      "InstanceType": "value",
      "VariantName": "value",
      "ServerlessConfig": {
        "MaxConcurrency": value,
        "MemorySizeInMb": value
      }
    },
    "InvocationEndTime": value,
    "InvocationStartTime": value,
    "Metrics": {
      "CostPerHour": value,
      "CostPerInference": value,
      "CpuUtilization": value,
      "MaxInvocations": value,
      "MemoryUtilization": value,
      "ModelLatency": value,
      "ModelSetupTime": value
    },
    "ModelConfiguration": {
      "Compiled": "False",
      "EnvironmentParameters": [],
      "InferenceSpecificationName": "value"
    },
    "RecommendationId": "value"
  }
]
```

You can interpret the recommendations for serverless inference similarly to the results for real-time inference, with the exception of the ServerlessConfig, which tells you the metrics returned for a serverless endpoint with the given MemorySizeInMB and when MaxConcurrency = 1. To increase the throughput possible on the endpoint, increase the value of MaxConcurrency linearly. For example, if the inference recommendation shows MaxInvocations as 1000, then increasing MaxConcurrency to 2 would support 2000 MaxInvocations. Note that this is true only up to a certain point, which can vary based on your model and code. Serverless recommendations also measure the metric ModelSetupTime, which measures (in microseconds) the time it takes to launch computer resources on a serverless endpoint. For more information about setting up serverless endpoints, see the [Serverless Inference documentation](#).

**AWS CLI**

Once an inference recommendation is complete, you can use `describe-inference-recommendations-job` to get the job details and recommended instance types. Provide the job name that you used when you created the inference recommendation job.

```
aws sagemaker describe-inference-recommendations-job
```
--job-name <job-name>\n--region <aws-region>

The JSON response similar should resemble the following example. Note that this example shows the recommended instance types for real-time inference (for an example showing serverless inference recommendations, see the example after this one).

```json
{
    'JobName': 'job-name',
    'JobDescription': 'job-description',
    'JobType': 'Default',
    'JobArn': 'arn:aws:sagemaker:region:account-id:inference-recommendations-
job/resource-id',
    'Status': 'COMPLETED',
    'CreationTime': datetime.datetime(2021, 10, 26, 20, 4, 57, 627000,
    tzinfo=tzlocal()),
    'LastModifiedTime': datetime.datetime(2021, 10, 26, 20, 25, 1, 997000,
    tzinfo=tzlocal()),
    'InputConfig': {
        'ModelPackageVersionArn': 'arn:aws:sagemaker:region:account-id:
model-package/resource-id',
        'JobDurationInSeconds': 0
    },
    'InferenceRecommendations': [{
        'Metrics': {
            'CostPerHour': 0.20399999618530273,
            'CostPerInference': 5.246913588052848e-06,
            'MaximumInvocations': 648,
            'ModelLatency': 263596
        },
        'EndpointConfiguration': {
            'EndpointName': 'endpoint-name',
            'VariantName': 'variant-name',
            'InstanceType': 'ml.c5.xlarge',
            'InitialInstanceCount': 1
        },
        'ModelConfiguration': {
            'Compiled': False,
            'EnvironmentParameters': []
        }
    },
    {
        'Metrics': {
            'CostPerHour': 0.11500000208616257,
            'CostPerInference': 2.92620870823157e-06,
            'MaximumInvocations': 658,
            'ModelLatency': 23596
        },
        'EndpointConfiguration': {
            'EndpointName': 'endpoint-name',
            'VariantName': 'variant-name',
            'InstanceType': 'ml.c5d.large',
            'InitialInstanceCount': 1
        },
        'ModelConfiguration': {
            'Compiled': False,
            'EnvironmentParameters': []
        }
    },
    {
        'Metrics': {
            'CostPerHour': 0.11500000208616257,
            'CostPerInference': 3.3625731248321244e-06,
            'MaximumInvocations': 570,
```
InferenceRecommendations dictionary contains a list of Inference Recommender inference recommendations. The EndpointConfiguration nested dictionary contains the instance type (InstanceType) recommendation along with the endpoint and variant name (a deployed AWS machine learning model) used during the recommendation job. You can use the endpoint and variant name for monitoring in Amazon CloudWatch Events. See Monitor Amazon SageMaker with Amazon CloudWatch (p. 3577) for more information.

The Metrics nested dictionary contains information about the estimated cost per hour (CostPerHour) in US dollars for your real-time endpoint, the estimated cost per inference (CostPerInference) in US dollars for your real-time endpoint, the expected maximum number of InvokeEndpoint requests per minute sent to the endpoint (MaxInvocations), and the model latency (ModelLatency), which is the interval of time (in milliseconds) that your model took to respond to SageMaker. The model latency includes the local communication times taken to send the request and to fetch the response from the container of a model and the time taken to complete the inference in the container.

The following example shows the InferenceRecommendations part of the response for an inference recommendations job configured to return serverless inference recommendations:

```json
"InferenceRecommendations": [
  {
    "EndpointConfiguration": {
      "EndpointName": "value",
      "InitialInstanceCount": value,
      "InstanceType": "value",
      "VariantName": "value",
      "ServerlessConfig": {
        "MaxConcurrency": value,
        "MemorySizeInMb": value
      }
    }
  }
]
You can interpret the recommendations for serverless inference similarly to the results for real-time inference, with the exception of the `ServerlessConfig`, which tells you the metrics returned for a serverless endpoint with the given `MemorySizeInMB` and when `MaxConcurrency = 1`. To increase the throughput possible on the endpoint, increase the value of `MaxConcurrency` linearly. For example, if the inference recommendation shows `MaxInvocations` as 1000, then increasing `MaxConcurrency` to 2 would support 2000 `MaxInvocations`. Note that this is true only up to a certain point, which can vary based on your model and code. Serverless recommendations also measure the metric `ModelSetupTime`, which measures (in microseconds) the time it takes to launch computer resources on a serverless endpoint. For more information about setting up serverless endpoints, see the [Serverless Inference documentation](https://docs.aws.amazon.com/sagemaker/latest/dg/serverless-inference.html).

**Amazon SageMaker Studio**

The inference recommendations populate in a new **Inference recommendations** tab within Studio. It can take up to 45 minutes for the results to show up. This tab contains **Results** and **Details** column headings.

The **Details** column provides information about the inference recommendation job, such as the name of the inference recommendation, when the job was created (**Creation time**), and more. It also provides **Settings** information, such as the maximum number of invocations that occurred per minute and information about the Amazon Resource Names used.

The **Results** column provides a **Deployment goals** and **SageMaker recommendations** window in which you can adjust the order that the results are displayed based on deployment importance. There are three dropdown menus that you can use to provide the level of importance of the Cost, Latency, and Throughput for your use case. For each goal (cost, latency, and throughput), you can set the level of importance: Lowest Importance, Low Importance, Moderate importance, High importance, or Highest importance.

Based on your selections of importance for each goal, Inference Recommender displays its top recommendation in the **SageMaker recommendation** field on the right of the panel, along with the estimated cost per hour and inference request. It also provides information about the expected model latency, maximum number of invocations, and the number of instances. For serverless recommendations, you can see the ideal values for the maximum concurrency and endpoint memory size.

In addition to the top recommendation displayed, you can also see the same information displayed for all instances that Inference Recommender tested in the **All runs** section.

**SageMaker console**

You can view your instance recommendation jobs in the SageMaker console by doing the following:
2. In the left navigation pane, choose Inference, and then choose Inference recommender.
3. On the Inference recommender jobs page, choose the name of your inference recommendation job.

On the details page for your job, you can view the Inference recommendations, which are the instance types SageMaker recommends for your model, as shown in the following screenshot.

In this section, you can compare the instance types by various factors such as Model latency, Cost per hour, Cost per inference, and Invocations per minute.

On this page, you can also view the configurations you specified for your job. In the Monitor section, you can view the Amazon CloudWatch metrics that were logged for each instance type. To learn more about interpreting these metrics, see Interpret results.

For more information about interpreting the results of your recommendation job, see Interpret recommendation results (p. 2368).

Stop your inference recommendation

Stop your Inference Recommender inference recommendation jobs programmatically with the StopInferenceRecommendationsJob API or with Studio.

AWS SDK for Python (Boto3)

Specify the name of the inference recommendation job for the JobName field:

```python
sagemaker_client.stop_inference_recommendations_job(
    JobName='<INSERT>'
)
```

AWS CLI

Specify the job name of the inference recommendation job for the job-name flag:

```bash
aws sagemaker stop-inference-recommendations-job --job-name <job-name>
```

Amazon SageMaker Studio

Close the tab in which you initiated the inference recommendation to stop your Inference Recommender inference recommendation.

SageMaker console

To stop your instance recommendation job through the SageMaker console, do the following:
2. In the left navigation pane, choose Inference, and then choose Inference recommender.
3. On the Inference recommender jobs page, select your instance recommendation job.
4. Choose Stop job.
5. In the dialog box that pops up, choose Confirm.

After stopping your job, the job's Status should change to Stopping.

Get an inference recommendation for an existing endpoint

Inference recommendation jobs run a set of load tests on recommended instance types and an existing endpoint. Inference recommendation jobs use performance metrics that are based on load tests using the sample data you provided during model version registration.

You can benchmark and get inference recommendations for an existing SageMaker Inference endpoint to help you improve the performance of your endpoint. The procedure of getting recommendations for an existing SageMaker Inference endpoint is similar to the procedure for getting inference recommendations without an endpoint. There are several feature exclusions to take note of when benchmarking an existing endpoint:

- You can only use one existing endpoint per Inference Recommender job.
- You can only have one variant on your endpoint.
- You can’t use an endpoint that enables autoscaling.
- This functionality is only supported for Real-Time Inference.
- This functionality doesn’t support Real-Time Multi-Model Endpoints.

Warning

We strongly recommend that you don’t run an Inference Recommender job on a production endpoint that handles live traffic. The synthetic load during benchmarking can affect your production endpoint and cause throttling or provide inaccurate benchmark results. We recommend that you use a non-production or developer endpoint for comparison purposes.

The following sections demonstrate how to use Amazon SageMaker Inference Recommender to create an inference recommendation for an existing endpoint based on your model type using the AWS SDK for Python (Boto3) and the AWS CLI.

Note

Before you create an Inference Recommender recommendation job, make sure you have satisfied the Prerequisites (p. 2341).

Prerequisites

If you don’t already have a SageMaker Inference endpoint, you can either get an inference recommendation without an endpoint, or you can create a Real-Time Inference endpoint by following the instructions in Create your endpoint and deploy your model.

Create an inference recommendation job for an existing endpoint

Create an inference recommendation programmatically using AWS SDK for Python (Boto3), or the AWS CLI. Specify a job name for your inference recommendation, the name of an existing SageMaker Inference endpoint, an AWS IAM role ARN, an input configuration, and your model package ARN from when you registered your model with the model registry.
AWS SDK for Python (Boto3)

Use the `CreateInferenceRecommendationsJob` API to get an inference recommendation. Set the `JobType` field to `Default` for inference recommendation jobs. In addition, provide the following:

- Provide a name for your Inference Recommender recommendation job for the `JobName` field. The Inference Recommender job name must be unique within the AWS Region and within your AWS account.
- The Amazon Resource Name (ARN) of an IAM role that enables Inference Recommender to perform tasks on your behalf. Define this for the `RoleArn` field.
- The ARN of the versioned model package you created when you registered your model with the model registry. Define this for the `ModelPackageVersionArn` field in the `InputConfig` field.
- Provide the name of an existing SageMaker Inference endpoint that you want to benchmark in Inference Recommender for `Endpoints` in the `InputConfig` field.

Import the AWS SDK for Python (Boto3) package and create a SageMaker client object using the client class. If you followed the steps in the Prerequisites section, the model package group ARN was stored in a variable named `model_package_arn`.

```python
# Create a low-level SageMaker service client.
import boto3
aws_region = '<region>'
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Provide your model package ARN that was created when you registered your
# model with Model Registry
model_package_arn = '<model-package-arn>'

# Provide a unique job name for SageMaker Inference Recommender job
job_name = '<job-name>'

# Inference Recommender job type. Set to Default to get an initial recommendation
job_type = 'Default'

# Provide an IAM Role that gives SageMaker Inference Recommender permission to
# access AWS services
role_arn = '<arn:aws:iam::<account>:role/*>'

# Provide endpoint name for your endpoint that want to benchmark in Inference
Recommender
endpoint_name = '<existing-endpoint-name>'

sagemaker_client.create_inference_recommendations_job(
    JobName = job_name,
    JobType = job_type,
    RoleArn = role_arn,
    InputConfig = {
        'ModelPackageVersionArn': model_package_arn,
        'Endpoints': ['EndpointName': endpoint_name]
    }
)
```

See the [Amazon SageMaker API Reference Guide](https://docs.aws.amazon.com/sagemaker/latest/dg/API_CreateInferenceRecommendationsJob.html) for a full list of optional and required arguments you can pass to `CreateInferenceRecommendationsJob`.

AWS CLI

Use the `create-inference-recommendations-job` API to get an instance endpoint recommendation. Set the `job-type` field to `Default` for instance endpoint recommendation jobs. In addition, provide the following:
• Provide a name for your Inference Recommender recommendation job for the job-name field. The Inference Recommender job name must be unique within the AWS Region and within your AWS account.

• The Amazon Resource Name (ARN) of an IAM role that enables Amazon SageMaker Inference Recommender to perform tasks on your behalf. Define this for the role-arn field.

• The ARN of the versioned model package you created when you registered your model with Model Registry. Define this for ModelPackageVersionArn in the input-config field.

• Provide the name of an existing SageMaker Inference endpoint that you want to benchmark in Inference Recommender for Endpoints in the input-config field.

```
aws sagemaker create-inference-recommendations-job
   --region <region>
   --job-name <job_name>
   --job-type Default
   --role-arn arn:aws:iam::<account:role/>
   --input-config "{
     "Endpoints": [{"EndpointName": <endpoint_name>}]"
   }
```

Get your inference recommendation job results

You can collect the results of your inference recommendation job programmatically with the same procedure for standard inference recommendation jobs. For more information, see Get your inference recommendation job results (p. 2356).

When you get inference recommendation job results for an existing endpoint, you should receive a JSON response similar to the following:

```
{
    "JobName": "job-name",
    "JobType": "Default",
    "RoleArn": "iam-role-arn",
    "Status": "COMPLETED",
    "CreationTime": 1664922919.2,
    "LastModifiedTime": 1664924208.291,
    "InputConfig": {
        "Endpoints": [
            {
                "EndpointName": "endpoint-name"
            }
        ],
    },
    "InferenceRecommendations": [
        {
            "Metrics": {
                "CostPerHour": 0.7360000014305115,
                "CostPerInference": 7.456940238625975e-06,
                "MaxInvocations": 1645,
                "ModelLatency": 171
            },
            "EndpointConfiguration": {
                "EndpointName": "sm-endpoint-name",
                "VariantName": "variant-name",
                "InstanceType": "ml.g4dn.xlarge",
```
The first few lines provide information about the inference recommendation job itself. This includes the job name, role ARN, and creation and latest modification times.

The `InferenceRecommendations` dictionary contains a list of Inference Recommender inference recommendations.

The `EndpointConfiguration` nested dictionary contains the instance type (`InstanceType`) recommendation along with the endpoint and variant name (a deployed AWS machine learning model) that was used during the recommendation job.

The `Metrics` nested dictionary contains information about the estimated cost per hour (`CostPerHour`) for your real-time endpoint in US dollars, the estimated cost per inference (`CostPerInference`) in US dollars for your real-time endpoint, the expected maximum number of `InvokeEndpoint` requests per minute sent to the endpoint (`MaxInvocations`), and the model latency (`ModelLatency`), which is the interval of time (in milliseconds) that your model took to respond to SageMaker. The model latency includes the local communication times taken to send the request and to fetch the response from the container of a model and the time taken to complete the inference in the container.

The `EndpointPerformances` nested dictionary contains the name of your existing endpoint on which the recommendation job was run (`EndpointName`) and the performance metrics for your endpoint (`MaxInvocations` and `ModelLatency`).

**Stop your instance endpoint recommendation**

You can stop your Inference Recommender inference recommendation jobs programmatically with the same procedure for standard inference recommendation jobs. For more information, see [Stop your inference recommendation](p. 2362).

**Get compiled recommendations with Neo**

In Inference Recommender, you can compile your model with Neo and get endpoint recommendations for your compiled model. SageMaker Neo is a service that can optimize your model for a target hardware platform (that is, a specific instance type or environment). Optimizing a model with Neo might improve the performance of your hosted model.
For Neo-supported frameworks and containers, Inference Recommender automatically suggests Neo-optimized recommendations. To be eligible for Neo compilation, your input must meet the following prerequisites:

- You are using a SageMaker owned DLC or XGBoost container.
- You are using a framework version supported by Neo. For the framework versions supported by Neo, see Cloud Instances (p. 2709) in the SageMaker Neo documentation.
- Neo requires that you provide a correct input data shape for your model. You can specify this data shape as the DataInputConfig in the InferenceSpecification when you create a model package. For information about the correct data shapes for each framework, see Prepare Model for Compilation in the SageMaker Neo documentation.

The following example shows how to specify the DataInputConfig field in the InferenceSpecification, where data_input_configuration is a variable that contains the data shape in dictionary format (for example, {'input':[1,1024,1024,3]}).

```
"InferenceSpecification": {
  "Containers": [
    {
      "Image": dlc_uri,
      "Framework": framework.upper(),
      "FrameworkVersion": framework_version,
      "NearestModelName": model_name,
      "ModelInput": {"DataInputConfig": data_input_configuration},
    }
  ],
  "SupportedContentTypes": input_mime_types,  # required, must be non-null
  "SupportedResponseMIMETypes": [],
  "SupportedRealtimeInferenceInstanceTypes": supported_realtime_inference_types,  # optional
}
```

If these conditions are met in your request, then Inference Recommender runs scenarios for both compiled and uncompiled versions of your model, giving you multiple recommendation combinations to choose from. You can compare the configurations for compiled and uncompiled versions of the same inference recommendation and determine which one best suits your use case. The recommendations are ranked by cost per inference.

To get the Neo compilation recommendations, you don’t have to do any additional configuration besides making sure that your input meets the above requirements. Inference Recommender automatically runs Neo compilation on your model if your input meets the requirements, and you'll receive a response that includes Neo recommendations.

If you run into errors during your Neo compilation, see Troubleshoot Neo Compilation Errors (p. 2754).

The following table is an example of a response you might get from an Inference Recommender job that includes recommendations for compiled models. If the InferenceSpecificationName field is None, then the recommendation is an uncompiled model. The last row, where the value for the InferenceSpecificationName field is neo-00011122-2333-4445-5566-677788899900, is for a model compiled with Neo. The value in the field is the name of the Neo job used to compile and optimize your model.

<table>

</tbody>
</table>
Get started

The general steps for creating an Inference Recommender job that includes Neo-optimized recommendations are as follows:

- Prepare your ML model for compilation. For more information, see Prepare Model for Compilation in the Neo documentation.
- Package your model in a model archive (.tar.gz file).
- Create a sample payload archive.
- Register your model in Model Registry.
- Create an Inference Recommender job.
- View the results of the Inference Recommender job and choose a configuration.
- Debug compilation failures, if any. For more information, see Troubleshoot Neo Compilation Errors.

For an example that demonstrates the previous workflow and how to get Neo-optimized recommendations using XGBoost, see the following example notebook. For an example that show how to get Neo-optimized recommendations using TensorFlow, see the following example notebook.

Interpret recommendation results

Each Inference Recommender job result includes InstanceType, InitialInstanceCount, and EnvironmentParameters, which are tuned environment variable parameters for your container to improve its latency and throughput. The results also include performance and cost metrics such as MaxInvocations, ModelLatency, CostPerHour, CostPerInference, CpuUtilization, and MemoryUtilization.

In the table below we provide a description of these metrics. These metrics can help you narrow down your search for the best endpoint configuration that suits your use case. For example, if your motivation is overall price performance with an emphasis on throughput, then you should focus on CostPerInference.
### Recommendation jobs

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
<th>Use case</th>
</tr>
</thead>
<tbody>
<tr>
<td>to complete the inference in the container.</td>
<td>Units: Milliseconds</td>
<td>Throughput-focused workloads such as video processing or batch inference</td>
</tr>
<tr>
<td>MaximumInvocations</td>
<td>The maximum number of InvokeEndpoint requests sent to a model endpoint in a minute.</td>
<td>Units: None</td>
</tr>
<tr>
<td>CostPerHour</td>
<td>The estimated cost per hour for your real-time endpoint.</td>
<td>Cost sensitive workloads with no latency deadlines</td>
</tr>
<tr>
<td>CostPerInference</td>
<td>The estimated cost per inference call for your real-time endpoint.</td>
<td>Maximize overall price performance with a focus on throughput</td>
</tr>
<tr>
<td>CpuUtilization</td>
<td>The expected CPU utilization at maximum invocations per minute for the endpoint instance.</td>
<td>Understand instance health during benchmarking by having visibility into core CPU utilization of the instance</td>
</tr>
<tr>
<td>MemoryUtilization</td>
<td>The expected memory utilization at maximum invocations per minute for the endpoint instance.</td>
<td>Understand instance health during benchmarking by having visibility into core memory utilization of the instance</td>
</tr>
</tbody>
</table>

In some cases you might want to explore other SageMaker Endpoint Invocation metrics such as CPUUtilization. Every Inference Recommender job result includes the names of endpoints spun up during the load test. You can use CloudWatch to review the logs for these endpoints even after they've been deleted.

The following image is an example of CloudWatch metrics and charts you can review for a single endpoint from your recommendation result. This recommendation result is from a Default job. The way to interpret the scalar values from the recommendation results is that they are based on the time point when the Invocations graph first begins to level out. For example, the ModelLatency value reported is at the beginning of the plateau around 03:00:31.
For full descriptions of the CloudWatch metrics used in the preceding charts, see SageMaker Endpoint Invocation metrics.

You can also see performance metrics like ClientInvocations and NumberOfUsers published by Inference Recommender in the /aws/sagemaker/InferenceRecommendationsJobs namespace. For a full list of metrics and descriptions published by Inference Recommender, see SageMaker Inference Recommender Jobs Metrics (p. 3585).

See the Amazon SageMaker Inference Recommender - CloudWatch Metrics Jupyter notebook in the amazon-sagemaker-examples Github repository for an example of how to use the AWS SDK for Python (Boto3) to explore CloudWatch metrics for your endpoints.

Get autoscaling policy recommendations

With Amazon SageMaker Inference Recommender, you can get recommendations for autoscaling policies for your SageMaker endpoint based on your anticipated traffic pattern. If you’ve already completed an inference recommendation job, you can provide the details of the job to get a recommendation for an autoscaling policy that you can apply to your endpoint.

Inference Recommender benchmarks different values for each metric to determine the ideal autoscaling configuration for your endpoint. The autoscaling recommendation returns a recommended autoscaling policy for each metric that was defined in your inference recommendation job. You can save the policies and apply them to your endpoint with the PutScalingPolicy API.

To get started, review the following prerequisites.

Prerequisites

Before you begin, you must have completed a successful inference recommendation job. In the following section, you can provide either an inference recommendation ID or the name of a SageMaker endpoint that was benchmarked during an inference recommendation job.
To retrieve your recommendation job ID or endpoint name, you can either view the details of your inference recommendation job in the SageMaker console, or you can use the RecommendationId or EndpointName fields returned by the DescribeInferenceRecommendationsJob API.

Create an autoscaling configuration recommendation

To create an autoscaling recommendation policy, you can use the AWS SDK for Python (Boto3).

The following example shows the fields for the GetScalingConfigurationRecommendation API. Use the following fields when you call the API:

- **InferenceRecommendationsJobName** – Enter the name of your inference recommendation job.
- **RecommendationId** – Enter the ID of an inference recommendation from a recommendation job. This is optional if you've specified the EndpointName field.
- **EndpointName** – Enter the name of an endpoint that was benchmarked during an inference recommendation job. This is optional if you've specified the RecommendationId field.
- **TargetCpuUtilizationPerCore** – (Optional) Enter a percentage value of how much utilization you want an instance on your endpoint to use before autoscaling. The default value if you don't specify this field is 50%.
- **ScalingPolicyObjective** – (Optional) An object where you specify your anticipated traffic pattern.
  - **MinInvocationsPerMinute** – (Optional) The minimum number of expected requests to your endpoint per minute.
  - **MaxInvocationsPerMinute** – (Optional) The maximum number of expected requests to your endpoint per minute.

```json
{
   "InferenceRecommendationsJobName": "string", // Required
   "RecommendationId": "string", // Optional, provide one of RecommendationId or EndpointName
   "EndpointName": "string", // Optional, provide one of RecommendationId or EndpointName
   "TargetCpuUtilizationPerCore": number, // Optional
   "ScalingPolicyObjective": { // Optional
      "MinInvocationsPerMinute": number,
      "MaxInvocationsPerMinute": number
   }
}
```

After submitting your request, you'll receive a response with autoscaling policies defined for each metric. See the following section for information about interpreting the response.

Review your autoscaling configuration recommendation results

The following example shows the response from the GetScalingConfigurationRecommendation API:

```json
{
   "InferenceRecommendationsJobName": "string",
   "RecommendationId": "string", // One of RecommendationId or EndpointName is shown
   "EndpointName": "string",
   "TargetUtilizationPercentage": Integer,
   "ScalingPolicyObjective": {
      "MinInvocationsPerMinute": Integer,
      "MaxInvocationsPerMinute": Integer
   },
   "Metric": {
      "ModelLatency": Integer,
      "InvocationsPerInstance": Integer
   }
}
```
The `InferenceRecommendationsJobName`, `RecommendationID` or `EndpointName`, `TargetCpuUtilizationPerCore`, and the `ScalingPolicyObjective` object fields are copied from your initial request.

The `Metric` object lists the metrics that were benchmarked in your inference recommendation job, along with a calculation of the values for each metric when the instance utilization would be the same as the `TargetCpuUtilizationPerCore` value. This is useful for anticipating the performance metrics on your endpoint when it scales in and out with the recommended autoscaling policy. For example, consider if your instance utilization was 50% in your inference recommendation job and your `InvocationsPerInstance` value was originally 4. If you specify the `TargetCpuUtilizationPerCore` value to be 100% in your autoscaling recommendation request, then the `InvocationsPerInstance` metric value returned in the response is 2 because you anticipated allocating twice as much instance utilization.

The `DynamicScalingConfiguration` object returns the values that you should specify for the `TargetTrackingScalingPolicyConfiguration` when you call the `PutScalingPolicy` API. This includes the recommended minimum and maximum capacity values, the recommended scale in and scale out cooldown times, and the `ScalingPolicies` object, which contains the recommended `TargetValue` you should specify for each metric.

**Run a custom load test**

Amazon SageMaker Inference Recommender load tests conduct extensive benchmarks based on production requirements for latency and throughput, custom traffic patterns, and either serverless endpoints or real-time instances (up to 10) that you select.

The following sections demonstrate how to create, describe, and stop a load test programmatically using the AWS SDK for Python (Boto3) and the AWS CLI, or interactively using Amazon SageMaker Studio or the SageMaker console.

**Create a load test job**

Create a load test programmatically using the AWS SDK for Python (Boto3), with the AWS CLI, or interactively using Studio or the SageMaker console. As with Inference Recommender inference recommendations, specify a job name for your load test, an AWS IAM role ARN, an input configuration,
and your model package ARN from when you registered your model with the model registry. Load tests require that you also specify a traffic pattern and stopping conditions.

AWS SDK for Python (Boto3)

Use the CreateInferenceRecommendationsJob API to create an Inference Recommender load test. Specify Advanced for the JobType field and provide:

- A job name for your load test (JobName). The job name must be unique within your AWS Region and within your AWS account.
- The Amazon Resource Name (ARN) of an IAM role that enables Inference Recommender to perform tasks on your behalf. Define this for the RoleArn field.
- An endpoint configuration dictionary (InputConfig) where you specify the following:
  - For TrafficPattern, specify either the phases or stairs traffic pattern. With the phases traffic pattern, new users spawn every minute at the rate you specify. With the stairs traffic pattern, new users spawn at timed intervals (or steps) at a rate you specify. Choose one of the following:
    - For TrafficType, specify PHASES. Then, for the Phases array, specify the InitialNumberOfUsers (how many concurrent users to start with, with a minimum of 1 and a maximum of 3), SpawnRate (the number of users to be spawned in a minute for a specific phase of load testing, with a minimum of 0 and maximum of 3), and DurationInSeconds (how long the traffic phase should be, with a minimum of 120 and maximum of 3600).
    - For TrafficType, specify STAIRS. Then, for the Stairs array, specify the DurationInSeconds (how long the traffic phase should be, with a minimum of 120 and maximum of 3600), NumberOfSteps (how many intervals are used during the phase), and UsersPerStep (how many users are added during each interval). Note that the length of each step is the value of DurationInSeconds / NumberOfSteps. For example, if your DurationInSeconds is 600 and you specify 5 steps, then each step is 120 seconds long.

  Note
  A user is defined as a system-generated actor that runs in a loop and invokes requests to an endpoint as part of Inference Recommender. For a typical XGBoost container running on an ml.c5.large instance, endpoints can reach 30,000 invocations per minute (500 tps) with just 15-20 users.
  - For ResourceLimit, specify MaxNumberOfTests (the maximum number of benchmarking load tests for an Inference Recommender job, with a minimum of 1 and a maximum of 10) and MaxParallelOfTests (the maximum number of parallel benchmarking load tests for an Inference Recommender job, with a minimum of 1 and a maximum of 10).
- For EndpointConfigurations, you can specify one of the following:
  - The InstanceType field, where you specify the instance type on which you want to run your load tests.
  - The ServerlessConfig, in which you specify your ideal values for MaxConcurrency and MemorySizeInMB for a serverless endpoint. For more information, see the Serverless Inference documentation.
- A stopping conditions dictionary (StoppingConditions), where if any of the conditions are met, the Inference Recommender job stops. For this example, specify the following fields in the dictionary:
  - For MaxInvocations, specify the maximum number of requests per minute expected for the endpoint, with a minimum of 1 and a maximum of 30,000.
  - For ModelLatencyThresholds, specify Percentile (the model latency percentile threshold) and ValueInMilliseconds (the model latency percentile value in milliseconds).
  - (Optional) For FlatInvocations, you can specify whether to continue the load test when the TPS (invocations per minute) rate flattens. A flattened TPS rate usually means that the endpoint has reached capacity. However, you might want to continue monitoring the endpoint
Recommendation jobs

under full capacity conditions. To continue the load test when this happens, specify this value as Continue. Otherwise, the default value is Stop.

```python
# Create a low-level SageMaker service client.
import boto3
aws_region=<INSERT>
sagemaker_client=boto3.client('sagemaker', region=aws_region)

# Provide a name to your recommendation based on load testing
load_test_job_name=<INSERT>

# Provide the name of the sagemaker instance type
instance_type=<INSERT>

# Provide the IAM Role that gives SageMaker permission to access AWS services
role_arn='arn:aws:iam::<account>:role/*'

# Provide your model package ARN that was created when you registered your # model with Model Registry
model_package_arn='arn:aws:sagemaker::<region>::<account>:role/*'

sagemaker_client.create_inference_recommendations_job(
    JobName=load_test_job_name,
    JobType="Advanced",
    RoleArn=role_arn,
    InputConfig={
        'ModelPackageVersionArn': model_package_arn,
        "JobDurationInSeconds": 7200,
        'TrafficPattern': {
            # Replace PHASES with STAIRS to use the stairs traffic pattern
            'TrafficType': 'PHASES',
            'Phases': [
                {'InitialNumberOfUsers': 1,
                 'SpawnRate': 1,
                 'DurationInSeconds': 120},
                {'InitialNumberOfUsers': 1,
                 'SpawnRate': 1,
                 'DurationInSeconds': 120}
            ]
        }#
    },
    'ResourceLimit': {
        'MaxNumberOfTests': 10,
        'MaxParallelOfTests': 3}
),

"EndpointConfigurations": [
    {
        'InstanceType': 'ml.c5.xlarge'
    },
    {
        'InstanceType': 'ml.m5.xlarge'
    },
    {
        'InstanceType': 'ml.r5.xlarge'
    }
]
```
# Uncomment the ServerlessConfig and comment out the InstanceType field if you want recommendations for a serverless endpoint
# "ServerlessConfig": {
#   "MaxConcurrency": value,
#   "MemorySizeInMB": value
# }

},

StoppingConditions={
  'MaxInvocations': 1000,
  'ModellLatencyThresholds':[[
    'Percentile': 'P95',
    'ValueInMilliseconds': 100
  ]],
  # Change 'Stop' to 'Continue' to let the load test continue if invocations flatten
  'FlatInvocations': 'Stop'
}

See the [Amazon SageMaker API Reference Guide](https://docs.aws.amazon.com/sagemaker/latest/dg/API_CreateInferenceRecommendationsJob.html) for a full list of optional and required arguments you can pass to CreateInferenceRecommendationsJob.

**AWS CLI**

Use the `create-inference-recommendations-job` API to create an Inference Recommender load test. Specify Advanced for the JobType field and provide:

- A job name for your load test (job-name). The job name must be unique within your AWS Region and within your AWS account.
- The Amazon Resource Name (ARN) of an IAM role that enables Inference Recommender to perform tasks on your behalf. Define this for the role-arn field.
- An endpoint configuration dictionary (input-config) where you specify the following:
  - For TrafficPattern, specify either the phases or stairs traffic pattern. With the phases traffic pattern, new users spawn every minute at the rate you specify. With the stairs traffic pattern, new users spawn at timed intervals (or steps) at a rate you specify. Choose one of the following:
    - For TrafficType, specify PHASES. Then, for the Phases array, specify the InitialNumberOfUsers (how many concurrent users to start with, with a minimum of 1 and a maximum of 3), SpawnRate (the number of users to be spawned in a minute for a specific phase of load testing, with a minimum of 0 and maximum of 3), and DurationInSeconds (how long the traffic phase should be, with a minimum of 120 and maximum of 3600).
    - For TrafficType, specify STAIRS. Then, for the Stairs array, specify the DurationInSeconds (how long the traffic phase should be, with a minimum of 120 and maximum of 3600), NumberOfSteps (how many intervals are used during the phase), and UsersPerStep (how many users are added during each interval). Note that the length of each step is the value of DurationInSeconds / NumberOfSteps. For example, if your DurationInSeconds is 600 and you specify 5 steps, then each step is 120 seconds long.

  **Note**
  A user is defined as a system-generated actor that runs in a loop and invokes requests to an endpoint as part of Inference Recommender. For a typical XGBoost container running on an ml.c5.large instance, endpoints can reach 30,000 invocations per minute (500 tps) with just 15-20 users.
  - For ResourceLimit, specify MaxNumberOfTests (the maximum number of benchmarking load tests for an Inference Recommender job, with a minimum of 1 and a maximum of 10) and MaxParallelNumberOfTests (the maximum number of parallel benchmarking load tests for an Inference Recommender job, with a minimum of 1 and a maximum of 10).
  - For EndpointConfigurations, you can specify one of the following:
• The **InstanceType** field, where you specify the instance type on which you want to run your load tests.

• The **ServerlessConfig**, in which you specify your ideal values for **MaxConcurrency** and **MemorySizeInMB** for a serverless endpoint.

• A stopping conditions dictionary (**stopping-conditions**), where if any of the conditions are met, the Inference Recommender job stops. For this example, specify the following fields in the dictionary:
  
  • For **MaxInvocations**, specify the maximum number of requests per minute expected for the endpoint, with a minimum of 1 and a maximum of 30,000.
  
  • For **ModelLatencyThresholds**, specify **Percentile** (the model latency percentile threshold) and **ValueInMilliseconds** (the model latency percentile value in milliseconds).

  • (Optional) For **FlatInvocations**, you can specify whether to continue the load test when the TPS (invocations per minute) rate flattens. A flattened TPS rate usually means that the endpoint has reached capacity. However, you might want to continue monitoring the endpoint under full capacity conditions. To continue the load test when this happens, specify this value as **Continue**. Otherwise, the default value is **Stop**.

```bash
aws sagemaker create-inference-recommendations-job
  --region <region>\n  --job-name <job-name>\n  --job-type ADVANCED\n  --role-arn arn:aws:iam::<account>:role/*\n  --input-config "{
    "JobDurationInSeconds": 7200,
    "TrafficPattern": {
      # Replace PHASES with STAIRS to use the stairs traffic pattern
      "TrafficType": "PHASES",
      "Phases": [
        {
          "InitialNumberOfUsers": 1,
          "SpawnRate": 60,
          "DurationInSeconds": 300
        }
      ],
      # Uncomment this section and comment out the Phases object above to use the stairs traffic pattern
      # 'Stairs': {
      #   'DurationInSeconds': 240,
      #   'NumberOfSteps': 2,
      #   'UsersPerStep': 2
      # }
    },
    "ResourceLimit": {
      "MaxNumberOfTests": 10,
      "MaxParallelOfTests": 3
    },
    "EndpointConfigurations": [
      {
        "InstanceType": "ml.c5.xlarge"
      },
      {
        "InstanceType": "ml.m5.xlarge"
      },
      {
        "InstanceType": "ml.r5.xlarge"
      }
    ]
    # Use the ServerlessConfig and leave out the InstanceType fields if you want recommendations for a serverless endpoint
    # "ServerlessConfig": {
  
```

2376
Create a load test with Studio.

1. In your Studio application, choose the home icon (🏠).
2. In the left sidebar of Studio, choose Deployments.
3. Choose Inference recommender from the dropdown list.
5. Select the name of your model group from the dropdown Model group field. The list includes all the model groups registered with the model registry in your account, including models registered outside of Studio.
6. Select a model version from the dropdown Model version field.
7. Choose Continue.
8. Provide a name for the job in the Name field.
9. (Optional) Provide a description of your job in the Description field.
10. Choose an IAM role that grants Inference Recommender permission to access AWS services. You can create a role and attach the AmazonSageMakerFullAccess IAM managed policy to accomplish this, or you can let Studio create a role for you.
11. Choose Stopping Conditions to expand the available input fields. Provide a set of conditions for stopping a deployment recommendation.
   a. Specify the maximum number of requests per minute expected for the endpoint in the Max Invocations Per Minute field.
   b. Specify the model latency threshold in microseconds in the Model Latency Threshold field. The Model Latency Threshold depicts the interval of time taken by a model to respond as viewed from Inference Recommender. The interval includes the local communication time taken to send the request and to fetch the response from the model container and the time taken to complete the inference in the container.
12. Choose Traffic Pattern to expand the available input fields.
   a. Set the initial number of virtual users by specifying an integer in the Initial Number of Users field.
   b. Provide an integer number for the Spawn Rate field. The spawn rate sets the number of users created per second.
   c. Set the duration for the phase in seconds by specifying an integer in the Duration field.
d. (Optional) Add additional traffic patterns. To do so, choose Add.

13. Choose the Additional setting to reveal the Max test duration field. Specify, in seconds, the maximum time a test can take during a job. New jobs are not scheduled after the defined duration. This helps ensure jobs that are in progress are not stopped and that you only view completed jobs.

15. Choose Selected Instances.

16. In the Instances for benchmarking field, choose Add instances to test. Select up to 10 instances for Inference Recommender to use for load testing.

17. Choose Additional settings.

   a. Provide an integer that sets an upper limit on the number of tests a job can make for the Max number of tests field. Note that each endpoint configuration results in a new load test.

   b. Provide an integer for the Max parallel test field. This setting defines an upper limit on the number of load tests that can run in parallel.

18. Choose Submit.

   The load test can take up to 2 hours.

   Warning
   Do not close this tab. If you close this tab, you cancel the Inference Recommender load test job.

SageMaker console

Create a custom load test through the SageMaker console by doing the following:

2. In the left navigation pane, choose Inference, and then choose Inference recommender.

3. On the Inference recommender jobs page, choose Create job.

4. For Step 1: Model configuration, do the following:

   a. For Job type, choose Advanced recommender job.

   b. If you're using a model registered in the SageMaker model registry, then turn on the Choose a model from the model registry toggle and do the following:

      i. For the Model group dropdown list, choose the model group in SageMaker model registry where your model is.

      ii. For the Model version dropdown list, choose the desired version of your model.

   c. If you're using a model that you've created in SageMaker, then turn off the Choose a model from the model registry toggle and do the following:

      • For the Model name field, enter the name of your SageMaker model.

   d. For IAM role, you can select an existing AWS IAM role that has the necessary permissions to create an instance recommendation job. Alternatively, if you don't have an existing role, you can choose Create a new role to open the role creation pop-up, and SageMaker adds the necessary permissions to the new role that you create.

   e. For S3 bucket for benchmarking payload, enter the Amazon S3 path to your sample payload archive, which should contain sample payload files that Inference Recommender uses to benchmark your model on different instance types.

   f. For Payload content type, enter the MIME types of your sample payload data.

   g. For Traffic pattern, configure phases for the load test by doing the following:
i. For **Initial number of users**, specify how many concurrent users you want to start with (with a minimum of 1 and a maximum of 3).

ii. For **Spawn rate**, specify the number of users to be spawned in a minute for the phase (with a minimum of 0 and a maximum of 3).

iii. For **Duration (seconds)**, specify how low the traffic phase should be in seconds (with a minimum of 120 and a maximum of 3600).

h. (Optional) If you turned off the **Choose a model from the model registry toggle** and specified a SageMaker model, then for **Container configuration**, do the following:

i. For the **Domain** dropdown list, select the machine learning domain of the model, such as computer vision, natural language processing, or machine learning.

ii. For the **Framework** dropdown list, select the framework of your container, such as TensorFlow or XGBoost.

iii. For **Framework version**, enter the framework version of your container image.

iv. For the **Nearest model name** dropdown list, select the pre-trained model that mostly closely matches your own.

v. For the **Task** dropdown list, select the machine learning task that the model accomplishes, such as image classification or regression.

i. (Optional) For **Model compilation using SageMaker Neo**, you can configure the recommendation job for a model that you’ve compiled using SageMaker Neo. For **Data input configuration**, enter the correct input data shape for your model in a format similar to `{'input': [1, 1024, 1024, 3]}`.

j. Choose **Next**.

5. For **Step 2: Instances and environment parameters**, do the following:

a. For **Select instances for benchmarking**, select up to 8 instance types that you want to benchmark against.

b. (Optional) For **Environment parameter ranges**, you can specify environment parameters that help optimize your model. Specify the parameters as **Key** and **Value** pairs.

c. Choose **Next**.

6. For **Step 3: Job parameters**, do the following:

a. (Optional) For the **Job name** field, enter a name for your instance recommendation job. When you create the job, SageMaker appends a timestamp to the end of this name.

b. (Optional) For the **Job description** field, enter a description for the job.

c. (Optional) For the **Encryption key** dropdown list, choose an AWS KMS key by name or enter its ARN to encrypt your data.

d. (Optional) For **Max number of tests**, enter the number of test that you want to run during the recommendation job.

e. (Optional) For **Max parallel tests**, enter the maximum number of parallel tests that you want to run during the recommendation job.

f. For **Max test duration (s)**, enter the maximum number of seconds you want each test to run for.

g. For **Max invocations per minute**, enter the maximum number of requests per minute the endpoint can reach before stopping the recommendation job. After reaching this limit, SageMaker ends the job.

h. For **P99 Model latency threshold (ms)**, enter the model latency percentile in milliseconds.

i. Choose **Next**.

7. For **Step 4: Review job**, review your configurations and then choose **Submit**.
Get your load test results

You can programmatically collect metrics across all load tests once the load tests are done with AWS SDK for Python (Boto3), the AWS CLI, Studio, or the SageMaker console.

**AWS SDK for Python (Boto3)**

Collect metrics with the `DescribeInferenceRecommendationsJob` API. Specify the job name of the load test for the `JobName` field:

```python
load_test_response = sagemaker_client.describe_inference_recommendations_job(
    JobName=load_test_job_name
)
```

Print the response object.

```python
load_test_response['Status']
```

This returns a JSON response similar to the following example. Note that this example shows the recommended instance types for real-time inference (for an example showing serverless inference recommendations, see the example after this one).

```json
{
    'JobName': 'job-name',
    'JobDescription': 'job-description',
    'JobType': 'Advanced',
    'Status': 'COMPLETED',
    'CreationTime': datetime.datetime(2021, 10, 26, 19, 38, 30, 957000, tzinfo=tzlocal()),
    'LastModifiedTime': datetime.datetime(2021, 10, 26, 19, 46, 31, 399000, tzinfo=tzlocal()),
    'InputConfig': {
        'JobDurationInSeconds': 7200,
        'TrafficPattern': {
            'TrafficType': 'PHASES'
        },
        'ResourceLimit': {
            'MaxNumberOfTests': 100,
            'MaxParallelOfTests': 100
        },
        'EndpointConfigurations': [{
            'InstanceType': 'ml.c5d.xlarge'
        }],
        'StoppingConditions': {
            'MaxInvocations': 1000,
            'ModellLatencyThresholds': [{
                'Percentile': 'P95',
                'ValueInMilliseconds': 100
            }],
        },
        'InferenceRecommendations': [{
            'Metrics': {
                'CostPerHour': 0.6899999976158142,
                'CostPerInference': 1.0332434612791985e-05,
                'MaximumInvocations': 1113,
                'ModellLatency': 100000
            },
```
The first few lines provide information about the load test job itself. This includes the job name, role ARN, creation, and deletion time.

The InferenceRecommendations dictionary contains a list of Inference Recommender inference recommendations.

The EndpointConfiguration nested dictionary contains the instance type (InstanceType) recommendation along with the endpoint and variant name (a deployed AWS machine learning model) used during the recommendation job. You can use the endpoint and variant name for monitoring in Amazon CloudWatch Events. See Monitor Amazon SageMaker with Amazon CloudWatch (p. 3577) for more information.

The EndpointConfiguration nested dictionary also contains the instance count (InitialInstanceCount) recommendation. This is the number of instances that you should provision in the endpoint to meet the MaxInvocations specified in the StoppingConditions. For example, if the InstanceType is ml.m5.large and the InitialInstanceCount is 2, then you should provision 2 ml.m5.large instances for your endpoint so that it can handle the TPS specified in the MaxInvocations stopping condition.

The Metrics nested dictionary contains information about the estimated cost per hour (CostPerHour) for your real-time endpoint in US dollars, the estimated cost per inference (CostPerInference) for your real-time endpoint, the maximum number of InvokeEndpoint requests sent to the endpoint, and the model latency (ModelLatency), which is the interval of time (in microseconds) that your model took to respond to SageMaker. The model latency includes the local communication times taken to send the request and to fetch the response from the model container and the time taken to complete the inference in the container.

The following example shows the InferenceRecommendations part of the response for a load test job that was configured to return serverless inference recommendations:

```
"InferenceRecommendations": [
  {
    "EndpointConfiguration": {
      "EndpointName": "value",
      "InitialInstanceCount": "value",
      "InstanceType": "value",
      "VariantName": "value",
      "ServerlessConfig": {
        }],
  },
],
"ResponseMetadata": {
  'RequestId': 'request-id',
  'HTTPStatusCode': 200,
  'HTTPHeaders': {
    'x-amzn-requestid': 'x-amzn-requestid',
    'content-type': 'content-type',
    'content-length': '1199',
    'date': 'Tue, 26 Oct 2021 19:57:42 GMT'
  },
  'RetryAttempts': 0
}
```
You can interpret the recommendations for serverless inference similarly to the results for real-time inference, with the exception of the ServerlessConfig, which tells you the values you specified for MaxConcurrency and MemorySizeInMB when setting up the load test. Serverless recommendations also measure the metric ModelSetupTime, which measures (in microseconds) the time it takes to launch compute resources on a serverless endpoint. For more information about setting up serverless endpoints, see the Serverless Inference documentation.

AWS CLI

Collect metrics with the describe-inference-recommendations-job API. Specify the job name of the load test for the job-name flag:

```bash
aws sagemaker describe-inference-recommendations-job --job-name <job-name>
```

This returns a response similar to the following. Note that this example shows the recommended instance types for real-time inference (for an example showing serverless inference recommendations, see the example after this one).

```json
{
    "JobName": "job-name",
    "JobDescription": "job-description",
    "JobType": "Advanced",
    "Status": "COMPLETED",
    "CreationTime": datetime.datetime(2021, 10, 26, 19, 38, 30, 957000, tzinfo=tzlocal()),
    "LastModifiedTime": datetime.datetime(2021, 10, 26, 19, 46, 31, 399000, tzinfo=tzlocal()),
    "InputConfig": {
        "JobDurationInSeconds": 7200,
        "TrafficPattern": {
            "TrafficType": "PHASES"
        },
        "ResourceLimit": {
            "MaxNumberOfTests": 100,
```
The first few lines provide information about the load test job itself. This includes the job name, role ARN, creation, and deletion time.

The InferenceRecommendations dictionary contains a list of Inference Recommender inference recommendations.

The EndpointConfiguration nested dictionary contains the instance type (InstanceType) recommendation along with the endpoint and variant name (a deployed AWS machine learning model) used during the recommendation job. You can use the endpoint and variant name for monitoring in Amazon CloudWatch Events. See Monitor Amazon SageMaker with Amazon CloudWatch (p. 3577) for more information.

The Metrics nested dictionary contains information about the estimated cost per hour (CostPerHour) for your real-time endpoint in US dollars, the estimated cost per inference (CostPerInference) for your real-time endpoint, the maximum number of InvokeEndpoint requests sent to the endpoint, and the model latency (ModellLatency), which is the interval of time (in microseconds) that your model took to respond to SageMaker. The model latency includes the local communication times taken to send the request and to fetch the response from the model container and the time taken to complete the inference in the container.
The following example shows the `InferenceRecommendations` part of the response for a load test job that was configured to return serverless inference recommendations:

```
"InferenceRecommendations": [
  {
    "EndpointConfiguration": {
      "EndpointName": "value",
      "InitialInstanceCount": value,
      "InstanceType": "value",
      "VariantName": "value",
      "ServerlessConfig": {
        "MaxConcurrency": value,
        "MemorySizeInMB": value
      }
    },
    "InvocationEndTime": value,
    "InvocationStartTime": value,
    "Metrics": {
      "CostPerHour": value,
      "CostPerInference": value,
      "CpuUtilization": value,
      "MaxInvocations": value,
      "MemoryUtilization": value,
      "ModelLatency": value,
      "ModelSetupTime": value
    },
    "ModelConfiguration": {
      "Compiled": "False",
      "EnvironmentParameters": [],
      "InferenceSpecificationName": "value"
    },
    "RecommendationId": "value"
  }
]
```

You can interpret the recommendations for serverless inference similarly to the results for real-time inference, with the exception of the `ServerlessConfig`, which tells you the values you specified for `MaxConcurrency` and `MemorySizeInMB` when setting up the load test. Serverless recommendations also measure the metric `ModelSetupTime`, which measures (in microseconds) the time it takes to launch computer resources on a serverless endpoint. For more information about setting up serverless endpoints, see the [Serverless Inference documentation](https://docs.aws.amazon.com/sagemaker/latest/dg/serverless-inference.html).

### Amazon SageMaker Studio

The recommendations populate in a new tab called **Inference recommendations** within Studio. It can take up to 2 hours for the results to show up. This tab contains **Results** and **Details** columns.

The **Details** column provides information about the load test job, such as the name given to the load test job, when the job was created (**Creation time**), and more. It also contains **Settings** information, such as the maximum number of invocations that occurred per minute and information about the Amazon Resource Names used.

The **Results** column provides **Deployment goals** and **SageMaker recommendations** windows in which you can adjust the order in which results are displayed based on deployment importance. There are three dropdown menus in which you can provide the level of importance of the **Cost**, **Latency**, and **Throughput** for your use case. For each goal (cost, latency, and throughput), you can set the level of importance: **Lowest Importance**, **Low Importance**, **Moderate importance**, **High importance**, or **Highest importance**.

Based on your selections of importance for each goal, Inference Recommender displays its top recommendation in the **SageMaker recommendation** field on the right of the panel, along with the estimated cost per hour and inference request. It also provides information about the expected model latency, maximum number of invocations, and the number of instances.
In addition to the top recommendation displayed, you can also see the same information displayed for all instances that Inference Recommender tested in the All runs section.

**SageMaker console**

You can view your custom load test job results in the SageMaker console by doing the following:

2. In the left navigation pane, choose Inference, and then choose Inference recommender.
3. On the Inference recommender jobs page, choose the name of your inference recommendation job.

On the details page for your job, you can view the Inference recommendations, which are the instance types SageMaker recommends for your model, as shown in the following screenshot.

<table>
<thead>
<tr>
<th>Instance</th>
<th>Status</th>
<th>Model latency</th>
<th>Cost per hour</th>
<th>Cost per inference</th>
<th>Invocations per minute</th>
</tr>
</thead>
<tbody>
<tr>
<td>ml.t2.medium</td>
<td>In progress</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>ml.m6.large</td>
<td>Success</td>
<td>11ms</td>
<td>$12.12</td>
<td>$12.12</td>
<td>14</td>
</tr>
<tr>
<td>ml.p3.8xlarge</td>
<td>Success</td>
<td>12ms</td>
<td>$12.12</td>
<td>$12.12</td>
<td>21</td>
</tr>
<tr>
<td>ml.p4.10xlarge</td>
<td>Error</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>

In this section, you can compare the instance types by various factors such as Model latency, Cost per hour, Cost per inference, and Invocations per minute.

On this page, you can also view the configurations you specified for your job. In the Monitor section, you can view the Amazon CloudWatch metrics that were logged for each instance type. To learn more about interpreting these metrics, see Interpret results.

**Stop your load test**

Stop your load test jobs programmatically with the StopInferenceRecommendationsJob API, or through Studio or the SageMaker console.

**AWS SDK for Python (Boto3)**

Specify the job name of the load test for the JobName field:

```python
sagemaker_client.stop_inference_recommendations_job(
    JobName='<INSERT>'
)
```

**AWS CLI**

Specify the job name of the load test for the job-name flag:

```bash
aws sagemaker stop-inference-recommendations-job --job-name <job-name>
```

**Amazon SageMaker Studio**

Close the tab where you initiated your custom load job to stop your Inference Recommender load test.

**SageMaker console**

To stop your load test job through the SageMaker console, do the following:
2. In the left navigation pane, choose Inference, and then choose Inference recommender.
3. On the Inference recommender jobs page, select your load test job.
4. Choose Stop job.
5. In the dialog box that pops up, choose Confirm.

After stopping your job, the job’s Status should change to Stopping.

### Troubleshoot Inference Recommender errors

This section contains information about how to understand and prevent common errors, the error messages they generate, and guidance on how to resolve these errors.

#### How to troubleshoot

You can attempt to resolve your error by going through the following steps:

- Check if you’ve covered all the prerequisites to use Inference Recommender. See the Inference Recommender Prerequisites.
- Check that you are able to deploy your model from Model Registry to an endpoint and that it can process your payloads without errors. See Deploy a Model from the Registry.
- When you kick off an Inference Recommender job, you should see endpoints being created in the console and you can review the CloudWatch logs.

#### Common errors

Review the following table for common Inference Recommender errors and their solutions.

<table>
<thead>
<tr>
<th>Error</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specify Domain in the Model Package version 1. Domain is a mandatory parameter for the job.</td>
<td>Make sure you provide the ML Domain or OTHER if unknown.</td>
</tr>
<tr>
<td>Provided role ARN cannot be assumed and an AWSSecurityTokenServiceException error occurred.</td>
<td>Make sure the execution role provided has the necessary permissions specified in the prerequisites.</td>
</tr>
<tr>
<td>Specify Framework in the Model Package version 1. Framework is a mandatory parameter for the job.</td>
<td>Make sure you provide the ML Framework or OTHER if unknown.</td>
</tr>
<tr>
<td>Users at the end of prev phase is 0 while initial users of current phase is 1.</td>
<td>Users here refers to virtual users or threads used to send requests. Each phase starts with A users and ends with B users such that B &gt; A. Between sequential phases, x_1 and x_2, we require that abs(x_2.A - x_1.B) &lt;= 3 and &gt;= 0.</td>
</tr>
<tr>
<td>Total Traffic duration (across) should not be more than Job duration.</td>
<td>The total duration of all your Phases cannot exceed the Job duration.</td>
</tr>
<tr>
<td>Burstable instance type ml.t2.medium is not allowed.</td>
<td>Inference Recommender doesn’t support load testing on t2 instance family because burstable instances do not provide consistent performance.</td>
</tr>
<tr>
<td>Error</td>
<td>Solution</td>
</tr>
<tr>
<td>----------------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ResourceLimitExceeded when calling CreateEndpoint operation</td>
<td>You have exceeded a SageMaker resource limit. For example, Inference Recommender might be unable to provision endpoints for benchmarking if the account has reached the endpoint quota. For more information about SageMaker limits and quotas, see Amazon SageMaker endpoints and quotas.</td>
</tr>
<tr>
<td>ModelError when calling InvokeEndpoint operation</td>
<td>A model error can happen for the following reasons:</td>
</tr>
<tr>
<td></td>
<td>• The invocation timed out while waiting for a response from the model container.</td>
</tr>
<tr>
<td></td>
<td>• The model couldn’t process the input payload.</td>
</tr>
<tr>
<td>PayloadError when calling InvokeEndpoint operation</td>
<td>A payload error can happen for following reasons:</td>
</tr>
<tr>
<td></td>
<td>• The payload source isn’t in the Amazon S3 bucket.</td>
</tr>
<tr>
<td></td>
<td>• The payload is in a non-file object format.</td>
</tr>
<tr>
<td></td>
<td>• The payload is in an invalid file type. For example, a model expects an image type payload but is passed a text file.</td>
</tr>
<tr>
<td></td>
<td>• The payload is empty.</td>
</tr>
</tbody>
</table>

**Check CloudWatch**

When you kick off an Inference Recommender job, you should see endpoints being created in the console. Select one of the endpoints and view the CloudWatch logs to monitor for any 4xx/5xx errors. If you have a successful Inference Recommender job, you will be able to see the endpoint names as part of the results. Even if your Inference Recommender job is unsuccessful, you can still check the CloudWatch logs for the deleted endpoints by following the steps below:

1. Open the Amazon CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. Select the Region in which you created the Inference Recommender job from the Region dropdown list in the top right.
3. In the navigation pane of CloudWatch, choose Logs, and then select Log groups.
4. Search for the log group called /aws/sagemaker/Endpoints/sm-epc-*. Select the log group based on your most recent Inference Recommender job.

You can also troubleshoot your job by checking the Inference Recommender CloudWatch logs. The Inference Recommender logs, which are published in the /aws/sagemaker/InferenceRecommendationsJobs CloudWatch log group, give a high level view on the progress of the job in the <jobName>/execution log stream. You can find detailed information on each of the endpoint configurations being tested in the <jobName>/Endpoint/<endpointName> log stream.

**Overview of the Inference Recommender log streams**

- <jobName>/execution contains overall job information such as endpoint configurations scheduled for benchmarking, compilation job skip reason, and validation failure reason.
- <jobName>/Endpoint/<endpointName> contains information such as resource creation progress, test configuration, load test stop reason, and resource cleanup status.
Create an alarm for Inference Recommender error messages

Inference Recommender outputs log statements for errors that might be helpful while troubleshooting. With a CloudWatch log group and a metric filter, you can look for terms and patterns in this log data as the data is sent to CloudWatch. Then, you can create a CloudWatch alarm based on the log group-metric filter. For more information, see Create a CloudWatch alarm based on a log group-metric filter.

Check benchmarks

When you kick off an Inference Recommender job, Inference Recommender creates several benchmarks to evaluate the performance of your model on different instance types. You can use the ListInferenceRecommendationsJobSteps API to view the details for all the benchmarks. If you have a failed benchmark, you can see the failure reasons as part of the results.

To use the ListInferenceRecommendationsJobSteps API, provide the following values:

- For JobName, provide the name of the Inference Recommender job.
- For StepType, use BENCHMARK to return details about the job’s benchmarks.
- For Status, use FAILED to return details about only the failed benchmarks. For a list of the other status types, see the Status field in the ListInferenceRecommendationsJobSteps API.

```python
# Create a low-level SageMaker service client.
import boto3
aws_region = '<region>'
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Provide the job name for the SageMaker Inference Recommender job
job_name = '<job-name>'

# Filter for benchmarks
step_type = 'BENCHMARK'

# Filter for benchmarks that have a FAILED status
status = 'FAILED'

response = sagemaker_client.list_inference_recommendations_job_steps(
    JobName = job_name,
    StepType = step_type,
    Status = status
)
```

You can print the response object to view the results. The preceding code example stored the response in a variable called response:

```python
print(response)
```

Real-time inference

Real-time inference is ideal for inference workloads where you have real-time, interactive, low latency requirements. You can deploy your model to SageMaker hosting services and get an endpoint that can be
used for inference. These endpoints are fully managed and support autoscaling (see Automatically Scale Amazon SageMaker Models (p. 2447)).

Topics
- Hosting options (p. 2389)
- Automatically Scale Amazon SageMaker Models (p. 2447)
- Host instance storage volumes (p. 2463)
- Safely validate models in production (p. 2463)
- Online Explainability with SageMaker Clarify (p. 2474)
- Invoke real-time endpoints (p. 2491)

Hosting options

The following topics describe available SageMaker realtime hosting options along with how to set up, invoke, and delete each hosting option.

Topics
- Host a single model (p. 2389)
- Host multiple models in one container behind one endpoint (p. 2399)
- Host multiple models which use different containers behind one endpoint (p. 2426)
- Host models along with pre-processing logic as serial inference pipeline behind one endpoint (p. 2433)

Host a single model

Create, update, and delete real-time inference endpoints that host a single model with the AWS SDK for Python (Boto3), the SageMaker Python SDK, the SageMaker console, or the AWS CLI.

Topics
- Create your endpoint and deploy your model (p. 2389)
- Delete Endpoints and Resources (p. 2395)

Create your endpoint and deploy your model

There are several options to deploy a model using SageMaker hosting services. You can programmatically deploy a model using an AWS SDK (for example, the SDK for Python (Boto3)), the SageMaker Python SDK, the AWS CLI, or you can interactively deploy a model with the SageMaker console. The AWS SDK is a low-level API and supports Java, C++, Go, JavaScript, Node.js, PHP, Ruby, and Python whereas the SageMaker Python SDK is a high-level Python API. The following documentation demonstrates how to deploy a model using the AWS SDK for Python (Boto3) and the SageMaker Python SDK.

Deploying a model using SageMaker hosting services is a three-step process if you use AWS SDK for Python (Boto3), the AWS CLI, or the SageMaker console:

2. Create an endpoint configuration for an HTTPS endpoint.
3. Create an HTTPS endpoint.

Deploying a model using the SageMaker Python SDK does not require that you create an endpoint configuration. It is therefore a two-step process:
1. Create a model object from the Model Class that can be deployed to an HTTPS endpoint.
2. Create an HTTPS endpoint with the Model object's pre-built deploy() method.

To use the proceeding code snippets, replace the italicized placeholder text in the example code with your own information.

Note

- SageMaker supports running (a) multiple models, (b) multiple variants of a model, or (c) combinations of models and variants on the same endpoint. Model variants can reference the same model inference container (i.e. run the same algorithm), but use different model artifacts (e.g., different model weight values based on other hyper-parameter configurations). In contrast, two different models may use the same algorithm, but focus on different business problems or underlying goals and may operate on different data sets.
- When you create an endpoint, SageMaker attaches an Amazon EBS storage volume to each ML compute instance that hosts the endpoint. The size of the storage volume depends on the instance type. For a list of instance types that SageMaker hosting service supports, see AWS Service Limits. For a list of the sizes of the storage volumes that SageMaker attaches to each instance, see Host instance storage volumes (p. 2463).
- Endpoints are scoped to an individual AWS account, and are not public. The URL does not contain the account ID, but SageMaker determines the account ID from the authentication token that is supplied by the caller.

For an example of how to use Amazon API Gateway and AWS Lambda to set up and deploy a web service that you can call from a client application that is not within the scope of your account, see Call a SageMaker model endpoint using Amazon API Gateway and AWS Lambda in the AWS Machine Learning Blog.

Before you begin

Before you create and deploy a SageMaker model, locate and make note of the:

- AWS region where your Amazon S3 bucket is located
- Amazon S3 URI path where the model artifacts are stored
- IAM role for SageMaker
- Docker Amazon ECR URI registry path for the custom image that contains the inference code, or the framework and version of a built-in Docker image that is supported and by AWS.

For a list of AWS Services available in each AWS Region, see Region Maps and Edge Networks. See Creating IAM roles for information on how to create an IAM role.

Important

The Amazon S3 bucket where the model artifacts are stored must be in the same region as the model that you are creating.

The following demonstrates how to define the aforementioned parameters programmatically.

AWS SDK for Python (Boto3)

Import Boto3. Define your AWS region. Next, initialize a low-level SageMaker service client object using the Client class. This will make it easy to send and receive requests to AWS services. In addition, define the AWS role that gives SageMaker permission to access AWS services on your behalf:

```python
import boto3
```
# Specify your AWS Region
aws_region='<aws_region>'

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Role to give SageMaker permission to access AWS services.
sagemaker_role = "arn:aws:iam::<region>:<account>:role/*"

The first few lines define:
- `sagemaker_client`: A low-level SageMaker client object that makes it easy to send and receive requests to AWS services.
- `sagemaker_role`: A string variable with the SageMaker IAM role Amazon Resource Name (ARN).
- `aws_region`: A string variable with the name of your AWS region.

Import the `image_uris` module from the SageMaker Python SDK. Use the `retrieve()` function to retrieve the Amazon ECR URI for the Docker image matching the given arguments. Provide both the name of the framework or algorithm (framework field) along with the version of the framework or algorithm (version field). For a list of built-in Docker images provided by AWS, see Available Deep Learning Containers Images. For more information on how to bring your own image, see Use your own inference code (p. 3327).

```python
from sagemaker import image_uris

# Name of the framework or algorithm
framework='<framework>'
# Example

# Version of the framework or algorithm
version = '<version-number>'
# Example

# Specify an AWS container image.
container = image_uris.retrieve(region=aws_region, framework=framework, version=version)
```

Next, provide the Amazon S3 URI of the pre-trained model. This model will be used to create a SageMaker Python SDK Model model object in the next step. In this example, the full Amazon S3 URI is stored in a string variable `model_url`:

```python
# Create a variable w/ the model S3 URI
# First, provide the name of your S3 bucket
s3_bucket = '<your-bucket-name>'

# Specify what directory within your S3 bucket your model is stored in
bucket_prefix = '<directory-name>'

# Replace with the name of your model artifact
model_filename = '<model-name>.tar.gz'

# Relative S3 path
model_s3_key = f'{bucket_prefix}'+model_filename

# Combine bucket name, model file name, and relate S3 path to create S3 model URI
model_url = f's3://{s3_bucket}/{model_s3_key}'
```
SageMaker Python SDK

Define your AWS region. In addition, define the AWS role that gives SageMaker permission to access AWS services on your behalf:

```python
# Specify your AWS Region
aws_region='<aws_region>'

# Role to give SageMaker permission to access AWS services.
sagemaker_role = "arn:aws:iam::<region>:<account>:role/*"
```

The first few lines define:

- **sagemaker_role**: A string variable with the SageMaker IAM role Amazon Resource Name (ARN).
- **aws_region**: A string variable with the name of your AWS region.

Import the `image_uris` module from the SageMaker Python SDK. Use the `retrieve()` function to retrieve the Amazon ECR URI for the Docker image matching the given arguments. Provide both the name of the framework or algorithm (framework field) along with the version of the framework or algorithm (version field). For a list of built-in Docker images provided by AWS, see Available Deep Learning Containers Images. For more information on how to bring your own image, see Use your own inference code (p. 3327).

```python
from sagemaker import image_uris

# Name of the framework or algorithm
framework='<framework>' # Example

# Version of the framework or algorithm
version = '<version-number>' # Example

# Specify an AWS container image.
container = image_uris.retrieve(region=aws_region,
                                framework=framework,
                                version=version)
```

Next, provide the Amazon S3 URI of the pre-trained model. This model will be used to create a SageMaker Python SDK Model model object in the next step. In this example, the full Amazon S3 URI is stored in a string variable `model_url`:

```python
# Create a variable w/ the model S3 URI
# First, provide the name of your S3 bucket
s3_bucket = '<your-bucket-name>'

# Specify what directory within your S3 bucket your model is stored in
bucket_prefix = '<directory-name>'

# Replace with the name of your model artifact
model_filename = '<model-name>.tar.gz'

# Relative S3 path
model_s3_key = f'{bucket_prefix}/'+model_filename

# Combine bucket name, model file name, and relate S3 path to create S3 model URI
```
Create a Model

By creating a model, you tell SageMaker where it can find the model components.

AWS SDK for Python (Boto3)

Create a model in SageMaker with CreateModel. Specify the following:

- ModelName: A name for your model (in this example it is stored as a string variable called `model_name`).
- ExecutionRoleArn: The Amazon Resource Name (ARN) of the IAM role that Amazon SageMaker can assume to access model artifacts and Docker images for deployment on ML compute instances or for batch transform jobs.
- PrimaryContainer: The location of the primary Docker image containing inference code, associated artifacts, and custom environment maps that the inference code uses when the model is deployed for predictions.

For the primary container, specify the Docker image that contains inference code, artifacts (from prior training), and a custom environment map that the inference code uses when you deploy the model for predictions.

```python
model_name = '<The_name_of_the_model>'

#Create model
create_model_response = sagemaker_client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = sagemaker_role,
    PrimaryContainer = {
        'Image': container,
        'ModelDataUrl': model_url,
    })
```

SageMaker Python SDK

Create a model object from the SageMaker Python SDK Model Class. You will use this object to deploy your model to an endpoint in a later step.

```python
from sagemaker.model import Model

model = Model(image_uri=container,
               model_data=model_url,
               role=sagemaker_role)
```

Create an Endpoint Configuration

Create an endpoint configuration for an HTTPS endpoint. Specify the name of one or more models in production (variants) and the ML compute instances that you want SageMaker to launch to host each production variant.

**Note**

Skip this section if you are exclusively using the SageMaker Python SDK.
When hosting models in production, you can configure the endpoint to elastically scale the deployed
ML compute instances. For each production variant, you specify the number of ML compute instances
that you want to deploy. When you specify two or more instances, SageMaker launches them in multiple
Availability Zones. This ensures continuous availability. SageMaker manages deploying the instances.

AWS SDK for Python (Boto3)

Create an endpoint configuration with CreateEndpointConfig. Amazon SageMaker hosting
services uses this configuration to deploy models. In the configuration, you identify one or
more models, created using with CreateModel, to deploy the resources that you want Amazon
SageMaker to provision.

The following example shows how to create an endpoint configuration using AWS SDK for Python
(Boto3):

```python
import datetime
from time import gmtime, strftime

# Create an endpoint config name. Here we create one based on the date
# so it we can search endpoints based on creation time.
endpoint_config_name = '<endpoint-config-name>'

# The name of the model that you want to host. This is the name that you specified when
# creating the model.
model_name='<The_name_of_your_model>'

instance_type = '<instance-type>'
# instance_type='ml.m5.xlarge' # Example

endpoint_config_response = sagemaker_client.create_endpoint_config(
    EndpointConfigName=endpoint_config_name, # You will specify this name in a
    # CreateEndpoint request.
    ProductionVariants=[
        {
            "VariantName": "variant1", # The name of the production variant.
            "ModelName": model_name,
            "InstanceType": instance_type, # Specify the compute instance type.
            "InitialInstanceCount": 1 # Number of instances to launch initially.
        }
    ]
)

print(f"Created EndpointConfig: {endpoint_config_response['EndpointConfigArn']}")
```

In the aforementioned example, you specify the following keys for the ProductionVariants field:

- **VariantName**: The name of the production variant.
- **ModelName**: The name of the model that you want to host. This is the name that you specified
  when creating the model.
- **InstanceType**: The compute instance type. See the InstanceType field in
  [https://docs.aws.amazon.com/sagemaker/latest/APIReference/API_ProductionVariant.html](https://docs.aws.amazon.com/sagemaker/latest/APIReference/API_ProductionVariant.html) and
  [SageMaker Pricing](https://docs.aws.amazon.com/sagemaker/latest/APIReference/API_ProductionVariant.html) for a list of supported compute instance types and pricing for each instance
type.

SageMaker Python SDK

You do not need to define an endpoint configuration for real-time endpoints if you use the
SageMaker Python SDK Model Class.
Deploy your model

Deploy your model and create an HTTPS endpoint.

AWS SDK for Python (Boto3)

Provide the endpoint configuration to SageMaker. The service launches the ML compute instances and deploys the model or models as specified in the configuration.

Once you have your model and endpoint configuration, use the `createEndpoint` API to create your endpoint. The endpoint name must be unique within an AWS Region in your AWS account.

The following creates an endpoint using the endpoint configuration specified in the request. Amazon SageMaker uses the endpoint to provision resources and deploy models.

```python
# The name of the endpoint. The name must be unique within an AWS Region in your AWS account.
endpoint_name = '<endpoint-name>'

# The name of the endpoint configuration associated with this endpoint.
endpoint_config_name = '<endpoint-config-name>'

create_endpoint_response = sagemaker_client.create_endpoint(
                           EndpointName=endpoint_name,
                           EndpointConfigName=endpoint_config_name)
```

For more information, see the `createEndpoint` API.

SageMaker Python SDK

Define a name for your endpoint. This step is optional. If you do not provide one, SageMaker will create a unique name for you:

```python
from datetime import datetime

endpoint_name = f'DEMO-{datetime.utcnow():%Y-%m-%d-%H%M}'
print("EndpointName = ", endpoint_name)
```

Deploy your model to a real-time, HTTPS endpoint with the Model object’s built-in `deploy()` method. Provide the name of the Amazon EC2 instance type to deploy this model to in the `instance_type` field along with the initial number of instances to run the endpoint on for the `initial_instance_count` field:

```python
initial_instance_count = <integer>
# initial_instance_count=1 # Example

instance_type = '<instance-type>'
# instance_type='ml.m4.xlarge' # Example

model.deploy(
    initial_instance_count=initial_instance_count,
    instance_type=instance_type,
    endpoint_name=endpoint_name
)
```

Delete Endpoints and Resources

Delete endpoints to stop incurring charges.
Delete Endpoint

Delete your endpoint programmatically using AWS SDK for Python (Boto3), with the AWS CLI, or interactively using the SageMaker console.

SageMaker frees up all of the resources that were deployed when the endpoint was created. Deleting an endpoint will not delete the endpoint configuration or the SageMaker model. See Delete Endpoint Configuration (p. 2396) and Delete Model (p. 2398) for information on how to delete your endpoint configuration and SageMaker model.

AWS SDK for Python (Boto3)

Use the DeleteEndpoint API to delete your endpoint. Specify the name of your endpoint for the EndpointName field.

```python
import boto3

# Specify your AWS Region
aws_region='<aws_region>'

# Specify the name of your endpoint
endpoint_name='<endpoint_name>'

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Delete endpoint
sagemaker_client.delete_endpoint(EndpointName=endpoint_name)
```

AWS CLI

Use the delete-endpoint command to delete your endpoint. Specify the name of your endpoint for the endpoint-name flag.

```
aws sagemaker delete-endpoint --endpoint-name <endpoint-name>
```

SageMaker Console

Delete your endpoint interactively with the SageMaker console.

2. Choose Endpoints from the drop down menu. A list of endpoints created in you AWS account will appear by name, Amazon Resource Name (ARN), creation time, status, and a time stamp of when the endpoint was last updated.
3. Select the endpoint you want to delete.
4. Select the Actions dropdown button in the top right corner.
5. Choose Delete.

Delete Endpoint Configuration

Delete your endpoint configuration programmaticially using AWS SDK for Python (Boto3), with the AWS CLI, or interactively using the SageMaker console. Deleting an endpoint configuration does not delete endpoints created using this configuration. See Delete Endpoint (p. 2396) for information on how to delete your endpoint.

Do not delete an endpoint configuration in use by an endpoint that is live or while the endpoint is being updated or created. You might lose visibility into the instance type the endpoint is using if you delete the endpoint configuration of an endpoint that is active or being created or updated.

2396
AWS SDK for Python (Boto3)

Use the `DeleteEndpointConfig` API to delete your endpoint. Specify the name of your endpoint configuration for the `EndpointConfigName` field.

```python
import boto3

# Specify your AWS Region
aws_region='<aws_region>'

# Specify the name of your endpoint configuration
endpoint_config_name='<endpoint_name>'

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Delete endpoint configuration
sagemaker_client.delete_endpoint_config(EndpointConfigName=endpoint_config_name)
```

You can optionally use the `DescribeEndpointConfig` API to return information about the name of your deployed models (production variants) such as the name of your model and the name of the endpoint configuration associated with that deployed model. Provide the name of your endpoint for the `EndpointConfigName` field.

```python
# Specify the name of your endpoint
endpoint_name='<endpoint_name>'

# Create a low-level SageMaker service client.

sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Store DescribeEndpointConfig response into a variable that we can index in the next step.
response = sagemaker_client.describe_endpoint_config(EndpointConfigName=endpoint_name)

# Delete endpoint
endpoint_config_name = response['ProductionVariants'][0]['EndpointConfigName']

# Delete endpoint configuration
sagemaker_client.delete_endpoint_config(EndpointConfigName=endpoint_config_name)
```

For more information about other response elements returned by `DescribeEndpointConfig`, see `DescribeEndpointConfig` in the SageMaker API Reference guide.

