The label attribute name parameter (for example, `image-label-attribute-name`) contains an array of all of the labels selected by at least one of the workers who completed this task. This array contains integer keys (for example, `[1, 0, 8]`) that correspond to the labels found in `class-map`. In the multi-label image classification example, bicycle, person, and clothing were selected by at least one of the workers who completed the labeling task for the image, `exampleimage.jpg`.

The confidence-map shows the confidence score that Ground Truth assigned to each label selected by a worker. To learn more about Ground Truth confidence scores, see Confidence Score (p. 892).

The red, italicized text in the examples below depends on labeling job specifications and output data.

The following is an example of a multi-label image classification output manifest file.

```json
{
  "source-ref": "s3://AWSDOC-EXAMPLE-BUCKET/example_image.jpg",
  "image-label-attribute-name": [1, 0, 8],
  "image-label-attribute-name-metadata": {
    "job-name": "labeling-job/image-label-attribute-name",
    "class-map": {
      "1": "bicycle",
      "0": "person",
      "8": "clothing"
    },
    "human-annotated": "yes",
    "creation-date": "2020-02-27T21:36:25.000201",
    "confidence-map": {
      "1": 0.95,
      "0": 0.77,
      "8": 0.2
    },
    "type": "groundtruth/image-classification-multilabel"
  }
}
```

The following is an example of a multi-label text classification output manifest file. In this example, approving, sad and critical were selected by at least one of the workers who completed the labeling task for the object `exampletext.txt` found in `AWSDOC-EXAMPLE-BUCKET`.

```json
{
  "source-ref": "AWSDOC-EXAMPLE-BUCKET/text_file.txt",
  "text-label-attribute-name": [1, 0, 4],
  "text-label-attribute-name-metadata": {
    "job-name": "labeling-job/text-label-attribute-name",
    "class-map": {
      "1": "approving",
      "0": "sad",
      "4": "critical"
    },
    "human-annotated": "yes",
    "creation-date": "2020-02-20T21:36:25.000201",
    "confidence-map": {
      "1": 0.95,
      "0": 0.77,
      "4": 0.2
    }
  }
}
```
Bounding Box Job Output

The following is sample output (output manifest file) from a bounding box job. For this task, three bounding boxes are returned. The label value contains information about the size of the image, and the location of the bounding boxes.

The class_id element is the index of the box's class in the list of available classes for the task. The class-map metadata element contains the text of the class.

The metadata has a separate confidence score for each bounding box. The metadata also includes the class-map element that maps the class_id to the text value of the class. For more information, see Object Detection - MXNet (p. 1778).

The red, italicized text in the examples below depends on labeling job specifications and output data.

```
{
  "source-ref": "s3://AWSDOC-EXAMPLE-BUCKET/example_image.png",
  "bounding-box-attribute-name": {
    "image_size": [{ "width": 500, "height": 400, "depth": 3 }],
    "annotations": [
      {"class_id": 0, "left": 111, "top": 134, 
      "width": 61, "height": 128},
      {"class_id": 5, "left": 161, "top": 250, 
      "width": 30, "height": 30},
      {"class_id": 5, "left": 20, "top": 20, 
      "width": 30, "height": 30}
    ],
    "bounding-box-attribute-name-metadata": {
      "objects": [
        {"confidence": 0.8},
        {"confidence": 0.9},
        {"confidence": 0.9}
      ],
      "class-map": {
        "0": "dog",
        "5": "bone"
      },
      "type": "groundtruth/object-detection",
      "human-annotated": "yes",
      "creation-date": "2018-10-18T22:18:13.527256",
      "job-name": "identify-dogs-and-toys"
    }
  }
}
```

The output of a bounding box adjustment job looks like the following JSON. Note that the original JSON is kept intact and two new jobs are listed, each with "adjust-" prepended to the original attribute's name.

```
[
  "source-ref": "S3 bucket location",
  "bounding-box-attribute-name": {
    "image_size": [{ "width": 500, "height": 400, "depth": 3 }],
  }
]```
In this output, the job's type doesn't change, but an adjustment-status field is added. This field has the value of adjusted or unadjusted. If multiple workers have reviewed the object and at least one adjusted the label, the status is adjusted.
Named Entity Recognition

The following is an example output manifest file from a named entity recognition (NER) labeling task. For this task, seven entities are returned.

In the output manifest, the JSON object, annotations, includes a list of the labels (label categories) that you provided.

Worker responses are in a list named entities. Each entity in this list is a JSON object that contains a label value that matches one in the labels list, an integer startOffset value for labeled span's starting Unicode offset, and an integer endOffset value for the ending Unicode offset.

The metadata has a separate confidence score for each entity. If a single worker labeled each data object, the confidence value for each entity will be zero.

The red, italicized text in the examples below depends on labeling job inputs and worker responses.

```json
{
"source": "Amazon SageMaker is a cloud machine-learning platform that was launched in November 2017. SageMaker enables developers to create, train, and deploy machine-learning (ML) models in the cloud. SageMaker also enables developers to deploy ML models on embedded systems and edge-devices",
"ner-labeling-job-attribute-name": {
"annotations": {
"labels": [
{
"label": "Date",
"shortDisplayName": "dt"
},
{
"label": "Verb",
"shortDisplayName": "vb"
},
{
"label": "Thing",
"shortDisplayName": "tng"
},
{
"label": "People",
"shortDisplayName": "ppl"
}
],
"entities": [
{
"label": "Thing",
"startOffset": 22,
"endOffset": 53
},
{
"label": "Thing",
"startOffset": 269,
"endOffset": 281
},
{
"label": "Verb",
"startOffset": 63,
"endOffset": 71
},
{
"label": "Verb",
"startOffset": 228,
"endOffset": 234
}
]
}
}```
Label Verification Job Output

The output (output manifest file) of a bounding box verification job looks different than the output of a bounding box annotation job. That's because the workers have a different type of task. They're not labeling objects, but evaluating the accuracy of prior labeling, making a judgment, and then providing that judgment and perhaps some comments.

If human workers are verifying or adjusting prior bounding box labels, the output of a verification job would look like the following JSON. The red, italicized text in the examples below depends on labeling job specifications and output data.

```json
{
  "source-ref": "s3://AWSDOC-EXAMPLE-BUCKET/image_example.png",
  "bounding-box-attribute-name": {
    "image_size": [[ { "width": 500, "height": 400, "depth": 3 } ]]
  }
}
```
"annotations": [
  {
    "class_id": 0, "left": 111, "top": 134,
    "width": 61, "height": 128
  },
  {
    "class_id": 5, "left": 161, "top": 250,
    "width": 30, "height": 30
  },
  {
    "class_id": 5, "left": 20, "top": 20,
    "width": 30, "height": 30
  }
],
"bounding-box-attribute-name-metadata": {
  "objects": [
    {
      "confidence": 0.8
    },
    {
      "confidence": 0.9
    },
    {
      "confidence": 0.9
    }
  ],
  "class-map": {
    "0": "dog",
    "5": "bone"
  },
  "type": "groundtruth/object-detection",
  "human-annotated": "yes",
  "creation-date": "2018-10-18T22:18:13.527256",
  "job-name": "identify-dogs-and-toys"
},
"verify-bounding-box-attribute-name": "1",
"verify-bounding-box-attribute-name-metadata": {
  "class-name": "bad",
  "confidence": 0.93,
  "type": "groundtruth/label-verification",
  "job-name": "verify-bounding-boxes",
  "human-annotated": "yes",
  "creation-date": "2018-11-20T22:18:13.527256",
  "worker-feedback": [
    {
      "comment": "The bounding box on the bird is too wide on the right side."
    },
    {
      "comment": "The bird on the upper right is not labeled."
    }
  ]
}

Although the type on the original bounding box output was groundtruth/object-detection, the new type is groundtruth/label-verification. Also note that the worker-feedback array provides worker comments. If the worker doesn't provide comments, the empty fields are excluded during consolidation.

**Semantic Segmentation Job Output**

The following is the output manifest file from a semantic segmentation labeling job. The value of the label for this job is a reference to a PNG file in an Amazon S3 bucket.

In addition to the standard elements, the metadata for the label includes a color map that defines which color is used to label the image, the class name associated with the color, and the confidence score for each color. For more information, see [Semantic Segmentation Algorithm](p. 1797).

The red, italicized text in the examples below depends on labeling job specifications and output data.

```json
{
  "source-ref": "s3://AWSDOC-EXAMPLE-BUCKET/example_city_image.png",
  "city-streets-ref": "S3 bucket location"
}
```
Confidence is scored on a per-image basis. Confidence scores are the same across all classes within an image.

The output of a semantic segmentation adjustment job looks similar to the following JSON.

```json
{
  "source-ref": "s3://AWSDOC-EXAMPLE-BUCKET/example_city_image.png",
  "city-streets-ref": "S3 bucket location",
  "city-streets-ref-metadata": {
    "internal-color-map": {
      "0": {
        "class-name": "BACKGROUND",
        "confidence": 0.9,
        "hex-color": "#ffffff"
      },
      "1": {
        "class-name": "buildings",
        "confidence": 0.9,
        "hex-color": "#2acf59"
      },
      "2": {
        "class-name": "road",
        "confidence": 0.9,
        "hex-color": "#f28333"
      }
    },
    "type": "groundtruth/semantic-segmentation",
    "human-annotated": "yes",
    "creation-date": "2018-10-18T22:18:13.527256",
    "job-name": "label-city-streets",
  },
  "verify-city-streets-ref": "1",
  "verify-city-streets-ref-metadata": {
    "class-name": "bad",
    "confidence": 0.93,
    "type": "groundtruth/label-verification",
    "job-name": "verify-city-streets",
    "human-annotated": "yes",
    "creation-date": "2018-11-20T22:18:13.527256",
    "worker-feedback": [
      {"comment": "The mask on the leftmost building is assigned the wrong side of the road."},
      {"comment": "The curb of the road is not labeled but the instructions say otherwise."}
    ]
  }
}
```
Video Frame Object Detection Output

The following is the output manifest file from a video frame object detection labeling job. The red, italicized text in the examples below depends on labeling job specifications and output data.

In addition to the standard elements, the metadata includes a class map that lists each class that has at least one label in the sequence. The metadata also includes job-name which is the name you assigned to the labeling job. For adjustment tasks, if one or more bounding boxes were modified, there is an adjustment-status parameter in the metadata for audit workflows that is set to adjusted.

```
{
  "source-ref": "s3://DOC-EXAMPLE-BUCKET/example-path/input-manifest.json",
  "CarObjectDetection-ref": "s3://AWSDOC-EXAMPLE-BUCKET/output/labeling-job-name/annotations/consolidated-annotation/output/0/SeqLabel.json",
  "CarObjectDetection-ref-metadata": {
    "class-map": {
      "0": "car",
      "1": "bus"
    },
    "job-name": "labeling-job/labeling-job-name",
    "human-annotated": "yes",
    "creation-date": "2021-09-29T05:50:35.566000",
    "type": "groundtruth/video-object-detection"
  }
}
```

Ground Truth creates one output sequence file for each sequence of video frames that was labeled. Each output sequence file contains the following:
• All annotations for all frames in a sequence in the detection-annotations list of JSON objects.
• For each frame that was annotated by a worker, the frame file name (frame), number (frame-no), a list of JSON objects containing annotations (annotations), and if applicable, frame-attributes. The name of this list is defined by the task type you use: polylines, polygons, keypoints, and for bounding boxes, annotations.

Each JSON object contains information about a single annotation and associated label. The following table outlines the parameters you'll see for each video frame type.

<table>
<thead>
<tr>
<th>Task Type</th>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bounding Box</td>
<td>Box dimensions: height and width</td>
</tr>
<tr>
<td></td>
<td>Box top, left corner pixel location: top and left</td>
</tr>
<tr>
<td>Keypoint</td>
<td>Keypoint vertices: { &quot;x&quot;: int, &quot;y&quot;: int }</td>
</tr>
<tr>
<td>Polygon</td>
<td>A list of polygon vertices: vertices</td>
</tr>
<tr>
<td></td>
<td>Polygon vertices: { &quot;x&quot;: int, &quot;y&quot;: int }</td>
</tr>
<tr>
<td></td>
<td>A polygon is a closed shape and so the first point will also represent the last point.</td>
</tr>
<tr>
<td>Polyline</td>
<td>A list of polyline vertices: vertices</td>
</tr>
<tr>
<td></td>
<td>Polyline vertices: { &quot;x&quot;: int, &quot;y&quot;: int }</td>
</tr>
</tbody>
</table>

In addition to task type specific values, you will see the following in each JSON object:
• Values of any label-category-attributes that were specified for that label.
• The class-id of the box. Use the class-map in the output manifest file to see which label category this ID maps to.

The following is an example of a SeqLabel.json file from a bounding box video frame object detection labeling job. This file will be located under s3://your-output-bucket/output-prefix/annotations/consolidated-annotation/output/annotation-number/

```json
{
    "detection-annotations": [
        {
            "annotations": [
                {
                    "height": 41,
                    "width": 53,
                    "top": 152,
                    "left": 339,
                    "class-id": "1",
                    "label-category-attributes": {
                        "occluded": "no",
                        "size": "medium"
                    }
                },
                {
                    "height": 24,
                    "width": 37,
                    "top": 148,
                    "left": 183,
                    "class-id": "0",
                    "label-category-attributes": {
```
Video Frame Object Tracking Output

The following is the output manifest file from a video frame object tracking labeling job. The red, italicized text in the examples below depends on labeling job specifications and output data.

In addition to the standard elements, the metadata includes a class map that lists each class that has at least one label in the sequence of frames. The metadata also includes job-name which is the name you assigned to the labeling job. For adjustment tasks, if one or more bounding boxes were modified, there is an adjustment-status parameter in the metadata for audit workflows that is set to adjusted.

```json
{
  "source-ref": "s3://DOC-EXAMPLE-BUCKET/example-path/input-manifest.json",
  "CarObjectTracking-ref": "s3://AWSDOC-EXAMPLE-BUCKET/output/labeling-job-name/annotations/consolidated-annotation/output/0/SeqLabel.json",
  "CarObjectTracking-ref-metadata": {
    "class-map": {
      "0": "car",
      "1": "bus"
    },
    "job-name": "labeling-job/labeling-job-name",
    "human-annotated": "yes",
    "creation-date": "2021-09-29T05:50:35.566000",
    "type": "groundtruth/video-object-tracking"
  }
}
```
Ground Truth creates one output sequence file for each sequence of video frames that was labeled. Each output sequence file contains the following:

- All annotations for all frames in a sequence in the tracking-annotations list of JSON objects.
- For each frame that was annotated by a worker, the frame (frame), number (frame-no), a list of JSON objects containing annotations (annotations), and if applicable, frame attributes (frame-attributes). The name of this list is defined by the task type you use: polylines, polygons, keypoints, and for bounding boxes, annotations.

Each JSON object contains information about a single annotation and associated label. The following table outlines the parameters you’ll see for each video frame task type.

<table>
<thead>
<tr>
<th>Task Type</th>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bounding Box</td>
<td>Box dimensions: height and width</td>
</tr>
<tr>
<td></td>
<td>Box top, left corner pixel location: top and left</td>
</tr>
<tr>
<td>Keypoint</td>
<td>Keypoint vertices: { &quot;x&quot;: int, &quot;y&quot;: int }</td>
</tr>
<tr>
<td>Polygon</td>
<td>A list of polygon vertices: vertices</td>
</tr>
<tr>
<td></td>
<td>Polygon vertices: { &quot;x&quot;: int, &quot;y&quot;: int }</td>
</tr>
<tr>
<td></td>
<td>A polygon is a closed shape and so the first point will also represent the last point.</td>
</tr>
<tr>
<td>Polyline</td>
<td>A list of polyline vertices: vertices</td>
</tr>
<tr>
<td></td>
<td>Polyline vertices: { &quot;x&quot;: int, &quot;y&quot;: int }</td>
</tr>
</tbody>
</table>

In addition to task type specific values, you will see the following in each JSON object:

- Values of any label-category-attributes that were specified for that label.
- The class-id of the box. Use the class-map in the output manifest file to see which label category this ID maps to.
- An object-id which identifies an instance of a label. This ID will be the same across frames if a worker identified the same instance of an object in multiple frames. For example, if a car appeared in multiple frames, all bounding boxes uses to identify that car would have the same object-id.
- The object-name which is the instance ID of that annotation.

The following is an example of a SeqLabel.json file from a bounding box video frame object tracking labeling job. This file will be located under s3://your-output-bucket/output-prefix/annotations/consolidated-annotation/output/annotation-number/

```json
{
   "tracking-annotations": [
      {
         "annotations": [
            {
               "height": 36,
               "width": 46,
               "top": 178,
               "left": 315,
               "class-id": "0",
               "label-category-attributes": {
                  "occluded": "no"
               },
               "object-id": "480dc450-c0ca-11ea-961f-a9b1c5c97972"
            }
         ]
      }
   ]
}```
3D Point Cloud Semantic Segmentation Output

The following is the output manifest file from a 3D point cloud semantic segmentation labeling job.

In addition to the standard elements, the metadata for the label includes a color map that defines which color is used to label the image, the class name associated with the color, and the confidence score for each color. Additionally, there is an adjustment-status parameter in the metadata for audit workflows that is set to adjusted if the color mask is modified. If you added one or more frameAttributes to your label category configuration file, worker responses for frame attributes are in the JSON object, dataset-object-attributes.

The your-label-attribute-ref parameter contains the location of a compressed file with a .zlib extension. When you uncompress this file, it contains an array. Each index in the array corresponds to the index of an annotated point in the input point cloud. The value of the array at a given index gives the class of the point at the same index in the point cloud, based on the semantic color map found in the color-map parameter of the metadata.

You can use Python code similar to the following to decompress a .zlib file:

```python
import zlib
from array import array
```
# read the label file
compressed_binary_file = open(zlib_file_path/file.zlib, 'rb').read()

# uncompress the label file
binary_content = zlib.decompress(compressed_binary_file)

# load labels to an array
my_int_array_data = array('B', binary_content);
print(my_int_array_data)

The code block above will produce an output similar to the following. Each element of the printed array contains the class of a point at the that index in the point cloud. For example, my_int_array_data[0] = 1 means point[0] in the input point cloud has a class 1. In the following output manifest file example, class 0 corresponds with "Background", 1 with Car, and 2 with Pedestrian.

```python
>> array('B', [1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2])
```

The following is an example of a semantic segmentation 3D point cloud labeling job output manifest file. The red, italicized text in the examples below depends on labeling job specifications and output data.

```json
{
    "source-ref": "s3://AWSDOC-EXAMPLE-BUCKET/examplefolder/frame1.bin",
    "source-ref-metadata": {
        "format": "binary/xyz",
        "unix-timestamp": 1566861644.759115,
        "ego-vehicle-pose": [...],
        "prefix": "s3://AWSDOC-EXAMPLE-BUCKET/lidar_singleframe_dataset/prefix",
        "images": [...]
    },
    "lidar-ss-label-attribute-ref": "s3://your-output-bucket/labeling-job-name/annotations/consolidated-annotation/output/dataset-object-id/filename.zlib",
    "lidar-ss-label-attribute-ref-metadata": {
        'color-map': {
            '0': {
                "class-name": "Background",
                "hex-color": "#ffffff",
                "confidence": 0.00
            },
            '1': {
                "class-name": "Car",
                "hex-color": "#2ca02c",
                "confidence": 0.00
            },
            '2': {
                "class-name": "Pedestrian",
                "hex-color": "#1f77b4",

        "only present for adjustment audit workflow": "adjusted"
    }
}
```
3D Point Cloud Object Detection Output

The following is sample output from a 3D point cloud objected detection job. For this task type, the data about 3D cuboids is returned in the 3d-bounding-box parameter, in a list named annotations. In this list, each 3D cuboid is described using the following information.

- Each class, or label category, that you specify in your input manifest is associated with a class-id. Use the class-map to identify the class associated with each class ID.
- These classes are used to give each 3D cuboid an object-name in the format <class>:<integer> where integer is a unique number to identify that cuboid in the frame.
- center-x, center-y, and center-z are the coordinates of the center of the cuboid, in the same coordinate system as the 3D point cloud input data used in your labeling job.
- length, width, and height describe the dimensions of the cuboid.
- yaw is used to describe the orientation (heading) of the cuboid in radians.

**Note**

yaw is now in the right-handed Cartesian system. Since this feature was added on September 02, 2022 19:02:17 UTC, you can convert the yaw measurement in the output data prior to that using the following (all units are in radians):

old_yaw_in_output = pi - yaw

- In our definition, +x is to the right, +y is to the forward, and +z is up from the ground plane. The rotation order is x - y - z. The roll, pitch and yaw are represented in the right-handed Cartesian system. In 3D space, roll is along the x-axis, pitch is along the y-axis and yaw is along the z-axis. All three are counterclockwise.
- If you included label attributes in your input manifest file for a given class, a label-category-attributes parameter is included for all cuboids for which workers selected label attributes.

If one or more cuboids were modified, there is an adjustment-status parameter in the metadata for audit workflows that is set to adjusted. If you added one or more frameAttributes to your label category configuration file, worker responses for frame attributes are in the JSON object, dataset-object-attributes.

The red, italicized text in the examples below depends on labeling job specifications and output data. The ellipses (...) denote a continuation of that list, where additional objects with the same format as the proceeding object can appear.

3D Point Cloud Object Tracking Output

The following is an example of an output manifest file from a 3D point cloud object tracking labeling job. The red, italicized text in the examples below depends on labeling job specifications and output data. The ellipses (...) denote a continuation of that list, where additional objects with the same format as the proceeding object can appear.

In addition to the standard elements, the metadata includes a class map that lists each class that has at least one label in the sequence. If one or more cuboids were modified, there is an adjustment-status parameter in the metadata for audit workflows that is set to adjusted.

```
{
  "source-ref": "s3://AWSDOC-EXAMPLE-BUCKET/myfolder/seq1.json",
  "lidar-label-attribute-ref": "s3://<CustomerOutputLocation>/<labelingJobName>/annotations/consolidated-annotation/output/<datasetObjectId>/SeqLabel.json",
  "lidar-label-attribute-ref-metadata": {
    "objects": [
      {
        "frame-no": 300,
        "confidence": []
      },
      {
        "frame-no": 301,
        "confidence": []
      },
      ...,
      'class-map': {'0': 'Car', '1': 'Person'},
      'type': 'groundtruth/point_cloud_object_tracking',
      'human-annotated': 'yes',
      'creation-date': '2019-11-12T01:18:14.271944',
      'job-name': 'identify-3d-objects',
      "adjustment-status": "adjusted"
    ]
  }
}
```

In the above example, the cuboid data for each frame in seq1.json is in SeqLabel.json in the Amazon S3 location, s3://<customerOutputLocation>/<labelingJobName>/annotations/
The following is an example of this label sequence file.

For each frame in the sequence, you see the frame-number, frame-name, if applicable, frame-attributes, and a list of annotations. This list contains 3D cuboids that were drawn for that frame. Each annotation includes the following information:

- An object-name in the format `<class>:<integer>` where class identifies the label category and integer is a unique ID across the dataset.
- When workers draw a cuboid, it is associated with a unique object-id which is associated with all cuboids that identify the same object across multiple frames.
- Each class, or label category, that you specified in your input manifest is associated with a class-id. Use the class-map to identify the class associated with each class ID.
- `center-x`, `center-y`, and `center-z` are the coordinates of the center of the cuboid, in the same coordinate system as the 3D point cloud input data used in your labeling job. length, width, and height describe the dimensions of the cuboid.
- `yaw` is used to describe the orientation (heading) of the cuboid in radians.

Note

`yaw` is now in the right-handed Cartesian system. Since this feature was added on September 02, 2022 19:02:17 UTC, you can convert the `yaw` measurement in the output data prior to that using the following (all units are in radians):

\[
\text{old}_\text{yaw}_\text{in}_\text{output} = \pi - \text{yaw}
\]

- In our definition, +x is to the right, +y is to the forward, and +z is up from the ground plane. The rotation order is x-y-z. The roll, pitch and yaw are represented in the right-handed Cartesian system. In 3D space, roll is along the x-axis, pitch is along the y-axis and yaw is along the z-axis. All three are counterclockwise.
- If you included label attributes in your input manifest file for a given class, a label-category-attributes parameter is included for all cuboids for which workers selected label attributes.

```json

The cuboid and bounding box for an object are linked through a common object-id.

**Enhanced Data Labeling**

Amazon SageMaker Ground Truth manages sending your data objects to workers to be labeled. Labeling each data object is a task. Workers complete each task until the entire labeling job is complete. Ground Truth divides the total number of tasks into smaller batches that are sent to workers. A new batch is sent to workers when the previous one is finished.

Ground Truth provides two features that help improve the accuracy of your data labels and reduce the total cost of labeling your data:

- **Annotation consolidation** helps to improve the accuracy of your data object labels. It combines the results of multiple workers' annotation tasks into one high-fidelity label.
- **Automated data labeling** uses machine learning to label portions of your data automatically without having to send them to human workers.

### Topics

- [Control the Flow of Data Objects Sent to Workers](p. 919)
- [Consolidate Annotations](p. 920)
- [Automate Data Labeling](p. 921)
- [Chaining Labeling Jobs](p. 927)
Control the Flow of Data Objects Sent to Workers

Depending on the type of labeling job you create, Amazon SageMaker Ground Truth sends data objects to workers in batches or in a streaming fashion. You can control the flow of data objects to workers in the following ways:

- For both types of labeling jobs, you can use `MaxConcurrentTaskCount` to control the total number of data objects available to all workers at a given point in time when the labeling job is running.
- For streaming labeling jobs, you can control the flow of data objects to workers by monitoring and controlling the number of data objects sent to the Amazon SQS associated with your labeling job.

Use the following sections to learn more about these options. To learn more about streaming labeling jobs, see `Ground Truth Streaming Labeling Jobs (p. 852)`.

Topics

- Use `MaxConcurrentTaskCount` to Control the Flow of Data Objects (`p. 919`)
- Use Amazon SQS to Control the Flow of Data Objects to Streaming Labeling Jobs (`p. 920`)

Use `MaxConcurrentTaskCount` to Control the Flow of Data Objects

`MaxConcurrentTaskCount` defines the maximum number of data objects that can be labeled by human workers at the same time. If you use the console, this parameter is set to 1,000. If you use `CreateLabelingJob`, you can set this parameter to any integer between 1 and 1,000, inclusive.

When you start a labeling job using an input manifest file, Ground Truth does the following:

1. For each data object listed in your input manifest file, one or more tasks are created, depending on the value you specify for `NumberOfHumanWorkersPerDataObject`. For example, if you set the number of workers per data object to 3, 3 tasks will be created for each dataset object. To be marked as successfully labeled, at least one worker must label the object. Alternatively, the tasks can expire or be declined.

2. If you are using the Mechanical Turk workforce, Ground Truth first sends a batch of 10 dataset objects to your workers. It uses this small batch to set up the labeling job and to make sure that the job is correctly configured.

3. Next, Ground Truth sends `MaxConcurrentTaskCount` number of dataset objects to workers. For example, if you have 2,000 input data objects in your input manifest file and have set the number of workers per data object to 3 and set `MaxConcurrentTaskCount` to 900, the first 900 data objects in your input manifest are sent to workers, corresponding to 2,700 tasks (900 x 3). This is the first full-sized set of objects sent to workers.

4. What happens next depends on the type of labeling job you create. This step assumes one or more dataset objects in your input manifest file, or sent using an Amazon SNS input data source (in a streaming labeling job) were not include in the set sent to workers in step 3.

   - **Streaming labeling job**: As long as the total number of objects available to workers is equal to `MaxConcurrentTaskCount`, all remaining dataset objects on your input manifest file and that you send in real time using Amazon SNS are placed on an Amazon SQS queue. When the total number of objects available to workers falls below `MaxConcurrentTaskCount` minus `NumberOfHumanWorkersPerDataObject`, a new data object from the queue is used to create `NumberOfHumanWorkersPerDataObject` tasks, which are sent to workers in real time.

   - **Non-streaming labeling job**: As workers finish labeling one set of objects, up to `MaxConcurrentTaskCount` times `NumberOfHumanWorkersPerDataObject` number of new tasks will be sent to workers. This process is repeated until all data objects in the input manifest file are labeled.
Use Amazon SQS to Control the Flow of Data Objects to Streaming Labeling Jobs

When you create a streaming labeling job, an Amazon SQS queue is automatically created in your account. Data objects are only added to the Amazon SQS queue when the total number of objects sent to workers is above \texttt{MaxConcurrentTaskCount}. Otherwise, objects are sent directly to workers.

You can use this queue to manage the flow of data objects to your labeling job. To learn more, see \texttt{Manage Labeling Requests with an Amazon SQS Queue} (p. 854).

Consolidate Annotations

An annotation is the result of a single worker's labeling task. Annotation consolidation combines the annotations of two or more workers into a single label for your data objects. A label, which is assigned to each object in the dataset, is a probabilistic estimate of what the true label should be. Each object in the dataset typically has multiple annotations, but only one label or set of labels.

You decide how many workers annotate each object in your dataset. Using more workers can increase the accuracy of your labels, but also increases the cost of labeling. To learn more about Ground Truth pricing, see \texttt{Amazon SageMaker Ground Truth pricing}.

If you use the Amazon SageMaker console to create a labeling job, the following are the defaults for the number of workers who can annotate objects:

- Text classification—3 workers
- Image classification—3 workers
- Bounding boxes—5 workers
- Semantic segmentation—3 workers
- Named entity recognition—3 workers

When you use the \texttt{CreateLabelingJob} operation, you set the number of workers to annotate each data object with the \texttt{NumberOfHumanWorkersPerDataObject} parameter. You can override the default number of workers that annotate a data object using the console or the \texttt{CreateLabelingJob} operation.

Ground Truth provides an annotation consolidation function for each of its predefined labeling tasks: bounding box, image classification, name entity recognition, semantic segmentation, and text classification. These are the functions:

- Multi-class annotation consolidation for image and text classification uses a variant of the Expectation Maximization approach to annotations. It estimates parameters for each worker and uses Bayesian inference to estimate the true class based on the class annotations from individual workers.
- Bounding box annotation consolidates bounding boxes from multiple workers. This function finds the most similar boxes from different workers based on the Jaccard index, or intersection over union, of the boxes and averages them.
- Semantic segmentation annotation consolidation treats each pixel in a single image as a multi-class classification. This function treats the pixel annotations from workers as "votes," with more information from surrounding pixels incorporated by applying a smoothing function to the image.
- Named entity recognition clusters text selections by Jaccard similarity and calculates selection boundaries based on the mode, or the median if the mode isn't clear. The label resolves to the most assigned entity label in the cluster, breaking ties by random selection.

You can use other algorithms to consolidate annotations. For information, see \texttt{Create Your Own Annotation Consolidation Function} (p. 921).
Create Your Own Annotation Consolidation Function

You can choose to use your own annotation consolidation function to determine the final labels for your labeled objects. There are many possible approaches for writing a function and the approach that you take depends on the nature of the annotations to consolidate. Broadly, consolidation functions look at the annotations from workers, measure the similarity between them, and then use some form of probabilistic judgment to determine what the most probable label should be.

If you want to use other algorithms to create annotation consolidations functions, you can find the worker responses in the \[project-name\]/annotations/worker-response folder of the Amazon S3 bucket where you direct the job output.

Assess Similarity

To assess the similarity between labels, you can use one of the following strategies, or you can use one that meets your data labeling needs:

- For label spaces that consist of discrete, mutually exclusive categories, such as multi-class classification, assessing similarity can be straightforward. Discrete labels either match or do not match.
- For label spaces that don't have discrete values, such as bounding box annotations, find a broad measure of similarity. For bounding boxes, one such measure is the Jaccard index. This measures the ratio of the intersection of two boxes with the union of the boxes to assess how similar they are. For example, if there are three annotations, then there can be a function that determines which annotations represent the same object and should be consolidated.

Assess the Most Probable Label

With one of the strategies detailed in the previous sections in mind, make some sort of probabilistic judgment on what the consolidated label should be. In the case of discrete, mutually exclusive categories, this can be straightforward. One of the most common ways to do this is to take the results of a majority vote between the annotations. This weights the annotations equally.

Some approaches attempt to estimate the accuracy of different annotators and weight their annotations in proportion to the probability of correctness. An example of this is the Expectation Maximization method, which is used in the default Ground Truth consolidation function for multi-class annotations.

For more information about creating an annotation consolidation function, see Step 3: Processing with AWS Lambda (p. 792).

Automate Data Labeling

If you choose, Amazon SageMaker Ground Truth can use active learning to automate the labeling of your input data for certain built-in task types. Active learning is a machine learning technique that identifies data that should be labeled by your workers. In Ground Truth, this functionality is called automated data labeling. Automated data labeling helps to reduce the cost and time that it takes to label your dataset compared to using only humans. When you use automated labeling, you incur SageMaker training and inference costs.

We recommend using automated data labeling on large datasets because the neural networks used with active learning require a significant amount of data for every new dataset. Typically, as you provide more data, the potential for high accuracy predictions goes up. Data will only be auto-labeled if the neural network used in the auto-labeling model can achieve an acceptably high level of accuracy. Therefore, with larger datasets, there is more potential to automatically label the data because the neural network can achieve high enough accuracy for auto-labeling. Automated data labeling is most appropriate when you have thousands of data objects. The minimum number of objects allowed for automated data labeling is 1,250, but we strongly suggest providing a minimum of 5,000 objects.

Automated data labeling is available only for the following Ground Truth built-in task types:
Streamlining labeling jobs do not support automated data labeling.

To learn how to create a custom active learning workflow using your own model, see Set up an active learning workflow with your own model (p. 927).

Input data quotas apply for automated data labeling jobs. See Input Data Quotas (p. 856) for information about dataset size, input data size and resolution limits.

**Note**
Before you use an the automated-labeling model in production, you need to fine-tune or test it, or both. You might fine-tune the model (or create and tune another supervised model of your choice) on the dataset produced by your labeling job to optimize the model's architecture and hyperparameters. If you decide to use the model for inference without fine-tuning it, we strongly recommend making sure that you evaluate its accuracy on a representative (for example, randomly selected) subset of the dataset labeled with Ground Truth and that it matches your expectations.

**How it Works**
You enable automated data labeling when you create a labeling job. This is how it works:

1. When Ground Truth starts an automated data labeling job, it selects a random sample of input data objects and sends them to human workers. If more than 10% of these data objects fail, the labeling job will fail. If the labeling job fails, in addition to reviewing any error message Ground Truth returns, check that your input data is displaying correctly in the worker UI, instructions are clear, and that you have given workers enough time to complete tasks.

2. When the labeled data is returned, it is used to create a training set and a validation set. Ground Truth uses these datasets to train and validate the model used for auto-labeling.

3. Ground Truth runs a batch transform job, using the validated model for inference on the validation data. Batch inference produces a confidence score and quality metric for each object in the validation data.