AWS CLI

Use the `delete-endpoint-config` command to delete your endpoint configuration. Specify the name of your endpoint configuration for the `endpoint-config-name` flag.

```bash
aws sagemaker delete-endpoint-config
  --endpoint-config-name <endpoint-config-name>
```

You can optionally use the `describe-endpoint-config` command to return information about the name of your deployed models (production variants) such as the name of your model and the name of the endpoint configuration associated with that deployed model. Provide the name of your endpoint for the `endpoint-config-name` flag.

```bash
aws sagemaker describe-endpoint-config --endpoint-config-name <endpoint-config-name>
```
This will return a JSON response. You can copy and paste, use a JSON parser, or use a tool built for JSON parsing to obtain the endpoint configuration name associated with that endpoint.

**SageMaker Console**

Delete your endpoint configuration interactively with the SageMaker console.

1. In the SageMaker console at https://console.aws.amazon.com/sagemaker/ navigation menu, choose **Inference**.
2. Choose **Endpoint configurations** from the dropdown menu. A list of endpoint configurations created in you AWS account will appear by name, Amazon Resource Name (ARN), and creation time.
3. Select the endpoint configuration you want to delete.
4. Select the **Actions** dropdown button in the top right corner.
5. Choose **Delete**.

**Delete Model**

Delete your SageMaker model programmatically using AWS SDK for Python (Boto3), with the AWS CLI, or interactively using the SageMaker console. Deleting a SageMaker model only deletes the model entry that was created in SageMaker. Deleting a model does not delete model artifacts, inference code, or the IAM role that you specified when creating the model.

**AWS SDK for Python (Boto3)**

Use the **DeleteModel** API to delete your SageMaker model. Specify the name of your model for the **ModelName** field.

```python
import boto3

# Specify your AWS Region
aws_region='<aws_region>'

# Specify the name of your endpoint configuration
model_name='<model_name>'

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Delete model
sagemaker_client.delete_model(ModelName=model_name)
```

You can optionally use the **DescribeEndpointConfig** API to return information about the name of the your deployed models (production variants) such as the name of your model and the name of the endpoint configuration associated with that deployed model. Provide the name of your endpoint for the **EndpointConfigName** field.

```python
# Specify the name of your endpoint
endpoint_name='<endpoint_name>'

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Store DescribeEndpointConfig response into a variable that we can index in the next step.
response = sagemaker_client.describe_endpoint_config(EndpointConfigName=endpoint_name)
```
# Delete endpoint

```python
model_name = response['ProductionVariants'][0]['ModelName']
sagemaker_client.delete_model(ModelName=model_name)
```

For more information about other response elements returned by DescribeEndpointConfig, see `DescribeEndpointConfig` in the SageMaker API Reference guide.

**AWS CLI**

Use the `delete-model` command to delete your SageMaker model. Specify the name of your model for the `model-name` flag.

```bash
aws sagemaker delete-model --model-name <model-name>
```

You can optionally use the `describe-endpoint-config` command to return information about the name of the your deployed models (production variants) such as the name of your model and the name of the endpoint configuration associated with that deployed model. Provide the name of your endpoint for the `endpoint-config-name` flag.

```bash
aws sagemaker describe-endpoint-config --endpoint-config-name <endpoint-config-name>
```

This will return a JSON response. You can copy and paste, use a JSON parser, or use a tool built for JSON parsing to obtain the name of the model associated with that endpoint.

**SageMaker Console**

Delete your SageMaker model interactively with the SageMaker console.

2. Choose `Models` from the dropdown menu. A list of models created in you AWS account will appear by name, Amazon Resource Name (ARN), and creation time.
3. Select the model you want to delete.
4. Select the `Actions` dropdown button in the top right corner.
5. Choose `Delete`.

---

**Host multiple models in one container behind one endpoint**

Multi-model endpoints provide a scalable and cost-effective solution to deploying large numbers of models. They use the same fleet of resources and a shared serving container to host all of your models. This reduces hosting costs by improving endpoint utilization compared with using single-model endpoints. It also reduces deployment overhead because Amazon SageMaker manages loading models in memory and scaling them based on the traffic patterns to your endpoint.

The following diagram shows how multi-model endpoints work compared to single-model endpoints.
Multi-model endpoints are ideal for hosting a large number of models that use the same ML framework on a shared serving container. If you have a mix of frequently and infrequently accessed models, a multi-model endpoint can efficiently serve this traffic with fewer resources and higher cost savings. Your application should be tolerant of occasional cold start-related latency penalties that occur when invoking infrequently used models.

Multi-model endpoints support hosting both CPU and GPU backed models. By using GPU backed models, you can lower your model deployment costs through increased usage of the endpoint and its underlying accelerated compute instances.

Multi-model endpoints also enable time-sharing of memory resources across your models. This works best when the models are fairly similar in size and invocation latency. When this is the case, multi-model endpoints can effectively use instances across all models. If you have models that have significantly higher transactions per second (TPS) or latency requirements, we recommend hosting them on dedicated endpoints.

You can use multi-model endpoints with the following features:

- **AWS PrivateLink** and VPCs
- **Auto scaling** (p. 2424)
- **Serial inference pipelines** (but only one multi-model enabled container can be included in an inference pipeline)
- **A/B testing**

You can't use multi-model-enabled containers with Amazon Elastic Inference.

You can use the AWS SDK for Python (Boto) or the SageMaker console to create a multi-model endpoint. For CPU backed multi-model endpoints, you can create your endpoint with custom-built containers by integrating the **Multi Model Server** library.

**Topics**

- Supported algorithms, frameworks, and instances (p. 2401)
- Sample notebooks for multi-model endpoints (p. 2402)
• How multi-model endpoints work (p. 2403)
• Setting SageMaker multi-model endpoint model caching behavior (p. 2403)
• Instance recommendations for multi-model endpoint deployments (p. 2404)
• Create a Multi-Model Endpoint (p. 2405)
• Invoke a Multi-Model Endpoint (p. 2411)
• Add or Remove Models (p. 2412)

Supported algorithms, frameworks, and instances

For information about the algorithms, frameworks, and instance types that you can use with multi-model endpoints, see the following sections.

Supported algorithms, frameworks, and instances for multi-model endpoints using CPU backed instances

The inference containers for the following algorithms and frameworks support multi-model endpoints:

• XGBoost Algorithm (p. 1617)
• K-Nearest Neighbors (k-NN) Algorithm (p. 1575)
• Linear Learner Algorithm (p. 1593)
• Random Cut Forest (RCF) Algorithm (p. 1745)
• Use TensorFlow with Amazon SageMaker (p. 3627)
• Use Scikit-learn with Amazon SageMaker (p. 3625)
• Use Apache MXNet with Amazon SageMaker (p. 3610)
• Use PyTorch with Amazon SageMaker (p. 3623)

To use any other framework or algorithm, use the SageMaker inference toolkit to build a container that supports multi-model endpoints. For information, see Build Your Own Container for SageMaker Multi-Model Endpoints (p. 2413).

Multi-model endpoints support all of the CPU instance types.

Supported algorithms, frameworks, and instances for multi-model endpoints using GPU backed instances

Hosting multiple GPU backed models on multi-model endpoints is supported through the SageMaker Triton Inference server. This supports all major inference frameworks such as NVIDIA® TensorRT™, PyTorch, MXNet, Python, ONNX, XGBoost, scikit-learn, RandomForest, OpenVINO, custom C++, and more.

To use any other framework or algorithm, you can use Triton backend for Python or C++ to write your model logic and serve any custom model. After you have the server ready, you can start deploying 100s of Deep Learning models behind one endpoint.

Multi-model endpoints support the following GPU instance types:
Sample notebooks for multi-model endpoints

To learn more about how to use multi-model endpoints, you can try the following sample notebooks:

- **Examples for multi-model endpoints using CPU backed instances**:
  - Multi-Model Endpoint XGBoost Sample Notebook – This notebook shows how to deploy multiple XGBoost models to an endpoint.
  - Multi-Model Endpoints BYOC Sample Notebook – This notebook shows how to set up and deploy a customer container that supports multi-model endpoints in SageMaker.

- **Example for multi-model endpoints using GPU backed instances**:
  - Run multiple deep learning models on GPUs with Amazon SageMaker Multi-model endpoints (MME) – This notebook shows how to use an NVIDIA Triton Inference container to deploy ResNet-50 models to a multi-model endpoint.

For instructions on how to create and access Jupyter notebook instances that you can use to run the previous examples in SageMaker, see Amazon SageMaker Notebook Instances (p. 298). After you’ve created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all the SageMaker samples. The multi-model endpoint notebooks are located in the ADVANCED FUNCTIONALITY section. To open a notebook, choose its Use tab and choose Create copy.

For more information about use cases for multi-model endpoints, see the following blogs and resources:

- Video: Hosting thousands of models on SageMaker
- Video: SageMaker ML for SaaS
- Blog: How to scale machine learning inference for multi-tenant SaaS use cases
- Case study: Veeva Systems
How multi-model endpoints work

SageMaker manages the lifecycle of models hosted on multi-model endpoints in the container's memory. Instead of downloading all of the models from an Amazon S3 bucket to the container when you create the endpoint, SageMaker dynamically loads and caches them when you invoke them. When SageMaker receives an invocation request for a particular model, it does the following:

1. Routes the request to an instance behind the endpoint.
2. Downloads the model from the S3 bucket to that instance's storage volume.
3. Loads the model to the container's memory (CPU or GPU, depending on whether you have CPU or GPU backed instances) on that accelerated compute instance. If the model is already loaded in the container's memory, invocation is faster because SageMaker doesn't need to download and load it.

SageMaker continues to route requests for a model to the instance where the model is already loaded. However, if the model receives many invocation requests, and there are additional instances for the multi-model endpoint, SageMaker routes some requests to another instance to accommodate the traffic. If the model isn't already loaded on the second instance, the model is downloaded to that instance's storage volume and loaded into the container's memory.

When an instance's memory utilization is high and SageMaker needs to load another model into memory, it unloads unused models from that instance's container to ensure that there is enough memory to load the model. Models that are unloaded remain on the instance's storage volume and can be loaded into the container's memory later without being downloaded again from the S3 bucket. If the instance's storage volume reaches its capacity, SageMaker deletes any unused models from the storage volume.

To delete a model, stop sending requests and delete it from the S3 bucket. SageMaker provides multi-model endpoint capability in a serving container. Adding models to, and deleting them from, a multi-model endpoint doesn't require updating the endpoint itself. To add a model, you upload it to the S3 bucket and invoke it. You don't need code changes to use it.

**Note**

When you update a multi-model endpoint, initial invocation requests on the endpoint might experience higher latencies as Smart Routing in multi-model endpoints adapt to your traffic pattern. However, once it learns your traffic pattern, you can experience low latencies for most frequently used models. Less frequently used models may incur some cold start latencies since the models are dynamically loaded to an instance.

Setting SageMaker multi-model endpoint model caching behavior

By default, multi-model endpoints cache frequently used models in memory (CPU or GPU, depending on whether you have CPU or GPU backed instances) and on disk to provide low latency inference. The cached models are unloaded and/or deleted from disk only when a container runs out of memory or disk space to accommodate a newly targeted model.

You can change the caching behavior of a multi-model endpoint and explicitly enable or disable model caching by setting the parameter `ModelCacheSetting` when you call `create_model`.

We recommend setting the value of the `ModelCacheSetting` parameter to `Disabled` for use cases that do not benefit from model caching. For example, when a large number of models need to be served from the endpoint but each model is invoked only once (or very infrequently). For such use cases, setting the value of the `ModelCacheSetting` parameter to `Disabled` allows higher transactions per second (TPS) for `invoke_endpoint` requests compared to the default caching mode. Higher TPS in these use cases is because SageMaker does the following after the `invoke_endpoint` request:

- Asynchronously unloads the model from memory and deletes it from disk immediately after it is invoked.
• Provides higher concurrency for downloading and loading models in the inference container. For both CPU and GPU backed endpoints, the concurrency is a factor of the number of the vCPUs of the container instance.

For guidelines on choosing a SageMaker ML instance type for a multi-model endpoint, see Instance recommendations for multi-model endpoint deployments (p. 2404).

Instance recommendations for multi-model endpoint deployments

There are several items to consider when selecting a SageMaker ML instance type for a multi-model endpoint:

• Provision sufficient Amazon Elastic Block Store (Amazon EBS) capacity for all of the models that need to be served.

• Balance performance (minimize cold starts) and cost (don’t over-provision instance capacity). For information about the size of the storage volume that SageMaker attaches for each instance type for an endpoint and for a multi-model endpoint, see Host instance storage volumes (p. 2463).

• For a container configured to run in MultiModel mode, the storage volume provisioned for its instances are larger than the default SingleModel mode. This allows more models to be cached on the instance storage volume than in SingleModel mode.

When choosing a SageMaker ML instance type, consider the following:

• Multi-model endpoints are currently supported for all CPU instances types and on single-GPU instance types.

• For the traffic distribution (access patterns) to the models that you want to host behind the multi-model endpoint, along with the model size (how many models could be loaded in memory on the instance), keep the following information in mind:

  • Think of the amount of memory on an instance as the cache space for models to be loaded, and think of the number of vCPUs as the concurrency limit to perform inference on the loaded models (assuming that invoking a model is bound to CPU).

  • For CPU backed instances, the number of vCPUs impacts your maximum concurrent invocations per instance (assuming that invoking a model is bound to CPU). A higher amount of vCPUs enables you to invoke more unique models concurrently.

  • For GPU backed instances, a higher amount of instance and GPU memory enables you to have more models loaded and ready to serve inference requests.

  • For both CPU and GPU backed instances, have some “slack” memory available so that unused models can be unloaded, and especially for multi-model endpoints with multiple instances. If an instance or an Availability Zone fails, the models on those instances will be rerouted to other instances behind the endpoint.

  • Determine your tolerance to loading/downloading times:

    • d instance type families (for example, m5d, c5d, or r5d) and g5s come with an NVMe (non-volatile memory express) SSD, which offers high I/O performance and might reduce the time it takes to download models to the storage volume and for the container to load the model from the storage volume.

    • Because d and g5 instance types come with an NVMe SSD storage, SageMaker does not attach an Amazon EBS storage volume to these ML compute instances that hosts the multi-model endpoint. Auto scaling works best when the models are similarly sized and homogenous, that is when they have similar inference latency and resource requirements.

You can also use the following guidance to help you optimize model loading on your multi-model endpoints:
Choosing an instance type that can't hold all of the targeted models in memory

In some cases, you might opt to reduce costs by choosing an instance type that can't hold all of the targeted models in memory at once. SageMaker dynamically unloads models when it runs out of memory to make room for a newly targeted model. For infrequently requested models, you sacrifice dynamic load latency. In cases with more stringent latency needs, you might opt for larger instance types or more instances. Investing time up front for performance testing and analysis helps you to have successful production deployments.

Evaluating your model cache hits

Amazon CloudWatch metrics can help you evaluate your models. For more information about metrics you can use with multi-model endpoints, see CloudWatch Metrics for Multi-Model Endpoint Deployments (p. 2419).

You can use the Average statistic of the Model1CacheHit metric to monitor the ratio of requests where the model is already loaded. You can use the SampleCount statistic for the Model1UnloadingTime metric to monitor the number of unload requests sent to the container during a time period. If models are unloaded too frequently (an indicator of thrashing, where models are being unloaded and loaded again because there is insufficient cache space for the working set of models), consider using a larger instance type with more memory or increasing the number of instances behind the multi-model endpoint. For multi-model endpoints with multiple instances, be aware that a model might be loaded on more than 1 instance.

Create a Multi-Model Endpoint

You can use the SageMaker console or the AWS SDK for Python (Boto) to create a multi-model endpoint. To create either a CPU or GPU backed endpoint through the console, see the console procedure in the following sections. If you want to create a multi-model endpoint with the AWS SDK for Python (Boto), use either the CPU or GPU procedure in the following sections. The CPU and GPU workflows are similar but have several differences, such as the container requirements.

Topics
- Create a multi-model endpoint (console) (p. 2405)
- Create a multi-model endpoint using CPUs with the AWS SDK for Python (Boto3) (p. 2407)
- Create a multi-model endpoint using GPUs with the AWS SDK for Python (Boto3) (p. 2409)

Create a multi-model endpoint (console)

You can create both CPU and GPU backed multi-model endpoints through the console. Use the following procedure to create a multi-model endpoint through the SageMaker console.

To create a multi-model endpoint (console)
1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Choose Model, and then from the Inference group, choose Create model.
3. For Model name, enter a name.
4. For IAM role, choose or create an IAM role that has the AmazonSageMakerFullAccess IAM policy attached.
5. In the Container definition section, for Provide model artifacts and inference image options, choose Use multiple models.
Create model

To deploy a model to Amazon SageMaker, first create the model by providing the location of the model artifacts and the inference code. See Deploying a Model on Amazon SageMaker Hosting Services [Learn more]

Model settings

Model name

mml-test-model
Maximum of 63 alphanumeric characters. Can include hyphens (-), but not spaces. Must be unique within your account in an AWS Region.

IAM role
Amazon SageMaker requires permissions to call other services on your behalf. Choose a role or let SageMaker create a role that has the AmazonSageMakerFullAccess IAM policy attached.

AmazonSageMaker-ExecutionRole- XXXXXXXXXXXXXXXXXXX

Container definition 1

Container input options

Provide model artifacts and inference image location

Provide model artifacts and inference image options

- Use a single model
  Use this to host a single model in this container.

- Use multiple models
  Use this to host multiple models in this container.

Location of inference code image
Type the registry path where the inference code image is stored in Amazon ECR.

123456789012.dkr.ecr.us-east-1.amazonaws.com/myimage:mytag

Location of model artifacts
Type the URL where model artifacts are stored in S3.

s3://my-bucket/path/to/artifacts/
6. For the **Inference container image**, enter the Amazon ECR path for your desired container image.

   For GPU models, you must use a container backed by the NVIDIA Triton Inference Server. For a list of container images that work with GPU backed endpoints, see the [NVIDIA Triton Inference Containers (SM support only)](https://docs.aws.amazon.com/sagemaker/latest/dg/nvidia-triton-inference-containers.html). For more information about the NVIDIA Triton Inference Server, see [Use Triton Inference Server with SageMaker](https://docs.aws.amazon.com/sagemaker/latest/dg/triton.html).

7. Choose **Create model**.

8. Deploy your multi-model endpoint as you would a single model endpoint. For instructions, see [Deploy the Model to SageMaker Hosting Services](https://docs.aws.amazon.com/sagemaker/latest/dg/deployment-options.html).

### Create a multi-model endpoint using CPUs with the AWS SDK for Python (Boto3)

Use the following section to create a multi-model endpoint backed by CPU instances. You create a multi-model endpoint using the Amazon SageMaker `create_model`, `create_endpoint_config`, and `create_endpoint` APIs just as you would create a single model endpoint, but with two changes. When defining the model container, you need to pass a new `Mode` parameter value, `MultiModel`. You also need to pass the `ModelDataUrl` field that specifies the prefix in Amazon S3 where the model artifacts are located, instead of the path to a single model artifact, as you would when deploying a single model.

For a sample notebook that uses SageMaker to deploy multiple XGBoost models to an endpoint, see [Multi-Model Endpoint XGBoost Sample Notebook](https://github.com/aws-samples/sagemaker-multi-model-endpoint-xgboost).

The following procedure outlines the key steps used in that sample to create a CPU backed multi-model endpoint.

#### To deploy the model (AWS SDK for Python (Boto 3))

1. Get a container with an image that supports deploying multi-model endpoints. For a list of built-in algorithms and framework containers that support multi-model endpoints, see [Supported algorithms, frameworks, and instances](https://docs.aws.amazon.com/sagemaker/latest/dg/algorithm-index.html). For this example, we use the [K-Nearest Neighbors (k-NN) Algorithm](https://en.wikipedia.org/wiki/K-nearest_neighbors_algorithm) built-in algorithm. We call the SageMaker Python SDK utility function `image_uris.retrieve()` to get the address for the K-Nearest Neighbors built-in algorithm image.

   ```python
   import sagemaker
   region = sagemaker_session.boto_region_name
   image = sagemaker.image_uris.retrieve("knn", region=region)
   container = {
       'Image':        image,
       'ModelDataUrl': 's3://<BUCKET_NAME>/<PATH_TO_ARTIFACTS>',
       'Mode':         'MultiModel'
   }
   ```

2. Get an AWS SDK for Python (Boto3) SageMaker client and create the model that uses this container.

   ```python
   import boto3
   sagemaker_client = boto3.client('sagemaker')
   response = sagemaker_client.create_model(
       ModelName        = '<MODEL_NAME>',
       ExecutionRoleArn = role,
       Containers       = [container])
   ```

3. (Optional) If you are using a serial inference pipeline, get the additional container(s) to include in the pipeline, and include it in the `Containers` argument of CreateModel:

   ```python
   preprocessor_container = {
       'Image':        '
   '<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/<PREPROCESSOR_IMAGE>:<TAG>'
   ```
multi_model_container = {
'Image':
'<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/<IMAGE>:<TAG>',
'ModelDataUrl': 's3://<BUCKET_NAME>/<PATH_TO_ARTIFACTS>',
'Mode': 'MultiModel'
}
response = sagemaker_client.create_model(
    ModelName = '<MODEL_NAME>',
    ExecutionRoleArn = role,
    Containers = [preprocessor_container, multi_model_container]
)

Note
You can use only one multi-model-enabled endpoint in a serial inference pipeline.

4. (Optional) If your use case does not benefit from model caching, set the value of the ModelCacheSetting field of the MultiModelConfig parameter to Disabled, and include it in the Container argument of the call to create_model. The value of the ModelCacheSetting field is Enabled by default.

container = {
'Image': image,
'ModelDataUrl': 's3://<BUCKET_NAME>/<PATH_TO_ARTIFACTS>',
'Mode': 'MultiModel'
'MultiModelConfig': {
    // Default value is 'Enabled'
    'ModelCacheSetting': 'Disabled'
}
}
response = sagemaker_client.create_model(
    ModelName = '<MODEL_NAME>',
    ExecutionRoleArn = role,
    Containers = [container]
)

5. Configure the multi-model endpoint for the model. We recommend configuring your endpoints with at least two instances. This allows SageMaker to provide a highly available set of predictions across multiple Availability Zones for the models.

response = sagemaker_client.create_endpoint_config(
    EndpointConfigName = '<ENDPOINT_CONFIG_NAME>',
    ProductionVariants=[
        {
            'InstanceType': 'ml.m4.xlarge',
            'InitialInstanceCount': 2,
            'InitialVariantWeight': 1,
            'ModelName': '<MODEL_NAME>',
            'VariantName': 'AllTraffic'
        }
    ]
)

Note
You can use only one multi-model-enabled endpoint in a serial inference pipeline.

6. Create the multi-model endpoint using the EndpointName and EndpointConfigName parameters.

response = sagemaker_client.create_endpoint(
    EndpointName = '<ENDPOINT_NAME>',
    EndpointConfigName = '<ENDPOINT_CONFIG_NAME>'
)
Create a multi-model endpoint using GPUs with the AWS SDK for Python (Boto3)

Use the following section to create a GPU backed multi-model endpoint. You create a multi-model endpoint using the Amazon SageMaker `create_model`, `create_endpoint_config`, and `create_endpoint` APIs similarly to creating single model endpoints, but there are several changes. When defining the model container, you need to pass a new `Mode` parameter value, `MultiModel`. You also need to pass the `ModelDataUrl` field that specifies the prefix in Amazon S3 where the model artifacts are located, instead of the path to a single model artifact, as you would when deploying a single model. For GPU backed multi-model endpoints, you also must use a container with the NVIDIA Triton Inference Server that is optimized for running on GPU instances. For a list of container images that work with GPU backed endpoints, see the NVIDIA Triton Inference Containers (SM support only).

For an example notebook that demonstrates how to create a multi-model endpoint backed by GPUs, see Run mulitple deep learning models on GPUs with Amazon SageMaker Multi-model endpoints (MME).

The following procedure outlines the key steps to create a GPU backed multi-model endpoint.

**To deploy the model (AWS SDK for Python (Boto 3))**

1. Define the container image. To create a multi-model endpoint with GPU support for ResNet models, define the container to use the NVIDIA Triton Server image. This container supports multi-model endpoints and is optimized for running on GPU instances. We call the SageMaker Python SDK utility function `image_uris.retrieve()` to get the address for the image. For example:

```python
import sagemaker
region = sagemaker_session.boto_region_name

// Find the sagemaker-tritonserver image at
// resnet50/triton_resnet50.ipynb
// Find available tags at https://github.com/aws/deep-learning-containers/blob/master/
// available_images.md#nvidia-triton-inference-containers-sm-support-only

image = "<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/sagemaker-tritonserver:<TAG>".format(
    account_id=account_id_map[region], region=region
)

container = {
    'Image':        image,
    'ModelDataUrl': 's3://<BUCKET_NAME>/<PATH_TO_ARTIFACTS>',
    'Mode':         'MultiModel',
    "Environment": {"SAGEMAKER_TRITON_DEFAULT_MODEL_NAME": "resnet"},
}
```

2. Get an AWS SDK for Python (Boto3) SageMaker client and create the model that uses this container.

```python
import boto3
sagemaker_client = boto3.client('sagemaker')
response = sagemaker_client.create_model(
    ModelName        = '<MODEL_NAME>',
    ExecutionRoleArn = role,
    Containers        = [container])
```

3. (Optional) If you are using a serial inference pipeline, get the additional container(s) to include in the pipeline, and include it in the `Containers` argument of `CreateModel`: 

```python
response = sagemaker_client.create_endpoint_config(
    EndpointName      = '<ENDPOINT_NAME>',
    EndpointConfigName = '<ENDPOINT_CONFIG_NAME>'
)"
Hosting options

preprocessor_container = {
  'Image':
  '<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/<PREPROCESSOR_IMAGE>:<TAG>
}

multi_model_container = {
  'Image':
  '<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/<IMAGE>:<TAG>',
  'ModelDataUrl': 's3://<BUCKET_NAME>/<PATH_TO_ARTIFACTS>',
  'Mode': 'MultiModel'
}

response = sagemaker_client.create_model(
  ModelName = '<MODEL_NAME>',
  ExecutionRoleArn = role,
  Containers = [preprocessor_container, multi_model_container]
)

Note
You can use only one multi-model-enabled endpoint in a serial inference pipeline.

4. (Optional) If your use case does not benefit from model caching, set the value of the ModelCacheSetting field of the MultiModelConfig parameter to Disabled, and include it in the Container argument of the call to create_model. The value of the ModelCacheSetting field is Enabled by default.

container = {
  'Image': image,
  'ModelDataUrl': 's3://<BUCKET_NAME>/<PATH_TO_ARTIFACTS>',
  'Mode': 'MultiModel'
  'MultiModelConfig': {
    // Default value is 'Enabled'
    'ModelCacheSetting': 'Disabled'
  }
}

response = sagemaker_client.create_model(
  ModelName = '<MODEL_NAME>',
  ExecutionRoleArn = role,
  Containers = [container]
)

5. Configure the multi-model endpoint with GPU backed instances for the model. We recommend configuring your endpoints with more than one instance to allow for high availability and higher cache hits.

response = sagemaker_client.create_endpoint_config(
  EndpointConfigName = '<ENDPOINT_CONFIG_NAME>',
  ProductionVariants=[
    {
      'InstanceType': 'ml.g4dn.4xlarge',
      'InitialInstanceCount': 2,
      'InitialVariantWeight': 1,
      'ModelName': '<MODEL_NAME>',
      'VariantName': 'AllTraffic'
    }
  ]
)

6. Create the multi-model endpoint using the EndpointName and EndpointConfigName parameters.
Invoke a Multi-Model Endpoint

To invoke a multi-model endpoint, use the `invoke_endpoint` from the SageMaker Runtime just as you would invoke a single model endpoint, with one change. Pass a new `TargetModel` parameter that specifies which of the models at the endpoint to target. The SageMaker Runtime `InvokeEndpoint` request supports `X-Amzn-SageMaker-Target-Model` as a new header that takes the relative path of the model specified for invocation. The SageMaker system constructs the absolute path of the model by combining the prefix that is provided as part of the `CreateModel` API call with the relative path of the model.

The following procedures are the same for both CPU and GPU-backed multi-model endpoints.

**AWS SDK for Python (Boto 3)**

The following example prediction request uses the AWS SDK for Python (Boto 3) in the sample notebook.

```python
response = runtime_sagemaker_client.invoke_endpoint(
    EndpointName = '"<ENDPOINT_NAME>"',
    ContentType = '"text/csv"',
    TargetModel = '"<MODEL_FILENAME>.tar.gz"',
    Body = body)
```

**AWS CLI**

The following example shows how to make a CSV request with two rows using the AWS Command Line Interface (AWS CLI):

```bash
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name '"<ENDPOINT_NAME>"' \
  --body "1.0,2.0,5.0""\n"2.0,3.0,4.0"" \n  --content-type "text/csv" \
  --target-model '"<MODEL_NAME>.tar.gz"' \
  output_file.txt
```

An `output_file.txt` with information about your inference requests is made if the inference was successful. For more examples on how to make predictions with the AWS CLI, see [Making predictions with the AWS CLI](https://docs.aws.amazon.com/machine-learning/latest/dg/making-predictions-with-aws-cli.html) in the SageMaker Python SDK documentation.

The multi-model endpoint dynamically loads target models as needed. You can observe this when running the MME Sample Notebook as it iterates through random invocations against multiple target models hosted behind a single endpoint. The first request against a given model takes longer because the model has to be downloaded from Amazon Simple Storage Service (Amazon S3) and loaded into memory. This is called a cold start, and it is expected on multi-model endpoints to optimize for better price performance for customers. Subsequent calls finish faster because there's no additional overhead after the model has loaded.

**Note**

For GPU backed instances, the HTTP response code with 507 from the GPU container indicates a lack of memory or other resources. This causes unused models to be unloaded from the container in order to load more frequently used models.
Retry Requests on ModelNotReadyException Errors

The first time you call `invoke_endpoint` for a model, the model is downloaded from Amazon Simple Storage Service and loaded into the inference container. This makes the first call take longer to return. Subsequent calls to the same model finish faster, because the model is already loaded.

SageMaker returns a response for a call to `invoke_endpoint` within 60 seconds. Some models are too large to download within 60 seconds. If the model does not finish loading before the 60 second timeout limit, the request to `invoke_endpoint` returns with the error code ModelNotReadyException, and the model continues to download and load into the inference container for up to 360 seconds. If you get a ModelNotReadyException error code for an `invoke_endpoint` request, retry the request. By default, the AWS SDKs for Python (Boto 3) (using Legacy retry mode) and Java retry invoke_endpoint requests that result in ModelNotReadyException errors. You can configure the retry strategy to continue retrying the request for up to 360 seconds. If you expect your model to take longer than 60 seconds to download and load into the container, set the SDK socket timeout to 70 seconds. For more information about configuring the retry strategy for the AWS SDK for Python (Boto3), see Configuring a retry mode. The following code shows an example that configures the retry strategy to retry calls to `invoke_endpoint` for up to 180 seconds.

```python
import boto3
from botocore.config import Config

# This example retry strategy sets the retry attempts to 2.
# With this setting, the request can attempt to download and/or load the model
# for up to 180 seconds: 1 original request (60 seconds) + 2 retries (120 seconds)
config = Config(
    read_timeout=70,
    retries={
        'max_attempts': 2  # This value can be adjusted to 5 to go up to the 360s max timeout
    }
)
runtime_sagemaker_client = boto3.client('sagemaker-runtime', config=config)
```

Add or Remove Models

You can deploy additional models to a multi-model endpoint and invoke them through that endpoint immediately. When adding a new model, you don't need to update or bring down the endpoint, so you avoid the cost of creating and running a separate endpoint for each new model. The process for adding and removing models is the same for CPU and GPU-backed multi-model endpoints.

SageMaker unloads unused models from the container when the instance is reaching memory capacity and more models need to be downloaded into the container. SageMaker also deletes unused model artifacts from the instance storage volume when the volume is reaching capacity and new models need to be downloaded. The first invocation to a newly added model takes longer because the endpoint takes time to download the model from S3 to the container's memory in instance hosting the endpoint.

With the endpoint already running, copy a new set of model artifacts to the Amazon S3 location there you store your models.

```bash
# Add an AdditionalModel to the endpoint and exercise it
aws s3 cp AdditionalModel.tar.gz s3://my-bucket/path/to/artifacts/
```

Important

To update a model, proceed as you would when adding a new model. Use a new and unique name. Don't overwrite model artifacts in Amazon S3 because the old version of the model might still be loaded in the containers or on the storage volume of the instances on the endpoint. Invocations to the new model could then invoke the old version of the model.
Client applications can request predictions from the additional target model as soon as it is stored in S3.

```python
response = runtime_sagemaker_client.invoke_endpoint(
    EndpointName='<ENDPOINT_NAME>',
    ContentType='text/csv',
    TargetModel='AdditionalModel.tar.gz',
    Body=body)
```

To delete a model from a multi-model endpoint, stop invoking the model from the clients and remove it from the S3 location where model artifacts are stored.

**Build Your Own Container for SageMaker Multi-Model Endpoints**

Refer to the following sections for bringing your own container and dependencies to multi-model endpoints.

**Topics**

- Bring your own dependencies for multi-model endpoints on CPU backed instances (p. 2413)
- Bring your own dependencies for multi-model endpoints on GPU backed instances (p. 2414)
- Use the SageMaker Inference Toolkit (p. 2414)
- Custom Containers Contract for Multi-Model Endpoints (p. 2416)

**Bring your own dependencies for multi-model endpoints on CPU backed instances**

If none of the pre-built container images serve your needs, you can build your own container for use with CPU backed multi-model endpoints.

Custom Amazon Elastic Container Registry (Amazon ECR) images deployed in Amazon SageMaker are expected to adhere to the basic contract described in Use Your Own Inference Code with Hosting Services (p. 3327) that govern how SageMaker interacts with a Docker container that runs your own inference code. For a container to be capable of loading and serving multiple models concurrently, there are additional APIs and behaviors that must be followed. This additional contract includes new APIs to load, list, get, and unload models, and a different API to invoke models. There are also different behaviors for error scenarios that the APIs need to abide by. To indicate that the container complies with the additional requirements, you can add the following command to your Docker file:

```bash
LABEL com.amazonaws.sagemaker.capabilities.multi-models=true
```

SageMaker also injects an environment variable into the container

```
SAGEMAKER_MULTI_MODEL=true
```

If you are creating a multi-model endpoint for a serial inference pipeline, your Docker file must have the required labels for both multi-models and serial inference pipelines. For more information about serial information pipelines, see Run Real-time Predictions with an Inference Pipeline (p. 2437).

To help you implement these requirements for a custom container, two libraries are available:

- **Multi Model Server** is an open source framework for serving machine learning models that can be installed in containers to provide the front end that fulfills the requirements for the new multi-model endpoint container APIs. It provides the HTTP front end and model management capabilities required by multi-model endpoints to host multiple models within a single container, load models into and unload models out of the container dynamically, and performs inference on a specified loaded model. It also provides a pluggable backend that supports a pluggable custom backend handler where you can implement your own algorithm.
Hosting options

- **SageMaker Inference Toolkit** is a library that bootstraps Multi Model Server with a configuration and settings that make it compatible with SageMaker multi-model endpoints. It also allows you to tweak important performance parameters, such as the number of workers per model, depending on the needs of your scenario.

Bring your own dependencies for multi-model endpoints on GPU backed instances

The bring your own container (BYOC) capability on multi-model endpoints with GPU backed instances is not currently supported by the Multi Model Server and SageMaker Inference Toolkit libraries.

For creating multi-model endpoints with GPU backed instances, you can use the SageMaker supported **NVIDIA Triton Inference Server**, with the **NVIDIA Triton Inference Containers**. To bring your own dependencies, you can build your own container with the SageMaker supported **NVIDIA Triton Inference Server** as the base image to your Docker file:

```
FROM 301217895009.dkr.ecr.us-west-2.amazonaws.com/sagemaker-tritonserver:22.07-py3
```

**Important**

Containers with the Triton Inference Server are the only supported containers you can use for GPU backed multi-model endpoints.

Use the SageMaker Inference Toolkit

**Note**

The SageMaker Inference Toolkit is only supported for CPU backed multi-model endpoints. The SageMaker Inference Toolkit is not currently not supported for GPU backed multi-model endpoints.

Pre-built containers that support multi-model endpoints are listed in **Supported algorithms, frameworks, and instances (p. 2401)**. If you want to use any other framework or algorithm, you need to build a container. The easiest way to do this is to use the **SageMaker Inference Toolkit** to extend an existing pre-built container. The SageMaker inference toolkit is an implementation for the multi-model server (MMS) that creates endpoints that can be deployed in SageMaker. For a sample notebook that shows how to set up and deploy a custom container that supports multi-model endpoints in SageMaker, see the **Multi-Model Endpoint BYOC Sample Notebook**.

**Note**

The SageMaker inference toolkit supports only Python model handlers. If you want to implement your handler in any other language, you must build your own container that implements the additional multi-model endpoint APIs. For information, see **Custom Containers Contract for Multi-Model Endpoints (p. 2416)**.

To extend a container by using the SageMaker inference toolkit

1. Create a model handler. MMS expects a model handler, which is a Python file that implements functions to pre-process, get predictions from the model, and process the output in a model handler. For an example of a model handler, see `model_handler.py` from the sample notebook.

2. Import the inference toolkit and use its `model_server.start_model_server` function to start MMS. The following example is from the `dockerd-entrypoint.py` file from the sample notebook. Notice that the call to `model_server.start_model_server` passes the model handler described in the previous step:

```python
import subprocess
import sys
import shlex
import os
from retrying import retry
from subprocess import CalledProcessError
```
from sagemaker_inference import model_server

def _retry_if_error(exception):
    return isinstance(exception, CalledProcessError or OSError)

@retry(stop_max_delay=1000 * 50,
       retry_on_exception=_retry_if_error)
def _start_mms():
    # by default the number of workers per model is 1, but we can configure it through
    # environment variable below if desired.
    # os.environ['SAGEMAKER_MODEL_SERVER_WORKERS'] = '2'
    model_server.start_model_server(handler_service='/home/model-server/model_handler.py:handle')

def main():
    if sys.argv[1] == 'serve':
        _start_mms()
    else:
        subprocess.check_call(shlex.split(' '.join(sys.argv[1:])))

        # prevent docker exit
        subprocess.call(['tail', '-f', '/dev/null'])

main()

3. In your Dockerfile, copy the model handler from the first step and specify the Python file from the previous step as the entrypoint in your Dockerfile. The following lines are from the Dockerfile used in the sample notebook:

```dockerfile
# Copy the default custom service file to handle incoming data and inference requests
COPY model_handler.py /home/model-server/model_handler.py

# Define an entrypoint script for the docker image
ENTRYPOINT ["python", "/usr/local/bin/dockerd-entrypoint.py"]
```

4. Build and register your container. The following shell script from the sample notebook builds the container and uploads it to an Amazon Elastic Container Registry repository in your AWS account:

```bash
%%sh
# The name of our algorithm
algorithm_name=demo-sagemaker-multimodel

cd container

account=$(aws sts get-caller-identity --query Account --output text)

# Get the region defined in the current configuration (default to us-west-2 if none defined)
region=$(aws configure get region)
region=${region:-us-west-2}

fullname="${account}.dkr.ecr.${region}.amazonaws.com/${algorithm_name}:latest"

# If the repository doesn't exist in ECR, create it.
aws ecr describe-repositories --repository-names "${{algorithm_name}}" > /dev/null 2>&1
if [ $? -ne 0 ]
then
    aws ecr create-repository --repository-name "${{algorithm_name}}" > /dev/null
fi

# Get the login command from ECR and execute it directly
```
$(aws ecr get-login --region ${region} --no-include-email)

# Build the docker image locally with the image name and then push it to ECR # with the full name.

docker build -q -t ${algorithm_name} .
docker tag ${algorithm_name} ${fullname}
docker push ${fullname}

You can now use this container to deploy multi-model endpoints in SageMaker.

**Topics**

- Custom Containers Contract for Multi-Model Endpoints (p. 2416)

**Custom Containers Contract for Multi-Model Endpoints**

To handle multiple models, your container must support a set of APIs that enable Amazon SageMaker to communicate with the container for loading, listing, getting, and unloading models as required. The `model_name` is used in the new set of APIs as the key input parameter. The customer container is expected to keep track of the loaded models using `model_name` as the mapping key. Also, the `model_name` is an opaque identifier and is not necessarily the value of the TargetModel parameter passed into the InvokeEndpoint API. The original TargetModel value in the InvokeEndpoint request is passed to container in the APIs as a X-Amzn-SageMaker-Target-Model header that can be used for logging purposes.

**Note**

Multi-model endpoints for GPU backed instances are currently supported only with SageMaker's NVIDIA Triton Inference Server container. This container already implements the contract defined below. Customers can directly use this container with their multi-model GPU endpoints, without any additional work.

You can configure the following APIs on your containers for CPU backed multi-model endpoints.

**Topics**

- Load Model API (p. 2416)
- List Model API (p. 2417)
- Get Model API (p. 2417)
- Unload Model API (p. 2418)
- Invoke Model API (p. 2418)

**Load Model API**

Instructs the container to load a particular model present in the url field of the body into the memory of the customer container and to keep track of it with the assigned `model_name`. After a model is loaded, the container should be ready to serve inference requests using this `model_name`.

```
POST /models HTTP/1.1
Content-Type: application/json
Accept: application/json

{
    "model_name": "{model_name}",
    "url": "*/opt/ml/models/{model_name}/model",
}
```
**Note**

If `model_name` is already loaded, this API should return 409. Any time a model cannot be loaded due to lack of memory or to any other resource, this API should return a 507 HTTP status code to SageMaker, which then initiates unloading unused models to reclaim.

### List Model API

Returns the list of models loaded into the memory of the customer container.

```
GET /models HTTP/1.1
Accept: application/json

Response =
{
    "models": [
        {
            "modelName" : "{model_name}",
            "modelUrl" : "/opt/ml/models/{model_name}/model",
        },
        {
            "modelName" : "{model_name}",
            "modelUrl" : "/opt/ml/models/{model_name}/model",
        },
        ....
    ]
}
```

This API also supports pagination.

```
GET /models HTTP/1.1
Accept: application/json

Response =
{
    "models": [
        {
            "modelName" : "{model_name}",
            "modelUrl" : "/opt/ml/models/{model_name}/model",
        },
        {
            "modelName" : "{model_name}",
            "modelUrl" : "/opt/ml/models/{model_name}/model",
        },
        ....
    ]
}
```

SageMaker can initially call the List Models API without providing a value for `next_page_token`. If a `nextPageToken` field is returned as part of the response, it will be provided as the value for `next_page_token` in a subsequent List Models call. If a `nextPageToken` is not returned, it means that there are no more models to return.

### Get Model API

This is a simple read API on the `model_name` entity.

```
GET /models/{model_name} HTTP/1.1
Accept: application/json

{
    "modelName" : "{model_name}",
}
```
"modelUrl" : "/opt/ml/models/{model_name}/model",
}

**Note**
If `model_name` is not loaded, this API should return 404.

### Unload Model API

Instructs the SageMaker platform to instruct the customer container to unload a model from memory. This initiates the eviction of a candidate model as determined by the platform when starting the process of loading a new model. The resources provisioned to `model_name` should be reclaimed by the container when this API returns a response.

```
DELETE /models/{model_name}
```

**Note**
If `model_name` is not loaded, this API should return 404.

### Invoke Model API

Makes a prediction request from the particular `model_name` supplied. The SageMaker Runtime InvokeEndpoint request supports `X-Amzn-SageMaker-Target-Model` as a new header that takes the relative path of the model specified for invocation. The SageMaker system constructs the absolute path of the model by combining the prefix that is provided as part of the CreateModel API call with the relative path of the model.

```
POST /models/{model_name}/invoke HTTP/1.1
Content-Type: Content-Type
Accept: Accept
X-Amzn-SageMaker-Custom-Attributes: CustomAttributes
X-Amzn-SageMaker-Target-Model: [relativePath]/{artifactName}.tar.gz
```

**Note**
If `model_name` is not loaded, this API should return 404.

Additionally, on GPU instances, if InvokeEndpoint fails due to a lack of memory or other resources, this API should return a 507 HTTP status code to SageMaker, which then initiates unloading unused models to reclaim.

### Multi-Model Endpoint Security

Models and data in a multi-model endpoint are co-located on instance storage volume and in container memory. All instances for Amazon SageMaker endpoints run on a single tenant container that you own. Only your models can run on your multi-model endpoint. It's your responsibility to manage the mapping of requests to models and to provide access for users to the correct target models. SageMaker uses IAM roles to provide IAM identity-based policies that you use to specify allowed or denied actions and resources and the conditions under which actions are allowed or denied.

By default, an IAM principal with InvokeEndpoint permissions on a multi-model endpoint can invoke any model at the address of the S3 prefix defined in the CreateModel operation, provided that the IAM Execution Role defined in operation has permissions to download the model. If you need to restrict InvokeEndpoint access to a limited set of models in S3, you can do one of the following:

- Restrict InvokeEndpoint calls to specific models hosted at the endpoint by using the sagemaker:TargetModel IAM condition key. For example, the following policy allows InvokeEndpoint requests only when the value of the TargetModel field matches one of the specified regular expressions:
Hosting options

For information about SageMaker condition keys, see Condition Keys for Amazon SageMaker in the AWS Identity and Access Management User Guide.

- Create multi-model endpoints with more restrictive S3 prefixes.

For more information about how SageMaker uses roles to manage access to endpoints and perform operations on your behalf, see SageMaker Roles (p. 3387). Your customers might also have certain data isolation requirements dictated by their own compliance requirements that can be satisfied using IAM identities.

CloudWatch Metrics for Multi-Model Endpoint Deployments

Amazon SageMaker provides metrics for endpoints so you can monitor the cache hit rate, the number of models loaded and the model wait times for loading, downloading, and uploading at a multi-model endpoint. Some of the metrics are different for CPU and GPU backed multi-model endpoints, so the following sections describe the Amazon CloudWatch metrics that you can use for each type of multi-model endpoint.

For more information about the metrics, see Multi-Model Endpoint Model Loading Metrics and Multi-Model Endpoint Model Instance Metrics in Monitor Amazon SageMaker with Amazon CloudWatch (p. 3577). Per-model metrics aren't supported.

CloudWatch metrics for CPU backed multi-model endpoints

You can monitor the following metrics on CPU backed multi-model endpoints.

The AWS/SageMaker namespace includes the following model loading metrics from calls to InvokeEndpoint.

Metrics are available at a 1-minute frequency.

For information about how long CloudWatch metrics are retained for, see GetMetricStatistics in the Amazon CloudWatch API Reference.

Multi-Model Endpoint Model Loading Metrics

<table>
<thead>

</tbody>
</table>
Set Auto Scaling Policies for Multi-Model Endpoint Deployments

SageMaker multi-model endpoints fully support automatic scaling, which manages replicas of models to ensure models scale based on traffic patterns. We recommend that you configure your multi-model endpoint and the size of your instances based on [Instance recommendations for multi-model endpoint deployments](p. 2404) and also set up instance based auto scaling for your endpoint. The invocation rates used to trigger an auto-scale event are based on the aggregate set of predictions across the full set of models served by the endpoint. For additional details on setting up endpoint auto scaling, see [Automatically Scale Amazon SageMaker Models](#).

You can set up auto scaling policies with predefined and custom metrics on both CPU and GPU backed multi-model endpoints.

**Note**

SageMaker multi-model endpoint metrics are available at one-minute granularity.

**Define a scaling policy**

To specify the metrics and target values for a scaling policy, you can configure a target-tracking scaling policy. You can use either a predefined metric or a custom metric.

Scaling policy configuration is represented by a JSON block. You save your scaling policy configuration as a JSON block in a text file. You use that text file when invoking the AWS CLI or the Application Auto Scaling API. For more information about policy configuration syntax, see [TargetTrackingScalingPolicyConfiguration](#) in the [Application Auto Scaling API Reference](#).

The following options are available for defining a target-tracking scaling policy configuration.

**Use a predefined metric**

To quickly define a target-tracking scaling policy for a variant, use the `SageMakerVariantInvocationsPerInstance` predefined metric. `SageMakerVariantInvocationsPerInstance` is the average number of times per minute that each instance for a variant is invoked. We strongly recommend using this metric.

To use a predefined metric in a scaling policy, create a target tracking configuration for your policy. In the target tracking configuration, include a `PredefinedMetricSpecification` for the predefined metric and a `TargetValue` for the target value of that metric.

The following example is a typical policy configuration for target-tracking scaling for a variant. In this configuration, we use the `SageMakerVariantInvocationsPerInstance` predefined metric to adjust the number of variant instances so that each instance has an `InvocationsPerInstance` metric of 70.

```json
{"TargetValue": 70.0,
  "PredefinedMetricSpecification":
   {
      "PredefinedMetricType": "InvocationsPerInstance"
   }
}
```

**Note**

We recommend that you use `InvocationsPerInstance` while using multi-model endpoints. The `TargetValue` for this metric depends on your application’s latency requirements. We also recommend that you load test your endpoints to set up suitable scaling parameter values. To learn more about load testing and setting up autoscaling for your endpoints, see the blog [Configuring autoscaling inference endpoints in Amazon SageMaker](#).
Use a custom metric

If you need to define a target-tracking scaling policy that meets your custom requirements, define a custom metric. You can define a custom metric based on any production variant metric that changes in proportion to scaling.

Not all SageMaker metrics work for target tracking. The metric must be a valid utilization metric, and it must describe how busy an instance is. The value of the metric must increase or decrease in inverse proportion to the number of variant instances. That is, the value of the metric should decrease when the number of instances increases.

Important
Before deploying automatic scaling in production, you must test automatic scaling with your custom metric.

Example custom metric for a CPU backed multi-model endpoint

The following example is a target-tracking configuration for a scaling policy. In this configuration, for a model named my-model, a custom metric of CPUUtilization adjusts the instance count on the endpoint based on an average CPU utilization of 50% across all instances.

```json
{"TargetValue": 50,
 "CustomizedMetricSpecification":
  {"MetricName": "CPUUtilization",
   "Namespace": "/aws/sagemaker/Endpoints",
   "Dimensions": [
    {"Name": "EndpointName", "Value": "my-endpoint" },
    {"Name": "ModelName", "Value": "my-model"}
   ],
   "Statistic": "Average",
   "Unit": "Percent"
  }
}
```

Example custom metric for a GPU backed multi-model endpoint

The following example is a target-tracking configuration for a scaling policy. In this configuration, for a model named my-model, a custom metric of GPUUtilization adjusts the instance count on the endpoint based on an average GPU utilization of 50% across all instances.

```json
{"TargetValue": 50,
 "CustomizedMetricSpecification":
  {"MetricName": "GPUUtilization",
   "Namespace": "/aws/sagemaker/Endpoints",
   "Dimensions": [
    {"Name": "EndpointName", "Value": "my-endpoint" },
    {"Name": "ModelName", "Value": "my-model"}
   ],
   "Statistic": "Average",
   "Unit": "Percent"
  }
}
```

Add a cooldown period

To add a cooldown period for scaling out your endpoint, specify a value, in seconds, for ScaleOutCooldown. Similarly, to add a cooldown period for scaling in your model, add a value, in seconds, for ScaleInCooldown. For more information about ScaleInCooldown and ScaleOutCooldown, see TargetTrackingScalingPolicyConfiguration in the Application Auto Scaling API Reference.
The following is an example target-tracking configuration for a scaling policy. In this configuration, the SageMakerVariantInvocationsPerInstance predefined metric is used to adjust scaling based on an average of 70 across all instances of that variant. The configuration provides a scale-in cooldown period of 10 minutes and a scale-out cooldown period of 5 minutes.

```json
{
  "TargetValue": 70.0,
  "PredefinedMetricSpecification": {
    "PredefinedMetricType": "SageMakerVariantInvocationsPerInstance"
  },
  "ScaleInCooldown": 600,
  "ScaleOutCooldown": 300
}
```

Host multiple models which use different containers behind one endpoint

SageMaker multi-container endpoints enable customers to deploy multiple containers, that use different models or frameworks, on a single SageMaker endpoint. The containers can be run in a sequence as an inference pipeline, or each container can be accessed individually by using direct invocation to improve endpoint utilization and optimize costs.

For information about invoking the containers in a multi-container endpoint in sequence, see Host models along with pre-processing logic as serial inference pipeline behind one endpoint (p. 2433).

For information about invoking a specific container in a multi-container endpoint, see Use a multi-container endpoint with direct invocation (p. 2427)

Topics
- Create a multi-container endpoint (Boto 3) (p. 2426)
- Update a multi-container endpoint (p. 2427)
- Delete a multi-container endpoint (p. 2427)
- Use a multi-container endpoint with direct invocation (p. 2427)

Create a multi-container endpoint (Boto 3)

Create a Multi-container endpoint by calling CreateModel, CreateEndpointConfig, and CreateEndpoint APIs as you would to create any other endpoints. You can run these containers sequentially as an inference pipeline, or run each individual container by using direct invocation. Multi-container endpoints have the following requirements when you call create_model:

- Use the Containers parameter instead of PrimaryContainer, and include more than one container in the Containers parameter.
- The ContainerHostname parameter is required for each container in a multi-container endpoint with direct invocation.
- Set the Mode parameter of the InferenceExecutionConfig field to Direct for direct invocation of each container, or Serial to use containers as an inference pipeline. The default mode is Serial.

Note
Currently there is a limit of up to 15 containers supported on a multi-container endpoint.

The following example creates a multi-container model for direct invocation.

1. Create container elements and InferenceExecutionConfig with direct invocation.

```python
container1 = {
```
2. Create the model with the container elements and set the `InferenceExecutionConfig` field.

```python
import boto3
sm_client = boto3.Session().client('sagemaker')
response = sm_client.create_model(
    ModelName = 'my-direct-mode-model-name',
    InferenceExecutionConfig = inferenceExecutionConfig,
    ExecutionRoleArn = role,
    Containers = [container1, container2]
)
```

To create an endpoint, you would then call `create_endpoint_config` and `create_endpoint` as you would to create any other endpoint.

**Update a multi-container endpoint**

To update a multi-container endpoint, complete the following steps.

1. Call `create_model` to create a new model with a new value for the `Mode` parameter in the `InferenceExecutionConfig` field.
2. Call `create_endpoint_config` to create a new endpoint config with a different name by using the new model you created in the previous step.
3. Call `update_endpoint` to update the endpoint with the new endpoint config you created in the previous step.

**Delete a multi-container endpoint**

To delete an endpoint, call `delete_endpoint`, and provide the name of the endpoint you want to delete as the `EndpointName` parameter.

**Use a multi-container endpoint with direct invocation**

SageMaker multi-container endpoints enable customers to deploy multiple containers to deploy different models on a SageMaker endpoint. You can host up to 15 different inference containers on a single endpoint. By using direct invocation, you can send a request to a specific inference container hosted on a multi-container endpoint.

**Topics**

- Allowlist (p. 2428)
- Invoke a multi-container endpoint with direct invocation (p. 2428)
- Security with multi-container endpoints with direct invocation (p. 2428)
- Metrics for multi-container endpoints with direct invocation (p. 2429)
• **Autoscale multi-container endpoints** (p. 2432)
• **Troubleshoot multi-container endpoints** (p. 2432)

**Allowlist**

To use multi-container direct invocation with GPU-based instances, you have to contact customer support and get your account allowlisted. To open a support case, see the [AWS Support Center](https://aws.amazon.com/support/contact/).

**Invoke a multi-container endpoint with direct invocation**

To invoke a multi-container endpoint with direct invocation, call `invoke_endpoint` as you would invoke any other endpoint, and specify which container you want to invoke by using the `TargetContainerHostname` parameter.

The following example directly invokes the `secondContainer` of a multi-container endpoint to get a prediction.

```python
import boto3
runtime_sm_client = boto3.Session().client('sagemaker-runtime')
response = runtime_sm_client.invoke_endpoint(  
    EndpointName = 'my-endpoint',  
    ContentType = 'text/csv',  
    TargetContainerHostname='secondContainer',  
    Body = body)
```

For each direct invocation request to a multi-container endpoint, only the container with the `TargetContainerHostname` processes the invocation request. You will get validation errors if you do any of the following:

• Specify a `TargetContainerHostname` that does not exist in the endpoint
• Do not specify a value for `TargetContainerHostname` in a request to an endpoint configured for direct invocation
• Specify a value for `TargetContainerHostname` in a request to an endpoint that is not configured for direct invocation.

**Security with multi-container endpoints with direct invocation**

For multi-container endpoints with direct invocation, there are multiple containers hosted in a single instance by sharing memory and a storage volume. It's your responsibility to use secure containers, maintain the correct mapping of requests to target containers, and provide users with the correct access to target containers. SageMaker uses IAM roles to provide IAM identity-based policies that you use to specify whether access to a resource is allowed or denied to that role, and under what conditions. For information about IAM roles, see [IAM roles](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_roles.html) in the *AWS Identity and Access Management User Guide.* For information about identity-based policies, see [Identity-based policies and resource-based policies](https://docs.aws.amazon.com/IAM/latest/UserGuide/policies-managing.html).

By default, an IAM principal with InvokeEndpoint permissions on a multi-container endpoint with direct invocation can invoke any container inside the endpoint with the endpoint name that you specify when you call `invoke_endpoint`. If you need to restrict `invoke_endpoint` access to a limited set of containers inside a multi-container endpoint, use the `sagemaker:TargetContainerHostname` IAM condition key. The following policies show how to limit calls to specific containers within an endpoint.

The following policy allows `invoke_endpoint` requests only when the value of the `TargetContainerHostname` field matches one of the specified regular expressions.
The following policy denies `invoke_endpoint` requests when the value of the `TargetContainerHostname` field matches one of the specified regular expressions in the `Deny` statement.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "sagemaker:InvokeEndpoint"
      ],
      "Effect": "Allow",
      "Condition": {
        "StringLike": {
          "sagemaker:TargetContainerHostname": ["customIps*", "common"]
        }
      }
    },
    {
      "Action": [
        "sagemaker:InvokeEndpoint"
      ],
      "Effect": "Deny",
      "Condition": {
        "StringLike": {
          "sagemaker:TargetContainerHostname": ["special"]
        }
      }
    }]
}
```

For information about SageMaker condition keys, see [Condition Keys for SageMaker](https://docs.aws.amazon.com/iam/latest/userguide/conditions_sagemaker.html) in the *AWS Identity and Access Management User Guide*.

**Metrics for multi-container endpoints with direct invocation**

In addition to the endpoint metrics that are listed in Monitor Amazon SageMaker with Amazon CloudWatch (p. 3577), SageMaker also provides per-container metrics.

Per-container metrics for multi-container endpoints with direct invocation are located in CloudWatch and categorized into two namespaces: `AWS/SageMaker` and `aws/sagemaker/Endpoints`. The `AWS/SageMaker` namespace includes invocation-related metrics, and the `aws/sagemaker/Endpoints` namespace includes memory and CPU utilization metrics.
The following table lists the per-container metrics for multi-container endpoints with direct invocation. All the metrics use the [EndpointName, VariantName, ContainerName] dimension, which filters metrics at a specific endpoint, for a specific variant and corresponding to a specific container. These metrics share the same metric names as in those for inference pipelines, but at a per-container level [EndpointName, VariantName, ContainerName].

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Dimension</th>
<th>NameSpace</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Invocations</strong></td>
<td>The number of InvokeEndpoint requests sent to a container inside an endpoint. To get the total number of requests sent to that container, use the Sum statistic. Units: None Valid statistics: Sum, Sample Count</td>
<td>EndpointName, VariantName, ContainerName</td>
<td>AWS/SageMaker</td>
</tr>
<tr>
<td><strong>Invocation4XX Errors</strong></td>
<td>The number of InvokeEndpoint requests that the model returned a 4xx HTTP response code for on a specific container. For each 4xx response, SageMaker sends a 1. Units: None Valid statistics: Average, Sum</td>
<td>EndpointName, VariantName, ContainerName</td>
<td>AWS/SageMaker</td>
</tr>
<tr>
<td><strong>Invocation5XX Errors</strong></td>
<td>The number of InvokeEndpoint requests that the model returned a 5xx HTTP response code for on a specific container. For each 5xx response, SageMaker sends a 1. Units: None Valid statistics: Average, Sum</td>
<td>EndpointName, VariantName, ContainerName</td>
<td>AWS/SageMaker</td>
</tr>
<tr>
<td><strong>ContainerLatency</strong></td>
<td>The time it took for the target container to respond as viewed from SageMaker. ContainerLatency includes the time it took to send the request, to fetch the response from the model's container, and to complete inference in the container. Units: Microseconds Valid statistics: Average,</td>
<td>EndpointName, VariantName, ContainerName</td>

<tr>
<th>MemoryUtilization</th>
<th>The percentage of memory that is used by each container running on an instance. This value ranges from 0% to 100%. Similar as CPUUtilization, in endpoints with direct invocation, the number of MemoryUtilization metrics equals the number of containers in that endpoint. Units: Percent</th>
</tr>
</thead>
<tbody>
<tr>
<td>EndpointName, VariantName, ContainerName</td>
<td>aws/sagemaker/Endpoints</td>
</tr>
</tbody>
</table>

All the metrics in the previous table are specific to multi-container endpoints with direct invocation. Besides these special per-container metrics, there are also metrics at the variant level with dimension [EndpointName, VariantName] for all the metrics in the table expect ContainerLatency.

**Autoscale multi-container endpoints**

If you want to configure automatic scaling for a multi-container endpoint using the InvocationsPerInstance metric, we recommend that the model in each container exhibits similar CPU utilization and latency on each inference request. This is recommended because if traffic to the multi-container endpoint shifts from a low CPU utilization model to a high CPU utilization model, but the overall call volume remains the same, the endpoint does not scale out and there may not be enough instances to handle all the requests to the high CPU utilization model. For information about automatically scaling endpoints, see [Automatically Scale Amazon SageMaker Models](#) (p. 2447).

**Troubleshoot multi-container endpoints**

The following sections can help you troubleshoot errors with multi-container endpoints.

**Ping Health Check Errors**

With multiple containers, endpoint memory and CPU are under higher pressure during endpoint creation. Specifically, the MemoryUtilization and CPUUtilization metrics are higher than for single-container endpoints, because utilization pressure is proportional to the number of containers. Because of this, we recommend that you choose instance types with enough memory and CPU to ensure that there is enough memory on the instance to have all the models loaded (the same guidance applies to deploying an inference pipeline). Otherwise, your endpoint creation might fail with an error such as XXX did not pass the ping health check.

**Missing accept-bind-to-port=true Docker label**

The containers in a multi-container endpoints listen on the port specified in the SAGEMAKER_BIND_TO_PORT environment variable instead of port 8080. When a container runs in a multi-container endpoint, SageMaker automatically provides this environment variable to the container. If this environment variable isn’t present, containers default to using port 8080. To indicate that your container complies with this requirement, use the following command to add a label to your Dockerfile:

```bash
LABEL com.amazonaws.sagemaker.capabilities.accept-bind-to-port=true
```

Otherwise, you will see an error message such as *Your Ecr Image XXX does not contain required com.amazonaws.sagemaker.capabilities.accept-bind-to-port=true Docker label(s).*
If your container needs to listen on a second port, choose a port in the range specified by the `SAGEMAKER_SAFE_PORT_RANGE` environment variable. Specify the value as an inclusive range in the format `XXXX-YYYY`, where `XXXX` and `YYYY` are multi-digit integers. SageMaker provides this value automatically when you run the container in a multi-container endpoint.

**Host models along with pre-processing logic as serial inference pipeline behind one endpoint**

An **inference pipeline** is a Amazon SageMaker model that is composed of a linear sequence of two to fifteen containers that process requests for inferences on data. You use an inference pipeline to define and deploy any combination of pretrained SageMaker built-in algorithms and your own custom algorithms packaged in Docker containers. You can use an inference pipeline to combine preprocessing, predictions, and post-processing data science tasks. Inference pipelines are fully managed.

You can add SageMaker Spark ML Serving and scikit-learn containers that reuse the data transformers developed for training models. The entire assembled inference pipeline can be considered as a SageMaker model that you can use to make either real-time predictions or to process batch transforms directly without any external preprocessing.

Within an inference pipeline model, SageMaker handles invocations as a sequence of HTTP requests. The first container in the pipeline handles the initial request, then the intermediate response is sent as a request to the second container, and so on, for each container in the pipeline. SageMaker returns the final response to the client.

When you deploy the pipeline model, SageMaker installs and runs all of the containers on each Amazon Elastic Compute Cloud (Amazon EC2) instance in the endpoint or transform job. Feature processing and inferences run with low latency because the containers are co-located on the same EC2 instances. You define the containers for a pipeline model using the `CreateModel` operation or from the console. Instead of setting one `PrimaryContainer`, you use the `Containers` parameter to set the containers that make up the pipeline. You also specify the order in which the containers are executed.

A pipeline model is immutable, but you can update an inference pipeline by deploying a new one using the `UpdateEndpoint` operation. This modularity supports greater flexibility during experimentation.

For information on how to create an inference pipeline with the SageMaker model registry, see [Register and Deploy Models with Model Registry](p. 2989).

There are no additional costs for using this feature. You pay only for the instances running on an endpoint.

- [Run Batch Transforms with Inference Pipelines](p. 2439)
- [Inference Pipeline Logs and Metrics](p. 2440)
- [Troubleshoot Inference Pipelines](p. 2445)

**Sample Notebooks for Inference Pipelines**

For an example that shows how to create and deploy inference pipelines, see the [Inference Pipeline with Scikit-learn and Linear Learner](sample notebook). For instructions on creating and accessing Jupyter notebook instances that you can use to run the example in SageMaker, see [Amazon SageMaker Notebook Instances](p. 298).
To see a list of all the SageMaker samples, after creating and opening a notebook instance, choose the SageMaker Examples tab. There are three inference pipeline notebooks. The first two inference pipeline notebooks just described are located in the advanced_functionality folder and the third notebook is in the sagemaker-python-sdk folder. To open a notebook, choose its Use tab, then choose Create copy.

Feature Processing with Spark ML and Scikit-learn

Before training a model with either Amazon SageMaker built-in algorithms or custom algorithms, you can use Spark and scikit-learn preprocessors to transform your data and engineer features.

Feature Processing with Spark ML

You can run Spark ML jobs with AWS Glue, a serverless ETL (extract, transform, load) service, from your SageMaker notebook. You can also connect to existing EMR clusters to run Spark ML jobs with Amazon EMR. To do this, you need an AWS Identity and Access Management (IAM) role that grants permission for making calls from your SageMaker notebook to AWS Glue.

**Note**
To see which Python and Spark versions AWS Glue supports, refer to AWS Glue Release Notes.

After engineering features, you package and serialize Spark ML jobs with MLeap into MLeap containers that you can add to an inference pipeline. You don't need to use externally managed Spark clusters. With this approach, you can seamlessly scale from a sample of rows to terabytes of data. The same transformers work for both training and inference, so you don't need to duplicate preprocessing and feature engineering logic or develop a one-time solution to make the models persist. With inference pipelines, you don't need to maintain outside infrastructure, and you can make predictions directly from data inputs.

When you run a Spark ML job on AWS Glue, a Spark ML pipeline is serialized into MLeap format. Then, you can use the job with the SparkML Model Serving Container in a SageMaker Inference Pipeline. MLeap is a serialization format and execution engine for machine learning pipelines. It supports Spark, Scikit-learn, and TensorFlow for training pipelines and exporting them to a serialized pipeline called an MLeap Bundle. You can deserialize Bundles back into Spark for batch-mode scoring or into the MLeap runtime to power real-time API services.

For an example that shows how to feature process with Spark ML, see the Train an ML Model using Apache Spark in Amazon EMR and deploy in SageMaker sample notebook.

Feature Processing with Scikit-Learn

You can run and package scikit-learn jobs into containers directly in Amazon SageMaker. For an example of Python code for building a scikit-learn featurizer model that trains on Fisher's Iris flower data set and predicts the species of Iris based on morphological measurements, see IRIS Training and Prediction with Sagemaker Scikit-learn.

Create a Pipeline Model

To create a pipeline model that can be deployed to an endpoint or used for a batch transform job, use the Amazon SageMaker console or the CreateModel operation.

To create an inference pipeline (console)

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Choose Models, and then choose Create models from the Inference group.
3. On the Create model page, provide a model name, choose an IAM role, and, if you want to use a private VPC, specify VPC values.
4. To add information about the containers in the inference pipeline, choose **Add container**, then choose **Next**.

5. Complete the fields for each container in the order that you want to execute them, up to the maximum of fifteen. Complete the **Container input options**, **Location of inference code image**, and, optionally, **Location of model artifacts**, **Container host name**, and **Environmental variables** fields.
The **MyInferencePipelineModel** page summarizes the settings for the containers that provide input for the model. If you provided the environment variables in a corresponding container definition, SageMaker shows them in the **Environment variables** field.

---

### Run Real-time Predictions with an Inference Pipeline

You can use trained models in an inference pipeline to make real-time predictions directly without performing external preprocessing. When you configure the pipeline, you can choose to use the built-in feature transformers already available in Amazon SageMaker. Or, you can implement your own transformation logic using just a few lines of scikit-learn or Spark code.
MLeap, a serialization format and execution engine for machine learning pipelines, supports Spark, scikit-learn, and TensorFlow for training pipelines and exporting them to a serialized pipeline called an MLeap Bundle. You can deserialize Bundles back into Spark for batch-mode scoring or into the MLeap runtime to power real-time API services.

The containers in a pipeline listen on the port specified in the SAGEMAKER_BIND_TO_PORT environment variable (instead of 8080). When running in an inference pipeline, SageMaker automatically provides this environment variable to containers. If this environment variable isn't present, containers default to using port 8080. To indicate that your container complies with this requirement, use the following command to add a label to your Dockerfile:

```
LABEL com.amazonaws.sagemaker.capabilities.accept-bind-to-port=true
```

If your container needs to listen on a second port, choose a port in the range specified by the SAGEMAKER_SAFE_PORT_RANGE environment variable. Specify the value as an inclusive range in the format "XXXX-YYYY", where XXXX and YYYY are multi-digit integers. SageMaker provides this value automatically when you run the container in a multicontainer pipeline.

**Note**

To use custom Docker images in a pipeline that includes SageMaker built-in algorithms, you need an Amazon Elastic Container Registry (Amazon ECR) policy. Your Amazon ECR repository must grant SageMaker permission to pull the image. For more information, see Troubleshoot Amazon ECR Permissions for Inference Pipelines (p. 2445).

Create and Deploy an Inference Pipeline Endpoint

The following code creates and deploys a real-time inference pipeline model with SparkML and XGBoost models in series using the SageMaker SDK.

```python
from sagemaker.model import Model
from sagemaker.pipeline_model import PipelineModel
from sagemaker.sparkml.model import SparkMLModel

sparkml_data = 's3://{}/{}{}'.format(s3_model_bucket, s3_model_key_prefix, 'model.tar.gz')
sparkml_model = SparkMLModel(model_data=sparkml_data)
xgb_model = Model(model_data=xgb_model.model_data, image=training_image)

model_name = 'serial-inference-' + timestamp_prefix
endpoint_name = 'serial-inference-ep-' + timestamp_prefix
sm_model = PipelineModel(name=model_name, role=role, models=[sparkml_model, xgb_model])
sm_model.deploy(initial_instance_count=1, instance_type='ml.c4.xlarge',
endpoint_name=endpoint_name)
```

Request Real-Time Inference from an Inference Pipeline Endpoint

The following example shows how to make real-time predictions by calling an inference endpoint and passing a request payload in JSON format:

```python
import sagemaker
from sagemaker.predictor import json_serializer, json_deserializer, Predictor

payload = {
    "input": [
    {
        "name": "Pclass",
        "type": "float",
        "val": "1.0"
    },
    {
        "name": "Embarked",
        "type": "string",
```
The response you get from `predictor.predict(payload)` is the model's inference result.

**Realtime inference pipeline example**

You can run this example notebook using the SKLearn predictor that shows how to deploy an endpoint, run an inference request, then deserialize the response. Find this notebook and more examples in the Amazon SageMaker example GitHub repository.

**Run Batch Transforms with Inference Pipelines**

To get inferences on an entire dataset you run a batch transform on a trained model. To run inferences on a full dataset, you can use the same inference pipeline model created and deployed to an endpoint for real-time processing in a batch transform job. To run a batch transform job in a pipeline, you download the input data from Amazon S3 and send it in one or more HTTP requests to the inference pipeline model. For an example that shows how to prepare data for a batch transform, see "Section 2 - Preprocess the raw housing data using Scikit Learn" of the Amazon SageMaker Multi-Model Endpoints using Linear Learner sample notebook. For information about Amazon SageMaker batch transforms, see Use Batch Transform (p. 2545).

**Note**

To use custom Docker images in a pipeline that includes Amazon SageMaker built-in algorithms, you need an Amazon Elastic Container Registry (ECR) policy. Your Amazon ECR repository must grant SageMaker permission to pull the image. For more information, see Troubleshoot Amazon ECR Permissions for Inference Pipelines (p. 2445).

The following example shows how to run a transform job using the Amazon SageMaker Python SDK. In this example, `model_name` is the inference pipeline that combines SparkML and XGBoost models.
(created in previous examples). The Amazon S3 location specified by `input_data_path` contains the input data, in CSV format, to be downloaded and sent to the Spark ML model. After the transform job has finished, the Amazon S3 location specified by `output_data_path` contains the output data returned by the XGBoost model in CSV format.

```python
import sagemaker
input_data_path = 's3://{}/{}'.format(default_bucket, 'key', 'file_name')
output_data_path = 's3://{}{}'.format(default_bucket, 'key')
transform_job = sagemaker.transformer.Transformer(
    model_name = model_name,
    instance_count = 1,
    instance_type = 'ml.m4.xlarge',
    strategy = 'SingleRecord',
    assemble_with = 'Line',
    output_path = output_data_path,
    base_transform_job_name='inference-pipelines-batch',
    sagemaker_session=sagemaker.Session(),
    accept = CONTENT_TYPE_CSV)
transform_job.transform(data = input_data_path,
    content_type = CONTENT_TYPE_CSV,
    split_type = 'Line')
```

Inference Pipeline Logs and Metrics

Monitoring is important for maintaining the reliability, availability, and performance of Amazon SageMaker resources. To monitor and troubleshoot inference pipeline performance, use Amazon CloudWatch logs and error messages. For information about the monitoring tools that SageMaker provides, see Monitor AWS resources provisioned while using Amazon SageMaker (p. 3577).

Use Metrics to Monitor Multi-container Models

To monitor the multi-container models in Inference Pipelines, use Amazon CloudWatch. CloudWatch collects raw data and processes it into readable, near real-time metrics. SageMaker training jobs and endpoints write CloudWatch metrics and logs in the AWS/SageMaker namespace.

The following tables list the metrics and dimensions for the following:
- Endpoint invocations
- Training jobs, batch transform jobs, and endpoint instances

A dimension is a name/value pair that uniquely identifies a metric. You can assign up to 10 dimensions to a metric. For more information on monitoring with CloudWatch, see Monitor Amazon SageMaker with Amazon CloudWatch (p. 3577).

Endpoint Invocation Metrics

The AWS/SageMaker namespace includes the following request metrics from calls to InvokeEndpoint.

Metrics are reported at a 1-minute intervals.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Invocation4XXErrors</td>
<td>The number of InvokeEndpoint requests that the model returned a 4xx HTTP response code for. For each 4xx response, SageMaker sends a 1. Units: None Valid statistics: Average, Sum</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Invocation5XXErrors</strong></td>
<td>The number of InvokeEndpoint requests that the model returned a 5xx HTTP response code for. For each 5xx response, SageMaker sends a 1. \nUnits: None \nValid statistics: Average, Sum</td>
</tr>
<tr>
<td><strong>Invocations</strong></td>
<td>The number of InvokeEndpoint requests sent to a model endpoint. \nTo get the total number of requests sent to a model endpoint, use the Sum statistic. \nUnits: None \nValid statistics: Sum, Sample Count</td>
</tr>
<tr>
<td><strong>InvocationsPerInstance</strong></td>
<td>The number of endpoint invocations sent to a model, normalized by InstanceCount in each ProductionVariant. SageMaker sends 1/numberOfInstances as the value for each request, where numberOfInstances is the number of active instances for the ProductionVariant at the endpoint at the time of the request. \nUnits: None \nValid statistics: Sum</td>
</tr>
<tr>
<td><strong>ModelLatency</strong></td>
<td>The time the model or models took to respond. This includes the time it took to send the request, to fetch the response from the model container, and to complete the inference in the container. ModelLatency is the total time taken by all containers in an inference pipeline. \nUnits: Microseconds \nValid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td><strong>OverheadLatency</strong></td>
<td>The time added to the time taken to respond to a client request by SageMaker for overhead. OverheadLatency is measured from the time that SageMaker receives the request until it returns a response to the client, minus the ModelLatency. Overhead latency can vary depending on request and response payload sizes, request frequency, and authentication or authorization of the request, among other factors. \nUnits: Microseconds \nValid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td><strong>ContainerLatency</strong></td>
<td>The time it took for an Inference Pipelines container to respond as viewed from SageMaker. ContainerLatency includes the time it took to send the request, to fetch the response from the model's container, and to complete inference in the container. \nUnits: Microseconds \nValid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
</tbody>
</table>

**Dimensions for Endpoint Invocation Metrics**
Hosting options

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EndpointName, VariantName, ContainerName</td>
<td>Filters endpoint invocation metrics for a ProductionVariant at the specified endpoint and for the specified variant.</td>
</tr>
</tbody>
</table>

For an inference pipeline endpoint, CloudWatch lists per-container latency metrics in your account as **Endpoint Container Metrics** and **Endpoint Variant Metrics** in the **SageMaker** namespace, as follows. The ContainerLatency metric appears only for inferences pipelines.