4. The auto labeling component will use these quality metrics and confidence scores to create a confidence score threshold that ensures quality labels.

5. Ground Truth runs a batch transform job on the unlabeled data in the dataset, using the same validated model for inference. This produces a confidence score for each object.

6. The Ground Truth auto labeling component determines if the confidence score produced in step 5 for each object meets the required threshold determined in step 4. If the confidence score meets the threshold, the expected quality of automatically labeling exceeds the requested level of accuracy and that object is considered auto-labeled.

7. Step 6 produces a dataset of unlabeled data with confidence scores. Ground Truth selects data points with low confidence scores from this dataset and sends them to human workers.

8. Ground Truth uses the existing human-labeled data and this additional labeled data from human workers to update the model.

9. The process is repeated until the dataset is fully labeled or until another stopping condition is met. For example, auto-labeling stops if your human annotation budget is reached.

The preceding steps happen in iterations. Select each tab in the following table to see an example of the processes that happen in each iteration for an object detection automated labeling job. The number of data objects used in a given step in these images (for example, 200) is specific to this example. If there are fewer than 5,000 objects to label, the validation set size is 20% of the whole dataset. If there are
more than 5,000 objects in your input dataset, the validation set size is 10% of the whole dataset. You can control the number of human labels collected per active learning iteration by changing the value for \texttt{MaxConcurrentTaskCount} when using the API operation \texttt{CreateLabelingJob}. This value is set to 1,000 when you create a labeling job using the console. In the active learning flow illustrated under the \textbf{Active Learning} tab, this value is set to 200.

Iteration 4: Automated
Active Learning

Accuracy of Automated Labels

The definition of accuracy depends on the built-in task type that you use with automated labeling. For all task types, these accuracy requirements are pre-determined by Ground Truth and cannot be manually configured.

- For image classification and text classification, Ground Truth uses logic to find a label-prediction confidence level that corresponds to at least 95% label accuracy. This means Ground Truth expects the accuracy of the automated labels to be at least 95% when compared to the labels that human labelers would provide for those examples.
- For bounding boxes, the expected mean Intersection Over Union (IoU) of the auto-labeled images is 0.6. To find the mean IoU, Ground Truth calculates the mean IoU of all the predicted and missed boxes on the image for every class, and then averages these values across classes.
- For semantic segmentation, the expected mean IoU of the auto-labeled images is 0.7. To find the mean IoU, Ground Truth takes the mean of the IoU values of all the classes in the image (excluding the background).

At every iteration of Active Learning (steps 3-6 in the list above), the confidence threshold is found using the human-annotated validation set so that the expected accuracy of the auto-labeled objects satisfies certain predefined accuracy requirements.

Create an Automated Data Labeling Job (Console)

To create a labeling job that uses automated labeling in the SageMaker console, use the following procedure.

**To create an automated data labeling job (console)**

2. Using Create a Labeling Job (Console) (p. 820) as a guide, complete the Job overview and Task type sections. Note that auto labeling is not supported for custom task types.
4. In the same section, choose **Enable automated data labeling**.
5. Using **Step 4: Configure the Bounding Box Tool (p. 645)** as a guide, create worker instructions in the section **Task Type labeling tool**. For example, if you chose **Semantic segmentation** as your labeling job type, this section is called **Semantic segmentation labeling tool**.
6. To preview your worker instructions and dashboard, choose **Preview**.
7. Choose **Create**. This creates and starts your labeling job and the auto labeling process.

You can see your labeling job appear in the **Labeling jobs** section of the SageMaker console. Your output data appears in the Amazon S3 bucket that you specified when creating the labeling job. For more information about the format and file structure of your labeling job output data, see **Output Data (p. 890)**.

### Create an Automated Data Labeling Job (API)

To create an automated data labeling job using the SageMaker API, use the `LabelingJobAlgorithmsConfig` parameter of the `CreateLabelingJob` operation. To learn how to start a labeling job using the `CreateLabelingJob` operation, see **Create a Labeling Job (API) (p. 823)**.

Specify the Amazon Resource Name (ARN) of the algorithm that you are using for automated data labeling in the `LabelingJobAlgorithmSpecificationArn` parameter. Choose from one of the four Ground Truth built-in algorithms that are supported with automated labeling:

- **Image Classification (Single Label) (p. 659)**
- **Image Semantic Segmentation (p. 652)**
- **Object detection (Bounding Box (p. 646))**
- **Text Classification (Single Label) (p. 670)**

When an automated data labeling job finishes, Ground Truth returns the ARN of the model it used for the automated data labeling job. Use this model as the starting model for similar auto-labeling job types by providing the ARN, in string format, in the `InitialActiveLearningModelArn` parameter. To retrieve the model's ARN, use an AWS Command Line Interface (AWS CLI) command similar to the following.

```bash
# Fetch the mARN of the model trained in the final iteration of the previous labeling job. Ground Truth
pretrained_model_arn = sagemaker_client.describe_labeling_job(LabelingJobName=job_name)['LabelingJobOutput']['FinalActiveLearningModelArn']
```

To encrypt data on the storage volume attached to the ML compute instance(s) that are used in automated labeling, include an AWS Key Management Service (AWS KMS) key in the `VolumeKmsKeyId` parameter. For information about AWS KMS keys, see **What is AWS Key Management Service?** in the **AWS Key Management Service Developer Guide**.

For an example that uses the `CreateLabelingJob` operation to create an automated data labeling job, see the `object_detection_tutorial` example in the **SageMaker Examples, Ground Truth Labeling Jobs** section of a SageMaker notebook instance. To learn how to create and open a notebook instance, see **Create a Notebook Instance (p. 319)**. To learn how to access SageMaker example notebooks, see **Example Notebooks (p. 330)**.

### Amazon EC2 Instances Required for Automated Data Labeling

The following table lists the Amazon Elastic Compute Cloud (Amazon EC2) instances that you need to run automated data labeling for training and batch inference jobs.
Enhanced Data Labeling

**Automated Data Labeling Job Type** | **Training Instance Type** | **Inference Instance Type**
--- | --- | ---
Image classification | ml.p3.2xlarge* | ml.c5.xlarge
Object detection (bounding box) | ml.p3.2xlarge* | ml.c5.4xlarge
Text classification | ml.c5.2xlarge | ml.m4.xlarge
Semantic segmentation | ml.p3.2xlarge* | ml.p3.2xlarge*

* In the Asia Pacific (Mumbai) Region (ap-south-1) use ml.p2.8xlarge instead.

Ground Truth manages the instances that you use for automated data labeling jobs. It creates, configures, and terminates the instances as needed to perform your job. These instances don't appear in your Amazon EC2 instance dashboard.

**Set up an active learning workflow with your own model**

You can create an active learning workflow with your own algorithm to run training and inferences in that workflow to auto-label your data. The notebook `bring_your_own_model_for_sagemaker_labeling_workflows_with_active_learning.ipynb` demonstrates this using the SageMaker built-in algorithm, BlazingText. This notebook provides an AWS CloudFormation stack that you can use to execute this workflow using AWS Step Functions. You can find the notebook and supporting files in this [GitHub repository](#).

You can also find this notebook in the SageMaker Examples repository. See [Use Example Notebooks](#) to learn how to find an Amazon SageMaker example notebook.

**Chaining Labeling Jobs**

Amazon SageMaker Ground Truth can reuse datasets from prior jobs in two ways: cloning and chaining.

**Cloning** copies the setup of a prior labeling job and allows you to make additional changes before setting it to run.

**Chaining** uses not only the setup of the prior job, but also the results. This allows you to continue an incomplete job and add labels or data objects to a completed job. Chaining is a more complex operation.

For data processing:

- Cloning uses the prior job's *input* manifest, with optional modifications, as the new job's input manifest.
- Chaining uses the prior job's *output* manifest as the new job's input manifest.

Chaining is useful when you need to:

- Continue a labeling job that was manually stopped.
- Continue a labeling job that failed mid-job, after fixing issues.
- Switch to automated data labeling after manually labeling part of a job (or the other way around).
- Add more data objects to a completed job and start the job from there.
- Add another annotation to a completed job. For example, you have a collection of phrases labeled for topic, then want to run the set again, categorizing them by the topic's implied audience.
In Amazon SageMaker Ground Truth you can configure a chained labeling job with either the console or the API.

**Key Term: Label Attribute Name**

The *label attribute name* (LabelAttributeName in the API) is a string used as the key for the key-value pair formed with the label that a worker assigns to the data object.

The following rules apply for the label attribute name:

- It can't end with `-metadata`.
- The names `source` and `source-ref` are reserved and can't be used.
- For semantic segmentation labeling jobs, it must end with `-ref`. For all other labeling jobs, it can't end with `-ref`. If you use the console to create the job, Amazon SageMaker Ground Truth automatically appends `-ref` to all label attribute names except for semantic segmentation jobs.
- For a chained labeling job, if you're using the same label attribute name from the originating job and you configure the chained job to use auto-labeling, then if it had been in auto-labeling mode at any point, Ground Truth uses the model from the originating job.

In an output manifest, the label attribute name appears similar to the following.

```json
"source-ref": "<S3 URI>",
"<label attribute name>": {
  "annotations": [
    {
      "class_id": 0,
      "width": 99,
      "top": 87,
      "height": 62,
      "left": 175
    }
  ],
  "image_size": [
    {
      "width": 344,
      "depth": 3,
      "height": 234
    }
  ],
  "<label attribute name>-metadata": {
    "job-name": "<job name>",
    "class-map": {
      "0": "<label attribute name>",
    },
    "human-annotated": "yes",
    "objects": [
      {
        "confidence": 0.09
      }
    ],
    "creation-date": "<timestamp>",
    "type": "groundtruth/object-detection"
  }
}
```

If you're creating a job in the console and don't explicitly set the label attribute name value, Ground Truth uses the job name as the label attribute name for the job.

**Start a Chained Job (Console)**

Choose a stopped, failed, or completed labeling job from the list of your existing jobs. This enables the Actions menu.

From the Actions menu, choose Chain.
Job Overview Panel

In the Job overview panel, a new Job name is set based on the title of the job from which you are chaining this one. You can change it.

You may also specify a label attribute name different from the labeling job name.

If you're chaining from a completed job, the label attribute name uses the name of the new job you're configuring. To change the name, select the check box.

If you're chaining from a stopped or failed job, the label attribute name uses the name of the job from which you're chaining. It's easy to see and edit the value because the name check box is checked.

Attribute label naming considerations

- The default uses the label attribute name Ground Truth has selected. All data objects without data connected to that label attribute name are labeled.
- Using a label attribute name not present in the manifest causes the job to process all the objects in the dataset.

The input dataset location in this case is automatically selected as the output manifest of the chained job. The input field is not available, so you cannot change it.

Adding data objects to a labeling job

You cannot specify an alternate manifest file. Manually edit the output manifest from the previous job to add new items before starting a chained job. The Amazon S3 URI helps you locate where you are storing the manifest in your Amazon S3 bucket. Download the manifest file from there, edit it locally on your computer, and then upload the new version to replace it. Make sure you are not introducing errors during editing. We recommend you use JSON linter to check your JSON. Many popular text editors and IDEs have linter plugins available.

Start a Chained Job (API)

The procedure is almost the same as setting up a new labeling job with CreateLabelingJob, except for two primary differences:

- Manifest location: Rather than use your original manifest from the prior job, the value for the ManifestS3Uri in the DataSource should point to the Amazon S3 URI of the output manifest from the prior labeling job.
- Label attribute name: Setting the correct LabelAttributeName value is important here. This is the key portion of a key-value pair where labeling data is the value. Sample use cases include:
  - Adding new or more specific labels to a completed job — Set a new label attribute name.
  - Labeling the unlabeled items from a prior job — Use the label attribute name from the prior job.

Use a Partially Labeled Dataset

You can get some chaining benefits if you use an augmented manifest that has already been partially labeled. Check the Label attribute name check box and set the name so that it matches the name in your manifest.

If you're using the API, the instructions are the same as those for starting a chained job. However, be sure to upload your manifest to an Amazon S3 bucket and use it instead of using the output manifest from a prior job.

The Label attribute name value in the manifest has to conform to the naming considerations discussed earlier.
Ground Truth Security and Permissions

Use the topics on this page to learn about Ground Truth security features and how to configure AWS Identity and Access Management (IAM) permissions to allow a user or role to create a labeling job. Additionally, learn how to create an execution role. An execution role is the role that you specify when you create a labeling job. This role is used to start your labeling job.

If you are a new user and want to get started quickly, or if you do not require granular permissions, see Use IAM Managed Policies with Ground Truth (p. 931).

For more information about IAM users and roles, see Identities (Users, Groups, and Roles) in the IAM User Guide.

To learn more about using IAM with SageMaker, see Identity and Access Management for Amazon SageMaker (p. 3349).

Topics
- CORS Permission Requirement (p. 930)
- Assign IAM Permissions to Use Ground Truth (p. 931)
- Using Amazon SageMaker Ground Truth in an Amazon Virtual Private Cloud (p. 942)
- Output Data and Storage Volume Encryption (p. 953)
- Workforce Authentication and Restrictions (p. 954)

CORS Permission Requirement

Earlier in 2020, widely used browsers like Chrome and Firefox changed their default behavior for rotating images based on image metadata, referred to as EXIF data. Previously, browsers would always display images in exactly the manner in which they are stored on disk, which is typically unrotated. After the change, images now rotate according to a piece of image metadata called orientation value. This has important implications for the entire machine learning (ML) community. For example, if applications that annotate images do not consider the EXIF orientation, they may display images in unexpected orientations, resulting in incorrect labels.

Starting with Chrome 89, AWS can no longer automatically prevent the rotation of images because the web standards group W3C has decided that the ability to control rotation of images violates the web's Same-origin Policy. Therefore, to ensure human workers annotate your input images in a predictable orientation when you submit requests to create a labeling job, you must add a CORS header policy to the Amazon S3 buckets that contain your input images.

Important
If you do not add a CORS configuration to the Amazon S3 buckets that contain your input data, labeling tasks for those input data objects will fail.

If you create a job through the Ground Truth console, CORS is enabled by default. If all of your input data is not located in the same Amazon S3 bucket as your input manifest file, you must add a CORS configuration to all Amazon S3 buckets that contain input data using the following instructions.

If you are using the CreateLabelingJob API to create a Ground Truth labeling job, you can add a CORS policy to an Amazon S3 bucket that contains input data in the S3 console. To set the required CORS headers on the Amazon S3 bucket that contain your input images in the Amazon S3 console, follow the directions detailed in How do I add cross-domain resource sharing with CORS?. Use the following CORS configuration code for the buckets that host your images. If you use the Amazon S3 console to add the policy to your bucket, you must use the JSON format.

Important
If you create a 3D point cloud or video frame labeling job, you must add additional rules to your CORS configuration. To learn more, see 3D Point Cloud Labeling Job Permission Requirements (p. 747) and Video Frame Job Permission Requirements (p. 693) respectively.

Assign IAM Permissions to Use Ground Truth

Use the topics in this section to learn how to use AWS Identity and Access Management (IAM) managed and custom policies to manage access to Ground Truth and associated resources.

You can use the sections on this page to learn the following:

- How to create IAM policies that grant a user or role permission to create a labeling job. Administrators can use IAM policies to restrict access to Amazon SageMaker and other AWS services that are specific to Ground Truth.
- How to create a SageMaker execution role. An execution role is the role that you specify when you create a labeling job. The role is used to start and manage your labeling job.

The following is an overview of the topics you’ll find on this page:

- If you are getting started using Ground Truth, or you do not require granular permissions for your use case, it is recommended that you use the IAM managed policies described in Use IAM Managed Policies with Ground Truth (p. 931).
- Learn about the permissions required to use the Ground Truth console in Grant IAM Permission to Use the Amazon SageMaker Ground Truth Console (p. 932). This section includes policy examples that grant an IAM entity permission to create and modify private work teams, subscribe to vendor work teams, and create custom labeling workflows.
- When you create a labeling job, you must provide an execution role. Use Create a SageMaker Execution Role for a Ground Truth Labeling Job (p. 936) to learn about the permissions required for this role.

Use IAM Managed Policies with Ground Truth

SageMaker and Ground Truth provide AWS managed policies that you can use to create a labeling job. If you are getting started using Ground Truth and you do not require granular permissions for your use case, it is recommended that you use the following policies:

- AmazonSageMakerFullAccess – Use this policy to give a user or role permission to create a labeling job. This is a broad policy that grants a entity permission to use SageMaker features, as well as features of necessary AWS services through the console and API. This policy gives the entity permission to create a labeling job and to create and manage workforces using Amazon Cognito. To learn more, see AmazonSageMakerFullAccess Policy.

931
• **AmazonSageMakerGroundTruthExecution** – To create an execution role, you can attach the policy AmazonSageMakerGroundTruthExecution to a role. An execution role is the role that you specify when you create a labeling job and it is used to start your labeling job. This policy allows you to create both streaming and non-streaming labeling jobs, and to create a labeling job using any task type. Note the following limits of this managed policy.

• **Amazon S3 permissions**: This policy grants an execution role permission to access Amazon S3 buckets with the following strings in the name: GroundTruth, Groundtruth, groundtruth, SageMaker, Sagemaker, and sagemaker or a bucket with an object tag that includes SageMaker in the name (case insensitive). Make sure your input and output bucket names include these strings, or add additional permissions to your execution role to grant it permission to access your Amazon S3 buckets. You must give this role permission to perform the following actions on your Amazon S3 buckets: AbortMultipartUpload, GetObject, and PutObject.