For each endpoint and each container, latency metrics display names for the container, endpoint, variant, and metric.

**Training Job, Batch Transform Job, and Endpoint Instance Metrics**

The namespaces /aws/sagemaker/TrainingJobs, /aws/sagemaker/TransformJobs, and /aws/sagemaker/Endpoints include the following metrics for training jobs and endpoint instances.

Metrics are reported at a 1-minute intervals.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPUUtilization</td>
<td>The percentage of CPU units that are used by the containers running on an instance. The value ranges from 0% to 100%, and is multiplied by the number of CPUs. For example, if there are four CPUs, CPUUtilization can range from 0% to 400%. For training jobs, CPUUtilization is the CPU utilization of the algorithm container running on the instance. For batch transform jobs, CPUUtilization is the CPU utilization of the transform container running on the instance. For multi-container models, CPUUtilization is the sum of CPU utilization by all containers running on the instance. For endpoint variants, CPUUtilization is the sum of CPU utilization by all of the containers running on the instance. Units: Percent</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>MemoryUtilization</td>
<td>The percentage of memory that is used by the containers running on an instance. This value ranges from 0% to 100%. For training jobs, MemoryUtilization is the memory used by the algorithm container running on the instance.</td>
</tr>
<tr>
<td></td>
<td>For batch transform jobs, MemoryUtilization is the memory used by the transform container running on the instance. For multi-container models, MemoryUtilization is the sum of memory used by all containers running on the instance.</td>
</tr>
<tr>
<td></td>
<td>For endpoint variants, MemoryUtilization is the sum of memory used by all of the containers running on the instance.</td>
</tr>
<tr>
<td></td>
<td>Units: Percent</td>
</tr>
<tr>
<td>GPUUtilization</td>
<td>The percentage of GPU units that are used by the containers running on an instance. GPUUtilization ranges from 0% to 100% and is multiplied by the number of GPUs. For example, if there are four GPUs, GPUUtilization can range from 0% to 400%.</td>
</tr>
<tr>
<td></td>
<td>For training jobs, GPUUtilization is the GPU used by the algorithm container running on the instance.</td>
</tr>
<tr>
<td></td>
<td>For batch transform jobs, GPUUtilization is the GPU used by the transform container running on the instance.</td>
</tr>
<tr>
<td></td>
<td>For multi-container models, GPUUtilization is the sum of GPU used by all containers running on the instance.</td>
</tr>
<tr>
<td></td>
<td>For endpoint variants, GPUUtilization is the sum of the GPU used by all of the containers running on the instance.</td>
</tr>
<tr>
<td></td>
<td>Units: Percent</td>
</tr>
<tr>
<td>GPUMemoryUtilization</td>
<td>The percentage of GPU memory used by the containers running on an instance. GPUMemoryUtilization ranges from 0% to 100% and is multiplied by the number of GPUs. For example, if there are four GPUs, GPUMemoryUtilization can range from 0% to 400%.</td>
</tr>
<tr>
<td></td>
<td>For training jobs, GPUMemoryUtilization is the GPU memory used by the algorithm container running on the instance.</td>

<td>For batch transform jobs, GPUMemoryUtilization is the GPU memory used by the transform container running on the instance.</td>
</tr>
<tr>
<td></td>
<td>For multi-container models, GPUMemoryUtilization is sum of GPU used by all containers running on the instance.</td>
</tr>
<tr>
<td></td>
<td>For endpoint variants, GPUMemoryUtilization is the sum of the GPU memory used by all of the containers running on the instance.</td>
</tr>
<tr>
<td></td>
<td>Units: Percent</td>
</tr>
</tbody>
</table>
### Dimensions for Training Job, Batch Transform Job, and Endpoint Instance Metrics

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
</table>
| Host      | For training jobs, Host has the format [training-job-name]/algo-[instance-number-in-cluster]. Use this dimension to filter instance metrics for the specified training job and instance. This dimension format is present only in the /aws/sagemaker/TrainingJobs namespace.  
For batch transform jobs, Host has the format [transform-job-name]/[instance-id]. Use this dimension to filter instance metrics for the specified batch transform job and instance. This dimension format is present only in the /aws/sagemaker/TransformJobs namespace.  
For endpoints, Host has the format [endpoint-name]/[production-variant-name]/[instance-id]. Use this dimension to filter instance metrics for the specified endpoint, variant, and instance. This dimension format is present only in the /aws/sagemaker/Endpoints namespace. |

To help you debug your training jobs, endpoints, and notebook instance lifecycle configurations, SageMaker also sends anything an algorithm container, a model container, or a notebook instance lifecycle configuration sends to stdout or stderr to Amazon CloudWatch Logs. You can use this information for debugging and to analyze progress.

**Use Logs to Monitor an Inference Pipeline**

The following table lists the log groups and log streams SageMaker sends to Amazon CloudWatch:

A **log stream** is a sequence of log events that share the same source. Each separate source of logs into CloudWatch makes up a separate log stream. A **log group** is a group of log streams that share the same retention, monitoring, and access control settings.

#### Logs

<table>
<thead>
<tr>
<th>Log Group Name</th>
<th>Log Stream Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>/aws/sagemaker/TrainingJobs</td>
<td>[training-job-name]/algo-[instance-number-in-cluster]-[epoch_timestamp]</td>
</tr>
<tr>
<td>/aws/sagemaker/Endpoints/[EndpointName]</td>
<td>[production-variant-name]/[instance-id]</td>
</tr>
<tr>
<td></td>
<td>[production-variant-name]/[instance-id]</td>
</tr>
</tbody>
</table>
### Hosting options

<table>
<thead>
<tr>
<th>Log Group Name</th>

</tr>
<tr>
<td></td>
<td>[transform-job-name]/[instance-id]-[epoch_timestamp]/data-log</td>
</tr>
<tr>
<td></td>
<td>[transform-job-name]/[instance-id]-[epoch_timestamp]/[container-name provided in the SageMaker model] (For Inference Pipelines) For Inference Pipelines logs, if you don't provide container names, CloudWatch uses <strong>container-1, container-2</strong>, and so on, in the order that containers are provided in the model.</td>
</tr>
</tbody>
</table>

**Note**

SageMaker creates the /aws/sagemaker/NotebookInstances log group when you create a notebook instance with a lifecycle configuration. For more information, see Customize a Notebook Instance Using a Lifecycle Configuration Script (p. 323).

For more information about SageMaker logging, see Log Amazon SageMaker Events with Amazon CloudWatch (p. 3591).

### Troubleshoot Inference Pipelines

To troubleshoot inference pipeline issues, use CloudWatch logs and error messages. If you are using custom Docker images in a pipeline that includes Amazon SageMaker built-in algorithms, you might also encounter permissions problems. To grant the required permissions, create an Amazon Elastic Container Registry (Amazon ECR) policy.

**Topics**

- Troubleshoot Amazon ECR Permissions for Inference Pipelines (p. 2445)
- Use CloudWatch Logs to Troubleshoot SageMaker Inference Pipelines (p. 2446)
- Use Error Messages to Troubleshoot Inference Pipelines (p. 2447)

### Troubleshoot Amazon ECR Permissions for Inference Pipelines

When you use custom Docker images in a pipeline that includes SageMaker built-in algorithms, you need an Amazon ECR policy. The policy allows your Amazon ECR repository to grant permission for SageMaker to pull the image. The policy must add the following permissions:

```json
{
    "Version": "2008-10-17",
    "Statement": [
        {
            "Sid": "allowSageMakerToPull",
            "Effect": "Allow",
            "Principal": {
                "Service": "sagemaker.amazonaws.com"
            }
        }
    ]
}
```
Hosting options

Use CloudWatch Logs to Troubleshoot SageMaker Inference Pipelines

SageMaker publishes the container logs for endpoints that deploy an inference pipeline to Amazon CloudWatch at the following path for each container.

/aws/sagemaker/Endpoints/{EndpointName}/{Variant}/{InstanceId}/{ContainerHostname}

For example, logs for this endpoint are published to the following log groups and streams:

<table>
<thead>
<tr>
<th>EndpointName: MyInferencePipelinesEndpoint</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variant: MyInferencePipelinesVariant</td>
</tr>
<tr>
<td>InstanceId: i-0179208609ff7e488</td>
</tr>
<tr>
<td>ContainerHostname: MyContainerName1 and MyContainerName2</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>logGroup: /aws/sagemaker/Endpoints/MyInferencePipelinesEndpoint</th>
</tr>
</thead>
<tbody>
<tr>
<td>logStream: MyInferencePipelinesVariant/i-0179208609ff7e488/MyContainerName1</td>
</tr>
<tr>
<td>logStream: MyInferencePipelinesVariant/i-0179208609ff7e488/MyContainerName2</td>
</tr>
</tbody>
</table>

A log stream is a sequence of log events that share the same source. Each separate source of logs into CloudWatch makes up a separate log stream. A log group is a group of log streams that share the same retention, monitoring, and access control settings.

To see the log groups and streams

2. In the navigation page, choose Logs.
3. In Log Groups, filter on MyInferencePipelinesEndpoint:

4. To see the log streams, on the CloudWatch Log Groups page, choose MyInferencePipelinesEndpoint, and then Search Log Group.
For a list of the logs that SageMaker publishes, see *Inference Pipeline Logs and Metrics (p. 2440)*.

**Use Error Messages to Troubleshoot Inference Pipelines**

The inference pipeline error messages indicate which containers failed.

If an error occurs while SageMaker is invoking an endpoint, the service returns a `ModelError` (error code 424), which indicates which container failed. If the request payload (the response from the previous container) exceeds the limit of 5 MB, SageMaker provides a detailed error message, such as:

```plaintext
Received response from MyContainerName1 with status code 200. However, the request payload from MyContainerName1 to MyContainerName2 is 6000000 bytes, which has exceeded the maximum limit of 5 MB.
```

If a container fails the ping health check while SageMaker is creating an endpoint, it returns a `ClientError` and indicates all of the containers that failed the ping check in the last health check.

**Automatically Scale Amazon SageMaker Models**

Amazon SageMaker supports automatic scaling (auto scaling) for your hosted models. *Auto scaling* dynamically adjusts the number of instances provisioned for a model in response to changes in your workload. When the workload increases, auto scaling brings more instances online. When the workload decreases, auto scaling removes unnecessary instances so that you don't pay for provisioned instances that you aren't using.

**Topics**

- Prerequisites (p. 2447)
- Configure model auto scaling with the console (p. 2450)
- Register a model (p. 2451)
- Define a scaling policy (p. 2452)
- Apply a scaling policy (p. 2455)
- Edit a scaling policy (p. 2456)
- Delete a scaling policy (p. 2457)
- Query Endpoint Auto scaling History (p. 2459)
- Update or delete endpoints that use automatic scaling (p. 2460)
- Load testing your auto scaling configuration (p. 2461)
- Use AWS CloudFormation to update auto scaling policies (p. 2462)

**Prerequisites**

Before you can use auto scaling, must have already created a Amazon SageMaker model deployment. Deployed models are referred to as a `production variant`. This includes information about the model and the resources used to host it.

For more information about deploying a model endpoint, see *Deploy the Model to SageMaker Hosting Services (p. 310)*.

To activate auto scaling for a model, you can use the console, the AWS CLI, or the Application Auto Scaling API. It is recommended to try to *Configure model auto scaling with the console (p. 2450)* to get familiar with the requirements and to test your first auto scaling configuration. When using the AWS CLI or Application Auto Scaling the flow is to register the model, define the scaling policy, then apply it. The
following overview provides further details on the prerequisites and components used with Application Auto Scaling.

**Auto scaling policy overview**

To use automatic scaling, you define and apply a scaling policy that uses Amazon CloudWatch metrics and target values that you assign. Automatic scaling uses the policy to increase or decrease the number of instances in response to actual workloads.

You can use the AWS Management Console to apply a scaling policy based on a predefined metric. A *predefined metric* is defined in an enumeration so that you can specify it by name in code or use it in the AWS Management Console. Alternatively, you can use either the AWS Command Line Interface (AWS CLI) or the Application Auto Scaling API to apply a scaling policy based on a predefined or custom metric.

There are two types of supported scaling policies: target-tracking scaling and step scaling. It is recommended to use target-tracking scaling policies for your auto scaling configuration. You configure the *target-tracking scaling policy* by specifying a predefined or custom metric and a target value for the metric. For more information about using Application Auto Scaling target-tracking scaling policies, see Target Tracking Scaling Policies.

You can use step scaling when you require an advanced configuration, such as specifying how many instances to deploy under what conditions. Otherwise, using target-tracking scaling is preferred as it will be fully automated. For more information about using Application Auto Scaling step scaling policies, see Step Scaling Policies.

A scaling policy has the following components:

- A target metric—The Amazon CloudWatch metric that SageMaker automatic scaling uses to determine when and how much to scale.
- Minimum and maximum capacity—The minimum and maximum number of instances to use for scaling.
- A cool down period—The amount of time, in seconds, after a scale-in or scale-out activity completes before another scale-out activity can start.
- Required permissions—Permissions that are required to perform automatic scaling actions.
- A service-linked role—An AWS Identity and Access Management (IAM) role that is linked to a specific AWS service. A service-linked role includes all of the permissions that the service requires to call other AWS services on your behalf. SageMaker automatic scaling automatically generates this role, AWSServiceRoleForApplicationAutoScaling_SageMakerEndpoint, for you.

**Target metric for auto scaling**

Amazon CloudWatch alarms trigger the scaling policy, which calculate how to adjust scaling based on the metric and target value that you set. The scaling policy adds or removes endpoint instances as required to keep the metric at, or close to, the specified target value. In addition, a scaling policy also adjusts to fluctuations in the metric when a workload changes. The scaling policy minimizes rapid fluctuations in the number of available instances for your model.

For example, a scaling policy that uses the predefined InvocationsPerInstance metric with a target value of 70 can keep InvocationsPerInstance at, or close to 70.

**Minimum and maximum capacity**

You may specify the maximum number of endpoint instances for the model. The maximum value must be equal to or greater than the value specified for the minimum number of endpoint instances. SageMaker automatic scaling does not enforce a limit for this value.
You must also specify the minimum number of instances for the model. This value must be at least 1, and equal to or less than the value specified for the maximum number of endpoint instances.

To determine the minimum and maximum number of instances that you need for typical traffic, test your auto scaling configuration with the expected rate of traffic to your model.

**Important**
Scaling-in occurs when there is no traffic: if a variant’s traffic becomes zero, SageMaker automatically scales in to the minimum number of instances specified. In this case, SageMaker emits metrics with a value of zero. Minimum instance count is required to be 1 or higher.

**Cooldown period**

Tune the responsiveness of your scaling policy by adding a cooldown period. A cooldown period controls when your model is scaled-in (by reducing instances) or scaled-out (by increasing instances). It does this by blocking subsequent scale-in or scale-out requests until the period expires. This slows the deletion of instances for scale-in requests, and the creation of instances for scale-out requests. A cooldown period helps to ensure that the scaling policy doesn't launch or terminate additional instances before the previous scaling activity takes effect. After automatic scaling dynamically scales using a scaling policy, it waits for the cooldown period to complete before resuming scaling activities.

You configure the cooldown period in your automatic scaling policy. You can specify the following cooldown periods:

- A scale-in activity reduces the number of instances. A scale-in cooldown period specifies the amount of time, in seconds, after a scale-in activity completes before another scale-in activity can start.
- A scale-out activity increases the number of instances. A scale-out cooldown period specifies the amount of time, in seconds, after a scale-out activity completes before another scale-out activity can start.

If you don’t specify a scale-in or a scale-out cooldown period automatic scaling use the default, which is 300 seconds for each.

If instances are being added or removed too quickly when you test your automatic scaling configuration, consider increasing this value. You can see this behavior if the traffic to your model has a lot of spikes, or if you have multiple automatic scaling policies defined for a variant.

If instances are not being added quickly enough to address increased traffic, consider decreasing this value.

**Permissions**

The SagemakerFullAccessPolicy IAM policy has all of the IAM permissions required to perform auto scaling. For more information about SageMaker IAM permissions, see [SageMaker Roles (p. 3387)](#).

If you are using a custom permission policy, you must include the following permissions:

```json
{
    "Effect": "Allow",
    "Action": [
        "sagemaker:DescribeEndpoint",
        "sagemaker:DescribeEndpointConfig",
        "sagemaker:UpdateEndpointWeightsAndCapacities"
    ],
    "Resource": "*"
}
```
Service-linked role

Auto scaling uses the AWSServiceRoleForApplicationAutoScaling_SageMakerEndpoint service-linked role; it is created for you automatically. A service-linked role is a unique type of IAM role that is linked directly to an AWS service. Service-linked roles are predefined by the service and include all of the permissions that the service requires to call other AWS services on your behalf. For more information, see Service-Linked Roles.

Configure model auto scaling with the console

To configure auto scaling for a model using the console

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, open Inference and choose Endpoints.
3. Choose the endpoint that you want to configure.
4. For Endpoint runtime settings, choose the model variant that you want to configure.
5. For Endpoint runtime settings, choose Configure auto scaling.

The Configure variant automatic scaling page appears.
6. For Minimum capacity, type the minimum number of instances that you want the scaling policy to maintain. At least 1 instance is required.
7. For Maximum capacity, type the maximum number of instances that you want the scaling policy to maintain.
8. For the target value, type the average number of invocations per instance per minute for the model. To determine this value, follow the guidelines in Load testing (p. 2461).

Application Auto Scaling adds or removes instances to keep the metric close to the value that you specify.
9. For Scale-in cool down (seconds) and Scale-out cool down (seconds), type the number seconds for each cool down period. Assuming that the order in the list is based on either most important to less important of first applied to last applied.

10. Select Deactivate scale in to prevent the scaling policy from deleting variant instances if you want to ensure that your variant scales out to address increased traffic, but are not concerned with removing instances to reduce costs when traffic decreases, deactivate scale-in activities.

Scale-out activities are always activated so that the scaling policy can create endpoint instances as needed.

11. Choose Save.

This procedure registers a model as a scalable target with Application Auto Scaling. When you register a model, Application Auto Scaling performs validation checks to ensure the following:

- The model exists
- The permissions are sufficient
- You aren't registering a variant with an instance that is a burstable performance instance such as T2

Note
SageMaker doesn't support auto scaling for burstable instances such as T2, because they already allow for increased capacity under increased workloads. For information about burstable performance instances, see Amazon EC2 Instance Types.

Register a model

You can add auto scaling for a model with the AWS CLI or the Application Auto Scaling API. You first must register the model, then you must define an auto scaling policy.

Register a model with the AWS CLI

With the AWS CLI, you can configure auto scaling based on either a predefined or a custom metric.

To register your endpoint, use the `register-scalable-target` AWS CLI command with the following parameters:

- `--service-namespace`—Set this value to sagemaker.
- `--resource-id`—The resource identifier for the model (specifically, the production variant). For this parameter, the resource type is endpoint and the unique identifier is the name of the production variant. For example, endpoint/MyEndpoint/variant/MyVariant.
- `--scalable-dimension`—Set this value to sagemaker:variant:DesiredInstanceCount.
- `--min-capacity`—The minimum number of instances that for this model. Set min-capacity to at least 1. It must be equal to or less than the value specified for max-capacity.
- `--max-capacity`—The maximum number of instances that Application Auto Scaling should manage. Set max-capacity to a minimum of 1, It must be equal to or greater than the value specified for min-capacity.

Example

The following example shows how to register a model named MyVariant that is dynamically scaled to have one to eight instances:

```bash
aws application-autoscaling register-scalable-target
  --service-namespace sagemaker
```
Register a model with the Application Auto Scaling API

To define the scaling limits for the model, register your model with Application Auto Scaling. Application Auto Scaling dynamically scales the number of production variant instances.

To register your model with Application Auto Scaling, use the `RegisterScalableTarget` Application Auto Scaling API action with the following parameters:

- **ServiceNamespace**—Set this value to `sagemaker`.
- **ResourceId**—The resource identifier for the production variant. For this parameter, the resource type is `endpoint` and the unique identifier is the name of the variant, for example `endpoint/MyEndPoint/variant/MyVariant`.
- **ScalableDimension**—Set this value to `sagemaker:variant:DesiredInstanceCount`.
- **MinCapacity**—The minimum number of instances to be managed by Application Auto Scaling. This value must be set to at least 1 and must be equal to or less than the value specified for **MaxCapacity**.
- **MaxCapacity**—The maximum number of instances to be managed by Application Auto Scaling. This value must be set to at least 1 and must be equal to or greater than the value specified for **MinCapacity**.

Example

The following example shows how to register a SageMaker production variant that is dynamically scaled to use one to eight instances:

```
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
X-Amz-Target: AnyScaleFrontendService.RegisterScalableTarget
X-Amz-Date: 20160506T182145Z
User-Agent: aws-cli/1.10.23 Python/2.7.11 Darwin/15.4.0 botocore/1.4.8
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS

{
    "ServiceNamespace": "sagemaker",
    "ResourceId": "endpoint/MyEndPoint/variant/MyVariant",
    "ScalableDimension": "sagemaker:variant:DesiredInstanceCount",
    "MinCapacity": 1,
    "MaxCapacity": 8
}
```

Define a scaling policy

To specify the metrics and target values for a scaling policy, you configure a target-tracking scaling policy. You can use either a predefined metric or a custom metric.

Scaling policy configuration is represented by a JSON block. You save your scaling policy configuration as a JSON block in a text file. You use that text file when invoking the AWS CLI or the Application Auto Scaling API. For more information about policy configuration syntax, see `TargetTrackingScalingPolicyConfiguration` in the Application Auto Scaling API Reference.

The following options are available for defining a target-tracking scaling policy configuration.
Use a predefined metric

To quickly define a target-tracking scaling policy for a variant, use the SageMakerVariantInvocationsPerInstance predefined metric. SageMakerVariantInvocationsPerInstance is the average number of times per minute that each instance for a variant is invoked. We strongly recommend using this metric.

To use a predefined metric in a scaling policy, create a target tracking configuration for your policy. In the target tracking configuration, include a PredefinedMetricSpecification for the predefined metric and a TargetValue for the target value of that metric.

Example

The following example is a typical policy configuration for target-tracking scaling for a variant. In this configuration, we use the SageMakerVariantInvocationsPerInstance predefined metric to adjust the number of variant instances so that each instance has an InvocationsPerInstance metric of 70.

```json
{
    "TargetValue": 70.0,
    "PredefinedMetricSpecification":
    {
        "PredefinedMetricType": "SageMakerVariantInvocationsPerInstance"
    }
}
```

Use a custom metric

If you need to define a target-tracking scaling policy that meets your custom requirements, define a custom metric. You can define a custom metric based on any production variant metric that changes in proportion to scaling.

Not all SageMaker metrics work for target tracking. The metric must be a valid utilization metric, and it must describe how busy an instance is. The value of the metric must increase or decrease in inverse proportion to the number of variant instances. That is, the value of the metric should decrease when the number of instances increases.

**Important**

Before deploying automatic scaling in production, you must test automatic scaling with your custom metric.

Example

The following example is a target-tracking configuration for a scaling policy. In this configuration, for a variant named my-variant, a custom metric adjusts the variant based on an average CPU utilization of 50 percent across all instances.

```json
{
    "TargetValue": 50,
    "CustomizedMetricSpecification":
    {
        "MetricName": "CPUUtilization",
        "Namespace": "/aws/sagemaker/Endpoints",
        "Dimensions": [
            {"Name": "EndpointName", "Value": "my-endpoint" },
            {"Name": "VariantName","Value": "my-variant"}
        ],
        "Statistic": "Average",
        "Unit": "Percent"
    }
}
```
Use an online explainability metric

This guide shows how to use a metric to track the scaling of endpoints with online explainability. When an endpoint has online explainability activated, it emits a `ExplanationsPerInstance` metric that outputs the average number of records explained per minute, per instance, for a `variant`. The resource utilization of explaining records can be more different than that of predicting records. We strongly recommend using this metric for target-tracking scaling of endpoints with online explainability activated.

To use this online explainability metric inside a scaling policy, create a target tracking configuration. In the tracking configuration, include a `CustomizedMetricSpecification` for the custom metrics and a `TargetValue` for the target value.

The following is an example of a policy configuration that uses `ExplanationsPerInstance`. It is used to adjust the number of variant instances so that each instance has an `ExplanationsPerInstance` metric of 20.

```
{
  "TargetValue": 20,
  "CustomizedMetricSpecification": {
    "MetricName": "ExplanationsPerInstance",
    "Namespace": "AWS/SageMaker",
    "Dimensions": [
      {"Name": "EndpointName", "Value": "my-endpoint" },
      {"Name": "VariantName","Value": "my-variant"}
    ],
    "Statistic": "Sum"
  }
}
```

**Application Auto Scaling** allows multiple target tracking scaling policies for a scalable target. Consider adding the `InvocationsPerInstance` policy from the predefined metric section (in addition to the `ExplanationsPerInstance` policy). For example, if most invocations don't return an explanation because of the threshold value set in the `EnableExplanations` parameter, then the endpoint can choose the `InvocationsPerInstance` policy. If there is a large number of explanations, the endpoint can use the `ExplanationsPerInstance` policy.

Add a cooldown period

To add a cooldown period for scaling-out your model, specify a value, in seconds, for `ScaleOutCoolDown`. Similarly, to add a cooldown period for scaling-in your model, add a value, in seconds, for `ScaleInCoolDown`. For more information about `ScaleInCoolDown` and `ScaleOutCoolDown`, see [TargetTrackingScalingPolicyConfiguration](#) in the [Application Auto Scaling API Reference](#).

**Example**

The following is an example target-tracking configuration for a scaling policy. In this configuration, the `SageMakerVariantInvocationsPerInstance` predefined metric is used to adjust scaling based on an average of 70 across all instances of that variant. The configuration provides a scale-in cooldown period of 10 minutes and a scale-out cooldown period of 5 minutes.

```
{
}
```
Apply a scaling policy

After registering your model and defining a scaling policy, apply the scaling policy to the registered model. To apply a scaling policy, you can use the AWS CLI or the Application Auto Scaling API.

Apply a scaling policy (AWS CLI)

To apply a scaling policy to your model, use the `put-scaling-policy` AWS CLI command with the following parameters:

- `--policy-name`—The name of the scaling policy.
- `--policy-type`—Set this value to TargetTrackingScaling.
- `--resource-id`—The resource identifier for the variant. For this parameter, the resource type is endpoint and the unique identifier is the name of the variant. For example `endpoint/MyEndpoint/variant/MyVariant`.
- `--service-namespace`—Set this value to `sagemaker`.
- `--scalable-dimension`—Set this value to `sagemaker:variant:DesiredInstanceCount`.
- `--target-tracking-scaling-policy-configuration`—The target-tracking scaling policy configuration to use for the model.

Example

The following example uses with Application Auto Scaling to apply a target-tracking scaling policy named `myscalablepolicy` to a model (variant) named `myscalablevariant`. The policy configuration is saved in a file named `config.json`.

```
aws application-autoscaling put-scaling-policy \
  --policy-name myscalablepolicy \
  --policy-type TargetTrackingScaling \
  --resource-id endpoint/MyEndpoint/variant/MyVariant \
  --service-namespace sagemaker \
  --scalable-dimension sagemaker:variant:DesiredInstanceCount \
  --target-tracking-scaling-policy-configuration file://config.json
```

Apply a scaling policy (Application Auto Scaling API)

To apply a scaling policy to a variant with the Application Auto Scaling API, use the `PutScalingPolicy` Application Auto Scaling API action with the following parameters:

- `PolicyName`—The name of the scaling policy.
- `ServiceNamespace`—Set this value to `sagemaker`.
- `ResourceId`—The resource identifier for the variant. For this parameter, the resource type is endpoint and the unique identifier is the name of the variant. For example, `endpoint/MyEndpoint/variant/MyVariant`.
- `ScalableDimension`—Set this value to `sagemaker:variant:DesiredInstanceCount`.

```
"TargetValue": 70.0,
"PredefinedMetricSpecification":
  {   "PredefinedMetricType": "SageMakerVariantInvocationsPerInstance"
  },
"ScaleInCooldown": 600,
"ScaleOutCooldown": 300
```
• **PolicyType**—Set this value to `TargetTrackingScaling`.
• **TargetTrackingScalingPolicyConfiguration**—The target-tracking scaling policy configuration to use for the variant.

**Example**

The following example uses Application Auto Scaling to apply a target-tracking scaling policy named `myscalablepolicy` to a variant named `myscalablevariant`. It uses a policy configuration based on the `SageMakerVariantInvocationsPerInstance` predefined metric.

```
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
X-Amz-Target: AnyScaleFrontendService.
X-Amz-Date: 20160506T182145Z
User-Agent: aws-cli/1.10.23 Python/2.7.11 Darwin/15.4.0 botocore/1.4.8
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS

{
  "PolicyName": "myscalablepolicy",
  "ServiceNamespace": "sagemaker",
  "ResourceId": "endpoint/MyEndpoint/variant/MyVariant",
  "ScalableDimension": "sagemaker:variant:DesiredInstanceCount",
  "PolicyType": "TargetTrackingScaling",
  "TargetTrackingScalingPolicyConfiguration": {
    "TargetValue": 70.0,
    "PredefinedMetricSpecification": {
      "PredefinedMetricType": "SageMakerVariantInvocationsPerInstance"
    }
  }
}
```

**Edit a scaling policy**

You can edit a scaling policy with the AWS Management Console, the AWS CLI, or the Application Auto Scaling API.

**Scale-in**

Scaling-in occurs when there is no traffic: if a variant's traffic becomes zero, SageMaker automatically scales in to the minimum number of instances specified. In this case, SageMaker emits metrics with a value of zero. Minimum instance count is required to be 1 or higher.

**Deactivate scale-in activity**

You can prevent the target-tracking scaling policy configuration from scaling in your variant by deactivating scale-in activity. Deactivating scale-in activity prevents the scaling policy from deleting instances, while still allowing it to create them as needed.

To activate or deactivate scale-in activity for your model, specify a Boolean value for `DisableScaleIn`. For more information about `DisableScaleIn`, see `TargetTrackingScalingPolicyConfiguration` in the Application Auto Scaling API Reference.

**Example**

The following is an example of a target-tracking configuration for a scaling policy where it will scale-out, but not scale-in. In this configuration, the `SageMakerVariantInvocationsPerInstance` predefined metric...
metric will scale-out based on an average of 70 invocations (inference requests) across all instances the model is on. The configuration also deactivates scale-in activity for the scaling policy.

```json
{
    "TargetValue": 70.0,
    "PredefinedMetricSpecification": {
        "PredefinedMetricType": "SageMakerVariantInvocationsPerInstance"
    },
    "DisableScaleIn": true
}
```

**Scale-out**

To manually scale-out, adjust the minimum capacity. You can use the console to update this value. Alternatively, use the AWS CLI with the `--min-capacity` argument, or use the Application Auto Scaling API's `MinCapacity` parameter.

**Deactivate scale-out activity**

To prevent scale-out, adjust the maximum capacity. You can use the console to update this value. Alternatively, use the AWS CLI with the `--max-capacity` argument, or use the Application Auto Scaling API's `MaxCapacity` parameter.

**Edit a scaling policy (Console)**

To edit a scaling policy with the AWS Management Console, use the same procedure that you used to Configure model auto scaling with the console (p. 2450).

**Edit a scaling policy (AWS CLI or Application Auto Scaling API)**

You can use the AWS CLI or the Application Auto Scaling API to edit a scaling policy in the same way that you apply a scaling policy:

- With the AWS CLI, specify the name of the policy that you want to edit in the `--policy-name` parameter. Specify new values for the parameters that you want to change.
- With the Application Auto Scaling API, specify the name of the policy that you want to edit in the `PolicyName` parameter. Specify new values for the parameters that you want to change.

For more information, see Apply a scaling policy (p. 2455).

**Delete a scaling policy**

You can delete a scaling policy with the AWS Management Console, the AWS CLI, or the Application Auto Scaling API. You must delete a scaling policy if you wish to update a model's endpoint.

**Delete a scaling policy (Console)**

To delete an automatic scaling policy with the AWS console:

2. In the navigation pane, choose Endpoints.
3. Choose the endpoint for which you want to delete automatic scaling.
4. For **Endpoint runtime settings**, choose the variant that you want to configure.
5. Choose **Configure auto scaling**.
6. Choose **Deregister auto scaling**.

**Delete a scaling policy (AWS CLI or Application Auto Scaling API)**

You can use the AWS CLI or the Application Auto Scaling API to delete a scaling policy from a variant.

**Delete a scaling policy (AWS CLI)**

To delete a scaling policy from a variant, use the [delete-scaling-policy](https://docs.aws.amazon.com/cli/latest/reference/application-autoscaling/delete-scaling-policy.html) AWS CLI command with the following parameters:

- **--policy-name**—The name of the scaling policy.
- **--resource-id**—The resource identifier for the variant. For this parameter, the resource type is endpoint and the unique identifier is the name of the variant. For example, endpoint/MyEndpoint/variant/MyVariant.
- **--service-namespace**—Set this value to sagemaker.
- **--scalable-dimension**—Set this value to sagemaker:variant:DesiredInstanceCount.

**Example**

The following example deletes a target-tracking scaling policy named myscalablepolicy from a variant named myscalablevariant.

```bash
aws application-autoscaling delete-scaling-policy \
  --policy-name myscalablepolicy \
  --resource-id endpoint/MyEndpoint/variant/MyVariant \
  --service-namespace sagemaker \
  --scalable-dimension sagemaker:variant:DesiredInstanceCount
```

**Delete a scaling policy (Application Auto Scaling API)**

To delete a scaling policy from your variant, use the [DeleteScalingPolicy](https://docs.aws.amazon.com/autoscaling/application/latest/userguide/autoscaling-api-ref-delete-scaling-policy.html) Application Auto Scaling API action with the following parameters:

- **PolicyName**—The name of the scaling policy.
- **ServiceNamespace**—Set this value to sagemaker.
- **ResourceId**—The resource identifier for the variant. For this parameter, the resource type is endpoint and the unique identifier is the name of the variant. For example, endpoint/MyEndpoint/variant/MyVariant.
- **ScalableDimension**—Set this value to sagemaker:variant:DesiredInstanceCount.

**Example**

The following example uses the Application Auto Scaling API to delete a target-tracking scaling policy named myscalablepolicy from a variant named myscalablevariant.

```http
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
X-Amz-Target: AnyScaleFrontendService.DeleteScalingPolicy
```
Query Endpoint Auto scaling History

You can view the status of scaling activities from your endpoint using `DescribeScalingActivities`. `DescribeScalingActivities` provides descriptive information about the scaling activities in the specified namespace from the previous six weeks.

**How To Query Endpoint Auto Scaling Actions**

Query your auto scaling endpoints with `DescribeScalingActivities`. To do so, specify `ServiceNamespace` parameter. `ServiceNamespace` is the name of the AWS service that provides the resource.

Valid service name values include the following:

ecs | elasticmapreduce | ec2 | appstream | dynamodb | rds | sagemaker | custom-resource | comprehend | lambda | cassandra

In this situation you need to set `ServiceNamespace` to `sagemaker`.

Use the following AWS CLI command to view details about all of your sagemaker endpoints that have a scaling policy:

```
aws application-autoscaling describe-scaling-activities \
  --service-namespace sagemaker
```

You can search for a specific endpoint using `ResourceId`:

```
aws application-autoscaling describe-scaling-activities \
  --service-namespace sagemaker \
  --resource-id endpoint/<endpoint_name>/variant/<variant_name>
```

When you run this command, it returns the following output:

```
{
  "ActivityId": "activity-id",
  "ServiceNamespace": "sagemaker",
  "ResourceId": "endpoint/<endpoint_name>/variant/<variant_name>",
  "ScalableDimension": "sagemaker:variant:DesiredInstanceCount",
  "Description": "string",
  "Cause": "string",
  "StartTime": timestamp,
  "EndTime": timestamp,
  "StatusCode": "string",
  "StatusMessage": "string"
}
```
Identify blocked auto scaling from instance quotas

When you scale out or add more instances, you might reach your account-level instance quota. You can use \texttt{DescribeScalingActivities} to check whether you have reached your instance quota. When you exceed your quota, automatic scaling is blocked.

To check if you have reached your instance quota, use the AWS CLI command as shown in the proceeding example where you specified the \texttt{ResourceId}:

\begin{verbatim}
aws application-autoscaling describe-scaling-activities \
  --service-namespace sagemaker \
  --resource-id endpoint/<endpoint_name>/variant/<variant_name>
\end{verbatim}

Within the return syntax, check the \texttt{StatusCode} and \texttt{StatusMessage} keys and their associated values. \texttt{StatusCode} returns Failed. Within \texttt{StatusMessage} there is a message indicating that the account-level service quota was reached. The following is an example of what that message might look like:

\begin{verbatim}
{
  "ActivityId": "activity-id",
  "ServiceNamespace": "sagemaker",
  "ResourceId": "endpoint/<endpoint_name>/variant/<variant_name>",
  " ScalableDimension": "sagemaker:variant:DesiredInstanceCount",
  "Description": "string",
  "Cause": "minimum capacity was set to 110",
  "StartTime": timestamp,
  "EndTime": timestamp,
  "StatusCode": "Failed",
  "StatusMessage": "Failed to set desired instance count to 110. Reason: The account-level service limit 'ml.xx.xxxxxx for endpoint usage' is 1000 Instances, with current utilization of 997 Instances and a request delta of 20 Instances. Please contact AWS support to request an increase for this limit. (Service: AmazonSageMaker; Status Code: 400; Error Code: ResourceLimitExceeded; Request ID: request-id)."
}
\end{verbatim}

Update or delete endpoints that use automatic scaling

Topics

- Update endpoints that use automatic scaling (p. 2460)
- Delete endpoints configured for automatic scaling (p. 2461)

Update endpoints that use automatic scaling

When you update an endpoint, Application Auto Scaling checks to see whether any of the models on that endpoint are targets for automatic scaling. If the update would change the instance type for any model that is a target for automatic scaling, the update fails.

In the AWS Management Console, you see a warning that you must deregister the model from automatic scaling before you can update it. If you are trying to update the endpoint by calling the \texttt{UpdateEndpoint} API, the call fails. Before you update the endpoint, delete any scaling policies configured for it by calling the \texttt{DeleteScalingPolicy} Application Auto Scaling API action, then call \texttt{DeregisterScalableTarget} to deregister the variant as a scalable target. After you update the endpoint, you can register the variant as a scalable target and attach an automatic scaling policy to the updated variant.

There is one exception. If you change the model for a variant that is configured for automatic scaling, Amazon SageMaker automatic scaling allows the update. This is because changing the model doesn't
typically affect performance enough to change automatic scaling behavior. If you do update a model for a variant configured for automatic scaling, ensure that the change to the model doesn't significantly affect performance and automatic scaling behavior.

When you update SageMaker endpoints that have automatic scaling applied, complete the following steps:

**To update an endpoint that has automatic scaling applied**

1. Deregister the endpoint as a scalable target by calling `DeregisterScalableTarget`.
2. Because automatic scaling is blocked while the update operation is in progress (or if you turned off automatic scaling in the previous step), you might want to take the additional precaution of increasing the number of instances for your endpoint during the update. To do this, update the instance counts for the production variants hosted at the endpoint by calling `UpdateEndpointWeightsAndCapacities`.
3. Call `DescribeEndpoint` repeatedly until the value of the `EndpointStatus` field of the response is `InService`.
4. Call `DescribeEndpointConfig` to get the values of the current endpoint config.
5. Create a new endpoint config by calling `CreateEndpointConfig`. For the production variants where you want to keep the existing instance count or weight, use the same variant name from the response from the call to `DescribeEndpointConfig` in the previous step. For all other values, use the values that you got as the response when you called `DescribeEndpointConfig` in the previous step.
6. Update the endpoint by calling `UpdateEndpoint`. Specify the endpoint config you created in the previous step as the `EndpointConfig` field. If you want to retain the variant properties like instance count or weight, set the value of the `RetainAllVariantProperties` parameter to `True`. This specifies that production variants with the same name will are updated with the most recent `DesiredInstanceCount` from the response from the call to `DescribeEndpoint`, regardless of the values of the `InitialInstanceCount` field in the new `EndpointConfig`.
7. (Optional) Re-activating automatic scaling by calling `RegisterScalableTarget`.

**Note**
Steps 1 and 7 are required only if you are updating an endpoint with the following changes:

- Changing the instance type for a production variant that has automatic scaling configured
- Removing a production variant that has automatic scaling configured.

**Delete endpoints configured for automatic scaling**

If you delete an endpoint, Application Auto Scaling checks to see whether any of the models on that endpoint are targets for automatic scaling. If any are and you have permission to deregister the model, Application Auto Scaling deregisters those models as scalable targets without notifying you. If you use a custom permission policy that doesn't provide permission for the `DeleteScalingPolicy` and `DeregisterScalableTarget` actions, you must delete automatic scaling policies and deregister scalable targets and before deleting the endpoint.

**Note**
As an IAM user, you might not have sufficient permission to delete an endpoint if another user configured automatic scaling for a variant on that endpoint.

**Load testing your auto scaling configuration**

Perform load tests to choose an automatic scaling configuration that works the way you want.
The following guidelines for load testing assume you are using an automatic scaling policy that uses the predefined target metric SageMakerVariantInvocationsPerInstance.

Topics

- Determine the performance characteristics (p. 2462)
- Calculate the target load (p. 2462)

Determine the performance characteristics

Perform load testing to find the peak InvocationsPerInstance that your model's production variant can handle, and the latency of requests, as concurrency increases.

This value depends on the instance type chosen, payloads that clients of your model typically send, and the performance of any external dependencies your model has.

To find the peak requests-per-second (RPS) your model's production variant can handle and latency of requests

1. Set up an endpoint with your model using a single instance. For information about how to set up an endpoint, see Deploy the Model to SageMaker Hosting Services (p. 310).
2. Use a load testing tool to generate an increasing number of parallel requests, and monitor the RPS and model latency in the output of the load testing tool.

   Note
   You can also monitor requests-per-minute instead of RPS. In that case don't multiply by 60 in the equation to calculate SageMakerVariantInvocationsPerInstance shown below.

   When the model latency increases or the proportion of successful transactions decreases, this is the peak RPS that your model can handle.

Calculate the target load

After you find the performance characteristics of the variant, you can determine the maximum RPS we should allow to be sent to an instance. The threshold used for scaling must be less than this maximum value. Use the following equation in combination with load testing to determine the correct value for the SageMakerVariantInvocationsPerInstance target metric in your automatic scaling configuration.

\[
\text{SageMakerVariantInvocationsPerInstance} = (\text{MAX\_RPS} \times \text{SAFETY\_FACTOR}) \times 60
\]

Where MAX_RPS is the maximum RPS that you determined previously, and SAFETY_FACTOR is the safety factor that you chose to ensure that your clients don't exceed the maximum RPS. Multiply by 60 to convert from RPS to invocations-per-minute to match the per-minute CloudWatch metric that SageMaker uses to implement automatic scaling (you don't need to do this if you measured requests-per-minute instead of requests-per-second).

   Note
   SageMaker recommends that you start testing with a SAFETY_FACTOR of 0.5. Test your automatic scaling configuration to ensure it operates in the way you expect with your model for both increasing and decreasing customer traffic on your endpoint.

Use AWS CloudFormation to update auto scaling policies

The following example shows how to activate Application Auto Scaling on an endpoint using AWS CloudFormation.
Host instance storage volumes

When you create an endpoint, Amazon SageMaker attaches an Amazon Elastic Block Store (Amazon EBS) storage volume to Amazon EC2 instances that hosts the endpoint. The size of the storage volume is scalable, and storage options are divided into two categories: SSD-backed storage and HDD-backed storage.

For more information about Amazon EBS storages and features, see the following pages.

- Amazon EBS Features
- Amazon EBS User Guide

For a full list of the host instance storage volumes, see Host Instance Storage Volumes Table

Note
Amazon SageMaker attaches an Amazon Elastic Block Store (Amazon EBS) storage volume to Amazon EC2 instances only when you create Asynchronous inference (p. 2522) or Real-time inference (p. 2388) endpoint types. For more information on customizing Amazon EBS storage volume, see SageMaker endpoint parameters for large model inference (p. 2557).

Safely validate models in production

With SageMaker, you can test multiple models or model versions behind the same endpoint using variants. A variant consists of an ML instance and the serving components specified in a SageMaker model. You can have multiple variants behind an endpoint. Each variant can have a different instance type or a SageMaker model that can be autoscaled independently of the others. The models within
the variants can be trained using different datasets, different algorithms, different ML frameworks, or any combination of all of these. All the variants behind an endpoint share the same inference code. SageMaker supports two types of variants, production variants and shadow variants.

If you have multiple production variants behind an endpoint, then you can allocate a portion of your inference requests to each variant. Each request is routed to only one of the production variants. The production variant to which the request was routed provides the response to the caller. You can compare how the production variants perform relative to each other.

You can also have a shadow variant corresponding to a production variant behind an endpoint. A portion of the inference requests that goes to the production variant is replicated to the shadow variant. The responses of the shadow variant are logged for comparison and not returned to the caller. This lets you test the performance of the shadow variant without exposing the caller to the response produced by the shadow variant.

**Topics**
- Production variants (p. 2464)
- Shadow variants (p. 2472)

### Production variants

In production ML workflows, data scientists and engineers frequently try to improve performance using various methods, such as Perform Automatic Model Tuning with SageMaker (p. 1863), training on additional or more-recent data, improving feature selection, using better updated instances and serving containers. You can use production variants to compare your models, instances and containers, and choose the best performing candidate to respond to inference requests.

With SageMaker multi-variant endpoints you can distribute endpoint invocation requests across multiple production variants by providing the traffic distribution for each variant, or you can invoke a specific variant directly for each request. In this topic, we look at both methods for testing ML models.

**Topics**
- Test models by specifying traffic distribution (p. 2464)
- Test models by invoking specific variants (p. 2465)
- Model A/B test example (p. 2466)

### Test models by specifying traffic distribution

To test multiple models by distributing traffic between them, specify the percentage of the traffic that gets routed to each model by specifying the weight for each production variant in the endpoint configuration. For information, see CreateEndpointConfig. The following diagram shows how this works in more detail.
Test models by invoking specific variants

To test multiple models by invoking specific models for each request, specify the specific version of the model you want to invoke by providing a value for the TargetVariant parameter when you call `InvokeEndpoint`. SageMaker ensures that the request is processed by the production variant you specify. If you have already provided traffic distribution and specify a value for the TargetVariant parameter, the targeted routing overrides the random traffic distribution. The following diagram shows how this works in more detail.
Performing A/B testing between a new model and an old model with production traffic can be an effective final step in the validation process for a new model. In A/B testing, you test different variants of your models and compare how each variant performs. If the newer version of the model delivers better performance than the previously existing version, replace the old version of the model with the new version in production.

The following example shows how to perform A/B model testing. For a sample notebook that implements this example, see "A/B Testing ML models in production."

**Step 1: Create and deploy models**

First, we define where our models are located in Amazon S3. These locations are used when we deploy our models in subsequent steps:

```python
model_url1 = f"s3://{path_to_model_1}"
model_url2 = f"s3://{path_to_model_2}"```

Next, we create the model objects with the image and model data. These model objects are used to deploy production variants on an endpoint. The models are developed by training ML models on different data sets, different algorithms or ML frameworks, and different hyperparameters:
from sagemaker.amazon.amazon_estimator import get_image_uri

model_name = f"DEMO-xgb-churn-pred-{datetime.now():%Y-%m-%d-%H-%M-%S}"  
model_name2 = f"DEMO-xgb-churn-pred2-{datetime.now():%Y-%m-%d-%H-%M-%S}"  
image_uri = get_image_uri(boto3.Session().region_name, 'xgboost', '0.90-1')  
image_uri2 = get_image_uri(boto3.Session().region_name, 'xgboost', '0.90-2')

sm_session.create_model(  
    name=model_name,  
    role=role,  
    container_defs={  
        'Image': image_uri,  
        'ModelDataUrl': model_url  
    }  
)

sm_session.create_model(  
    name=model_name2,  
    role=role,  
    container_defs={  
        'Image': image_uri2,  
        'ModelDataUrl': model_url2  
    }  
)

We now create two production variants, each with its own different model and resource requirements (instance type and counts). This enables you to also test models on different instance types.

We set an initial_weight of 1 for both variants. This means that 50% of requests go to Variant1, and the remaining 50% of requests to Variant2. The sum of weights across both variants is 2 and each variant has weight assignment of 1. This means that each variant receives 1/2, or 50%, of the total traffic.

from sagemaker.session import production_variant

variant1 = production_variant(  
    model_name=model_name,  
    instance_type="ml.m5.xlarge",  
    initial_instance_count=1,  
    variant_name='Variant1',  
    initial_weight=1,  
)

variant2 = production_variant(  
    model_name=model_name2,  
    instance_type="ml.m5.xlarge",  
    initial_instance_count=1,  
    variant_name='Variant2',  
    initial_weight=1,  
)

Finally we're ready to deploy these production variants on a SageMaker endpoint.

endpoint_name = f"DEMO-xgb-churn-pred-{datetime.now():%Y-%m-%d-%H-%M-%S}"  
print(f"EndpointName={endpoint_name}"')

sm_session.endpoint_from_production_variants(  
    name=endpoint_name,  
    production_variants=[variant1, variant2]  
)
### Step 2: Invoke the deployed models

Now we send requests to this endpoint to get inferences in real time. We use both traffic distribution and direct targeting.

First, we use traffic distribution that we configured in the previous step. Each inference response contains the name of the production variant that processes the request, so we can see that traffic to the two production variants is roughly equal.

```python
# get a subset of test data for a quick test
!tail -120 test_data/test-dataset-input-cols.csv > test_data/test_sample_tail_input_cols.csv
print(f"Sending test data traffic to the endpoint {endpoint_name}. \nPlease wait...")

with open('test_data/test_sample_tail_input_cols.csv', 'r') as f:
    for row in f:
        print('.', end='', flush=True)
        payload = row.rstrip('
')
        sm_runtime.invoke_endpoint(
            EndpointName=endpoint_name,
            ContentType="text/csv",
            Body=payload
        )
        time.sleep(0.5)

print("Done!")
```

SageMaker emits metrics such as Latency and Invocations for each variant in Amazon CloudWatch. For a complete list of metrics that SageMaker emits, see Monitor Amazon SageMaker with Amazon CloudWatch (p. 3577). Let's query CloudWatch to get the number of invocations per variant, to show how invocations are split across variants by default:

<table>
<thead>
<tr>
<th>Timestamp</th>
<th>Variant1</th>
<th>Variant2</th>
</tr>
</thead>
<tbody>
<tr>
<td>2020-06-05 15:34:00+00:00</td>
<td>44.0</td>
<td>60.0</td>
</tr>
<tr>
<td>2020-06-05 15:35:00+00:00</td>
<td>7.0</td>
<td>9.0</td>
</tr>
</tbody>
</table>

Now let's invoke a specific version of the model by specifying Variant1 as the TargetVariant in the call to `invoke_endpoint`.

```python
print(f"Sending test data traffic to the endpoint {endpoint_name}. \nPlease wait...")
with open('test_data/test_sample_tail_input_cols.csv', 'r') as f:
    for row in f:
        print('.', end='', flush=True)
        payload = row.rstrip('
')
```
sm_runtime.invoke_endpoint(
    EndpointName=endpoint_name,
    ContentType="text/csv",
    Body=payload,
    TargetVariant="Variant1"
)

time.sleep(0.5)

To confirm that all new invocations were processed by Variant1, we can query CloudWatch to get the number of invocations per variant. We see that for the most recent invocations (latest timestamp), all requests were processed by Variant1, as we had specified. There were no invocations made for Variant2.

<table>
<thead>
<tr>
<th>Timestamp</th>
<th>Variant1</th>
<th>Variant2</th>
</tr>
</thead>
<tbody>
<tr>
<td>2020-06-05 15:34:00+00:00</td>
<td>44.0</td>
<td>60.0</td>
</tr>
<tr>
<td>2020-06-05 15:35:00+00:00</td>
<td>7.0</td>
<td>9.0</td>
</tr>
<tr>
<td>2020-06-05 15:36:00+00:00</td>
<td>99.0</td>
<td>NaN</td>
</tr>
</tbody>
</table>

**Step 3: Evaluate model performance**

To see which model version performs better, let's evaluate the accuracy, precision, recall, F1 score, and Receiver operating characteristic/Area under the curve for each variant. First, let's look at these metrics for Variant1:

- Accuracy: 0.958333333333334
- Precision: 0.9411764705882353
- Recall: 0.8
- F1 Score: 0.8648484848484848
- AUC is 0.895

![Receiver Operating Characteristic curve](image)

Now let's look at the metrics for Variant2:
For most of our defined metrics, Variant2 is performing better, so this is the one that we want to use in production.

**Step 4: Increase traffic to the best model**

Now that we have determined that Variant2 performs better than Variant1, we shift more traffic to it. We can continue to use TargetVariant to invoke a specific model variant, but a simpler approach is to update the weights assigned to each variant by calling `UpdateEndpointWeightsAndCapacities`. This changes the traffic distribution to your production variants without requiring updates to your endpoint. Recall from the setup section that we set variant weights to split traffic 50/50. The CloudWatch metrics for the total invocations for each variant below show us the invocation patterns for each variant:

```
sm.update_endpoint_weights_and_capacities(
    EndpointName=endpoint_name,
    DesiredWeightsAndCapacities=[
        {
            "DesiredWeight": 25,
            "VariantName": variant1["VariantName"]
        },
        {
            "DesiredWeight": 75,
            "VariantName": variant2["VariantName"]
        }
    ]
)
```
The CloudWatch metrics for total invocations for each variant shows us higher invocations for Variant2 than for Variant1:

We can continue to monitor our metrics, and when we're satisfied with a variant's performance, we can route 100% of the traffic to that variant. We use `UpdateEndpointWeightsAndCapacities` to update the traffic assignments for the variants. The weight for Variant1 is set to 0 and the weight for Variant2 is set to 1. SageMaker now sends 100% of all inference requests to Variant2.

```python
sm.update_endpoint_weights_and_capacities(  
    EndpointName=endpoint_name,  
    DesiredWeightsAndCapacities=[  
        {  
            "DesiredWeight": 0,  
            "VariantName": variant1["VariantName"]  
        },  
        {  
            "DesiredWeight": 1,  
            "VariantName": variant2["VariantName"]  
        }  
    ]  
)
```

The CloudWatch metrics for the total invocations for each variant show that all inference requests are being processed by Variant2 and there are no inference requests processed by Variant1.

You can now safely update your endpoint and delete Variant1 from your endpoint. You can also continue testing new models in production by adding new variants to your endpoint and following steps 2 - 4.
Shadow variants

You can use SageMaker Model Shadow Deployments to create long running shadow variants to validate any new candidate component of your model serving stack before promoting it to production. The following diagram shows how shadow variants work in more detail.

Deploy shadow variants

The following code example shows how you can programmatically deploy shadow variants. Replace the user placeholder text in the example with your own information.

1. Create two SageMaker models: one for your production variant, and one for your shadow variant.

```python
import boto3
from sagemaker import get_execution_role, Session

aws_region = "aws-region"
boto_session = boto3.Session(region_name=aws_region)
```
sagemaker_client = boto_session.client("sagemaker")

role = get_execution_role()

bucket = Session(boto_session).default_bucket()

model_name1 = "name-of-your-first-model"
model_name2 = "name-of-your-second-model"

sagemaker_client.create_model(
ModelName = model_name1,
ExecutionRoleArn = role,
Containers=[
  {
    "Image": "ecr-image-uri-for-first-model",
    "ModelDataUrl": "s3-location-of-trained-first-model"
  }
]
)

sagemaker_client.create_model(
ModelName = model_name2,
ExecutionRoleArn = role,
Containers=[
  {
    "Image": "ecr-image-uri-for-second-model",
    "ModelDataUrl": "s3-location-of-trained-second-model"
  }
]
)

2. Create an endpoint configuration. Specify both your production and shadow variants in the configuration.

```
endpoint_config_name = name-of-your-endpoint-config

create_endpoint_config_response = sagemaker_client.create_endpoint_config(
  EndpointConfigName=endpoint_config_name,
  ProductionVariants=[
    {
      "VariantName": "name-of-your-production-variant",
      "ModelName": model_name1,
      "InstanceType": "ml.m5.xlarge",
      "InitialInstanceCount": 1,
      "InitialVariantWeight": 1,
    }
  ],
  ShadowProductionVariants=[
    {
      "VariantName": "name-of-your-shadow-variant",
      "ModelName": model_name2,
      "InstanceType": "ml.m5.xlarge",
      "InitialInstanceCount": 1,
      "InitialVariantWeight": 1,
    }
  ]
)
```

3. Create an endpoint.

```
create_endpoint_response = sm.create_endpoint(
  EndpointName="name-of-your-endpoint",
)"
Online Explainability with SageMaker Clarify

This guide shows how to configure online explainability with SageMaker Clarify. With SageMaker real-time inference endpoints, you can analyze explainability in real time, continuously. The online explainability function fits into the Deploy to production part of the Amazon SageMaker Machine Learning workflow.

How Clarify Online Explainability Works

The following graphic depicts SageMaker architecture for hosting an endpoint that serves explainability requests. It depicts interactions between an endpoint, the model container, and the SageMaker Clarify explainer.

Here's how Clarify online explainability works. The application sends a REST-style InvokeEndpoint request to the SageMaker Runtime Service. The service routes this request to a SageMaker endpoint to obtain predictions and explanations. Then, the service receives the response from the endpoint. Lastly, the service sends the response back to the application.

To increase the endpoint availability, SageMaker automatically attempts to distribute endpoint instances in multiple Availability Zones, according to the instance count in the endpoint configuration. On an
endpoint instance, upon a new explainability request, the SageMaker Clarify explainer calls the model container for predictions. Then it computes and returns the feature attributions.

Here are the four steps to create an endpoint that uses SageMaker Clarify online explainability:

1. Check if your pre-trained SageMaker model is compatible with online explainability by following the pre-check steps.
2. Create an endpoint configuration with the SageMaker Clarify explainer configuration using the CreateEndpointConfig API.
3. Create an endpoint and provide the endpoint configuration to SageMaker using the CreateEndpoint API. The service launches the ML compute instance and deploys the model as specified in the configuration.
4. Invoke the endpoint: After the endpoint is in service, call the SageMaker Runtime API InvokeEndpoint to send requests to the endpoint. The endpoint then returns explanations and predictions.

Pre-check the model container

This section shows how to pre-check the model container inputs and outputs for compatibility before configuring an endpoint. The SageMaker Clarify explainer is model agnostic, but it has requirements for model container input and output.

Note

You can increase efficiency by configuring your container to support batch requests, which support two or more records in a single request. For example, a single record is a single line of CSV data, or a single line of JSON Lines data. SageMaker Clarify will attempt to send a mini-batch of records to the model container first before falling back to single record requests.

Model container input

CSV

The model container supports input in CSV with MIME type: text/csv. The following table shows example inputs that SageMaker Clarify supports.

<table>
<thead>
<tr>
<th>Model container input (string representation)</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>'1,2,3,4'</td>
<td>Single record that uses four numerical features.</td>
</tr>
<tr>
<td>'1,2,3,4\n5,6,7,8'</td>
<td>Two records, separated by line break '\n'.</td>
</tr>
<tr>
<td>&quot;This is a good product&quot;,5</td>
<td>Single record that contains a text feature and a numerical feature.</td>
</tr>
<tr>
<td>&quot;This is a good product&quot;,&quot;Bad shopping experience&quot;,1</td>
<td>Two records.</td>
</tr>
</tbody>
</table>

JSON Lines

SageMaker also supports input in JSON Lines dense format with MIME type: application/jsonlines, as shown in the following table.

<table>
<thead>
<tr>
<th>Model container input</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>'{&quot;data&quot;:{&quot;features&quot;:[1,2,3,4]}}'</td>
<td>Single record; a list of features can be extracted by JMESPath expression data.features.</td>
</tr>
</tbody>
</table>
## Model container input

<table>
<thead>
<tr>
<th>Model container input</th>
<th>Comments</th>
</tr>
</thead>
</table>
| {'data':{"features':[1,2,3,4]}}
{'data':{"features':[5,6,7,8]}}                                                      | Two records.                                  |
| {'features':["This is a good product",5]}                                             | Single record; a list of features can be extracted by JMESPath expression features. |
| {'features':["This is a good product",5]}

## Model container output

Your model container output should also be in either CSV, or JSON Lines dense format. Additionally the model container should include the probabilities of the input records, which SageMaker Clarify uses to compute feature attributions.

The following data examples are for model container outputs in **CSV format**.

### Probability only

For regression and binary classification problems, the model container outputs a single probability value (score) of the predicted label. These probabilities can be extracted using column index 0. For multi-class problems, the model container outputs a list of probabilities (scores). For multi-class problems, if no index is provided, all values are extracted.

<table>
<thead>
<tr>
<th>Model container input</th>
<th>Model container output (string representation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record</td>
<td>'0.6'</td>
</tr>
<tr>
<td>Two records (results in one line)</td>
<td>'0.6,0.3'</td>
</tr>
</tbody>
</table>
| Two records (results in two lines)                                                    | '0.6
0.3'                                       |
| Single record of a multi-class model (three classes)                                  | '0.1,0.6,0.3'                                 |
| Two records of a multi-class model (three classes)                                    | '0.1,0.6,0.3
0.2,0.5,0.3'                                |

### Predicted label and probabilities

The model container outputs the predicted label followed by its probability in **CSV format**. The probabilities can be extracted using index 1.

<table>
<thead>
<tr>
<th>Model container input</th>
<th>Model container output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record</td>
<td>'1,0.6'</td>
</tr>
</tbody>
</table>
| Two records                                                                           | '1,0.6
0.0,0.3'           |
Predicted labels header and probabilities

A multi-class model container trained by Autopilot can be configured to output the string representation of the list of predicted labels and probabilities in CSV format. In the following example, the probabilities can be extracted by index 1. The label headers can be extracted by index 1, and the label headers can be extracted using index 0.

<table>
<thead>
<tr>
<th>Model container input</th>
<th>Model container output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record</td>
<td>&quot;[&quot;cat&quot;,&quot;dog&quot;,&quot;fish&quot;],[0.1,0.6,0.3]&quot;</td>
</tr>
<tr>
<td>Two records</td>
<td>&quot;[&quot;cat&quot;,&quot;dog&quot;,&quot;fish&quot;],[0.1,0.6,0.3]\n&quot;&quot;[&quot;cat &quot;,&quot;dog&quot;,&quot;fish&quot;]],[0.2,0.5,0.3]&quot;</td>
</tr>
</tbody>
</table>

The following data examples are for model container outputs in JSON Lines format.

Probability only

In this example, the model container outputs the probability that can be extracted by JMESPath expression `score` in JSON Lines format.

<table>
<thead>
<tr>
<th>Model container input</th>
<th>Model container output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record</td>
<td>&quot;score&quot;:0.6'</td>
</tr>
<tr>
<td>Two records</td>
<td>&quot;score&quot;:0.6\n&quot;score&quot;:0.3'</td>
</tr>
</tbody>
</table>

Predicted label and probabilities

In this example, a multi-class model container outputs a list of label headers along with a list of probabilities in JSON Lines format. The probabilities can be extracted by JMESPath expression predicted probability, and the label headers can be extracted by JMESPath expression predicted labels.

<table>
<thead>
<tr>
<th>Model container input</th>
<th>Model container output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record</td>
<td>&quot;predicted_labels&quot;:\n&quot;cat&quot;,&quot;dog&quot;,&quot;fish&quot;\n&quot;probabilities&quot;:\n&quot;[0.1,0.6,0.3]&quot;</td>
</tr>
<tr>
<td>Two records</td>
<td>&quot;predicted_labels&quot;:\n&quot;predicted_labels&quot;:\n&quot;[0.1,0.6,0.3]\n&quot;predicted_labels&quot;:\n&quot;[0.2,0.5,0.3]&quot;</td>
</tr>
</tbody>
</table>

Predicted labels header and probabilities

In this example, a multi-class model container outputs a list of label headers and probabilities in JSON Lines format. The probabilities can be extracted by JMESPath expression predicted probability, and the label headers can be extracted by JMESPath expression predicted labels.

<table>
<thead>
<tr>
<th>Model container input</th>
<th>Model container output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single record</td>
<td>&quot;predicted_labels&quot;:\n&quot;predicted_labels&quot;:\n&quot;[0.1,0.6,0.3]&quot;</td>
</tr>
</tbody>
</table>
Model container validation

We recommend that you deploy your model to a SageMaker real-time inference endpoint, and send requests to the endpoint. Manually examine the requests (model container inputs) and responses (model container outputs) to make sure that both are compliant with the requirements in the Model Container Input section and Model Container Output section. If your model container supports batch requests, you can start with a single record request, and then try two or more records.

The following commands show how to request a response using the AWS CLI. The AWS CLI is pre-installed in SageMaker Studio, and SageMaker Notebook instances. If you need to install the AWS CLI, follow this installation guide.

```
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name $ENDPOINT_NAME \
  --content-type $CONTENT_TYPE \
  --accept $ACCEPT_TYPE \
  --body $REQUEST_DATA \
  $CLI_BINARY_FORMAT \
  /dev/stderr 1>/dev/null
```

The parameters are defined, as follows:

- $ENDPOINT_NAME: The name of the endpoint.
- $CONTENT_TYPE: The MIME type of the request (model container input).
- $ACCEPT_TYPE: The MIME type of the response (model container output).
- $REQUEST_DATA: The requested payload string.
- $CLI_BINARY_FORMAT: The format of the command line interface (CLI) parameter. For AWS CLI v1, this parameter should remain blank. For v2, this parameter should be set to `--cli-binary-format raw-in-base64-out`.

**Note**

AWS CLI v2 passes binary parameters as base64-encoded strings default.

The following examples use AWS CLI v1:

Request and response in CSV format

- The request consists of a single record and the response is its probability value.

```
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name test-endpoint-sagemaker-xgboost-model \
  --content-type text/csv \
  --accept text/csv \
  --body '1,2,3,4' \
  /dev/stderr 1>/dev/null
```

Output:

```
2478
```
The request consists of two records, and the response includes their probabilities, and the model separates the probabilities by a comma. The `$content` expression in the `--body` tells the command to interpret \n in the content as a line break.

```bash
aws sagemaker-runtime invoke-endpoint
  --endpoint-name test-endpoint-sagemaker-xgboost-model
  --content-type text/csv
  --accept text/csv
  --body $'1,2,3,4\n5,6,7,8'
/dev/stderr 1>/dev/null
```

Output:

```
0.6,0.3
```

The request consists of two records, the response includes their probabilities, and the model separates the probabilities with a line break.

```bash
aws sagemaker-runtime invoke-endpoint
  --endpoint-name test-endpoint-csv-1
  --content-type text/csv
  --accept text/csv
  --body $'1,2,3,4\n5,6,7,8'
/dev/stderr 1>/dev/null
```

Output:

```
0.6
0.3
```

The request consists of a single record, and the response is probability values (multi-class model, three classes).

```bash
aws sagemaker-runtime invoke-endpoint
  --endpoint-name test-endpoint-csv-1
  --content-type text/csv
  --accept text/csv
  --body '1,2,3,4'
/dev/stderr 1>/dev/null
```

Output:

```
0.1,0.6,0.3
```

The request consists of two records, and the response includes their probability values (multi-class model, three classes).

```bash
aws sagemaker-runtime invoke-endpoint
  --endpoint-name test-endpoint-csv-1
  --content-type text/csv
  --accept text/csv
  --body $'1,2,3,4\n5,6,7,8'
/dev/stderr 1>/dev/null
```

Output:
The request consists of two records, and the response includes predicted label and probability.

```bash
aws sagemaker-runtime invoke-endpoint \
--endpoint-name test-endpoint-csv-2 \
--content-type text/csv \
--accept text/csv \
--body $'1,2,3,4\n5,6,7,8' \
/dev/stderr 1>/dev/null
```

Output:

```
1,0.6
0,0.3
```

The request consists of two records and the response includes label headers and probabilities.

```bash
aws sagemaker-runtime invoke-endpoint \
--endpoint-name test-endpoint-csv-3 \
--content-type text/csv \
--accept text/csv \
--body $'1,2,3,4\n5,6,7,8' \
/dev/stderr 1>/dev/null
```

Output:

```
"['cat','dog','fish']","[0.1,0.6,0.3]
"['cat','dog','fish']","[0.2,0.5,0.3]
```

Request and response in JSON Lines format

The request consists of a single record and the response is its probability value.

```bash
aws sagemaker-runtime invoke-endpoint \
--endpoint-name test-endpoint-jsonlines \
--content-type application/jsonlines \
--accept application/jsonlines \
--body '{"features":["This is a good product",5]}' \
/dev/stderr 1>/dev/null
```

Output:

```json
{"score":0.6}
```

The request contains two records, and the response includes predicted label and probability.

```bash
aws sagemaker-runtime invoke-endpoint \
--endpoint-name test-endpoint-jsonlines-2 \
--content-type application/jsonlines \
--accept application/jsonlines \
--body "$'{"features":[1,2,3,4]}\n{"features":[5,6,7,8]}' \
/dev/stderr 1>/dev/null
```

Output:
Amazon SageMaker Developer Guide
Clarify online explainability

{"predicted_label":1,"probability":0.6}
{"predicted_label":0,"probability":0.3}
• The request contains two records and the response includes label headers and probabilities.
aws sagemaker-runtime invoke-endpoint \
--endpoint-name test-endpoint-jsonlines-3 \
--content-type application/jsonlines \
--accept application/jsonlines \
--body $'{"data":{"features":[1,2,3,4]}}\n{"data":{"features":[5,6,7,8]}}' \
/dev/stderr 1>/dev/null

Output:
{"predicted_labels":["cat","dog","fish"],"probabilities":[0.1,0.6,0.3]}
{"predicted_labels":["cat","dog","fish"],"probabilities":[0.2,0.5,0.3]}
Request and response in diﬀerent formats
• The request is in CSV format and the response is in JSON Lines format:
aws sagemaker-runtime invoke-endpoint \
--endpoint-name test-endpoint-csv-in-jsonlines-out \
--content-type text/csv \
--accept application/jsonlines \
--body $'1,2,3,4\n5,6,7,8' \
/dev/stderr 1>/dev/null

Output:
{"probability":0.6}
{"probability":0.3}
• The request is in JSON Lines format and the response is in CSV format:
aws sagemaker-runtime invoke-endpoint \
--endpoint-name test-endpoint-jsonlines-in-csv-out \
--content-type application/jsonlines \
--accept text/csv \
--body $'{"features":[1,2,3,4]}\n{"features":[5,6,7,8]}' \
/dev/stderr 1>/dev/null

Output:
0.6
0.3
After the validations are complete, delete the testing endpoint.

Conﬁgure and create an endpoint
Create a new endpoint conﬁguration to ﬁt your model, and use this conﬁguration to create the endpoint.
You can use the model container validated in the pre-check step to create an endpoint and enable the
SageMaker Clarify online explainability feature.

2481


Use the sagemaker_client object to create an endpoint using the CreateEndpointConfig API. Set the member ClarifyExplainerConfig inside the ExplainerConfig parameter as follows:

```python
sagemaker_client.create_endpoint_config(
    EndpointConfigName='name-of-your-endpoint-config',
    ExplainerConfig={
        'ClarifyExplainerConfig': {
            'EnableExplanations': 'true',
            'InferenceConfig': {
                ...
            },
            'ShapConfig': {
                ...
            }
        }
    },
    ProductionVariants=[[{
        'VariantName': 'AllTraffic',
        'ModelName': 'name-of-your-model',
        'InitialInstanceCount': 1,
        'InstanceType': 'ml.m5.xlarge',
    }]
}
)
```

The first call to the sagemaker_client object creates a new endpoint configuration with the explainability feature enabled. The second call uses the endpoint configuration to launch the endpoint.

**Note**
You can also host multiple models in one container behind a SageMaker real-time inference multi-model endpoint and configure online explainability with SageMaker Clarify.

### The EnableExplanations expression

The EnableExplanations parameter is a JMESPath Boolean expression string. It is evaluated for each record in the explainability request. If this parameter is evaluated to be `true`, then the record will be explained. If this parameter is evaluated to be `false`, then explanations are not generated.

SageMaker Clarify deserializes the model container output for each record into a JSON compatible data structure, and then uses the EnableExplanations parameter to evaluate the data.

**Notes**

There are two options for records depending on the format of the model container output.

- If the model container output is in CSV format, then a record is loaded as a JSON array.
- If the model container output is in JSON Lines format, then a record is loaded as a JSON object.

The EnableExplanations parameter is a JMESPath expression that can be passed either during the InvokeEndpoint or CreateEndpointConfig operations. If the JMESPath expression that you supplied is not valid, the endpoint creation will fail. If the expression is valid, but the expression evaluation result is unexpected, then the endpoint will be created successfully, but an error will be generated when the endpoint is invoked. Test your EnableExplanations expression by using the InvokeEndpoint API, and then apply it to the endpoint configuration.

The following are some examples of valid EnableExplanations expression. In the examples, a JMESPath expression encloses a literal using backtick characters. For example, `true` means true.
### Expression (string representation) | Model container output (string representation) | Evaluation result (Boolean) | Meaning
--- | --- | --- | ---
```
true
``` | (N/A) | True | Activate online explainability unconditionally.
```
false
``` | (N/A) | False | Deactivate online explainability unconditionally.
```
[1] > `0.5`
``` | `1,0.6` | True | For each record, the model container outputs its predicted label and probability. Explains a record if its probability (at index 1) is greater than 0.5.
```
`probability > `0.5`
``` | `{"predicted_label":1,"probability":0.6}` | True | For each record, the model container outputs JSON data. Explain a record if its probability is greater than 0.5.
```
`! contains(probabilities[:-1], max(probabilities))`
``` | `{"probabilities": [0.4, 0.1, 0.4], "labels": ["cat","dog","fish"]}` | False | For a multi-class model: Explains a record if its predicted label (the class that has the max probability value) is the last class. Literally, the expression means that the max probability value is not in the list of probabilities excluding the last one.

### Synthetic dataset

SageMaker Clarify uses the Kernel SHAP algorithm. Given a record (also called a sample or an instance) and the SHAP configuration, the explainer first generates a synthetic dataset. SageMaker Clarify then queries the model container for the predictions of the dataset, and then computes and returns the feature attributions. The size of the synthetic dataset affects the runtime for the Clarify explainer. Larger synthetic datasets take more time to obtain model predictions than smaller ones.

The synthetic dataset size is determined by the following formula:

\[
\text{Synthetic dataset size} = \text{SHAP baseline size} \times n_{\text{samples}}
\]

The SHAP baseline size is the number of records in the SHAP baseline data. This information is taken from the `ShapBaselineConfig`.

The size of \(n_{\text{samples}}\) is set by the parameter `NumberOfSamples` in the explainer configuration and the number of features. If the number of features is \(n_{\text{features}}\), then \(n_{\text{samples}}\) is the following:
\[ n_{\text{samples}} = \text{MIN}(\text{NumberOfSamples}, 2^n_{\text{features}} - 2) \]

The following shows \( n_{\text{samples}} \) if \( \text{NumberOfSamples} \) is not provided.

\[ n_{\text{samples}} = \text{MIN}(2*n_{\text{features}} + 2^{11}, 2^n_{\text{features}} - 2) \]

For example, a tabular record with 10 features has a SHAP baseline size of 1. If \( \text{NumberOfSamples} \) is not provided, the synthetic dataset contains 1022 records. If the record has 20 features, the synthetic dataset contains 2088 records.

For NLP problems, \( n_{\text{features}} \) is equal to the number of non-text features plus the number of text units.

**Note**
The InvokeEndpoint API has a request timeout limit. If the synthetic dataset is too large, the explainer may not be able to complete the computation within this limit. If necessary, use the previous information to understand and reduce the SHAP baseline size and \( \text{NumberOfSamples} \).

If your model container is set up to handle batch requests, then you can also adjust the value of MaxRecordCount.

### Invoke the endpoint

After the endpoint is running, use the SageMaker Runtime InvokeEndpoint API in the SageMaker Runtime service to send requests to, or invoke the endpoint. In response, the requests are handled as explainability requests by the SageMaker Clarify explainer.

**Note**
To invoke an endpoint, choose one of the following options:

- For instructions to use Boto3 or the AWS CLI to invoke an endpoint, see real-time endpoints.
- To use the SageMaker SDK for Python to invoke an endpoint, see the Predictor API.

### Request

The InvokeEndpoint API has an optional parameter EnableExplanations, which is mapped to the HTTP header X-Amzn-SageMaker-Enable-Explanations. If this parameter is provided, it overrides the EnableExplanations parameter of the ClarifyExplainerConfig.

**Note**
The ContentType and Accept parameters of the InvokeEndpoint API are required. Supported formats include MIME type text/csv and application/jsonlines.

Use the sagemaker_runtime_client to send a request to the endpoint, as follows:

```python
response = sagemaker_runtime_client.invoke_endpoint(  
    EndpointName='name-of-your-endpoint',  
    EnableExplanations='true',  
    ContentType='text/csv',  
    Accept='text/csv',  
    Body='1,2,3,4',  
    # single record (of four numerical features)
)
```

For multi-model endpoints, pass an additional TargetModel parameter in the previous example request to specifies which model to target at the endpoint. The multi-model endpoint dynamically loads target models as needed. See the SageMaker Clarify Online Explainability on Multi-Model Endpoint Sample Notebook for an example of how to set up and invoke multiple target models from a single endpoint.
Response

If the endpoint is created with ExplainerConfig, then a new response schema is used. This new schema is different from, and is not compatible with, an endpoint that lacks the ExplainerConfig parameter provided.

The MIME type of the response is application/json, and the response payload can be decoded from UTF-8 bytes to a JSON object. The following shows the members of this JSON object are as follows:

- **version**: The version of the response schema in string format. For example, 1.0.
- **predictions**: The predictions that the request makes have the following:
  - **content_type**: The MIME type of the predictions, referring to the ContentType of the model container response.
  - **data**: The predictions data string delivered as the payload of the model container response for the request.
- **label_headers**: The label headers from the LabelHeaders parameter. This is provided in either the explainer configuration or the model container output.
- **explanations**: The explanations provided in the request payload. If no records are explained, then this member returns the empty object {}.
- **kernel_shap**: A key that refers to an array of Kernel SHAP explanations for each record in the request. If a record is not explained, the corresponding explanation is null.

The `kernel_shap` element has the following members:

- **feature_header**: The header name of the features provided by the FeatureHeaders parameter in the explainer configuration ExplainerConfig.
- **feature_type**: The feature type inferred by explainer or provided in the FeatureTypes parameter in the ExplainerConfig. This element is only available for NLP explainability problems.
- **attributions**: An array of attribution objects. Text features can have multiple attribution objects, each for a unit. The attribution object has the following members:
  - **attribution**: A list of probability values, given for each class.
  - **description**: The description of the text units, available only for NLP explainability problems.
  - **partial_text**: The portion of the text explained by the explainer.
  - **start_idx**: A zero-based index to identify the array location of the beginning of the partial text fragment.

Code examples: SDK for Python

This section provides sample code to create and invoke an endpoint that uses SageMaker Clarify online explainability. These code examples use the AWS SDK for Python.

Tabular data

The following example uses tabular data and a SageMaker model called `model_name`. In this example, the model container accepts data in CSV format, and each record has four numerical features. In this minimal configuration, for demonstration purposes only, the SHAP baseline data is set to zero. Refer to the SHAP Baselines for Explainability to choose more appropriate values for ShapBaseline.

Configure the endpoint, as follows:

```python
endpoint_config_name = 'tabular_explainer_endpoint_config'
```
response = sagemaker_client.create_endpoint_config(
    EndpointConfigName=endpoint_config_name,
    ProductionVariants=[
        {'VariantName': 'AllTraffic',
         'ModelName': model_name,
         'InitialInstanceCount': 1,
         'InstanceType': 'ml.m5.xlarge',
        },
    ],
    ExplainerConfig={
        'ClarifyExplainerConfig': {
            'ShapConfig': {
                'ShapBaselineConfig': {
                    'ShapBaseline': '0,0,0,0',
                },
            },
        },
    },
)

Use the endpoint configuration to create an endpoint, as follows:

endpoint_name = 'tabular_explainer_endpoint'
response = sagemaker_client.create_endpoint(
    EndpointName=endpoint_name,
    EndpointConfigName=endpoint_config_name,
)

Use the DescribeEndpoint API to inspect the progress of creating an endpoint, as follows:

response = sagemaker_client.describe_endpoint(
    EndpointName=endpoint_name,
)
response['EndpointStatus']

After the endpoint status is "InService", invoke the endpoint with a test record, as follows:

response = sagemaker_runtime_client.invoke_endpoint(
    EndpointName=endpoint_name,
    ContentType='text/csv',
    Accept='text/csv',
    Body='1,2,3,4',
)

**Note**

In the previous code example, for multi-model endpoints, pass an additional TargetModel parameter in the request to specify which model to target at the endpoint.

Assume that the response has a status code of 200 (no error), and load the response body, as follows:

import codecs
import json
json.load(codecs.getreader('utf-8')(response['Body']))

The default action for the endpoint is to explain the record. The following shows example output in the returned JSON object.

{
Use the `EnableExplanations` parameter to enable on-demand explanations, as follows:

```python
response = sagemaker_runtime_client.invoke_endpoint(
    EndpointName=endpoint_name,
    ContentType='text/csv',
    Accept='text/csv',
    Body='1,2,3,4',
    EnableExplanations='[0]>0.8',
)
```

**Note**

In the previous code example, for multi-model endpoints, pass an additional `TargetModel` parameter in the request to specify which model to target at the endpoint.

In this example, the prediction value is less than the threshold value of 0.8, so the record is not explained:
Use visualization tools to help interpret the returned explanations. The following image shows how SHAP plots can be used to understand how each feature contributes to the prediction. The base value on the diagram, also called the expected value, is the mean predictions of the training dataset. Features that push the expected value higher are red, and features that push the expected value lower are blue. See \textit{SHAP additive force layout} for additional information.

See the \textit{full example notebook for tabular data}.

\textbf{Text data}

This section provides a code example to create and invoke an online explainability endpoint for text data. The code example uses SDK for Python.

The following example uses text data and a SageMaker model called \texttt{model\_name}. In this example, the model container accepts data in CSV format, and each record is a single string.

```python
endpoint_config_name = 'text_explainer_endpoint_config'
response = sagemaker_client.create_endpoint_config(
    EndpointConfigName=endpoint_config_name,
    ProductionVariants=[
        {'VariantName': 'AllTraffic',
         'ModelName': model_name,
         'InitialInstanceCount': 1,
         'InstanceType': 'ml.m5.xlarge',
        },
    ],
    ExplainerConfig={
        'ClarifyExplainerConfig': {
            'InferenceConfig': {
                'FeatureTypes': ['text'],
                'MaxRecordCount': 100,
            },
            'ShapConfig': {
                'ShapBaselineConfig': {
                    'ShapBaseline': '<MASK>',
                },
                'TextConfig': {
                    'Granularity': 'token',
                    'Language': 'en',
                },
                'NumberOfSamples': 100,
            },
        },
    },
)
```

- \texttt{ShapBaseline}: A special token reserved for natural language processing (NLP) processing.
• **FeatureTypes**: Identifies the feature as text. If this parameter is not provided, the explainer will attempt to infer the feature type.

• **TextConfig**: Specifies the unit of granularity and language for the analysis of text features. In this example, the language is English, and granularity token means a word in English text.

• **NumberOfSamples**: A limit to set the upper bounds of the size of the synthetic dataset.

• **MaxRecordCount**: The maximum number of records in a request that the model container can handle. This parameter is set to stabilize performance.

Use the endpoint configuration to create the endpoint, as follows:

```python
endpoint_name = 'text_explainer_endpoint'
response = sagemaker_client.create_endpoint(
    EndpointName=endpoint_name,
    EndpointConfigName=endpoint_config_name,
)
```

After the status of the endpoint becomes InService, invoke the endpoint. The following code sample uses a test record as follows:

```python
response = sagemaker_runtime_client.invoke_endpoint(
    EndpointName=endpoint_name,
    ContentType='text/csv',
    Accept='text/csv',
    Body='"This is a good product"',
)
```

If the request completes successfully, the response body will return a valid JSON object that's similar to the following:

```json
{
   "version": "1.0",
   "predictions": {
      "content_type": "text/csv",
      "data": "0.9766594\n"
   },
   "explanations": {
      "kernel_shap": [
         {
            "attributions": [
               {
                  "attribution": [
                     -0.007270948666666712
                  ],
                  "description": {
                     "partial_text": "This",
                     "start_idx": 0
                  }
               },
               {
                  "attribution": [
                     -0.018199033666666628
                  ],
                  "description": {
                     "partial_text": "is",
                     "start_idx": 5
                  }
               }
            ],
            "start_field": 0,
            "start_token": 0
         }
      ]
   }
}
```
Use visualization tools to help interpret the returned text attributions. The following image shows how the captum visualization utility can be used to understand how each word contributes to the prediction. The higher the color saturation, the higher the importance given to the word. In this example, a highly saturated bright red color indicates a strong negative contribution. A highly saturated green color indicates a strong positive contribution. The color white indicates that the word has a neutral contribution. See the captum library for additional information on parsing and rendering the attributions.

<table>
<thead>
<tr>
<th>Legend:</th>
<th>Negative</th>
<th>Neutral</th>
<th>Positive</th>

**Troubleshooting guide**

If you encounter errors using SageMaker Clarify online explainability, consult the topics in this section.

**InvokeEndpoint API fails with the error "ReadTimeoutError:Read timeout on endpoint..."**

This error means that the request could not be completed within the 60-second time limit set by the request timeout.

To reduce the request latency, try the following:
• Tune the model’s performance during inference. For example, SageMaker Neo can optimize models for inference.
• Allow the model container to handle batch requests.
• Use a larger MaxRecordCount to reduce the number of calls from the explainer to the model container. This will reduce network latency and overhead.
• Use an instance type that has more resources allocated to it. Alternately, assign more instances to the endpoint to help balance the load.
• Reduce the number of records inside a single InvokeEndpoint request.
• Reduce the number of records in the baseline data.
• Use a smaller NumberOfSamples value to reduce the size of the synthetic dataset. For more information, see the Synthetic dataset section in Configure and create an endpoint.

Invoke real-time endpoints

After you deploy your model using SageMaker hosting services, you can test your model on that endpoint by sending it test data. You can test your endpoints using Amazon SageMaker Studio, the AWS SDKs, or the AWS CLI.

Invoke Your Endpoint Using Amazon SageMaker Studio

After you deploy your model to an endpoint (see Create your endpoint and deploy your model (p. 2389)) you can check that endpoint with Amazon SageMaker Studio.

Note
Note: SageMaker only supports endpoint testing with Amazon SageMaker Studio for real-time endpoints.

To send a test inference request to your endpoint

1. Launch Amazon SageMaker Studio.
2. In the Home section of the navigation pane on the left, choose Deployments.
3. From the dropdown, choose Endpoints.
4. Find for your endpoint by name, and choose the name in the table. The endpoint names listed in the Endpoints panel are defined when you deploy a model. The Studio workspace opens the Endpoints page in a new tab.
5. In the Test inference tab, send a request to your endpoint by providing sample data in JSON format. Use the JSON editor to submit a request to your endpoint.
6. (Optional) You can provide a custom URL to send your request to. In the Configure endpoint URL and headers section, for the Custom URL field, provide the URL of where your model is hosted. Leave this field blank if you are using a SageMaker endpoint. Under Headers, you can also optionally add key-value headers to pass additional information with the inference request.
7. Choose Send Request. The Studio shows the inference output in a card to the right of the JSON editor.

The top of the card shows the type of request that was sent to the endpoint (only JSON is accepted). The card shows the following fields:

• Status – displays one of the following status types:
  • Complete – The request succeeded.
  • Failed – The request failed. A response appears under Failure Reason.
Amazon SageMaker Developer Guide
Invoke real-time endpoints

• Pending – While the inference request is pending, the status shows a spinning, circular icon.
• Execution Length – How long the invocation took (end time minus the start time) in milliseconds.
• Request Time – How many minutes have passed since the request was sent.
• Result Time – How many minutes have passed since the result was returned.

Invoke Your Endpoint by Using the AWS SDK for Python (Boto3)
After you deploy your model to an endpoint (see Create your endpoint and deploy your model (p. 2389))
you can check your endpoint by using one of the AWS SDKs, including as the AWS SDK for Python
(Boto3). To test your endpoint with this SDK, you use one of the following methods:
• invoke_endpoint– Sends an inference request to a model endpoint and returns the response that
the model generates. This method returns the inference payload as one response after the model
ﬁnishes generating it. For more information, see invoke_endpoint in the AWS SDK for Python (Boto3)
API Reference.
• invoke_endpoint_with_response_stream – Sends an inference request to a model endpoint
and streams the response in incremental parts while the model generates the inference. With this
method, your client application immediately starts receiving parts of the response as the parts become
available. Your client doesn't need to wait for the model to generate the whole response payload. You
can implement streaming to support fast interactive experiences, such as chatbots, virtual assistants,
and music generators.
Use this method only to invoke models that support inference streaming.
When a container handles a streaming inference request, it returns the model's inference as a series
of parts incrementally as the model generates them. Client applications start receiving responses
immediately when they're available. They don't need to wait for the model to generate the entire
response. You can implement streaming to support fast interactive experiences, such as chatbots,
virtual assistants, and music generators.
Before you can use these methods in your client code, you must create a SageMaker Runtime client, and
you must specify the name of your endpoint. The following example sets up the client and endpoint for
the rest of the examples that follow:
import boto3
# Create a low-level client representing Amazon SageMaker Runtime
sagemaker_runtime = boto3.client(
"sagemaker-runtime", region_name='aws_region')
# The endpoint name must be unique within
# an AWS Region in your AWS account.
endpoint_name='endpoint-name'

Invoke to Get an Inference Response
The following example uses the invoke_endpoint method to invoke an endpoint with the AWS SDK
for Python (Boto3):
# Gets inference from the model hosted at the specified endpoint:
response = sagemaker_runtime.invoke_endpoint(
EndpointName=endpoint_name,
Body=bytes('{"features": ["This is great!"]}', 'utf-8')
)

2492


Invoke real-time endpoints

# Decodes and prints the response body:
print(response['Body'].read().decode('utf-8'))

This example provides input data in the Body field for SageMaker to pass to the model. This data must be in the same format that was used for training. The example stores the response in the response variable.

The response variable provides access to the HTTP status, the name of the deployed model, and other fields. The following snippet prints the HTTP status code:

print(response['HTTPStatusCode'])

**Invoke to Stream an Inference Response**

If you deployed a model that supports inference streaming, you can invoke the model to receive its inference payload as a stream of parts. The model delivers these parts incrementally as the model generates them. When an application receives an inference stream, the application doesn't need to wait for the model to generate the whole response payload. Instead, the application immediately starts receiving parts of the response as they become available.

By consuming an inference stream in your application, you can create interactions where your users perceive the inference to be fast because they get the first part immediately. For example, you could create a chatbot that incrementally shows the text generated by a large language model (LLM).

To get an inference stream, you can use the `invoke_endpoint_with_response_stream` method in the SDK for Python (Boto3). In the response body, the SDK provides an `EventStream` object, which gives the inference as a series of `PayloadPart` objects.

**Example Inference Stream**

The following example is a stream of `PayloadPart` objects:

```json
[{
    "PayloadPart": {
        "Bytes": b'"a"
    }
},
{
    "PayloadPart": {
        "Bytes": b'"challenging"
    }
},
{
    "PayloadPart": {
        "Bytes": b'"problem"
    }
}]
```

In each payload part, the `Bytes` field provides a portion of the inference response from the model. This portion can be any content type that a model generates, such as text, image, or audio data. In this example, the portions are JSON objects that contain generated text from an LLM.

Usually, the payload part contains a discrete chunk of data from the model. In this example, the discrete chunks are whole JSON objects. Occasionally, the streaming response splits the chunks over multiple payload parts, or it combines multiple chunks into one payload part. The following example shows a chunk of data in JSON format that's split over two payload parts:

```json
[{
    "PayloadPart": {
        "Bytes": b'
    }
},
{
    "PayloadPart": {
        "Bytes": b'"problem"
    }
}]
```

When you write application code that processes an inference stream, include logic that handles these occasional splits and combinations of data. As one strategy, you could write code that concatenates the contents of `Bytes` while your application receives the payload parts. By concatenating the example JSON data here, you would combine the data into a newline-delimited JSON body. Then, your code could process the stream by parsing the whole JSON object on each line.

The following example shows the newline-delimited JSON that you would create when you concatenate the example contents of `Bytes`:
Example Code to Process an Inference Stream

The following example Python class, `SmrInferenceStream`, demonstrates how you can process an inference stream that sends text data in JSON format:

```python
import io
import json

# Example class that processes an inference stream:
class SmrInferenceStream:
    def __init__(self, sagemaker_runtime, endpoint_name):
        self.sagemaker_runtime = sagemaker_runtime
        self.endpoint_name = endpoint_name
        # A buffered I/O stream to combine the payload parts:
        self.buff = io.BytesIO()
        self.read_pos = 0

    def stream_inference(self, request_body):
        # Gets a streaming inference response
        # from the specified model endpoint:
        response = self.sagemaker_runtime.
                      invoke_endpoint_with_response_stream(
                      EndpointName=self.endpoint_name,
                      Body=json.dumps(request_body),
                      ContentType="application/json"
                      )
        # Gets the EventStream object returned by the SDK:
        event_stream = response['Body']
        for event in event_stream:
            # Passes the contents of each payload part
            # to be concatenated:
            self._write(event['PayloadPart']['Bytes'])
            # Iterates over lines to parse whole JSON objects:
            for line in self._readlines():
                resp = json.loads(line)
                part = resp.get("outputs")[0]
                # Returns parts incrementally:
                yield part

        # Writes to the buffer to concatenate the contents of the parts:
        def _write(self, self, content):
            self.buff.seek(0, io.SEEK_END)
            self.buff.write(content)

        # The JSON objects in buffer end with '\n'.
        # This method reads lines to yield a series of JSON objects:
        def _readlines(self):
            self.buff.seek(self.read_pos)
            for line in self.buff.readlines():
                self.read_pos += len(line)
                yield line[:-1]
```

This example processes the inference stream by doing the following:

- Gets initialized with a SageMaker Runtime client and the name of a model endpoint. Before you can get an inference stream, the model that the endpoint hosts must support inference streaming.
• In the example stream_inference method, receives a request body and passes it to the
invoke_endpoint_with_response_stream method of the SDK.
• Iterates over each event in the EventStream object that the SDK returns.
• From each event, gets the contents of the Bytes object in the PayloadPart object.
• In the example _write method, writes to a buffer to concatenate the contents of the Bytes objects.
The combined contents form a newline-delimited JSON body.
• Uses the example _readlines method to get an iterable series of JSON objects.
• In each JSON object, gets a piece of the inference.
• With the yield expression, returns the pieces incrementally.

The following example creates and uses a SmrInferenceStream object:

```python
request_body = {"inputs": ["Large model inference is"],
        "parameters": {
            "max_new_tokens": 100,
            "enable_sampling": "true"}}
smr_inference_stream = SmrInferenceStream(
    sagemaker_runtime, endpoint_name)
stream = smr_inference_stream.stream_inference(request_body)
for part in stream:
    print(part, end='')
```

This example passes a request body to the stream_inference method. It iterates over the response to
print each piece that the inference stream returns.

The example assumes that the model at the specified endpoint is an LLM that generates text. The output
from this example is a body of generated text that prints incrementally:

```
    a challenging problem in machine learning. The goal is to . . .
```

Invoke Your Endpoint by Using the AWS CLI

You can test your endpoint by running commands with the AWS Command Line Interface (AWS CLI). The
AWS CLI supports standard inference requests with the invoke-endpoint command, and it supports
asynchronous inference requests with the invoke-endpoint-async command.

**Note**
The AWS CLI doesn't support streaming inference requests.

The following example uses the invoke-endpoint command to send an inference request to a model
datepoint:

```bash
aws sagemaker-runtime invoke-endpoint \
   --endpoint-name endpoint_name \
   --body fileb://$file_name \
   output_file.txt
```

For the --endpoint-name parameter, provide the name you specified for EndpointName when you
created your endpoint with CreateEndpoint. For the --body parameter, provide input data for
SageMaker to pass to the model. The data must be in the same format that was used for training. This
eample shows how to send binary data to your endpoint.

For more information on when to use file:// over fileb:// when passing the contents of a file to a
parameter of the AWS CLI, see [Best Practices for Local File Parameters](#).
For more information, and to see additional parameters that you can pass, see `invoke-endpoint` in the AWS CLI Command Reference.

If the `invoke-endpoint` command succeeds it returns a response such as the following:

```json
{
    "ContentType": "<content_type>; charset=utf-8",
    "InvokedProductionVariant": "<Variant>
}
```

If the command doesn't succeed, check whether the input payload is in the correct format.

View the output of the invocation by checking the file output file (output_file.txt in this example).

```
more output_file.txt
```

## Serverless Inference

Amazon SageMaker Serverless Inference is a purpose-built inference option that enables you to deploy and scale ML models without configuring or managing any of the underlying infrastructure. On-demand Serverless Inference is ideal for workloads which have idle periods between traffic spurts and can tolerate cold starts. Serverless endpoints automatically launch compute resources and scale them in and out depending on traffic, eliminating the need to choose instance types or manage scaling policies. This takes away the undifferentiated heavy lifting of selecting and managing servers. Serverless Inference integrates with AWS Lambda to offer you high availability, built-in fault tolerance and automatic scaling. With a pay-per-use model, Serverless Inference is a cost-effective option if you have an infrequent or unpredictable traffic pattern. During times when there are no requests, Serverless Inference scales your endpoint down to 0, helping you to minimize your costs. For more information about pricing for on-demand Serverless Inference, see Amazon SageMaker Pricing.

Optionally, you can also use Provisioned Concurrency with Serverless Inference. Serverless Inference with provisioned concurrency is a cost-effective option when you have predictable bursts in your traffic. Provisioned Concurrency allows you to deploy models on serverless endpoints with predictable performance, and high scalability by keeping your endpoints warm. SageMaker ensures that for the number of Provisioned Concurrency that you allocate, the compute resources are initialized and ready to respond within milliseconds. For Serverless Inference with Provisioned Concurrency, you pay for the compute capacity used to process inference requests, billed by the millisecond, and the amount of data processed. You also pay for Provisioned Concurrency usage, based on the memory configured, duration provisioned, and the amount of concurrency enabled. For more information about pricing for Serverless Inference with Provisioned Concurrency, see Amazon SageMaker Pricing.

You can integrate Serverless Inference with your MLOps Pipelines to streamline your ML workflow, and you can use a serverless endpoint to host a model registered with Model Registry (p. 2989).

Serverless Inference is generally available in 21 AWS Regions: US East (N. Virginia), US East (Ohio), US West (N. California), US West (Oregon), Africa (Cape Town), Asia Pacific (Hong Kong), Asia Pacific (Mumbai), Asia Pacific (Tokyo), Asia Pacific (Seoul), Asia Pacific (Osaka), Asia Pacific (Singapore), Asia Pacific (Sydney), Canada (Central), Europe (Frankfurt), Europe (Ireland), Europe (London), Europe (Paris), Europe (Stockholm), Europe (Milan), Middle East (Bahrain), South America (São Paulo). For more information about Amazon SageMaker regional availability, see the AWS Regional Services List.

## How it works

The following diagram shows the workflow of on-demand Serverless Inference and the benefits of using a serverless endpoint.
When you create an on-demand serverless endpoint, SageMaker provisions and manages the compute resources for you. Then, you can make inference requests to the endpoint and receive model predictions in response. SageMaker scales the compute resources up and down as needed to handle your request traffic, and you only pay for what you use.

For Provisioned Concurrency, Serverless Inference also integrates with Application Auto Scaling, so that you can manage Provisioned Concurrency based on a target metric or on a schedule. For more information, see *Automatically scale Provisioned Concurrency for a serverless endpoint* (p. 2513).

The following sections provide additional details about Serverless Inference and how it works.

### Topics
- Container support (p. 2497)
- Memory size (p. 2497)
- Concurrent invocations (p. 2498)
- Minimizing cold starts (p. 2498)
- Feature exclusions (p. 2499)

### Container support

For your endpoint container, you can choose either a SageMaker-provided container or bring your own. SageMaker provides containers for its built-in algorithms and prebuilt Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. For a list of available SageMaker images, see [Available Deep Learning Containers Images](#). If you are bringing your own container, you must modify it to work with SageMaker. For more information about bringing your own container, see [Adapting Your Own Inference Container](#).

The maximum size of the container image you can use is 10 GB. For serverless endpoints, we recommend creating only one worker in the container and only loading one copy of the model. Note that this is unlike real-time endpoints, where some SageMaker containers may create a worker for each vCPU to process inference requests and load the model in each worker.

If you already have a container for a real-time endpoint, you can use the same container for your serverless endpoint, though some capabilities are excluded. To learn more about the container capabilities that are not supported in Serverless Inference, see [Feature exclusions](#). If you choose to use the same container, SageMaker escrows (retains) a copy of your container image until you delete all endpoints that use the image. SageMaker encrypts the copied image at rest with a SageMaker-owned AWS KMS key.

### Memory size

Your serverless endpoint has a minimum RAM size of 1024 MB (1 GB), and the maximum RAM size you can choose is 6144 MB (6 GB). The memory sizes you can choose are 1024 MB, 2048 MB, 3072 MB, 4096 MB.
MB, 5120 MB, or 6144 MB. Serverless Inference auto-assigns compute resources proportional to the memory you select. If you choose a larger memory size, your container has access to more vCPUs. Choose your endpoint's memory size according to your model size. Generally, the memory size should be at least as large as your model size. You may need to benchmark in order to choose the right memory selection for your model based on your latency SLAs. For a step by step guide to benchmark, see Introducing the Amazon SageMaker Serverless Inference Benchmarking Toolkit. The memory size increments have different pricing; see the Amazon SageMaker pricing page for more information.

Regardless of the memory size you choose, your serverless endpoint has 5 GB of ephemeral disk storage available. For help with container permissions issues when working with storage, see Troubleshooting (p. 2521).

**Concurrent invocations**

On-demand Serverless Inference manages predefined scaling policies and quotas for the capacity of your endpoint. Serverless endpoints have a quota for how many concurrent invocations can be processed at the same time. If the endpoint is invoked before it finishes processing the first request, then it handles the second request concurrently.

The total concurrency that you can share between all serverless endpoints in your account depends on your region:

- For the US East (Ohio), US East (N. Virginia), US West (Oregon), Asia Pacific (Singapore), Asia Pacific (Sydney), Asia Pacific (Tokyo), Europe (Frankfurt), and Europe (Ireland) Regions, the total concurrency you can share between all serverless endpoints per Region in your account is 1000.
- For the US West (N. California), Africa (Cape Town), Asia Pacific (Hong Kong), Asia Pacific (Mumbai), Asia Pacific (Osaka), Asia Pacific (Seoul), Canada (Central), Europe (London), Europe (Milan), Europe (Paris), Europe (Stockholm), Middle East (Bahrain), and South America (São Paulo) Regions, the total concurrency per Region in your account is 500.

You can set the maximum concurrency for a single endpoint up to 200, and the total number of serverless endpoints you can host in a Region is 50. The maximum concurrency for an individual endpoint prevents that endpoint from taking up all of the invocations allowed for your account, and any endpoint invocations beyond the maximum are throttled.

**Note**

Provisioned Concurrency that you assign to a serverless endpoint should always be less than or equal to the maximum concurrency that you assigned to that endpoint.

To learn how to set the maximum concurrency for your endpoint, see Create an endpoint configuration (p. 2503). For more information about quotas and limits, see Amazon SageMaker endpoints and quotas in the AWS General Reference. To request a service limit increase, contact AWS Support. For instructions on how to request a service limit increase, see Supported Regions and Quotas (p. 43).

**Minimizing cold starts**

If your on-demand Serverless Inference endpoint does not receive traffic for a while and then your endpoint suddenly receives new requests, it can take some time for your endpoint to spin up the compute resources to process the requests. This is called a cold start. Since serverless endpoints provision compute resources on demand, your endpoint may experience cold starts. A cold start can also occur if your concurrent requests exceed the current concurrent request usage. The cold start time depends on your model size, how long it takes to download your model, and the start-up time of your container.

To monitor how long your cold start time is, you can use the Amazon CloudWatch metric OverheadLatency to monitor your serverless endpoint. This metric tracks the time it takes to launch...
new compute resources for your endpoint. To learn more about using CloudWatch metrics with serverless endpoints, see Monitor a serverless endpoint (p. 2511).

You can minimize cold starts by using Provisioned Concurrency. SageMaker keeps the endpoint warm and ready to respond in milliseconds, for the number of Provisioned Concurrency that you allocated.

**Feature exclusions**

Some of the features currently available for SageMaker Real-time Inference are not supported for Serverless Inference, including GPUs, AWS marketplace model packages, private Docker registries, Multi-Model Endpoints, VPC configuration, network isolation, data capture, multiple production variants, Model Monitor, and inference pipelines.

You cannot convert your instance-based, real-time endpoint to a serverless endpoint. If you try to update your real-time endpoint to serverless, you receive a ValidationError message. You can convert a serverless endpoint to real-time, but once you make the update, you cannot roll it back to serverless.

**Getting started**

You can create, update, describe, and delete a serverless endpoint using the SageMaker console, the AWS SDKs, the Amazon SageMaker Python SDK, and the AWS CLI. You can invoke your endpoint using the AWS SDKs, the Amazon SageMaker Python SDK, and the AWS CLI. For serverless endpoints with Provisioned Concurrency, you can use Application Auto Scaling to auto scale Provisioned Concurrency based on a target metric or a schedule. For more information about how to set up and use a serverless endpoint, read the guide Create, invoke, update, and delete a serverless endpoint (p. 2499). For more information on auto scaling serverless endpoints with Provisioned Concurrency, see Automatically scale Provisioned Concurrency for a serverless endpoint (p. 2513).

**Note**

Application Auto Scaling for Serverless Inference with Provisioned Concurrency is currently not supported on AWS CloudFormation.

**Example notebooks and blogs**

For Jupyter notebook examples that show end-to-end serverless endpoint workflows, see the Serverless Inference example notebooks.

**Create, invoke, update, and delete a serverless endpoint**

Unlike other SageMaker real-time endpoints, Serverless Inference manages compute resources for you, reducing complexity so you can focus on your ML model instead of on managing infrastructure. The following guide highlights the key capabilities of serverless endpoints: how to create, invoke, update, describe, or delete an endpoint. You can use the SageMaker console, the AWS SDKs, the Amazon SageMaker Python SDK, or the AWS CLI to manage your serverless endpoints.

**Topics**

- Prerequisites (p. 2500)
- Create a serverless endpoint (p. 2501)
- Invoke a serverless endpoint (p. 2509)
- Update a serverless endpoint (p. 2509)
- Describe a serverless endpoint (p. 2510)
- Delete a serverless endpoint (p. 2511)
Prerequisites

Before you can create a serverless endpoint, complete the following prerequisites.

1. **Set up an AWS account.** You first need an AWS account and an AWS Identity and Access Management administrator user. For instructions on how to set up an AWS account, see [How do I create and activate a new AWS account?](#). For instructions on how to secure your account with an IAM administrator user, see [Creating your first IAM admin user and user group](#) in the IAM User Guide.

2. **Create an Amazon S3 bucket.** You use an Amazon S3 bucket to store your model artifacts. To learn how to create a bucket, see [Create your first S3 bucket](#) in the Amazon S3 User Guide.

3. **Upload your model artifacts to your S3 bucket.** For instructions on how to upload your model to your bucket, see [Upload an object to your bucket](#) in the Amazon S3 User Guide.

4. **Create an IAM role for Amazon SageMaker.** Amazon SageMaker needs access to the S3 bucket that stores your model. Create an IAM role with a policy that gives SageMaker read access to your bucket. The following procedure shows how to create a role in the console, but you can also use the [CreateRole](#) API from the IAM User Guide. For information on giving your role more granular permissions based on your use case, see [SageMaker Roles](#).
   
   a. Sign in to the [IAM console](#).
   
   b. In the navigation tab, choose Roles.
   
   c. Choose Create Role.
   
   d. For **Select type of trusted entity**, choose AWS service and then choose SageMaker.
   
   e. Choose Next: Permissions and then choose Next: Tags.
   
   f. (Optional) Add tags as key-value pairs if you want to have metadata for the role.
   
   g. Choose Next: Review.
   
   h. For **Role name**, enter a name for the new role that is unique within your AWS account. You cannot edit the role name after creating the role.
   
   i. (Optional) For **Role description**, enter a description for the new role.
   
   j. Choose Create role.

5. **Attach S3 bucket permissions to your SageMaker role.** After creating an IAM role, attach a policy that gives SageMaker permission to access the S3 bucket containing your model artifacts.

   a. In the IAM console navigation tab, choose Roles.
   
   b. From the list of roles, search for the role you created in the previous step by name.
   
   c. Choose your role, and then choose Attach policies.
   
   d. For **Attach permissions**, choose Create policy.
   
   e. In the **Create policy** view, select the JSON tab.
   
   f. Add the following policy statement into the JSON editor. Make sure to replace `<your-bucket-name>` with the name of the S3 bucket that stores your model artifacts. If you want to restrict the access to a specific folder or file in your bucket, you can also specify the Amazon S3 folder path, for example, `<your-bucket-name>/model-folder`.

   ```json
   {
   "Version": "2012-10-17",
   "Statement": [
   {
   "Sid": "VisualEditor0",
   "Effect": "Allow",
   "Action": "s3:GetObject",
   "Resource": "arn:aws:s3:::<your-bucket-name>/**"
   }
   ]
   }
   ```
g. Choose Next: Tags.

h. (Optional) Add tags in key-value pairs to the policy.

i. Choose Next: Review.

j. For Name, enter a name for the new policy.

k. (Optional) Add a Description for the policy.

l. Choose Create policy.

m. After creating the policy, return to Roles in the IAM console and select your SageMaker role.

n. Choose Attach policies.

o. For Attach permissions, search for the policy you created by name. Select it and choose Attach policy.

6. Select a prebuilt Docker container image or bring your own. The container you choose serves inference on your endpoint. SageMaker provides containers for built-in algorithms and prebuilt Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. For a full list of the available SageMaker images, see Available Deep Learning Containers Images.

If none of the existing SageMaker containers meet your needs, you may need to create your own Docker container. For information about how to create your Docker image and make it compatible with SageMaker, see Use your own inference code (p. 3327). To use your container with a serverless endpoint, the container image must reside in an Amazon ECR repository within the same AWS account that creates the endpoint.

7. (Optional) Register your model with Model Registry. SageMaker Model Registry (p. 2989) helps you catalog and manage versions of your models for use in ML pipelines. For more information about registering a version of your model, see Create a Model Group (p. 2990) and Register a Model Version (p. 2992). For an example of a Model Registry and Serverless Inference workflow, see the following example notebook.

8. (Optional) Bring an AWS KMS key. When setting up a serverless endpoint, you have the option to specify a KMS key that SageMaker uses to encrypt your Amazon ECR image. Note that the key policy for the KMS key must grant access to the IAM role you specify when setting up your endpoint. To learn more about KMS keys, see the AWS Key Management Service Developer Guide.

Create a serverless endpoint

To create a serverless endpoint, you can use the Amazon SageMaker console, the APIs, or the AWS CLI. You can create a serverless endpoint using a similar process as a real-time endpoint (p. 2388).

Topics
- Create a model (p. 2501)
- Create an endpoint configuration (p. 2503)
- Create an endpoint (p. 2506)

Create a model

To create your model, you must provide the location of your model artifacts and container image. You can also use a model version from SageMaker Model Registry (p. 2989). The examples in the following sections show you how to create a model using the CreateModel API, Model Registry, and the Amazon SageMaker console.

To create a model (using Model Registry)

Model Registry (p. 2989) is a feature of SageMaker that helps you catalog and manage versions of your model for use in ML pipelines. To use Model Registry with Serverless Inference, you must first register
a model version in a Model Registry model group. To learn how to register a model in Model Registry, follow the procedures in Create a Model Group (p. 2990) and Register a Model Version (p. 2992).

The following example requires you to have the ARN of a registered model version and uses the AWS SDK for Python (Boto3) to call the CreateModel API. For Serverless Inference, Model Registry is currently only supported by the AWS SDK for Python (Boto3). For the example, specify the following values:

- For model_name, enter a name for the model.
- For sagemaker_role, you can use the default SageMaker-created role or a customized SageMaker IAM role from Step 4 of the Prerequisites (p. 2500) section.
- For ModelPackageName, specify the ARN for your model version, which must be registered to a model group in Model Registry.

```python
#Setup
import boto3
import sagemaker
region = boto3.Session().region_name
client = boto3.client("sagemaker", region_name=region)

#Role to give SageMaker permission to access AWS services.
sagemaker_role = sagemaker.get_execution_role()

#Specify a name for the model
model_name = "<name-for-model>"

#Specify a Model Registry model version
container_list = [
    {
        "ModelPackageName": <model-version-arn>
    }
]

#Create the model
response = client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = sagemaker_role,
    container_list
)
```

To create a model (using API)

The following example uses the AWS SDK for Python (Boto3) to call the CreateModel API. Specify the following values:

- For sagemaker_role, you can use the default SageMaker-created role or a customized SageMaker IAM role from Step 4 of the Prerequisites (p. 2500) section.
- For model_url, specify the Amazon S3 URI to your model.
- For container, retrieve the container you want to use by its Amazon ECR path. This example uses a SageMaker-provided XGBoost container. If you have not selected a SageMaker container or brought your own, see Step 6 of the Prerequisites (p. 2500) section for more information.
- For model_name, enter a name for the model.

```python
#Setup
import boto3
import sagemaker
region = boto3.Session().region_name
client = boto3.client("sagemaker", region_name=region)
```
#Role to give SageMaker permission to access AWS services.
sagemaker_role = sagemaker.get_execution_role()

#Get model from S3
model_url = "s3://DOC-EXAMPLE-BUCKET/models/model.tar.gz"

#Get container image (prebuilt example)
from sagemaker import image_uris
container = image_uris.retrieve("xgboost", region, "0.90-1")

#Create model
model_name = "<name-for-model>"

response = client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = sagemaker_role,
    Containers = [{
        "Image": container,
        "Mode": "SingleModel",
        "ModelDataUrl": model_url,
    }]
)

To create a model (using the console)

1. Sign in to the Amazon SageMaker console.
2. In the navigation tab, choose Inference.
3. Next, choose Models.
4. Choose Create model.
5. For Model name, enter a name for the model that is unique to your account and AWS Region.
6. For IAM role, either select an IAM role you have already created (see Prerequisites (p. 2500)) or allow SageMaker to create one for you.
7. In Container definition 1, for Container input options, select Provide model artifacts and input location.
8. For Provide model artifacts and inference image options, select Use a single model.
9. For Location of inference code image, enter an Amazon ECR path to a container. The image must either be a SageMaker-provided first party image (e.g. TensorFlow, XGBoost) or an image that resides in an Amazon ECR repository within the same account in which you are creating the endpoint. If you do not have a container, go back to Step 6 of the Prerequisites (p. 2500) section for more information.
10. For Location of model artifacts, enter the Amazon S3 URI to your ML model. For example, s3://DOC-EXAMPLE-BUCKET/models/model.tar.gz.
11. (Optional) For Tags, add key-value pairs to create metadata for your model.
12. Choose Create model.

Create an endpoint configuration

After you create a model, create an endpoint configuration. You can then deploy your model using the specifications in your endpoint configuration. In the configuration, you specify whether you want a real-time or serverless endpoint. To create a serverless endpoint configuration, you can use the Amazon SageMaker console, the CreateEndpointConfig API, or the AWS CLI. The API and console approaches are outlined in the following sections.

To create an endpoint configuration (using API)

The following example uses the AWS SDK for Python (Boto3) to call the CreateEndpointConfig API. Specify the following values:
• For **EndpointConfigName**, choose a name for the endpoint configuration. The name should be unique within your account in a Region.

• (Optional) For **KmsKeyId**, use the key ID, key ARN, alias name, or alias ARN for an AWS KMS key that you want to use. SageMaker uses this key to encrypt your Amazon ECR image.

• For **ModelName**, use the name of the model you want to deploy. It should be the same model that you used in the **Create a model (p. 2501)** step.

• For **ServerlessConfig**:
  • Set **MemorySizeInMB** to 2048. For this example, we set the memory size to 2048 MB, but you can choose any of the following values for your memory size: 1024 MB, 2048 MB, 3072 MB, 4096 MB, 5120 MB, or 6144 MB.
  • Set **MaxConcurrency** to 20. For this example, we set the maximum concurrency to 20. The maximum number of concurrent invocations you can set for a serverless endpoint is 200, and the minimum value you can choose is 1.
  • (Optional) To use Provisioned Concurrency, set **ProvisionedConcurrency** to 10. For this example, we set the Provisioned Concurrency to 10. The ProvisionedConcurrency number for a serverless endpoint must be lower than or equal to the MaxConcurrency number. You can leave it empty if you want to use on-demand Serverless Inference endpoint. You can dynamically scale Provision Concurrency. For more information, see [Automatically scale Provisioned Concurrency for a serverless endpoint (p. 2513)](#).

```python
response = client.create_endpoint_config(  
    EndpointConfigName="<your-endpoint-configuration>",  
    KmsKeyId="arn:aws:kms:us-east-1:123456789012:key/143ef68f-76fd-45e3-abba-ed28fc8d3d5e",  
    ProductionVariants=[  
        {  
            "ModelName": "<your-model-name>",  
            "VariantName": "AllTraffic",  
            "ServerlessConfig": {  
                "MemorySizeInMB": 2048,  
                "MaxConcurrency": 20,  
                "ProvisionedConcurrency": 10,  
            }  
        }  
    ]  
)
```

**To create an endpoint configuration (using the console)**

1. Sign in to the Amazon SageMaker console.
2. In the navigation tab, choose Inference.
3. Next, choose Endpoint configurations.
4. Choose Create endpoint configuration.
5. For **Endpoint configuration name**, enter a name that is unique within your account in a Region.
6. For **Type of endpoint**, select Serverless.
7. For Production variants, choose Add model.
8. Under Add model, select the model you want to use from the list of models and then choose Save.
9. After adding your model, under Actions, choose Edit.
10. For Memory size, choose the memory size you want in GB.
Create, invoke, update, and delete a serverless endpoint

For **Max Concurrency**, enter your desired maximum concurrent invocations for the endpoint. The maximum value you can enter is 200 and the minimum is 1.

12. (Optional) To use Provisioned Concurrency, enter the desired number of concurrent invocations in the **Provisioned Concurrency setting** field. The number of provisioned concurrent invocations must be less than or equal to the number of maximum concurrent invocations.

13. Choose **Save**.

14. (Optional) For **Tags**, enter key-value pairs if you want to create metadata for your endpoint configuration.

15. Choose **Create endpoint configuration**.

**Create an endpoint**

To create a serverless endpoint, you can use the Amazon SageMaker console, the CreateEndpoint API, or the AWS CLI. The API and console approaches are outlined in the following sections. Once you create your endpoint, it can take a few minutes for the endpoint to become available.

**To create an endpoint (using API)**

The following example uses the AWS SDK for Python (Boto3) to call the CreateEndpoint API. Specify the following values:
• For EndpointName, enter a name for the endpoint that is unique within a Region in your account.
• For EndpointConfigName, use the name of the endpoint configuration that you created in the previous section.

```python
response = client.create_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<your-endpoint-config>"
)
```

To create an endpoint (using the console)

1. Sign in to the Amazon SageMaker console.
2. In the navigation tab, choose Inference.
3. Next, choose Endpoints.
4. Choose Create endpoint.
5. For Endpoint name, enter a name than is unique within a Region in your account.
6. For Attach endpoint configuration, select Use an existing endpoint configuration.
7. For Endpoint configuration, select the name of the endpoint configuration you created in the previous section and then choose Select endpoint configuration.
8. (Optional) For Tags, enter key-value pairs if you want to create metadata for your endpoint.
9. Choose Create endpoint.
Create and configure endpoint

To deploy models to Amazon SageMaker, first create an endpoint. Provide an endpoint configuration to specify which models to deploy and the hardware requirements for each. See Deploying a Model on Amazon SageMaker Hosting Services. Learn more about the API.

### Endpoint

**Endpoint name**

Your application uses this name to access this endpoint.

Maximum of 63 alphanumeric characters. Can include hyphens (-), but not spaces. Must be unique within your account in an AWS Region.

### Attach endpoint configuration

- **Use an existing endpoint configuration**
  - Use an existing endpoint configuration or clone an endpoint configuration

- **Create a new endpoint configuration**
  - Add models and configure the instance and initial weight for each model.

### Endpoint configuration

<table>

</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Add tag
Invoke a serverless endpoint

In order to perform inference using a serverless endpoint, you must send an HTTP request to the endpoint. You can use the `InvokeEndpoint` API or the AWS CLI, which make a POST request to invoke your endpoint. The maximum request and response payload size for serverless invocations is 4 MB. For serverless endpoints:

- The model must download and the server must respond successfully to `/ping` within 3 minutes.
- The timeout for the container to respond to inference requests to `/invocations` is 1 minute.

To invoke an endpoint

The following example uses the AWS SDK for Python (Boto3) to call the `InvokeEndpoint` API. Note that unlike the other API calls in this guide, for `InvokeEndpoint`, you must use SageMaker Runtime Runtime as the client. Specify the following values:

- For `endpoint_name`, use the name of the in-service serverless endpoint you want to invoke.
- For `content_type`, specify the MIME type of your input data in the request body (for example, `application/json`).
- For `payload`, use your request payload for inference. Your payload should be in bytes or a file-like object.

```python
runtime = boto3.client("sagemaker-runtime")
endpoint_name = "<your-endpoint-name>"
content_type = "<request-mime-type>"
payload = <your-request-body>
response = runtime.invoke_endpoint(
    EndpointName=endpoint_name,
    ContentType=content_type,
    Body=payload
)
```

Update a serverless endpoint

Before updating your endpoint, create a new endpoint configuration or use an existing endpoint configuration. The endpoint configuration is where you specify the changes for your update. Then, you can update your endpoint with the SageMaker console, the `UpdateEndpoint` API, or the AWS CLI. The process for updating a serverless endpoint is the same as the process for updating a real-time endpoint (p. 2388). Note that when updating your endpoint, you can experience cold starts when making requests to the endpoint because SageMaker must re-initialize your container and model.

You may want to update an on-demand serverless endpoint to a serverless endpoint with provisioned concurrency or adjust the Provisioned Concurrency value for an existing serverless endpoint with provisioned concurrency. For both cases, you will have to create a new serverless endpoint configuration with the desired value for Provisioned Concurrency, and apply `UpdateEndpoint` to the existing serverless endpoint. For more information on creating a new serverless endpoint configuration with Provisioned Concurrency, see Create an endpoint configuration (p. 2503).

If you want to remove Provisioned Concurrency from a serverless endpoint, you will have to create a new endpoint configuration without specifying any value for Provisioned Concurrency, and then apply `UpdateEndpoint` to the endpoint.
Note
Updating a real-time inference endpoint to either an on-demand serverless endpoint or a serverless endpoint with Provisioned Concurrency is currently not supported.

Update the endpoint

After creating a new serverless endpoint configuration you can use the `UpdateEndpoint` and the `SageMaker console` to update an existing serverless endpoint. Examples of how to update your endpoint using the `UpdateEndpoint` API and the SageMaker console are outlined in the following sections.

To update the endpoint (using API)

The following example uses the AWS SDK for Python (Boto3) to call the `UpdateEndpoint` API. Specify the following values:

- For `EndpointName`, use the name of the endpoint you're updating.
- For `EndpointConfigName`, use the name of the endpoint configuration that you want to use for the update.

```python
response = client.update_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<new-endpoint-config>",
)
```

To update the endpoint (using the console)

1. Sign in to the Amazon SageMaker console.
2. In the navigation tab, choose Inference.
3. Next, choose Endpoints.
4. From the list of endpoints, select the endpoint you want to update.
5. Choose Change in Endpoint configuration settings section.
6. For Change the Endpoint configuration, choose Use an existing endpoint configuration.
7. From the list of endpoint configurations, select the one you want to use for your update.
8. Choose Select endpoint configuration.
9. Choose Update endpoint.

Describe a serverless endpoint

You might want to retrieve information about your endpoint, including details such as the endpoint's ARN, current status, deployment configuration, and failure reasons. You can find information about your endpoint using the SageMaker console, the `DescribeEndpoint` API, or the AWS CLI.

To describe an endpoint (using API)

The following example uses the AWS SDK for Python (Boto3) to call the `DescribeEndpoint` API. For EndpointName, use the name of the endpoint you want to check.

```python
response = client.describe_endpoint(
    EndpointName="<your-endpoint-name>",
)
```

To describe an endpoint (using the console)

1. Sign in to the Amazon SageMaker console.
2. In the navigation tab, choose **Inference**.
3. Next, choose **Endpoints**.
4. From the list of endpoints, choose the endpoint you want to check.

The endpoint page contains the information about your endpoint.

**Delete a serverless endpoint**

You can delete your serverless endpoint using the SageMaker console, the `DeleteEndpoint` API, or the AWS CLI. The following examples show you how to delete your endpoint through the API and the SageMaker console.

**To delete an endpoint (using API)**

The following example uses the AWS SDK for Python (Boto3) to call the `DeleteEndpoint` API. For `EndpointName`, use the name of the serverless endpoint you want to delete.

```python
response = client.delete_endpoint(
    EndpointName="<your-endpoint-name>",
)
```

**To delete an endpoint (using the console)**

1. Sign in to the Amazon SageMaker console.
2. In the navigation tab, choose **Inference**.
3. Next, choose **Endpoints**.
4. From the list of endpoints, select the endpoint you want to delete.
5. Choose the **Actions** drop-down list, and then choose **Delete**.
6. When prompted again, choose **Delete**.

Your endpoint should now begin the deletion process.

**Monitor a serverless endpoint**

To monitor your serverless endpoint, you can use Amazon CloudWatch alarms. CloudWatch is a service that collects metrics in real time from your AWS applications and resources. An alarm watches metrics as they are collected and gives you the ability to pre-specify a threshold and the actions to take if that threshold is breached. For example, your CloudWatch alarm can send you a notification if your endpoint breaches an error threshold. By setting up CloudWatch alarms, you gain visibility into the performance and functionality of your endpoint. For more information about CloudWatch alarms, see Using Amazon CloudWatch alarms in the Amazon CloudWatch User Guide.

**Monitoring with CloudWatch**

The metrics below are an exhaustive list of metrics for serverless endpoints. Any metric not listed below is not published for serverless endpoints. For information about the following metrics, see Monitor Amazon SageMaker with Amazon CloudWatch.

**Common endpoint metrics**

These CloudWatch metrics are the same as the metrics published for real-time endpoints.
The OverheadLatency metric tracks all additional latency that SageMaker added which includes the cold start time for launching new compute resources for your serverless endpoint. Compared to on-demand serverless endpoints, the OverheadLatency for serverless endpoints with provision concurrency is generally significantly less.

Serverless endpoints can also use the Invocations4XXErrors, Invocations5XXErrors, Invocations, ModelLatency, ModelSetupTime and MemoryUtilization metrics. To learn more about these metrics, see SageMaker Endpoint Invocation Metrics (p. 3578).

**Common serverless endpoint metrics**

These CloudWatch metrics are published for both on-demand serverless endpoints and serverless endpoint with Provisioned Concurrency.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Unit/Stats</th>
</tr>
</thead>
<tbody>
<tr>
<td>ServerlessConcurrentExecutionsUtilization</td>
<td>The number of concurrent executions divided by the maximum concurrency.</td>
<td>Units: None&lt;br&gt;Valid statistics: Average, Max, Min</td>
</tr>
</tbody>
</table>

**Serverless endpoint with Provisioned Concurrency metrics**

These CloudWatch metrics are published for serverless endpoints with Provisioned Concurrency.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Unit/Stats</th>
</tr>
</thead>
<tbody>
<tr>
<td>ServerlessProvisionedConcurrencyExecutions</td>
<td>The number of concurrent executions handled by the endpoint.</td>
<td>Units: Count&lt;br&gt;Valid statistics: Average, Max, Min</td>
</tr>
<tr>
<td>ServerlessProvisionedConcurrencyUtilization</td>
<td>The number of concurrent executions divided by the allocated Provisioned Concurrency.</td>
<td>Units: None&lt;br&gt;Valid statistics: Average, Max, Min</td>
</tr>
<tr>
<td>ServerlessProvisionedConcurrencyInvocations</td>
<td>The number of InvokeEndpoint requests handled by Provisioned Concurrency.</td>
<td>Units: Count&lt;br&gt;Valid statistics: Average, Max, Min</td>
</tr>
<tr>
<td>ServerlessProvisionedConcurrencySpillover invokes</td>
<td>The number of InvokeEndpoint requests not handled by Provisioned Concurrency, that is handled by on-demand Serverless Inference.</td>
<td>Units: Count&lt;br&gt;Valid statistics: Average, Max, Min</td>
</tr>
</tbody>
</table>

**Logs**

If you want to monitor the logs from your endpoint for debugging or progress analysis, you can use Amazon CloudWatch Logs. The SageMaker-provided log group that you can use for serverless endpoints is /aws/sagemaker/Endpoints/[EndpointName]. For more information about using CloudWatch Logs in SageMaker, see Log Amazon SageMaker Events with Amazon CloudWatch (p. 3591). To learn
Automatically scale Provisioned Concurrency for a serverless endpoint

Amazon SageMaker automatically scales in or out on-demand serverless endpoints. For serverless endpoints with Provisioned Concurrency you can use Application Auto Scaling to scale up or down the Provisioned Concurrency based on your traffic profile, thus optimizing costs.

The following are the prerequisites to autoscale Provisioned Concurrency on serverless endpoints:

- Register a model (p. 2513)
- Define a scaling policy (p. 2514)
- Apply a scaling policy (p. 2515)

Before you can use autoscaling, you must have already deployed a model to a serverless endpoint with Provisioned Concurrency. Deployed models are referred to as production variants. See Create an endpoint configuration (p. 2503) and Create an endpoint (p. 2506) for more information about deploying a model to a serverless endpoint with Provisioned Concurrency. To specify the metrics and target values for a scaling policy, you must configure a scaling policy. For more information on how to define a scaling policy, see Define a scaling policy (p. 2514). After registering your model and defining a scaling policy, apply the scaling policy to the registered model. For information on how to apply the scaling policy, see Apply a scaling policy (p. 2515).

For details on other prerequisites and components used with autoscaling, see the Prerequisites (p. 2447) section in the SageMaker autoscaling documentation (p. 2447).

Register a model

To add autoscaling to a serverless endpoint with Provisioned Concurrency, you first must register your model (production variant) using AWS CLI or Application Auto Scaling API.

Register a model (AWS CLI)

To register your model, use the register-scaleable-target AWS CLI command with the following parameters:

- --service-namespace – Set this value to sagemaker.
- --resource-id – The resource identifier for the model (specifically the production variant). For this parameter, the resource type is endpoint and the unique identifier is the name of the production variant. For example endpoint/MyEndpoint/variant/MyVariant.
- --scalable-dimension – Set this value to sagemaker:variant:DesiredProvisionedConcurrency.
- --min-capacity – The minimum number of Provisioned Concurrency for the model. Set --min-capacity to at least 1. It must be equal to or less than the value specified for --max-capacity.
- --max-capacity – The maximum number of Provisioned Concurrency that should be enabled through Application Auto Scaling. Set --max-capacity to a minimum of 1. It must be greater than or equal to the value specified for --min-capacity.

The following example shows how to register a model named MyVariant that is dynamically scaled to have 1 to 10 Provisioned Concurrency value:
automatically scale provisioned concurrency for a serverless endpoint

aws application-autoscaling register-scalable-target
--service-namespace sagemaker
--scalable-dimension sagemaker:variant:DesiredProvisionedConcurrency
--resource-id endpoint/MyEndpoint/variant/MyVariant
--min-capacity 1
--max-capacity 10

Register a model (Application Auto Scaling API)

To register your model, use the RegisterScalableTarget Application Auto Scaling API action with the following parameters:

- **ServiceNamespace** – Set this value to sagemaker.
- **ResourceId** – The resource identifier for the model (specifically the production variant). For this parameter, the resource type is endpoint and the unique identifier is the name of the production variant. For example, endpoint/MyEndpoint/variant/MyVariant.
- **ScalableDimension** – Set this value to sagemaker:variant:DesiredProvisionedConcurrency.
- **MinCapacity** – The minimum number of Provisioned Concurrency for the model. Set MinCapacity to at least 1. It must be equal to or less than the value specified for MaxCapacity.
- **MaxCapacity** – The maximum number of Provisioned Concurrency that should be enabled through Application Auto Scaling. Set MaxCapacity to a minimum of 1. It must be greater than or equal to the value specified for MinCapacity.

The following example shows how to register a model named MyVariant that is dynamically scaled to have 1 to 10 Provisioned Concurrency value:

```json

POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
X-Amz-Target: AnyScaleFrontendService.RegisterScalableTarget
X-Amz-Date: 20160506T182145Z
User-Agent: aws-cli/1.10.23 Python/2.7.11 Darwin/15.4.0 botocore/1.4.8
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS

{
    "ServiceNamespace": "sagemaker",
    "ResourceId": "endpoint/MyEndPoint/variant/MyVariant",
    "ScalableDimension": "sagemaker:variant:DesiredProvisionedConcurrency",
    "MinCapacity": 1,
    "MaxCapacity": 10
}
```

Define a scaling policy

To specify the metrics and target values for a scaling policy, you can configure a target-tracking scaling policy. Define the scaling policy as a JSON block in a text file. You can then use that text file when invoking the AWS CLI or the Application Auto Scaling API. To quickly define a target-tracking scaling policy for a serverless endpoint, use the SageMakerVariantProvisionedConcurrencyUtilization predefined metric.

```
{
    "TargetValue": 0.5,
}
```
"PredefinedMetricSpecification":
{
  "PredefinedMetricType": "SageMakerVariantProvisionedConcurrencyUtilization",
},
"ScaleOutCooldown": 1,
"ScaleInCooldown": 1
}

Apply a scaling policy

After registering your model, you can apply a scaling policy to your serverless endpoint with Provisioned Concurrency. See Apply a target-tracking scaling policy (p. 2515) to apply a target-tracking scaling policy that you have defined. If the traffic flow to your serverless endpoint has a predictable routine then instead of applying a target-tracking scaling policy you might want to schedule scaling actions at specific times. For more information on scheduling scaling actions, see Scheduled scaling (p. 2518).

Apply a target-tracking scaling policy

You can use the AWS Management Console, AWS CLI or the Application Auto Scaling API to apply a target-tracking scaling policy to your serverless endpoint with Provisioned Concurrency.

Apply a target-tracking scaling policy (AWS CLI)

To apply a scaling policy to your model, use the put-scaling-policy AWS CLI command with the following parameters:

- **--policy-name** – The name of the scaling policy.
- **--policy-type** – Set this value to TargetTrackingScaling.
- **--resource-id** – The resource identifier for the variant. For this parameter, the resource type is endpoint and the unique identifier is the name of the variant. For example endpoint/MyEndpoint/variant/MyVariant.
- **--service-namespace** – Set this value to sagemaker.
- **--scalable-dimension** – Set this value to sagemaker:variant:DesiredProvisionedConcurrency.
- **--target-tracking-scaling-policy-configuration** – The target-tracking scaling policy configuration to use for the model.

The following example shows how to apply a target-tracking scaling policy named MyScalingPolicy to a model named MyVariant. The policy configuration is saved in a file named scaling-policy.json.

```
aws application-autoscaling put-scaling-policy
   --policy-name MyScalingPolicy
   --policy-type TargetTrackingScaling
   --service-namespace sagemaker
   --scalable-dimension sagemaker:variant:DesiredProvisionedConcurrency
   --resource-id endpoint/MyEndpoint/variant/MyVariant
   --target-tracking-scaling-policy-configuration file://[/file-location]/scaling-policy.json
```

Apply a target-tracking scaling policy (Application Auto Scaling API)

To apply a scaling policy to your model, use the PutScalingPolicy Application Auto Scaling API action with the following parameters:
• **PolicyName** – The name of the scaling policy.

• **PolicyType** – Set this value to TargetTrackingScaling.

• **ResourceId** – The resource identifier for the variant. For this parameter, the resource type is endpoint and the unique identifier is the name of the variant. For example endpoint/MyEndpoint/variant/MyVariant.

• **ServiceNamespace** – Set this value to sagemaker.

• **ScalableDimension** – Set this value to sagemaker:variant:DesiredProvisionedConcurrency.

• **TargetTrackingScalingPolicyConfiguration** – The target-tracking scaling policy configuration to use for the model.

The following example shows how to apply a target-tracking scaling policy named MyScalingPolicy to a model named MyVariant. The policy configuration is saved in a file named scaling-policy.json.

```json
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
X-Amz-Target: AnyScaleFrontendService.PutScalingPolicy
X-Amz-Date: 20160506T182145Z

         "PredefinedMetricType": "SageMakerVariantProvisionedConcurrencyUtilization"
      }
   }
}
```

### Apply a target-tracking scaling policy (AWS Management Console)

To apply a target-tracking scaling policy with the AWS Management Console:

1. Sign in to the [Amazon SageMaker console](https://console.aws.amazon.com/sagemaker/).  
2. In the navigation panel, choose **Inference**.  
3. Choose **Endpoints** to view a list of all of your endpoints.  
4. Choose the endpoint to which you want to apply the scaling policy. A page with the settings of the endpoint will appear, with the models (production variant) listed under **Endpoint runtime settings** section.  
5. Select the production variant to which you want to apply the scaling policy, and choose **Configure auto scaling**. The **Configure variant automatic scaling** dialog box appears.
6. Enter the minimum and maximum Provisioned Concurrency values in the **Minimum provisioned concurrency** and **Maximum provisioned concurrency** fields, respectively, in the **Variant automatic scaling** section. Minimum Provisioned Concurrency must be less than or equal to maximum Provisioned Concurrency.
7. Enter the target value in the **Target value** field for the target metric, SageMakerVariantProvisionedConcurrencyUtilization.

8. (Optional) Enter scale in cool down and scale out cool down values (in seconds) in **Scale in cool down** and **Scale out cool down** fields respectively.

9. (Optional) Select **Disable scale in** if you don’t want auto scaling to delete instance when traffic decreases.

10. Select **Save**.

### Scheduled scaling

If the traffic to your serverless endpoint with Provisioned Concurrency follows a routine pattern you might want to schedule scaling actions at specific times, to scale in or scale out Provisioned Concurrency. You can use the AWS CLI or the Application Auto Scaling to schedule scaling actions.

#### Scheduled scaling (AWS CLI)

To apply a scaling policy to your model, use the `put-scheduled-action AWS CLI` command with the following parameters:

- `--scheduled-action-name` – The name of the scaling action.
- `--schedule` – A cron expression that specifies the start and end times of the scaling action with a recurring schedule.
- `--resource-id` – The resource identifier for the variant. For this parameter, the resource type is `endpoint` and the unique identifier is the name of the variant. For example `endpoint/MyEndpoint/variant/MyVariant`.
- `--service-namespace` – Set this value to `sagemaker`.
- `--scalable-dimension` – Set this value to `sagemaker:variant:DesiredProvisionedConcurrency`.
- `--scalable-target-action` – The target of the scaling action.

The following example shows how to add a scaling action named `MyScalingAction` to a model named `MyVariant` on a recurring schedule. On the specified schedule (every day at 12:15 PM UTC), if the current Provisioned Concurrency is below the value specified for `MinCapacity`, Application Auto Scaling scales out the Provisioned Concurrency to the value specified by `MinCapacity`.

```bash
aws application-autoscaling put-scheduled-action \
  --scheduled-action-name 'MyScalingAction' \
  --schedule 'cron(15 12 * * ? *)' \
  --service-namespace sagemaker \
  --resource-id endpoint/MyEndpoint/variant/MyVariant \
  --scalable-dimension sagemaker:variant:DesiredProvisionedConcurrency \
  --scalable-target-action 'MinCapacity=10'
```

#### Scheduled scaling (Application Auto Scaling API)

To apply a scaling policy to your model, use the `PutScheduledAction Application Auto Scaling API` action with the following parameters:

- `ScheduleActionName` – The name of the scaling action.
- `Schedule` – A cron expression that specifies the start and end times of the scaling action with a recurring schedule.
- `ResourceId` – The resource identifier for the variant. For this parameter, the resource type is `endpoint` and the unique identifier is the name of the variant. For example `endpoint/MyEndpoint/variant/MyVariant`. 
Automatically scale Provisioned Concurrency for a serverless endpoint

- **ServiceNamespace** – Set this value to sagemaker.
- **ScalableDimension** – Set this value to sagemaker:variant:DesiredProvisionedConcurrency.
- **ScalableTargetAction** – The target of the scaling action.

The following example shows how to add a scaling action named MyScalingAction to a model named MyVariant on a recurring schedule. On the specified schedule (every day at 12:15 PM UTC), if the current Provisioned Concurrency is below the value specified for MinCapacity, Application Auto Scaling scales out the Provisioned Concurrency to the value specified by MinCapacity.

```json
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
X-Amz-Target: AnyScalefrontendService.PutScheduledAction
X-Amz-Date: 20160506T182145Z
User-Agent: aws-cli/1.10.23 Python/2.7.11 Darwin/15.4.0 botocore/1.4.8
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS

{
  "ScheduledActionName": "MyScalingAction",
  "Schedule": "cron(15 12 * * ? *)",
  "ServiceNamespace": "sagemaker",
  "ResourceId": "endpoint/MyEndpoint/variant/MyVariant",
  "ScalableDimension": "sagemaker:variant:DesiredProvisionedConcurrency",
  "ScalableTargetAction": "MinCapacity=10"
}
}
```

## Delete a scaling policy

You can delete a scaling policy with the AWS Management Console, the AWS CLI, or the Application Auto Scaling API. For more information on deleting a scaling policy with the AWS Management Console, see Delete a scaling policy (p. 2457) in the SageMaker autoscaling documentation (p. 2447).

### Delete a scaling policy (AWS CLI)

To apply a scaling policy to your model, use the delete-scaling-policy AWS CLI; command with the following parameters:

- **--policy-name** – The name of the scaling policy.
- **--resource-id** – The resource identifier for the variant. For this parameter, the resource type is endpoint and the unique identifier is the name of the variant. For example endpoint/MyEndpoint/variant/MyVariant.
- **--service-namespace** – Set this value to sagemaker.
- **--scalable-dimension** – Set this value to sagemaker:variant:DesiredProvisionedConcurrency.

The following example deletes scaling policy named MyScalingPolicy from a model named MyVariant.

```bash
aws application-autoscaling delete-scaling-policy
    --policy-name MyScalingPolicy
    --service-namespace sagemaker
    --scalable-dimension sagemaker:variant:DesiredProvisionedConcurrency
```
Delete a scaling policy (Application Auto Scaling API)

To delete a scaling policy to your model, use the DeleteScalingPolicy Application Auto Scaling API action with the following parameters:

- **PolicyName** – The name of the scaling policy.
- **ResourceId** – The resource identifier for the variant. For this parameter, the resource type is `endpoint` and the unique identifier is the name of the variant. For example `endpoint/MyEndpoint/variant/MyVariant`.
- **ServiceNamespace** – Set this value to `sagemaker`.
- **ScalableDimension** – Set this value to `sagemaker:variant:DesiredProvisionedConcurrency`.

The following example uses the Application Auto Scaling API to delete a scaling policy named `MyScalingPolicy` from a model named `MyVariant`.

```
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
X-Amz-Target: AnyScaleFrontendService.DeleteScalingPolicy
X-Amz-Date: 20160506T182145Z
User-Agent: aws-cli/1.10.23 Python/2.7.11 Darwin/15.4.0 botocore/1.4.8
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS
{
   "PolicyName": "MyScalingPolicy",
   "ServiceNamespace": "sagemaker",
   "ResourceId": "endpoint/MyEndpoint/variant/MyVariant",
   "ScalableDimension": "sagemaker:variant:DesiredProvisionedConcurrency",
}
```

Deregister a model

You can deregister a model with the AWS Management Console, the AWS CLI, or the Application Auto Scaling API.

Deregister a model (AWS CLI)

To deregister a model from Application Auto Scaling, use the `deregister-scalable-target` AWS CLI command with the following parameters:

- **--resource-id** – The resource identifier for the variant. For this parameter, the resource type is `endpoint` and the unique identifier is the name of the variant. For example `endpoint/MyEndpoint/variant/MyVariant`.
- **--service-namespace** – Set this value to `sagemaker`.
- **--scalable-dimension** – Set this value to `sagemaker:variant:DesiredProvisionedConcurrency`.

The following example deregisters a model named `MyVariant` from Application Auto Scaling.

```
aws application-autoscaling deregister-scalable-target \
```
Deregister a model (Application Auto Scaling API)

To deregister a model from Application Auto Scaling use the DeregisterScalableTarget Application Auto Scaling API action with the following parameters:

- **ResourceId** – The resource identifier for the variant. For this parameter, the resource type is `endpoint` and the unique identifier is the name of the variant. For example `endpoint/MyEndpoint/variant/MyVariant`.
- **ServiceNamespace** – Set this value to `sagemaker`.
- **ScalableDimension** – Set this value to `sagemaker:variant:DesiredProvisionedConcurrency`.

The following example uses the Application Auto Scaling API to deregister a model named `MyVariant` from Application Auto Scaling.

```
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
X-Amz-Target: AnyScaleFrontendService.DeregisterScalableTarget
X-Amz-Date: 20160506T182145Z
User-Agent: aws-cli/1.10.23 Python/2.7.11 Darwin/15.4.0 botocore/1.4.8
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS

{
    "ServiceNamespace": "sagemaker",
    "ResourceId": "endpoint/MyEndpoint/variant/MyVariant",
    "ScalableDimension": "sagemaker:variant:DesiredProvisionedConcurrency",
}
```

Deregister a model (AWS Management Console)

To deregister a model (production variant) with the AWS Management Console:

1. Open the [Amazon SageMaker console](https://console.aws.amazon.com/sagemaker/
2. In the navigational panel, choose **Inference**.
3. Choose **Endpoints** to view a list of your endpoints.
4. Choose the serverless endpoint hosting the production variant. A page with the settings of the endpoint will appear, with the production variants listed under **Endpoint runtime settings** section.
5. Select the production variant that you want to deregister, and choose **Configure auto scaling**. The **Configure variant automatic scaling** dialog box appears.
6. Choose **Deregister auto scaling**.

**Troubleshooting**

If you are having trouble with Serverless Inference, refer to the following troubleshooting tips.
Container issues

If the container you use for a serverless endpoint is the same one you used on an instance-based endpoint, your container may not have permissions to write files. This can happen for the following reasons:

- Your serverless endpoint fails to create or update due to a ping health check failure.
- The Amazon CloudWatch logs for the endpoint show that the container is failing to write to some file or directory due to a permissions error.

To fix this issue, you can try to add read, write, and execute permissions for other on the file or directory and then rebuild the container. You can perform the following steps to complete this process:

1. In the Dockerfile you used to build your container, add the following command: `RUN chmod o+rwx <file or directory name>`
2. Rebuild the container.
3. Upload the new container image to Amazon ECR.
4. Try to create or update the serverless endpoint again.

Asynchronous inference

Amazon SageMaker Asynchronous Inference is a capability in SageMaker that queues incoming requests and processes them asynchronously. This option is ideal for requests with large payload sizes (up to 1GB), long processing times (up to one hour), and near real-time latency requirements. Asynchronous Inference enables you to save on costs by autoscaling the instance count to zero when there are no requests to process, so you only pay when your endpoint is processing requests.

How It Works

Creating an asynchronous inference endpoint is similar to creating real-time inference endpoints. You can use your existing SageMaker models and only need to specify the AsyncInferenceConfig object while creating your endpoint configuration with the EndpointConfig field in the CreateEndpointConfig API. The following diagram shows the architecture and workflow of Asynchronous Inference.
To invoke the endpoint, you need to place the request payload in Amazon S3 and provide a pointer to this payload as a part of the InvokeEndpointAsync request. Upon invocation, SageMaker queues the request for processing and returns an identifier and output location as a response. Upon processing, SageMaker places the result in the Amazon S3 location. You can optionally choose to receive success or error notifications with Amazon SNS. For more information about how to set up asynchronous notifications, see Check prediction results (p. 2535).

**Note**

The presence of an asynchronous inference configuration (AsyncInferenceConfig) object in the endpoint configuration implies that the endpoint can only receive asynchronous invocations.

### How Do I Get Started?

If you are a first-time user of Amazon SageMaker Asynchronous Inference, we recommend that you do the following:

- Read Create, invoke, and update an Asynchronous Endpoint (p. 2523) for information on how to create, invoke, update, and delete an asynchronous endpoint.
- Explore the Asynchronous Inference example notebook in the aws/amazon-sagemaker-examples GitHub repository.

Note that if your endpoint uses any of the features listed in this Exclusions (p. 2606) page, you cannot use Asynchronous Inference.

### Create, invoke, and update an Asynchronous Endpoint

This guide demonstrates the prerequisites you must satisfy to create an asynchronous endpoint, along with how to create, invoke, and delete your asynchronous endpoints. You can create, update, delete, and invoke asynchronous endpoints with the AWS SDKs and the Amazon SageMaker Python SDK.

**Topics**

- Prerequisites (p. 2524)
• Create an Asynchronous Inference Endpoint (p. 2526)
• Invoke an Asynchronous Endpoint (p. 2530)
• Update an Asynchronous Endpoint (p. 2531)
• Delete an Asynchronous Endpoint (p. 2531)

Prerequisites

To use asynchronous endpoints, first make sure you have met these prerequisites.

1. **Create an IAM role for Amazon SageMaker.**

   Asynchronous Inference needs access to your Amazon S3 bucket URI. To facilitate this, create an IAM role that can run SageMaker and has permission to access Amazon S3 and Amazon SNS. Using this role, SageMaker can run under your account and access your Amazon S3 bucket and Amazon SNS topics.

   You can create an IAM role by using the IAM console, AWS SDK for Python (Boto3), or AWS CLI. The following is an example of how to create an IAM role and attach the necessary policies with the IAM console.

   a. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
   b. In the navigation pane of the IAM console, choose Roles, and then choose Create role.
   c. For Select type of trusted entity, choose AWS service.
   d. Choose the service that you want to allow to assume this role. In this case, choose SageMaker. Then choose Next: Permissions.
      • This automatically creates an IAM policy that grants access to related services such as Amazon S3, Amazon ECR, and CloudWatch Logs.
   e. Choose Next: Tags.
   f. (Optional) Add metadata to the role by attaching tags as key–value pairs. For more information about using tags in IAM, see Tagging IAM resources.
   g. Choose Next: Review.
   h. Type in a Role name.
   i. If possible, type a role name or role name suffix. Role names must be unique within your AWS account. They are not distinguished by case. For example, you cannot create roles named both PR0DROLE and prodrole. Because other AWS resources might reference the role, you cannot edit the name of the role after it has been created.
   j. (Optional) For Role description, type a description for the new role.
   k. Review the role and then choose Create role.

   Note the SageMaker role ARN. To find the role ARN using the console, do the following:
   i. Go to the IAM console: https://console.aws.amazon.com/iam/
   ii. Select Roles.
   iii. Search for the role you just created by typing in the name of the role in the search field.
   iv. Select the role.
   v. The role ARN is at the top of the Summary page.

2. **Add Amazon SageMaker, Amazon S3 and Amazon SNS Permissions to your IAM Role.**

   Once the role is created, grant SageMaker, Amazon S3, and optionally Amazon SNS permissions to your IAM role.
Choose **Roles** in the IAM console. Search for the role you created by typing in your role name in the **Search** field.

a. Choose your role.

b. Next, choose **Attach Policies**.

c. Amazon SageMaker Asynchronous Inference needs permission to perform the following actions: "sagemaker:CreateModel", "sagemaker:CreateEndpointConfig", "sagemaker:CreateEndpoint", and "sagemaker:InvokeEndpointAsync".

These actions are included in the AmazonSageMakerFullAccess policy. Add this policy to your IAM role. Search for AmazonSageMakerFullAccess in the **Search** field. Select AmazonSageMakerFullAccess.

d. Choose **Attach policy**.

e. Next, choose **Attach Policies** to add Amazon S3 permissions.

f. Select **Create policy**.

g. Select the JSON tab.

h. Add the following policy statement:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "s3:GetObject",
        "s3:PutObject",
        "s3:AbortMultipartUpload",
        "s3:ListBucket"
      ],
      "Effect": "Allow",
      "Resource": "arn:aws:s3:::bucket_name/*"
    }
  ]
}
```

i. Choose **Next: Tags**.

j. Type in a **Policy name**.

k. Choose **Create policy**.

l. Repeat the same steps you completed to add Amazon S3 permissions in order to add Amazon SNS permissions. For the policy statement, attach the following:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "sns:Publish"
      ],
      "Effect": "Allow",
    }
  ]
}
```

3. **Upload your inference data (e.g., machine learning model, sample data) to Amazon S3.**

4. **Select a prebuilt Docker inference image or create your own Inference Docker Image.**
SageMaker provides containers for its built-in algorithms and prebuilt Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. For a full list of the available SageMaker images, see Available Deep Learning Containers Images. If you choose to use a SageMaker provided container, you can increase the endpoint timeout and payload sizes from the default by setting the environment variables in the container. To learn how to set the different environment variables for each framework, see the Create a Model step of creating an asynchronous endpoint.

If none of the existing SageMaker containers meet your needs and you don't have an existing container of your own, you may need to create a new Docker container. See Use your own inference code (p. 3327) for information on how to create your Docker image.

5. **Create an Amazon SNS topic (optional)**

Create an Amazon Simple Notification Service (Amazon SNS) topic that sends notifications about requests that have completed processing. Amazon SNS is a notification service for messaging-oriented applications, with multiple subscribers requesting and receiving "push" notifications of time-critical messages via a choice of transport protocols, including HTTP, Amazon SQS, and email. You can specify Amazon SNS topics when you create an EndpointConfig object when you specify AsyncInferenceConfig using the EndpointConfig API.

Follow the steps to create and subscribe to an Amazon SNS topic.

a. Using Amazon SNS console, create a topic. For instructions, see Creating an Amazon SNS topic in the Amazon Simple Notification Service Developer Guide.

b. Subscribe to the topic. For instructions, see Subscribing to an Amazon SNS topic in the Amazon Simple Notification Service Developer Guide.

c. When you receive email requesting that you confirm your subscription to the topic, confirm the subscription.

d. Note the topic Amazon Resource Name (ARN). The Amazon SNS topic you created is another resource in your AWS account, and it has a unique ARN. The ARN is in the following format:

```
arn:aws:sns:aws-region:account-id:topic-name
```

For more information about Amazon SNS, see the Amazon SNS Developer Guide.