• **Custom Workflows**: When you create a custom labeling workflow, this execution role is restricted to invoking AWS Lambda functions with one of the following strings as part of the function name: GtRecipe, SageMaker, Sagemaker, sagemaker, or LabelingFunction. This applies to both your pre-annotation and post-annotation Lambda functions. If you choose to use names without those strings, you must explicitly provide lambda:InvokeFunction permission to the execution role used to create the labeling job.

To learn how to attach an AWS managed policy to a user or role, refer to Adding and removing IAM identity permissions in the IAM User Guide.

**Grant IAM Permission to Use the Amazon SageMaker Ground Truth Console**

To use the Ground Truth area of the SageMaker console, you need to grant permission to an entity to access SageMaker and other AWS services that Ground Truth interacts with. Required permissions to access other AWS services depends on your use-case:

• Amazon S3 permissions are required for all use cases. These permissions must grant access to the Amazon S3 buckets that contain input and output data.

• AWS Marketplace permissions are required to use a vendor workforce.

• Amazon Cognito permission are required for private work team setup.

• AWS KMS permissions are required to view available AWS KMS keys that can be used for output data encryption.

• IAM permissions are required to either list pre-existing execution roles, or to create a new one. Additionally, you must use add a PassRole permission to allow SageMaker to use the execution role chosen to start the labeling job.

The following sections list policies you may want to grant to a role to use one or more functions of Ground Truth.

**Topics**

- [Ground Truth Console Permissions](p. 932)
- [Custom Labeling Workflow Permissions](p. 935)
- [Private Workforce Permissions](p. 936)
- [Vendor Workforce Permissions](p. 936)

**Ground Truth Console Permissions**

To grant permission to a user or role to use the Ground Truth area of the SageMaker console to create a labeling job, attach the following policy to the user or role. The following policy will give an IAM role permission to create a labeling job using a built-in task type task type. If you want to create a custom
labeling workflow, add the policy in Custom Labeling Workflow Permissions (p. 935) to the following policy. Each Statement included in the following policy is described below this code block.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "SageMakerApis",
            "Effect": "Allow",
            "Action": ["sagemaker:*"],
            "Resource": "*"
        },
        {
            "Sid": "KmsKeysForCreateForms",
            "Effect": "Allow",
            "Action": ["kms:DescribeKey", "kms:ListAliases"],
            "Resource": "*"
        },
        {
            "Sid": "AccessAwsMarketplaceSubscriptions",
            "Effect": "Allow",
            "Action": ["aws-marketplace:ViewSubscriptions"],
            "Resource": "*"
        },
        {
            "Sid": "SecretsManager",
            "Effect": "Allow",
            "Action": ["secretsmanager:CreateSecret", "secretsmanager:DescribeSecret", "secretsmanager:ListSecrets"],
            "Resource": "*"
        },
        {
            "Sid": "ListAndCreateExecutionRoles",
            "Effect": "Allow",
            "Action": ["iam:ListRoles", "iam:CreateRole", "iam:CreatePolicy", "iam:AttachRolePolicy"],
            "Resource": "*"
        },
        {
            "Sid": "PassRoleForExecutionRoles",
            "Effect": "Allow",
            "Action": ["iam:PassRole"],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "iam:PassedToService": "sagemaker.amazonaws.com"
                }
            }
        }
    ]
}
```
This policy includes the following statements. You can scope down any of these statements by adding specific resources to the Resource list for that statement.

**SageMakerApis**

This statement includes `sagemaker:*`, which allows the user to perform all SageMaker API actions. You can reduce the scope of this policy by restricting users from performing actions that are not used to create and monitoring a labeling job.

**KmsKeysForCreateForms**

You only need to include this statement if you want to grant a user permission to list and select AWS KMS keys in the Ground Truth console to use for output data encryption. The policy above grants a user permission to list and select any key in the account in AWS KMS. To restrict the keys that a user can list and select, specify those key ARNs in Resource.

**SecretsManager**

This statement gives the user permission to describe, list, and create resources in AWS Secrets Manager required to create the labeling job.

**ListAndCreateExecutionRoles**

This statement gives a user permission to list (ListRoles) and create (CreateRole) IAM roles in your account. It also grants the user permission to create (CreatePolicy) policies and attach
(AttachRolePolicy) policies to entities. These are required to list, select, and if required, create an execution role in the console.

If you have already created an execution role, and want to narrow the scope of this statement so that users can only select that role in the console, specify the ARNs of the roles you want the user to have permission to view in Resource and remove the actions CreateRole, CreatePolicy, and AttachRolePolicy.

AccessAwsMarketplaceSubscriptions

These permissions are required to view and choose vendor work teams that you are already subscribed to when creating a labeling job. To give the user permission to subscribe to vendor work teams, add the statement in Vendor Workforce Permissions (p. 936) to the policy above.

PassRoleForExecutionRoles

This is required to give the labeling job creator permission to preview the worker UI and verify that input data, labels, and instructions display correctly. This statement gives an entity permissions to pass the IAM execution role used to create the labeling job to SageMaker to render and preview the worker UI. To narrow the scope of this policy, add the role ARN of the execution role used to create the labeling job under Resource.

GroundTruthConsole

- `groundtruthlabeling` – This allows a user to perform actions required to use certain features of the Ground Truth console. These include permissions to describe the labeling job status (DescribeConsoleJob), list all dataset objects in the input manifest file (ListDatasetObjects), filter the dataset if dataset sampling is selected (RunFilterOrSampleDatasetJob), and to generate input manifest files if automated data labeling is used (RunGenerateManifestByCrawlingJob). These actions are only available when using the Ground Truth console and cannot be called directly using an API.
- `lambda:InvokeFunction` and `lambda:ListFunctions` – these actions give users permission to list and invoke Lambda functions that are used to run a custom labeling workflow.
- `s3:*` – All Amazon S3 permissions included in this statement are used to view Amazon S3 buckets for automated data setup (ListAllMyBuckets), access input data in Amazon S3 (ListBucket, GetObject), check for and create a CORS policy in Amazon S3 if needed (GetBucketCors and PutBucketCors), and write labeling job output files to S3 (PutObject).
- `cognito-idp` – These permissions are used to create, view and manage a private workforce using Amazon Cognito. To learn more about these actions, refer to the Amazon Cognito API References.

Custom Labeling Workflow Permissions

Add the following statement to a policy similar to the one in Ground Truth Console Permissions (p. 932) to give a user permission to select pre-existing pre-annotation and post-annotation Lambda functions while creating a custom labeling workflow.

```json
{
    "Sid": "GroundTruthConsoleCustomWorkflow",
    "Effect": "Allow",
    "Action": [
        "lambda:InvokeFunction",
        "lambda:ListFunctions"
    ],
    "Resource": "*"
}
```

To learn how to give an entity permission to create and test pre-annotation and post-annotation Lambda functions, see Required Permissions To Use Lambda With Ground Truth.
Private Workforce Permissions

When added to a permissions policy, the following permission grants access to create and manage a private workforce and work team using Amazon Cognito. These permissions are not required to use an OIDC IdP workforce.

```json
{
  "Effect": "Allow",
  "Action": [
    "cognito-idp:AdminAddUserToGroup",
    "cognito-idp:AdminCreateUser",
    "cognito-idp:AdminDeleteUser",
    "cognito-idp:AdminDisableUser",
    "cognito-idp:AdminEnableUser",
    "cognito-idp:AdminRemoveUserFromGroup",
    "cognito-idp:CreateGroup",
    "cognito-idp:CreateUserPool",
    "cognito-idp:CreateUserPoolClient",
    "cognito-idp:CreateUserPoolDomain",
    "cognito-idp:DescribeUserPool",
    "cognito-idp:DescribeUserPoolClient",
    "cognito-idp:DescribeUserPoolDomain",
    "cognito-idp:ListGroups",
    "cognito-idp:ListIdentityProviders",
    "cognito-idp:ListUserPoolClients",
    "cognito-idp:ListUserPools",
    "cognito-idp:ListUserPoolClients",
    "cognito-idp:ListUsers",
    "cognito-idp:ListUsersInGroup",
    "cognito-idp:ListUserPoolClients",
    "cognito-idp:ListUserPools",
    "cognito-idp:UpdateUserPool",
    "cognito-idp:UpdateUserPoolClient"
  ],
  "Resource": "*"
}
```

To learn more about creating private workforce using Amazon Cognito, see [Create and Manage Amazon Cognito Workforce](p. 982).

Vendor Workforce Permissions

You can add the following statement to the policy in [Grant IAM Permission to Use the Amazon SageMaker Ground Truth Console](p. 932) to grant an entity permission to subscribe to a vendor workforce.

```json
{
  "Sid": "AccessAwsMarketplaceSubscriptions",
  "Effect": "Allow",
  "Action": [
    "aws-marketplace:Subscribe",
    "aws-marketplace:Unsubscribe",
    "aws-marketplace:ViewSubscriptions"
  ],
  "Resource": "*"
}
```

Create a SageMaker Execution Role for a Ground Truth Labeling Job

When you configure your labeling job, you need to provide an execution role, which is a role that SageMaker has permission to assume to start and run your labeling job.

This role must give Ground Truth permission to access the following:

- Amazon S3 to retrieve your input data and write output data to an Amazon S3 bucket. You can either grant permission for an IAM role to access an entire bucket by providing the bucket ARN, or you can
grant access to the role to access specific resources in a bucket. For example, the ARN for a bucket may look similar to arn:aws:s3:::awsexamplebucket1 and the ARN of a resource in an Amazon S3 bucket may look similar to arn:aws:s3:::awsexamplebucket1/prefix/file-name.png. To apply an action to all resources in an Amazon S3 bucket, you can use the wild card: *. For example, arn:aws:s3:::awsexamplebucket1/prefix/*. For more information, see Amazon Amazon S3 Resources in the Amazon Simple Storage Service User Guide.

- CloudWatch to log worker metrics and labeling job statuses.
- AWS KMS for data encryption. (Optional)
- AWS Lambda for processing input and output data when you create a custom workflow.

Additionally, if you create a streaming labeling job, this role must have permission to access:

- Amazon SQS to create an interact with an SQS queue used to manage labeling requests.
- Amazon SNS to subscribe to and retrieve messages from your Amazon SNS input topic and to send messages to your Amazon SNS output topic.

All of these permissions can be granted with the AmazonSageMakerGroundTruthExecution managed policy except:

- Data and storage volume encryption of your Amazon S3 buckets. To learn how to configure these permissions, see Encrypt Output Data and Storage Volume with AWS KMS (p. 941).
- Permission to select and invoke Lambda functions that do not include GtRecipe, SageMaker, Sagemaker, or LabelingFunction in the function name.
- Amazon S3 buckets that do not include either GroundTruth, Groundtruth, groundtruth, SageMaker, Sagemaker, and sagemaker in the prefix or bucket name or an object tag that includes SageMaker in the name (case insensitive).

If you require more granular permissions than the ones provided in AmazonSageMakerGroundTruthExecution, use the following policy examples to create an execution role that fits your specific use case.

Topics
- Built-In Task Types (Non-streaming) Execution Role Requirements (p. 937)
- Built-In Task Types (Streaming) Execution Role Requirements (p. 938)
- Execution Role Requirements for Custom Task Types (p. 940)
- Automated Data Labeling Permission Requirements (p. 940)

Built-In Task Types (Non-streaming) Execution Role Requirements

The following policy grants permission to create a labeling job for a built-in task type. This execution policy does not include permissions for AWS KMS data encryption or decryption. Replace each red, italicized ARN with your own Amazon S3 ARNs.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "S3ViewBuckets",
            "Effect": "Allow",
            "Action": [
                "s3:ListBucket",
                "s3:GetBucketLocation"
            ]
        }
    ]
}
```
Built-In Task Types (Streaming) Execution Role Requirements

If you create a streaming labeling job, you must add a policy similar to the following to the execution role you use to create the labeling job. To narrow the scope of the policy, replace the * in Resource with specific AWS resources that you want to grant the IAM role permission to access and use.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:AbortMultipartUpload",
        "s3:GetObject",
        "s3:PutObject"
      ],
      "Resource": [
        "arn:aws:s3:::<input-bucket-name>/*",
        "arn:aws:s3:::<output-bucket-name>/*"
      ]
    },
    {
      "Effect": "Allow",
      "Action": ["s3:GetObject"],
      "Resource": ["*", "arn:aws:s3:::<input-bucket-name>/*", "arn:aws:s3:::<output-bucket-name>/*"]
    }
  ]
}
```
"Effect": "Allow",
"Action": [
  "s3:GetBucketLocation",
  "s3:ListBucket"
],
"Resource": [
  "arn:aws:s3:::<input-bucket-name>",
  "arn:aws:s3:::<output-bucket-name>"
],
"Sid": "CloudWatch",
"Effect": "Allow",
"Action": [
  "cloudwatch:PutMetricData",
  "logs:CreateLogStream",
  "logs:CreateLogGroup",
  "logs:DescribeLogStreams",
  "logs:PutLogEvents"
],
"Resource": "*"
],
"Sid": "StreamingQueue",
"Effect": "Allow",
"Action": [
  "sqs:CreateQueue",
  "sqs:DeleteMessage",
  "sqs:GetQueueAttributes",
  "sqs:GetQueueUrl",
  "sqs:ReceiveMessage",
  "sqs:SendMessage",
  "sqs:SendMessageBatch",
  "sqs:SetQueueAttributes"
],
"Resource": "arn:aws:sqs:*:*:*GroundTruth*"
],
"Sid": "StreamingTopicSubscribe",
"Effect": "Allow",
"Action": "sns:Subscribe",
"Resource": [
  "arn:aws:sns:<aws-region>:<aws-account-number>:<output-topic-name>"
],
"Condition": {
  "StringEquals": {
    "sns:Protocol": "sqs"
  },
  "StringLike": {
  }
}
],
"Sid": "StreamingTopic",
"Effect": "Allow",
"Action": ["sns:Publish"],
"Resource": ["arn:aws:sns:*:*:*GroundTruth*"
Execution Role Requirements for Custom Task Types

If you want to create a custom labeling workflow, add the following statement to an execution role policy like the ones found in Built-In Task Types (Non-streaming) Execution Role Requirements (p. 937) or Built-In Task Types (Streaming) Execution Role Requirements (p. 938).

This policy gives the execution role permission to Invoke your pre-annotation and post-annotation Lambda functions.

```json
{
   "Sid": "LambdaFunctions",
   "Effect": "Allow",
   "Action": [
      "lambda:InvokeFunction"
   ],
   "Resource": [
      "arn:aws:lambda:<region>:<account-id>:function:<post-annotation-lambda-name>"
   ]
}
```

Automated Data Labeling Permission Requirements

If you want to create a labeling job with automated data labeling enabled, you must 1) add one policy to the IAM policy attached to the execution role and 2) update the trust policy of the execution role.

The following statement allows the IAM execution role to be passed to SageMaker so that it can be used to run the training and inference jobs used for active learning and automated data labeling respectively. Add this statement to an execution role policy like the ones found in Built-In Task Types (Non-streaming) Execution Role Requirements (p. 937) or Built-In Task Types (Streaming) Execution Role Requirements (p. 938). Replace `arn:aws:iam::<account-number>:role/<role-name>` with the execution role ARN. You can find your IAM role ARN in the IAM console under Roles.

```json
{
   "Effect": "Allow",
   "Action": [
      "iam:PassRole"
   ],
   "Resource": "arn:aws:iam::<account-number>:role/<execution-role-name>",
   "Condition": {
      "StringEquals": {
         "iam:PassedToService": [
            "sagemaker.amazonaws.com"
         ]
      }
   }
}
```
The following statement allows SageMaker to assume the execution role to create and manage the SageMaker training and inference jobs. This policy must be added to the trust relationship of the execution role. To learn how to add or modify an IAM role trust policy, see Modifying a role in the IAM User Guide.

```
{
    "Version": "2012-10-17",
    "Statement": {
        "Effect": "Allow",
        "Principal": {"Service": "sagemaker.amazonaws.com"},
        "Action": "sts:AssumeRole"
    }
}
```

Encrypt Output Data and Storage Volume with AWS KMS

You can use AWS Key Management Service (AWS KMS) to encrypt output data from a labeling job by specifying a customer managed key when you create the labeling job. If you use the API operation CreateLabelingJob to create a labeling job that uses automated data labeling, you can also use a customer managed key to encrypt the storage volume attached to the ML compute instances to run the training and inference jobs.

This section describes the IAM policies you must attach to your customer managed key to enable output data encryption and the policies you must attach to your customer managed key and execution role to use storage volume encryption. To learn more about these options, see Output Data and Storage Volume Encryption (p. 953).

Encrypt Output Data using KMS

If you specify an AWS KMS customer managed key to encrypt output data, you must add an IAM policy similar to the following to that key. This policy gives the IAM execution role that you use to create your labeling job permission to use this key to perform all of the actions listed in "Action". To learn more about these actions, see AWS KMS permissions in the AWS Key Management Service Developer Guide.

To use this policy, replace the IAM service-role ARN in "Principal" with the ARN of the execution role you use to create the labeling job. When you create a labeling job in the console, this is the role you specify for IAM Role under the Job overview section. When you create a labeling job using CreateLabelingJob, this is ARN you specify for RoleArn.