### Create an Asynchronous Inference Endpoint

Create an asynchronous endpoint the same way you would create an endpoint using SageMaker hosting services:

- Create a model in SageMaker with `CreateModel`.
- Create an endpoint configuration with `CreateEndpointConfig`.
- Create an HTTPS endpoint with `CreateEndpoint`.

To create an endpoint, you first create a model with `CreateModel`, where you point to the model artifact and a Docker registry path (Image). You then create a configuration using `CreateEndpointConfig` where you specify one or more models that were created using the `CreateModel` API to deploy and the resources that you want SageMaker to provision. Create your endpoint with `CreateEndpoint` using the endpoint configuration specified in the request. You can update an asynchronous endpoint with the `UpdateEndpoint` API. Send and receive inference requests from the model hosted at the endpoint with `InvokeEndpointAsync`. You can delete your endpoints with the `DeleteEndpoint` API.
For a full list of the available SageMaker Images, see Available Deep Learning Containers Images. See Use your own inference code (p. 3327) for information on how to create your Docker image.

Create a Model

The following example shows how to create a model using the AWS SDK for Python (Boto3). The first few lines define:

- `sagemaker_client`: A low-level SageMaker client object that makes it easy to send and receive requests to AWS services.
- `sagemaker_role`: A string variable with the SageMaker IAM role Amazon Resource Name (ARN).
- `aws_region`: A string variable with the name of your AWS region.

```python
import boto3

# Specify your AWS Region
aws_region = '<aws_region>'

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Role to give SageMaker permission to access AWS services.
sagemaker_role = 'arn:aws:iam::<account>:role/*'
```

Next, specify the location of the pre-trained model stored in Amazon S3. In this example, we use a pre-trained XGBoost model named demo-xgboost-model.tar.gz. The full Amazon S3 URI is stored in a string variable `model_url`:

```python
# Create a variable w/ the model S3 URI
s3_bucket = '<your-bucket-name>'  # Provide the name of your S3 bucket
bucket_prefix = 'saved_models'
model_s3_key = f'{bucket_prefix}/demo-xgboost-model.tar.gz'

# Specify S3 bucket w/ model
model_url = f's3://{s3_bucket}/{model_s3_key}'
```

Specify a primary container. For the primary container, you specify the Docker image that contains inference code, artifacts (from prior training), and a custom environment map that the inference code uses when you deploy the model for predictions.

In this example, we specify an XGBoost built-in algorithm container image:

```python
from sagemaker import image_uris

# Specify an AWS container image.
container = image_uris.retrieve(region=aws_region, framework='xgboost', version='0.90-1')
```

Create a model in Amazon SageMaker with `CreateModel`. Specify the following:

- **ModelName**: A name for your model (in this example it is stored as a string variable called `model_name`).
- **ExecutionRoleArn**: The Amazon Resource Name (ARN) of the IAM role that Amazon SageMaker can assume to access model artifacts and Docker images for deployment on ML compute instances or for batch transform jobs.
- **PrimaryContainer**: The location of the primary Docker image containing inference code, associated artifacts, and custom environment maps that the inference code uses when the model is deployed for predictions.
model_name = '<The_name_of_the_model>'

#Create model
create_model_response = sagemaker_client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = sagemaker_role,
    PrimaryContainer = {
        'Image': container,
        'ModelDataUrl': model_url,
    })

If you're using a SageMaker provided container, you can increase the model server timeout and payload sizes from the default values to the framework-supported maximums by setting environment variables in this step. You might not be able to leverage the maximum timeout and payload sizes that Asynchronous Inference supports if you don't explicitly set these variables. The following example shows how you can set the environment variables for a PyTorch Inference container based on TorchServe.

model_name = '<The_name_of_the_model>'

#Create model
create_model_response = sagemaker_client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = sagemaker_role,
    PrimaryContainer = {
        'Image': container,
        'ModelDataUrl': model_url,
        'Environment': {
            'TS_MAX_REQUEST_SIZE': '100000000',
            'TS_MAX_RESPONSE_SIZE': '100000000',
            'TS_DEFAULT_RESPONSE_TIMEOUT': '1000'
        }
    })

After you finish creating your endpoint, you should test that you've set the environment variables correctly by printing them out from your inference.py script. The following table lists the environment variables for several frameworks that you can set to change the default values.

<table>
<thead>
<tr>
<th>Framework</th>
<th>Environment variables</th>
</tr>
</thead>
<tbody>
<tr>
<td>PyTorch 1.8 (based on TorchServe)</td>
<td>'TS_MAX_REQUEST_SIZE': '1000000000'</td>
</tr>
<tr>
<td></td>
<td>'TS_MAX_RESPONSE_SIZE': '1000000000'</td>
</tr>
<tr>
<td></td>
<td>'TS_DEFAULT_RESPONSE_TIMEOUT': '1000'</td>
</tr>
<tr>
<td>PyTorch 1.4 (based on MMS)</td>
<td>'MMS_MAX_REQUEST_SIZE': '1000000000'</td>
</tr>
<tr>
<td></td>
<td>'MMS_MAX_RESPONSE_SIZE': '1000000000'</td>
</tr>
<tr>
<td></td>
<td>'MMS_DEFAULT_RESPONSE_TIMEOUT': '900'</td>
</tr>
<tr>
<td>HuggingFace Inference Container (based on MMS)</td>
<td>'MMS_MAX_REQUEST_SIZE': '2000000000'</td>
</tr>
<tr>
<td></td>
<td>'MMS_MAX_RESPONSE_SIZE': '2000000000'</td>
</tr>
<tr>
<td></td>
<td>'MMS_DEFAULT_RESPONSE_TIMEOUT': '900'</td>
</tr>
</tbody>
</table>
Create an Endpoint Configuration

Once you have a model, create an endpoint configuration with `CreateEndpointConfig`. Amazon SageMaker hosting services uses this configuration to deploy models. In the configuration, you identify one or more models, created using `CreateModel`, to deploy the resources that you want Amazon SageMaker to provision. Specify the AsyncInferenceConfig object and provide an output Amazon S3 location for OutputConfig. You can optionally specify Amazon SNS topics on which to send notifications about prediction results. For more information about Amazon SNS topics, see Configuring Amazon SNS.

The following example shows how to create an endpoint configuration using AWS SDK for Python (Boto3):

```python
import datetime
from time import gmtime, strftime
# Create an endpoint config name. Here we create one based on the date
# so it we can search endpoints based on creation time.
endpoint_config_name = f"XGBoostEndpointConfig-{strftime('%Y-%m-%d-%H-%M-%S', gmtime())}"
# The name of the model that you want to host. This is the name that you specified when creating the model.
model_name='<The_name_of_your_model>
create_endpoint_config_response = sagemaker_client.create_endpoint_config(
    EndpointConfigName=endpoint_config_name, # You will specify this name in a CreateEndpoint request.
    # List of ProductionVariant objects, one for each model that you want to host at this endpoint.
    ProductionVariants=[
        {
            "VariantName": "variant1", # The name of the production variant.
            "ModelName": model_name,
            "InstanceType": "ml.m5.xlarge", # Specify the compute instance type.
            "InitialInstanceCount": 1 # Number of instances to launch initially.
        }
    ],
    AsyncInferenceConfig={
        "OutputConfig": {
            "S3OutputPath": f"s3://{s3_bucket}/{bucket_prefix}/output" # Location to upload response outputs when no location is provided in the request.
        },
        "NotificationConfig": {
        }
    },
    # (Optional) Specify the max number of inflight invocations per instance
    # If no value is provided, Amazon SageMaker will choose an optimal value for you
    "MaxConcurrentInvocationsPerInstance": 4
)
print(f"Created EndpointConfig: {create_endpoint_config_response['EndpointConfigArn']}")
```

In the aforementioned example, you specify the following keys for OutputConfig for the AsyncInferenceConfig field:

- **S3OutputPath**: Location to upload response outputs when no location is provided in the request.
• NotificationConfig (Optional) SNS topics that post notifications to you when an inference request is successful (SuccessTopic) or if it fails (ErrorTopic).

You can also specify the following optional argument for ClientConfig in the AsyncInferenceConfig field:
• MaxConcurrentInvocationsPerInstance (Optional) The maximum number of concurrent requests sent by the SageMaker client to the model container.

**Create Endpoint**

Once you have your model and endpoint configuration, use the CreateEndpoint API to create your endpoint. The endpoint name must be unique within an AWS Region in your AWS account.

The following creates an endpoint using the endpoint configuration specified in the request. Amazon SageMaker uses the endpoint to provision resources and deploy models.

```python
# The name of the endpoint. The name must be unique within an AWS Region in your AWS account.
endpoint_name = '<endpoint-name>'

# The name of the endpoint configuration associated with this endpoint.
endpoint_config_name = '<endpoint-config-name>'

create_endpoint_response = sagemaker_client.create_endpoint(
    EndpointName=endpoint_name,
    EndpointConfigName=endpoint_config_name)

When you call the CreateEndpoint API, Amazon SageMaker Asynchronous Inference sends a test notification to check that you have configured an Amazon SNS topic. Amazon SageMaker Asynchronous Inference also sends test notifications after calls to UpdateEndpoint and UpdateEndpointWeightsAndCapacities. This lets SageMaker check that you have the required permissions. The notification can simply be ignored. The test notification has the following form:

```json
{
    "eventVersion": "1.0",
    "eventSource": "aws:sagemaker",
    "eventName": "TestNotification"
}
```

**Invoke an Asynchronous Endpoint**

Get inferences from the model hosted at your asynchronous endpoint with InvokeEndpointAsync.

**Note**
If you have not done so already, upload your inference data (e.g., machine learning model, sample data) to Amazon S3.

Specify the following fields in your request:

• For InputLocation, specify the location of your inference data.
• For EndpointName, specify the name of your endpoint.
• (Optional) For InvocationTimeoutSeconds, you can set the max timeout for the requests. You can set this value to a maximum of 3600 seconds (one hour) on a per-request basis. If you don't specify this field in your request, by default the request times out at 15 minutes.
Create, invoke, and update an Asynchronous Endpoint

# Create a low-level client representing Amazon SageMaker Runtime
sagemaker_runtime = boto3.client("sagemaker-runtime", region_name=<aws_region>)

# Specify the location of the input. Here, a single SVM sample
input_location = "s3://bucket-name/test_point_0.libsvm"

# The name of the endpoint. The name must be unique within an AWS Region in your AWS account.
endpoint_name='<endpoint-name>'

# After you deploy a model into production using SageMaker hosting
# services, your client applications use this API to get inferences
# from the model hosted at the specified endpoint.
response = sagemaker_runtime.invoke_endpoint_async(
    EndpointName=endpoint_name,
    InputLocation=input_location,
    InvocationTimeoutSeconds=3600)

You receive a response as a JSON string with your request ID and the name of the Amazon S3 bucket that will have the response to the API call after it is processed.

Update an Asynchronous Endpoint

Update an asynchronous endpoint with the UpdateEndpoint API. When you update an endpoint, SageMaker first provisions and switches to the new endpoint configuration you specify before it deletes the resources that were provisioned in the previous endpoint configuration. Do not delete an EndpointConfig with an endpoint that is live or while the UpdateEndpoint or CreateEndpoint operations are being performed on the endpoint.

# The name of the endpoint. The name must be unique within an AWS Region in your AWS account.
endpoint_name='<endpoint-name>'

# The name of the endpoint configuration associated with this endpoint.
endpoint_config_name='<endpoint-config-name>'

sagemaker_client.update_endpoint(
    EndpointConfigName=endpoint_config_name,
    EndpointName=endpoint_name
)

When Amazon SageMaker receives the request, it sets the endpoint status to Updating. After updating the asynchronous endpoint, it sets the status to InService. To check the status of an endpoint, use the DescribeEndpoint API. For a full list of parameters you can specify when updating an endpoint, see the UpdateEndpoint API.

Delete an Asynchronous Endpoint

Delete an asynchronous endpoint in a similar manner to how you would delete a SageMaker hosted endpoint with the DeleteEndpoint API. Specify the name of the asynchronous endpoint you want to delete. When you delete an endpoint, SageMaker frees up all of the resources that were deployed when the endpoint was created. Deleting a model does not delete model artifacts, inference code, or the IAM role that you specified when creating the model.

Delete your SageMaker model with the DeleteModel API or with the SageMaker console.

Boto3

```python
import boto3
```
# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=<aws_region>)
sagemaker_client.delete_endpoint(EndpointName='<endpoint-name>')</sagemaker_client.delete_endpoint(EndpointName='<endpoint-name>')</sagemaker_client.delete_endpoint(EndpointName='<endpoint-name>')

SageMaker console

2. Expand the Inference dropdown list.
3. Select Endpoints.
4. Search for endpoint in the Search endpoints search bar.
5. Select your endpoint.
6. Choose Delete.

In addition to deleting the asynchronous endpoint, you might want to clear up other resources that were used to create the endpoint, such as the Amazon ECR repository (if you created a custom inference image), the SageMaker model, and the asynchronous endpoint configuration itself.

Monitor asynchronous endpoint

You can monitor SageMaker using Amazon CloudWatch, which collects raw data and processes it into readable, near real-time metrics. With Amazon CloudWatch, you can access historical information and gain a better perspective on how your web application or service is performing. For more information about Amazon CloudWatch, see What is Amazon CloudWatch?

Monitoring with CloudWatch

The metrics below are an exhaustive list of metrics for asynchronous endpoints and are in the AWS/SageMaker namespace. Any metric not listed below is not published if the endpoint is enabled for asynchronous inference. Such metrics include (but are not limited to):

- OverheadLatency
- Invocations
- InvocationsPerInstance

Common Endpoint Metrics

These metrics are the same as the metrics published for real-time endpoints today. For more information about other metrics in Amazon CloudWatch, see Monitor SageMaker with Amazon CloudWatch.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Unit/Stats</th>
</tr>
</thead>
<tbody>
<tr>
<td>Invocation4XXErrors</td>
<td>The number of requests where the model returned a 4xx HTTP response code. For each 4xx response, 1 is sent; otherwise, 0 is sent.</td>
<td>Units: None</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid statistics: Average, Sum</td>
</tr>
<tr>
<td>Invocation5XXErrors</td>
<td>The number of InvokeEndpoint requests where the model returned a 5xx HTTP response code. For each 5xx response, 1 is sent; otherwise, 0 is sent.</td>
<td>Units: None</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid statistics: Average, Sum</td>
</tr>
</tbody>
</table>
### Metric Name | Description | Unit/Stats
--- | --- | ---
ModelLatency | The interval of time taken by a model to respond as viewed from SageMaker. This interval includes the local communication times taken to send the request and to fetch the response from the container of a model and the time taken to complete the inference in the container. | Units: Microseconds
| | | Valid statistics: Average, Sum, Min, Max, Sample Count

### Asynchronous Inference Endpoint Metrics
These metrics are published for endpoints enabled for asynchronous inference. The following metrics are published with the EndpointName dimension:

| Metric Name | Description | Unit/Stats
--- | --- | ---
ApproximateBacklogSize | The number of items in the queue for an endpoint that are currently being processed or yet to be processed. | Units: Count
| | | Valid statistics: Average, Max, Min

| Metric Name | Description | Unit/Stats
--- | --- | ---
ApproximateBacklogSizePerInstance | Number of items in the queue divided by the number of instances behind an endpoint. This metric is primarily used for setting up application autoscaling for an async-enabled endpoint. | Units: Count
| | | Valid statistics: Average, Max, Min

| Metric Name | Description | Unit/Stats
--- | --- | ---
ApproximateAgeOfOldestRequest | Age of the oldest request in the queue. | Units: Seconds
| | | Valid statistics: Average, Max, Min

| Metric Name | Description | Unit/Stats
--- | --- | ---
HasBacklogWithoutCapacity | The value of this metric is 1 when there are requests in the queue but zero instances behind the endpoint. The value is 0 at all other times. You can use this metric for autoscaling your endpoint up from zero instances upon receiving a new request in the queue. | Units: Count
| | | Valid statistics: Average

The following metrics are published with the EndpointName and VariantName dimensions:

| Metric Name | Description | Unit/Stats
--- | --- | ---
RequestDownloadFailures | When an inference failure occurs due to an issue downloading the request from Amazon S3. | Units: Count
| | | Valid statistics: Sum
### Monitor asynchronous endpoint

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Unit/Stats</th>
</tr>
</thead>
<tbody>
<tr>
<td>ResponseUploadFailures</td>
<td>When an inference failure occurs due to an issue uploading the response to Amazon S3.</td>
<td>Units: Count&lt;br&gt;Valid statistics: Sum</td>
</tr>
<tr>
<td>NotificationFailures</td>
<td>When an issue occurs publishing notifications.</td>
<td>Units: Count&lt;br&gt;Valid statistics: Sum</td>
</tr>
<tr>
<td>RequestDownloadLatency</td>
<td>Total time to download the request payload.</td>
<td>Units: Microseconds&lt;br&gt;Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td>ResponseUploadLatency</td>
<td>Total time to upload the response payload.</td>
<td>Units: Microseconds&lt;br&gt;Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td>ExpiredRequests</td>
<td>Number of requests in the queue that fail due to reaching their specified request TTL.</td>
<td>Units: Count&lt;br&gt;Valid statistics: Sum</td>
</tr>
<tr>
<td>InvocationFailures</td>
<td>If an invocation fails for any reason.</td>
<td>Units: Count&lt;br&gt;Valid statistics: Sum</td>
</tr>
<tr>
<td>InvocationsProcessed</td>
<td>Number of async invocations processed by the endpoint.</td>
<td>Units: Count&lt;br&gt;Valid statistics: Sum</td>
</tr>
<tr>
<td>TimeInBacklog</td>
<td>Total time the request was queued before being processed. This does not include the actual processing time (i.e. downloading time, uploading time, model latency).</td>
<td>Units: Milliseconds&lt;br&gt;Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td>TotalProcessingTime</td>
<td>Time the inference request was received by SageMaker to the time the request finished processing. This includes time in backlog and time to upload and send response notifications, if any.</td>
<td>Units: Milliseconds&lt;br&gt;Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
</tbody>
</table>

Amazon SageMaker Asynchronous Inference also includes host-level metrics. For information on host-level metrics, see [SageMaker Jobs and Endpoint Metrics](https://docs.aws.amazon.com/sagemaker/latest/dg/monitor-endpoint-host-level-metrics.html).

**Logs**

In addition to the [Model container logs](https://docs.aws.amazon.com/sagemaker/latest/dg/monitor-endpoint-host-level-metrics.html) that are published to Amazon CloudWatch in your account, you also get a new platform log for tracing and debugging inference requests.

The new logs are published under the Endpoint Log Group:

/aws/sagemaker/Endpoints/[EndpointName]
The log stream name consists of:

```
[production-variant-name]/[instance-id]/data-log.
```

Log lines contain the request's inference ID so that errors can be easily mapped to a particular request.

Check prediction results

There are several ways you can check predictions results from your asynchronous endpoint. Some options are:

1. Amazon SNS topics.
2. Check for outputs in your Amazon S3 bucket.

Amazon SNS Topics

Amazon SNS is a notification service for messaging-oriented applications, with multiple subscribers requesting and receiving 'push' notifications of time-critical messages via a choice of transport protocols, including HTTP, Amazon SQS, and email. Amazon SageMaker Asynchronous Inference posts notifications when you create an endpoint with `CreateEndpointConfig` and specify an Amazon SNS topic.

**Note**

In order to receive Amazon SNS notifications, your IAM role must have `sns:Publish` permissions. See the Prerequisites (p. 2524) for information on requirements you must satisfy to use Asynchronous Inference.

To use Amazon SNS to check prediction results from your asynchronous endpoint, you first need to create a topic, subscribe to the topic, confirm your subscription to the topic, and note the Amazon Resource Name (ARN) of that topic. For detailed information on how to create, subscribe, and find the Amazon ARN of an Amazon SNS topic, see Configuring Amazon SNS.

Provide the Amazon SNS topic ARN(s) in the `AsyncInferenceConfig` field when you create an endpoint configuration with `CreateEndpointConfig`. You can specify both an Amazon SNS ErrorTopic and a SuccessTopic.

```python
import boto3

sagemaker_client = boto3.client('sagemaker', region_name=<aws_region>)

sagemaker_client.create_endpoint_config(  
  EndpointConfigName=<endpoint_config_name>,  
  # You specify this name in a CreateEndpoint request.  
  ProductionVariants=[  
    {  
      "VariantName": "variant1",  
      "ModelName": "model_name",  
      "InstanceType": "ml.m5.xlarge",  
      "InitialInstanceCount": 1  
    }  
  ],  
  AsyncInferenceConfig={  
    "OutputConfig": {  
      # Location to upload response outputs when no location is provided in the  
      request.  
      "S3OutputPath": "s3://<bucket>/<output_directory>"  
    }  
  }
)
```
After creating your endpoint and invoking it, you receive a notification from your Amazon SNS topic. For example, if you subscribed to receive email notifications from your topic, you receive an email notification every time you invoke your endpoint. The following example shows the JSON content of a successful invocation email notification.

```json
{
    "awsRegion": "us-east-1",
    "eventTime": "2022-01-25T22:46:00.608Z",
    "receivedTime": "2022-01-25T22:46:00.455Z",
    "invocationStatus": "Completed",
    "requestParameters": {
        "contentType": "text/csv",
        "endpointName": "<example-endpoint>",
        "inputLocation": "s3://<bucket>/input-data.csv"
    },
    "responseParameters": {
        "contentType": "text/csv; charset=utf-8",
        "outputLocation": "s3://<bucket>/prediction.out"
    },
    "inferenceId": "1111111-2222-3333-4444-555555555555",
    "eventVersion": "1.0",
    "eventSource": "aws:sagemaker",
    "eventName": "InferenceResult"
}
```

## Check Your S3 Bucket

When you invoke an endpoint with `InvokeEndpointAsync`, it returns a response object. You can use the response object to get the Amazon S3 URI where your output is stored. With the output location, you can use a SageMaker Python SDK SageMaker session class to programmatically check for an output.

The following stores the output dictionary of `InvokeEndpointAsync` as a variable named `response`. With the response variable, you then get the Amazon S3 output URI and store it as a string variable called `output_location`.

```python
import uuid
import boto3

sagemaker_runtime = boto3.client("sagemaker-runtime", region_name=<aws_region>)

# Specify the S3 URI of the input. Here, a single SVM sample
input_location = "s3://bucket-name/test_point_0.libsvm"

response = sagemaker_runtime.invoke_endpoint_async(
    EndpointName='<endpoint-name>',
    InputLocation=input_location,
    InferenceId=str(uuid.uuid4()),
    ContentType="text/libsvm" #Specify the content type of your data
)

output_location = response['OutputLocation']
print(f"OutputLocation: {output_location}")
```
For information about supported content types, see Common Data Formats for Inference (p. 1541).

With the Amazon S3 output location, you can then use a SageMaker Python SDK SageMaker Session Class to read in Amazon S3 files. The following code example shows how to create a function (get_output) that repeatedly attempts to read a file from the Amazon S3 output location:

```python
import sagemaker
import urllib, time
from botocore.exceptions import ClientError

sagemaker_session = sagemaker.session.Session()

def get_output(output_location):
    output_url = urllib.parse.urlparse(output_location)
    bucket = output_url.netloc
    key = output_url.path[1:]
    while True:
        try:
            return sagemaker_session.read_s3_file(
                bucket=output_url.netloc,
                key_prefix=output_url.path[1:])
        except ClientError as e:
            if e.response['Error']['Code'] == 'NoSuchKey':
                print("waiting for output...")
                time.sleep(2)
                continue
            raise

output = get_output(output_location)
print(f"Output: {output}"

Autoscale an asynchronous endpoint

Amazon SageMaker supports automatic scaling (autoscaling) your asynchronous endpoint. Autoscaling dynamically adjusts the number of instances provisioned for a model in response to changes in your workload. Unlike other hosted models Amazon SageMaker supports, with Asynchronous Inference you can also scale down your asynchronous endpoints instances to zero. Requests that are received when there are zero instances are queued for processing once the endpoint scales up.

To autoscale your asynchronous endpoint you must at a minimum:

- Register a deployed model (production variant).
- Define a scaling policy.
- Apply the autoscaling policy.

Before you can use autoscaling, you must have already deployed a model to a SageMaker endpoint. Deployed models are referred to as a production variant. See Deploy the Model to SageMaker Hosting Services for more information about deploying a model to an endpoint. To specify the metrics and target values for a scaling policy, you configure a scaling policy. For information on how to define a scaling policy, see Define a scaling policy. After registering your model and defining a scaling policy, apply the scaling policy to the registered model. For information on how to apply the scaling policy, see Apply a scaling policy.

For more information on how to define an optional additional scaling policy that scales up your endpoint upon receiving a request after your endpoint has been scaled down to zero, see Optional: Define a scaling policy that scales up from zero for new requests (p. 2539). If you don’t specify this optional policy, then your endpoint only initiates scaling up from zero after the number of backlog requests exceeds the target tracking value.

2537
For details on other prerequisites and components used with autoscaling, see the Prerequisites section in the SageMaker autoscaling documentation.

**Note**
If you attach multiple scaling policies to the same autoscaling group, you might have scaling conflicts. When a conflict occurs, Amazon EC2 Auto Scaling chooses the policy that provisions the largest capacity for both scale out and scale in. For more information about this behavior, see Multiple dynamic scaling policies in the Amazon EC2 Auto Scaling documentation.

## Define a scaling policy

To specify the metrics and target values for a scaling policy, you configure a target-tracking scaling policy. Define the scaling policy as a JSON block in a text file. You use that text file when invoking the AWS CLI or the Application Auto Scaling API. For more information about policy configuration syntax, see TargetTrackingScalingPolicyConfiguration in the Application Auto Scaling API Reference.

For asynchronous endpoints SageMaker strongly recommends that you create a policy configuration for target-tracking scaling for a variant. In this configuration example, we use a custom metric, CustomizedMetricSpecification, called ApproximateBacklogSizePerInstance.

```
TargetTrackingScalingPolicyConfiguration={
    'TargetValue': 5.0, # The target value for the metric. Here the metric is: ApproximateBacklogSizePerInstance
    'CustomizedMetricSpecification': {
        'MetricName': 'ApproximateBacklogSizePerInstance',
        'Namespace': 'AWS/SageMaker',
        'Dimensions': [
            {'Name': 'EndpointName', 'Value': '<endpoint_name>'}
        ],
        'Statistic': 'Average',
    }
}
```

## Define a scaling policy that scales to zero

The following shows you how to both define and register your endpoint variant with application autoscaling using the AWS SDK for Python (Boto3). After defining a low-level client object representing application autoscaling with Boto3, we use the RegisterScalableTarget method to register the production variant. We set MinCapacity to 0 because Asynchronous Inference enables you to autoscale to 0 when there are no requests to process.

```python
# Common class representing application autoscaling for SageMaker
client = boto3.client('application-autoscaling')

# This is the format in which application autoscaling references the endpoint
resource_id='endpoint/' + '<endpoint_name>' + '/variant/' + '<variant1>'

# Define and register your endpoint variant
response = client.register_scalable_target(
    ServiceNamespace='sagemaker',
    ResourceId=resource_id,
    ScalableDimension='sagemaker:variant:DesiredInstanceCount', # The number of EC2 instances for your Amazon SageMaker model endpoint variant.
    MinCapacity=0,
    MaxCapacity=5
)
```

For detailed description about the Application Autoscaling API, see the Application Scaling Boto3 documentation.
Optional: Define a scaling policy that scales up from zero for new requests

You might have a use case where you have sporadic requests or periods with low numbers of requests. If your endpoint has been scaled down to zero instances during these periods, then your endpoint won’t scale up again until the number of requests in the queue exceeds the target specified in your scaling policy. This can result in long waiting times for requests in the queue. The following section shows you how to create an additional scaling policy that scales your endpoint up from zero instances after receiving any new request in the queue. Your endpoint will be able to respond to new requests more quickly instead of waiting for the queue size to exceed the target.

To create a scaling policy for your endpoint that scales up from zero instances, do the following:

1. Create a scaling policy that defines the desired behavior, which is to scale up your endpoint when it’s at zero instances but has requests in the queue. The following shows you how to define a scaling policy called HasBacklogWithoutCapacity-ScalingPolicy using the AWS SDK for Python (Boto3). When the queue is greater than zero and the current instance count for your endpoint is also zero, the policy scales your endpoint up. In all other cases, the policy does not affect scaling for your endpoint.

```python
response = client.put_scaling_policy(
    PolicyName="HasBacklogWithoutCapacity-ScalingPolicy",
    ServiceNamespace="sagemaker", # The namespace of the service that provides the resource.
    ResourceId=resource_id, # Endpoint name
    ScalableDimension="sagemaker:variant:DesiredInstanceCount", # SageMaker supports only Instance Count
    PolicyType="StepScaling", # 'StepScaling' or 'TargetTrackingScaling'
    StepScalingPolicyConfiguration={
        "AdjustmentType": "ChangeInCapacity", # Specifies whether the ScalingAdjustment value in the StepAdjustment property is an absolute number or a percentage of the current capacity.
        "MetricAggregationType": "Average", # The aggregation type for the CloudWatch metrics.
        "Cooldown": 300, # The amount of time, in seconds, to wait for a previous scaling activity to take effect.
        "StepAdjustments": # A set of adjustments that enable you to scale based on the size of the alarm breach.
        [
            {"MetricIntervalLowerBound": 0,
             "ScalingAdjustment": 1
            }]
    },
)
```

2. Create a CloudWatch alarm with the custom metric HasBacklogWithoutCapacity. When triggered, the alarm initiates the previously defined scaling policy. For more information about the HasBacklogWithoutCapacity metric, see Asynchronous Inference Endpoint Metrics (p. 2533).

```python
response = cw_client.put_metric_alarm(
    AlarmName=step_scaling_policy_alarm_name,
    MetricName='HasBacklogWithoutCapacity',
    Namespace='AWS/SageMaker',
    Statistic='Average',
    EvaluationPeriods= 2,
    DatapointsToAlarm= 2,
    Threshold= 1,
    ComparisonOperator='GreaterThanOrEqualToThreshold',
    TreatMissingData='missing',
)
```

2539
You should now have a scaling policy and CloudWatch alarm that scale up your endpoint from zero instances whenever your queue has pending requests.

**Troubleshooting**

The following FAQs can help you troubleshoot issues with your Amazon SageMaker Asynchronous Inference endpoints.

**Q:** I have autoscaling enabled. How can I find the instance count behind the endpoint at any given point?

You can use the following methods to find the instance count behind your endpoint:

- You can use the SageMaker `DescribeEndpoint` API to describe the number of instances behind the endpoint at any given point in time.
- You can get the instance count by viewing your Amazon CloudWatch metrics. View the metrics for your endpoint instances, such as CPUUtilization or MemoryUtilization and check the sample count statistic for a 1 minute period. The count should be equal to the number of active instances. The following screenshot shows the CPUUtilization metric graphed in the CloudWatch console, where the **Statistic** is set to **Sample count**, the **Period** is set to **1 minute**, and the resulting count is 5.

![CPUUtilization metric graph](image)

**Q:** What are the common tunable environment variables for SageMaker containers?

The following tables outline the common tunable environment variables for SageMaker containers by framework type.

**TensorFlow**

<table>
<thead>
<tr>
<th>Environment variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAGEMAKER_TFS_INSTANCE_COUNT</td>
<td>For TensorFlow-based models, the <code>tensorflow_model_server</code> binary is the operational piece that is responsible for loading a model in memory, running inputs against a model graph, and deriving outputs. Typically, a single</td>
</tr>
<tr>
<td>Environment variable</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>SAGEMAKER_TFS_FRACTIONAL_GPU_MEM_MARGIN</td>
<td>This parameter governs the fraction of the available GPU memory to initialize CUDA/cuDNN and other GPU libraries. 0.2 means 20% of the available GPU memory is reserved for initializing CUDA/cuDNN and other GPU libraries, and 80% of the available GPU memory is allocated equally across the TF processes. GPU memory is pre-allocated unless the allow_growth option is enabled.</td>
</tr>
<tr>
<td>SAGEMAKER_TFS_INTER_OP_PARALLELISM</td>
<td>This ties back to the inter_op_parallelism_threads variable. This variable determines the number of threads used by independent non-blocking operations. 0 means that the system picks an appropriate number.</td>
</tr>
<tr>
<td>SAGEMAKER_TFS_INTRA_OP_PARALLELISM</td>
<td>This ties back to the intra_op_parallelism_threads variable. This determines the number of threads that can be used for certain operations like matrix multiplication and reductions for speedups. A value of 0 means that the system picks an appropriate number.</td>
</tr>
<tr>
<td>SAGEMAKER_GUNICORN_WORKERS</td>
<td>This governs the number of worker processes that Gunicorn is requested to spawn for handling requests. This value is used in combination with other parameters to derive a set that maximizes inference throughput. In addition to this, the SAGEMAKER_GUNICORN_WORKER_CLASS governs the type of workers spawned, typically async or gevent.</td>
</tr>
<tr>
<td>SAGEMAKER_GUNICORN_WORKER_CLASS</td>
<td>This governs the number of worker processes that Gunicorn is requested to spawn for handling requests. This value is used in combination with other parameters to derive a set that maximizes inference throughput. In addition to this, the SAGEMAKER_GUNICORN_WORKER_CLASS governs the type of workers spawned, typically async or gevent.</td>
</tr>
</tbody>
</table>
### Environment variable

<table>
<thead>
<tr>
<th>Environment variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OMP_NUM_THREADS</td>
<td>Python internally uses OpenMP for implementing multithreading within processes. Typically, threads equivalent to the number of CPU cores are spawned. But when implemented on top of Simultaneous Multi Threading (SMT), such Intel's HypeThreading, a certain process might oversubscribe a particular core by spawning twice as many threads as the number of actual CPU cores. In certain cases, a Python binary might end up spawning up to four times as many threads as available processor cores. Therefore, an ideal setting for this parameter, if you have oversubscribed available cores using worker threads, is 1, or half the number of CPU cores on a CPU with SMT turned on.</td>
</tr>
<tr>
<td>TF_DISABLE_MKL</td>
<td>In some cases, turning off MKL can speed up inference if TF_DISABLE_MKL and TF_DISABLE_POOL_ALLOCATOR are set to 1.</td>
</tr>
<tr>
<td>TF_DISABLE_POOL_ALLOCATOR</td>
<td></td>
</tr>
</tbody>
</table>

### PyTorch

<table>
<thead>
<tr>
<th>Environment variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAGEMAKER_TS_MAX_BATCH_DELAY</td>
<td>This is the maximum batch delay time TorchServe waits to receive.</td>
</tr>
<tr>
<td>SAGEMAKER_TS_BATCH_SIZE</td>
<td>If TorchServe doesn't receive the number of requests specified in batch_size before the timer runs out, it sends the requests that were received to the model handler.</td>
</tr>
<tr>
<td>SAGEMAKER_TS_MIN_WORKERS</td>
<td>The minimum number of workers to which TorchServe is allowed to scale down.</td>
</tr>
<tr>
<td>SAGEMAKER_TS_MAX_WORKERS</td>
<td>The maximum number of workers to which TorchServe is allowed to scale up.</td>
</tr>
<tr>
<td>SAGEMAKER_TS_RESPONSE_TIMEOUT</td>
<td>The time delay, after which inference times out in absence of a response.</td>
</tr>
<tr>
<td>SAGEMAKER_TS_MAX_REQUEST_SIZE</td>
<td>The maximum payload size for TorchServe.</td>
</tr>
<tr>
<td>SAGEMAKER_TS_MAX_RESPONSE_SIZE</td>
<td>The maximum response size for TorchServe.</td>
</tr>
</tbody>
</table>

### Multi Model Server (MMS)

<table>
<thead>
<tr>
<th>Environment variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_queue_size</td>
<td>This parameter is useful to tune when you have a scenario where the type of the inference request payload is large, and due to the size of payload being larger, you may have higher heap memory</td>
</tr>
</tbody>
</table>

---

<table>
<thead>
<tr>
<th>Environment variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_queue_size</td>
<td>consumption of the JVM in which this queue is being maintained. Ideally you might want to keep the heap memory requirements of JVM lower and allow Python workers to allot more memory for actual model serving. JVM is only for receiving the HTTP requests, queuing them, and dispatching them to the Python-based workers for inference. If you increase the job_queue_size, you might end up increasing the heap memory consumption of the JVM and ultimately taking away memory from the host that could have been used by Python workers. Therefore, exercise caution when tuning this parameter as well.</td>
</tr>
<tr>
<td>default_workers_per_model</td>
<td>This parameter is for the backend model serving and might be valuable to tune since this is the critical component of the overall model serving, based on which the Python processes spawn threads for each Model. If this component is slower (or not tuned properly), the front-end tuning might not be effective.</td>
</tr>
</tbody>
</table>

Q: How do I make sure my container supports Asynchronous Inference?

You can use the same container for Asynchronous Inference that you do for Real-Time Inference or Batch Transform. You should confirm that the timeouts and payload size limits on your container are set to handle larger payloads and longer timeouts.

Q: What are the limits specific to Asynchronous Inference, and can they be adjusted?

Refer to the following limits for Asynchronous Inference:

- Payload size limit: 1 GB
- Timeout limit: A request can take up to 60 minutes.
- Queue message TimeToLive (TTL): 6 hours
- Number of messages that can be put inside Amazon SQS: Unlimited. However, there is a quota of 120,000 for the number of in-flight messages for a standard queue, and 20,000 for a queue.

Q: What metrics are best to define for autoscaling on Asynchronous Inference? Can I have multiple scaling policies?

In general, with Asynchronous Inference, you can scale out based on invocations or instances. For invocation metrics, it's a good idea to look at your ApproximateBacklogSize, which is a metric that defines the number of items in your queue that have yet to be processed. You can utilize this metric or your InvocationsPerInstance metric to understand what TPS you may be getting throttled at. At the instance level, check your instance type and its CPU/GPU utilization to define when to scale out. If a singular instance is above 60-70% capacity, this is often a good sign that you are saturating your hardware.

We don't recommend having multiple scaling policies, as these can conflict and lead to confusion at the hardware level, causing delays when scaling out.
Q: Why is my asynchronous endpoint terminating an instance as Unhealthy and the update requests from autoscaling are failing?

Check if your container is able to handle ping and invoke requests concurrently. SageMaker invoke requests take approximately 3 minutes, and in this duration, usually multiple ping requests end up failing due to the timeout causing SageMaker to detect your container as Unhealthy.

Q: Can MaxConcurrentInvocationsPerInstance work for my BYOC model container with the nginx/gunicorn/flask settings?

Yes. MaxConcurrentInvocationsPerInstance is a feature of asynchronous endpoints. This does not depend on the custom container implementation. MaxConcurrentInvocationsPerInstance controls the rate at which invoke requests are sent to the customer container. If this value is set as 1, then only 1 request is sent to the container at a time, no matter how many workers are on the customer container.

Q: How can I debug model server errors (500) on my asynchronous endpoint?

The error means that the customer container returned an error. SageMaker does not control the behavior of customer containers. SageMaker simply returns the response from the ModelContainer and does not retry. If you want, you can configure the invocation to retry on failure. We suggest that you turn on container logging and check your container logs to find the root cause of the 500 error from your model. Check the corresponding CPUUtilization and MemoryUtilization metrics at the point of failure as well. You can also configure the S3FailurePath to the model response in Amazon SNS as part of the Async Error Notifications to investigate failures.

Q: How can I know if MaxConcurrentInvocationsPerInstance=1 takes effect? Are there any metrics that I can check?

You can check the metric InvocationsProcessed, which should align with the number of invocations that you expect to be processed in a minute based on single concurrency.

Q: How can I track the success and failures of my invocation requests? What are the best practices?

The best practice is to enable Amazon SNS, which is a notification service for messaging-oriented applications, with multiple subscribers requesting and receiving “push” notifications of time-critical messages from a choice of transport protocols, including HTTP, Amazon SQS, and email. Asynchronous Inference posts notifications when you create an endpoint with CreateEndpointConfig and specify an Amazon SNS topic.

To use Amazon SNS to check prediction results from your asynchronous endpoint, you first need to create a topic, subscribe to the topic, confirm your subscription to the topic, and note the Amazon Resource Name (ARN) of that topic. For detailed information on how to create, subscribe, and find the Amazon ARN of an Amazon SNS topic, see Configuring Amazon SNS in the Amazon SNS Developer Guide. For more information about how to use Amazon SNS with Asynchronous Inference, see Check prediction results.

Q: Can I define a scaling policy that scales up from zero instances upon receiving a new request?

Yes. Asynchronous Inference provides a mechanism to scale down to zero instances when there are no requests. If your endpoint has been scaled down to zero instances during these periods, then your endpoint won't scale up again until the number of requests in the queue exceeds the target specified in your scaling policy. This can result in long waiting times for requests in the queue. In such cases, if you want to scale up from zero instances for new requests less than the queue target specified, you can use
an additional scaling policy called HasBacklogWithoutCapacity. For more information about how to define this scaling policy, see Autoscale an asynchronous endpoint.

Q: I'm getting an error that the instance type is not supported for Asynchronous Inference. What are the instance types Asynchronous Inference supports?

For an exhaustive list of instances supported by Asynchronous Inference per region, see SageMaker pricing. Check if the required instance is available in your region before proceeding.

**Use Batch Transform**

Use batch transform when you need to do the following:

- Preprocess datasets to remove noise or bias that interferes with training or inference from your dataset.
- Get inferences from large datasets.
- Run inference when you don't need a persistent endpoint.
- Associate input records with inferences to assist the interpretation of results.

To filter input data before performing inferences or to associate input records with inferences about those records, see Associate Prediction Results with Input Records (p. 2547). For example, you can filter input data to provide context for creating and interpreting reports about the output data.

**Topics**

- Use Batch Transform to Get Inferences from Large Datasets (p. 2545)
- Speed up a Batch Transform Job (p. 2547)
- Use Batch Transform to Test Production Variants (p. 2547)
- Batch Transform Sample Notebooks (p. 2547)
- Associate Prediction Results with Input Records (p. 2547)
- Storage in Batch Transform (p. 2553)
- Troubleshooting (p. 2553)

**Use Batch Transform to Get Inferences from Large Datasets**

Batch transform automatically manages the processing of large datasets within the limits of specified parameters. For example, suppose that you have a dataset file, input1.csv, stored in an S3 bucket. The content of the input file might look like the following example.

```
Record1-Attribute1, Record1-Attribute2, Record1-Attribute3, ..., Record1-AttributeM
Record2-Attribute1, Record2-Attribute2, Record2-Attribute3, ..., Record2-AttributeM
Record3-Attribute1, Record3-Attribute2, Record3-Attribute3, ..., Record3-AttributeM
...
RecordN-Attribute1, RecordN-Attribute2, RecordN-Attribute3, ..., RecordN-AttributeM
```

When a batch transform job starts, SageMaker initializes compute instances and distributes the inference or preprocessing workload between them. Batch Transform partitions the Amazon S3 objects in the input by key and maps Amazon S3 objects to instances. When you have multiple files, one instance might
process input1.csv, and another instance might process the file named input2.csv. If you have one input file but initialize multiple compute instances, only one instance processes the input file and the rest of the instances are idle.

You can also split input files into mini-batches. For example, you might create a mini-batch from input1.csv by including only two of the records.

```
Record3-Attribute1, Record3-Attribute2, Record3-Attribute3, ..., Record3-AttributeM
Record4-Attribute1, Record4-Attribute2, Record4-Attribute3, ..., Record4-AttributeM
```

**Note**

SageMaker processes each input file separately. It doesn't combine mini-batches from different input files to comply with the `MaxPayloadInMB` limit.

To split input files into mini-batches when you create a batch transform job, set the `SplitType` parameter value to Line. If SplitType is set to None or if an input file can't be split into mini-batches, SageMaker uses the entire input file in a single request. Note that Batch Transform doesn't support CSV-formatted input that contains embedded newline characters. You can control the size of the mini-batches by using the `BatchStrategy` and `MaxPayloadInMB` parameters. `MaxPayloadInMB` must not be greater than 100 MB. If you specify the optional `MaxConcurrentTransforms` parameter, then the value of `(MaxConcurrentTransforms * MaxPayloadInMB)` must also not exceed 100 MB.

If the batch transform job successfully processes all of the records in an input file, it creates an output file with the same name and the .out file extension. For multiple input files, such as input1.csv and input2.csv, the output files are named input1.csv.out and input2.csv.out. The batch transform job stores the output files in the specified location in Amazon S3, such as `s3://awsexamplebucket/output/`.

The predictions in an output file are listed in the same order as the corresponding records in the input file. The output file `input1.csv.out`, based on the input file shown earlier, would look like the following.

```
Inference1-Attribute1, Inference1-Attribute2, Inference1-Attribute3, ..., Inference1-AttributeM
Inference2-Attribute1, Inference2-Attribute2, Inference2-Attribute3, ..., Inference2-AttributeM
Inference3-Attribute1, Inference3-Attribute2, Inference3-Attribute3, ..., Inference3-AttributeM
...
InferenceN-Attribute1, InferenceN-Attribute2, InferenceN-Attribute3, ..., InferenceN-AttributeM
```

If you set `SplitType` to Line, you can set the `AssembleWith` parameter to Line to concatenate the output records with a line delimiter. This does not change the number of output files. The number of output files is equal to the number of input files, and using `AssembleWith` does not merge files. If you don't specify the `AssembleWith` parameter, by default the output records are concatenated in a binary format.

When the input data is very large and is transmitted using HTTP chunked encoding, to stream the data to the algorithm, set `MaxPayloadInMB` to 0. Amazon SageMaker built-in algorithms don't support this feature.

For information about using the API to create a batch transform job, see the `CreateTransformJob` API. For more information about the correlation between batch transform input and output objects, see `OutputDataConfig`. For an example of how to use batch transform, see *(Optional) Make Prediction with Batch Transform (p. 311).*
Speed up a Batch Transform Job

If you are using the CreateTransformJob API, you can reduce the time it takes to complete batch transform jobs by using optimal values for parameters such as MaxPayloadInMB, MaxConcurrentTransforms, or BatchStrategy. The ideal value for MaxConcurrentTransforms is equal to the number of compute workers in the batch transform job. If you are using the SageMaker console, you can specify these optimal parameter values in the Additional configuration section of the Batch transform job configuration page. SageMaker automatically finds the optimal parameter settings for built-in algorithms. For custom algorithms, provide these values through an execution-parameters endpoint.

Use Batch Transform to Test Production Variants

To test different models or various hyperparameter settings, create a separate transform job for each new model variant and use a validation dataset. For each transform job, specify a unique model name and location in Amazon S3 for the output file. To analyze the results, use Inference Pipeline Logs and Metrics (p. 2440).

Batch Transform Sample Notebooks

For a sample notebook that uses batch transform with a principal component analysis (PCA) model to reduce data in a user-item review matrix, followed by the application of a density-based spatial clustering of applications with noise (DBSCAN) algorithm to cluster movies, see Batch Transform with PCA and DBSCAN Movie Clusters. For instructions on creating and accessing Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Jupyter Notebook Instances (p. 298). After creating and opening a notebook instance, choose the SageMaker Examples tab to see a list of all the SageMaker examples. The topic modeling example notebooks that use the NTM algorithms are located in the Advanced functionality section. To open a notebook, choose its Use tab, then choose Create copy.

Associate Prediction Results with Input Records

When making predictions on a large dataset, you can exclude attributes that aren’t needed for prediction. After the predictions have been made, you can associate some of the excluded attributes with those predictions or with other input data in your report. By using batch transform to perform these data processing steps, you can often eliminate additional preprocessing or postprocessing. You can use input files in JSON and CSV format only.

Topics
- Workflow for Associating Inferences with Input Records (p. 2547)
- Use Data Processing in Batch Transform Jobs (p. 2548)
- Supported JSONPath Operators (p. 2549)
- Batch Transform Examples (p. 2550)

Workflow for Associating Inferences with Input Records

The following diagram shows the workflow for associating inferences with input records.
To associate inferences with input data, there are three main steps:

1. Filter the input data that is not needed for inference before passing the input data to the batch transform job. Use the `InputFilter` parameter to determine which attributes to use as input for the model.
2. Associate the input data with the inference results. Use the `JoinSource` parameter to combine the input data with the inference.
3. Filter the joined data to retain the inputs that are needed to provide context for interpreting the predictions in the reports. Use `OutputFilter` to store the specified portion of the joined dataset in the output file.

**Use Data Processing in Batch Transform Jobs**

When creating a batch transform job with `CreateTransformJob` to process data:

1. Specify the portion of the input to pass to the model with the `InputFilter` parameter in the `DataProcessing` data structure.
2. Join the raw input data with the transformed data with the `JoinSource` parameter.
3. Specify which portion of the joined input and transformed data from the batch transform job to include in the output file with the `OutputFilter` parameter.
4. Choose either JSON- or CSV-formatted files for input:
   - For JSON- or JSON Lines-formatted input files, SageMaker either adds the `SageMakerOutput` attribute to the input file or creates a new JSON output file with the `SageMakerInput` and `SageMakerOutput` attributes. For more information, see `DataProcessing`.
   - For CSV-formatted input files, the joined input data is followed by the transformed data and the output is a CSV file.

If you use an algorithm with the `DataProcessing` structure, it must support your chosen format for both input and output files. For example, with the `TransformOutput` field of the...
CreateTransformJob API, you must set both the ContentType and Accept parameters to one of the following values: text/csv, application/json, or application/jsonlines. The syntax for specifying columns in a CSV file and specifying attributes in a JSON file are different. Using the wrong syntax causes an error. For more information, see Batch Transform Examples (p. 2550). For more information about input and output file formats for built-in algorithms, see Use Amazon SageMaker Built-in Algorithms or Pre-trained Models (p. 1528).

The record delimiters for the input and output must also be consistent with your chosen file input. The SplitType parameter indicates how to split the records in the input dataset. The AssembleWith parameter indicates how to reassemble the records for the output. If you set input and output formats to text/csv, you must also set the SplitType and AssembleWith parameters to line. If you set the input and output formats to application/jsonlines, you can set both SplitType and AssembleWith to line.

For CSV files, you cannot use embedded newline characters. For JSON files, the attribute name SageMakerOutput is reserved for output. The JSON input file can't have an attribute with this name. If it does, the data in the input file might be overwritten.

**Supported JSONPath Operators**

To filter and join the input data and inference, use a JSONPath subexpression. SageMaker supports only a subset of the defined JSONPath operators. The following table lists the supported JSONPath operators. For CSV data, each row is taken as a JSON array, so only index based JSONPaths can be applied, e.g. $[0], $[1:]. CSV data should also follow RFC format.

<table>
<thead>
<tr>
<th>JSONPath Operator</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>$</td>
<td>The root element to a query. This operator is required at the beginning of all path expressions.</td>
<td>$</td>
</tr>
<tr>
<td>$.&lt;name&gt;</td>
<td>A dot-notated child element.</td>
<td>$.id</td>
</tr>
<tr>
<td>*</td>
<td>A wildcard. Use in place of an attribute name or numeric value.</td>
<td>$.id.*</td>
</tr>
<tr>
<td>['&lt;name&gt;', '&lt;name&gt;']</td>
<td>A bracket-notated element or multiple child elements.</td>
<td>$['id', 'SageMakerOutput']</td>
</tr>
<tr>
<td>[&lt;number&gt; (,&lt;number&gt;)]</td>
<td>An index or array of indexes. Negative index values are also supported. A -1 index refers to the last element in an array.</td>
<td>$[1], $[1,3,5]</td>
</tr>
<tr>
<td>[&lt;start&gt;:&lt;end&gt;]</td>
<td>An array slice operator. The array slice() method extracts a section of an array and returns a new array. If you omit &lt;start&gt;, SageMaker uses the first element of the array. If you omit &lt;end&gt;, SageMaker uses the last element of the array.</td>
<td>$[2:5], $[:5], $[2:]</td>
</tr>
</tbody>
</table>

When using the bracket-notation to specify multiple child elements of a given field, additional nesting of children within brackets is not supported. For example, $.field1[‘child1’, ‘child2’] is supported while $.field1[‘child1’, ‘child2.grandchild’] is not.

For more information about JSONPath operators, see JsonPath on GitHub.

Amazon SageMaker Developer Guide
Associate Prediction Results with Input

Batch Transform Examples
The following examples show some common ways to join input data with prediction results.
Topics
• Example: Output Only Inferences (p. 2550)
• Example: Output Inferences Joined with Input Data (p. 2550)
• Example: Output Inferences Joined with Input Data and Exclude the ID Column from the Input
(CSV) (p. 2551)
• Example: Output Inferences Joined with an ID Column and Exclude the ID Column from the Input
(CSV) (p. 2552)

Example: Output Only Inferences
By default, the DataProcessing parameter doesn't join inference results with input. It outputs only the
inference results.
If you want to explicitly specify to not join results with input, use the Amazon SageMaker Python SDK
and specify the following settings in a transformer call.
sm_transformer = sagemaker.transformer.Transformer(…)
sm_transformer.transform(…, input_filter="$", join_source= "None", output_filter="$")

To output inferences using the AWS SDK for Python, add the following code to your CreateTransformJob
request. The following code mimics the default behavior.
{

}

"DataProcessing": {
"InputFilter": "$",
"JoinSource": "None",
"OutputFilter": "$"
}

Example: Output Inferences Joined with Input Data
If you're using the Amazon SageMaker Python SDK to combine the input data with the inferences in
the output ﬁle, specify the assemble_with and accept parameters when initializing the transformer
object. When you use the transform call, specify Input for the join_source parameter, and specify the
split_type and content_type parameters as well. The split_type parameter must have the same
value as assemble_with, and the content_type parameter must have the same value as accept.
For more information about the parameters and their accepted values, see the Transformer page in the
Amazon SageMaker Python SDK.
sm_transformer = sagemaker.transformer.Transformer(…, assemble_with="Line", accept="text/
csv")
sm_transformer.transform(…, join_source="Input", split_type="Line", content_type="text/
csv")

If you're using the AWS SDK for Python (Boto 3), join all input data with the inference by adding the
following code to your CreateTransformJob request. The values for Accept and ContentType must
match, and the values for AssembleWith and SplitType must also match.
{

2550


For JSON or JSON Lines input files, the results are in the SageMakerOutput key in the input JSON file. For example, if the input is a JSON file that contains the key-value pair `{"key":1}`, the data transform result might be `{"label":1}`. SageMaker stores both in the input file in the SageMakerInput key.

```json
{
  "key":1,
  "SageMakerOutput":{"label":1}
}
```

**Note**

The joined result for JSON must be a key-value pair object. If the input isn't a key-value pair object, SageMaker creates a new JSON file. In the new JSON file, the input data is stored in the SageMakerInput key and the results are stored as the SageMakerOutput value.

For a CSV file, for example, if the record is `[1,2,3]`, and the label result is `[1]`, then the output file would contain `[1,2,3,1]`.

**Example: Output Inferences Joined with Input Data and Exclude the ID Column from the Input (CSV)**

If you are using the Amazon SageMaker Python SDK to join your input data with the inference output while excluding an ID column from the transformer input, specify the same parameters from the preceding example as well as a JSONPath subexpression for the input_filter in your transformer call. For example, if your input data includes five columns and the first one is the ID column, use the following transform request to select all columns except the ID column as features. The transformer still outputs all of the input columns joined with the inferences. For more information about the parameters and their accepted values, see the Transformer page in the Amazon SageMaker Python SDK.

```
sm_transformer = sagemaker.transformer.Transformer(…, assemble_with="Line", accept="text/csv")
sm_transformer.transform(…, split_type="Line", content_type="text/csv",
input_filter="$[1:]", join_source="Input")
```

If you are using the AWS SDK for Python (Boto 3), add the following code to your CreateTransformJob request.

```json
{
  "DataProcessing": {
    "InputFilter": "$[1:]",
    "JoinSource": "Input"
  },
  "TransformOutput": {
    "Accept": "text/csv",
```

2551
To specify columns in SageMaker, use the index of the array elements. The first column is index 0, the second column is index 1, and the sixth column is index 5.

To exclude the first column from the input, set `InputFilter` to `"[1:]"`. The colon (:) tells SageMaker to include all of the elements between two values, inclusive. For example, `"[1:4]"` specifies the second through fifth columns.

If you omit the number after the colon, for example, `[5:]`, the subset includes all columns from the 6th column through the last column. If you omit the number before the colon, for example, `[:5]`, the subset includes all columns from the first column (index 0) through the sixth column.

**Example: Output Inferences Joined with an ID Column and Exclude the ID Column from the Input (CSV)**

If you are using the Amazon SageMaker Python SDK, you can specify the output to join only specific input columns (such as the ID column) with the inferences by specifying the `output_filter` in the transformer call. The `output_filter` uses a JSONPath subexpression to specify which columns to return as output after joining the input data with the inference results. The following request shows how you can make predictions while excluding an ID column and then join the ID column with the inferences. Note that in the following example, the last column (-1) of the output contains the inferences. If you are using JSON files, SageMaker stores the inference results in the attribute `SageMakerOutput`. For more information about the parameters and their accepted values, see the Transformer page in the Amazon SageMaker Python SDK.

```python
sm_transformer = sagemaker.transformer.Transformer(…, assemble_with="Line", accept="text/csv")
sm_transformer.transform(…, split_type="Line", content_type="text/csv",
                     input_filter="[1:]",
                     join_source="Input",
                     output_filter="[0,-1]"
)
```

If you are using the AWS SDK for Python (Boto 3), join only the ID column with the inferences by adding the following code to your CreateTransformJob request.

```json
{
   "DataProcessing": {
      "InputFilter": "[1:]",
      "JoinSource": "Input",
      "OutputFilter": "[0,-1]"
   },
   "TransformOutput": {
      "Accept": "text/csv",
      "AssembleWith": "Line"
   },
   "TransformInput": {
      "ContentType": "text/csv",
      "SplitType": "Line"
   }
}
```

**Warning**

If you are using a JSON-formatted input file, the file can't contain the attribute name `SageMakerOutput`. This attribute name is reserved for the inferences in the output file. If your
JSON-formatted input file contains an attribute with this name, values in the input file might be overwritten with the inference.

**Storage in Batch Transform**

When you run a batch transform job, Amazon SageMaker attaches an Amazon Elastic Block Store storage volume to Amazon EC2 instances that process your job. The volume stores your model, and the size of the storage volume is fixed at 30 GB. You have the option to encrypt your model at rest in the storage volume.

**Note**
If you have a large model, you may encounter an `InternalServerError`.

For more information about Amazon EBS storage and features, see the following pages:

- Amazon EBS in the Amazon EC2 User Guide for Linux Instances
- Amazon EBS volumes in the Amazon EC2 User Guide for Linux Instances

**Note**
G4dn instances come with their own local SSD storage. To learn more about G4dn instances, see the Amazon EC2 G4 Instances page.

**Troubleshooting**

If you are having errors in Amazon SageMaker Batch Transform, refer to the following troubleshooting tips.

**Max timeout errors**

If you are getting max timeout errors when running batch transform jobs, try the following:

- Begin with the single-record BatchStrategy, a batch size of the default (6 MB) or smaller which you specify in the MaxPayloadInMB parameter, and a small sample dataset. Tune the maximum timeout parameter InvocationsTimeoutInSeconds (which has a maximum of 1 hour) until you receive a successful invocation response.

- After you receive a successful invocation response, increase the MaxPayloadInMB (which has a maximum of 100 MB) and the InvocationsTimeoutInSeconds parameters together to find the maximum batch size that can support your desired model timeout. You can use either the single-record or multi-record BatchStrategy in this step.

  **Note**
  Exceeding the MaxPayloadInMB limit causes an error. This might happen with a large dataset if it can't be split, the SplitType parameter is set to none, or individual records within the dataset exceed the limit.

- (Optional) Tune the MaxConcurrentTransforms parameter, which specifies the maximum number of parallel requests that can be sent to each instance in a batch transform job. However, the value of MaxConcurrentTransforms * MaxPayloadInMB must not exceed 100 MB.

**Incomplete output**

SageMaker uses the Amazon S3 Multipart Upload API to upload results from a batch transform job to Amazon S3. If an error occurs, the uploaded results are removed from Amazon S3. In some cases, such as when a network outage occurs, an incomplete multipart upload might remain in Amazon S3. An incomplete upload might also occur if you have multiple input files but some of the files can't
be processed by SageMaker Batch Transform. The input files that couldn't be processed won't have corresponding output files in Amazon S3.

To avoid incurring storage charges, we recommend that you add the S3 bucket policy to the S3 bucket lifecycle rules. This policy deletes incomplete multipart uploads that might be stored in the S3 bucket. For more information, see Object Lifecycle Management.

**Job shows as failed**

If a batch transform job fails to process an input file because of a problem with the dataset, SageMaker marks the job as failed. If an input file contains a bad record, the transform job doesn't create an output file for that input file because doing so prevents it from maintaining the same order in the transformed data as in the input file. When your dataset has multiple input files, a transform job continues to process input files even if it fails to process one. The processed files still generate useable results.

If you are using your own algorithms, you can use placeholder text, such as ERROR, when the algorithm finds a bad record in an input file. For example, if the last record in a dataset is bad, the algorithm places the placeholder text for that record in the output file.

**Model parallelism and large model inference**

State-of-the-art deep learning models for applications such as natural language processing (NLP) are large, typically with tens or hundreds of billions of parameters. Larger models are often more accurate, which makes them attractive to machine learning practitioners. However, these models are often too large to fit on a single accelerator or GPU device, making it difficult to achieve low-latency inference. You can avoid this memory bottleneck by using model parallelism techniques to partition a model across multiple accelerators or GPUs.

Amazon SageMaker includes specialized deep learning containers (DLCs), libraries, and tooling for model parallelism and large model inference (LMI). In the following sections, you can find resources to get started with LMI on SageMaker.

**Topics**

- Deep learning containers for large model inference (p. 2554)
- SageMaker endpoint parameters for large model inference (p. 2557)
- Large model inference tutorials (p. 2558)
- Configurations and settings (p. 2571)
- Choosing instance types for large model inference (p. 2576)
- Deploying uncompressed models (p. 2579)
- Large model inference FAQs (p. 2580)
- Large model inference troubleshooting (p. 2581)
- Release notes for large model inference deep learning containers (p. 2582)

**Deep learning containers for large model inference**

SageMaker maintains deep learning containers (DLCs) with popular open source libraries for hosting large models such as GPT, T5, OPT, BLOOM, and Stable Diffusion on AWS infrastructure. With these DLCs you can use third party libraries such as DeepSpeed, Accelerate, and FasterTransformer to partition model parameters using model parallelism techniques to leverage the memory of multiple GPUs for inference. The following table lists the DLCs available with SageMaker for large model inference (LMI).
We recommend that you start with these DLCs for LMI on SageMaker. These include components, libraries, and drivers that have been optimized and tested for use on SageMaker.

<table>
<thead>
<tr>
<th>DLC URI</th>

</tbody>
</table>
In addition to PyTorch, LMI DLCs include libraries to facilitate LMI. SageMaker supports the following categories of libraries.

- **Model zoo** – Model zoos provide simple API access to pre-trained models. SageMaker provides the following model zoos:
  - **Hugging Face Transformers** is a popular library for pre-trained deep learning models that use a transformer architecture such as GPT, OPT, and BLOOM.
  - **Hugging Face Diffusers** is a library with pre-trained deep learning models that use a diffusion technique such as Stable Diffusion.

- **Model parallelism and inference optimization libraries** – These libraries handle model parallel inference by partitioning a model artifact so that its comprising parameters can be spread across multiple GPUs. SageMaker supports the following model parallelism and inference optimization libraries:
  - **DeepSpeed Inference** is an open-source inference optimization library. It includes model partitioning schemes for model parallelism with supported models, including many transformer models. It also has optimized kernels for popular models such as OPT, GPT, and BLOOM that can significantly improve inference latency. The version of DeepSpeed in the LMI DLCs is optimized and tested to work on SageMaker. It includes several enhancements, including support for BF16 precision models.
  - **Hugging Face Accelerate** is an open-source model parallel inference library. It supports model parallelism for most models in the Hugging Face Transformers library.
  - **FasterTransformer** is an open source library from Nvidia that provides an accelerated engine for efficiently running transformer-based neural network inference. It has been designed to handle large models that require multiple GPUs and nodes in a distributed manner. The library includes an optimized version of the transformer block, which comprises both the encoder and decoder parts, enabling you to run the inference of full encoder-decoder architectures like T5, as well as encoder-only models like BERT and decoder-only models like GPT.

- **Model server** – Model servers handle an inference request end to end. They accept requests, invoke pre-processing and post-processing scripts, and respond to users. Model servers that are compatible with model parallelism, also organize workers and threads across multiple devices. SageMaker supports the following model servers:
  - **DJL-Serving** is an open-source, high-performance model server powered by DJL. It takes multiple deep learning models or workflows, and makes them available through an HTTP endpoint. Versions 0.19 and above are supported by SageMaker and work with Amazon EC2 instances with multiple GPUs to facilitate LMI with model parallelism.
Supported instance types

AWS LMI DLCs support the p4d, p3, g5, and g4dn instance types.

SageMaker endpoint parameters for large model inference

You can customize the following parameters to facilitate low-latency large model inference (LMI) with SageMaker:

- **Maximum Amazon EBS volume size on the instance (VolumeSizeInGB)** – If the size of the model is larger than 30 GB and you are using an instance without a local disk, you should increase this parameter to be slightly larger than the size of your model.
- **Health check timeout quota (ContainerStartupHealthCheckTimeoutInSeconds)** – If your container is correctly set up and the CloudWatch logs indicate a health check timeout, you should increase this quota so the container has enough time to respond to health checks.
- **Model download timeout quota (ModelDataDownloadTimeoutInSeconds)** – If the size of your model is larger than 40 GB, then you should increase this quota to provide sufficient time to download the model from Amazon S3 to the instance.

For more information on low latency inference with large models, see [Deploy large models on Amazon SageMaker using DJL Serving and DeepSpeed model parallel inference](#). The following code snippet demonstrates how to programatically configure the aforementioned parameters. Replace the *italicized placeholder text* in the example with your own information.

```python
import boto3

aws_region = "aws-region"
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# The name of the endpoint. The name must be unique within an AWS Region in your AWS account.
endpoint_name = "endpoint-name"

# Create an endpoint config name.
endpoint_config_name = "endpoint-config-name"

# The name of the model that you want to host.
model_name = "the-name-of-your-model"

instance_type = "instance-type"

sagemaker_client.create_endpoint_config(
    EndpointConfigName = endpoint_config_name
    ProductionVariants=[
        {
            "VariantName": "variant1", # The name of the production variant.
            "ModelName": model_name,
            "InstanceType": instance_type, # Specify the compute instance type.
            "InitialInstanceCount": 1, # Number of instances to launch initially.
            "VolumeSizeInGB": 256, # Specify the size of the Amazon EBS volume.
            "ModelDataDownloadTimeoutInSeconds": 1800, # Specify the model download timeout in seconds.
            "ContainerStartupHealthCheckTimeoutInSeconds": 1800, # Specify the health checkup timeout in seconds
        },
    ],
)
```

2557
sagemaker_client.create_endpoint(EndpointName=endpoint_name,
   EndpointConfigName=endpoint_config_name)

For more information on the keys for ProductionVariants, see ProductionVariant and Create an Endpoint Configuration (p. 2393).

Large model inference tutorials

The following tutorials demonstrate the use of different model parallelization and inference optimization libraries available inside a large model inference (LMI) DLC. You can use these to get started with LMI on SageMaker.

Topics
- Large model inference with DeepSpeed and DJL Serving (p. 2558)
- Large model inference with FasterTransformer and DJL Serving (p. 2561)
- Large model inference with TorchServe (p. 2564)
- Additional resources to get started (p. 2571)

Large model inference with DeepSpeed and DJL Serving

This tutorial demonstrates how to deploy large models with DJL Serving using DeepSpeed and Hugging Face Accelerate model parallelization frameworks. This example uses a GPT-J model with 6 billion parameters and an ml.95 instance. You can modify this to work with other models and instance types. Replace the italicized placeholder text in the examples with your own information.

Topics
- Large model inference container image with DJL Serving (p. 2558)
- Preparing your model artifacts (p. 2559)
- Deploy the model using the SageMaker SDK (p. 2560)

Large model inference container image with DJL Serving

Large model inference (LMI) DLCs are available as Docker images on the Amazon Elastic Container Registry (Amazon ECR). These containers include the necessary components, libraries, and drivers to host large models on SageMaker or using Amazon EC2 infrastructure. You can find a list of LMI DLCs in the Large model inference section of the DLCs list. This tutorial uses the following container:

<table>
<thead>
<tr>
<th>Framework</th>
<th>Job type</th>
<th>CPU/GPU</th>
<th>Python version options</th>
<th>Example URL</th>
</tr>
</thead>
<tbody>
<tr>
<td>DJL Serving 0.23.0 with DeepSpeed 0.9.5, Hugging Face Transformers 4.30.2, and Hugging Face Accelerate 0.20.3</td>
<td>Inference</td>
<td>GPU</td>
<td>3.9 (py39)</td>
<td>763104351884.dkr.ecr.us-west-2.amazonaws.com/djl-inference:0.23.0-deepspeed0.9.5-cu118</td>
</tr>
</tbody>
</table>

LMI DLCs are regularly updated and tested on SageMaker. You can directly reference these Docker image URLs when you host on SageMaker, selecting the container that suits your need the most. Each LMI DLC image includes DeepSpeed, Accelerate, Transformers and DJL Serving.
Preparing your model artifacts

LMI DLCs use DJL Serving to serve your model for inference. You have to configure DJL Serving and package your model in a format supported by DJL Serving and DeepSpeed for LMI.

1. Create a `serving.properties` configuration file to indicate to DJL Serving which model parallelization and inference optimization libraries you would like to use. You can find the configuration options for both DeepSpeed and Hugging Face Accelerate in Configurations and settings (p. 2571). Modify the following example `serving.properties` file below to suit your needs.

```properties
engine=DeepSpeed
#engine=Python # for Hugging Face Accelerate
option.entryPoint=djl_python.deepspeed
#option.entryPoint=djl_python.huggingface # for Hugging Face Accelerate
option.tensor_parallel_degree=2
option.model_id=EleutherAI/gpt-j-6B
#option.max_rolling_batch_size=64 # for Hugging Face Accelerate
#option.rolling_batch=lmi-dist # for Hugging Face Accelerate
option.task=text-generation
option.dtype=fp16
```

For a complete list of configuration options, see Configurations and settings (p. 2571). The following list describes some of the options used in the example `serving.properties` file.

- **option.entryPoint** – This option is used to specify which handler offered by DJL Serving you would like to use. The possible values are huggingface, deepspeed, and stable-diffusion. Here we use deepspeed.
- **option.model_id** – Only provide this option if you also provide option.entryPoint. The value of this option is either the Hugging Face ID of a model or the S3 URL of the model artifacts. DJL Serving uses this value to download the model from Hugging Face or the S3 URL.
- **option.task** – Model architectures generally require you specify a task as one of the parameters in transformers.pipeline.

For more information, see the DeepSpeed, and Hugging Face handler implementations.

2. Package your model artifacts into a compressed `.tar` file. DJL Serving and DeepSpeed expect the model artifacts to be packaged and formatted in a specific way. This example uses the following directory structure for this purpose.

```
- deepspeed-gptj # root directory
  - serving.properties
  - model.py # your custom handler file, if you choose not to use the handlers provided with DJL Serving
    - model binary files # if you do not want to use option.model_id
```

The root directory contains the `serving.properties` file, along with any other necessary files. This tutorial only needs the `serving.properties` file because it uses DJL Serving's handler and the `model_id` option to download the model directly from Hugging Face. The following code snippet packages the model artifacts into a compressed `.tar` file.

```
mkdir deepspeed-gptj
cp serving.properties deepspeed-gptj/
tar -czf deepspeed-gptj.tar.gz deepspeed-gptj
aws s3 sync deepspeed-gptj.tar.gz s3://djl-sm-test/tutorial/
```
Deploy the model using the SageMaker SDK

This example uses SageMaker to handle the end to end model deployment process to an inference endpoint.

1. Create a SageMaker session.

   ```python
   import boto3
   import sagemaker

   aws_region = "aws-region"
   sagemaker_session = sagemaker.Session(boto_session=boto3.Session(region_name=aws_region))
   ```

2. Create a model in SageMaker.

   ```python
   from sagemaker.model import Model
   from sagemaker import image_uris, get_execution_role

   role = get_execution_role()
   def create_model(model_name, model_s3_url):
       # Get the DJL DeepSpeed image uri
       image_uri = image_uris.retrieve(
           framework="djl-deepspeed",
           region=sagemaker_session.boto_session.region_name,
           version="0.23.0"
       )
       model = Model(
           image_uri=image_uri,
           model_data=model_s3_url,
           role=role,
           name=model_name,
           sagemaker_session=sagemaker_session,
       )
       return model
   ```

   The g5.12xlarge instance has 4 Nvidia A10G GPUs. The `serving.properties` in [Preparing your model artifacts](p. 2559) specified a tensor parallel degree of 2. DJL Serving automatically loads 2 copies of the model with 2 tensor parallel partitions to make use of all the 4 GPUs on the instance. This doubles the throughput.

3. Deploy the model to a g5.12xlarge instance.

   ```python
   from sagemaker import serializers, deserializers

   def deploy_model(model, _endpoint_name):
       model.deploy(
           initial_instance_count=1,
           instance_type="ml.g5.12xlarge",
           endpoint_name=_endpoint_name
       )
       predictor = sagemaker.Predictor(
           endpoint_name=_endpoint_name,
           sagemaker_session=sagemaker_session,
           serializer=serializers.JSONSerializer(),
           deserializer=deserializers.JSONDeserializer()
       )
       return predictor
   ```
4. Make a prediction.

```python
import argparse
if __name__ == '__main__':
    arg_parser = argparse.ArgumentParser()
    group = arg_parser.add_mutually_group()
    group.add_argument('--deepspeed', action='store_const', dest='framework',
                       const='deepspeed')
    group.add_argument('--accelerate', action='store_const', dest='framework',
                       const='accelerate')
    args = arg_parser.parse_args()

    _model_name = f'{args.framework}-gptj'
    _model_s3_url = f's3://djl-sm-test/tutorial/{args.framework}-gptj.tar.gz'
    _endpoint_name = f'{args.framework}-gptj'

    model = create_model(_model_name, _model_s3_url)
    predictor = deploy_model(model, _endpoint_name)
    print(predictor.predict(
        {
            'inputs': 'Large model inference is',
            'parameters': { 'max_length': 50 },
        }
    ))
```

Large model inference with FasterTransformer and DJL Serving

This tutorial demonstrates how to deploy a T5 model with large model inference (LMI) deep learning containers (DLCs), DJL Serving, and the FasterTransformer model parallelization framework. Here we use a flan-t5-xl model with 3 billion parameters and an ml.g5 instance. You can modify this to work with other variants of T5 models and instance types. Replace the italicized placeholder text in the examples with your own information.

Large model inference container image with FasterTransformer backend for DJL Serving

LMI DLCs are available as Docker images on the Amazon Elastic Container Registry (Amazon ECR). These containers include the necessary components, libraries, and drivers to host large models on SageMaker or using Amazon EC2 infrastructure. You can find a list of LMI DLCs in the Large model inference section of the DLCs list. This tutorial uses the following container:

<table>
<thead>
<tr>
<th>Framework</th>
<th>Job type</th>
<th>CPU/GPU</th>
<th>Python version options</th>
<th>Example URL</th>
</tr>
</thead>
<tbody>
<tr>
<td>DJL Serving 0.23.0 with FasterTransformer 5.3, Hugging Face Transformers 4.30.1.</td>
<td>Inference</td>
<td>GPU</td>
<td>3.9 (py39)</td>
<td>763104351884.dkr.ecr.us-west-2.amazonaws.com/djl-inference:0.23.0-fastertransformer5.3.0-cu118</td>
</tr>
</tbody>
</table>

LMI DLCs are regularly updated and tested on SageMaker. You can directly reference these Docker image URLs when you host on SageMaker, selecting the container that suits your need the most. Each LMI DLC image includes DeepSpeed, Accelerate, Transformers and DJL Serving.
Preparing your model artifacts

LMI DLCs use DJL Serving to serve your model for inference. You must configure DJL Serving and package your model in a format supported by DJL Serving and FasterTransformer.

1. Create a `serving.properties` configuration file to indicate to DJL Serving which model parallelization and inference optimization libraries you would like to use.

   ```properties
   engine=FasterTransformer
   option.tensor_parallel_degree=2
   option.model_id=google/flan-t5-xl
   option.dtype=fp32
   ```

   For a complete list of configuration options, see Configurations and settings (p. 2571). The following list describes some of the options used in the aforementioned example.

   - `option.tensor_parallel_degree` – This option specifies number of tensor parallel partitions performed on the model.
   - `option.model_id` – The value of this option is either the Hugging Face ID of a model or the S3 URL of the model artifacts. DJL Serving uses this value to download the model from Hugging Face or the S3 URL.
   - `option.dtype` – This option specifies data type that you want to run inference with.