```
{
    "Sid": "AllowUseOfKmsKey",
    "Effect": "Allow",
    "Principal": {
        "AWS": "arn:aws:iam::111122223333:role/service-role/example-role"
    },
    "Action": [
        "kms:Encrypt",
        "kms:Decrypt",
        "kms:ReEncrypt**",
        "kms:GenerateDataKey**",
        "kms:DescribeKey"
    ],
    "Resource": "*"
}
```
Encrypt Automated Data Labeling ML Compute Instance Storage Volume

If you specify a `VolumeKmsKeyId` to encrypt the storage volume attached to the ML compute instance used for automated data labeling training and inference, you must do the following:

- Attach permissions described in *Encrypt Output Data using KMS (p. 941)* to the customer managed key.
- Attach a policy similar to the following to the IAM execution role you use to create your labeling job. This is the IAM role you specify for `RoleArn` in `CreateLabelingJob`. To learn more about the "kms:CreateGrant" action that this policy permits, see `CreateGrant` in the AWS Key Management Service API Reference.

```json
{
 "Version": "2012-10-17",
 "Statement": [
 {  
 "Effect": "Allow",
 "Action": [
 "kms:CreateGrant"
 ],
 "Resource": "*"
 }
 ]
}
```

To learn more about Ground Truth storage volume encryption, see *Use Your KMS Key to Encrypt Automated Data Labeling Storage Volume (API Only) (p. 954)*.

Using Amazon SageMaker Ground Truth in an Amazon Virtual Private Cloud

*Amazon Virtual Private Cloud* (Amazon VPC) is a service with which you can launch AWS resources in a logically isolated virtual network that you define. You can create and run a Ground Truth labeling job inside of an Amazon VPC instead of connecting over the internet. When you launch a labeling job in an Amazon VPC, communication between your VPC and Ground Truth is conducted entirely and securely within the AWS network.

A Ground Truth labeling job in Amazon VPC follows the same behavior as PrivateLink Endpoints. For more information, see *Shared subnets*.

This guide shows how you can use Ground Truth in an Amazon VPC in the following ways:

1. Run an Amazon SageMaker Ground Truth Labeling Job in an Amazon Virtual Private Cloud (p. 942)
2. Use Amazon VPC Mode from a Private Worker Portal (p. 949)

Run an Amazon SageMaker Ground Truth Labeling Job in an Amazon Virtual Private Cloud

Amazon SageMaker Ground Truth supports the following functionalities.

- You can use Amazon S3 bucket policies to control access to buckets from specific Amazon VPC endpoints, or specific VPCs. If you launch a labeling job and your input data is located in an Amazon S3 bucket with access restricted to users in your VPC, you can add a bucket policy to also grant a Ground
Truth endpoint permission to access the bucket. To learn more, see Allow Ground Truth to Access VPC Restricted Amazon S3 Buckets (p. 943).

- You can launch an automated data labeling job in your VPC. You use a VPC configuration to specify VPC subnets and security groups. SageMaker uses this configuration to launch the training and inference jobs used for automated data labeling in your VPC. To learn more, see Create an Automated Data Labeling Job in a VPC (p. 947).

You may want to use these options in any of the following ways.

- You can use both of these methods to launch a labeling job using a VPC-protected Amazon S3 bucket with automated data labeling enabled.
- You can launch a labeling job using any built-in task type using a VPC-protected bucket.
- You can launch a custom labeling workflow using a VPC-protected bucket. Ground Truth interacts with your pre-annotation and post-annotation Lambda functions using an AWS PrivateLink endpoint.

We recommend that you review Prerequisites to Run a Ground Truth Labeling Job in a VPC (p. 943) before you create a labeling job in an Amazon VPC.

Prerequisites to Run a Ground Truth Labeling Job in a VPC

Review the following prerequisites before you create a Ground Truth labeling job in an Amazon VPC.

- If you are a new user of Ground Truth, review Getting started to learn how to create a labeling job.
- If your input data is located in a VPC-protected Amazon S3 bucket, your workers must access the worker portal from your VPC.

  **Note**
  When you launch a labeling job in your VPC, you must use a private work team. To learn more about creating a private work team, see Use a Private Workforce.

- If you want to launch an automated data labeling job in your VPC, review the following prerequisites.
  - Use the instructions in Create an Amazon S3 VPC Endpoint. Training and inference containers used in the automated data labeling workflow use this endpoint to communicate with your buckets in Amazon S3.
  - Review Automate Data Labeling to learn more about this feature. Note that automated data labeling is supported for the following built-in task types: Image Classification (Single Label), Image Semantic Segmentation, Bounding Box, and Text Classification (Single Label). Streaming labeling jobs do not support automated data labeling.

- Review the Ground Truth Security and Permissions section and ensure that you have met the following conditions.
  - The user creating the labeling job has all necessary permissions
  - You have created an IAM execution role with required permissions. If you do not require fine-tuned permissions for your use case, we recommend you use the IAM managed policies described in Grant General Permissions To Get Started Using Ground Truth.
  - Allow your VPC to have access to the sagemaker-labeling-data-region and sm-bxcb-region-saved-task-states S3 buckets. These are system owned regionalized S3 buckets that are accessed from worker portal when worker is working on a task. We use these buckets to interact with system managed data.

Allow Ground Truth to Access VPC Restricted Amazon S3 Buckets

The following sections provide details about the permissions Ground Truth requires to launch labeling jobs using Amazon S3 buckets that have access restricted to your VPC and VPC endpoints. To learn how
to restrict access to an Amazon S3 bucket to a VPC, see Controlling access from VPC endpoints with bucket policies in the Amazon Simple Storage Service User Guide guide. To learn how to add a policy to an S3 bucket, see Adding a bucket policy using the Amazon S3 console.

**Note**
Modifying policies on existing buckets can cause IN_PROGRESS Ground Truth jobs to fail. We recommend you start new jobs using a new bucket. If you want to continue using the same bucket, you can do one of the following.

- Wait for an IN_PROGRESS job to finish.
- Terminate the job using the console or the AWS CLI.

You can restrict Amazon S3 bucket access to users in your VPC using an AWS PrivateLink endpoint. For example, the following S3 bucket policy allows access to a specific bucket, `<bucket-name>`, from `<vpc>` and the endpoint `<vpc-endpoint>` only. When you modify this policy, you must replace all red-italicized text with your resources and specifications.

**Note**
The following policy *denies* all entities *other than* users within a VPC to perform the actions listed in **Action**. If you do not include actions in this list, they are still accessible to any entity that has access to this bucket and permission to perform those actions. For example, if a user has permission to perform GetBucketLocation on your Amazon S3 bucket, the policy below does not restrict the user from performing this action outside of your VPC.

```json
{
  "Version": "2012-10-17",
  "Id": "Policy1415115909152",
  "Statement": [
    {
      "Sid": "Access-to-specific-VPCE-only",
      "Principal": "*",
      "Action": [
        "s3:GetObject",
        "s3:PutObject"
      ],
      "Effect": "Deny",
      "Resource": [
        "arn:aws:s3:::<bucket-name>",
        "arn:aws:s3:::<bucket-name>/*"
      ],
      "Condition": {
        "StringNotEquals": {
          "aws:sourceVpce": [
            "<vpc-endpoint>",
            "<vpc>"
          ]
        }
      }
    }
  ]
}
```

Ground Truth must be able to perform the following Amazon S3 actions on the S3 buckets you use to configure the labeling job.

```
"s3:AbortMultipartUpload",
"s3:GetObject",
"s3:PutObject",
"s3:ListBucket",
"s3:GetBucketLocation"
```
You can do this by adding a Ground Truth endpoint to the bucket policy like the one previously mentioned. The following table includes Ground Truth service endpoints for each AWS Region. Add an endpoint in the same AWS Region you use to run your labeling job to your bucket policy.

<table>
<thead>
<tr>
<th>AWS Region</th>
<th>Ground Truth endpoint</th>
</tr>
</thead>
<tbody>
<tr>
<td>us-east-2</td>
<td>vpce-02569ba1c40aad0bc</td>
</tr>
<tr>
<td>us-east-1</td>
<td>vpce-08408e335ebf95b40</td>
</tr>
<tr>
<td>us-west-2</td>
<td>vpce-0ea07aa498eb78469</td>
</tr>
<tr>
<td>ca-central-1</td>
<td>vpce-0d46ea4c9ff55e1b7</td>
</tr>
<tr>
<td>eu-central-1</td>
<td>vpce-0865e7194a099183d</td>
</tr>
<tr>
<td>eu-west-2</td>
<td>vpce-0bccd56798f4c5df0</td>
</tr>
<tr>
<td>eu-west-1</td>
<td>vpce-0788e7ed8628e595d</td>
</tr>
<tr>
<td>ap-south-1</td>
<td>vpce-0d7fda14e1783f11</td>
</tr>
<tr>
<td>ap-southeast-2</td>
<td>vpce-0b7609e6f305a77d4</td>
</tr>
<tr>
<td>ap-southeast-1</td>
<td>vpce-0e7e67b32e9efed27</td>
</tr>
<tr>
<td>ap-northeast-2</td>
<td>vpce-007893f89e05f2bbf</td>
</tr>
<tr>
<td>ap-northeast-1</td>
<td>vpce-0247996a1a1807dbd</td>
</tr>
</tbody>
</table>

For example, the following policy restricts GetObject and PutObject actions on:

- An Amazon S3 bucket to users in a VPC (<vpc>)
- A VPC endpoint (<vpc-endpoint>)
- A Ground Truth service endpoint (<ground-truth-endpoint>)

```json
{
  "Version": "2012-10-17",
  "Id": "1",
  "Statement": [
    {
      "Sid": "DenyAccessFromNonGTandCustomerVPC",
      "Effect": "Deny",
      "Principal": "*",
      "Action": ["s3:GetObject", "s3:PutObject"],
      "Resource": ["arn:aws:s3:::<bucket-name>", "arn:aws:s3:::<bucket-name>/*"],
      "Condition": {
        "ForAllValues:StringNotEquals": {
          "aws:sourceVpce": ["<vpc-endpoint>", "<ground-truth-endpoint>"],
          "aws:sourceVpc": "<vpc>"
        }
      }
    }
  ]
}
```
If you want a user to have permission to launch a labeling job using the Ground Truth console, you must also add the user's ARN to the bucket policy using the `aws:PrincipalArn` condition. This user must also have permission to perform the following Amazon S3 actions on the bucket you use to launch the labeling job.

"s3:GetObject",
"s3:PutObject",
"s3:ListBucket",
"s3:GetBucketCors",
"s3:PutBucketCors",
"s3:ListAllMyBuckets",

The following code is an example of a bucket policy that restricts permission to perform the actions listed in `Action` on the S3 bucket `<bucket-name>` to the following.

- `<role-name>`
- The VPC endpoints listed in `aws:sourceVpce`
- Users within the VPC named `<vpc>`

```json
{
    "Version": "2012-10-17",
    "Id": "1",
    "Statement": [
        {
            "Sid": "DenyAccessFromNonGTandCustomerVPC",
            "Effect": "Deny",
            "Principal": "*",
            "Action": [
                "s3:GetObject",
                "s3:PutObject"
            ],
            "Resource": [
                "arn:aws:s3:::<bucket-name>/*",
                "arn:aws:s3::<bucket-name>"
            ],
            "Condition": {
                "ForAllValues:StringNotEquals": {
                    "aws:sourceVpce": [
                        "<vpc-endpoint>",
                        "<ground-truth-endpoint>"
                    ],
                    "aws:PrincipalArn": "arn:aws:iam::<aws-account-id>:role/<role-name>",
                    "aws:SourceVpc": "<vpc>"
                }
            }
        }
    ]
}
```

**Note**

The Amazon VPC interface endpoints and the protected Amazon S3 buckets you use for input and output data must be located in the same AWS Region that you use to create the labeling job.
After you have granted Ground Truth permission to access your Amazon S3 buckets, you can use one of the topics in Create a Labeling Job to launch a labeling job. Specify the VPC-restricted Amazon S3 buckets for your input and output data buckets.

Create an Automated Data Labeling Job in a VPC

To create an automated data labeling job using an Amazon VPC, you provide a VPC configuration using the Ground Truth console or CreateLabelingJob API operation. SageMaker uses the subnets and security groups you provide to launch the training and inferences jobs used for automated labeling.

**Important**
Before you launch an automated data labeling job with a VPC configuration, make sure you have created an Amazon S3 VPC endpoint using the VPC you want to use for the labeling job. To learn how, see Create an Amazon S3 VPC Endpoint. Additionally, if you create an automated data labeling job using a VPC-restricted Amazon S3 bucket, you must follow the instructions in Allow Ground Truth to Access VPC Restricted Amazon S3 Buckets (p. 943) to give Ground Truth permission to access the bucket.

Use the following procedures to learn how to add a VPC configuration to your labeling job request.

**Add a VPC configuration to an automated data labeling job (console):**

1. Follow the instructions in Create a Labeling Job (Console) and complete each step in the procedure, up to step 15.
2. In the Workers section, select the checkbox next to Enable automated data labeling.
3. Maximize the VPC configuration section of the console by selecting the arrow.
4. Specify the Virtual private cloud (VPC) that you want to use for your automated data labeling job.
5. Choose the dropdown list under Subnets and select one or more subnets.
6. Choose the dropdown list under Security groups and select one or more groups.
7. Complete all remaining steps of the procedure in Create a Labeling Job (Console).

**Add a VPC configuration to an automated data labeling job (API):**

To configure a labeling job using the Ground Truth API operation, CreateLabelingJob, follow the instructions in Create an Automated Data Labeling Job (API) to configure your request. In addition to the parameters described in this documentation, you must include a VpcConfig parameter in LabelingJobResourceConfig to specify one or more subnets and security groups using the following schema.

```
"LabelingJobAlgorithmsConfig": {
  "InitialActiveLearningModelArn": "string",
  "LabelingJobAlgorithmSpecificationArn": "string",
  "LabelingJobResourceConfig": {
    "VolumeKmsKeyId": "string",
    "VpcConfig": {
      "SecurityGroupIds": [ "string" ],
      "Subnets": [ "string" ]
    }
  }
}
```

The following is an example of an AWS Python SDK (Boto3) request to create an automated data labeling job in the US East (N. Virginia) Region using a private workforce. Replace all red-italicized text with your labeling job resources and specifications. To learn more about the CreateLabelingJob operation, see the Create a Labeling Job (API) tutorial and CreateLabelingJob API documentation.

```python
import boto3
client = boto3.client(service_name='sagemaker')
```
response = client.create_labeling_job(
    LabelingJobName="example-labeling-job",
    LabelAttributeName="label",
    InputConfig={
        'DataSource': {
            'S3DataSource': {
                'ManifestS3Uri': "s3://bucket/path/manifest-with-input-data.json"
            }
        }
    },
    "LabelingJobAlgorithmsConfig": {
        "LabelingJobResourceConfig": {
            "VpcConfig": {
                "SecurityGroupIds": [ "sg-0123456789", "sg-987654321" ],
                "Subnets": [ "subnet-e0123456", "subnet-e7891011" ]
            }
        }
    },
    OutputConfig={
        'S3OutputPath': "s3://bucket/path/file-to-store-output-data",
        'KmsKeyId': "string"
    },
    RoleArn="arn:aws:iam::*:role/*",
    LabelCategoryConfigS3Uri="s3://bucket/path/label-categories.json",
    StoppingConditions={
        'MaxHumanLabeledObjectCount': 123,
        'MaxPercentageOfInputDatasetLabeled': 123
    },
    HumanTaskConfig={
        'WorkteamArn': "arn:aws:sagemaker:region::*:workteam/private-crowd/**",
        'UiConfig': {
            'UiTemplateS3Uri': "s3://bucket/path/custom-worker-task-template.html"
        },
        'TaskKeywords': [ "Images", "Classification", "Multi-label" ],
        'TaskTitle': "Add task title here",
        'TaskDescription': "Add description of task here for workers",
        'NumberOfHumanWorkersPerDataObject': 1,
        'TaskTimeLimitInSeconds': 3600,
        'TaskAvailabilityLifetimeInSeconds': 21600,
        'MaxConcurrentTaskCount': 1000,
        'AnnotationConsolidationConfig': {
        },
        Tags=[
            { 'Key': "string", 'Value': "string" }
        ]
    )
Use Amazon VPC Mode from a Private Worker Portal

To restrict worker portal access to labelers working inside of your Amazon VPC, you can add a VPC configuration when you create a Ground Truth private workforce. You can also add a VPC configuration to an existing private workforce. Ground Truth automatically creates VPC interface endpoints in your VPC and sets up AWS PrivateLink between your VPC endpoint and the Ground Truth services. The worker portal URL associated with the workforce can be accessed from your VPC. The worker portal URL can also be accessed from public internet until you set the restriction on the public internet. When you delete the workforce or remove the VPC configuration from your workforce, Ground Truth automatically deletes the VPC endpoints associated with the workforce.

Note
There can be only one VPC supported for a workforce.

Point Cloud and video tasks do not support loading through a VPC.

The guide demonstrates how to complete the necessary steps to add and delete an Amazon VPC configuration to your workforce, and satisfy the prerequisites.

Prerequisites

To run a Ground Truth labeling job in Amazon VPC, review the following prerequisites.

- You have an Amazon VPC configured that you can use. If you have not configured a VPC, follow these instructions for creating a VPC.
- Depending on how a Worker Task Template is written, labeling data stored in an Amazon S3 bucket may be accessed directly from Amazon S3 during labeling tasks. In these cases, the VPC network must be configured to allow traffic from the device used by the human labeler to the S3 bucket containing labeling data.
- Follow View and update DNS attributes for your VPC to enable DNS hostnames and DNS resolution for your VPC.

Note
There are two ways to configure your VPC for your workforce. You can do this through the console or the AWS SageMaker CLI.

Using the SageMaker console to manage a VPC config

You can use the SageMaker console to add or remove a VPC configuration. You can also delete an existing workforce.

Adding a VPC configuration to your workforce

Create a private workforce

- Create a private workforce using Amazon Cognito
- Create a private workforce using OpenID Connect (OIDC) Identity Provider(IdP).

After you have created your private workforce, add a VPC configuration to it.

1. Navigate to Amazon SageMaker Runtime in your console.
2. Select Labeling workforces in the left panel.
3. Select Private to access your private workforce. After your Workforce status is Active, select Add next to VPC.
4. When you are prompted to configure your VPC, provide the following:
   a. Your VPC
b. Subnets
   i. Ensure that your VPC has an existing subnet

c. Security groups
   i. **Note**
      You cannot select more than 5 security groups.
   d. After filling in this information, choose **Confirm**.

5. After you choose **Confirm**, you are redirected back to the **Private** page under **Labeling workforces**. You should see a green banner at the top that reads *Your private workforce update with VPC configuration was successfully initialized*. The workforce status is **Updating**. Next to the **Delete workforce** button is the **Refresh** button, which can be used to retrieve the latest **Workforce status**. After the workforce status has changed to **Active**, the VPC endpoint ID is updated as well.

### Removing a VPC configuration from your workforce

Use the following information to remove a VPC configuration from your workforce using the console.

1. Navigate to **Amazon SageMaker Runtime** in your console.
2. Select **Labeling workforces** in the left panel.
3. Find and select your workforce.
4. Under **Private workforce summary**, find **VPC** and choose **Remove** next to it.
5. Select **Remove**.

### Deleting a workforce through the console

If you delete a workforce, you should not have any teams associated with it. You can delete a workforce only if the workforce status is **Active** or **Failed**.

Use the following information to delete a workforce using the console.

1. Navigate to **Amazon SageMaker Runtime** in your console.
2. Select **Labeling workforces** in the left panel.
3. Find and select your workforce.
4. Choose **Delete workforce**.
5. Choose **Delete**.

### Using the SageMaker AWS API to manage a VPC config

Download the following files to use a new VpcConfig parameter into the SageMaker workforce CLI:

- sagemaker-2017-07-24.normal.json
- sagemaker-2017-07-24.paginators.json
- sagemaker-2017-07-24.waiters-2.json

After downloading the files, run the following commands in your CLI:

```bash
aws configure add-model --service-model file://./sagemaker-2017-07-24.normal.json --service-name sagemaker

```
You can now test your API changes using AWS CLI. You can either create a new workforce with a VPC configuration or update an existing workforce to add a VPC configuration. You can also remove a VPC configuration from an existing workforce.

**Create a workforce with a VPC configuration**

If the account already has a workforce, then you must delete it first. You can also update the workforce with VPC configuration.

```bash
aws sagemaker create-workforce --cognito-config '{"ClientId": "app-client-id", "UserPool": "Pool_ID"}' --workforce-vpc-config "{"VpcId": "vpc-id", "SecurityGroupIds": ["sg-0123456789abcdef0"], "Subnets": ["subnet-0123456789abcdef0"]}" --workforce-name workforce-name
```

Describe the workforce and make sure the status is Initializing.

```bash
aws sagemaker describe-workforce --workforce-name workforce-name
```

Navigate to the Amazon VPC console. Select **Endpoints** from the left panel. There should be two VPC endpoints created in your account.

**Adding a VPC configuration your workforce**

Update a non-VPC private workforce with a VPC configuration using the following command.
aws sagemaker update-workforce --workforce-name workforce-name
--workforce-vpc-config "{"VpcId": "vpc-id", "SecurityGroupIds": ["sg-0123456789abcdef0"], "Subnets": ["subnet-0123456789abcdef0"]}"

Describe the workforce and make sure the status is Updating.

aws sagemaker describe-workforce --workforce-name workforce-name
{
  "Workforce": {
    "WorkforceName": "workforce-name",
    "LastUpdatedDate": 1622151252.451,
    "SourceIpConfig": {
      "Cidrs": []
    },
    "SubDomain": "subdomain.us-west-2.sagamaker.aws.com",
    "CognitoConfig": {
      "UserPool": "Pool_ID",
      "ClientId": "app-client-id"
    },
    "CreateDate": 1622151252.451,
    "WorkforceVpcConfig": {
      "VpcId": "vpc-id",
      "SecurityGroupIds": ["sg-0123456789abcdef0"],
      "Subnets": ["subnet-0123456789abcdef0"
    ],
    "Status": "Updating"
  }
}

Navigate to your Amazon VPC console. Select **Endpoints** from the left panel. There should be two VPC endpoints created in your account.

**Removing a VPC configuration from your workforce**

Update a VPC private workforce with an empty VPC configuration to remove VPC resources.

aws sagemaker update-workforce --workforce-name workforce-name
--workforce-vpc-config "{}"

Describe the workforce and make sure the status is Updating.

aws sagemaker describe-workforce --workforce-name workforce-name
{
  "Workforce": {
    "WorkforceName": "workforce-name",
    "LastUpdatedDate": 1622151252.451,
    "SourceIpConfig": {
      "Cidrs": []
    },
    "SubDomain": "subdomain.us-west-2.sagamaker.aws.com",
  }
}
Navigate to your Amazon VPC console. Select **Endpoints** from the left panel. The two VPC endpoints should be deleted.

**Restrict public access to the worker portal while maintaining access through a VPC**

The workers in a VPC or non-VPC worker portal are be able to see the labeling job tasks assigned to them. The assignment comes from assigning workers in a work team through OIDC groups. It is the customer's responsibility to restrict the access to their public worker portal by setting the `sourceIpConfig` in their workforce.

**Note**
You can restrict access to the worker portal only through the SageMaker API. This cannot be done through the console.

Use the following command to restrict public access to the worker portal.

```
aws sagemaker update-workforce --region us-west-2 \  
--workforce-name workforce-demo --source-ip-config '{"Cidrs":["10.0.0.0/16"]}'
```

After the `sourceIpConfig` is set on the workforce, the workers can access the worker portal in VPC but not through public internet.

**Note**
You can not set the `sourceIp` restriction for worker portal in VPC.

**Output Data and Storage Volume Encryption**

With Amazon SageMaker Ground Truth, you can label highly sensitive data, stay in control of your data, and employ security best practices. While your labeling job is running, Ground Truth encrypts data in transit and at rest. Additionally, you can use AWS Key Management Service (AWS KMS) with Ground Truth to do the following:

- Use a **customer managed key** to encrypt your output data.
- Use AWS KMS customer managed key with your automated data labeling job to encrypt the storage volume attached to the compute instance used for model training and inference.

Use the topics on this page to learn more about these Ground Truth security features.

**Use Your KMS Key to Encrypt Output Data**

Optionally, you can provide an AWS KMS customer managed key when you create a labeling job, which Ground Truth uses to encrypt your output data.

If you don't provide a customer managed key, Amazon SageMaker uses the default AWS managed key for Amazon S3 for your role's account to encrypt your output data.
If you provide a customer managed key, you must add the required permissions to the key described in Encrypt Output Data and Storage Volume with AWS KMS (p. 941). When you use the API operation CreateLabelingJob, you can specify your customer managed key ID using the parameter KmsKeyId. See the following procedure to learn how to add a customer managed key when you create a labeling job using the console.

**To add an AWS KMS key to encrypt output data (console):**

1. Complete the first 7 steps in Create a Labeling Job (Console) (p. 820).
2. In step 8, select the arrow next to Additional configuration to expand this section.
3. For Encryption key, select the AWS KMS key that you want to use to encrypt output data.
4. Complete the rest of steps in Create a Labeling Job (Console) (p. 820) to create a labeling job.

**Use Your KMS Key to Encrypt Automated Data Labeling Storage Volume (API Only)**

When you create a labeling job with automated data labeling using the CreateLabelingJob API operation, you have the option to encrypt the storage volume attached to the ML compute instances that run the training and inference jobs. To add encryption to your storage volume, use the parameter VolumeKmsKeyId to input an AWS KMS customer managed key. For more information about this parameter, see LabelingJobResourceConfig.

If you specify a key ID or ARN for VolumeKmsKeyId, your SageMaker execution role must include permissions to call kms:CreateGrant. To learn how to add this permission to an execution role, see Create a SageMaker Execution Role for a Ground Truth Labeling Job (p. 936).

**Note**

If you specify an AWS KMS customer managed key when you create a labeling job in the console, that key is only used to encrypt your output data. It is not used to encrypt the storage volume attached to the ML compute instances used for automated data labeling.

**Workforce Authentication and Restrictions**

Ground Truth enables you to use your own private workforce to work on labeling jobs. A private workforce is an abstract concept which refers to a set of people who work for you. Each labeling job is created using a work team, composed of workers in your workforce. Ground Truth supports private workforce creation using Amazon Cognito.

A Ground Truth workforce maps to a Amazon Cognito user pool. A Ground Truth work team maps to a Amazon Cognito user group. Amazon Cognito manages the worker authentication. Amazon Cognito supports Open ID connection (OIDC) and customers can set up Amazon Cognito federation with their own identity provider (IdP).

Ground Truth only allows one workforce per account per AWS Region. Each workforce has a dedicated Ground Truth work portal login URL.

You can also restrict workers to a Classless Inter-Domain Routing (CIDR) block/IP address range. This means annotators must be on a specific network to access the annotation site. You can add up to ten CIDR blocks for one workforce. To learn more, see Manage Private Workforce Using the Amazon SageMaker API (p. 999).

To learn how you can create a private workforce, see Create a Private Workforce (Amazon Cognito) (p. 982).

**Restrict Access to Workforce Types**

Amazon SageMaker Ground Truth work teams fall into one of three workforce types: public (with Amazon Mechanical Turk), private, and vendor. To restrict user access to a specific work team
using one of these types or the work team ARN, use the `sagemaker:WorkteamType` and/or the `sagemaker:WorkteamArn` condition keys. For the `sagemaker:WorkteamType` condition key, use string condition operators. For the `sagemaker:WorkteamArn` condition key, use Amazon Resource Name (ARN) condition operators. If the user attempts to create a labeling job with a restricted work team, SageMaker returns an access denied error.

The policies below demonstrate different ways to use the `sagemaker:WorkteamType` and `sagemaker:WorkteamArn` condition keys with appropriate condition operators and valid condition values.

The following example uses the `sagemaker:WorkteamType` condition key with the `StringEquals` condition operator to restrict access to a public work team. It accepts condition values in the following format: `workforcetype-crowd`, where `workforcetype` can equal public, private, or vendor.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "RestrictWorkteamType",
            "Effect": "Deny",
            "Action": "sagemaker:CreateLabelingJob",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "sagemaker:WorkteamType": "public-crowd"
                }
            }
        }
    ]
}
```

The following policies show how to restrict access to a public work team using the `sagemaker:WorkteamArn` condition key. The first shows how to use it with a valid IAM regex-variant of the work team ARN and the `ArnLike` condition operator. The second shows how to use it with the `ArnEquals` condition operator and the work team ARN.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "RestrictWorkteamType",
            "Effect": "Deny",
            "Action": "sagemaker:CreateLabelingJob",
            "Resource": "*",
            "Condition": {
                "ArnLike": {
                    "sagemaker:WorkteamArn": "arn:aws:sagemaker:*:*:workteam/public-crowd/*
                }
            }
        }
    ]
}
```

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "RestrictWorkteamType",
            "Effect": "Deny",
            "Action": "sagemaker:CreateLabelingJob",
            "Resource": "*",
            "Condition": {
                "ArnEquals": {
                    "sagemaker:WorkteamArn": "arn:aws:sagemaker:*:*:workteam/public-crowd/",
                }
            }
        }
    ]
}
```
Monitor Labeling Job Status

To monitor the status of your labeling jobs, you can set up an Amazon CloudWatch Events (CloudWatch Events) rule for Amazon SageMaker Ground Truth (Ground Truth) to send an event to CloudWatch Events when a labeling job status changes to Completed, Failed, or Stopped or when a worker accepts, declines, submits, or returns a task.

Once you create a rule, you can add a target to it. CloudWatch Events uses this target to invoke another AWS service to process the event. For example, you can create a target using a Amazon Simple Notification Service (Amazon SNS) topic to send a notification to your email when a labeling job status changes.

Prerequisites:

To create a CloudWatch Events rule, you will need an AWS Identity and Access Management (IAM) role with an events.amazonaws.com trust policy attached. The following is an example of an events.amazonaws.com trust policy.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "",
            "Effect": "Allow",
            "Principal": {
                "Service": ["events.amazonaws.com"
            ],
            "Action": "sts:AssumeRole"
        }
    ]
}
```

Topics
- Send Events to CloudWatch Events (p. 956)
- Set Up a Target to Process Events (p. 957)
- Labeling Job Expiration (p. 958)
- Declining Tasks (p. 958)

Send Events to CloudWatch Events

To configure a CloudWatch Events rule to get status updates, or events, for your Ground Truth labeling jobs, use the AWS Command Line Interface (AWS CLI) `put-rule` command. You can filter events that are sent to your rule by status change. For example, you can create a rule that notifies you only if a labeling
job status changes to Completed. When using the put-rule command, specify the following to receive labeling job statuses:

- "source": ["aws.sagemaker"]
- "detail-type": ["SageMaker Ground Truth Labeling Job State Change"]

To configure a CloudWatch Events rule to watch for all status changes, use the following command and replace the placeholder text. For example, replace "GTLabelingJobStateChanges" with a unique CloudWatch Events rule name and "arn:aws:iam::111122223333:role/MyRoleForThisRule" with the Amazon Resource Number (ARN) of an IAM role with an events.amazonaws.com trust policy attached.

```bash
aws events put-rule --name "GTLabelingJobStateChanges"
--event-pattern "{"source": ["aws.sagemaker"], "detail-type": ["SageMaker Ground Truth Labeling Job State Change"]})"
--role-arn "arn:aws:iam::111122223333:role/MyRoleForThisRule"
--region "region"
```

To filter by job status, use the "detail": {"LabelingJobStatus": ["Status"]}" syntax. Valid values for Status are Completed, Failed, and Stopped.

The following example creates a CloudWatch Events rule that notifies you when a labeling job in us-west-2 (Oregon) changes to Completed.

```bash
aws events put-rule --name "LabelingJobCompleted"
--event-pattern "{"source": ["aws.sagemaker"], "detail-type": ["SageMaker Ground Truth Labeling Job State Change"], "detail": {"LabelingJobStatus": ["Completed"]}}"
--role-arn "arn:aws:iam::111122223333:role/MyRoleForThisRule"
--region us-west-2
```

The following example creates a CloudWatch Events rule that notifies you when a labeling job in us-east-1 (Virginia) changes to Completed or Failed.

```bash
aws events put-rule --name "LabelingJobCompletedOrFailed"
--event-pattern "{"source": ["aws.sagemaker"], "detail-type": ["SageMaker Ground Truth Labeling Job State Change"], "detail": {"LabelingJobStatus": ["Completed", "Failed"]}}"
--role-arn "arn:aws:iam::111122223333:role/MyRoleForThisRule"
--region us-east-1
```

To learn more about the put-rule request, see Event Patterns in CloudWatch Events in the Amazon CloudWatch Events User Guide.

### Set Up a Target to Process Events

After you have created a rule, events similar to the following are sent to CloudWatch Events. In this example, the labeling job test-labeling-job's status changed to Completed.