2. Create a `model.py` handler script with a `handle` method that will be invoked by DJL Serving when inference requests are received. This tutorial uses the following `model.py`:

   ```python
   import fastertransformer as ft
   from djl_python import Input, Output
   from transformers import AutoTokenizer
   import logging
   import os

   model = None

   def load_model(properties):
       model_name = properties['model_id']
       tensor_parallel_degree = int(properties['tensor_parallel_degree'])
       pipeline_parallel_degree = 1
       dtype = properties['dtype']

       logging.info(f'Loading model: {model_name}')
       # Initializing model with FasterTransformer
       model = ft.init_inference(model_name, tensor_parallel_degree,
                                   pipeline_parallel_degree, dtype)
       return model

   def handle(inputs: Input):
       global model

       if not model:
           model = load_model(inputs.get_properties())

       if inputs.is_empty():
           # Model server makes an empty call to warmup the model on startup
           return None

       data = inputs.get_as_json()
       input_text = data['text']
       result = model.pipeline_generate(input_text)
       return Output().add(result)
   ```
3. Package your model artifacts into a compressed tar file. DJL Serving expects the model artifacts to be packaged and formatted in a specific way. This example uses the following directory structure for this purpose.

```
- deepspeed-gptj # root directory
  - serving.properties
  - model.py # your custom handler file, if you choose not to use the handlers provided with DJL Serving
```

The root directory contains the `serving.properties` and `model.py` files. The following code snippet packages the model artifacts into a compressed `.tar` file.

```
mkdir fastertransformer-t5
cp serving.properties fastertransformer-t5/
cp model.py fastertransformer-t5/
tar -czvf fastertransformer-t5.tar.gz fastertransformer-t5/
aws s3 cp fastertransformer-t5.tar.gz s3://djl-sm-test/tutorial/
```

**Deploy the model using the SageMaker SDK**

This example uses SageMaker to handle the end to end model deployment process to an inference endpoint.

1. Create a SageMaker session.

   ```python
   import boto3
   import sagemaker
   aws_region = "aws-region"
sagemaker_session = sagemaker.Session(boto_session=boto3.Session(region_name=aws_region))
   ```

2. Create a model in SageMaker.

   ```python
   from sagemaker.model import Model
   from sagemaker import image_uris, get_execution_role
   role = get_execution_role()

   def create_model(model_name, model_s3_url):
       image_uri = "763104351884.dkr.ecr.us-west-2.amazonaws.com/djl-inference:0.23.0-
                  fastertransformer5.3.0-cu118"
       model = Model(  
                       image_uri=image_uri,  
                       model_data=model_s3_url,  
                       role=role,  
                       name=model_name,  
                       sagemaker_session=sagemaker_session,
                     )
   return model
   ```

The `g5.12xlarge` instance has 4 Nvidia A10G GPUs. The `serving.properties` in [Preparing your model artifacts](p. 2559) specified a tensor parallel degree of 2. DJL Serving automatically loads 2 copies of the model with 2 tensor parallel partitions to make use of all the 4 GPUs on the instance. This doubles the throughput.

3. Deploy the model to a `g5.12xlarge` instance.
from sagemaker import serializers, deserializers

def deploy_model(model, _endpoint_name):
    model.deploy(
        initial_instance_count=1,
        instance_type="ml.g5.12xlarge",
        endpoint_name=_endpoint_name
    )
    predictor = sagemaker.Predictor(
        endpoint_name=_endpoint_name,
        sagemaker_session=sagemaker_session,
        serializer=serializers.JSONSerializer(),
        deserializer=deserializers.JSONDeserializer()
    )
    return predictor

4. Make a prediction

```python
_model_name = "ft-flan-t5-xl"
_model_s3_url = "s3://djl-sm-test/tutorial/fastertransformer-t5.tar.gz"
_endpoint_name="ft-flan-t5-xl"

model = create_model(_model_name, _model_s3_url)
predictor = deploy_model(model, _endpoint_name)
predictor.predict(
    {"text" : ["translate English to German: The house is wonderful."],
    })
```

5. Spin down the resources

```python
predictor.delete_endpoint(delete_endpoint_config=True)
```

**Large model inference with TorchServe**

This tutorial demonstrates how to deploy large models and serve inference in Amazon SageMaker with TorchServe on GPUs. This example deploys the OPT-30b model to an ml.g5 instance. You can modify this to work with other models and instance types. Replace the italicized placeholder text in the examples with your own information.

TorchServe is a powerful open platform for large distributed model inference. By supporting popular libraries like PyTorch, native PiPPy, DeepSpeed, and HuggingFace Accelerate, it offers uniform handler APIs that remain consistent across distributed large model and non-distributed model inference scenarios. For more information, see [TorchServe's large model inference documentation](#).

**Deep learning containers with TorchServe**

To deploy a large model with TorchServe on SageMaker, you can use one of the SageMaker deep learning containers (DLCs). By default, TorchServe is installed in all AWS PyTorch DLCs. During model loading, TorchServe is able to install specialized libraries tailored for large models such as PiPPy, Deepspeed, and Accelerate.

The following table lists all of the [SageMaker DLCs with TorchServe](#).
## Getting started

Before deploying your model, complete the prerequisites. You can also configure your model parameters and customize the handler code.

### Prerequisites

To get started, ensure that you have the following prerequisites:

1. Ensure you have access to an AWS account. Set up your environment so that the AWS CLI can access your account through either an AWS IAM user or an IAM role. We recommend using an IAM role. For the purposes of testing in your personal account, you can attach the following managed permissions policies to the IAM role:

   - AmazonEC2ContainerRegistryFullAccess
   - AmazonEC2FullAccess
   - AWSServiceRoleForAmazonEKSNodegroup
   - AmazonSageMakerFullAccess
   - AmazonS3FullAccess

   For more information about attaching IAM policies to a role, see Adding and removing IAM identity permissions in the AWS IAM User Guide.

2. Locally configure your dependencies, as shown in the following examples.

<table>
<thead>
<tr>
<th>DLC category</th>
<th>Framework</th>
<th>Hardware</th>
<th>Example URL</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>SageMaker Framework</strong></td>

2565
a. Install version 2 of the AWS CLI:

```bash
# Install the latest AWS CLI v2 if it is not installed
curl "https://awscli.amazonaws.com/awscli-exe-linux-x86_64.zip" -o "awscliv2.zip" !unzip awscliv2.zip #Follow the instructions to install v2 on the terminal
cat aws/README.md
```

b. Install SageMaker and the Boto3 client:

```bash
# If already installed, update your client
!%pip install sagemaker pip --upgrade --quiet
!pip install -U sagemaker
!pip install -U boto
!pip install -U botocore
!pip install -U boto3
```

Configure model settings and parameters

TorchServe uses `torchrun` to set up the distributed environment for model parallel processing. TorchServe has the capability to support multiple workers for a large model. By default, TorchServe uses a round-robin algorithm to assign GPUs to a worker on a host. In the case of large model inference, the number of GPUs assigned to each worker is automatically calculated based on the number of GPUs specified in the `model_config.yaml` file. The environment variable `CUDA_VISIBLE_DEVICES`, which specifies the GPU device IDs that are visible at a given time, is set based this number.

For example, suppose there are eight GPUs on a node and one worker needs four GPUs on a node (`nproc_per_node=4`). In this case, TorchServe assigns four GPUs to the first worker (`CUDA_VISIBLE_DEVICES="0,1,2,3"`) and four GPUs to the second worker (`CUDA_VISIBLE_DEVICES="4,5,6,7"`).

In addition to this default behavior, TorchServe provides the flexibility for users to specify GPUs for a worker. For instance, if you set the variable `deviceIds: [2,3,4,5]` in the `model config YAML file`, and set `nproc_per_node=2`, then TorchServe assigns `CUDA_VISIBLE_DEVICES="2,3"` to the first worker and `CUDA_VISIBLE_DEVICES="4,5"` to the second worker.

In the following `model_config.yaml` example, we configure both front-end and back-end parameters for the `OPT-30b` model. The configured front-end parameters are `parallelType`, `deviceType`, `deviceIds` and `torchrun`. For more detailed information about the front-end parameters you can configure, see the PyTorch GitHub documentation. The back-end configuration is based on a YAML map that allows for free-style customization. For the back-end parameters, we define the DeepSpeed configuration and additional parameters used by custom handler code.

```yaml
# TorchServe front-end parameters
minWorkers: 1
maxWorkers: 1
maxBatchDelay: 100
responseTimeout: 1200
parallelType: "tp"
deviceType: "gpu"
# example of user specified GPU deviceIds
deviceIds: [0,1,2,3] # sets CUDA_VISIBLE_DEVICES
torchrun:
  nproc-per-node: 4

# TorchServe back-end parameters
deepspeed:
  config: ds-config.json
```
checkpoint: checkpoints.json

handler: # parameters for custom handler code
    model_name: "facebook/opt-30b"
    model_path: "model/models--facebook--opt-30b/snapshots/ceea0a90ac0f6fae7c2c34bc60a77438c152546"
    max_length: 50
    max_new_tokens: 10
    manual_seed: 40

Customize handlers

TorchServe offers base handlers and handler utilities for large model inference built with popular libraries. The following example demonstrates how the custom handler class TransformersSeqClassifierHandler extends BaseDeepSpeedHandler and uses the handler utilities. For a full code example, see the custom_handler.py code on the PyTorch GitHub documentation.

class TransformersSeqClassifierHandler(BaseDeepSpeedHandler, ABC):
    
    Transformers handler class for sequence, token classification and question answering.
    
    def __init__(self):
        super(TransformersSeqClassifierHandler, self).__init__()
        self.max_length = None
        self.max_new_tokens = None
        self.tokenizer = None
        self.initialized = False

    def initialize(self, ctx: Context):
        
        super().initialize(ctx)
        model_dir = ctx.system_properties.get("model_dir")
        self.max_length = int(ctx.model_yaml_config["handler"]["max_length"]) 
        self.max_new_tokens = int(ctx.model_yaml_config["handler"]["max_new_tokens"]) 
        model_name = ctx.model_yaml_config["handler"]["model_name"]
        model_path = ctx.model_yaml_config["handler"]["model_path"]
        seed = int(ctx.model_yaml_config["handler"]["manual_seed"]) 
        torch.manual_seed(seed)

        logger.info("Model %s loading tokenizer", ctx.model_name)
        self.tokenizer = AutoTokenizer.from_pretrained(model_name)
        self.tokenizer.pad_token = self.tokenizer.eos_token
        config = AutoConfig.from_pretrained(model_name)
        with torch.device("meta"):
            self.model = AutoModelForCausalLM.from_config(config, torch_dtype=torch.float16)
        self.model = self.model.eval()
        ds_engine = get_ds_engine(self.model, ctx)
        self.model = ds_engine.module
        logger.info("Model %s loaded successfully", ctx.model_name)
        self.initialized = True

    def preprocess(self, requests):
        
        Basic text preprocessing, based on the user's choice of application mode.
def inference(self, input_batch):
    
    Predicts the class (or classes) of the received text using the serialized transformers checkpoint.
    Args:
        input_batch (tuple): A tuple with two tensors: the batch of input ids and the batch of attention masks, as returned by the preprocess function.
    Returns:
        list: A list of strings with the predicted values for each input text in the batch.

    

def postprocess(self, inference_output):
    
    """Post Process Function converts the predicted response into Torchserve readable format.
    Args:
        inference_output (list): It contains the predicted response of the input text.
    Returns:
        (list): Returns a list of the Predictions and Explanations.
    """

Prepare your model artifacts

Before deploying your model on SageMaker, you must package your model artifacts. For large models, we recommend that you use the PyTorch `torch-model-archiver` tool with the argument `--archive-format no-archive`, which skips compressing model artifacts. The following example saves all of the model artifacts to a new folder named opt/.

```
torch-model-archiver --model-name opt --version 1.0 --handler custom_handler.py --extra-files ds-config.json -r requirements.txt --config-file opt/model-config.yaml --archive-format no-archive
```

Once the opt/ folder is created, download the OPT-30b model to the folder using the PyTorch `Download_model` tool.

```
cd opt
python path_to/Download_model.py --model_path model --model_name facebook/opt-30b --revision main
```

Lastly, upload the model artifacts to an Amazon S3 bucket.

```
aws s3 cp opt {your_s3_bucket}/opt --recursive
```

You should now have model artifacts stored in Amazon S3 that are ready to deploy to a SageMaker endpoint.

Deploy the model using the SageMaker Python SDK

After preparing your model artifacts, you can deploy your model to a SageMaker Hosting endpoint. This section describes how to deploy a single large model to an endpoint and make streaming response
predictions. For more information about streaming responses from endpoints, see Invoke real-time endpoints.

To deploy your model, complete the following steps:

1. Create a SageMaker session, as shown in the following example.

```python
import boto3
import sagemaker
from sagemaker import Model, image_uris, serializers, deserializers

boto3_session = boto3.session.Session(region_name="us-west-2")
smr = boto3.client('sagemaker-runtime-demo')
sm = boto3.client('sagemaker')
role = sagemaker.get_execution_role()  # execution role for the endpoint
sess= sagemaker.session.Session(boto3_session, sagemaker_client=sm,
sagemaker_runtime_client=smr)  # SageMaker session for interacting with different AWS APIs
region = sess._region_name  # region name of the current SageMaker Studio environment
account = sess.account_id()  # account_id of the current SageMaker Studio environment

# Configuration:
bucket_name = sess.default_bucket()
prefix = "torchserve"
output_path = f"s3://{bucket_name}/{prefix}"
print(f"account={account}, region={region}, role={role}, output_path={output_path}")
```

2. Create an uncompressed model in SageMaker, as shown in the following example.

```python
from datetime import datetime
instance_type = "ml.g5.24xlarge"
endpoint_name = sagemaker.utils.name_from_base("ts-opt-30b")
s3_uri = {your_s3_bucket}/opt
model = Model(
    name="torchserve-opt-30b" + datetime.now().strftime("%Y-%m-%d-%H-%M-%S"),
    # Enable SageMaker uncompressed model artifacts
    model_data={
        "$3DataSource": {
            "$3Uri": s3_uri,
            "$3DataType": "$3Prefix",
            "$CompressionType": "None",
        }
    },
    image_uri=container,
    role=role,
    sagemaker_session=sess,
    env={"TS_INSTALL_PY_DEP_PER_MODEL": "true"},
)
print(model)
```

3. Deploy the model to an Amazon EC2 instance, as shown in the following example.

```python
model.deploy(
    initial_instance_count=1,
    instance_type=instance_type,
    endpoint_name=endpoint_name,
    volume_size=512,  # increase the size to store large model
    model_data_download_timeout=3600,  # increase the timeout to download large model
    container_startup_health_check_timeout=600,  # increase the timeout to load large model
)
```
4. Initialize a class to process the streaming response, as shown in the following example.

```python
import io
class Parser:
    """
    A helper class for parsing the byte stream input.
    
    The output of the model will be in the following format:
    ```
b'"outputs": [" a"]\n'b'"outputs": [" challenging"]\n'b'"outputs": [" problem"]\n'````

    While usually each PayloadPart event from the event stream will contain a byte array with a full json, this is not guaranteed and some of the json objects may be split across PayloadPart events. For example:
    ```
    {'PayloadPart': {'Bytes': b'"outputs": '}}
    {'PayloadPart': {'Bytes': b'" problem"]\n'```}

    This class accounts for this by concatenating bytes written via the 'write' function and then exposing a method which will return lines (ending with a '\n' character) within the buffer via the 'scan_lines' function. It maintains the position of the last read position to ensure that previous bytes are not exposed again.
    """
    def __init__(self):
        self.buff = io.BytesIO()
        self.read_pos = 0
    def write(self, content):
        self.buff.seek(0, io.SEEK_END)
        self.buff.write(content)
        data = self.buff.getvalue()
    def scan_lines(self):
        self.buff.seek(self.read_pos)
        for line in self.buff.readlines():
            if line[-1] != b'
':  # '\n' character
                self.read_pos += len(line)
                yield line[:-1]
    def reset(self):
        self.read_pos = 0
```

5. Test a streaming response prediction, as shown in the following example.

```python
import json
body = "Today the weather is really nice and I am planning on".encode('utf-8')
resp = smr.invoke_endpoint_with_response_stream(EndpointName=endpoint_name, Body=body,
    ContentType="application/json")
earvent_stream = resp['Body']
parser = Parser()
for event in event_stream:
```
You have now deployed your model to a SageMaker endpoint and should be able to invoke it for responses. For more information about SageMaker real-time endpoints, see Host a single model (p. 2389).

Additional resources to get started

For more information about using SageMaker LMI DLCs, see the following resources:

- Blog: Deploy large language models on AWS Inferentia2 using large model inference containers
- Blog: Deploy BLOOM-176B and OPT-30B on Amazon SageMaker with large model inference Deep Learning Containers and DeepSpeed
- Blog: Deploy large models on Amazon SageMaker using DJL Serving and DeepSpeed model parallel inference
- Example notebooks: AWS SageMaker examples GitHub repository.

Configurations and settings

The following sections describe the configuration options you can use inside the serving.properties file.

**DJL Serving general settings**

The following table identifies the general DJL Serving configuration options that you can use in serving.properties, irrespective of whatever handler you choose.

<table>
<thead>
<tr>
<th>Item</th>
<th>Required</th>
<th>Description</th>
<th>Example value</th>
</tr>
</thead>
<tbody>
<tr>
<td>engine</td>
<td>Yes</td>
<td>The runtime engine of the code.</td>
<td>Python, DeepSpeed, FasterTransformer, MPI</td>
</tr>
<tr>
<td>option.dtype</td>
<td>No</td>
<td>The precision with which you want to run inference.</td>
<td>fp16, int8 (default = fp32)</td>
</tr>
<tr>
<td>option.enable_streaming</td>
<td>No</td>
<td>Enables response streaming. Set the value huggingface to activate streaming output in the style of Hugging Face.</td>
<td>false, true, huggingface</td>
</tr>
<tr>
<td>option.entryPoint</td>
<td>No</td>
<td>If you don't provide this option, DJL Serving looks for model.py in the model directory.</td>
<td>djl_python.deepspeed, djl_python.huggingface, djl_python.fastertransformer</td>
</tr>
<tr>
<td>option.s3url</td>
<td>No</td>
<td>Set to download model artifacts from an s3:/djl-llm/gpt-j-6b</td>
<td></td>
</tr>
</tbody>
</table>
### Item | Required | Description | Example value
--- | --- | --- | ---
Amazon S3 bucket using the built-in s5cmd library. | | |
**option.tensor_parallel_degree** | No | If you plan to run in multiple GPUs, use this option to set the number of GPUs per worker. | 2, 4, 8

### Hugging Face handler settings

If you use the Hugging Face handler provided by DJL Serving, you can configure the options in the following table in `serving.properties`.

| Item | Required | Description | Example value |
--- | --- | --- | ---
**option.decoding_strategy** | No | This option is only supported for `option.rolling_batch=scheduler`. Default: greedy | sample, greedy, contrastive
| **option.device_id** | No | Set to load the model on a specific device. Don't set this option if you use `option.tensor_parallel_device`. | 0, 1
| **option.device_map** | No | Hugging Face Accelerate options to choose device mapping config. | balanced, auto, sequential, or any custom dictionary
| **option.dtype** | No | The data type to which you plan to cast the model default. | float16, float32, bfloat16
| **option.load_in_4bit** | No | Use bitsandbytes quantization. Supported only on certain models. | Default: false
| **option.load_in_8bit** | No | Use bitsandbytes quantization. Supported only on certain models. | true
| **option.low_cpu_mem_usage** | No | Reduces CPU memory usage when loading models. We recommend that you set this option to true. | true
<table>
<thead>
<tr>
<th>Item</th>
<th>Required</th>
<th>Description</th>
<th>Example value</th>
</tr>
</thead>
<tbody>
<tr>
<td>option.max_rolling_batch_prefill_tokens</td>
<td>No</td>
<td>Only supported for option.rolling_batch=lmi-dist. Limits the number of tokens for caching. This needs to be tuned based on batch size and input sequence length to avoid GPU OOM.</td>
<td>Default: 1088</td>
</tr>
<tr>
<td>option.max_rolling_batch_size</td>
<td>No</td>
<td>Limits the number of concurrent requests.</td>
<td>Default: 32</td>
</tr>
<tr>
<td>option.model_dir</td>
<td>No</td>
<td>The directory path to load the model from. The default is set to the current path with model files.</td>
<td>/opt/djl/ml</td>
</tr>
<tr>
<td>option.model_id</td>
<td>No</td>
<td>Set this option to download a model from Hugging Face. If set, this option overrides option.model_dir.</td>
<td>Any ID used in Hugging Face</td>
</tr>
<tr>
<td>optionpaged_attention</td>
<td>No</td>
<td>Only supported for option.rolling_batch=lmi-dist. Enabling this would require more GPU memory to be preallocated for caching.</td>
<td>Default: true</td>
</tr>
<tr>
<td>option.revision</td>
<td>No</td>
<td>Use a particular version or commit hash of a Hugging Face hub model.</td>
<td>Default: None</td>
</tr>
<tr>
<td>option.rolling_batch</td>
<td>No</td>
<td>Enable iteration level batching using one of the supported strategies.</td>
<td>auto, scheduler, lmi-dist</td>
</tr>
<tr>
<td>option.task</td>
<td>No</td>
<td>The task used in Hugging Face for different pipelines.</td>
<td>text-generation</td>
</tr>
<tr>
<td>option.trust_remote_code</td>
<td>No</td>
<td>Set to true to use a HF hub model with custom code.</td>
<td>Default: false</td>
</tr>
<tr>
<td>option.quantize</td>
<td>No</td>
<td>Only supported for option.rolling_batch=lmi-dist. Only supported value is bitsandbytes.</td>
<td>bitsandbytes</td>
</tr>
</tbody>
</table>

2573
## DeepSpeed handler settings

If you use the DeepSpeed handler provided by DJL Serving, you can configure the options in the following table in `serving.properties`.

<table>
<thead>
<tr>
<th>Item</th>
<th>Required</th>
<th>Description</th>
<th>Example value</th>
</tr>
</thead>
<tbody>
<tr>
<td>option.checkpoint</td>
<td>No</td>
<td>The path to the DeepSpeed compatible checkpoint file.</td>
<td>ds_inference_checkpoint.json</td>
</tr>
<tr>
<td>option.dtype</td>
<td>No</td>
<td>The data type to which you plan to cast the model default.</td>
<td>fp16, fp32, bf16, int8</td>
</tr>
<tr>
<td>option.enable_cuda_graph</td>
<td>No</td>
<td>Activates capturing the CUDA graph of the forward pass to accelerate subsequent inference passes. Cannot be used with tensor parallelism.</td>
<td>true</td>
</tr>
<tr>
<td>option.low_cpu_mem_usage</td>
<td>No</td>
<td>Reduce CPU memory usage when loading models. We recommend that you set this to true.</td>
<td>true</td>
</tr>
<tr>
<td>option.max_tokens</td>
<td>No</td>
<td>Total number of tokens (input and output) with which DeepSpeed can work. The number of output tokens is the difference between the total number of tokens and the number of input tokens.</td>
<td>1024</td>
</tr>
<tr>
<td>option.model_dir</td>
<td>No</td>
<td>The directory path to load the model. Default is set to the current path with model files.</td>
<td>/opt/djl/ml</td>
</tr>
<tr>
<td>option.model_id</td>
<td>No</td>
<td>This overrides <code>option.model_dir</code> if set. Used to download model from Hugging Face.</td>
<td>Any ID used in Hugging Face</td>
</tr>
<tr>
<td>option.return_tuple</td>
<td>No</td>
<td>Whether transformer layers need to return a tuple or a tensor.</td>
<td>false</td>
</tr>
<tr>
<td>option.task</td>
<td>No</td>
<td>The task used in Hugging Face for different pipelines.</td>
<td>text-generation</td>
</tr>
<tr>
<td>Item</td>
<td>Required</td>
<td>Description</td>
<td>Example value</td>
</tr>
<tr>
<td>--------------------------</td>
<td>----------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------------</td>
</tr>
<tr>
<td>option.training_mp_size</td>
<td>No</td>
<td>If the model was trained with DeepSpeed, this indicates the tensor parallelism degree with which the model was trained. Can be different than the tensor parallel degree desired for inference.</td>
<td>2</td>
</tr>
<tr>
<td>option.triangular_masking</td>
<td>No</td>
<td>Whether to use triangular masking for the attention mask. This is application or model specific.</td>
<td>false</td>
</tr>
</tbody>
</table>

**FasterTransformer handler settings**

If you use the FasterTransformer handler provided by DJL Serving, you can configure the options in the following table in `serving.properties`.

<table>
<thead>
<tr>
<th>Item</th>
<th>Required</th>
<th>Description</th>
<th>Example value</th>
</tr>
</thead>
<tbody>
<tr>
<td>option.model_dir</td>
<td>No</td>
<td>The directory path to load the model. Default is set to the current path with model files.</td>
<td>Default: /opt/djl/ml</td>
</tr>
<tr>
<td>option.model_id</td>
<td>No</td>
<td>This overrides option.model_dir if set. Used to download model from Hugging Face or S3 bucket</td>
<td>google/flan-t5-xl, s3://my-bucket/google/flan-t5-xl</td>
</tr>
</tbody>
</table>

**Neuronx LMI handler settings**

If you use the Neuronx LMI handler provided by DJL Serving, you can configure the options in the following table in `serving.properties`.

<table>
<thead>
<tr>
<th>Item</th>
<th>Required</th>
<th>Description</th>
<th>Example value</th>
</tr>
</thead>
<tbody>
<tr>
<td>option.n_positions</td>
<td>No</td>
<td>The input sequence length.</td>
<td>Default: 128</td>
</tr>
<tr>
<td>option.unroll</td>
<td>No</td>
<td>Set to unroll the model graph for compilation. If you set unroll=None, the compiler will have more opportunities</td>
<td>Default: None</td>
</tr>
</tbody>
</table>
Choosing instance types for large model inference

When deploying deep learning models, we typically balance the cost of hosting these models against the performance in terms of latency, throughput, and accuracy. A core input to this equation is the SageMaker instance type. SageMaker offers many instance types with different GPU devices. For a given model, there are likely multiple suitable instances for hosting the model for inference. Benchmarking can help you to decide with which instance to proceed.

The following sections provide some guidelines that you can follow to determine which instance type to choose for hosting large models. To use these guidelines, you should know the following characteristics of your use case:

- Model architecture or type, such as OPT, GPTJ, BLOOM, or Bert
- Data type precision, such as fp32, fp16, bf16, or int8
- Model size in MB or GB
- Input and output token sizes

Determining possible instance types

When choosing an instance type, consider the size of the model as well as available GPU devices. The large model inference (LMI) containers are currently only supported on instances with NVIDIA GPUs, and are not supported on Graviton instances. For the most up-to-date information on available GPU instances, see Recommended GPU Instances.

When deploying large models, the ideal situation is to fit the model on a single GPU. This is the best option with respect to performance as it eliminates the overhead of communication between GPU devices. For some models it is simply impossible to fit them on a single GPU due to model size. For other models, they may fit on a single GPU, but it may be more cost effective to partition the model across multiple cheaper GPUs.

The following sections show how you can develop a metric to filter the list of available GPUs to ones that are likely to work for your use case.

Determining possible instance types based on data type

The GPUs available on SageMaker differ in their native support of data types. If you are planning to deploy your model with bf16, choose an instance with GPU devices that support compute capability 7.5+. If you are planning to deploy with int8, we highly recommend that you select an instance with GPU devices that support compute capability 7.5+ as these GPUs contain int8 tensor cores. However, you can still deploy with int8 using either HuggingFace Accelerate (using bitsandbytes quantization) or DeepSpeed (using ZeroQuant quantization) on lower compute capabilities. You should expect lower performance if you go this route compared to using GPUs with native support for int8 math.

To verify the compute capability of the GPU, see Your GPU Compute Capability on NVIDIA's website.

Estimating a lower bound for the memory required to host a model

To further filter the list of GPUs, determine how large your model is for the data type precision with which you wish to host the model. If the size of the model can fit on a single GPU, and low latency is
Choosing an instance type for LMI

the highest priority, we recommend choosing an instance with a GPU that has sufficient memory to host this model. You can estimate a lower bound for the memory required to host your model based on the number of parameters in your model and the data type. This lower bound memory estimate (LBME) represents the bare minimum memory in bytes required to load the model parameters into the GPU memory. Calculate the LBME using the following equations:

- int8 – LBME = number of parameters
- fp16 and bf16 – LBME = 2 × number of parameters
- fp32 – LBME = 4 × number of parameters

Determining possible instances based on number of partitions

Determining the level of partitioning to use with your model comes down to the following factors:

- Size of the model
- Cost you are willing to pay for an instance
- Availability of a given instance
- Your latency requirements

For example, the EleutherAI/GPT-NEOX-20b model takes about 45 GB to host in fp16. You can deploy this model using a p4de.24xlarge instance without any sharing since the GPU memory available per device is 80 GB. This is the only GPU currently on AWS that would support fitting this model fully on the device. With 8 GPUs on that instance, you can host 8 copies of the model. Alternatively, you can also deploy this model with 2-way partitioning on a g5.12xlarge. With 4 GPUs, you can host 2 copies of the model. Using 4 g5.12xlarge instances to host 8 copies of this model compared to 1 p4de.24xlarge instance is close to half the cost (though the remaining GPU memory on the p4de.24xlarge supports larger batch sizes). While performance is likely lower on the g5.12xlarge, it might make more sense from a cost perspective.

Some instances may not be readily available in certain AWS Regions. You can check the availability of an instance with a Region/Availability Zone using the AWS CLI:

```
aws ec2 describe-instance-type-offerings --location-type "availability-zone" --filters Name=location,Values=us-east-2a --region us-east-2 --query "InstanceTypeOfferings[*].[InstanceType]" --output text | sort
```

Choosing an engine

LMI deep learning containers (DLCs) provide support for DeepSpeed, FasterTransformer and HuggingFace Accelerate backends. All of these frameworks can be used to deploy and host large models partitioned across multiple GPUs. You can typically expect higher performance (lower latency or higher throughput) with DeepSpeed or FasterTransformer, but these engines do not offer optimized inference
for all model architectures. All frameworks also implement model parallelism differently. DeepSpeed and FasterTransformer use tensor parallelism, which is typically more performant at the cost of higher GPU memory usage. HuggingFace Accelerate uses pipeline parallelism which uses less memory but is also less performant.

We recommend that you use DeepSpeed or FasterTransformer when possible because the fused CUDA kernels significantly improve performance compared to using HuggingFace Accelerate. DeepSpeed currently offers fused kernel implementations for the following model architectures:

- Bert
- DistilBert
- GPT Neo, GPT Neo X, GPT2
- OPT
- BLOOM
- Megatron
- Stable Diffusion

FasterTransformer offers fused kernel implementations for the following model architectures:

- GPT2
- OPT
- BLOOM
- T5

For other model architectures there aren't any significant difference. We recommend that you experiment with both DeepSpeed and HuggingFace Accelerate to determine which engine works best for your model. To see which models FasterTransformer supports, see the FasterTransformer support matrix.

To choose an instance type, adjust your LBME for the specific engines. Estimating the expected GPU usage also differs between DeepSpeed, FasterTransformer and HuggingFace Accelerate due to differences in how they run model parallelism.

DeepSpeed and FasterTransformer use tensor parallelism. Some modules, such as embeddings, do not support tensor parallelism. These modules are replicated across all GPUs. HuggingFace Accelerate uses naive pipeline partitioning, which does not result in replicated modules. Thus with DeepSpeed or FasterTransformer you can typically expect memory requirements to increase with the tensor parallelism degree.

The following sections show how you can adjust your LBME to get a loaded model memory estimate (LMME), which is an estimate of the memory required per GPU to load your model.

**HuggingFace Accelerate**

With HuggingFace Accelerate, the pipeline partitioning does not significantly increase the memory required to load the model. No sub-modules need to be duplicated across GPUs.

- For single GPU deployment, $\text{LMME} = 1.15 \times \text{LBME}$.
- For multiple GPUs deployment, $\text{LMME} = (1.15 + 0.035 \times \text{number of partitions}) \times \text{LBME}$.
  Here the number of partitions is assumed to be a multiple of 2.

**DeepSpeed or FasterTransformer**

With DeepSpeed or FasterTransformer, the tensor parallel partitioning results in some sub-modules of the model being duplicated since not every module supports tensor parallelism. The level of module replication strongly depends on the model architecture.
• For single GPU deployment, \( \text{LMME} = 1.20 \times \text{LBME} \).
• For multiple GPUs deployment, \( \text{LMME} = \text{multiplier} \times \text{LBME} \), where the multiplier strongly depends on the model architecture, and the data type. For some popular architectures, we present the recommended multipliers in the following table:

<table>
<thead>
<tr>
<th>Model architecture</th>
<th>fp32</th>
<th>fp16</th>
<th>int8</th>
</tr>
</thead>
<tbody>
<tr>
<td>GPT variants</td>
<td>1.45</td>
<td>1.55</td>
<td>1.55</td>
</tr>
<tr>
<td>Bloom variants</td>
<td>1.5</td>
<td>1.55</td>
<td>1.55</td>
</tr>
<tr>
<td>OPT variants</td>
<td>1.55</td>
<td>1.75</td>
<td>1.75</td>
</tr>
<tr>
<td>Other models</td>
<td>1.5</td>
<td>1.5</td>
<td>1.5</td>
</tr>
</tbody>
</table>

### Adjusting loaded model memory estimate for sequence length and batch size

During inference more memory is required for the input tensors, intermediate tensors, and output tensors, than what your LMME suggests. You also need to account for additional memory required as a result of partitioning the model.

The runtime model memory estimate (RMME), defined in the following equation, accounts for the additional memory requirement based on the sequence length (total number of input and output tokens):

\[
\text{RMME per GPU} = \text{multiplier} \times \frac{\text{LMME}}{\text{number of partitions}}
\]

The recommended multipliers listed below are based on a sequence length of 1024. If you plan to use shorter or longer sequences you can further adjust these multipliers by multiplying them by sequence length / 1024.

• GPT variants – \( 1.1 + 0.05 \times (\text{number of partitions} - 1) \)
• BLOOM variants – \( 1.15 + 0.05 \times (\text{number of partitions} - 1) \)
• OPT variants – \( 1.20 + 0.1 \times (\text{number of partitions} - 1) \)

If you plan on accommodating batch sizes larger than 1, multiply the aforementioned multiplier by your expected batch size, to get the final multiplier for calculating RMME per GPU.

### Finalizing possible instance types

With the RMME per GPU you can filter the list of available GPUs to ones that are likely to work for your use case. RMME per GPU is an intentionally cautious metric to account for the performance variance between different model architectures with different data types and engine framework versions. If you find that any instances are barely excluded by your estimate, we recommend trying them out.

### Deploying uncompressed models

When deploying ML models, one option is to archive and compress the model artifacts into a \texttt{tar.gz} format. Although this method works well for small models, compressing a large model artifact with hundreds of billions of parameters and then decompressing it on an endpoint can take a significant amount of time. For large model inference, we recommend that you deploy uncompressed ML model. This guide shows how you can deploy uncompressed ML model.
To deploy uncompressed ML models, upload all model artifacts to Amazon S3 and organize them under a common Amazon S3 prefix. A Amazon S3 prefix is a string of characters at the beginning of an Amazon S3 object key name, separated from the rest of the name by a delimiter. For more information on Amazon S3 prefix, see Organizing objects using prefixes.

For deploying with SageMaker, you must use slash (/) as the delimiter. You have to ensure that only artifacts associated with your ML model are organized with the prefix. For ML models with a single uncompressed artifact, the prefix will be identical to the key name. You can check which objects are associated with your prefix with the AWS CLI:

```bash
aws s3 ls --recursive s3://bucket/prefix
```

After uploading the model artifacts to Amazon S3 and organizing them under a common prefix, you can specify their location as part of the `ModelDataSource` field when you invoke the `CreateModel` request. SageMaker will automatically download the uncompressed model artifacts to `/opt/ml/model` for inference. For more information about the rules that SageMaker when downloading the artifacts, see `S3ModelDataSource`.

The following code snippet shows how you can invoke the `CreateModel` API when deploying an uncompressed model. Replace the italicized user text with your own information.

```python
model_name = "model-name"
sagemaker_role = "arn:aws:iam::123456789012:role/SageMakerExecutionRole"
container = "123456789012.dkr.ecr.us-west-2.amazonaws.com/inference-image:latest"

create_model_response = sagemaker_client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = sagemaker_role,
    PrimaryContainer = {
        "Image": container,
        "ModelDataSource": {
            "S3DataSource": {
                "S3Uri": "s3://my-bucket/prefix/to/model/data/",
                "S3DataType": "S3Prefix",
                "CompressionType": "None",
            },
        },
    },
)
```

The aforementioned example assumes that your model artifacts are organized under a common prefix. If instead your model artifact is a single uncompressed Amazon S3 object, then change "S3Uri" to point to the Amazon S3 object, and change "S3DataType" to "S3Object".

**Note**

## Large model inference FAQs

Refer to the following FAQ items for answers to commonly asked questions about large model inference (LMI) with SageMaker.

### Q: When should I use LMI DLCs?

**A:** Large model inference deep learning containers (LMI DLCs) include tested versions of popular model parallelization and optimization libraries for hosting models with tens or hundreds of billions of...
parameters. You should use an LMI DLC if your deep learning model requires multiple accelerators for hosting or if you want to accelerate inference with a popular, supported model such as GPT, Bloom, and OPT.

Q: Who can I contact if something doesn't work?

A: If, after reviewing the documentation, you continue to have problems hosting your large model, contact us at LMI-DLC-feedback@amazon.com.

Q: Can I use large model inference deep learning containers (LMI DLCs) outside of SageMaker?

A: AWS LMI DLCs have been tested on and designed for SageMaker, but can be used on Amazon EC2 with supported instance types (p. 2557).

Q: What model formats can I use with LMI DLCs?

AWS LMI DLCs include a convenience function to load a Hugging Face model format. You can bring models in another format, such as Megatron checkpoint, but you need to write logic to load that format or convert to a Hugging Face format.

Q: How can I switch between model parallelization libraries such as Hugging Face Accelerate and DeepSpeed?

If you're using the DJL handler (like in the tutorial (p. 2558) example), then switch the default engine and handler in the serving.properties file. For example, modify the engine and option.entryPoint settings to switch from DeepSpeed to Hugging Face. In general, you can switch the engine and use the same tensor parallel degree.

Large model inference troubleshooting

If you run into any problem or error, you can try to use the following list to troubleshoot. If the problem persists, contact us at LMI-DLC-feedback@amazon.com.

Topics

- Downloading a model to my instance takes a long time (p. 2581)
- Inference latency or throughput performance is poor (p. 2581)
- SageMaker endpoint failed to start with a timeout or out of memory error (p. 2582)

Downloading a model to my instance takes a long time

Consider using option.s3url in your serving.properties configuration file. This downloading method uses s5cmd and speeds up data downloading. Make sure that the container has permission to access the specified Amazon S3 bucket.

Inference latency or throughput performance is poor

Even with model parallelism, large models can still have poor performance such as high latency or low throughput. First, if your model is supported, consider using the DeepSpeed engine that includes optimized kernels for inference. This can improve performance by up to 3 times. Next, consider using a more powerful instance type, such as a p4d.24xlarge instance. Finally, consider using a smaller model. To achieve the best performance and lowest cost, try to find the smallest model that meets the accuracy bar for your use case, as more parameters can result in higher latency, lower throughput, or higher cost. Consider fine-tuning a smaller model to improve accuracy.
SageMaker endpoint failed to start with a timeout or out of memory error

Large models can require more time to load to memory. You must adjust default endpoint configurations to handle this incremental time. If an endpoint fails a health check or is out of memory, check that you have configured your endpoint appropriately. For example, if Amazon CloudWatch Logs indicate a health check timeout, you should increase the `ContainerStartupHealthCheckTimeoutInSeconds` parameter of `ProductionVariant` during the `create_endpoint_config` step of hosting on SageMaker.

For more information on these parameters, see SageMaker endpoint parameters for large model inference (p. 2557).

Release notes for large model inference deep learning containers

You can find a list of deep learning containers (DLCs) supported by SageMaker on the AWS DLC GitHub repository. Below are the associated release notes.

Topics

- LMI DLC Release Notes: August 4, 2023 (1) (p. 2582)
- LMI DLC Release Notes: August 4, 2023 (2) (p. 2583)
- LMI DLC Release Notes: August 4, 2023 (3) (p. 2584)
- LMI DLC Release Notes: March 7, 2023 (p. 2584)
- LMI DLC Release Notes: February 24, 2023 (p. 2585)
- LMI DLC Release Notes: December 16, 2022 (p. 2585)
- LMI DLC Release Notes: November 4, 2022 (p. 2586)

LMI DLC Release Notes: August 4, 2023 (1)

Container URI

- 763104351884.dkr.ecr.region.amazonaws.com/djl-inference:0.23.0-fastertransformer5.3.0-cu118

Highlights

- Added support for serving GPT-NeoX models.
- New containers support response streaming.
- FasterTransformer handler updated to support PEFT and LORA.
- DJLServing provides integration to the Triton inference backend through the java-cpp API.

Version updates

- DJL Serving 0.23.0
- PyTorch 2.0.1
- FasterTransformer 5.3.0
- Hugging Face Accelerate 0.20.3
- Hugging Face Transformers 4.30.1
- Hugging Face Diffusers 0.12.0
- Python 3.9
- CUDA 11.8

**Supported model architectures**

- GPT
- GPT-J
- GPT-NeoX
- T5
- OPT
- Bloom

**LMI DLC Release Notes: August 4, 2023 (2)**

**Container URI**

- 763104351884.dkr.ecr.region.amazonaws.com/djl-inference:0.23.0-deepspeed0.9.5-cu118

**Highlights**

- Upgrades the DeepSpeed DLC container to DeepSpeed 0.9.5.
- Improvements made to enable 2-3x memory savings over oss DeepSpeed.
- Added PyTorch-2.0.1, PEFT, and LORA support to DeepSpeed default handlers. This new release of DeepSpeed adds support for LLaMA v1 models.
- Added iteration-level batching support to the Hugging Face backend for GPT, LLaMA, Falcon, and T5 model architectures. This improves model serving throughput.

**Version updates**

- DJL Serving 0.23.0
- DeepSpeed 0.9.5
- Hugging Face Accelerate 0.20.3
- Hugging Face Transformers 4.30.2
- Python 3.9
- CUDA 11.8

**Supported model architectures**

- Models supported by DeepSpeed 0.9.5 using the DeepSpeed engine
- Models supported by HuggingFace Accelerate using the Accelerate engine
- Iteration-level batching support for GPT, LLaMA, LLaMA 2, Falcon, and T5 model architectures using the MPI engine
- Paged Attention and Flash Attention support for GPT, LLaMA, LLaMA 2, Falcon and T5 model architectures using the MPI engine
LMI DLC Release Notes: August 4, 2023 (3)

Container URI

- 763104351884.dkr.ecr.region.amazonaws.com/djl-inference:0.23.0-neuronx-sdk2.12.0

Highlights

- [Experimental] Added support for GPT-NeoX models.
- [Experimental] Added support for BLOOM models.
- [Prototype] Added support for LLaMA models.
- Added support for more flexible tensor-parallel configurations to GPT2, OPT, and BLOOM.
- Added multi-query/multi-group attention support for GPT2.

Version updates

- DJL Serving 0.23.0
- Torch Neuronx 1.13.1.1.9.0
- Transformers NeuronX 0.4.149
- Hugging Face Accelerate 0.20.3
- Hugging Face Transformers 4.30.1
- Hugging Face Diffusers 0.14.0

Supported model architectures

- OPT
- GPT2
- GPT-J
- GPT-NeoX
- LLaMA
- LLaMA-2 7B and 13B
- Bloom

LMI DLC Release Notes: March 7, 2023

Container URI

- 763104351884.dkr.ecr.region.amazonaws.com/djl-inference:0.21.0-fastertransformer5.3.0-cu117

Highlights

- The FasterTransformer (FT) model parallel library is now available in LMI DLCs, adding support for popular models such as flan-t5-xxl and flan-ul2. FT is an open-source library from Nvidia that provides an accelerated engine for efficiently running transformer-based neural network inference. It is designed to handle large models that require multiple GPUs and nodes in a distributed manner. The library includes an optimized version of the transformer block, which comprises both the encoder and decoder parts, enabling you to run the inference of full encoder-decoder architectures like T5, as well as encoder-only models like BERT and decoder-only models like GPT.
Version updates

- DJL Serving 0.21.0
- FasterTransformer 5.3.0
- Hugging Face Accelerate 0.16.0
- Hugging Face Transformers 4.26.0
- Hugging Face Diffusers 0.12.0
- Python 3.9
- CUDA 11.6

Known issues

- In this first release, you may see long model loading times when using the FT library. Make sure to configure health check and timeout values (see SageMaker endpoint parameters for large model inference (p. 2557)) to allow sufficient time to load the model. In our tests, 1 hour was sufficient. Future releases will address this long model loading time with FT.

LMI DLC Release Notes: February 24, 2023

Container URI

- 763104351884.dkr.ecr.region.amazonaws.com/djl-inference:0.21.0-deepspeed0.8.0-cu117

Highlights

- SageMaker Python SDK integration is new in this release, enabling no-code deployment of large language models

  Ahead-of-time partitioning support with DeepSpeed reduces endpoint start up time by separating model partitioning from runtime

Version updates

- DJL Serving 0.21.0
- DeepSpeed 0.8.0
- Hugging Face Accelerate 0.16.0
- Hugging Face Transformers 4.26.0
- Hugging Face Diffusers 0.12.0
- Python 3.9
- CUDA 11.6

LMI DLC Release Notes: December 16, 2022

Container URI

- 763104351884.dkr.ecr.region.amazonaws.com/djl-inference:0.20.0-deepspeed0.7.5-cu116

Highlights

• Added BF16 precision support for models supported by DeepSpeed inference (Bloom, GPT, OPT, etc.). Training in BF16 does not require any extra transformations to the model weights before hosting with DeepSpeed.
• Added support for Hugging Face Diffusers and StableDiffusion models.
• Includes latest versions of DJL Serving, DeepSpeed, Hugging Face Transformers, and CUDA drivers, which bring stability improvement, better error handling, improved model coverage, and latency.

Version updates

• DJL Serving 0.20.0
• DeepSpeed 0.7.5
• Hugging Face Accelerate 0.13.2
• Hugging Face Transformers 4.23.1
• Hugging Face Diffusers 0.7.2
• CUDA 11.6

LMI DLC Release Notes: November 4, 2022

Highlights

• Launched LMI DLCs on AWS. SageMaker and Amazon EC2 support LMI DLCs for inference using model parallelism.

Container URI

• 763104351884.dkr.ecr.{region}.amazonaws.com/djl-inference:0.19.0-deepspeed0.7.3-cu113

Blogs

• For more information, see Deploy BLOOM-176B and OPT-30B on Amazon SageMaker with large model inference Deep Learning Containers and DeepSpeed.

Update models in production

Deployment guardrails are a set of model deployment options in Amazon SageMaker Inference to update your machine learning models in production. Using the fully managed deployment options, you can control the switch from the current model in production to a new one. Traffic shifting modes in blue/green deployments, such as canary and linear, give you granular control over the traffic shifting process from your current model to the new one during the course of the update. There are also built-in safeguards such as auto-rollbacks that help you catch issues early and automatically take corrective action before they significantly impact production.

Deployment guardrails provide the following benefits:

• Deployment safety while updating production environments. A regressive update to a production environment can cause unplanned downtime and business impact, such as increased model latency and high error rates. Deployment guardrails help you mitigate those risks by providing best practices and built-in operational safety guardrails.

• Fully managed deployment. SageMaker takes care of setting up and orchestrating these deployments and integrates them with endpoint update mechanisms. You do not need to build and maintain
orchestration, monitoring, or rollback mechanisms. You can leverage SageMaker to set up and orchestrate these deployments and focus on leveraging ML for your applications.

- **Visibility.** You can track the progress of your deployment through the `DescribeEndpoint` API or through Amazon CloudWatch Events (for supported endpoints [p. 2606]). To learn more about events in SageMaker, see the Endpoint deployment state change section in Automating Amazon SageMaker with Amazon EventBridge (p. 3597). Note that if your endpoint uses any of the features in the Exclusions (p. 2606) page, you cannot use CloudWatch Events.

**Note**
Deployment guardrails only apply to Asynchronous inference (p. 2522) and Real-time inference (p. 2388) endpoint types.

## How to get started

We support two types of deployments to update models in production: blue/green deployments and rolling deployments.

- **Blue/Green Deployments (p. 2590):** You can shift traffic from your old fleet (the blue fleet) to a new fleet (green fleet) with the updates. Blue/green deployments offer multiple traffic shifting modes. A traffic shifting mode is a configuration that specifies how SageMaker routes endpoint traffic to a new fleet containing your updates. The following traffic shifting modes provide you with different levels of control over the endpoint update process:
  
  - **All At Once Traffic Shifting (p. 2591)** shifts all of your endpoint traffic from the blue fleet to the green fleet. Once the traffic shifts to the green fleet, your pre-specified Amazon CloudWatch alarms begin monitoring the green fleet for a set amount of time (the *baking period*). If no alarms trip during the baking period, then SageMaker terminates the blue fleet.
  
  - **Canary Traffic Shifting (p. 2594)** shifts one small portion of your traffic (a *canary*) to the green fleet and monitor it for a baking period. If the canary succeeds on the green fleet, then SageMaker shifts the rest of the traffic from the blue fleet to the green fleet before terminating the blue fleet.
  
  - **Linear Traffic Shifting (p. 2599)** provides even more customization over the number of traffic-shifting steps and the percentage of traffic to shift for each step. While canary shifting lets you shift traffic in two steps, linear shifting extends this to *n* linearly spaced steps.

- **Rolling Deployments (p. 2603):** You can update your endpoint as SageMaker incrementally provisions capacity and shifts traffic to a new fleet in steps of a batch size that you specify. Instances on the new fleet are updated with the new deployment configuration, and if no CloudWatch alarms trip during the baking period, then SageMaker cleans up instances on the old fleet. This option gives you granular control over the instance count or capacity percentage shifted during each step.

You can create and manage your deployment through the `UpdateEndpoint` and `CreateEndpoint` SageMaker API and AWS Command Line Interface commands. See the individual deployment pages for more details on how to set up your deployment. Note that if your endpoint uses any of the features listed in the Exclusions (p. 2606) page, you cannot use deployment guardrails.

To follow guided examples that shows how to use deployment guardrails, see our example Jupyter notebooks for the canary and linear traffic shifting modes.

## Auto-Rollback Configuration and Monitoring

Amazon CloudWatch alarms are a prerequisite for using baking periods in deployment guardrails. You can only use the auto-rollback functionality in deployment guardrails if you set up CloudWatch alarms that can monitor an endpoint. If any of your alarms trip during the specified monitoring period, SageMaker initiates a complete rollback to the old endpoint to protect your application. If you do not have any CloudWatch alarms set up to monitor your endpoint, then the auto-rollback functionality does not work during your deployment.
To learn more about Amazon CloudWatch, see What is Amazon CloudWatch? in the Amazon CloudWatch User Guide.

**Note**
Ensure that your IAM execution role has permission to perform the cloudwatch:DescribeAlarms action on the auto-rollback alarms you specify.

### Alarm Examples

To help you get started, we provide the following examples to demonstrate the capabilities of CloudWatch alarms. In addition to using or modifying the following examples, you can create your own alarms and configure the alarms to monitor various metrics on the specified fleets for a certain period of time. To see more SageMaker metrics and dimensions you can add to your alarms, see Monitor Amazon SageMaker with Amazon CloudWatch (p. 3577).

**Topics**
- Monitor invocation errors on both old and new fleets (p. 2588)
- Monitor model latency on the new fleet (p. 2589)

#### Monitor invocation errors on both old and new fleets

The following CloudWatch alarm monitors an endpoint's average error rate. You can use this alarm with any deployment guardrails traffic shifting type to provide overall monitoring on both the old and new fleets. If the alarm trips, then SageMaker initiates a rollback to the old fleet.

Invocation errors coming from both the old fleet and new fleet contribute to the average error rate. If the average error rate exceeds the specified threshold, then the alarm trips. This particular example monitors the 4xx errors (client errors) on both the old and new fleets for the duration of a deployment. You can also monitor the 5xx errors (server errors) by using the metric Invocation5XXErrors.

**Note**
For this alarm type, if your old fleet trips the alarm during the deployment, SageMaker terminates your deployment. Therefore, if your current production fleet already causes errors, consider using or modifying one of the following examples that only monitors the new fleet for errors.

```json
#Applied deployment type: all types
{
    "AlarmName": "EndToEndDeploymentHighErrorRateAlarm",
    "AlarmDescription": "Monitors the error rate of 4xx errors",
    "MetricName": "Invocation4XXErrors",
    "Namespace": "AWS/SageMaker",
    "Statistic": "Average",
    "Dimensions": [ 
        { 
            "Name": "EndpointName",
            "Value": <your-endpoint-name>
        },
        { 
            "Name": "VariantName",
            "Value": "AllTraffic"
        }
    ],
    "Period": 600,
    "EvaluationPeriods": 2,
    "Threshold": 1,
    "ComparisonOperator": "GreaterThanThreshold",
    "TreatMissingData": "notBreaching"
}
```

2588
In the previous example, note the values for the following fields:

- For **AlarmName** and **AlarmDescription**, enter a name and description you choose for the alarm.
- For **MetricName**, use the value **Invocation4XXErrors** to monitor for 4xx errors on the endpoint.
- For **Namespace**, use the value **AWS/SageMaker**. You can also specify your own custom metric, if applicable.
- For **Statistic**, use **Average**. This means that the alarm takes the average error rate over the evaluation periods when calculating whether the error rate has exceeded the threshold.
- For the dimension **EndpointName**, use the name of the endpoint you are updating as the value.
- For the dimension **VariantName**, use the value **AllTraffic** to specify all endpoint traffic.
- For **Period**, use 600. This sets the alarm's evaluation periods to 10 minutes long.
- For **EvaluationPeriods**, use 2. This value tells the alarm to consider the two most recent evaluation periods when determining the alarm status.

**Monitor model latency on the new fleet**

The following CloudWatch alarm example monitors the new fleet's model latency during your deployment. You can use this alarm to monitor only the new fleet and exclude the old fleet. The alarm lasts for the entire deployment. This example gives you comprehensive, end-to-end monitoring of the new fleet and initiates a rollback to the old fleet if the new fleet has any response time issues.

CloudWatch publishes the metrics with the dimension **EndpointConfigName**: {New-Ep-Config} after the new fleet starts receiving traffic, and these metrics last even after the deployment is complete.

You can use the following alarm example with any deployment type.

```json
#Applied deployment type: all types
{
    "AlarmName": "NewEndpointConfigVersionHighModelLatencyAlarm",
    "AlarmDescription": "Monitors the model latency on new fleet",
    "MetricName": "ModelLatency",
    "Namespace": "AWS/SageMaker",
    "Statistic": "Average",
    "Dimensions": [
        {
            "Name": "EndpointName",
            "Value": "<your-endpoint-name>"
        },
        {
            "Name": "VariantName",
            "Value": "AllTraffic"
        },
        {
            "Name": "EndpointConfigName",
            "Value": "<your-config-name>"
        }
    ],
    "Period": 300,
    "EvaluationPeriods": 2,
    "Threshold": 100000, # 100ms
    "ComparisonOperator": "GreaterThanThreshold",
    "TreatMissingData": "notBreaching"
}
```

In the previous example, note the values for the following fields:

- For **MetricName**, use the value **ModelLatency** to monitor the model's response time.
- For **Namespace**, use the value **AWS/SageMaker**. You can also specify your own custom metric, if applicable.
For the dimension `EndpointName`, use the name of the endpoint you are updating as the value.

For the dimension `VariantName`, use the value `AllTraffic` to specify all endpoint traffic.

For the dimension `EndpointConfigName`, the value should refer to the endpoint configuration name for your new or updated endpoint.

**Note**
If you want to monitor your old fleet instead of the new fleet, you can change the dimension `EndpointConfigName` to specify the name of your old fleet's configuration.

### Blue/Green Deployments

When you update your endpoint, Amazon SageMaker automatically uses a blue/green deployment to maximize the availability of your endpoints. In a blue/green deployment, SageMaker provisions a new fleet with the updates (the green fleet). Then, SageMaker shifts traffic from the old fleet (the blue fleet) to the green fleet. Once the green fleet operates smoothly for a set evaluation period (called the baking period), SageMaker terminates the blue fleet. With the additional capabilities in blue/green deployments, you can utilize traffic shifting modes and auto-rollback monitoring to protect your endpoint from significant production impact.

The following list describes the key features of blue/green deployments in SageMaker:

- **Traffic shifting modes.** The traffic shifting modes for deployment guardrails let you control the volume of traffic and number of traffic-shifting steps between the blue fleet and the green fleet. This capability gives you the ability to progressively evaluate the performance of the green fleet without fully committing to a 100% traffic shift.

- **Baking period.** The baking period is a set amount of time to monitor the green fleet before proceeding to the next deployment stage. If any of the pre-specified alarms trip during any baking period, then all endpoint traffic rolls back to the blue fleet. The baking period helps you to build confidence in your update before making the traffic shift permanent.

- **Auto-rollback.** You can specify Amazon CloudWatch alarms that SageMaker uses to monitor the green fleet. If an issue with the updated code trips any of the alarms, SageMaker initiates an auto-rollback to the blue fleet in order to maintain availability thereby minimizing risk.

### Traffic Shifting Modes

The various traffic shifting modes in blue/green deployments give you more granular control over traffic shifting between the blue fleet and the green fleet. The available traffic shifting modes for blue/green deployments are all at once, canary, and linear. The following table shows a comparison of the options.

**Important**
For blue/green deployments that involve multiple stage traffic shifting or baking periods, you are billed for both the fleets for the duration of the update, irrespective of the traffic to the fleet. This is in contrast to blue/green deployments with all at once traffic shifting and no baking periods, where you are only billed for one fleet during the course of the update.

</table>

### Get Started

Once you specify your desired deployment configuration, SageMaker handles provisioning new instances, terminating old instances, and shifting traffic for you. You can create and manage your deployment through the existing `UpdateEndpoint` and `CreateEndpoint` SageMaker API and AWS Command Line Interface commands. Note that if your endpoint uses any of the features listed in the Exclusions (p. 2606) page, you cannot use deployment guardrails. See the individual deployment pages for more details on how to set up your deployment:

- Blue/Green Update with All At Once Traffic Shifting (p. 2591)
- Blue/Green Update with Canary Traffic Shifting (p. 2594)
- Blue/Green Update with Linear Traffic Shifting (p. 2599)

To follow guided examples that show how to use deployment guardrails, see our example Jupyter notebooks for the canary and linear traffic shifting modes.

### All At Once Traffic Shifting

With all at once traffic shifting, you can quickly roll out an endpoint update using the safety guardrails of a blue/green deployment. You can use this traffic shifting option to minimize the update duration while still taking advantage of the availability guarantees of blue/green deployments. The baking period feature helps you to monitor the performance and functionality of your new instances before terminating your old instances, ensuring that your new fleet is fully operational.

The following diagram shows how all at once traffic shifting manages the old and new fleets.
When you use all at once traffic shifting, SageMaker routes 100% of the traffic to the new fleet (green fleet). Once the green fleet starts receiving traffic, the baking period begins. The baking period is a set amount of time in which pre-specified Amazon CloudWatch alarms monitor the performance of the green fleet. If no alarms trip during the baking period, SageMaker terminates the old fleet (blue fleet). If any alarms trip during the baking period, then an auto-rollback initiates and 100% of the traffic shifts back to the blue fleet.

**Prerequisites**

Before setting up a deployment with all at once traffic shifting, you must create Amazon CloudWatch alarms to watch metrics from your endpoint. If any of the alarms trip during the baking period, then the traffic rolls back to your blue fleet. To learn how to set up CloudWatch alarms on an endpoint, see...
Configure All At Once Traffic Shifting

Once you are ready for your deployment and have set up CloudWatch alarms for your endpoint, you can use either the SageMaker UpdateEndpoint API or the update-endpoint command in the AWS Command Line Interface to initiate the deployment.

Topics
- How to update an endpoint (API) (p. 2593)
- How to update an endpoint with an existing blue/green update policy (API) (p. 2594)
- How to update an endpoint (CLI) (p. 2594)

How to update an endpoint (API)

The following example shows how you can update your endpoint with all at once traffic shifting using UpdateEndpoint in the Amazon SageMaker API.

```python
import boto3
client = boto3.client("sagemaker")
response = client.update_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<your-config-name>",
    DeploymentConfig={
        "BlueGreenUpdatePolicy": {
            "TrafficRoutingConfiguration": {
                "Type": "ALL_AT_ONCE"
            },
            "TerminationWaitIn Seconds": 600,
            "MaximumExecutionTimeoutIn Seconds": 1800
        },
        "AutoRollbackConfiguration": {
            "Alarms": [
                {
                    "AlarmName": "<your-cw-alarm>"
                }
            ]
        }
    }
)
```

To configure the all at once traffic shifting option, do the following:

- For EndpointName, use the name of the existing endpoint you want to update.
- For EndpointConfigName, use the name of the endpoint configuration you want to use.
- Under DeploymentConfig and BlueGreenUpdatePolicy, in TrafficRoutingConfiguration, set the Type parameter to ALL_AT_ONCE. This specifies that the deployment uses the all at once traffic shifting mode.
- For TerminationWaitIn Seconds, use 600. This parameter tells SageMaker to wait for the specified amount of time (in seconds) after your green fleet is fully active before terminating the instances in the blue fleet. In this example, SageMaker waits for 10 minutes after the final baking period before terminating the blue fleet.
- For MaximumExecutionTimeoutIn Seconds, use 1800. This parameter sets the maximum amount of time that the deployment can run before it times out. In the preceding example, your deployment has a limit of 30 minutes to finish.
In AutoRollbackConfiguration, within the Alarms field, you can add your CloudWatch alarms by name. Create one AlarmName: `<your-cw-alarm>` entry for each alarm you want to use.

### How to update an endpoint with an existing blue/green update policy (API)

When you use the `CreateEndpoint` API to create an endpoint, you can optionally specify a deployment configuration to reuse for future endpoint updates. You can use the same DeploymentConfig options as the previous UpdateEndpoint API example. There are no changes to the CreateEndpoint API behavior. Specifying the deployment configuration does not automatically perform a blue/green update on your endpoint.

The option to use a previous deployment configuration happens when using the `UpdateEndpoint` API to update your endpoint. When updating your endpoint, you can use the RetainDeploymentConfig option to keep the deployment configuration you specified when you created the endpoint.

When calling the `UpdateEndpoint` API, set RetainDeploymentConfig to `True` to keep the DeploymentConfig options from your original endpoint configuration.

```python
response = client.update_endpoint(  
    EndpointName='`your-endpoint-name`',  
    EndpointConfigName='`your-config-name`',  
    RetainDeploymentConfig=True
)
```

### How to update an endpoint (CLI)

If you are using the AWS CLI, the following example shows how to start a blue/green all at once deployment using the `update-endpoint` command.

```bash
update-endpoint  
--endpoint-name `your-endpoint-name`  
--endpoint-config-name `your-config-name`  
--deployment-config '{"BlueGreenUpdatePolicy": {"TrafficRoutingConfiguration": {"Type": "ALL_AT_ONCE"},  
"TerminationWaitInSeconds": 600,  
"MaximumExecutionTimeoutInSeconds": 1800},  
"AutoRollbackConfiguration": {"Alarms": [{"AlarmName": "`your-alarm`"}]}}'
```

To configure the all at once traffic shifting option, do the following:

- For endpoint-name, use the name of the endpoint you want to update.
- For endpoint-config-name, use the name of the endpoint configuration you want to use.
- For deployment-config, use a `BlueGreenUpdatePolicy` JSON object.

**Note**

If you would rather save your JSON object in a file, see Generating AWS CLI skeleton and input parameters in the AWS CLI User Guide.

### Canary Traffic Shifting

With canary traffic shifting, you can test a portion of your endpoint traffic on the new fleet while the old fleet serves the remainder of the traffic. This testing step is a safety guardrail that validates the new fleet's functionality before shifting all of your traffic to the new fleet. You still have the benefits of a blue/green deployment, and the added canary feature lets you ensure that your new (green) fleet can serve inference before letting it handle 100% of the traffic.
The portion of your green fleet that turns on to receive traffic is called the canary, and you can choose the size of this canary. Note that the canary size should be less than or equal to 50% of the new fleet's capacity. Once the baking period finishes and no pre-specified Amazon CloudWatch alarms trip, the rest of the traffic shifts from the old (blue) fleet to the green fleet. Canary traffic shifting provides you with more safety during your deployment since any issues with the updated model only impact the canary.

The following diagram shows how canary traffic shifting manages the distribution of traffic between the blue and green fleets.
Once SageMaker provisions the green fleet, SageMaker routes a portion of the incoming traffic (for example, 25%) to the canary. Then the baking period begins, during which your CloudWatch alarms monitor the performance of the green fleet. During this time, both the blue fleet and green fleet are partially active and receiving traffic. If any of the alarms trip during the baking period, then SageMaker initiates a rollback and all traffic returns to the blue fleet. If none of the alarms trip, then all of the traffic shifts to the green fleet and there is a final baking period. If the final baking period finishes without tripping any alarms, then the green fleet serves all traffic and SageMaker terminates the blue fleet.

**Prerequisites**

Before setting up a deployment with canary traffic shifting, you must create Amazon CloudWatch alarms to monitor metrics from your endpoint. The alarms are active during the baking period, and if any alarms trip, then all endpoint traffic rolls back to the blue fleet. To learn how to set up CloudWatch alarms on an endpoint, see the prerequisite page [Auto-Rollback Configuration and Monitoring](p. 2587). To learn more about CloudWatch alarms, see [Using Amazon CloudWatch alarms](in the *Amazon CloudWatch User Guide*).

**Configure Canary Traffic Shifting**

Once you are ready for your deployment and have set up Amazon CloudWatch alarms for your endpoint, you can use either the Amazon SageMaker [UpdateEndpoint API](p. 2597) or the [update-endpoint](p. 2598) command in the AWS CLI to initiate the deployment.

**Topics**

- [How to update an endpoint (API) (p. 2597)]
- [How to update an endpoint with an existing blue/green update policy (API) (p. 2598)]
- [How to update an endpoint (CLI) (p. 2598)]

**How to update an endpoint (API)**

The following example of the [UpdateEndpoint API](p. 2597) shows how you can update an endpoint with canary traffic shifting.

```python
import boto3
client = boto3.client("sagemaker")
response = client.update_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<your-config-name>",
    DeploymentConfig={
        "BlueGreenUpdatePolicy": {
            "TrafficRoutingConfiguration": {
                "Type": "CANARY",
                "CanarySize": {
                    "Type": "CAPACITY_PERCENT",
                    "Value": 30
                },
                "WaitIntervalInSeconds": 600
            },
            "TerminationWaitInSeconds": 600,
            "MaximumExecutionTimeoutInSeconds": 1800
        },
        "AutoRollbackConfiguration": {
            "Alarms": [ {
                "AlarmName": "<your-cw-alarm>
            }
        }
    }
```

2597
To configure the canary traffic shifting option, do the following:

- For EndpointName, use the name of the existing endpoint you want to update.
- For EndpointConfigName, use the name of the endpoint configuration you want to use.
- Under DeploymentConfig and BlueGreenUpdatePolicy, in TrafficRoutingConfiguration, set the Type parameter to CANARY. This specifies that the deployment uses canary traffic shifting.
- In the CanarySize field, you can change the size of the canary by modifying the Type and Value parameters. For Type, use CAPACITY_PERCENT, meaning the percentage of your green fleet you want to use as the canary, and then set Value to 30. In this example, you use 30% of the green fleet's capacity as the canary. Note that the canary size should be equal to or less than 50% of the green fleet's capacity.
- For WaitIntervalInSeconds, use 600. The parameter tells SageMaker to wait for the specified amount of time (in seconds) between each interval shift. This interval is the duration of the canary baking period. In the preceding example, SageMaker waits for 10 minutes after the canary shift and then completes the second and final traffic shift.
- For TerminationWaitInSeconds, use 600. This parameter tells SageMaker to wait for the specified amount of time (in seconds) after your green fleet is fully active before terminating the instances in the blue fleet. In this example, SageMaker waits for 10 minutes after the final baking period before terminating the blue fleet.
- For MaximumExecutionTimeoutInSeconds, use 1800. This parameter sets the maximum amount of time that the deployment can run before it times out. In the preceding example, your deployment has a limit of 30 minutes to finish.
- In AutoRollbackConfiguration, within the Alarms field, you can add your CloudWatch alarms by name. Create one AlarmName: <your-cw-alarm> entry for each alarm you want to use.

How to update an endpoint with an existing blue/green update policy (API)

When you use the CreateEndpoint API to create an endpoint, you can optionally specify a deployment configuration to reuse for future endpoint updates. You can use the same DeploymentConfig options as the previous UpdateEndpoint API example. There are no changes to the CreateEndpoint API behavior. Specifying the deployment configuration does not automatically perform a blue/green update on your endpoint.

The option to use a previous deployment configuration happens when using the UpdateEndpoint API to update your endpoint. When updating your endpoint, you can use the RetainDeploymentConfig option to keep the deployment configuration you specified when you created the endpoint.

When calling the UpdateEndpoint API, set RetainDeploymentConfig to True to keep the DeploymentConfig options from your original endpoint configuration.

```python
response = client.update_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<your-config-name>",
    RetainDeploymentConfig=True
)
```

How to update an endpoint (CLI)

If you are using the AWS CLI, the following example shows how to start a blue/green canary deployment using the update-endpoint command.
To configure the canary traffic shifting option, do the following:

- For `endpoint-name`, use the name of the endpoint you want to update.
- For `endpoint-config-name`, use the name of the endpoint configuration you want to use.
- For `deployment-config`, use a `BlueGreenUpdatePolicy` JSON object.

**Note**
If you would rather save your JSON object in a file, see [Generating AWS CLI skeleton and input parameters](#) in the AWS CLI User Guide.

**Linear Traffic Shifting**

Linear traffic shifting enables you to gradually shift traffic from your old fleet (blue fleet) to your new fleet (green fleet). With linear traffic shifting, you can shift traffic in multiple steps, minimizing the chance of a disruption to your endpoint. This blue/green deployment option gives you the most granular control over traffic shifting.

You can choose either the number of instances or the percentage of the green fleet's capacity to activate during each step. Each linear step should only be between 10-50% of the green fleet's capacity. For each step, there is a baking period during which your pre-specified Amazon CloudWatch alarms monitor metrics on the green fleet. Once the baking period finishes and no alarms trip, the active portion of your green fleet continues receiving traffic and a new step begins. If alarms trip during any of the baking periods, 100% of the endpoint traffic rolls back to the blue fleet.

The following diagram shows how linear traffic shifting routes traffic to the blue and green fleets.
Once SageMaker provisions the new fleet, the first portion of the green fleet turns on and receives traffic. SageMaker deactivates the same size portion of the blue fleet, and the baking period begins. If any alarms trip, all of the endpoint traffic rolls back to the blue fleet. If the baking period finishes, then the next step begins. Another portion of the green fleet activates and receives traffic, part of the blue fleet deactivates, and another baking period begins. The same process repeats until the blue fleet is fully deactivated and the green fleet is fully active and receiving all traffic. If an alarm goes off at any point, SageMaker terminates the shifting process and 100% of the traffic rolls back to the blue fleet.

Prerequisites

Before setting up a deployment with linear traffic shifting, you must create CloudWatch alarms to monitor metrics from your endpoint. The alarms are active during the baking period, and if any alarms trip, then all endpoint traffic rolls back to the blue fleet. To learn how to set up CloudWatch alarms on an endpoint, see the prerequisite page Auto-Rollback Configuration and Monitoring (p. 2587). To learn more about CloudWatch alarms, see Using Amazon CloudWatch alarms in the Amazon CloudWatch User Guide.

Configure Linear Traffic Shifting

Once you are ready for your deployment and have set up CloudWatch alarms for your endpoint, you can use either the Amazon SageMaker UpdateEndpoint API or the update-endpoint command in the AWS CLI to initiate the deployment.

Topics

- How to update an endpoint (API) (p. 2601)
- How to update an endpoint with an existing blue/green update policy (API) (p. 2602)
- How to update an endpoint (CLI) (p. 2598)

How to update an endpoint (API)

The following example of the UpdateEndpoint API shows how you can update an endpoint with linear traffic shifting.

```python
import boto3
client = boto3.client("sagemaker")
response = client.update_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<your-config-name>",
    DeploymentConfig={
        "BlueGreenUpdatePolicy": {
            "TrafficRoutingConfiguration": {
                "Type": "LINEAR",
                "LinearStepSize": {
                    "Type": "CAPACITY_PERCENT",
                    "Value": 20
                },
                "WaitIntervalInSeconds": 300
            },
            "TerminationWaitInSeconds": 300,
            "MaximumExecutionTimeoutInSeconds": 3600
        },
        "AutoRollbackConfiguration": {
            "Alarms": [
                {
                    "AlarmName": "<your-cw-alarm>
                }
            ]
        }
    }
)
```
To configure the linear traffic shifting option, do the following:

- For **EndpointName**, use the name of the existing endpoint you want to update.
- For **EndpointConfigName**, use the name of the endpoint configuration you want to use.
- Under **DeploymentConfig** and **BlueGreenUpdatePolicy**, in **TrafficRoutingConfiguration**, set the **Type** parameter to **LINEAR**. This specifies that the deployment uses linear traffic shifting.
- In the **LinearStepSize** field, you can change the size of the steps by modifying the **Type** and **Value** parameters. For **Type**, use **CAPACITY_PERCENT**, meaning the percentage of your green fleet you want to use as the step size, and then set **Value** to 20. In this example, you turn on 20% of the green fleet's capacity for each traffic shifting step. Note that when customizing your linear step size, you should only use steps that are 10-50% of the green fleet's capacity.
- For **WaitIntervalInSeconds**, use 300. The parameter tells SageMaker to wait for the specified amount of time (in seconds) between each traffic shift. This interval is the duration of the baking period between each linear step. In the preceding example, SageMaker waits for 5 minutes between each traffic shift.
- For **TerminationWaitInSeconds**, use 300. This parameter tells SageMaker to wait for the specified amount of time (in seconds) after your green fleet is fully active before terminating the instances in the blue fleet. In this example, SageMaker waits for 5 minutes after the final baking period before terminating the blue fleet.
- For **MaximumExecutionTimeoutInSeconds**, use 3600. This parameter sets the maximum amount of time that the deployment can run before it times out. In the preceding example, your deployment has a limit of 1 hour to finish.
- In **AutoRollbackConfiguration**, within the **Alarms** field, you can add your CloudWatch alarms by name. Create one **AlarmName**: `<your-cw-alarm>` entry for each alarm you want to use.

How to update an endpoint with an existing blue/green update policy (API)

When you use the [CreateEndpoint](https://docs.aws.amazon.com/sagemaker/latest/dg/API_CreateEndpoint.html) API to create an endpoint, you can optionally specify a deployment configuration to reuse for future endpoint updates. You can use the same **DeploymentConfig** options as the previous UpdateEndpoint API example. There are no changes to the CreateEndpoint API behavior. Specifying the deployment configuration does not automatically perform a blue/green update on your endpoint.

The option to use a previous deployment configuration happens when using the [UpdateEndpoint](https://docs.aws.amazon.com/sagemaker/latest/dg/API_UpdateEndpoint.html) API to update your endpoint. When updating your endpoint, you can use the **RetainDeploymentConfig** option to keep the deployment configuration you specified when you created the endpoint.

When calling the [UpdateEndpoint](https://docs.aws.amazon.com/sagemaker/latest/dg/API_UpdateEndpoint.html) API, set **RetainDeploymentConfig** to True to keep the deployment configuration options from your original endpoint configuration.

```python
response = client.update_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<your-config-name>",
    RetainDeploymentConfig=True
)
```

How to update an endpoint (CLI)

If you are using the AWS CLI, the following example shows how to start a blue/green linear deployment using the `update-endpoint` command.
update-endpoint
--endpoint-name  <your-endpoint-name>
--endpoint-config-name  <your-config-name>
--deployment-config  '{"BlueGreenUpdatePolicy": {"TrafficRoutingConfiguration": {"Type": "LINEAR",
  "LinearStepSize": {"Type": "CAPACITY_PERCENT", "Value": 20}, "WaitIntervalInSeconds": 300,
  "TerminationWaitInSeconds": 300, "MaximumExecutionTimeoutInSeconds": 3600},
  "AutoRollbackConfiguration": {"Alarms": [{"AlarmName": "<your-alarm>"}]}"}}'

To configure the linear traffic shifting option, do the following:

- For `endpoint-name`, use the name of the endpoint you want to update.
- For `endpoint-config-name`, use the name of the endpoint configuration you want to use.
- For `deployment-config`, use a BlueGreenUpdatePolicy JSON object.

**Note**
If you would rather save your JSON object in a file, see Generating AWS CLI skeleton and input parameters in the AWS CLI User Guide.

## Rolling Deployments

When you update your endpoint, you can specify a rolling deployment to gradually shift traffic from your old fleet to a new fleet. You can control the size of the traffic shifting steps, as well as specify an evaluation period to monitor the new instances for issues before terminating instances from the old fleet. With rolling deployments, instances on the old fleet are cleaned up after each traffic shift to the new fleet, reducing the amount of additional instances needed to update your endpoint. This is useful especially for accelerated instances that are in high demand.

Rolling deployments gradually replace the previous deployment of your model version with the new version by updating your endpoint in configurable batch sizes. The traffic shifting behavior of rolling deployments is similar to the linear traffic shifting mode in blue/green deployments, but rolling deployments provide you with the benefit of reduced capacity requirements when compared to blue/green deployments. With rolling deployments, fewer instances are active at a time, and you have more granular control over how many instances you want to update in the new fleet. You should consider using a rolling deployment instead of a blue/green deployment if you have large models or a large endpoint with many instances.

The following list describes the key features of rolling deployments in Amazon SageMaker:

- **Baking period.** The baking period is a set amount of time to monitor the new fleet before proceeding to the next deployment stage. If any of the pre-specified alarms trip during any baking period, then all endpoint traffic rolls back to the old fleet. The baking period helps you to build confidence in your update before making the traffic shift permanent.