```json
{
    "version": "0",
    "id": "111e1111-11d1-111f-b111-1111b11dcb11",
    "detail-type": "SageMaker Ground Truth Labeling Job State Change",
    "source": "aws.sagemaker",
    "account": "111122223333",
    "time": "2018-10-06T12:26:13Z",
    "region": "us-west-2",
    "resources": [
```
To process events, you need to set up a target. For example, if you want to receive an email when your labeling job status changes, use a procedure in Setting Up Amazon SNS Notifications in the Amazon CloudWatch User Guide to set up an Amazon SNS topic and subscribe your email to it. Once you have create a topic, you can use it to create a target.

**To add a target to your CloudWatch Events rule**

1. Open the CloudWatch console: https://console.aws.amazon.com/cloudwatch/home
2. In the navigation pane, choose Rules.
3. Choose the rule that you want to add a target to.
4. Choose Actions, and then choose Edit.
5. Under Targets, choose Add Target and choose the AWS service you want to act when a labeling job status change event is detected.
6. Configure your target. For instructions, see the topic for configuring a target in the AWS documentation for that service.
7. Choose Configure details.
8. For Name, enter a name and, optionally, provide details about the purpose of the rule in Description.
9. Make sure that the check box next to State is selected so that your rule is listed as Enabled.
10. Choose Update rule.

**Labeling Job Expiration**

If your labeling job is not completed after 30 days, it will expire. If your labeling job expires, you can chain the job to create a new labeling job that will only send unlabeled data to workers. For more information, and to learn how to create a labeling job using chaining, see Chaining Labeling Jobs (p. 927).

**Declining Tasks**

Workers are able to decline tasks.

Workers decline a task if the instructions are not clear, input data is not displaying correctly, or if they encounter some other issue with the task. If the number of workers per dataset object (NumberOfHumanWorkersPerDataObject) decline the task, the data object is marked as expired and will not be sent to additional workers.

**Use Amazon SageMaker Ground Truth Plus to Label Data**

Amazon SageMaker Ground Truth Plus is a turnkey data labeling service that uses an expert workforce to deliver high-quality annotations quickly and reduces costs by up to 40%. Using SageMaker Ground Truth Plus, data scientists and business managers, such as data operations managers and program managers, can create high-quality training datasets without having to build labeling applications and manage
labeling workforces on their own. You can get started with Amazon SageMaker Ground Truth Plus by uploading data along with the labeling requirements in Amazon S3.

**Why use SageMaker Ground Truth Plus?**

To train a machine learning (ML) model, data scientists need large, high-quality, labeled datasets. As ML adoption grows, labeling needs increase. This forces data scientists to spend weeks on building data labeling workflows and managing a data labeling workforce. Unfortunately, this slows down innovation and increases cost. To ensure data scientists can spend their time building, training, and deploying ML models, data scientists typically task other in-house teams consisting of data operations managers and program managers to produce high-quality training datasets. However, these teams typically don’t have access to skills required to deliver high-quality training datasets, which affects ML results. As a result, you look for a data labeling partner that can help them create high-quality training datasets at scale without consuming their in-house resources.

When you upload the data, SageMaker Ground Truth Plus sets up the data labeling workflows and operates them on your behalf. From there, an expert workforce trained on a variety of machine learning (ML) tasks performs data labeling. SageMaker Ground Truth Plus currently offers two types of expert workforce: an Amazon employed workforce and a curated list of third-party vendors. SageMaker Ground Truth Plus provides you with the flexibility to choose the labeling workforce. AWS experts select the best labeling workforce based on your project requirements. For example, if you need people proficient in labeling audio files, specify that in the guidelines provided to SageMaker Ground Truth Plus, and the service automatically selects labelers with those skills.

**Important**

SageMaker Ground Truth Plus does not support PHI, PCI or FedRAMP certified data, and you should not provide this data to SageMaker Ground Truth Plus.

**How does SageMaker Ground Truth Plus work?**

There are five main components to a workflow.

- Requesting a project
- Creating a project team
- Accessing the project portal to monitor progress of training datasets and review labeled data
- Creating a batch
- Receiving the labeled data

**How do I use SageMaker Ground Truth Plus?**

If you are a first-time user of SageMaker Ground Truth Plus, use [Getting Started with Amazon SageMaker Ground Truth Plus](#) get started. To access SageMaker Ground Truth Plus using the SageMaker console, you must be in US East (N. Virginia) (us-east-1).

**Getting Started with Amazon SageMaker Ground Truth Plus.**

The guide demonstrates how to complete the necessary steps to start an Amazon SageMaker Ground Truth Plus project, review labels, and satisfy SageMaker Ground Truth Plus prerequisites.

To get started using SageMaker Ground Truth Plus, review [Set Up Amazon SageMaker Ground Truth Plus Prerequisites](#) and [Core Components of Amazon SageMaker Ground Truth Plus](#).

**Set Up Amazon SageMaker Ground Truth Plus Prerequisites**

Use the following information to sign up for an AWS account. If you already have an AWS account, skip this step.
Sign up for an AWS account

If you do not have an AWS account, complete the following steps to create one.

To sign up for an AWS account

2. Follow the online instructions.

Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

When you sign up for an AWS account, an AWS account root user is created. The root user has access to all AWS services and resources in the account. As a security best practice, assign administrative access to an administrative user, and use only the root user to perform tasks that require root user access.

AWS sends you a confirmation email after the sign-up process is complete. At any time, you can view your current account activity and manage your account by going to https://aws.amazon.com/ and choosing My Account.

Create an administrative user

After you sign up for an AWS account, create an administrative user so that you don't use the root user for everyday tasks.

Secure your AWS account root user

1. Sign in to the AWS Management Console as the account owner by choosing Root user and entering your AWS account email address. On the next page, enter your password.

   For help signing in by using root user, see Signing in as the root user in the AWS Sign-In User Guide.

2. Turn on multi-factor authentication (MFA) for your root user.

   For instructions, see Enable a virtual MFA device for your AWS account root user (console) in the IAM User Guide.

Create an administrative user

• For your daily administrative tasks, grant administrative access to an administrative user in AWS IAM Identity Center.

   For instructions, see Getting started in the AWS IAM Identity Center User Guide.

Sign in as the administrative user

• To sign in with your IAM Identity Center user, use the sign-in URL that was sent to your email address when you created the IAM Identity Center user.

   For help signing in using an IAM Identity Center user, see Signing in to the AWS access portal in the AWS Sign-In User Guide.

Core Components of Amazon SageMaker Ground Truth Plus

The following terms are key to understanding the capabilities of SageMaker Ground Truth Plus:
• **Project:** Each qualified engagement with an AWS expert results in a SageMaker Ground Truth Plus project. A project can be in the pilot or production stage.

• **Batch:** A batch is a collection of similar recurring data objects such as images, video frames and text to be labeled. A project can have multiple batches.

• **Metrics:** Metrics are data about your SageMaker Ground Truth Plus project for a specific date or over a date range.

• **Task type:** SageMaker Ground Truth Plus supports five task types for data labeling. You can also have a custom task type. These include text, image, video, audio, and 3D point cloud.

• **Data objects:** Individual items that are to be labeled.

### Request a Project

To use Amazon SageMaker Ground Truth Plus, get started by requesting a project.

1. Under the Ground Truth tab of Amazon SageMaker, choose **Plus**.
2. On the **SageMaker Ground Truth Plus** page, choose **Request project**.
3. A page titled **Request a project** opens. The page includes fields for **General information** and **Project overview**. Enter the following information

   a. Under **General information**, enter your **First name**, **Last name** and **Business email address**. An AWS expert uses this information for contacting you to discuss the project after you submit the request.

   b. Under **Project overview**, enter your **Project name** and **Project description**. Choose the **Task type** based on your data and use case. You can also indicate if your data contains personally identifiable information (PII).

   c. Create or select an IAM role that grants SageMaker Ground Truth Plus permissions to perform a labeling job by choosing one of the options below.

      i. You can **Create an IAM role** that provides access to any S3 bucket you specify.

      ii. You can **Enter a custom IAM role ARN**.

      iii. You can choose an existing role.

      iv. If you use an existing role or a custom IAM role ARN, make sure you have the following IAM role and trust policy.

        **IAM role**

        ```
        {
            "Version": "2012-10-17",
            "Statement": [
                {
                    "Effect": "Allow",
                    "Action": [
                        "s3:GetObject",
                        "s3:GetBucketLocation",
                        "s3:ListBucket",
                        "s3:PutObject"
                    ],
                    "Resource": [
                        "arn:aws:s3:::your-bucket-name",
                        "arn:aws:s3:::your-bucket-name/**
                        //Ex: "arn:aws:s3:::input-data-to-label/**"
                    ]
                }
            ]
        }
        ```
Trust policy

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "sagemaker-ground-truth-plus.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}

4. Choose Request a project.

Once you create a project, you can find it on the SageMaker Ground Truth Plus page, under the Projects section. The project status should be Review in-progress

Note
You cannot have more than 5 projects with the Review in progress status.

Create a Project Team

A project team provides access to the members from your organization or team to track projects, view metrics, and review annotations. You can create a SageMaker Ground Truth Plus project team once you have shared your data in an Amazon S3 bucket.

To add team members using Amazon Cognito, you have two options:

1. Create a new Amazon Cognito user group
   a. Enter an Amazon Cognito user group name. This name cannot be changed.
   b. Enter the email addresses of up to 50 team members in the Email addresses field. The addresses must be separated by a comma.
   c. Choose Create project team.
      d. Your team members receive an email inviting them to join the SageMaker Ground Truth Plus project team as shown in the following image.
2. Import team members from existing Amazon Cognito user groups.
   a. Choose a user pool that you have created. User pools require a domain and an existing user group. If you get an error that the domain is missing, set it in the Domain name options on the App integration page of the Amazon Cognito console for your group.
   b. Choose an app client. We recommend using a client generated by Amazon SageMaker.
   c. Choose a user group from your pool to import its members.
   d. Choose Create project team.

You can view and manage the list of team members through the AWS console.

**To add team members after creating the project team:**

1. Choose Invite new members in the Members section.
2. Enter the email addresses of up to 50 team members in the Email addresses field. The addresses must be separated by a comma.
3. Choose Invite new members

**To delete existing team members:**

1. Choose the team member to be deleted in the Members section.
2. Choose Delete.

Once you have added members to your project team, you can open the project portal to access your projects.

**Open the Project Portal**

Once you have successfully submitted the intake form and created a project team, you can access the SageMaker Ground Truth Plus project by choosing the Open project portal on the AWS console.

Each project consists of one or more batches. A batch is a collection of recurring similar data objects (text, image, video frame, and point cloud) to be labeled. The project portal provides you with transparency into the data labeling process. You can stay updated about a project, create batches within a project, review the progress of the datasets across multiple projects, and analyze project metrics. The project portal also allows you to review a subset of the labeled data and provide feedback. You can configure the columns displayed in your project and batch table.
You can use the SageMaker Ground Truth Plus project portal to track the following details about your project.

**Project name:** Each project is identified using a unique name.

**Status:** A SageMaker Ground Truth Plus project has one of the following status types:

1. **Review in progress:** You have successfully submitted the project request form. An AWS expert is currently reviewing your request.
2. **Request approved:** Your project request is approved. You can now share your data by creating a new batch from the project portal.
3. **Workflow design and setup progress:** An AWS expert is setting up your project.
4. **Pilot in-progress:** Object labeling for the project in the pilot stage is currently in progress.
5. **Pilot complete:** Object labeling is complete and the labeled data is stored in your Amazon S3 bucket.
6. **Pricing complete:** An AWS expert shares the pricing for the production project with you.
7. **Contract executed:** The contract is complete.
8. **Production in-progress:** Labeling for the project in the production stage is in progress.
9. **Production complete:** Object labeling is complete and the labeled data is stored in your Amazon S3 bucket.
10. **Paused:** Project is currently paused at your request.

**Task type:** SageMaker Ground Truth Plus lets you label five types of tasks that include text, image, video, audio, and point cloud.

**Batches:** Total number of batches within a project.
**Create a Batch**

You can use the project portal to create batches for a project after the project status is changed to **Request approved**.

To create a batch, do the following.

1. Select a project by choosing the project name.
2. A page titled with the project name opens. Under the **Batches** section, choose **Create batch**.
3. Enter the **Batch name**, **Batch description**, **S3 location for input datasets**, and **S3 location for output datasets**.
4. Choose **Submit**.

To create a batch successfully, make sure you meet the following criteria:

- Your data is in the US East (N. Virginia) Region.
- The maximum size for each file is no more than 2 gigabytes.
- The maximum number of files in a batch is 10,000.
- The total size of a batch is less than 100 gigabytes.
- You have no more than 5 batches with the **Data transfer in-progress** status.

**Note**

You cannot create a batch before the project status changes to **Request approved**.

**Review Metrics**

Metrics are data about your SageMaker Ground Truth Plus project for a specific date or over a date range.
You can review metrics for all batches or choose a batch of your choice as shown in the following image.

**Total objects**: Total number of objects in a batch or across all batches.

**Objects completed by day**: Total numbers of objects labeled on a specific date or over a date range.

**Labels completed by day**: Total numbers of labels completed on a specific date or over a date range. An object can have more than one label.

**Review Batches**

Every Amazon SageMaker Ground Truth Plus project consists of one or more batches. Each batch is made up of data objects to be labeled. You can view all the batches for your project using the project portal as shown in the following image.
You can use the SageMaker Ground Truth Plus project portal to track the following details about every batch:

**Batch name**: Each batch is identified with a unique batch name.

**Status**: A SageMaker Ground Truth Plus batch has one of the following status types:

1. **Request submitted**: You have successfully submitted a new batch.
2. **Data transfer failed**: Data transfer failed with errors. Check the error reason and create a new batch after fixing the error.
3. **Data received**: We have received your unlabeled input data.
4. **In-progress**: Data labeling is in progress.
5. **Ready for review**: Data labeling is completed. A subset of labeled objects from the batch are ready for you to review. This is an optional step.
6. **Review submission in-progress**: Review feedback is currently being processed.
7. **Review complete**: You have successfully reviewed the batch. Next, you have to accept or reject it. This action can not be undone.
8. **Accepted**: You have accepted the labeled data and will receive it in your Amazon S3 bucket shortly.
9. **Rejected**: Labeled data needs to be reworked.
10. **Sent for rework**: Labeled data is sent for rework. You can review the batch after its status changes to **Ready for review**.
11. **Ready for delivery**: Labeled data is ready to be transferred to your Amazon S3 bucket.
12. **Data delivered**: Object labeling is complete and the labeled data is stored in your Amazon S3 bucket.
13. **Paused**: Batch is paused at your request.

**Task type**: SageMaker Ground Truth Plus lets you label five types of tasks that include text, image, video, audio, and point cloud.

**Batch creation date**: Date when the batch was created.

**Total objects**: Total number of objects to be labeled across a batch.

**Completed objects**: Number of labeled objects.

**Remaining objects**: Number of objects left to be labeled.

**Failed objects**: Number of objects that cannot be labeled due to an issue with the input data.

**Objects to review**: Number of objects that are ready for your review.

**Objects with feedback**: Number of objects that have gotten feedback from the team members.

SageMaker Ground Truth Plus lets you review a sample set of your labeled data (determined during the initial consultation call) through the review UI shown in the following image.
Hello,

Please review the following sample set of the batch selected and provide your feedback.

**Feedback**
Provide feedback for each object. The Feedback section is in the lower right panel.

**Navigation**
Use the arrow controls in the lower left panel to navigate through the images.

**Submit**
Choose Submit to submit feedback for all data objects.

**Image controls**
Use the image controls in the bottom tray to zoom, pan, control brightness and, contrast.

**Save**
Choose Save to save your progress. It's also autosaved every 15 minutes.

**Close**
To exit the review UI, choose the Close button on the upper right corner.

Verify the label attributes and frame attributes on each frame. You can't create new objects or modify existing objects in this task.
The portal allows your project team members and you to review a small sample set of the labeled objects for each batch. You can provide feedback for each labeled object within that subset through this UI. The review UI allows you to navigate across the subset of labeled objects and provide feedback for those labeled objects.

You can perform the following actions using the review UI.

- Use the arrow controls on the bottom left to navigate through the data objects.
- You can provide feedback for each object. The Feedback section is in the right panel. Choose Submit to submit feedback for all images.
- Use the image controls in the bottom tray to zoom, pan, and control contrast.
- If you plan on returning to finish up your review, choose Stop and resume later on the top right.
- Choose Save to save your progress. Your progress is also autosaved every 15 minutes.
- To exit the review UI, choose Close on the upper right corner of the review UI.
- You can verify the Label attributes and Frame attributes on each frame using the panel on the right. You cannot create new objects or modify existing objects in this task.

Accept or Reject Batches

After you have reviewed a batch, you must choose to accept or reject it.

If you accept a batch, the output from that labeling job is placed in the Amazon S3 bucket that you specify. Once the data is delivered to your S3 bucket, the status of your batch changes from Accepted to Data delivered.

If you reject a batch, you can provide feedback and explain your reasons for rejecting the batch.

SageMaker Ground Truth Plus allows you to provide feedback at the data object level as well as the batch level. You can provide feedback for data objects through the review UI. You can use the project portal to provide feedback for each batch. When you reject a batch, an AWS expert contacts you to determine the rework process and the next steps for the batch.

Note
Accepting or rejecting a batch is a one-time action and cannot be undone. It is necessary to either accept or reject every batch of the project.

Use Amazon SageMaker Ground Truth Synthetic Data to Generate and Label Data

Amazon SageMaker Ground Truth synthetic data is a turnkey data generation and labeling service that makes it quicker and more cost effective for machine learning (ML) scientists to acquire images that are used to train computer vision (CV) models. To train a CV model, ML scientists need large, high-quality, labeled datasets. With Ground Truth synthetic data, ML scientists can generate and label thousands of images within days. Ground Truth synthetic data uses computer-generated 3D models to create virtual environments representing real-world scenarios, generates synthetic images captured from these environments, and automatically annotates each image with labels. You can use the labeled synthetic images with AWS's CV model training services such as Amazon SageMaker and Amazon Lookout for Vision.

Why use Ground Truth Synthetic Data?
Collecting and labeling data in dynamic environments with variations in object size, shape, color, position, background, and lighting is often a time-consuming and expensive process. To effectively
train a model to operate in a dynamic environment, ML scientists must collect a large set of real-world images to represent all possible scenarios, a process that can take months. For scenarios that don't occur frequently, such as rare product defects and faulty product placement, it can take years to capture a sufficient number of images to train a CV model. To acquire images with product defects, ML scientists may intentionally damage products in order to acquire defective images. Ground Truth synthetic data makes it faster and more cost effective for ML scientists to quickly acquire labeled images that represent real-world scenarios, a core requirement for training CV models. ML scientists can use Ground Truth synthetic data to generate thousands of synthetic images from 3D virtual environments representing real world scenarios in hours instead of months. Ground Truth provides a synthetic image fidelity and diversity report and a manifest file along with the labeled synthetic data. The synthetic image fidelity and diversity report provides statistics and plots that help you better understand the generated synthetic images. The manifest file contains information about the images and image labels that you can use to train and test a model.