- **Rolling batch size.** You have granular control over the size of each batch for traffic shifting, or the number of instances you want to update in each batch. This number can range for 5–50% of the size of your fleet. You can specify the batch size as a number of instances or as the overall percentage of your fleet.

- **Auto-rollback.** You can specify Amazon CloudWatch alarms that SageMaker uses to monitor the new fleet. If an issue with the updated code trips any of the alarms, SageMaker initiates an auto-rollback to the old fleet in order to maintain availability, thereby minimizing risk.

**Note**
If your endpoint uses any of the features listed in the Exclusions page, you cannot use rolling deployments.
How it works

During a rolling deployment, SageMaker provides the infrastructure to shift traffic from the old fleet to the new fleet without having to provision all of the new instances at once. SageMaker uses the following steps to shift traffic:

1. SageMaker provisions the first batch of instances in the new fleet.
2. A portion of traffic is shifted from the old instances to the first batch of new instances.
3. After the baking period, if no Amazon CloudWatch alarms are tripped, then SageMaker cleans up a batch of old instances.
4. SageMaker continues to provision, shift, and clean up instances in batches until the deployment is complete.

If an alarm is tripped during one of the baking periods, then traffic is rolled back to the old fleet in batches of a size that you specify. Alternatively, you can specify the rolling deployment to shift 100% of the traffic back to the old fleet if an alarm is tripped.

The following diagram shows the progression of a successful rolling deployment, as described in the previous steps.

To create a rolling deployment, you only have to specify your desired deployment configuration. Then SageMaker handles provisioning new instances, terminating old instances, and shifting traffic for you. You can create and manage your deployment through the existing **UpdateEndpoint** and **CreateEndpoint** SageMaker API and AWS Command Line Interface commands.

Prerequisites

Before setting up a rolling deployment, you must create Amazon CloudWatch alarms to watch metrics from your endpoint. If any of the alarms trip during the baking period, then the traffic begins rolling back to your old fleet. To learn how to set up CloudWatch alarms on an endpoint, see the prerequisite.
Auto-Rollback Configuration and Monitoring. To learn more about CloudWatch alarms, see Using Amazon CloudWatch alarms in the Amazon CloudWatch User Guide.

Also, review the Exclusions page to make sure that your endpoint meets the requirements for a rolling deployment.

Determine the rolling batch size

Before updating your endpoint, determine the batch size that you want to use for incrementally shifting traffic to the new fleet.

For rolling deployments, you can specify a batch size that is 5–50% of the capacity of your fleet. If you choose a large batch size, the deployment completes more quickly. However, keep in mind that the endpoint requires more capacity while updating, roughly the batch size overhead. If you choose a smaller batch size, the deployment takes longer, but you use less capacity during the deployment.

Configure a rolling deployment

Once you are ready for your deployment and have set up CloudWatch alarms for your endpoint, you can use the SageMaker UpdateEndpoint API or the update-endpoint command in the AWS Command Line Interface to initiate the deployment.

How to update an endpoint

The following example shows how you can update your endpoint with a rolling deployment using the update_endpoint method of the Boto3 SageMaker client.

To configure a rolling deployment, use the following example and fields:

- For EndpointName, use the name of the existing endpoint you want to update.
- For EndpointConfigName, use the name of the endpoint configuration you want to use.
- In the AutoRollbackConfiguration object, within the Alarms field, you can add your CloudWatch alarms by name. Create one AlarmName: <your-cw-alarm> entry for each alarm you want to use.
- Under DeploymentConfig, for the RollingUpdatePolicy object, specify the following fields:
  - MaximumExecutionTimeoutInSeconds — The time limit for the total deployment. Exceeding this limit causes a timeout. The maximum value you can specify for this field is 28800 seconds, or 8 hours.
  - WaitIntervalInSeconds — The length of the baking period, during which SageMaker monitors alarms for each batch on the new fleet.
  - MaximumBatchSize — Specify the Type of batch you want to use (either instance count or overall percentage of your fleet) and the Value, or the size of each batch.
  - RollbackMaximumBatchSize — Use this object to specify the rollback strategy in case an alarm trips. Specify the Type of batch you want to use (either instance count or overall percentage of your fleet), and the Value, or the size of each batch. If you don’t specify these fields, or if you set the value to 100% of your endpoint, then SageMaker uses a blue/green rollback strategy and rolls all traffic back to the old fleet when an alarm trips.

```python
import boto3
client = boto3.client("sagemaker")

response = client.update_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<your-config-name>",
    DeploymentConfig={
```

2605
After updating your endpoint, you might want to check the status of your rolling deployment and check the health of your endpoint. You can review your endpoint's status in the SageMaker console, or you can review the status of your endpoint by using the `DescribeEndpoint` API.

In the `VariantStatus` object returned by the `DescribeEndpoint` API, the `Status` field tells you the current deployment or operational status of your endpoint. For more information about the possible statuses and what they mean, see `ProductionVariantStatus`.

If you attempted to do a rolling deployment and the status of your endpoint is `UpdateRollbackFailed`, see the following section for troubleshooting help.

**Failure handling**

If your rolling deployments fails and the auto-rollback fails as well, your endpoint can be left with a status of `UpdateRollbackFailed`. This status means that different endpoint configurations are deployed to the instances behind your endpoint, and your endpoint is in service with a mix of old and new endpoint configurations.

You can make another call to the `UpdateEndpoint` API to return your endpoint to a healthy state. Specify your desired endpoint configuration and deployment configuration (either as a rolling deployment, a blue/green deployment, or neither) to update your endpoint.

You can call the `DescribeEndpoint` API to check the health of your endpoint again, which is returned in the `VariantStatus` object as the `Status` field. If your update is successful, your endpoint's `Status` returns to `InService`.

**Exclusions**

When doing a blue/green or rolling deployment, your new endpoint configuration must have the same variant name as the old endpoint configuration. There are also feature-based exclusions that make your endpoint incompatible with deployment guardrails at this time. If your endpoint uses any of the following features, you cannot use deployment guardrails on your endpoint, and your endpoint will fall back to using a blue/green deployment with all at once traffic shifting and no final baking period:

- Marketplace containers
- Endpoints that use Inf1 (Inferentia-based) instances
Monitor endpoint metrics and create alarms

After creating a SageMaker Hosting endpoint, you can monitor your endpoint using Amazon CloudWatch, which collects raw data and processes it into readable, near real-time metrics. Using these metrics, you can access historical information and gain a better perspective on how your endpoint is performing. You can also set alarms that watch for certain thresholds and send notifications when those thresholds are met. For more information, see the Amazon CloudWatch User Guide. You can view your CloudWatch metrics and static threshold metric alarms that you’ve created for your endpoint from the endpoint details page in the SageMaker console. From this page, you can also create metric alarms.

To view these details, do the following:

2. In the left navigation pane, choose Inference.
3. From the dropdown list, choose Endpoints.
4. On the Endpoints page, choose your endpoint.

The endpoint details page should open, showing you a summary of your endpoint and metrics that have been collected for your endpoint.

You can choose the Settings tab to view additional information about your endpoint, such as the data capture settings, the endpoint configuration, and tags.

The following sections describe the Monitoring and Alarms tabs and how to view metrics and CloudWatch alarms for your endpoint.

Monitor endpoint metrics

From the Monitoring tab on the endpoint details page, you can view CloudWatch metrics data that has been collected from your endpoint.

The Monitoring tab includes the following sections:

- **Operational metrics**: View metrics that track the utilization of your endpoint's resources, such as CPU Utilization and Memory Utilization.
- **Invocation metrics**: View metrics that track the number, health, and status of InvokeEndpoint requests coming to your endpoint, such as Invocation Model Errors and Model Latency.
- **Health metrics**: View metrics that track your endpoint's overall health, such as Invocation Failures and Notification Failures.

For detailed descriptions of each metric, see Monitor SageMaker with CloudWatch.

The following screenshot shows the Operational metrics section for a serverless endpoint.
You can adjust the **Period** and **Statistic** that you want to track for the metrics in a given section, as well as the length of time for which you want to view metrics data. You can also add and remove metric widgets from the view for each section by choosing **Add widget**. In the **Add widget** dialog box, you can select and deselect the metrics that you want to see.
The metrics that are available may depend on your endpoint type. For example, serverless endpoints have some metrics that aren’t available for real-time endpoints. For more specific metrics information by endpoint type, see the following pages:

- Monitor a serverless endpoint
- Monitor an asynchronous endpoint
- CW Metrics for Multi-Model Endpoint Deployments
- Inference Pipeline Logs and Metrics

## Create metrics alarms

From your endpoint details page, you can view and create simple static threshold metric alarms, where you specify a threshold value for a metric. If the metric breaches the threshold value, the alarm goes into the ALARM state. For more information about CloudWatch alarms, see Using Amazon CloudWatch alarms.

In the **Endpoint summary** section, you can view the **Alarms** field, which tells you how many alarms are currently active on your endpoint.

To view which alarms are in the ALARM state, choose the **Alarms** tab. The **Alarms** tab shows you a full list of your endpoint alarms, along with details about their status and conditions. The following screenshot shows a list of alarms in this section that have been configured for an endpoint.

An alarm’s status can be **In alarm**, **OK**, or **Insufficient data** if there isn’t enough metrics data being collected.

To create a new alarm for your endpoint, do the following:

1. In the **Alarms** tab, choose **Create alarm**.
2. The **Create alarm** page opens. For **Alarm name**, enter a name for the alarm.
3. (Optional) Enter a description for the alarm.
4. For **Metric**, choose the CloudWatch metric that you want the alarm to track.
5. For **Variant name**, choose the endpoint model variant that you want to monitor.
6. For **Statistic**, choose one of the available statistics for the metric you selected.
7. For **Period**, choose the time period to use for calculating each statistical value. For example, if you choose the Average statistic and a 5 minute period, each data point monitored by the alarm is the average of the metric’s data points at 5 minute intervals.
8. For **Evaluation periods**, enter the number of data points that you want the alarm to consider when evaluating whether to enter the alarm state or not.
9. For **Condition**, choose the conditional that you want to use for your alarm threshold.
10. For **Threshold value**, enter the desired value for your threshold.

11. (Optional) For **Notification**, you can choose **Add notification** to create or specify an Amazon SNS topic that receives a notification when your alarm state changes.

12. Choose **Create alarm**.

After creating your alarm, you can return to the **Alarms** tab to view its status at any time. From this section, you can also select the alarm and either **Edit** or **Delete** it.

## Shadow tests

With Amazon SageMaker you can evaluate any changes to your model serving infrastructure by comparing its performance against the currently deployed infrastructure. This practice is known as shadow testing. Shadow testing can help you catch potential configuration errors and performance issues before they impact end users. With SageMaker, you don't need to invest in building your shadow testing infrastructure, so you can focus on model development.

You can use this capability to validate changes to any component of your production variant, namely the model, the container, or the instance, without any end user impact. It is useful in situations including but not limited to the following:

- You are considering promoting a new model that has been validated offline to production, but want to evaluate operational performance metrics such as latency and error rate before making this decision.
- You are considering changes to your serving infrastructure container, such as patching vulnerabilities or upgrading to newer versions, and want to assess the impact of these changes prior to promotion to production.
- You are considering changing your ML instance and want to evaluate how the new instance would perform with live inference requests.

The SageMaker console provides a guided experience to manage the workflow of shadow testing. You can setup shadow tests for a predefined duration of time, monitor the progress of the test through a live dashboard, clean up upon completion, and act on the results. Select a production variant you want to test against, and SageMaker automatically deploys the new variant in shadow mode and routes a copy of the inference requests to it in real time within the same endpoint. Only the responses of the production variant are returned to the calling application. You can choose to discard or log the responses of the shadow variant for offline comparison. For more information on production and shadow variants, see Safely validate models in production (p. 2463). Note that if your endpoint uses any of the features listed in the **Exclusions** (p. 2624) page, you cannot use shadow tests.

See [Create a shadow test](p. 2610) for instructions on creating a shadow test.

## Create a shadow test

You can create a shadow test to compare the performance of a shadow variant against a production variant. You can run the test on an existing endpoint that is serving inference requests or you can create a new endpoint on which to run the test.

To create a shadow test you need to specify the following:

- **A production variant** that receives and responds to 100 percent of the incoming inference requests.
- **A shadow variant** that receives a percentage of the incoming requests, replicated from the production variant, but does not return any responses.
For each variant, you can use SageMaker to control the model, instance type, and instance count. You can configure the percentage of incoming requests, known as the traffic sampling percentage, that you want replicated to your shadow variant. SageMaker manages the replication of requests to your shadow variant and you can modify the traffic sampling percentage when your test is scheduled or running. You can also optionally turn on Data Capture to log requests and responses of your production and shadow variants.

**Note**

SageMaker supports a maximum of one shadow variant per endpoint. For an endpoint with a shadow variant, there can be a maximum of one production variant.

You can schedule the test to start at any time and continue for a specified duration. The default duration is 7 days and the maximum is 30 days. After the test is complete, the endpoint reverts to the state it was in prior to starting the test. This ensures that you do not have to manually clean up resources upon the completion of the test.

You can monitor a test that is running through a dashboard in the SageMaker console. The dashboard provides a side by side comparison of invocation metrics and instance metrics between the production and shadow variants, along with a tabular view with relevant metric statistics. This dashboard is also available for completed tests. Once you have reviewed the metrics, you can either choose to promote the shadow variant to be the new production variant or retain the existing production variant. Once you promote the shadow variant, it responds to all incoming requests. For more information, see [Promote a shadow variant](p. 2623).

The following procedure describes how to create a shadow test through the SageMaker console. There are variations in the workflow depending on whether you want to use an existing endpoint or to create a new endpoint for the shadow test.

**Topics**

- Prerequisites (p. 2611)
- Enter shadow test details (p. 2611)
- Enter shadow test settings (p. 2612)

**Prerequisites**

Before creating a shadow test with the SageMaker console, you must have a SageMaker model ready to use. For more information about how to create a SageMaker model, see [Create a Model](p. 2393).

You can get started with shadow tests with an existing endpoint with a production variant and a shadow variant, an existing endpoint with only a production variant, or just the SageMaker models you’d like to compare. Shadow tests support creating an endpoint and adding variants before your test begins.

**Enter shadow test details**

To start creating your shadow test, fill out the Enter shadow test details page by doing the following:

1. Open the SageMaker console.
2. In the left navigation panel, choose Inference, and then choose Shadow tests.
3. Choose Create shadow test.
4. Under Name, enter a name for the test.
5. (Optional) Under Description, enter a description for the test.
6. (Optional) Specify Tags using Key and Value pairs.
7. Choose Next.
Enter shadow test settings

After filling out the Enter shadow test details page, fill out the Enter shadow test settings page. If you already have a SageMaker Inference endpoint and a production variant, follow the Use an existing endpoint workflow. If you don't already have an endpoint, follow the Create a new endpoint workflow.

Use an existing endpoint

If you want to use an existing endpoint for your test, fill out the Enter shadow test settings page by doing the following:

1. Choose a role that has the AmazonSageMakerFullAccess IAM policy attached.
2. Choose Use an existing endpoint, and then choose one of the available endpoints.
3. (Optional) To encrypt the storage volume on your endpoint, either choose an existing KMS key or choose Enter a KMS key ARN from the dropdown list under Encryption key. If you choose the second option, a field to enter the KMS key ARN appears. Enter the KMS key ARN in that field.
4. If you have multiple production variants behind that endpoint, remove the ones you don't want to use for the test. You can remove a model variant by selecting it and then choosing Remove.
5. If you do not already have a shadow variant, add a shadow variant. To add a shadow variant, do the following:
   a. Choose Add.
   b. Choose Shadow variant.
   c. In the Add model dialog box, choose the model you want to use for your shadow variant.
   d. Choose Save.
6. (Optional) In the preceding step, the shadow variant is added with the default settings. To modify these settings, select the shadow variant and choose Edit. The Edit shadow variant dialog box appears. For more information on filling out this dialog box, see Edit a shadow test (p. 2621).
7. In the Schedule section, enter the duration of the test by doing the following:
   a. Choose the box under Duration. A popup calendar appears.
   b. Select the start and end dates from the calender, or enter the start and end dates in the fields for Start date and End date, respectively.
   c. (Optional) For the fields Start time and End time, enter the start and end times, respectively, in the 24 hour format.
   d. Choose Apply.

The minimum duration is 1 hour, and the maximum duration is 30 days.

8. (Optional) Turn on Enable data capture to save inference request and response information from your endpoint to an Amazon S3 bucket, and then enter the location of the Amazon S3 bucket.

9. Choose Create shadow test.

Create a new endpoint

If you don't have an existing endpoint, or you want to create a new endpoint for your test, fill out the Enter shadow test settings page by doing the following:

1. Choose a role that has the AmazonSageMakerFullAccess IAM policy attached.
2. Choose Create a new endpoint.
3. Under Name, enter a name for the endpoint.
4. Add one production variant and one shadow variant to the endpoint:
   • To add a production variant choose **Add**, and then choose **Production variant**. In the **Add model** dialog box, choose the model you want to use for your production variant, and then choose **Save**.
   • To add a shadow variant choose **Add**, and then choose **Shadow variant**. In the **Add model** dialog box, choose the model you want to use for your shadow variant, and then choose **Save**.

5. (Optional) In the preceding step, the shadow variant is added with the default settings. To modify these settings, select the shadow variant and choose **Edit**. The **Edit shadow variant** dialog box appears. For more information on filling out this dialog box, see **Edit a shadow test** (p. 2621).

6. In the **Schedule** section, enter the duration of the test by doing the following:
   a. Choose the box under **Duration**. A popup calendar appears.
   b. Select the start and end dates from the calendar, or enter the start and end dates under **Start date** and **End date**, respectively.
   c. (Optional) Under **Start time** and **End time**, enter the start and end times, respectively, in the 24 hour format.
   d. Choose **Apply**.

   The minimum duration is 1 hour, and the maximum duration is 30 days.

7. (Optional) Turn on **Enable data capture** to save inference request and response information from your endpoint to an Amazon S3 bucket, and then enter the location of the Amazon S3 bucket.

8. Choose **Create shadow test**.

After completing the preceding procedures, you should now have a test scheduled to begin at your specified start date and time. You can view the progress of the test from a dashboard. For more information about viewing your test and the actions you can take, see **View, monitor, and edit shadow tests** (p. 2613).

**View, monitor, and edit shadow tests**

You can view the statuses of your shadow tests, monitor their progress from a dashboard, and perform actions, such as starting or stopping an test early or deleting an test. The following sections show how you can view and modify your shadow tests using the SageMaker console.

**Topics**
- **View shadow tests** (p. 2613)
- **Monitor a shadow test** (p. 2616)
- **Start a shadow test early** (p. 2620)
- **Complete a shadow test early** (p. 2621)
- **Delete a shadow test** (p. 2621)
- **Edit a shadow test** (p. 2621)

**View shadow tests**

You can view the statuses of all of your shadow tests on the **Shadow tests** page on the SageMaker console.

To view your tests in the console, do the following:
1. Open the SageMaker console.
2. In the navigation panel, choose Inference.
3. Choose Shadow tests to view the page that lists all of your shadow tests. The page should look like the following screenshot, with all the tests listed under the Shadow test section.
Shadow testing

Create shadow tests to monitor and edit your model's behavior before it goes into production. This allows you to understand how your model will perform in production without actually releasing it. Shadow testing helps you avoid unexpected issues after deployment.

Get started

Create a shadow test to simulate production-like usage over a specified duration in your SageMaker endpoint. This helps you to free up resources when done.

Shadow test

<table>
<thead>
<tr>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>shadow test</td>
</tr>
</tbody>
</table>
You can see the status of a test in the console on the **Shadow tests** page by checking the **Status** field for the test.

The following are the possible statuses for a test:

- **Creating** – SageMaker is creating your test.
- **Created** – SageMaker has finished creating your test, and it will begin at the scheduled time.
- **Updating** – When you make changes to your test, your test shows as updating.
- **Starting** – SageMaker is beginning your test.
- **Running** – Your test is in progress.
- **Stopping** – SageMaker is stopping your test.
- **Completed** – Your test has completed.
- **Cancelled** – When you conclude your test early, it shows as cancelled.

### Monitor a shadow test

You can view the details of a shadow test and monitor it while it is in progress or after it has completed. SageMaker presents a live dashboard comparing the operational metrics like model latency, and error rate aggregated, of the production and shadow variants.

To view the details of an individual test in the console, do the following:

1. **Select** the test you want to monitor from the **Shadow test** section on the **Shadow tests** page.
2. From the **Actions** dropdown list, choose **View**. An overview page with the details of the test and a metrics dashboard appears.

The overview page has the following three sections.

**Summary**

This section summarizes the progress and status of the test. It also shows the summary statistics of the metric chosen from the **Select metric** dropdown list in the **Metrics** subsection. The following screenshot shows this section.
shadow-test-demo-2

**Summary**

**Status**

Running

**Reason**

-

**Metrics**

**Select metric**

View the selected metric summary and statistics from the start of experiment to present.

- **ModelLatency**

⚠️ A lower value of the latency metric usually indicates a faster response.
In the preceding screenshot, the **Settings** and **Details** tabs show the settings that you selected, and the details that you entered when creating the test.

**Analysis**

This section shows a metrics dashboard with separate graphs for the following metrics:

- Invocations
- InvocationsPerInstance
- ModelLatency
- Invocation4XXErrors
- Invocation5XXErrors
- InvocationModelErrors
- CPUUtilization
- MemoryUtilization
- DiskUtilization

The last three metrics monitor the model container runtime resource usage. The rest are CloudWatch metrics that you can use to analyse the performance of your variant. In general, fewer errors indicate a more stable model. A lower latency indicates either a faster model or a faster infrastructure. For more information about CloudWatch metrics, see [SageMaker Endpoint Invocation Metrics](p. 3578). The following screenshot shows the metrics dashboard.
Environment

This section shows the variants that you compared in the test. If you are satisfied by the performance of the shadow variant, based on the aforementioned metrics, you can promote the shadow variant to production, by choosing **Deploy shadow variant**. For more details about deploying a shadow variant, see **Promote a shadow variant (p. 2623)**. You can also change the traffic sampling percentage, and continue testing, by choosing **Edit traffic**. For more details about editing a shadow variant, see **Edit a shadow test (p. 2621)**. The following screenshot shows this section.

Start a shadow test early

You can start your test before its scheduled start time. If the new duration of the test exceeds 30 days, SageMaker automatically sets the end of the test to 30 days after the new start time. This action starts the test immediately. If you want to change the start or end time of the test, see **Edit a shadow test (p. 2621)**.

To immediately start your test, before its scheduled start time, through the console, do the following:
1. Select the test you want to start immediately from the Shadow test section on the Shadow tests page.
2. From the Actions dropdown list, choose Start. The Start shadow test? dialog box appears.
3. Choose Start now.

Complete a shadow test early

You can complete an in-progress test before the end of its scheduled duration. For more information see Complete a shadow test early (p. 2622).

Delete a shadow test

You can delete a test that you no longer need. Deleting your test only deletes the test metadata and not your endpoint, variants, or data captured in Amazon S3. If you want your endpoint to stop running, you must delete your endpoint. For more information about deleting an endpoint, see Delete Endpoints and Resources (p. 2395)

To delete a test through the console, do the following:
1. Select the test you want to delete from the Shadow test section on the Shadow tests page.
2. From the Actions dropdown list, choose Delete. The Delete shadow test dialog box appears.
3. In the To confirm deletion, type delete in the field. text box, enter delete.
4. Choose Delete.

Edit a shadow test

You can modify both scheduled and in-progress tests. Before your test starts, you can change the description, the shadow variant configuration, the start date, and the end date of the test. You can also turn on or turn off data capture.

After your test starts, you can only change the description, the traffic sampling percentage for the shadow variant, and the end date.

To edit the details of your test through the console, do the following:
1. Select the test you want to edit from the Shadow test section on the Shadow tests page.
2. From the Actions dropdown list, choose Edit. The Enter shadow test details page appears.
3. (Optional) Under Description, enter a description of your test.
4. Choose Next. The Enter shadow test settings page appears.
5. (Optional) To edit your shadow variant, do the following:
   a. Select the shadow variant and choose Edit. The Edit shadow variant dialog box appears. If your test has already started, then you can only change the traffic sampling percentage.
   b. (Optional) Under Name, enter the new name to replace the old name.
   c. (Optional) Under Traffic sample, enter the new traffic sampling percentage to replace the old traffic sampling percentage.
   d. (Optional) Under Instance type, select the new instance type from the dropdown list.
   e. (Optional) Under Instance count, enter the new instance count to replace the old instance count.
   f. Choose Apply.
Complete a shadow test

You cannot change the model in your shadow variant using the above procedure. If you want to change the model, first remove the shadow variant by selecting it and choosing Remove. Then add a new shadow variant.

6. (Optional) To edit the duration of the test, do the following:
   a. Choose the box under Duration in the Schedule section. A popup calendar appears.
   b. If your test is yet to start, you can change both the start and end dates. Select the new start and end dates from the calendar, or enter the new start and end dates under Start date and End date, respectively.
      If your test has already started, you can only change the end date. Enter the new end date under End date.
   c. (Optional) If your test is yet to start, you can change both the start and end times. Enter the new start and end times under Start time, and End time, respectively, in the 24 hour format.
      If your test has already started, you can only change the end time. Enter the new end time under End time, in the 24 hour format.
   d. Choose Apply.

7. (Optional) Turn on or turn off Enable data capture.

8. Choose Update shadow test.

Complete a shadow test

Your test automatically completes at the end of the scheduled duration, or you can stop an in-progress test early. After your test has completed, the test’s status in the Shadow tests section on the Shadow tests page shows as Complete. Then you can review and analyze the final metrics of your test.

You can use the metrics dashboard to decide whether to promote the shadow variant to production. For more information about analyzing the metrics dashboard of your test, see Monitor a shadow test (p. 2616).

For instructions on how to complete your test before the end of its scheduled completion time, see Complete a shadow test early (p. 2622).

For instructions on promoting your shadow variant to production, see Promote a shadow variant (p. 2623).

Complete a shadow test early

One reason you might want to complete an in-progress shadow test is if you've decided that the metrics for your shadow variant look good and you want to promote it to production. You might also decide to complete the test if one or more of the variants aren’t performing well.

To complete your test before its scheduled end date, do the following:

1. Select the test you want to mark complete from the Shadow tests section on the Shadow tests page.
2. From the Actions dropdown list, choose Complete, and the Complete shadow test dialog box appears.
3. In the dialog box, choose one of the following options:
   a. Yes, deploy shadow variant
   b. No, remove shadow variant

2622
4. (Optional) In the **Comment** text box, enter your reason for completing the test before its scheduled end time.

5. 1. If you decided to deploy the shadow variant, choose **Complete and proceed to deploy**. The **Deploy shadow variant** page appears. For instructions on how to fill out this page, see [Promote a shadow variant](p. 2623).

    2. If you decide to remove the shadow variant, choose **Confirm**.

### Promote a shadow variant

If you've decided that you want to replace your production variant with your shadow variant, you can update your endpoint and promote your shadow variant to respond to inference requests. This removes your current production variant from production and replaces it with your shadow variant.

If your shadow test is still in-progress, you must first complete your test. To complete your shadow test before its scheduled end, follow the instructions in [Complete a shadow test early](p. 2622) before continuing with this section.

When you promote a shadow variant to production, you have the following options for the instance count of the shadow variant.

- You can retain the instance count and type from the production variant. If you select this option, then your shadow variant launches in production with the current instance count, ensuring that your model can continue to process request traffic at the same scale.

- You can retain the instance count and type of your shadow variant. If you want to use this option, we recommend that you shadow test with 100 percent traffic sampling to ensure that the shadow variant can process request traffic at the current scale.

- You can use custom values for the instance count and type. If you want to use this option, we recommend that you shadow test with 100 percent traffic sampling to ensure that the shadow variant can process request traffic at the current scale.

Unless you are validating the instance type or count or both of the shadow variant, we highly recommend that you retain the instance count and type from the production variant when promoting your shadow variant.

To promote your shadow variant, do the following:

1. If your test has completed, do the following:
   a. Select the test from the **Shadow test** section on the **Shadow tests** page.
   b. From the **Actions** dropdown list, choose **View**. The dashboard appears.
   c. Choose **Deploy shadow variant** in the **Environment** section. The **Deploy shadow variant** page appears.

   If your test has not completed, see [Complete a shadow test early](p. 2622) to complete it.

2. In the **Variant settings** section, select one of the following options:

   - **Retain production settings**
   - **Retain shadow settings**
   - **Custom instance settings**

   If you selected **Custom instance settings**, do the following:
   a. Select the instance type from the **Instance type** dropdown list.
b. Under **Instance count**, enter the number of instances.
3. In **Enter ‘deploy’ to confirm deployment** text box, enter **deploy**.
4. Choose **Deploy shadow variant**.

Your SageMaker Inference endpoint is now using the shadow variant as your production variant, and your production variant has been removed from the endpoint.

**Best Practices**

When creating an inference experiment, keep the following information in mind:

- **Traffic sampling percentage** – Sampling 100 percent of the inference requests lets you validate that your shadow variant can handle production traffic when promoted. You may start off with a lower traffic sampling percentage and dial up as you gain confidence in your variant, but it is best practice to ensure that you’ve increased the traffic to 100 percent prior to promotion.

- **Instance type** – Unless you are using shadow variants to evaluate alternate instance types or sizes, we recommend that you use the same instance type, size, and count so that you can be certain that your shadow variant can handle the volume of inference requests after you promote it.

- **Auto scaling** – To ensure that your shadow variant can respond to spikes in the number of inference requests or changes in inference requests patterns, we highly recommend that you configure autoscaling on your shadow variants. To learn how to configure autoscaling, see [Automatically Scale Amazon SageMaker Models](p. 2447). If you have configured autoscaling, you can also validate changes to autoscaling policies without causing impact to users.

- **Metrics monitoring** – After you initiate a shadow experiment and have sufficient invocations, monitor the metrics dashboard to ensure that the metrics such as latency and error rate are within acceptable bounds. This helps you catch misconfigurations early and take corrective action. For information about how to monitor the metrics of an in-progress inference experiment, see [View, monitor, and edit shadow tests](p. 2613).

**Exclusions**

There are feature-based exclusions that make your endpoint incompatible with shadow tests at this time. If your endpoint uses any of the following features you cannot use shadow tests on your endpoint, and your request to setup shadow tests will lead to validation errors.

- Serverless inference
- Asynchronous inference
- Marketplace containers
- Multiple-containers endpoints
- Multi-model endpoints
- Endpoints that use Inf1 (Inferentia-based) instances
- Amazon Elastic Inference endpoints

**Access containers through SSM**

Amazon SageMaker allows you to securely connect to the Docker containers on which your models are deployed on for Inference using AWS Systems Manager (SSM). This gives you shell level access to the container so that you can debug the processes running within the container and log commands and responses with Amazon CloudWatch. You can also set up an AWS PrivateLink connection to the ML instances that host your containers for accessing the containers via SSM privately.
Warning
Enabling SSM access can impact the performance of your endpoint. We recommend using this feature with your dev or test endpoints and not with the endpoints in production. Also, SageMaker automatically applies security patches, and replaces or terminates faulty endpoint instances within 10 minutes. However for endpoints with SSM enabled production variants, SageMaker delays security patching and replacing or terminating faulty endpoint instances by a day, to allow you to debug.

The following sections detail how you can use this feature.

Allowlist
You have to contact customer support, and get your account allowlisted, to use this feature. You cannot create an endpoint with SSM access enabled, if your account is not allowlisted for this access.

Enable SSM access
To enable SSM access for an existing container on an endpoint, update the endpoint with a new endpoint configuration, with the `EnableSSMAccess` parameter set to `true`. The following example provides a sample endpoint configuration.

```json
{
  "EndpointConfigName": "endpoint-config-name",
  "ProductionVariants": [
    {
      "InitialInstanceCount": 1,
      "InitialVariantWeight": 1.0,
      "InstanceType": "ml.t2.medium",
      "ModelName": "model-name",
      "VariantName": "variant-name",
      "EnableSSMAccess": true,
    }
  ]
}
```

For more information on enabling SSM access, see [EnableSSMAccess](#).

IAM configuration

Endpoint IAM permissions
If you have enabled SSM access for an endpoint instance, SageMaker starts and manages the SSM agent when it initiates the endpoint instance. To allow the SSM agent to communicate with the SSM services, add the following policy to the execution role that the endpoint runs under.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssmmessages:CreateControlChannel",
        "ssmmessages:CreateDataChannel",
        "ssmmessages:OpenControlChannel",
        "ssmmessages:OpenDataChannel"
      ],
      "Resource": "*"
    }
  ]
}
```
User IAM permissions

Add the following policy to give an IAM user SSM session permissions to connect to a SSM target.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "ssm:StartSession",
            "ssm:TerminateSession"
         ],
         "Resource": "*"
      }
   ]
}
```

You can restrict the endpoints that an IAM user can connect to, with the following policy. Replace the italicized placeholder text with your own information.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "ssm:StartSession",
         ],
         "Resource": [
            "sagemaker-endpoint-arn"
         ]
      }
   ]
}
```

SSM access with AWS PrivateLink

If your endpoints run within a virtual private cloud (VPC) that is not connected to the public internet, you can use AWS PrivateLink to enable SSM. AWS PrivateLink restricts all network traffic between your endpoint instances, SSM, and Amazon EC2 to the Amazon network. For more information on how to setup SSM access with AWS PrivateLink, see [Set up a VPC endpoint for Session Manager](#).

Logging with Amazon CloudWatch Logs

For SSM access enabled endpoints, you can log errors from the SSM agent with Amazon CloudWatch Logs. For more information on how to log errors with CloudWatch Logs, see [Logging session activity](#). The log is available at the SSM log stream, `variant-name/ec2-instance-id/ssm`, under the endpoint log group `aws/sagemaker/endpoints/endpoint-name`. For more information on how to view the log, see [View log data sent to CloudWatch Logs](#).
Production variants behind your endpoint can have multiple model containers. The log for each model container is recorded in the log stream. Each log is preceded by `[sagemaker ssm logs][container-name]`, where `container-name` is either the name that you gave to the container, or the default name, such as `container_0`, and `container_1`.

**Accessing model containers**

To access a model container on your endpoint instance, you need its target ID. The target ID is in one of the following formats:

- `sagemaker-endpoint:endpoint-name_variant-name_ec2-instance-id` for containers on single container endpoints
- `sagemaker-endpoint:endpoint-name_variant-name_ec2-instance-id_container-name` for containers on multi-container endpoints

The following example shows how you can use the AWS CLI to access a model container using its target ID.

```bash
aws ssm start-session --target sagemaker-endpoint:prod-image-classifier_variant1_i-003a121c1b21a90a9_container_1
```

If you enable logging, as mentioned in **Logging with Amazon CloudWatch Logs (p. 2626)**, you can find the target IDs for all the containers listed at the beginning of the SSM log stream.

**Note**

- You cannot connect to 1P algorithm containers or containers of models obtained from SageMaker MarketPlace with SSM. However you can connect to deep learning containers (DLCs) provided by AWS or any custom container that you own.
- If you have enabled network isolation for a model container that prevents it from making outbound network calls, you cannot start an SSM session for that container.
- You can only access one container from one SSM session. To access another container, even if it is behind the same endpoint, start a new SSM session with the target ID of that endpoint.

**Deploy models with model servers**

The following content shows you how to deploy your models on SageMaker using popular model servers, such as TorchServe and Triton.

**Deploy models with TorchServe**

TorchServe is the recommended model server for PyTorch, preinstalled in the AWS PyTorch Deep Learning Container (DLC). This powerful tool offers customers a consistent and user-friendly experience, delivering high performance in deploying multiple PyTorch models across various AWS instances, including CPU, GPU, Neuron, and Graviton, regardless of the model size or distribution.

TorchServe supports a wide array of advanced features, including dynamic batching, microbatching, model A/B testing, streaming, torch XLA, tensorRT, ONNX and IPEX. Moreover, it seamlessly integrates PyTorch's large model solution, PiPPy, enabling efficient handling of large models. Additionally, TorchServe extends its support to popular open-source libraries like DeepSpeed, Accelerate, Fast Transformers, and more, expanding its capabilities even further. With TorchServe, AWS users can...
confidently deploy and serve their PyTorch models, taking advantage of its versatility and optimized performance across various hardware configurations and model types. For more detailed information, you can refer to the PyTorch documentation and TorchServe on GitHub.

The following table lists the AWS PyTorch DLCs supported by TorchServe.

<table>
<thead>
<tr>
<th>Instance type</th>
<th>SageMaker PyTorch DLC link</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPU and GPU</td>
<td>SageMaker PyTorch containers</td>
</tr>
<tr>
<td>Neuron</td>
<td>PyTorch Neuron containers</td>
</tr>
<tr>
<td>Graviton</td>
<td>SageMaker PyTorch Graviton containers</td>
</tr>
</tbody>
</table>

The following sections describe the setup to build and test PyTorch DLCs on Amazon SageMaker.

**Getting started**

To get started, ensure that you have the following prerequisites:

1. Ensure that you have access to an AWS account. Set up your environment so that the AWS CLI can access your account through either an AWS IAM user or an IAM role. We recommend using an IAM role. For the purposes of testing in your personal account, you can attach the following managed permissions policies to the IAM role:
   - AmazonEC2ContainerRegistryFullAccess
   - AmazonEC2FullAccess
   - AWSServiceRoleForAmazonEKSNodegroup
   - AmazonSageMakerFullAccess
   - AmazonS3FullAccess

2. Locally configure your dependencies, as shown in the following example:

```python
from datetime import datetime
import os
import json
import logging
import time

# External Dependencies:
import boto3
from botocore.exceptions import ClientError
import sagemaker

sess = boto3.Session()
sm = sess.client("sagemaker")
region = sess.region_name
account = boto3.client("sts").get_caller_identity().get("Account")

smsess = sagemaker.Session(boto_session=sess)
role = sagemaker.get_execution_role()

# Configuration:
bucket_name = smsess.default_bucket()
prefix = "torchserve"
output_path = f"s3://{bucket_name}/{prefix}/models"
print(f"account={account}, region={region}, role={role}"

3. Retrieve the PyTorch DLC image, as shown in the following example.
SageMaker PyTorch DLC images are available in all AWS regions. For more information, see the list of DLC container images.

```python
baseimage = sagemaker.image_uris.retrieve(
    framework="pytorch",
    region="<region>",
    py_version="py310",
    image_scope="inference",
    version="2.0.1",
    instance_type="ml.g4dn.16xlarge",
)
```

4. Create a local workspace.

```bash
mkdir -p workspace/
```

## Adding a package

The following sections describe how to add and preinstall packages to your PyTorch DLC image.

### BYOC use cases

The following steps outline how to add a package to your PyTorch DLC image. For more information about customizing your container, see Building AWS Deep Learning Containers Custom Images.

1. Suppose you want to add a package to the PyTorch DLC docker image. Create a Dockerfile under the docker directory, as shown in the following example:

```bash
mkdir -p workspace/docker
cat workspace/docker/Dockerfile
ARG BASE_IMAGE
FROM $BASE_IMAGE
#Install any additional libraries
RUN pip install transformers==4.28.1
```

2. Build and publish the customized docker image by using the following `build_and_push.sh` script.

```bash
# Download script build_and_push.sh to workspace/docker
ls workspace/docker
build_and_push.sh Dockerfile

# Build and publish your docker image
reponame = "torchserve"
versiontag = "demo-0.1"
./build_and_push.sh {reponame} {versiontag} {baseimage} {region} {account}
```

### SageMaker preinstall use cases

The following example shows you how to preinstall a package to your PyTorch DLC container. You must create a `requirements.txt` file locally under the directory workspace/code.

```bash
mkdir -p workspace/code
```
Create TorchServe model artifacts

In the following example, we use the pre-trained MNIST model. We create a directory workspace/mnist, implement mnist_handler.py by following the TorchServe custom service instructions, and configure the model parameters (such as batch size and workers) in model-config.yaml. Then, we use the TorchServe tool torch-model-archiver to build the model artifacts and upload to Amazon S3.

1. Configure the model parameters in model-config.yaml.

   ```
   ls -al workspace/mnist-dev
   mnist.py
   mnist_handler.py
   mnist_cnn.pt
   model-config.yaml
   # config the model
   cat workspace/mnist-dev/model-config.yaml
   minWorkers: 1
   maxWorkers: 1
   batchSize: 4
   maxBatchDelay: 200
   responseTimeout: 300
   ```

2. Build the model artifacts by using torch-model-archiver.

   ```
   ```

   If you want to preinstall a package, you must include the code directory in the tar.gz file.

   ```
   cd workspace
   torch-model-archiver --model-name mnist --version 1.0 --model-file mnist-dev/mnist.py --serialized-file mnist-dev/mnist_cnn.pt --handler mnist-dev/mnist_handler.py --config-file mnist-dev/model-config.yaml --archive-format no-archive
   cd mnist
   mv ../code .
   tar cvzf mnist.tar.gz .
   ```

3. Upload mnist.tar.gz to Amazon S3.

   ```
   # upload mnist.tar.gz to S3
   output_path = f"s3://{bucket_name}/{prefix}/models" 
   aws s3 cp mnist.tar.gz {output_path}/mnist.tar.gz
   ```

Using single model endpoints to deploy with TorchServe

The following example shows you how to create a single model real-time inference endpoint, deploy the model to the endpoint, and test the endpoint by using the Amazon SageMaker Python SDK.
from sagemaker.model import Model
from sagemaker.predictor import Predictor

# create the single model endpoint and deploy it on SageMaker
model = Model(model_data = f'{output_path}/mnist.tar.gz',
               image_uri = baseimage,
               role = role,
               predictor_cls = Predictor,
               name = "mnist",
               sagemaker_session = smsess)

endpoint_name = 'torchserve-endpoint-' + time.strftime("%Y-%m-%d-%H-%M-%S",
               time.gmtime())
predictor = model.deploy(instance_type='ml.g4dn.xlarge',
                         initial_instance_count=1,
                         endpoint_name = endpoint_name,
                         serializer=JSONSerializer(),
                         deserializer=JSONDeserializer())

# test the endpoint
import random
import numpy as np
dummy_data ={"inputs": np.random.rand(16, 1, 28, 28).tolist()}
res = predictor.predict(dummy_data)

Using multi-model endpoints to deploy with TorchServe

Multi-model endpoints are a scalable and cost-effective solution to hosting large numbers of models behind one endpoint. They improve endpoint utilization by sharing the same fleet of resources and serving container to host all of your models. They also reduce deployment overhead because SageMaker manages dynamically loading and unloading models, as well as scaling resources based on traffic patterns. Multi-model endpoints are particularly useful for deep learning and generative AI models that require accelerated compute power.

By using TorchServe on SageMaker multi-model endpoints, you can speed up your development by using a serving stack that you are familiar with while leveraging the resource sharing and simplified model management that SageMaker multi-model endpoints provide.

The following example shows you how to create a multi-model endpoint, deploy the model to the endpoint, and test the endpoint by using the Amazon SageMaker Python SDK. Additional details can be found in this notebook example.

from sagemaker.multidatamodel import MultiDataModel
from sagemaker.model import Model
from sagemaker.predictor import Predictor

# create the single model endpoint and deploy it on SageMaker
model = Model(model_data = f'{output_path}/mnist.tar.gz',
               image_uri = baseimage,
               role = role,
               sagemaker_session = smsess)

endpoint_name = 'torchserve-endpoint-' + time.strftime("%Y-%m-%d-%H-%M-%S",
               time.gmtime())
mme = MultiDataModel(
               name = endpoint_name,
               model_data_prefix = output_path,
               model = model,
               sagemaker_session = smsess)
mme.deploy(
    initial_instance_count = 1,
    instance_type = "ml.g4dn.xlarge",
    serializer=sagemaker.serializers.JSONSerializer(),
    deserializer=sagemaker.deserializers.JSONDeserializer())

# list models
list(mme.list_models())

# create mnist v2 model artifacts
cp mnist.tar.gz mnistv2.tar.gz

# add mnistv2
mme.add_model(mnistv2.tar.gz)

# list models
list(mme.list_models())

predictor = Predictor(endpoint_name=mme.endpoint_name, sagemaker_session=smsess)

# test the endpoint
import random
import numpy as np
dummy_data = {"inputs": np.random.rand(16, 1, 28, 28).tolist()}
res = predictor.predict(date=dummy_data, target_model="mnist.tar.gz")

Metrics

TorchServe supports both system level and model level metrics. You can enable metrics in either log format mode or Prometheus mode through the environment variable TS_METRICS_MODE. You can use the TorchServe central metrics config file metrics.yaml to specify the types of metrics to be tracked, such as request counts, latency, memory usage, GPU utilization, and more. By referring to this file, you can gain insights into the performance and health of the deployed models and effectively monitor the TorchServe server's behavior in real-time. For more detailed information, see the TorchServe metrics documentation.

You can access TorchServe metrics logs that are similar to the StatsD format through the Amazon CloudWatch log filter. The following is an example of a TorchServe metrics log:

```
CPUUtilization.Percent:0.0|#Level:Host|#hostname:my_machine_name,timestamp:1682098185
DiskAvailable.Gigabytes:318.0416717529297|#Level:Host|
#hostname:my_machine_name,timestamp:1682098185
```

Deploy models with DJL Serving

DJL Serving is a high performance universal stand-alone model serving solution. It takes a deep learning model, several models, or workflows and makes them available through an HTTP endpoint.

You can use one of the DJL Serving Deep Learning Containers (DLCs) to serve your models on AWS. To learn about the supported model types and frameworks, see the DJL Serving GitHub repository.

DJL Serving offers many features that help you to deploy your models with high performance:

- Ease of use – DJL Serving can serve most models without any modifications. You bring your model artifacts, and DJL Serving can host them.
- Multiple device and accelerator support – DJL Serving supports deploying models on CPUs, GPUs, and AWS Inferentia.
• **Performance** – DJL Serving runs multithreaded inference in a single Java virtual machine (JVM) to boost throughput.
• **Dynamic batching** – DJL Serving supports dynamic batching to increase throughput.
• **Auto scaling** – DJL Serving automatically scales workers up or down based on the traffic load.
• **Multi-engine support** – DJL Serving can simultaneously host models using different frameworks (for example, PyTorch and TensorFlow).
• **Ensemble and workflow models** – DJL Serving supports deploying complex workflows comprised of multiple models and can execute parts of the workflow on CPUs and other parts on GPUs. Models within a workflow can leverage different frameworks.

The following sections describe how to set up an endpoint with DJL Serving on SageMaker.

**Getting started**

To get started, ensure that you have the following prerequisites:

1. Ensure that you have access to an AWS account. Set up your environment so that the AWS CLI can access your account through either an AWS IAM user or an IAM role. We recommend using an IAM role. For the purposes of testing in your personal account, you can attach the following managed permissions policies to the IAM role:
   • **AmazonEC2ContainerRegistryFullAccess**
   • **AmazonEC2FullAccess**
   • **AmazonSageMakerFullAccess**
   • **AmazonS3FullAccess**
2. Ensure that you have the **docker** client set up on your system.
3. Log in to Amazon Elastic Container Registry and set the following environment variables:

   ```bash
   export ACCOUNT_ID=<your_account_id>
   export REGION=<your_region>
   aws ecr get-login-password --region $REGION | docker login --username AWS --password-stdin $ACCOUNT_ID.dkr.ecr.$REGION.amazonaws.com
   ```
4. Pull the docker image.

   ```bash
   docker pull 763104351884.dkr.ecr.us-west-2.amazonaws.com/djl-inference:0.22.1-deepspeed0.9.2-cu118
   ```

For all of the available DJL Serving container images, see the [large model inference containers](#) and the [DJL Serving CPU inference containers](#). When choosing an image from the tables in the preceding links, replace the AWS region in the example URL column with the region you are in. The DLCs are available in the regions listed in the table at the top of the [Available Deep Learning Containers Images](#) page.

**Customize your container**

You can add packages to the base DLC images to customize your container. Suppose you want to add a package to the `763104351884.dkr.ecr.us-west-2.amazonaws.com/djl-inference:0.22.1-deepspeed0.9.2-cu118` docker image. You must create a dockerfile with your desired image as the base image, add the required packages, and push the image to Amazon ECR.

To add a package, complete the following steps:

1. Specify instructions for running your desired libraries or packages in the base image's dockerfile.
### Add custom packages/libraries

```
FROM 763104351884.dkr.ecr.us-west-2.amazonaws.com/djl-inference:0.22.1-deepspeed0.9.2-cu118

## add custom packages/libraries
RUN git clone https://github.com/awslabs/amazon-sagemaker-examples
```

2. Build the Docker image from the dockerfile. Specify your Amazon ECR repository, the name of the base image, and a tag for the image. If you don't have an Amazon ECR repository, see [Using Amazon ECR with the AWS CLI](https://docs.aws.amazon.com/AmazonECR/latest/userguide/using-ecr-with-aws-cli.html) in the *Amazon ECR User Guide* for instructions on how to create one.

   ```bash
docker build -f Dockerfile -t <registry>/<image_name>:<image_tag>
```

3. Push the Docker image to your Amazon ECR repository.

   ```bash
docker push $ACCOUNT_ID.dkr.ecr.$REGION.amazonaws.com/<image_name>:<image_tag>
```

You should now have a customized container image that you can use for model serving. For more examples of customizing your container, see [Building AWS Deep Learning Containers Custom Images](https://docs.aws.amazon.com/sagemaker/latest/dg/djl-deploying.html).

### Prepare your model artifacts

Before deploying your model on SageMaker, you must package your model artifacts in a `.tar.gz` file. DJL Serving accepts the following artifacts in your archive:

- **Model checkpoint**: Files that store your model weights.
- **serving.properties**: A configuration file that you can add for each model. Place serving.properties in the same directory as your model file.
- **model.py**: The inference handler code. This is only applicable when using Python mode. If you don't specify model.py, djl-serving uses one of the default handlers.

The following is an example of a model.tar.gz structure:

```
- model_root_dir # root directory
  - serving.properties
  - model.py # your custom handler file for Python, if you choose not to use the default handlers provided by DJL Serving
  - model binary files # used for Java mode, or if you don't want to use option.model_id and option.s3_url for Python mode
```

DJL Serving supports Java engines powered by DJL or Python engines. Not all of the preceding artifacts are required; the required artifacts vary based on the mode you choose. For example, in Python mode, you only need to specify option.model_id in the serving.properties file; you don't need to specify the model checkpoint inside LMI containers. In Java mode, you are required to package the model checkpoint. For more details on how to configure serving.properties and operate with different engines, see [DJL Serving Operation Modes](https://docs.aws.amazon.com/sagemaker/latest/dg/djl-deploying.html).

### Use single model endpoints to deploy with DJL Serving

After preparing your model artifacts, you can deploy your model to a SageMaker endpoint. This section describes how to deploy a single model to an endpoint with DJL Serving. If you're deploying multiple models, skip this section and go to [Use multi-model endpoints to deploy with DJL Serving](https://docs.aws.amazon.com/sagemaker/latest/dg/djl-deploying.html) (p. 2635).

The following example shows you a method to create a model object using the Amazon SageMaker Python SDK. You'll need to specify the following fields:
Deploy models with DJL Serving

- **image_uri**: You can either retrieve one of the base DJL Serving images as shown in this example, or you can specify a custom Docker image from your Amazon ECR repository, if you followed the instructions in [Customize your container (p. 2633)].
- **model_s3_url**: This should an Amazon S3 URI that points to your `.tar.gz` file.
- **model_name**: Specify a name for the model object.

```python
import boto3
import sagemaker
from sagemaker.model import Model
from sagemaker import image_uris, get_execution_role

aws_region = "aws-region"
sagemaker_session = sagemaker.Session(boto_session=boto3.Session(region_name=aws_region))
role = get_execution_role()

def create_model(model_name, model_s3_url):
    # Get the DJL DeepSpeed image uri
    image_uri = image_uris.retrieve(
        framework="djl-deepspeed",
        region=sagemaker_session.boto_session.region_name,
        version="0.20.0"
    )
    model = Model(
        image_uri=image_uri,
        model_data=model_s3_url,
        role=role,
        name=model_name,
        sagemaker_session=sagemaker_session,
    )
    return model
```

After you create the model object, you can deploy the model to an endpoint and make predictions. For an end-to-end example of how to perform these steps, see the tutorial [Large model inference with DeepSpeed and DJL Serving (p. 2558)].

### Use multi-model endpoints to deploy with DJL Serving

If you want to deploy multiple models to an endpoint, SageMaker offers multi-model endpoints, which are a scalable and cost-effective solution to deploying large numbers of models. DJL Serving also supports loading multiple models simultaneously and running inference on each of the models concurrently. DJL Serving containers adhere to the SageMaker multi-model endpoints contracts and can be used to deploy multi-model endpoints.

Each individual model artifact needs to be packaged in the same way as described in the previous section [Prepare your model artifacts (p. 2634)]. You can set model-specific configurations in the `serving.properties` file and model-specific inference handler code in `model.py`. For a multi-model endpoint, models need to be arranged in the following way:

```
root_dir
    |-- model_1.tar.gz
    |-- model_2.tar.gz
    |-- model_3.tar.gz
    ...
```

The Amazon SageMaker Python SDK uses the [MultiDataModel](https://boto3.amazonaws.com/v1/documentation/api/latest/reference/services/sagemaker.html#Sagemaker.Client.create_model) object to instantiate a multi-model endpoint. The Amazon S3 URI for the root directory should be passed as the `model_data_prefix` argument to the `MultiDataModel` constructor.
Deploy models with Triton Inference Server

Triton Inference Server is an open source inference serving software that streamlines AI inference. With Triton, you can deploy any model built with multiple deep learning and machine learning frameworks, including TensorRT, TensorFlow, PyTorch, ONNX, OpenVINO, Python, RAPIDS FIL, and more.

The SageMaker Triton containers help you deploy Triton Inference Server on the SageMaker Hosting platform to serve trained models in production. It supports the different modes in which SageMaker operates. For a list of available Triton Inference Server containers available on SageMaker, see NVIDIA Triton Inference Containers (SM support only).

For end-to-end notebook examples, we recommend taking a look at the amazon-sagemaker-examples repository.

Hosting modes

The following SageMaker Hosting modes are supported by Triton containers:

- Single model endpoints
  - This is SageMaker's default mode of operation. In this mode, the Triton container can load a single model, or a single ensemble model.
  - The name of the model must be passed as a property of the container environment, which is part of the CreateModel SageMaker API call. The environment variable used to pass in the model name is SAGEMAKER_TRITON_DEFAULT_MODEL_NAME.
- Single model endpoints with ensemble
  - Triton Inference Server supports ensemble, which is a pipeline, or a DAG (directed acyclic graph) of models. While an ensemble technically comprises of multiple models, in the default single model endpoint mode, SageMaker can treat the ensemble proper (the meta-model that represents the pipeline) as the main model to load, and can subsequently load the associated models.
  - The ensemble proper's model name must be used to load the model. It must be passed as a property of the container environment, which is part of the CreateModel SageMaker API call. The environment variable used to pass in the model name is SAGEMAKER_TRITON_DEFAULT_MODEL_NAME.
Multi-model endpoints

- In this mode, SageMaker can serve multiple models on a single endpoint. You can use this mode by specifying the environment variable ‘MultiModel’: true as a property of the container environment, which is part of the CreateModel SageMaker API call.

- By default, no model is loaded when the instance starts. To run an inference request against a particular model, specify the corresponding model’s *.tar.gz file as an argument to the TargetModel property of the InvokeEndpoint SageMaker API call.

Multi-model endpoints with ensemble

- In this mode, SageMaker functions as described for multi-model endpoints. However, the SageMaker Triton container can load multiple ensemble models, meaning that multiple model pipelines can run on the same instance. SageMaker treats every ensemble as one model, and the ensemble proper of each model can be invoked by specifying the corresponding *.tar.gz archive as the TargetModel.

For better memory management during dynamic memory LOAD and UNLOAD, we recommend that you keep the ensemble size small.

Inference payload types

Triton supports two methods of sending an inference payload over the network – json and binary + json (or binary encoded json). The JSON payload in both cases includes the datatype, shape and the actual inference request tensor. The request tensor must be a binary tensor.

With the binary+json format, you must specify the length of the request metadata in the header to allow Triton to correctly parse the binary payload. In the SageMaker Triton container, this is done using a custom Content-Type header: application/vnd.sagemaker-triton.binary+json;json-header-size={}. This is different from using the Inference-Header-Content-Length header on a stand-alone Triton Inference Server because custom headers are not allowed in SageMaker.

Using config.pbtxt to set the model config

For Triton Inference Servers on SageMaker, each model must include a config.pbtxt file that specifies, at a minimum, the following configurations for the model:

- name: While this is optional for models running outside of SageMaker, we recommend that you always provide a name for the models to be run in Triton on SageMaker.

  - platform and/or backend: Setting a backend is essential to specify the type of the model. Some backends have further classification, such as tensorflow_savedmodel or tensorflow_graphdef. Such options can be specified as part of the platform key in addition to the backend key. The most common backends are tensorrt, onnxruntime, tensorflow, pytorch, python, dali, fil, and openvino.

- input: Specify three attributes for the input: name, data_type and dims (the shape).

- output: Specify three attributes for the output: name, data_type and dims (the shape).

- max_batch_size: Set the batch size to a value greater than or equal to 1 that indicates the maximum batch size that Triton should use with the model.

For more details on configuring config.pbtxt, see Triton’s GitHub repository. Triton provides several configurations for tweaking model behavior. Some of the most common and important configuration options are:

- instance_groups: Instance groups help with specifying the number and location for a given model. They have the attributes count, kind, and gpus (used when kind is KIND_GPU). The count attribute is equivalent to the number of workers. For regular model serving, each worker has its own copy of the
model. Similarly, in Triton, the count specifies the number of model copies per device. For example, if the instance_group type is KIND_CPU, then the CPU has count number of model copies.

**Note**
On a GPU instance, the instance_group configuration applies per GPU device. For example, count number of model copies are placed on each GPU device unless you explicitly specify which GPU devices should load the model.

- **dynamic_batching** and **sequence_batching**: Dynamic batching is used for stateless models, and sequence batching is used for stateful models (where you want to route a request to the same model instance every time). Batching schedulers enable a per-model queue, which help in increasing throughput, depending on the batching configuration.

- **ensemble**: An ensemble model represents a pipeline of one or more models and the connection of input and output tensors between those models. It can be configured by specifying platform as ensemble. The ensemble configuration is just a representation of the model pipeline. On SageMaker, all the models under an ensemble are treated as dependents of the ensemble model and are counted as a single model for SageMaker metrics, such as LoadedModelCount.

### Publishing default Triton metrics to Amazon CloudWatch

The NVIDIA Triton Inference Container exposes metrics at port 8002 (configurable) for the different models and GPUs that are utilized in the Triton Inference Server. For full details of the default metrics that are available, see the GitHub page for the Triton Inference Server metrics. These metrics are in Prometheus format and can be scraped using a Prometheus scraper configuration.

Starting with version v23.07 onwards, the SageMaker Triton container supports publishing these metrics to Amazon CloudWatch by specifying a few environment variables. In order to scrape the Prometheus metrics, the SageMaker Triton container leverages the Amazon CloudWatch agent.

The required environment variables that you must specify to collect metrics are as follows:

<table>
<thead>
<tr>
<th>Environment variable</th>
<th>Description</th>
<th>Example value</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAGEMAKER_TRITON_ALLOW_METRICS</td>
<td>Specify this option to allow Triton to publish metrics to its Prometheus endpoint.</td>
<td>&quot;true&quot;</td>
</tr>
<tr>
<td>SAGEMAKER_TRITON_PUBLISH_METRICS</td>
<td>Specify this option to start the pre-checks necessary to publish metrics to Amazon CloudWatch.</td>
<td>&quot;true&quot;</td>
</tr>
<tr>
<td>SAGEMAKER_TRITON_CLOUDWATCH_LOG_GROUP</td>
<td>Specify this option to point to the log group to which metrics are written.</td>
<td>&quot;/aws/SageMaker/Endpoints/TritonMetrics/SageMakerTwoEnsemblesTest&quot;</td>
</tr>
<tr>
<td>SAGEMAKER_TRITON_CLOUDWATCH_METRIC_NAMESPACE</td>
<td>Specify this option to point to the metric namespace where you want to see and plot the metrics.</td>
<td>&quot;/aws/SageMaker/Endpoints/TritonMetrics/SageMakerTwoEnsemblesPublicTest&quot;</td>
</tr>
<tr>
<td>SAGEMAKER_TRITON_METRICS_PORT</td>
<td>Specify this as 8002, or any other port. If SageMaker has not blocked the specified port, it is used. Otherwise, another non-blocked port is chosen automatically.</td>
<td>&quot;8002&quot;</td>
</tr>
</tbody>
</table>

When publishing metrics with Triton on SageMaker, keep in mind the following limitations:
• While you can generate custom metrics through the C-API and Python backend (v23.05 onwards), these are currently not supported for publishing to Amazon CloudWatch.

• In SageMaker multi-model endpoints (MME) mode, Triton runs in an environment that requires model namespaceing to be enabled because each model (except ensemble models) are treated as if they are in their own model repository. Currently, this creates a limitation for metrics. When model namespaceing is enabled, Triton does not distinguish the metrics between two models with the same name belonging to different ensembles. As a workaround, make sure that every model being deployed has a unique name. This also makes it easier to look up your metrics in CloudWatch.

Environment variables

The following table lists the supported environment variables for Triton on SageMaker.

<table>
<thead>
<tr>
<th>Environment variable</th>
<th>Description</th>
<th>Type</th>
<th>Possible values</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAGEMAKER_MULTI_MODEL</td>
<td>Allows Triton to operate in SageMaker multi-model endpoints mode.</td>
<td>Boolean</td>
<td>true, false</td>
</tr>
<tr>
<td>SAGEMAKER_TRITON_DEFAULT_MODEL_NAME</td>
<td>Specify the model to be loaded in the SageMaker single model (default) mode. For ensemble mode, specify the name of the ensemble proper.</td>
<td>String</td>
<td>&lt;model_name&gt; as specified in config.pbtxt</td>
</tr>
<tr>
<td>SAGEMAKER_TRITON_PING_MODE</td>
<td>'ready' is the default mode in SageMaker's single model mode, and 'live' is the default in SageMaker's multi-model endpoints mode.</td>
<td>String</td>
<td>ready, live</td>
</tr>
<tr>
<td>SAGEMAKER_TRITON_DISABLE_MODEL_NAMESPACING</td>
<td>In the SageMaker Triton container, this is set to true by default.</td>
<td>Boolean</td>
<td>true, false</td>
</tr>
<tr>
<td>SAGEMAKER_BIND_TO_PORT</td>
<td>While on SageMaker, the default port is 8080. You can customize to a different port in multi-container scenarios.</td>
<td>String</td>
<td>&lt;port_number&gt;</td>
</tr>
<tr>
<td>SAGEMAKER_SAFE_PORT_RANGE</td>
<td>Set by the SageMaker platform when using multi-container mode.</td>
<td>String</td>
<td>&lt;port_1&gt;-&lt;port_2&gt;</td>
</tr>
<tr>
<td>SAGEMAKER_TRITON_ALLOW_GRPC</td>
<td>While SageMaker doesn't support GRPC currently, if you're using Triton in front of a custom reverse proxy,</td>
<td>Boolean</td>
<td>true, false</td>
</tr>
<tr>
<td>Environment variable</td>
<td>Description</td>
<td>Type</td>
<td>Possible values</td>
</tr>
<tr>
<td>--------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>--------------------------</td>
</tr>
<tr>
<td>SAGEMAKER_TRITON_GRPC_PORT</td>
<td>The default port for GRPC is 8001, but you can change it.</td>
<td>String</td>
<td>&lt;port_number&gt;</td>
</tr>
<tr>
<td>SAGEMAKER_TRITON_THREAD_COUNT</td>
<td>The number of default HTTP request handler threads.</td>
<td>String</td>
<td>&lt;number&gt;</td>
</tr>
<tr>
<td>SAGEMAKER_TRITON_LOG_VERBOSE</td>
<td>Default on SageMaker, but you can selectively turn this option off.</td>
<td>Boolean</td>
<td>true, false</td>
</tr>
<tr>
<td>SAGEMAKER_TRITON_LOG_INFO</td>
<td>Default on SageMaker.</td>
<td>Boolean</td>
<td>true, false</td>
</tr>
<tr>
<td>SAGEMAKER_TRITON_LOG_WARNING</td>
<td>Default on SageMaker.</td>
<td>Boolean</td>
<td>true, false</td>
</tr>
<tr>
<td>SAGEMAKER_TRITON_LOG_ERROR</td>
<td>Default on SageMaker.</td>
<td>Boolean</td>
<td>true, false</td>
</tr>
<tr>
<td>SAGEMAKER_TRITON_SHM_DEFAULT_BYTE_SIZE</td>
<td>Specify the shm size for the Python backend, in bytes. The default value is 16 MB but can be increased.</td>
<td>String</td>
<td>&lt;number&gt;</td>
</tr>
<tr>
<td>SAGEMAKER_TRITON_SHM_GROWTH_BYTE_SIZE</td>
<td>Specify the shm growth size for the Python backend, in bytes. The default value is 1 MB but can be increased to allow greater increments.</td>
<td>String</td>
<td>&lt;number&gt;</td>
</tr>
<tr>
<td>SAGEMAKER_TRITON_TENSORFLOW_VERSION</td>
<td>The default value is 2. Triton no longer supports Tensorflow 2 from Triton v23.04. You can configure this variable for previous versions.</td>
<td>String</td>
<td>&lt;number&gt;</td>
</tr>
<tr>
<td>SAGEMAKER_TRITON_MODEL_LOAD_GPU_LIMIT</td>
<td>Restrict the maximum GPU memory percentage which is used for model loading, allowing the remainder to be used for the inference requests.</td>
<td>String</td>
<td>&lt;number&gt;</td>
</tr>
<tr>
<td>SAGEMAKER_TRITON_ALLOW_METRICS</td>
<td>Default on SageMaker.</td>
<td>Boolean</td>
<td>true, false</td>
</tr>
</tbody>
</table>
Deploy models at the edge with SageMaker Edge Manager

**Warning**
SageMaker Edge Manager is being discontinued on April 26th, 2024. For more information about continuing to deploy your models to edge devices, see [SageMaker Edge Manager end of life](p. 2692).

Amazon SageMaker Edge Manager provides model management for edge devices so you can optimize, secure, monitor, and maintain machine learning models on fleets of edge devices such as smart cameras, robots, personal computers, and mobile devices.

**Why Use Edge Manager?**

Many machine learning (ML) use cases require running ML models on a fleet of edge devices, which allows you to get predictions in real-time, preserves the privacy of the end users, and lowers the cost of network connectivity. With the increasing availability of low-power edge hardware designed for ML, it is now possible to run multiple complex neural network models on edge devices.

However, operating ML models on edge devices is challenging, because devices, unlike cloud instances, have limited compute, memory, and connectivity. After the model is deployed, you need to continuously monitor the models, because model drift can cause the quality of model to decay overtime. Monitoring

models across your device fleets is difficult because you need to write custom code to collect data samples from your device and recognize skew in predictions. In addition, models are often hard-coded into the application. To update the model, you must rebuild and update the entire application or device firmware, which can disrupt your operations.

With SageMaker Edge Manager, you can optimize, run, monitor, and update machine learning models across fleets of devices at the edge.

**How Does it Work?**

At a high level, there are five main components in the SageMaker Edge Manager workflow: compiling models with SageMaker Neo, packaging Neo-compiled models, deploying models to your devices, running models on the SageMaker inference engine (Edge Manager agent), and maintaining models on the devices.

SageMaker Edge Manager uses SageMaker Neo to optimize your models for the target hardware in one click, then to cryptographically sign your models before deployment. Using SageMaker Edge Manager, you can sample model input and output data from edge devices and send it to the cloud for monitoring and analysis, and view a dashboard that tracks and visually reports on the operation of the deployed models within the SageMaker console.

SageMaker Edge Manager extends capabilities that were previously only available in the cloud to the edge, so developers can continuously improve model quality by using Amazon SageMaker Model Monitor for drift detection, then relabel the data with SageMaker Ground Truth and retrain the models in SageMaker.

**How Do I Use SageMaker Edge Manager?**

If you are a first time user of SageMaker Edge Manager, we recommend that you do the following:

1. **Read the Getting Started section** - This section walks you through setting up your first edge packaging job and creating your first fleet.

2. **Explore Edge Manager Jupyter notebook examples** - Example notebooks are stored in the [amazon-sagemaker-examples](https://github.com/aws-samples/amazon-sagemaker-examples) GitHub repository in the `sagemaker_edge_manager` folder.
Getting Started

This guide demonstrates how to complete the necessary steps to register, deploy, and manage a fleet of devices, and how to satisfy Amazon SageMaker Edge Manager prerequisites.

Topics

- Setting Up (p. 2643)
- Train, Compile, and Package Your Model (p. 2646)
- Create and Register Fleets and Authenticate Devices (p. 2649)
- Download and Set Up Edge Manager (p. 2652)
- Run Agent (p. 2656)

Setting Up

Before you begin using SageMaker Edge Manager to manage models on your device fleets, you must first create IAM Roles for both SageMaker and AWS IoT. You will also want to create at least one Amazon S3 bucket where you will store your pre-trained model, the output of your SageMaker Neo compilation job, as well as input data from your edge devices.

Sign up for an AWS account

If you do not have an AWS account, complete the following steps to create one.

To sign up for an AWS account

2. Follow the online instructions.

Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

When you sign up for an AWS account, an AWS account root user is created. The root user has access to all AWS services and resources in the account. As a security best practice, assign administrative access to an administrative user, and use only the root user to perform tasks that require root user access.

AWS sends you a confirmation email after the sign-up process is complete. At any time, you can view your current account activity and manage your account by going to https://aws.amazon.com/ and choosing My Account.

Create an administrative user

After you sign up for an AWS account, create an administrative user so that you don't use the root user for everyday tasks.

Secure your AWS account root user

1. Sign in to the AWS Management Console as the account owner by choosing Root user and entering your AWS account email address. On the next page, enter your password.

   For help signing in by using root user, see Signing in as the root user in the AWS Sign-In User Guide.

2. Turn on multi-factor authentication (MFA) for your root user.

   For instructions, see Enable a virtual MFA device for your AWS account root user (console) in the IAM User Guide.
Create an administrative user

- For your daily administrative tasks, grant administrative access to an administrative user in AWS IAM Identity Center.

For instructions, see Getting started in the AWS IAM Identity Center User Guide.

Sign in as the administrative user

- To sign in with your IAM Identity Center user, use the sign-in URL that was sent to your email address when you created the IAM Identity Center user.

For help signing in using an IAM Identity Center user, see Signing in to the AWS access portal in the AWS Sign-In User Guide.

Create roles and storage

SageMaker Edge Manager needs access to your Amazon S3 bucket URI. To facilitate this, create an IAM role that can run SageMaker and has permission to access Amazon S3. Using this role, SageMaker can run under your account and access to your Amazon S3 bucket.

You can create an IAM role by using the IAM console, AWS SDK for Python (Boto3), or AWS CLI. The following is an example of how to create an IAM role, attach the necessary policies with the IAM console, and create an Amazon S3 bucket.

1. **Create an IAM role for Amazon SageMaker.**
   a. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
   b. In the navigation pane of the IAM console, choose Roles, and then choose Create role.
   c. For Select type of trusted entity, choose AWS service.
   d. Choose the service that you want to allow to assume this role. In this case, choose SageMaker. Then choose Next: Permissions.
      - This automatically creates an IAM policy that grants access to related services such as Amazon S3, Amazon ECR, and CloudWatch Logs.
   e. Choose Next: Tags.
   f. (Optional) Add metadata to the role by attaching tags as key-value pairs. For more information about using tags in IAM, see Tagging IAM resources.
   g. Choose Next: Review.
   h. Type in a Role name.
   i. If possible, type a role name or role name suffix. Role names must be unique within your AWS account. They are not distinguished by case. For example, you cannot create roles named both PRODROLE and prodrole. Because other AWS resources might reference the role, you cannot edit the name of the role after it has been created.
   j. (Optional) For Role description, type a description for the new role.
   k. Review the role and then choose Create role.

   Note the SageMaker Role ARN, which you use to create a compilation job with SageMaker Neo and a packaging job with Edge Manager. To find out the role ARN using the console, do the following:
   i. Go to the IAM console: https://console.aws.amazon.com/iam/
   ii. Select Roles.
iii. Search for the role you just created by typing in the name of the role in the search field.
iv. Select the role.
v. The role ARN is at the top of the **Summary** page.

2. **Create an IAM role for AWS IoT.**

The AWS IoT IAM role you create is used to authorize your thing objects. You also use the IAM role ARN to create and register device fleets with a SageMaker client object.

Configure an IAM role in your AWS account for the credentials provider to assume on behalf of the devices in your device fleet. Then, attach a policy to authorize your devices to interact with AWS IoT services.

Create a role for AWS IoT either programmatically or with the IAM console, similar to what you did when you created a role for SageMaker.

a. Sign in to the AWS Management Console and open the IAM console at [https://console.aws.amazon.com/iam/](https://console.aws.amazon.com/iam/).

b. In the navigation pane of the IAM console, choose **Roles**, and then choose **Create role**.

c. For **Select type of trusted entity**, choose **AWS service**.

d. Choose the service that you want to allow to assume this role. In this case, choose **IoT**. Select **IoT** as the **Use Case**.

e. Choose **Next: Permissions**.

f. Choose **Next: Tags**.

g. (Optional) Add metadata to the role by attaching tags as key–value pairs. For more information about using tags in IAM, see [Tagging IAM resources](#).

h. Choose **Next: Review**.

i. Type in a **Role name**. The role name must start with **SageMaker**.

j. (Optional) For **Role description**, type a description for the new role.

k. Review the role and then choose **Create role**.

l. Once the role is created, choose **Roles** in the IAM console. Search for the role you created by typing in role name in the **Search** field.

m. Choose your role.

n. Next, choose **Attach Policies**.

o. Search for **AmazonSageMakerEdgeDeviceFleetPolicy** in the **Search** field. Select AmazonSageMakerEdgeDeviceFleetPolicy.

p. Choose **Attach policy**.

q. Add the following policy statement to the trust relationship:

```json
{
   "Version": "2012-10-17",
   "Statement": [
     {
       "Effect": "Allow",
       "Principal": {"Service": "credentials.iot.amazonaws.com"},
       "Action": "sts:AssumeRole"
     },
     {
       "Effect": "Allow",
       "Principal": {"Service": "sagemaker.amazonaws.com"},
       "Action": "sts:AssumeRole"
     }
   ]
}
```
A trust policy is a **JSON policy document** in which you define the principals that you trust to assume the role. For more information about trust policies, see [Roles terms and concepts](#).

1. Note the AWS IoT role ARN. You use the AWS IoT Role ARN to create and register the device fleet. To find the IAM role ARN with the console:
   1. Go to the IAM console: [https://console.aws.amazon.com/iam/](https://console.aws.amazon.com/iam/)
   2. Choose **Roles**.
   3. Search for the role you created by typing in the name of the role in the **Search** field.
   4. Select the role.
   5. The role ARN is on the Summary page.

3. **Create an Amazon S3 bucket.**

   SageMaker Neo and Edge Manager access your pre-compiled model and compiled model from an Amazon S3 bucket. Edge Manager also stores sample data from your device fleet in Amazon S3.

   1. Open the Amazon S3 console at [https://console.aws.amazon.com/s3/](https://console.aws.amazon.com/s3/).
   2. Choose **Create bucket**.
   3. In **Bucket name**, enter a name for your bucket.
   4. In **Region**, choose the AWS Region where you want the bucket to reside.
   5. In **Bucket settings for Block Public Access**, choose the settings that you want to apply to the bucket.
   6. Choose **Create bucket**.

   For more information about creating Amazon S3 buckets, see [Getting started with Amazon S3](#).

### Train, Compile, and Package Your Model

In this section you will create SageMaker and AWS IoT client objects, download a pre-trained machine learning model, upload your model to your Amazon S3 bucket, compile your model for your target device with SageMaker Neo, and package your model so that it can be deployed with the Edge Manager agent.

1. **Import libraries and create client objects.**

   This tutorial uses the AWS SDK for Python (Boto3) to create clients to interact with SageMaker, Amazon S3, and AWS IoT.

   Import Boto3, specify your Region, and initialize the client objects you need as shown in the following example:

   ```python
   import boto3
   import json
   import time
   AWS_REGION = 'us-west-2' # Specify your Region
   bucket = 'bucket-name'
   sagemaker_cClient = boto3.client('sagemaker', region_name=AWS_REGION)
   iot_cClient = boto3.client('iot', region_name=AWS_REGION)
   ```

   Define variables and assign them the role ARN you created for SageMaker and AWS IoT as strings:

   ```python
   # Replace with the role ARN you created for SageMaker
   ```
sagemaker_role_arn = "arn:aws:iam::<account>:role/*"

# Replace with the role ARN you created for AWS IoT.
# Note: The name must start with 'SageMaker'

iot_role_arn = "arn:aws:iam::<account>:role/SageMaker*"

2. **Train a machine learning model.**

See [Train a Model with Amazon SageMaker](#) for more information on how to train a machine learning model using SageMaker. You can optionally upload your locally trained model directly into an Amazon S3 URI bucket.

If you do not have a model yet, you can use a pre-trained model for the next steps in this tutorial. For example, you can save the MobileNet V2 models from the TensorFlow framework. MobileNet V2 is an image classification model optimized for mobile applications. For more information about MobileNet V2, see the [MobileNet GitHub README](#).

Type the following into your Jupyter Notebook to save the pre-trained MobileNet V2 model:

```python
# Save the MobileNet V2 model to local storage
import tensorflow as tf
model = tf.keras.applications.MobileNetV2()
model.save("mobilenet_v2.h5")
```

**Note**

- If you do not have TensorFlow installed, you can do so by running `pip install tensorflow==2.4`
- Use TensorFlow version 2.4 or lower for this tutorial.

The model will be saved into the `mobilenet_v2.h5` file. Before packaging the model, you will need to first compile your model using SageMaker Neo. See [Supported Frameworks, Devices, Systems, and Architectures (p. 2736)](#) to check if your version of TensorFlow (or other framework of choice) is currently supported by SageMaker Neo.

SageMaker Neo requires models to be stored as a compressed TAR file. Repackage it as a compressed TAR file (*.tar.gz):

```python
# Package MobileNet V2 model into a TAR file
import tarfile
tarfile_name='mobilenet-v2.tar.gz'
with tarfile.open(tarfile_name, mode='w:gz') as archive:
    archive.add('mobilenet-v2.h5')
```

3. **Upload your model to Amazon S3.**

Once you have a machine learning model, store it in an Amazon S3 bucket. The following example uses an AWS CLI command to upload the model the to the Amazon S3 bucket you created earlier in a directory called `models`. Type in the following into your Jupyter Notebook:

```bash
!aws s3 cp mobilenet-v2.tar.gz s3://{bucket}/models/
```

4. **Compile your model with SageMaker Neo.**
Compile your machine learning model with SageMaker Neo for an edge device. You need to know your Amazon S3 bucket URI where you stored the trained model, the machine learning framework you used to train your model, the shape of your model's input, and your target device.

For the MobileNet V2 model, use the following:

```python
framework = 'tensorflow'
target_device = 'jetson_nano'
data_shape = '{"data": [1, 3, 224, 224]}'
```

SageMaker Neo requires a specific model input shape and model format based on the deep learning framework you use. For more information about how to save your model, see What input data shapes does SageMaker Neo expect? (p. 2695). For more information about devices and frameworks supported by Neo, see Supported Frameworks, Devices, Systems, and Architectures (p. 2736).

Use the CreateCompilationJob API to create a compilation job with SageMaker Neo. Provide a name to the compilation job, the SageMaker Role ARN, the Amazon S3 URI where your model is stored, the input shape of the model, the name of the framework, the Amazon S3 URI where you want SageMaker to store your compiled model, and your edge device target.

```python
# Specify the path where your model is stored
model_directory = 'models'
s3_model_uri = 's3://{}/models.tar.gz'.format(bucket, model_directory, tarfile_name)

# Store compiled model in S3 within the 'compiled-models' directory
compilation_output_dir = 'compiled-models'
s3_output_location = 's3://{}/compiled-models/'.format(bucket, compilation_output_dir)

# Give your compilation job a name
compilation_job_name = 'getting-started-demo'

sagemaker_client.create_compilation_job(CompilationJobName=compilation_job_name,
RoleArn=sagemaker_role_arn,
InputConfig={
    'S3Uri': s3_model_uri,
    'DataInputConfig': data_shape,
    'Framework': framework.upper(),
},
OutputConfig={
    'S3OutputLocation': s3_output_location,
    'TargetDevice': target_device,
    'StoppingCondition': {'MaxRuntimeInSeconds': 900}
})
```

5. **Package your compiled model.**

Packaging jobs take SageMaker Neo–compiled models and make any changes necessary to deploy the model with the inference engine, Edge Manager agent. To package your model, create an edge packaging job with the create_edge_packaging API or the SageMaker console.

You need to provide the name that you used for your Neo compilation job, a name for the packaging job, a role ARN (see Setting Up (p. 2643) section), a name for the model, a model version, and the Amazon S3 bucket URI for the output of the packaging job. Note that Edge Manager packaging job names are case-sensitive. The following is an example of how to create a packaging job using the API.

```python
edge_packaging_name='edge-packaging-demo'
model_name="sample-model"
model_version="1.1"
```
Define the Amazon S3 URI where you want to store the packaged model.

```python
# Output directory where you want to store the output of the packaging job
packaging_output_dir = 'packaged_models'
packaging_s3_output = 's3://{}/{}'.format(bucket, packaging_output_dir)
```

Use CreateEdgePackagingJob to package your Neo-compiled model. Provide a name for your edge packaging job and the name you provided for your compilation job (in this example, it was stored in the variable compilation_job_name). Also provide a name for your model, a version for your model (this is used to help you keep track of what model version you are using), and the S3 URI where you want SageMaker to store the packaged model.

```python
sagemaker_client.create_edge_packaging_job(
    EdgePackagingJobName=edge_packaging_name,
    CompilationJobName=compilation_job_name,
    RoleArn=sagemaker_role_arn,
    ModelName=model_name,
    ModelVersion=model_version,
    OutputConfig={
        "S3OutputLocation": packaging_s3_output
    }
)
```

Create and Register Fleets and Authenticate Devices

In this section you will create your AWS IoT thing object, create a device fleet, register your device fleet so it can interact with the cloud, create X.509 certificates to authenticate your devices to AWS IoT Core, associate the role alias with AWS IoT that was generated when you created your fleet, get your AWS account-specific endpoint for the credentials provider, get an official Amazon Root CA file, and upload the Amazon CA file to Amazon S3.

1. **Create AWS IoT things.**

   SageMaker Edge Manager takes advantage of the AWS IoT Core services to facilitate the connection between the edge devices and endpoints in the AWS cloud. You can take advantage of existing AWS IoT functionality after you set up your devices to work with Edge Manager.

   To connect your device to AWS IoT, you need to create AWS IoT thing objects, create and register a client certificate with AWS IoT, and create and configure the IAM role for your devices.

   First, create AWS IoT thing objects with the AWS IoT client (`iot_client`) you created earlier with Boto3. The following example shows how to create two thing objects:

   ```python
   iot_thing_name = 'sample-device'
iot_thing_type = 'getting-started-demo'
iot_client.create_thing_type(
    thingTypeName=iot_thing_type
  )
iot_client.create_thing(
    thingName=iot_thing_name,
    thingTypeName=iot_thing_type
  )
```

2. **Create your device fleet.**
Create a device fleet with the SageMaker client object defined in a previous step. You can also use the SageMaker console to create a device fleet.

```python
import time
device_fleet_name="demo-device-fleet" + str(time.time()).split('.')[0]
device_name="sagemaker-edge-demo-device" + str(time.time()).split('.')[0]
```

Specify your IoT role ARN. This lets AWS IoT grant temporary credentials to devices.

```python
device_model_directory='device_output'
s3_device_fleet_output = 's3://{}/{}'.format(bucket, device_model_directory)
sagemaker_client.create_device_fleet(
    DeviceFleetName=device_fleet_name,
    RoleArn=iot_role_arn, # IoT Role ARN specified in previous step
    OutputConfig={
        'S3OutputLocation': s3_device_fleet_output
    }
)
```

An AWS IoT role alias is created when you create a device fleet. This role alias is associated with AWS IoT using the `iot_client` object in a later step.

3. **Register your device fleet.**

To interact with the cloud, you need to register your device with SageMaker Edge Manager. In this example, you register a single device with the fleet you created. To register the device, you need to provide a device name and the AWS IoT thing name as shown in the following example:

```python
# Device name should be 36 characters
device_name = "sagemaker-edge-demo-device" + str(time.time()).split('.')[0]
sagemaker_client.register_devices(
    DeviceFleetName=device_fleet_name,
    Devices=[
        {"DeviceName": device_name,
         "IotThingName": iot_thing_name
        }
    ]
)
```

4. **Create X.509 certificates.**

After creating the AWS IoT thing object, you must create a X.509 device certificate for your thing object. This certificate authenticates your device to AWS IoT Core.

Use the following to create a private key, public key, and a X.509 certificate file using the AWS IoT client defined (`iot_client`) earlier.

```python
# Creates a 2048-bit RSA key pair and issues an X.509 # certificate
# using the issued public key.
cert = iot_client.create_keys_and_certificate(usetAsActive=True)
```

```python
# Get certificate from dictionary object and save in its own
# with open('/device.pem.crt', 'w') as f:
    # for line in create_cert['certificatePem'].split('n'):
        # f.write(line)
```

2650
5. **Associate the role alias with AWS IoT.**

When you create a device fleet with SageMaker (sagemaker_client.create_device_fleet()), a role alias is generated for you. An AWS IoT role alias provides a mechanism for connected devices to authenticate to AWS IoT using X.509 certificates, and then obtain short-lived AWS credentials from an IAM role that is associated with an AWS IoT role alias. The role alias allows you to change the role of the device without having to update the device. Use `DescribeDeviceFleet` to get the role alias name and ARN.

```python
# Print Amazon Resource Name (ARN) and alias that has access to AWS Internet of Things (IoT).
sagemaker_client.describe_device_fleet(DeviceFleetName=device_fleet_name)

# Store iot role alias string in a variable
# Grabs role ARN
full_role_alias_name = sagemaker_client.describe_device_fleet(DeviceFleetName=device_fleet_name)['IotRoleAlias']
start_index = full_role_alias_name.find('SageMaker') # Find beginning of role name
role_alias_name = full_role_alias_name[start_index:]
```

Use the `iot_client` to facilitate associating the role alias generated from creating the device fleet with AWS IoT:

```python
role_alias = iot_client.describe_role_alias(roleAlias=role_alias_name)
```

For more information about IAM role alias, see [Role alias allows access to unused services](https://docs.aws.amazon.com/iot/latest/developerguide/role-alias.html).

You created and registered a certificate with AWS IoT earlier for successful authentication of your device. Now, you need to create and attach a policy to the certificate to authorize the request for the security token.

```python
alias_policy = {
    "Version": "2012-10-17",
    "Statement": {
        "Effect": "Allow",
        "Action": "iot:AssumeRoleWithCertificate",
        "Resource": role_alias['roleAliasDescription']['roleAliasArn']
    }
}
```

```python
policy_name = 'aliaspolicy-{}'.format(time.time())
aliaspolicy = iot_client.create_policy(policyName=policy_name,
                                        policyDocument=json.dumps(alias_policy))
```

# Attach policy
```python
iot_client.attach_policy(policyName=policy_name,
```
6. **Get your AWS account-specific endpoint for the credentials provider.**

Edge devices need an endpoint in order to assume credentials. Obtain your AWS account-specific endpoint for the credentials provider.

```python
# Get the unique endpoint specific to your AWS account that is making the call.
iot_endpoint = iot_client.describe_endpoint(
    endpointType='iot:CredentialProvider'
)
endpoint="https://{}/role-aliases/{}/
credentials".format(iot_endpoint['endpointAddress'],role_alias_name)
```

7. **Get the official Amazon root CA file and upload it to the Amazon S3 bucket.**

Use the following in your Jupyter Notebook or AWS CLI (if you use your terminal, remove the '!' magic function):

```bash
!wget https://www.amazontrust.com/repository/AmazonRootCA1.pem
```

Use the endpoint to make an HTTPS request to the credentials provider to return a security token. The following example command uses `curl`, but you can use any HTTP client.

```bash
!curl --cert device.pem.crt --key private.pem.key --cacert AmazonRootCA1.pem $endpoint
```

If the certificate is verified, upload the keys and certificate to your Amazon S3 bucket URI:

```bash
!aws s3 cp private.pem.key s3://{bucket}/authorization-files/
!aws s3 cp device.pem.crt s3://{bucket}/authorization-files/
!aws s3 cp AmazonRootCA1.pem s3://{bucket}/authorization-files/
```

Clean your working directory by moving your keys and certificate to a different directory:

```bash
# Optional - Clean up working directory
!mkdir authorization-files
!mv private.pem.key device.pem.crt AmazonRootCA1.pem authorization-files/
```

---

**Download and Set Up Edge Manager**

The Edge Manager agent is an inference engine for your edge devices. Use the agent to make predictions with models loaded onto your edge devices. The agent also collects model metrics and captures data at specific intervals.

In this section you will set up your device with the agent. To do so, first copy a release artifact and signing root certificate from the release bucket locally to your machine. After you unzip the release artifact, upload it to Amazon S3. Next, define and save a configuration file for the agent. A template is provided for you to copy and paste. Finally, copy the release artifacts, configuration file, and credentials to your device.

1. **Download the SageMaker Edge Manager agent.**

   The agent is released in binary format for supported operating systems. This example runs inference on a Jetson Nano which uses a Linux operating system and has an ARM64 architecture. For more
information about what operating system and architecture supported devices use, see Supported Devices, Chip Architectures, and Systems (p. 2737).

Fetch the latest version of binaries from the SageMaker Edge Manager release bucket from the us-west-2 Region.

```
!aws s3 ls s3://sagemaker-edge-release-store-us-west-2-linux-armv8/Releases/ | sort -r
```

This returns release artifacts sorted by their version.

```
PRE 1.20210512.96da6cc/
PRE 1.20210305.a4bc999/
PRE 1.20201218.81f481f/
PRE 1.20201207.02d0e97/
```

The version has the following format: `<MAJOR_VERSION>.<YYYY-MM-DD>.<SHA-7>`. It consists of three components:

- `<MAJOR_VERSION>`: The release version. The release version is currently set to 1.
- `<YYYY-MM-DD>`: The time stamp of the artifact release.
- `<SHA-7>`: The repository commit ID from which the release is built.

Copy the zipped TAR file locally or to your device directly. The following example shows how to copy the latest release artifact at the time this document was released.

```
!aws s3 cp s3://sagemaker-edge-release-store-us-west-2-linux-x64/Releases/1.20201218.81f481f/1.20201218.81f481f.tgz ./
```

Once you have the artifact, unzip the zipped TAR file. The following unzips the TAR file and stores it in a directory called `agent_demo`:

```
!mkdir agent_demo
!tar -xvzf 1.20201218.81f481f.tgz -C ./agent_demo
```

Upload the agent release artifacts to your Amazon S3 bucket. The following code example copies the content within `agent_demo` and uploads it to a directory within your Amazon S3 bucket called `agent_demo`:

```
!aws s3 cp --recursive ./agent_demo s3://{bucket}/agent_demo
```

You also need the signing root certificates from the release bucket:

```
!aws s3 cp s3://sagemaker-edge-release-store-us-west-2-linux-x64/Certificates/us-west-2/us-west-2.pem ./
```

Upload the signing root certificate to your Amazon S3 bucket:

```
!aws s3 cp us-west-2.pem s3://{bucket}/authorization-files/
```

2. **Define a SageMaker Edge Manager agent configuration file.**

First, define the agent configuration file as follows:
sagemaker_edge_config = {
    "sagemaker_edge_core_device_name": "device_name",
    "sagemaker_edge_core_device_fleet_name": "device_fleet_name",
    "sagemaker_edge_core_capture_data_buffer_size": 30,
    "sagemaker_edge_core_capture_data_push_period_seconds": 4,
    "sagemaker_edge_core_folder_prefix": "demo_capture",
    "sagemaker_edge_core_region": "us-west-2",
    "sagemaker_edge_core_capture_data_destination": "Cloud"
}

Replace the following:

- "device_name" with the name of your device (this string was stored in an earlier step in a variable named device_name).
- "device_fleet_name" with the name of your device fleet (this string was stored in an earlier step in a variable named device_fleet_name)
- "endpoint" with your AWS account-specific endpoint for the credentials provider (this string was stored in an earlier step in a variable named endpoint).

Next, save it as a JSON file:

```python
edge_config_file = open("sagemaker_edge_config.json", "w")
json.dump(sagemaker_edge_config, edge_config_file, indent = 6)
edge_config_file.close()
```

Upload the configuration file to your Amazon S3 bucket:

```
!aws s3 cp sagemaker_edge_config.json s3://{bucket}/
```

3. **Copy the release artifacts, configuration file, and credentials to your device.**

The following instructions are performed on the edge device itself.

**Note**
You must first install Python, the AWS SDK for Python (Boto3), and the AWS CLI on your edge device.

Open a terminal on your device. Create a folder to store the release artifacts, your credentials, and the configuration file.

```bash
mkdir agent_demo
cd agent_demo
```

Copy the contents of the release artifacts that you stored in your Amazon S3 bucket to your device:

```
# Copy release artifacts
```
aws s3 cp s3://<bucket-name>/agent_demo/ ./ --recursive

(The contents of the release artifact was stored in a directory called agent_demo in a previous step). Replace <bucket-name> and agent_demo with the name of your Amazon S3 bucket and the file path to your release artifacts, respectively.

Go the /bin directory and make the binary files executable:

cd bin
chmod +x sagemaker_edge_agent_binary
chmod +x sagemaker_edge_agent_client_example

cd agent_demo

Make a directory to store your AWS IoT credentials and copy your credentials from your Amazon S3 bucket to your edge device (use the same on you define in the variable bucket):

mkdir iot-credentials
cd iot-credentials
aws s3 cp s3://<bucket-name>/authorization-files/AmazonRootCA1.pem ./
aws s3 cp s3://<bucket-name>/authorization-files/device.pem.crt ./
aws s3 cp s3://<bucket-name>/authorization-files/private.pem.key ./
cd ../

Make a directory to store your model signing root certificates:

mkdir certificates
cd certificates
aws s3 cp s3://<bucket-name>/authorization-files/us-west-2.pem ./
cd agent_demo

Copy your configuration file to your device:

#Download config file from S3
aws s3 cp s3://<bucket-name>/sagemaker_edge_config.json ./
cd agent_demo

Your agent_demo directory on your edge device should look similar to the following:
Run Agent

In this section you will run the agent as a binary using gRPC, and check that both your device and fleet are working and collecting sample data.

1. Launch the agent.

   The SageMaker Edge Manager agent can be run as a standalone process in the form of an Executable and Linkable Format (ELF) executable binary or can be linked against as a Dynamic Shared Object (.dll). Running as a standalone executable binary is the preferred mode and is supported on Linux.

   This example uses gRPC to run the agent. gRPC is an open source high-performance Remote Procedure Call (RPC) framework that can run in any environment. For more information about gRPC, see the [gRPC documentation](https://grpc.io).

   To use gRPC, perform the following steps:
   
   b. Generate server and client code using the protocol buffer compiler.
   c. Use the Python (or other languages supported by gRPC) gRPC API to write the server for your service.
   d. Use the Python (or other languages supported by gRPC) gRPC API to write a client for your service.

   The release artifact you downloaded contains a gRPC application ready for you to run the agent. The example is located within the /bin directory of your release artifact. The sagemaker_edge_agent_binary executable binary is in this directory.

   To run the agent with this example, provide the path to your socket file (.sock) and JSON .config file:

   ```
   ./bin/sagemaker_edge_agent_binary -a /tmp/sagemaker_edge_agent_example.sock -c sagemaker_edge_config.json
   ```

2. Check your device.

   Check that your device is connected and sampling data. Making periodic checks, manually or automatically, allows you to check that your device or fleet is working properly.

   Provide the name of the fleet to which the device belongs and the unique device identifier. From your local machine, run the following:

   ```
   sagemaker_client.describe_device(
       DeviceName=device_name,
       DeviceFleetName=device_fleet_name
   )
   ```

   For the given model, you can see the name, model version, latest sample time, and when the last inference was made.

   ```
   
   ```
"DeviceName": "sample-device",
"DeviceFleetName": "demo-device-fleet",
"IoTThingName": "sample-thing-name-1",
"RegistrationTime": 1600977370,
"LatestHeartbeat": 1600977370,
"Models": [
  {
    "ModelName": "mobilenet_v2.tar.gz",
    "ModelVersion": "1.1",
    "LatestSampleTime": 1600977370,
    "LatestInference": 1600977370
  }
]
}

The timestamp provided by LastetHeartbeat indicates the last signal that was received from the device. LatestSampleTime and LatestInference describe the time stamp of the last data sample and inference, respectively.

3. Check your fleet.

Check that your fleet is working with GetDeviceFleetReport. Provide the name of the fleet the device belongs to.

```python
sagemaker_client.get_device_fleet_report(
    DeviceFleetName=device_fleet_name
)
```

For a given model, you can see the name, model version, latest sample time, and when the last inference was made, along with the Amazon S3 bucket URI where the data samples are stored.

```bash
# Sample output
{
    "DeviceFleetName": "sample-device-fleet",
    "OutputConfig": {
        "S3OutputLocation": "s3://fleet-bucket/package_output",
    },
    "AgentVersions": [{"Version": "1.1", "AgentCount": 2}],
    "DeviceStats": {"Connected": 2, "Registered": 2},
    "Models": [{
        "ModelName": "sample-model",
        "ModelVersion": "1.1",
        "OfflineDeviceCount": 0,
        "ConnectedDeviceCount": 2,
        "ActiveDeviceCount": 2,
        "SamplingDeviceCount": 100
    }]
}
```

**Set Up Devices and Fleets**

Fleets are collections of logically grouped devices you can use to collect and analyze data. You can use SageMaker Edge Manager to operate machine learning models on a fleet of smart cameras, smart speakers, robots, and other edge devices.

Create a fleet and register your devices either programmatically with the AWS SDK for Python (Boto3) or through the SageMaker console.
Create a Fleet

You can create a fleet programmatically with the AWS SDK for Python (Boto3) or through the SageMaker console https://console.aws.amazon.com/sagemaker.

Create a Fleet (Boto3)

Use the `create_device_fleet` API to create a fleet. Specify a name for the fleet, your AWS IoT Role ARN for the `RoleArn` field, as well as an Amazon S3 URI where you want the device to store sampled data.

You can optionally include a description of the fleet, tags, and an AWS KMS Key ID.

```python
import boto3

# Create SageMaker client so you can interact and manage SageMaker resources
sagemaker_client = boto3.client("sagemaker", region_name="aws-region")

sagemaker_client.create_device_fleet(
    DeviceFleetName="sample-fleet-name",
    RoleArn="arn:aws:iam::999999999:role/rolename", # IoT Role ARN
    Description="fleet description",
    OutputConfig={
        S3OutputLocation="s3://bucket/",
        KMSKeyId: "1234abcd-12ab-34cd-56ef-1234567890ab",
    },
    Tags=[
        {"Key": "string",
         "Value": "string" }
    ],
)
```

An AWS IoT Role Alias is created for you when you create a device fleet. The AWS IoT role alias provides a mechanism for connected devices to authenticate to AWS IoT using X.509 certificates and then obtain short-lived AWS credentials from an IAM role that is associated with the AWS IoT role alias.

Use `describe_device_fleet` API to get a description of fleets you created.

```python
# Print Amazon Resource Name (ARN) and alias that has access
# to AWS Internet of Things (IoT).
sagemaker_client.describe_device_fleet(DeviceFleetName=device_fleet_name)['IotRoleAlias']
```

By default, it returns the name of the fleet, the device fleet ARN, the Amazon S3 bucket URI, the IAM role, the role alias created in AWS IoT, a timestamp of when the fleet was created, and a timestamp of when the fleet was last modified.
Create a Fleet (Console)

You can create a Edge Manager packaging job using the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker.

1. In the SageMaker console, choose Edge Manager and then choose Edge device fleets.
2. Choose Create device fleet.
   
   ![Amazon SageMaker Console](image)

3. Enter a name for the device fleet in the Device fleet name field. Choose Next.
4. On the Output configuration page, specify the Amazon S3 bucket URI where you want to store sample data from your device fleet. You can optionally add an encryption key as well by electing an existing AWS KMS key from the dropdown list or by entering a key's ARN. Choose Submit.
5. Choose the name of your device fleet to be redirected to the device fleet details. This page displays the name of the device fleet, ARN, description (if you provided one), create date the fleet was created, last time the fleet was modified, Amazon S3 bucket URI, AWS KMS key ID (if provided), AWS IoT alias (if provided), and IAM role. If you added tags, they appear in the **Device fleet tags** section.

### Register a Device

**Important**

Device registration is required to use any part of SageMaker Edge Manager.

You can create a fleet programmatically with the AWS SDK for Python (Boto3) or through the SageMaker console at [https://console.aws.amazon.com/sagemaker](https://console.aws.amazon.com/sagemaker).

#### Register a Device (Boto3)

To register your device, first create and register an AWS IoT thing object and configure an IAM role. SageMaker Edge Manager takes advantage of the AWS IoT Core services to facilitate the connection between the edge devices and the cloud. You can take advantage of existing AWS IoT functionality after you set up your devices to work with Edge Manager.

To connect your device to AWS IoT you need to create AWS IoT thing objects, create and register a client certificate with AWS IoT, and create and configure IAM role for your devices.

See the [Getting Started Guide](https://docs.aws.amazon.com/sagemaker/latest/dg/edge-manager-getting-started.html) for an in-depth example or the [Explore AWS IoT Core services in hands-on tutorial](https://docs.aws.amazon.com/sagemaker/latest/dg/edge-manager-getting-started.html).

Use the `RegisterDevices` API to register your device. Provide the name of the fleet of which you want the devices to be a part, as well as a name for the device. You can optionally add a description to the device, tags, and AWS IoT thing name associated with the device.

```
sagemaker_client.register_devices(
    DeviceFleetName="sample-fleet-name",
```

---

### Output configuration

Use the fields below to specify the S3 bucket URI where you want devices to store sample data. You can also (optionally) specify an AWS KMS key.

#### S3 bucket URI

Enter your S3 bucket URI where you want devices to store sample data.

```
s3://bucket-example/sagmaker-edge/device-output
```

To find a path, [go to Amazon S3](https://s3.amazonaws.com/).  

**Encryption key - optional**

Encrypt your data. Choose an existing KMS key or enter a key's ARN.

```
No Custom Encryption
```
Register a Device (Console)

You can register your device using the SageMaker console at https://console.aws.amazon.com/sagemaker.

1. In the SageMaker console, choose Edge Inference and then choose choose Edge devices.
2. Choose Register devices.

3. In the Device properties section, enter the name of the fleet the device belongs to under the Device fleet name field. Choose Next.

4. In the Device source section, add your devices one by one. You must include a Device Name for each device in your fleet. You can optionally provide a description (in the Description field) and an
Internet of Things (IoT) object name (in the **IoT name** field). Choose **Submit** once you have added all your devices.

<table>
<thead>
<tr>
<th>Device source</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Add devices one by one</strong></td>
</tr>
<tr>
<td><strong>Device Name</strong></td>
</tr>
<tr>
<td>Enter device name</td>
</tr>
<tr>
<td><strong>Add another device</strong></td>
</tr>
<tr>
<td>You can add up to 50 devices</td>
</tr>
</tbody>
</table>

The **Devices** page displays the name of the device you have added, the fleet to which it belongs, when it was registered, the last heartbeat, and the description and AWS IoT name, if you provided one.

Choose a device to view the device’s details, including the device name, fleet, ARN, description, IoT Thing name, when the device was registered, and the last heartbeat.

**Check Status**

Check that your device or fleet is connected and sampling data. Making periodic checks, manually or automatically, allows you to check that your device or fleet is working properly.

Use the Amazon S3 console at [https://console.aws.amazon.com/s3/](https://console.aws.amazon.com/s3/) to interactively choose a fleet for a status check. You can also use the AWS SDK for Python (Boto3). The following describes different APIs from Boto3 you can use to check the status of your device or fleet. Use the API that best fits your use case.

- **Check an individual device.**

  To check the status of an individual device, use `DescribeDevice` API. A list containing one or more models is provided if a model has been deployed to the device.

  ```python
  sagemaker_client.describe_device(
    DeviceName="sample-device-1",
    DeviceFleetName="sample-fleet-name"
  )
  ```

  Running `DescribeDevice` returns:

  ```json
  {
    "DeviceName": "sample-device",
    "Description": "this is a sample device",
    "DeviceFleetName": "sample-device-fleet",
    "IoTThingName": "SampleThing",
  }
  ```
• Check a fleet of devices.

To check the status of the fleet, use the GetDeviceFleetReport API. Provide the name of the device fleet to get a summary of the fleet.

```python
sagemaker_client.get_device_fleet_report(
    DeviceFleetName="sample-fleet-name"
)
```

• Check for a heartbeat.

Each device within a fleet periodically generates a signal, or “heartbeat”. The heartbeat can be used to check that the device is communicating with Edge Manager. If the timestamp of the last heartbeat is not being updated, the device may be failing.

Check the last heartbeat with made by a device with the DescribeDevice API. Specify the name of the device and the fleet to which the edge device belongs.

```python
sagemaker_client.describe_device(
    DeviceName="sample-device-1",
    DeviceFleetName="sample-fleet-name"
)
```

Package Model

SageMaker Edge Manager packaging jobs take Amazon SageMaker Neo–compiled models and make any changes necessary to deploy the model with the inference engine, Edge Manager agent.

Topics

• Prerequisites (p. 2664)
• Package a Model (Amazon SageMaker Console) (p. 2666)
• Package a Model (Boto3) (p. 2669)

Prerequisites

To package a model, you must do the following:

1. **Compile your machine learning model with SageMaker Neo.**

   If you have not already done so, compile your model with SageMaker Neo. For more information on how to compile your model, see [Compile and Deploy Models with Neo](#). If you are first-time user of SageMaker Neo, go through [Getting Started with Neo Edge Devices](#).

2. **Get the name of your compilation job.**
Provide the name of the compilation job name you used when you compiled your model with SageMaker Neo. Open the SageMaker console at https://console.aws.amazon.com/sagemaker/ and choose **Compilation jobs** to find a list of compilations that have been submitted to your AWS account. The names of submitted compilation jobs are in the **Name** column.

3. **Get your IAM ARN.**

You need an Amazon Resource Name (ARN) of an IAM role that you can use to download and upload the model and contact SageMaker Neo.

Use one of the following methods to get your IAM ARN:

- **Programmatically with the SageMaker Python SDK**

```python
import sagemaker

# Initialize SageMaker Session object so you can interact with AWS resources
sess = sagemaker.Session()

# Get the role ARN
role = sagemaker.get_execution_role()

print(role)
>> arn:aws:iam::<your-aws-account-id>:role/<your-role-name>
```

For more information about using the SageMaker Python SDK, see the [SageMaker Python SDK API](https://boto3.amazonaws.com/v1/documentation/api/latest/index.html).

- **Using the AWS Identity and Access Management (IAM) console**

Navigate to the IAM console at https://console.aws.amazon.com/iam/. In the IAM **Resources** section, choose **Roles** to view a list of roles in your AWS account. Select or create a role that has **AmazonSageMakerFullAccess**, **AWSIoTFullAccess**, and **AmazonS3FullAccess**.

For more information on IAM, see [What is IAM?](https://aws.amazon.com/iam/)

4. **Have an S3 bucket URI.**

You need to have at least one Amazon Simple Storage Service (Amazon S3) bucket URI to store your Neo-compiled model, the output of the Edge Manager packaging job, and sample data from your device fleet.

Use one of the following methods to create an Amazon S3 bucket:

- **Programmatically with the SageMaker Python SDK**

You can use the default Amazon S3 bucket during a session. A default bucket is created based on the following format: sagemaker-{-region}-{aws-account-id}. To create a default bucket with the SageMaker Python SDK, use the following:

```python
import sagemaker

session=sagemaker.create_session()

bucket=session.default_bucket()
```

- **Using the Amazon S3 console**

Package a Model (Amazon SageMaker Console)

You can create a SageMaker Edge Manager packaging job using the SageMaker console at https://console.aws.amazon.com/sagemaker/. Before continuing, make sure you have satisfied the Prerequisites (p. 2664).

1. In the SageMaker console, choose Edge Inference and then choose Edge packaging jobs, as shown in the following image.

![Image of Edge packaging jobs in SageMaker console]

2. On the Job properties page, enter a name for your packaging job under Edge packaging job name. Note that Edge Manager packaging job names are case-sensitive. Name your model and give it a version: enter this under Model name and Model version, respectively.

3. Next, select an IAM role. You can chose a role or let AWS create a role for you. You can optionally specify a resource key ARN and job tags.

4. Choose Next.
5. Specify the name of the compilation job you used when compiling your model with SageMaker Neo in the **Compilation job name** field. Choose **Next**.
6. On the **Output configuration** page, enter the Amazon S3 bucket URI in which you want to store the output of the packaging job.

**Output configuration**

Use the fields below to specify the S3 bucket URI where you want devices to store sample data. You can also (optionally) specify a KMS key.

**S3 bucket URI**

Enter your S3 bucket URI where you want devices to store sample data.

```s3://bucket-example/sagmaker-edge/device-output```

To find a path, [go to Amazon S3](https://aws.amazon.com/s3/

**Encryption key - optional**

Encrypt your data. Choose an existing KMS key or enter a key's ARN.

```
No Custom Encryption
```

The **Status** column on the **Edge packaging** jobs page should read **IN PROGRESS**. Once the packaging job is complete, the status updates to **COMPLETED**.

Selecting a packaging job directs you to that job's settings. The **Job settings** section displays the job name, ARN, status, creation time, last modified time, duration of the packaging job, and role ARN.

The **Input configuration** section displays the location of the model artifacts, the data input configuration, and the machine learning framework of the model.
The **Output configuration** section displays the output location of the packaging job, the target device for which the model was compiled, and any tags you created.

7. Choose the name of your device fleet to be redirected to the device fleet details. This page displays the name of the device fleet, ARN, description (if you provided one), date the fleet was created, last time the fleet was modified, Amazon S3 bucket URI, AWS KMS key ID (if provided), AWS IoT alias (if provided), and IAM role. If you added tags, they appear in the **Device fleet tags** section.

---

### Package a Model (Boto3)

You can create a SageMaker Edge Manager packaging job with the AWS SDK for Python (Boto3). Before continuing, make sure you have satisfied the Prerequisites (p. 2664).

To request an edge packaging job, use `CreateEdgePackagingJob`. You need to provide a name to your edge packaging job, the name of your SageMaker Neo compilation job, your role Amazon resource name (ARN), a name for your model, a version for your model, and the Amazon S3 bucket URI where you want to store the output of your packaging job. Note that Edge Manager packaging job names and SageMaker Neo compilation job names are case-sensitive.

```python
# Import AWS SDK for Python (Boto3)
import boto3

# Create Edge client so you can submit a packaging job
sagemaker_client = boto3.client("sagemaker", region_name='aws-region')

sagemaker_client.create_edge_packaging_job(
    EdgePackagingJobName="edge-packaging-name",
    CompilationJobName="neo-compilation-name",
    RoleArn="arn:aws:iam::99999999999:role/rolename",
    ModelName="sample-model-name",
    ModelVersion="model-version",
    OutputConfig={
        "S3OutputLocation": "s3://your-bucket/",
    }
)
```

You can check the status of an edge packaging job using `DescribeEdgePackagingJob` and providing the case-sensitive edge packaging job name:

```python
response = sagemaker_client.describe_edge_packaging_job(
    EdgePackagingJobName="edge-packaging-name")
```

This returns a dictionary that can be used to poll the status of the packaging job:

```python
# Optional - Poll every 30 sec to check completion status
import time

while True:
    response = sagemaker_client.describe_edge_packaging_job(
        EdgePackagingJobName="edge-packaging-name")

    if response['EdgePackagingJobStatus'] == 'Completed':
        break
    elif response['EdgePackagingJobStatus'] == 'Failed':
        raise RuntimeError('Packaging job failed')
    print('Packaging model...')
    time.sleep(30)
print('Done!')
```
For a list of packaging jobs, use `ListEdgePackagingJobs`. You can use this API to search for a specific packaging job. Provide a partial name to filter packaging job names for `NameContains`, a partial name for `ModelNameContains` to filter for jobs in which the model name contains the name you provide. Also specify with which column to sort with `SortBy`, and by which direction to sort for `SortOrder` (either `Ascending` or `Descending`).

```python
sagemaker_client.list_edge_packaging_jobs(
    "NameContains": "sample",
    "ModelNameContains": "sample",
    "SortBy": "column-name",
    "SortOrder": "Descending"
)
```

To stop a packaging job, use `StopEdgePackagingJob` and provide the name of your edge packaging job.

```python
sagemaker_client.stop_edge_packaging_job(
    EdgePackagingJobName="edge-packaging-name"
)
```

For a full list of Edge Manager APIs, see the [Boto3 documentation](https://boto3.amazonaws.com/v1/documentation/api/latest/guide/sage-maker.html).

## The Edge Manager Agent

The Edge Manager agent is an inference engine for your edge devices. Use the agent to make predictions with models loaded onto your edge devices. The agent also collects model metrics and captures data at specific intervals. Sample data is stored in your Amazon S3 bucket.

There are two methods of installing and deploying the Edge Manager agent onto your edge devices:

1. Download the agent as a binary from the Amazon S3 release bucket. For more information, see [Download and Set Up the Edge Manager Agent Manually](p. 2670).
2. Use the AWS IoT Greengrass V2 console or the AWS CLI to deploy `aws.greengrass.SageMakerEdgeManager`. See [Create the AWS IoT Greengrass V2 Components](p. 2676).

### Download and Set Up the Edge Manager Agent Manually

Download the Edge Manager agent based on your operating system, architecture, and AWS Region. The agent is periodically updated, so you have the option to choose your agent based on release dates and versions. Once you have the agent, create a JSON configuration file. Specify the device IoT thing name, fleet name, device credentials, and other key-value pairs. See [Running the Edge Manager agent](p. 2672) for full a list of keys you must specify in the configuration file. You can run the agent as an executable binary or link against it as a dynamic shared object (DSO).

### How the agent works

The agent runs on the CPU of your devices. The agent runs inference on the framework and hardware of the target device you specified during the compilation job. For example, if you compiled your model for the Jetson Nano, the agent supports the GPU in the provided [Deep Learning Runtime](https://docs.aws.amazon.com/sagemaker/latest/dg/edge-ec2-deeplram.html) (DLR).

The agent is released in binary format for supported operating systems. Check that your operating system is supported and meets the minimum OS requirement in the following table:

### Linux

| Version: Ubuntu 18.04 |
**Supported Binary Formats:** x86-64 bit (ELF binary) and ARMv8 64 bit (ELF binary)

**Windows**

**Version:** Windows 10 version 1909

**Supported Binary Formats:** x86-32 bit (DLL) and x86-64 bit (DLL)

### Installing the Edge Manager agent

To use the Edge Manager agent, you first must obtain the release artifacts and a root certificate. The release artifacts are stored in an Amazon S3 bucket in the us-west-2 Region. To download the artifacts, specify your operating system (<OS>) and the <VERSION>.

Based on your operating system, replace <OS> with one of the following:

<table>
<thead>
<tr>
<th>Windows 32-bit</th>
<th>Windows 64-bit</th>
<th>Linux x86-64</th>
<th>Linux ARMv8</th>
</tr>
</thead>
<tbody>
<tr>
<td>windows-x86</td>
<td>windows-x64</td>
<td>linux-x64</td>
<td>linux-armv8</td>
</tr>
</tbody>
</table>

The VERSION is broken into three components: <MAJOR_VERSION>.<YYYY-MM-DD>-<SHA-7>, where:

- <MAJOR_VERSION>: The release version. The release version is currently set to 1.
- <YYYY-MM-DD>: The time stamp of the artifacts release.
- <SHA-7>: The repository commit ID from which the release is built.

You must provide the <MAJOR_VERSION> and the time stamp in YYYY-MM-DD format. We suggest you use the latest artifact release time stamp.

Run the following in your command line to get the latest time stamp. Replace <OS> with your operating system:

```bash
aws s3 ls s3://sagemaker-edge-release-store-us-west-2-<OS>/Releases/ | sort -r
```

For example, if you have a Windows 32-bit OS, run:

```bash
aws s3 ls s3://sagemaker-edge-release-store-us-west-2-windows-x86/Releases/ | sort -r
```

This returns:

```
2020-12-01 23:33:36 0
  PRE 1.20201218.81f481f/
  PRE 1.20201207.02d0e97/
```

The return output in this example shows two release artifacts. The first release artifact file notes that the release version has a major release version of 1, a time stamp of 20201218 (in YYYY-MM-DD format), and a 81f481f SHA-7 commit ID.

**Note**

The preceding command assumes you have configured the AWS Command Line Interface. For more information, about how to configure the settings that the AWS CLI uses to interact with AWS, see [Configuring the AWS CLI](#).

Based on your operating system, use the following commands to install the artifacts:
You also must download a root certificate. This certificate validates model artifacts signed by AWS before loading them onto your edge devices.

Replace <OS> corresponding to your platform from the list of supported operation systems and replace <REGION> with your AWS Region.

Running the Edge Manager agent

You can run the SageMaker Edge Manager agent as a standalone process in the form of an Executable and Linkable Format (ELF) executable binary or you can link against it as a dynamic shared object (.dll). Linux supports running it as a standalone executable binary and is the preferred mode. Windows supports running it as a shared object (.dll).

On Linux, we recommend that you run the binary via a service that’s a part of your initialization (init) system. If you want to run the binary directly, you can do so in a terminal as shown in the following example. If you have a modern OS, there are no other installations necessary prior to running the agent, since all the requirements are statically built into the executable. This gives you flexibility to run the agent on the terminal, as a service, or within a container.

To run the agent, first create a JSON configuration file. Specify the following key-value pairs:

- sagemaker_edge_core_device_name: The name of the device. This device name needs to be registered along with the device fleet in the SageMaker Edge Manager console.
- sagemaker_edge_core_device_fleet_name: The name of the fleet to which the device belongs.
- sagemaker_edge_core_region: The AWS Region associated with the device, the fleet and the Amazon S3 buckets. This corresponds to the Region where the device is registered and where the
Amazon S3 bucket is created (they are expected to be the same). The models themselves can be compiled with SageMaker Neo in a different Region, this configuration is not related to model compilation Region.

- **sagemaker_edge_core_root_certs_path**: The absolute folder path to root certificates. This is used to validate the device with the relevant AWS account.
- **sagemaker_edge_provider_aws_root_ca_cert_file**: The absolute path to Amazon Root CA certificate (AmazonRootCA1.pem). This is used to validate the device with the relevant AWS account. AmazonCA is a certificate owned by AWS.
- **sagemaker_edge_provider_aws_certificate_file**: The absolute path to AWS IoT signing root certificate (*.pem.crt).
- **sagemaker_edge_provider_aws_certificate_pk_file**: The absolute path to AWS IoT private key (*.pem.key).
- **sagemaker_edge_provider_aws_iot_credential_endpoint**: The AWS IoT credentials endpoint (identifier.iot.region.amazonaws.com). This endpoint is used for credential validation. See [Connecting devices to AWS IoT](#) for more information.
- **sagemaker_edge_provider_provider**: This indicates the implementation of the provider interface being used. The provider interface communicates with the end network services for uploads, heartbeats and registration validation. By default this is set to "Aws". We allow custom implementations of the provider interface. It can be set to None for no provider or Custom for custom implementation with the relevant shared object path provided.
- **sagemaker_edge_provider_provider_path**: Provides the absolute path to the provider implementation shared object (.so or .dll file). The "Aws" provider .dll or .so file is provided with the agent release. This field is mandatory.
- **sagemaker_edge_provider_s3_bucket_name**: The name of your Amazon S3 bucket (not the Amazon S3 bucket URI). The bucket must have a sagemaker string within its name.
- **sagemaker_edge_log_verbose**: (Boolean.): Optional. This sets the debug log. Select either True or False.
- **sagemaker_edge_telemetry_libsystemd_path**: For Linux only, systemd implements the agent crash counter metric. Set the absolute path of libsystemd to turn on the crash counter metric. You can find the default libsystemd path can be found by running `whereis libsystemd` in the device terminal.
- **sagemaker_edge_capture_data_destination**: The destination for uploading capture data. Choose either "Cloud" or "Disk". The default is set to "Disk". Setting it to "Disk" writes the input and output tensor(s) and auxiliary data to the local file system at your preferred location of. When writing to "Cloud" use the Amazon S3 bucket name provided in the **sagemaker_edge_core_capture_data_destination** configuration.
- **sagemaker_edge_capture_data_disk_path**: Set the absolute path in the local file system, into which capture data files are written when "Disk" is the destination. This field is not used when "Cloud" is specified as the destination.
- **sagemaker_edge_folder_prefix**: The parent prefix in Amazon S3 where captured data is stored when you specify "Cloud" as the capture data destination (sagemaker_edge_capture_data_disk_path). Captured data is stored in a sub-folder under sagemaker_edge_capture_data_disk_path if "Disk" is set as the data destination.
- **sagemaker_edge_capture_data_buffer_size**: (Integer value): The capture data circular buffer size. It indicates the maximum number of requests stored in the buffer.
- **sagemaker_edge_capture_data_batch_size**: (Integer value): The capture data batch size. It indicates the size of a batch of requests that are handled from the buffer. This value must to be less than sagemaker_edge_capture_data_buffer_size. A maximum of half the size of the buffer is recommended for batch size.
- **sagemaker_edge_capture_data_push_period_seconds**: (Integer value): The capture data push period in seconds. A batch of requests in the buffer is handled when there are batch size requests
in the buffer, or when this time period has completed (whichever comes first). This configuration sets
that time period.

- `sagemaker_edge_core_capture_data_base64_embed_limit`: The limit for uploading capture
data in bytes. Integer value.

Your configuration file should look similar to the following example (with your specific values specified).
This example uses the default AWS provider ("Aws") and does not specify a periodic upload.

```json
{
    "sagemaker_edge_core_device_name": "device-name",
    "sagemaker_edge_core_device_fleet_name": "fleet-name",
    "sagemaker_edge_core_region": "region",
    "sagemaker_edge_core_root_certs_path": "<Absolute path to root certificates>",
    "sagemaker_edge_provider_provider": "Aws",
    "sagemaker_edge_provider_provider_path": "/path/to/libprovider_aws.so",
    "sagemaker_edge_provider_aws_ca_cert_file": "<Absolute path to Amazon Root CA
    certificate>/AmazonRootCA1.pem",
    "sagemaker_edge_provider_aws_cert_file": "<Absolute path to AWS IoT signing root
certificate>/device.pem.crt",
    "sagemaker_edge_provider_aws_cert_pk_file": "<Absolute path to AWS IoT private key.>/
    private.pem.key",
    "sagemaker_edge_provider_aws_iot_cred_endpoint": "https://<AWS IoT Endpoint Address>",
    "sagemaker_edge_core_capture_data_destination": "Cloud",
    "sagemaker_edge_core_capture_data_s3_bucket_name": "sagemaker-bucket-name",
    "sagemaker_edge_core_capture_data_buffer_size": 30,
    "sagemaker_edge_core_capture_data_batch_size": 10,
    "sagemaker_edge_core_capture_data_push_period_seconds": 4000,
    "sagemaker_edge_core_capture_data_base64_embed_limit": 2,
    "sagemaker_edge_log_verbose": false
}
```

The release artifact includes a binary executable called `sagemaker_edge_agent_binary` in the `/bin`
directory. To run the binary, use the `-a` flag to create a socket file descriptor (.sock) in a directory of your
choosing and specify the path of the agent JSON config file you created with the `-c` flag.

```
./sagemaker_edge_agent_binary -a <ADDRESS_TO_SOCKET> -c <PATH_TO_CONFIG_FILE>
```

The following example shows the code snippet with a directory and file path specified:

```
./sagemaker_edge_agent_binary -a /tmp/sagemaker_edge_agent_example.sock -c
sagemaker_edge_config.json
```

In this example, a socket file descriptor named `sagemaker_edge_agent_example.sock` is created in
the `/tmp` directory and points to a configuration file that is in the same working directory as the agent
called `sagemaker_edge_config.json`.

**Deploy the Model Package and Edge Manager Agent with AWS IoT Greengrass**

SageMaker Edge Manager integrates AWS IoT Greengrass version 2 to simplify accessing, maintaining,
and deploying the Edge Manager agent and model to your devices. Without AWS IoT Greengrass V2,
setting up your devices and fleets to use SageMaker Edge Manager requires you to manually copy the
Edge Manager agent from an Amazon S3 release bucket. You use the agent to make predictions with
models loaded onto your edge devices. With AWS IoT Greengrass V2 and SageMaker Edge Manager
integration, you can use AWS IoT Greengrass V2 components. Components are pre-built software
modules that can connect your edge devices to AWS services or third-party service via AWS IoT Greengrass.

You must install the AWS IoT Greengrass Core software on your device(s) if you want to use AWS IoT Greengrass V2 to deploy the Edge Manager agent and your model. For more information about device requirements and how to set up your devices, see Setting up AWS IoT Greengrass core devices in the AWS IoT Greengrass documentation.

You use the following three components to deploy the Edge Manager agent:

- **A pre-built public component**: SageMaker maintains the public Edge Manager component.
- **A autogenerated private component**: The private component is autogenerated when you package your machine learning model with the CreateEdgePackagingJob API and specify GreengrassV2Component for the Edge Manager API field PresetDeploymentType.
- **A custom component**: This is the inference application that is responsible for preprocessing and making inferences on your device. You must create this component. See either Create a Hello World custom component (p. 2678) in the SageMaker Edge Manager documentation or Create custom AWS IoT Greengrass components in the AWS IoT Greengrass documentation for more information on how to create custom components.

### Prerequisites

SageMaker Edge Manager uses AWS IoT Greengrass V2 to simplify the deployment of the Edge Manager agent, your machine learning models, and your inference application to your devices with the use of components. To make it easier to maintain your AWS IAM roles, Edge Manager allows you to reuse your existing AWS IoT role alias. If you do not have one yet, Edge Manager generates a role alias as part of the Edge Manager packaging job. You no longer need to associate a role alias generated from the SageMaker Edge Manager packaging job with your AWS IoT role.

Before you start, you must complete the following prerequisites:

1. Install the AWS IoT Greengrass Core software. For detailed information, see Install the AWS IoT Greengrass Core software.
2. Set up AWS IoT Greengrass V2. For more information, see Install AWS IoT Greengrass Core software with manual resource provisioning.

   **Note**

   - Make sure the AWS IoT thing name is all lowercase and does not contain characters except (optionally) dashes (-).
   - The IAM Role must start with SageMaker*

3. Attach the following permission and inline policy to the IAM role created during AWS IoT Greengrass V2 setup.

   - Navigate to the IAM console [https://console.aws.amazon.com/iam/](https://console.aws.amazon.com/iam/).
   - Search for the role you created by typing in the role name in the Search field.
   - Choose your role.
   - Next, choose Attach policies.
   - Search for AmazonSageMakerEdgeDeviceFleetPolicy.
   - Select AmazonSageMakerFullAccess (This is an optional step that makes it easier for you to reuse this IAM role in model compilation and packaging).
   - Add required permissions to a role's permissions policy, don't attach inline policies to IAM users.

```json
{
    "Version":"2012-10-17",
    "Statement": [

```
"Sid": "GreengrassComponentAccess",
"Effect": "Allow",
"Action": [
    "greengrass:CreateComponentVersion",
    "greengrass:DescribeComponent"
],
"Resource": "*"
]}

- Choose Attach policy.
- Choose Trust relationship.
- Choose Edit trust relationship.
- Replace the content with the following.

```
{  
  "Version": "2012-10-17",
  "Statement": [
    
    
    
    
  ]
}
```

4. Create an Edge Manager device fleet. For information on how to create a fleet, see Set Up Devices and Fleets (p. 2657).
5. Register your device with the same name as your AWS IoT thing name created during the AWS IoT Greengrass V2 setup.
6. Create at least one custom private AWS IoT Greengrass component. This component is the application that runs inference on the device. For more information, see Create a Hello World custom component (p. 2678)

**Note**

- The SageMaker Edge Manager and AWS IoT Greengrass integration only works for AWS IoT Greengrass v2.
- Both your AWS IoT thing name and Edge Manager device name must be the same.
- SageMaker Edge Manager does not load local AWS IoT certificates and call the AWS IoT credential provider endpoint directly. Instead, SageMaker Edge Manager uses the AWS IoT Greengrass v2 TokenExchangeService and it fetches a temporary credential from a TES endpoint.

**Create the AWS IoT Greengrass V2 Components**

AWS IoT Greengrass uses components, a software module that is deployed to and runs on a AWS IoT Greengrass core device. You need (at a minimum) three components:
1. A public Edge Manager Agent AWS IoT Greengrass component which deploys the Edge Manager agent binary.

2. A model component that is autogenerated when you package your machine learning model with either the AWS SDK for Python (Boto3) API or with the SageMaker console. For information, see Create an autogenerated component (p. 2677).

3. A private, custom component to implement the Edge Manager agent client application, and do any preprocessing and post-processing of the inference results. For more information about how to create a custom component, see Create an autogenerated component (p. 2677) or Create custom AWS IoT Greengrass components.

Create an autogenerated component

Generate the model component with the CreateEdgePackagingJob API and specify GreengrassV2Component for the SageMaker Edge Manager packaging job API field PresetDeploymentType. When you call the CreateEdgePackagingJob API, Edge Manager takes your SageMaker Neo–compiled model in Amazon S3 and creates a model component. The model component is automatically stored in your account. You can view any of your components by navigating to the AWS IoT console https://console.aws.amazon.com/iot/. Select Greengrass and then select Core devices. The page has a list of AWS IoT Greengrass core devices associated with your account. If a model component name is not specified in PresetDeploymentConfig, the default name generated consists of "SagemakerEdgeManager" and the name of your Edge Manager agent packaging job. The following example demonstrates how to specify to Edge Manager to create a AWS IoT Greengrass V2 component with the CreateEdgePackagingJob API.

```python
import sagemaker
import boto3

# Create a SageMaker client object to make it easier to interact with other AWS services.
sagemaker_client = boto3.client('sagemaker', region='YOUR_REGION')

# Replace with your IAM Role ARN
sagemaker_role_arn = "arn:aws:iam::<account>:role/*"

# Replace string with the name of your already created S3 bucket.
bucket = 'edge-manager-demo-bucket'

# Specify a name for your edge packaging job.
edge_packaging_name = "edge_packag_job_demo"

# Replace the following string with the name you used for the SageMaker Neo compilation job.
compilation_job_name = "getting-started-demo"

# The name of the model and the model version.
model_name = "sample-model"
model_version = "1.1"

# Output directory in S3 where you want to store the packaged model.
packaging_output_dir = "packaged_models"
packaging_s3_output = 's3://{}/{}'.format(bucket, packaging_output_dir)

# The name you want your Greengrass component to have.
component_name = "SagemakerEdgeManager" + edge_packaging_name

sagemaker_client.create_edge_packaging_job(
    EdgePackagingJobName=edge_packaging_name,
    CompilationJobName=compilation_job_name,
    RoleArn=sagemaker_role_arn,
    ModelName=model_name,
    ModelVersion=model_version,
    OutputConfig={
```
You can also create the autogenerated component with the SageMaker console. Follow steps 1-6 in Package a Model (Amazon SageMaker Console) (p. 2666)

Enter the Amazon S3 bucket URI where you want to store the output of the packaging job and optional encryption key.

Complete the following to create the model component:

1. Choose Preset deployment.
2. Specify the name of the component for the Component name field.
3. Optionally, provide a description of the component, a component version, the platform OS, or the platform architecture for the Component description, Component version, Platform OS, and Platform architecture, respectively.
4. Choose Submit.

Create a Hello World custom component

The custom application component is used to perform inference on the edge device. The component is responsible for loading models to SageMaker Edge Manager, invoking the Edge Manager agent for inference, and unloading the model when the component is shut down. Before you create your component, ensure the agent and application can communicate with Edge Manager. To do this, configure gRPC. The Edge Manager agent uses methods defined in Protobuf Buffers and the gRPC server to establish communication with the client application on the edge device and the cloud.

To use gRPC, you must:

1. Create a gRPC stub using the .proto file provided when you download the Edge Manager agent from Amazon S3 release bucket.
2. Write client code with the language you prefer.

You do not need to define the service in a .proto file. The service .proto files are included in the compressed TAR file when you download the Edge Manager agent release binary from the Amazon S3 release bucket.

Install gRPC and other necessary tools on your host machine and create the gRPC stubs agent_pb2_grpc.py and agent_pb2.py in Python. Make sure you have agent.proto in your local directory.

```bash
pip install grpcio
pip install grpcio-tools
python3 -m grpc_tools.protoc --proto_path=. --python_out=. --grpc_python_out=. agent.proto
```

The preceding code generates the gRPC client and server interfaces from your .proto service definition. In other words, it creates the gRPC model in Python. The API directory contains the Protobuf specification for communicating with the agent.

Next, use the gRPC API to write a client and server for your service (2). The following example script, edge_manager_python_example.py, uses Python to load, list, and unload a yolov3 model to the edge device.
import grpc
from PIL import Image
import agent_pb2
import agent_pb2_grpc
import os

model_path = '<PATH-TO-SagemakerEdgeManager-COMPONENT>'
agent_socket = 'unix:///tmp/aws.greengrass.SageMakerEdgeManager.sock'
agent_channel = grpc.insecure_channel(agent_socket, options=(('grpc.enable_http_proxy', 0),))
agent_client = agent_pb2_grpc.AgentStub(agent_channel)

def list_models():
    return agent_client.ListModels(agent_pb2.ListModelsRequest())

def list_model_tensors(models):
    return {
        model.name: {
            'inputs': model.input_tensor_metadatas,
            'outputs': model.output_tensor_metadatas
        }
        for model in list_models().models
    }

def load_model(model_name, model_path):
    load_request = agent_pb2.LoadModelRequest()
    load_request.url = model_path
    load_request.name = model_name
    return agent_client.LoadModel(load_request)

def unload_model(name):
    unload_request = agent_pb2.UnLoadModelRequest()
    unload_request.name = name
    return agent_client.UnLoadModel(unload_request)

def predict_image(model_name, image_path):
    image_tensor = agent_pb2.Tensor()
    image_tensor.byte_data = Image.open(image_path).tobytes()
    image_tensor_metadata = list_model_tensors(list_models())[model_name]['inputs'][0]
    image_tensor.tensor_metadata.name = image_tensor_metadata.name
    image_tensor.tensor_metadata.data_type = image_tensor_metadata.data_type
    for shape in image_tensor_metadata.shape:
        image_tensor.tensor_metadata.shape.append(shape)
    predict_request = agent_pb2.PredictRequest()
    predict_request.name = model_name
    predict_request.tensors.append(image_tensor)
    predict_response = agent_client.Predict(predict_request)
    return predict_response

def main():
    try:
        unload_model('your-model')
    except:
        pass
    print('LoadModel...', end='')

2679
try:

if __name__ == '__main__':
    main()
For detailed information about creating a Hello World recipe, see Create your first component in the AWS IoT Greengrass documentation.

**Deploy the components to your device**

Deploy your components with the AWS IoT console or with the AWS CLI.

**To deploy your components (console)**

Deploy your AWS IoT Greengrass components with the AWS IoT console.

1. In the AWS IoT Greengrass console at https://console.aws.amazon.com/iot/navigation menu, choose Deployments.
2. On the Components page, on the Public components tab, choose awsgreengrass.SageMakerEdgeManager.
4. From Add to deployment, choose one of the following:
   a. To merge this component to an existing deployment on your target device, choose Add to existing deployment, and then select the deployment that you want to revise.
   b. To create a new deployment on your target device, choose Create new deployment. If you have an existing deployment on your device, choosing this step replaces the existing deployment.
5. On the Specify target page, do the following:
   a. Under Deployment information, enter or modify the friendly name for your deployment.
   b. Under Deployment targets, select a target for your deployment, and choose Next. You cannot change the deployment target if you are revising an existing deployment.
6. On the Select components page, under My components, choose:
   - com.<CUSTOM-COMPONENT-NAME>
   - aws.greengrass.SageMakerEdgeManager
   - SagemakerEdgeManager.<YOUR-PACKAGING-JOB>
7. On the Configure components page, choose com.greengrass.SageMakerEdgeManager, and do the following.
   a. Choose Configure component.
   b. Under Configuration update, in Configuration to merge, enter the following configuration.

```
{
    "DeviceFleetName": "device-fleet-name",
    "BucketName": "DOC-EXAMPLE-BUCKET"
}
```

Replace device-fleet-name with the name of the edge device fleet that you created, and replace DOC-EXAMPLE-BUCKET with the name of the Amazon S3 bucket that is associated with your device fleet.
   c. Choose Confirm, and then choose Next.
8. On the Configure advanced settings page, keep the default configuration settings, and choose Next.
To deploy your components (AWS CLI)

1. Create a deployment.json file to define the deployment configuration for your SageMaker Edge Manager components. This file should look like the following example.

```json
{
    "targetArn": "targetArn",
    "components": {
        "aws.greengrass.SageMakerEdgeManager": {
            "componentVersion": 1.0.0,
            "configurationUpdate": {
                "merge": {
                    "DeviceFleetName": "device-fleet-name",
                    "BucketName": "DOC-EXAMPLE-BUCKET"
                }
            }
        },
        "com.greengrass.SageMakerEdgeManager.ImageClassification": {
            "componentVersion": 1.0.0,
            "configurationUpdate": {
            }
        },
        "com.greengrass.SageMakerEdgeManager.ImageClassification.Model": {
            "componentVersion": 1.0.0,
            "configurationUpdate": {
            }
        }
    }
}
```

- In the targetArn field, replace targetArn with the Amazon Resource Name (ARN) of the thing or thing group to target for the deployment, in the following format:
  - Thing: arn:aws:iot:region:account-id:thing/thingName
  - Thing group: arn:aws:iot:region:account-id:thinggroup/thingGroupName
- In the merge field, replace device-fleet-name with the name of the edge device fleet that you created, and replace DOC-EXAMPLE-BUCKET with the name of the Amazon S3 bucket that is associated with your device fleet.
- Replace the component versions for each component with the latest available version.

2. Run the following command to deploy the components on the device:

```bash
aws greengrassv2 create-deployment \
  --cli-input-json file://path/to/deployment.json
```

The deployment can take several minutes to complete. In the next step, check the component log to verify that the deployment completed successfully and to view the inference results.

For more information about deploying components to individual devices or groups of devices, see Deploy AWS IoT Greengrass components to devices.

## Deploy the Model Package Directly with SageMaker Edge Manager Deployment API

SageMaker Edge Manager provides a deployment API that you can use to deploy models to device targets without AWS IoT Greengrass. It is useful in situations where you want to update models independently of firmware updates or application deployment mechanisms. You can use the API to integrate your edge deployments into a CI/CD workflow to automatically deploy models once you have
validated your model for accuracy. The API also has convenient rollback and staged rollout options for you to ensure models work well in a particular environment before wider rollout.

To use the Edge Manager deployment API first compile and package your model. For information on how to compile and package your model, see Train, Compile, and Package Your Model (p. 2646). The following sections of this guide show how you can create edge deployments using SageMaker API, after you have compiled and packaged your models.

Topics
- Create an edge deployment plan (p. 2683)
- Start the edge deployment (p. 2684)
- Check the status of the deployment (p. 2684)

Create an edge deployment plan

You can create an edge deployment plan with the CreateEdgeDeploymentPlan API. The deployment plan can have multiple stages. You can configure each stage to rollout the deployment to a subset of edge devices (by percentage, or by device name). You can also configure how rollout failures are handled at each stage.

The following code snippet shows how you can create an edge deployment plan with 1 stage to deploy a compiled and package model to 2 specific edge devices:

```python
import boto3
client = boto3.client("sagemaker")
client.create_edge_deployment_plan(
    EdgeDeploymentPlanName="edge-deployment-plan-name",
    DeviceFleetName="device-fleet-name",
    ModelConfigs=[
        {
            "EdgePackagingJobName": "edge-packaging-job-name",
            "ModelHandle": "model-handle"
        }
    ],
    Stages=[
        {
            "StageName": "stage-name",
            "DeviceSelectionConfig": {
                "DeviceSubsetType": "SELECTION",
                "DeviceNames": ["device-name-1", "device-name-2"]
            },
            "DeploymentConfig": {
                "FailureHandlingPolicy": "ROLLBACK_ON_FAILURE"
            }
        }
    ]
)
```

Instead of specific devices, if you want to deploy to the model to a percentage of devices in your fleet, then set the value of DeviceSubsetType to "PERCENTAGE" and replace "DeviceNames": ["device-name-1", "device-name-2"] with "Percentage": desired-percentage in the above example.

Stages can be added after the deployment plan has been created with the CreateEdgeDeploymentStage API, in case you want to start rolling out new stages after validating your test rollout success. For more information about deployment stages see DeploymentStage.
Start the edge deployment

After creating the deployment plan and the deployment stages, you can start the deployment with the `StartEdgeDeploymentStage` API.

```python
client.start_edge_deployment_stage(
    EdgeDeploymentPlanName="edge-deployment-plan-name",
    StageName="stage-name"
)
```

Check the status of the deployment

You can check the status of the edge deployment with the `DescribeEdgeDeploymentPlan` API.

```python
client.describe_edge_deployment_plan(
    EdgeDeploymentPlanName="edge-deployment-plan-name"
)
```

Manage Model

The Edge Manager agent can load multiple models at a time and make inference with loaded models on edge devices. The number of models the agent can load is determined by the available memory on the device. The agent validates the model signature and loads into memory all the artifacts produced by the edge packaging job. This step requires all the required certificates described in previous steps to be installed along with rest of the binary installation. If the model's signature cannot be validated, then loading of the model fails with appropriate return code and reason.

SageMaker Edge Manager agent provides a list of Model Management APIs that implement control plane and data plane APIs on edge devices. Along with this documentation, we recommend going through the sample client implementation which shows canonical usage of the below described APIs.

The `proto` file is available as a part of the release artifacts (inside the release tarball). In this doc, we list and describe the usage of APIs listed in this `proto` file.

**Note**
There is one-to-one mapping for these APIs on Windows release and a sample code for an application implement in C# is shared with the release artifacts for Windows. Below instructions are for running the Agent as a standalone process, applicable for to the release artifacts for Linux.

Extract the archive based on your OS. Where VERSION is broken into three components: `<MAJOR_VERSION>.<YYYY-MM-DD>-<SHA-7>`. See *Installing the Edge Manager agent (p. 2671)* for information on how to obtain the release version (`<MAJOR_VERSION>`), time stamp of the release artifact (`<YYYY-MM-DD>`), and the repository commit ID (SHA-7)

Linux

The zip archive can be extracted with the command:

```
tar -xvzf <VERSION>.tgz
```

Windows

The zip archive can be extracted with the UI or command:
unzip <VERSION>.tgz

The release artifact hierarchy (after extracting the tar/zip archive) is shown below. The agent proto file is available under api/.

Topics

- Load Model (p. 2685)
- Unload Model (p. 2686)
- List Models (p. 2687)
- Describe Model (p. 2687)
- Capture Data (p. 2688)
- Get Capture Status (p. 2689)
- Predict (p. 2690)

Load Model

The Edge Manager agent supports loading multiple models. This API validates the model signature and loads into memory all the artifacts produced by the EdgePackagingJob operation. This step requires all the required certificates to be installed along with rest of the agent binary installation. If the model's signature cannot be validated then this step fails with appropriate return code and error messages in the log.

```plaintext
// perform load for a model
// Note:
// 1. currently only local filesystem paths are supported for loading models.
// 2. multiple models can be loaded at the same time, as limited by available device memory
// 3. users are required to unload any loaded model to load another model.
// Status Codes:
// 1. OK - load is successful
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// 4. NOT_FOUND - model doesn't exist at the url
// 5. ALREADY_EXISTS - model with the same name is already loaded
// 6. RESOURCE_EXHAUSTED - memory is not available to load the model
```
// 7. FAILED_PRECONDITION - model is not compiled for the machine.
//
// rpc LoadModel(LoadModelRequest) returns (LoadModelResponse);

Input

// request for LoadModel rpc call
//
message LoadModelRequest {
  string url = 1;
  string name = 2;  // Model name needs to match regex "^[a-zA-Z0-9][-*[a-zA-Z0-9]]*$"
}

Output

// response for LoadModel rpc call
//
message LoadModelResponse {
  Model model = 1;
}

// Model represents the metadata of a model
// url - url representing the path of the model
// name - name of model
// input_tensor_metadatas - TensorMetadata array for the input tensors
// output_tensor_metadatas - TensorMetadata array for the output tensors
//
// Note:
// 1. input and output tensor metadata could empty for dynamic models.
//
message Model {
  string url = 1;
  string name = 2;
  repeated TensorMetadata input_tensor_metadatas = 3;
  repeated TensorMetadata output_tensor_metadatas = 4;
}

Unload Model

Unloads a previously loaded model. It is identified via the model alias which was provided during loadModel. If the alias is not found or model is not loaded then returns error.

// perform unload for a model
// Status Codes:
// 1. OK - unload is successful
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// 4. NOT_FOUND - model doesn't exist
//
// rpc UnLoadModel(UnLoadModelRequest) returns (UnLoadModelResponse);

Input

//
// request for UnLoadModel rpc call
message UnLoadModelRequest {
  string name = 1; // Model name needs to match regex "^[a-zA-Z0-9](-*[a-zA-Z0-9])*" 
}

Output

// response for UnLoadModel rpc call
message UnLoadModelResponse {}

List Models

Lists all the loaded models and their aliases.

// lists the loaded models
// Status Codes:
// 1. OK - unload is successful
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// rpc ListModels(ListModelsRequest) returns (ListModelsResponse);

Input

// request for ListModels rpc call
message ListModelsRequest {}

Output

// response for ListModels rpc call
message ListModelsResponse {
  repeated Model models = 1;
}

Describe Model

Describes a model that is loaded on the agent.

// Status Codes:
// 1. OK - load is successful
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// 4. NOT_FOUND - model doesn’t exist at the url
// rpc DescribeModel(DescribeModelRequest) returns (DescribeModelResponse);
Capture Data

Allows the client application to capture input and output tensors in Amazon S3 bucket, and optionally the auxiliary. The client application is expected to pass a unique capture ID along with each call to this API. This can be later used to query status of the capture.

// allows users to capture input and output tensors along with auxiliary data. // Status Codes: // 1. OK - data capture successfully initiated // 2. UNKNOWN - unknown error has occurred // 3. INTERNAL - an internal error has occurred // 5. ALREADY_EXISTS - capture initiated for the given capture_id // 6. RESOURCE_EXHAUSTED - buffer is full cannot accept any more requests. // 7. OUT_OF_RANGE - timestamp is in the future. // 8. INVALID_ARGUMENT - capture_id is not of expected format. // rpc CaptureData(CaptureDataRequest) returns (CaptureDataResponse);
// Tensor represents a tensor, encoded as contiguous multi-dimensional array.
// tensor_metadata - represents metadata of the shared memory segment
// data_or_handle - represents the data of shared memory, this could be passed in two
// ways:
// a. send across the raw bytes of the multi-dimensional tensor array
// b. send a SharedMemoryHandle which contains the posix shared memory segment
// id and offset in bytes to location of multi-dimensional tensor array.

message Tensor {
    TensorMetadata tensor_metadata = 1; // optional in the predict request
    oneof data {
        bytes byte_data = 4;
        // will only be used for input tensors
        SharedMemoryHandle shared_memory_handle = 5;
    }
}

// request for CaptureData rpc call
//
message CaptureDataRequest {
    string model_name = 1;
    string capture_id = 2; // uuid string
    Timestamp inference_timestamp = 3;
    repeated Tensor input_tensors = 4;
    repeated Tensor output_tensors = 5;
    repeated AuxilaryData inputs = 6;
    repeated AuxilaryData outputs = 7;
}

Output

// response for CaptureData rpc call
//
message CaptureDataResponse {}

Get Capture Status

Depending on the models loaded the input and output tensors can be large (for many edge devices). Capture to the cloud can be time consuming. So the CaptureData() is implemented as an asynchronous operation. A capture ID is a unique identifier that the client provides during capture data call, this ID can be used to query the status of the asynchronous call.

// allows users to query status of capture data operation
// Status Codes:
// 1. OK - data capture successfully initiated
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// 4. NOT_FOUND - given capture id doesn't exist.
//
rpc GetCaptureDataStatus(GetCaptureDataStatusRequest) returns (GetCaptureDataStatusResponse);
Input

```protobuf
// request for GetCaptureDataStatus rpc call
message GetCaptureDataStatusRequest {
  string capture_id = 1;
}
```

Output

```protobuf
enum CaptureDataStatus {
  FAILURE = 0;
  SUCCESS = 1;
  IN_PROGRESS = 2;
  NOT_FOUND = 3;
}
```

```protobuf
// response for GetCaptureDataStatus rpc call
message GetCaptureDataStatusResponse {
  CaptureDataStatus status = 1;
}
```

**Predict**

The **Predict** API performs inference on a previously loaded model. It accepts a request in the form of a tensor that is directly fed into the neural network. The output is the output tensor (or scalar) from the model. This is a blocking call.

```protobuf
// perform inference on a model.
// Note:
// 1. users can chose to send the tensor data in the protobuf message or
// through a shared memory segment on a per tensor basis, the Predict
// method will handle the decode transparently.
// 2. serializing large tensors into the protobuf message can be quite expensive,
// based on our measurements it is recommended to use shared memory of
// tenors larger than 256KB.
// 3. SMEdge IPC server will not use shared memory for returning output tensors,
// i.e., the output tensor data will always send in byte form encoded
// in the tensors of PredictResponse.
// 4. currently SMEdge IPC server cannot handle concurrent predict calls, all
// these call will be serialized under the hood. this shall be addressed
// in a later release.
// Status Codes:
// 1. OK - prediction is successful
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// 4. NOT_FOUND - when model not found
// 5. INVALID_ARGUMENT - when tenors types mismatch
// rpc Predict(PredictRequest) returns (PredictResponse);
```

Input

```protobuf
// request for Predict rpc call
```
// message PredictRequest {
string name = 1;
repeated Tensor tensors = 2;
}

// Tensor represents a tensor, encoded as contiguous multi-dimensional array.
// tensor_metadata - represents metadata of the shared memory segment
// data_or_handle - represents the data of shared memory, this could be passed in
two ways:
// a. send across the raw bytes of the multi-dimensional tensor
// array
// b. send a SharedMemoryHandle which contains the posix shared
memory segment
// id and offset in bytes to location of multi-dimensional
tensor array.
// message Tensor {
TensorMetadata tensor_metadata = 1; //optional in the predict request
oneof data {
  bytes byte_data = 4;
  // will only be used for input tensors
  SharedMemoryHandle shared_memory_handle = 5;
}
}

// TensorMetadata represents the metadata for a tensor
// name - name of the tensor
// data_type - data type of the tensor
// shape - array of dimensions of the tensor
// message TensorMetadata {
string name = 1;
DataType data_type = 2;
repeated int32 shape = 3;
}

// SharedMemoryHandle represents a posix shared memory segment
// offset - offset in bytes from the start of the shared memory segment.
// segment_id - shared memory segment id corresponding to the posix shared memory
// segment.
// size - size in bytes of shared memory segment to use from the offset position.
SageMaker Edge Manager end of life

Starting in April 26, 2024, you can no longer access Amazon SageMaker Edge Manager through the AWS management console, make edge packaging jobs, and manage edge device fleets.

FAQs

Use the following sections to get answers to commonly asked questions about the SageMaker Edge Manager end of life (EOL).

Q: What happens to my Amazon SageMaker Edge Manager after the EOL date?
A: After April 26, 2024, all references to edge packaging jobs, devices, and device fleets are deleted from the Edge Manager service. You can no longer discover or access the Edge Manager service from your AWS console and applications that call on the Edge Manager service APIs no longer work.

Q: Will I be billed for Edge Manager resources remaining in my account after the EOL date?
A: Resources created by Edge Manager, such as edge packages inside Amazon S3 buckets, AWS IoT things, and AWS IAM roles, continue to exist on their respective services after April 26, 2024. To avoid being billed after Edge Manager is no longer supported, delete your resources. For more information on deleting your resources, see Delete Edge Manager resources (p. 2693).

Q: How do I delete my Amazon SageMaker Edge Manager resources?
A: Resources created by Edge Manager, such as edge packages inside Amazon S3 buckets, AWS IoT things, and AWS IAM roles, continue to exist on their respective services after April 26, 2024. To avoid being billed after Edge Manager is no longer supported, delete your resources. For more information on deleting your resources, see Delete Edge Manager resources (p. 2693).

Q: How can I continue deploying models on the edge?
A: We suggest you try one the following machine learning tools. For a cross-platform edge runtime, use ONNX. ONNX is a popular, well-maintained open-source solution that translates your models into instructions that many types of hardware can run, and is compatible with the latest ML frameworks. ONNX can be integrated into your SageMaker workflows as an automated step for your edge deployments.

For edge deployments and monitoring use AWS IoT Greengrass V2. AWS IoT Greengrass V2 has an extensible packaging and deployment mechanism that can fit models and applications at the edge. You
can use the built-in MQTT channels to send model telemetry back for Amazon SageMaker Model Monitor or use the built-in permissions system to send data captured from the model back to Amazon Simple Storage Service (Amazon S3). If you don't or can't use AWS IoT Greengrass V2, we suggest using MQTT and IoT Jobs (C/C++ library) to create a lightweight OTA mechanism to deliver models.

We have prepared sample code available at this GitHub repository to help you transition to these suggested tools.

**Delete Edge Manager resources**

Resources created by Edge Manager continue to exist after April 26, 2024. To avoid billing, delete these resources.

To delete AWS IoT Greengrass resources, do the following:

1. In the AWS IoT Core console, choose **Greengrass devices** under **Manage**.
2. Choose **Components**.
3. Under **My components**, Edge Manager created components are in the format `SageMakerEdge (EdgePackagingJobName)`. Select the component you want to delete.
4. Then choose **Delete version**.

To delete a AWS IoT role alias, do the following:

1. In the AWS IoT Core console, choose **Security** under **Manage**.
2. Choose **Role aliases**.
3. Edge Manager created role aliases are in the format `SageMakerEdge-{DeviceFleetName}`. Select the role you want to delete.
4. Choose **Delete**.

To delete packaging jobs in Amazon S3 buckets, do the following:

1. In the SageMaker console, choose **Edge Inference**.
2. Choose **Edge packaging jobs**.