**Note**
Ground Truth synthetic data does not support PHI, PCI, or FedRAMP certified data, and you should not provide this data to Ground Truth synthetic data.

Ground Truth synthetic data has the following functionalities.

- Full 3D scenes and multiple cameras in a scene
- Ground truth depth maps that provide 3D depth data for all generated images
- Sequences of images (video) from multiple synchronized cameras
- A moving conveyor belt that supports dynamic scenes

**How do I use Ground Truth Synthetic Data?**

If you are a first-time user of Ground Truth synthetic data, we recommend that you follow the procedures outlined in the [Getting Started with Amazon SageMaker Ground Truth Synthetic Data](p. 970) section.

**Getting Started with Amazon SageMaker Ground Truth Synthetic Data**

The guide demonstrates how to complete the necessary steps to satisfy the prerequisites, start a Ground Truth synthetic data project, and review labels.

To get started using synthetic data, review [Set Up Amazon SageMaker Ground Truth Synthetic Data Prerequisites](p. 970) and [Core Components of Amazon SageMaker Ground Truth Synthetic Data](p. 971).

**Set Up Amazon SageMaker Ground Truth Synthetic Data Prerequisites**

To use Ground Truth synthetic data, you need an AWS account. If you already have an AWS account, skip this step.

**Sign up for an AWS account**

If you do not have an AWS account, complete the following steps to create one.

**To sign up for an AWS account**

2. Follow the online instructions.
Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

When you sign up for an AWS account, an AWS account root user is created. The root user has access to all AWS services and resources in the account. As a security best practice, assign administrative access to an administrative user, and use only the root user to perform tasks that require root user access.

AWS sends you a confirmation email after the sign-up process is complete. At any time, you can view your current account activity and manage your account by going to https://aws.amazon.com/ and choosing My Account.

Create an administrative user

After you sign up for an AWS account, create an administrative user so that you don't use the root user for everyday tasks.

Secure your AWS account root user

1. Sign in to the AWS Management Console as the account owner by choosing Root user and entering your AWS account email address. On the next page, enter your password. For help signing in by using root user, see Signing in as the root user in the AWS Sign-In User Guide.

2. Turn on multi-factor authentication (MFA) for your root user. For instructions, see Enable a virtual MFA device for your AWS account root user (console) in the IAM User Guide.

Create an administrative user

- For your daily administrative tasks, grant administrative access to an administrative user in AWS IAM Identity Center.

  For instructions, see Getting started in the AWS IAM Identity Center User Guide.

Sign in as the administrative user

- To sign in with your IAM Identity Center user, use the sign-in URL that was sent to your email address when you created the IAM Identity Center user.

  For help signing in using an IAM Identity Center user, see Signing in to the AWS access portal in the AWS Sign-In User Guide.

Core Components of Amazon SageMaker Ground Truth Synthetic Data

The following terms are key to understanding the capabilities of Ground Truth synthetic data:

- **Project**: Each qualified engagement with an AWS expert results in a Ground Truth synthetic data project.

- **Batch**: A batch is a collection of similar labeled images. A project can have multiple batches. A batch can be in the test or production stage. A project can have multiple batches.

- **Synthetic Image Fidelity and Diversity Report**: Ground Truth synthetic data provides a metrics report that helps you compare the generated synthetic images with your typical dataset.
Request a Project

To get started with Amazon SageMaker Ground Truth synthetic data, go to the SageMaker console and complete the intake form.

Once you submit the intake form in the AWS console, an AWS expert from the Ground Truth synthetic data team reaches out to discuss your data labeling project requirements and pricing.

Share Data from Your Amazon S3 Bucket

After an AWS expert reaches out to discuss your project, you may be required to fill out an intake form with questions specific to your synthetic data requirements. The intake form, along with assets shared with Ground Truth synthetic data, allows the Ground Truth synthetic data team to evaluate your project and the estimated work required to complete your project.

Create an Amazon S3 bucket to share your project assets with Ground Truth synthetic data and store your project's output data.

To create an Amazon S3 bucket and share it with us:

1. Follow the instructions in Create a Bucket in the Amazon Simple Storage Service Console User Guide.
2. We recommend using the following naming convention while storing your data in an Amazon S3 bucket.
   a. The bucket-name should contain fewer than 63 characters.
   b. The bucket-name can include hyphens, but no spaces and underscores.
3. In the Buckets list, choose the name of the bucket you created. 
4. Choose Permissions. 
5. In the Bucket policy section, choose Edit.
6. Confirm that ACLs disabled is selected.

   Note
   Under Object Ownership should have ACLs disabled as shown in the image below.

   ![Edit Object Ownership](image)

   7. Choose Save changes.

   Note
   If you have additional requirements for accessing your data in an Amazon S3 bucket, please contact your AWS expert.
To share your project assets with the Ground Truth synthetic data team for project evaluation, work estimation, and synthetic data generation, follow the steps in the Send Project Data to Ground Truth Synthetic Data (p. 973) section below.

After receiving your intake form and project assets, we return a statement of work (SOW) within 5 business days. The SOW outlines your engagement with Ground Truth synthetic data generation and labeling. After you approve the SOW, the Ground Truth synthetic data team produces a test batch consisting of 50 synthetic images. An AWS expert meets with you to review the test batch, approve or reject images, and complete the final production. The timeline for this is based on the responses in your intake form.

Send Project Data to Ground Truth Synthetic Data

After an AWS expert has been assigned to your project, you can send project data to the Ground Truth synthetic data team to assist in project evaluation, work estimation, and synthetic data generation.

To send project data to Ground Truth synthetic data:

1. Under the Project data transfers table in the project portal, choose Send project data.
2. Enter the name of your S3 bucket from which you would like to send project data as the Amazon S3 source location of the project data transfer.
3. Select an IAM role for the project data transfer. If you select Automatic, Ground Truth synthetic data creates an IAM role in your account with the required permissions to run the project data transfer and call other services on your behalf (recommended). If you select an existing IAM role in your account, Ground Truth synthetic data uses that IAM role to run the project data transfer and call other services on your behalf.
4. Choose Create to create and start the project data transfer.

After creating a project data transfer, you can view the status of the transfer in the Project data transfers table on the project details page in the project portal. When the project data transfer status is Completed, the project data is available to the Ground Truth synthetic data team.

Project Portal

Each project consists of one or more batches. A batch is a collection of similar generated and labeled images. The project portal provides you access to the projects you have contracted with Ground Truth synthetic data. You can view the status of your projects and access completed batches along with the synthetic image fidelity and diversity report. You also review your batches to accept or reject them through the project portal.
You can use the Ground Truth synthetic data project portal to track the following details about your project:

**Project name:** Each project is identified using a unique name.

**Status:** A Ground Truth synthetic data project has one of the following status types:

1. **Request submitted:** You have successfully submitted the project request form. Next, an AWS expert schedules a call with you to discuss the details for your project.
2. **Review in progress:** We are reviewing your project. An AWS expert has been assigned to your project.
3. **Production in progress:** We are currently working on generating labeled data for your project.
4. **Data ready for review:** At least one batch is ready for your review.
5. **Project complete:** We have completed the generation of the required labeled images. The images are stored in your Amazon S3 bucket.

**Batches:** Total number of batches within a project.

**Project start date:** Starting date of a project.

**Total images:** Number of images you requested.

**Completed images:** Number of labeled images generated across all accepted production batches.

### Delete a Project

You can delete a project using the console if the project status is **Request submitted** or **Project complete**. To delete a project with any other status, contact your AWS expert. Deleting a Ground Truth synthetic data project does not delete your data from the Amazon S3 buckets and can be subject to charge.

You can delete a project based on its status as follows:

- **Request submitted:** Deleting a requested project deletes all the project and customer information from the Ground Truth synthetic data database.
- **Review in progress / Production in progress / Data ready for review:** You can request your AWS expert to delete a project having one of these statuses. Deleting a project deletes all the project and personal information from Ground Truth synthetic data database and S3 buckets.
- **Project complete:** Once a project is marked as **Project complete**, we delete all customer information from the Ground Truth synthetic data database and S3 buckets. You can view the project and batches as long as you want, or delete them using the console.

**Note**

Deleting a project does not delete the images from your S3 bucket. To learn more about deleting images from your S3 bucket, refer to [Deleting Amazon S3 objects](#).

### Review Batches

Every Amazon SageMaker Ground Truth synthetic data project consists of one or more batches. Each batch is made up of labeled synthetic images. Batches are of two types, **Test Batch** and **Production Batch**. A test batch provides a small preview of how the synthetic images look using your 3D assets and environment. Images in the test batch are not counted towards the total number of synthetic images you contract. After you approve the test batch for a specific configuration of images, Ground Truth synthetic data starts generating images for your production batch. Images in a production batch are counted towards the total required images.
For every batch, Ground Truth synthetic data provides a **Synthetic Image Fidelity and Diversity Report**. This report provides image and object level statistics and plots that help you make sense of the generated synthetic images. The statistics are used to describe the diversity and the fidelity of the synthetic images and compare them with real images. Examples of the statistics and plots provided are the distributions of object classes, object sizes, image brightness, image contrast, as well as the plots evaluating the indistinguishability between synthetic and real images. The raw data for all the computed dataset statistics is also provided as CSV files to help you accelerate model debugging and enable further analyses.

You can view all the batches for your project using the project portal.

You can use the Ground Truth synthetic data project portal to track the following details about every batch:

**Batch name**: Each batch is identified with a unique batch name.

**Status**: A Ground Truth synthetic data batch has one of the following status types:

1. **In progress**: We are currently generating labeled images for this batch. It will soon be ready for your review.
2. **Ready for review**: A batch of labeled synthetic images is now ready for your review. Follow the steps in the [Transfer Batch Data to Your Amazon S3 bucket](#) section to view the images and review the batch.
3. **Accepted**: You have accepted this batch.
4. **Rejected**: You have rejected this batch and it needs to be reworked. When you reject a batch, an AWS expert contacts you to discuss this further.
**Batch type:** A batch can either be a test batch or a production batch.

**Creation date:** Date when the batch was created.

**Images:** Total number of images in the batch.

### Transfer Batch Data to Your Amazon S3 bucket

When the batch status is **Ready for review**, you must transfer the batch data to your S3 bucket to view the images and review the batch.

**To transfer batch data to your S3 bucket:**

1. On the batch details page in the project portal, choose **Get batch data**.
2. Under **S3 destination location**, enter the name of the S3 bucket where you would like to receive your batch data.
3. Select an IAM role for the project data transfer. If you select **Automatic**, Ground Truth synthetic data creates an IAM role in your account with the required permissions to run the project data transfer and call other services on your behalf (recommended). If you select an existing IAM role in your account, Ground Truth synthetic data uses that IAM role to run the project data transfer and call other services on your behalf.
4. Choose **Create** to create and start the batch data transfer.

After creating a batch data transfer, you can view the status of the transfer in the **Batch data transfers** table on the batch details page in the project portal. When the batch data transfer status is **Completed**, the batch data is available in your S3 bucket, the batch images are viewable on the batch details page in the project portal, and you can proceed to review the batch.

### Accept or Reject Batches

After you have reviewed a batch, you can choose to accept or reject it from the project portal as shown below.

Accepting a batch informs your AWS expert to continue or complete the project, based on the number of remaining images you contracted.

When you reject a batch, an AWS expert contacts you to determine the rework process and the next steps for the batch.

Accepting or rejecting a batch is a one-time action and can only be undone by contacting your AWS expert. It is necessary to either accept or reject every batch of the project.
Create and Manage Workforces

A workforce is the group of workers that you have selected to label your dataset. You can choose either the Amazon Mechanical Turk workforce, a vendor-managed workforce, or you can create your own private workforce to label or review your dataset. Whichever workforce type you choose, Amazon SageMaker takes care of sending tasks to workers.

When you use a private workforce, you also create work teams, a group of workers from your workforce that are assigned to specific jobs—Amazon SageMaker Ground Truth labeling jobs or Amazon Augmented AI human review tasks. You can have multiple work teams and can assign one or more work teams to each job.

You can use Amazon Cognito or your own private OpenID Connect (OIDC) Identity Provider (IdP) to manage your private workforce and work teams. For more information about the permissions required to manage your workforce this way, see Permissions Required to Use the Amazon SageMaker Ground Truth Console (p. 3359).

Topics

• Using the Amazon Mechanical Turk Workforce (p. 977)
• Managing Vendor Workforces (p. 980)
• Use a Private Workforce (p. 981)

Using the Amazon Mechanical Turk Workforce

The Amazon Mechanical Turk (Mechanical Turk) workforce provides the most workers for your Amazon SageMaker Ground Truth labeling job and Amazon Augmented AI human review task. The Amazon Mechanical Turk workforce is a world-wide resource. Workers are available 24 hours a day, 7 days a week. You typically get the fastest turnaround for your human review tasks and labeling jobs when you use the Amazon Mechanical Turk workforce.

Any Amazon Mechanical Turk workforce billing is handled as part of your Ground Truth or Amazon Augmented AI billing. You do not need to create a separate Mechanical Turk account to use the Amazon Mechanical Turk workforce.

Important

You should not share confidential information, personal information, or protected health information with this workforce. You should not use the Amazon Mechanical Turk workforce when you use Amazon A2I in conjunction with AWS HIPAA-eligible services, such as Amazon Textract and Amazon Rekognition, for workloads containing protected health information.

You can choose Mechanical Turk as your workforce when you create a Ground Truth labeling job or Amazon A2I human review workflow (flow definition). You can create a labeling job and a human review workflow using the SageMaker console and API.

When you use an API operation to create a labeling job or human review workflow, you use the following ARN for the Amazon Mechanical Turk workforce for your WorkteamArn. Replace region with the AWS Region you are using to create the labeling job or human loops. For example, if you create a labeling job in US West (Oregon), replace region with us-west-2.

• arn:aws:sagemaker:region:394669845002:workteam/public-crowd/default

Ground Truth and Amazon A2I require that your input data is free of personally identifiable information (PII) when you use Mechanical Turk. If you use the Mechanical Turk workforce and do not specify that your input data is free of PII, your Ground Truth labeling jobs and Augmented AI tasks will fail. You specify that your input data is free of PII when you create a Ground Truth labeling job and when you create a Amazon A2I human loop using a built-in integration or the StartHumanLoop operation.
Use the following sections to learn how to use Mechanical Turk with these services.

Topics
• Use Mechanical Turk with Ground Truth (p. 978)
• Use Mechanical Turk with Amazon A2I (p. 979)
• When is Mechanical Turk Not Supported? (p. 980)

Use Mechanical Turk with Ground Truth

You can use Mechanical Turk with Ground Truth when you create a labeling job using the console, or the CreateLabelingJob operation.

When you create a labeling job, we recommend you adjust the number of workers that annotate each data object based on the complexity of the job and the quality that you need. Amazon SageMaker Ground Truth uses annotation consolidation to improve the quality of the labels. More workers can make a difference in the quality of the labels for more complex labeling jobs, but might not make a difference for simpler jobs. For more information, see Consolidate Annotations (p. 920). Note that annotation consolidation is not supported for Amazon A2I human review workflows.

To use Mechanical Turk when you create a labeling job (console):

1. Use the following to create a labeling job using the Ground Truth area of the SageMaker console: Create a Labeling Job (Console) (p. 820).
2. When you are selecting Worker types in the Workers section, select Amazon Mechanical Turk.
3. Specify the total amount of time workers have to complete a task using Task timeout.
4. Specify the total amount of time a task remains available to workers in Task expiration. This is how long workers have to pick up a task before it fails.
5. Select the Price per task using the dropdown list. This is the amount of money a worker receives for completing a single task.
6. (Optional) If applicable, select The dataset does not contain adult content. SageMaker may restrict the Mechanical Turk workers that can view your task if it contains adult content.
7. You must read and confirm the following statement by selecting the check box to use the Mechanical Turk workforce. If your input data contains confidential information, personal information, or protected health information, you must select another workforce.
   You understand and agree that the Mechanical Turk workforce consists of independent contractors located worldwide and that you should not share confidential information, personal information, or protected health information with this workforce.
8. (Optional) Select the check box next to Enable automated data labeling if you want to enable automated data labeling. To learn more about this feature, see Automate Data Labeling (p. 921).
9. You can specify the Number of workers per dataset object under Additional configuration. For example, if you enter 3 in this field, each data object will be labeled by 3 workers.

When you create your labeling job by selecting Create, your labeling tasks are sent to Mechanical Turk workers.

To use Mechanical Turk when you create a labeling job (API):

1. Use the following to create a labeling job using the CreateLabelingJob operation: Create a Labeling Job (API) (p. 823).
2. Use the following for the WorkteamArn. Replace region with the AWS Region you are using to create the labeling job.
3. Use `TaskTimeLimitInSeconds` to specify the total amount of time workers have to complete a task.

4. Use `TaskAvailabilityLifetimeInSeconds` to specify the total amount of time a task remains available to workers. This is how long workers have to pick up a task before it fails.

5. Use `NumberOfHumanWorkersPerDataObject` to specify the number of workers per dataset object.

6. Use `PublicWorkforceTaskPrice` to set the price per task. This is the amount of money a worker receives for completing a single task.

7. Use `DataAttributes` to specify that your input data is free of confidential information, personal information, or protected health information.

   Ground Truth requires that your input data is free of personally identifiable information (PII) if you use the Mechanical Turk workforce. If you use Mechanical Turk and do not specify that your input data is free of PII using the `FreeOfPersonallyIdentifiableInformation` flag, your labeling job will fail.

   Use the `FreeOfAdultContent` flag to declare that your input data is free of adult content. SageMaker may restrict the Mechanical Turk workers that can view your task if it contains adult content.

You can see examples of how to use this API in the following notebooks, found on GitHub: Ground Truth Jupyter Notebook Examples. You can access these notebooks under the SageMaker Example Notebooks (p. 330) in a notebook instance.

**Use Mechanical Turk with Amazon A2I**

You can specify that you want to use Mechanical Turk with Amazon A2I when you create a human review workflow, also referred to as a flow definition, in the console, or with the `CreateFlowDefinition` API operation. When you use this human review workflow to configure human loops, you must specify that your input data is free of PII.

**To use Mechanical Turk when you create a human review workflow (console):**

1. Use the following to create a human review workflow in the Augmented AI section of the SageMaker console: Create a Human Review Workflow (Console) (p. 1111).

2. When you are selecting Worker types in the Workers section, select Amazon Mechanical Turk.

3. Select the Price per task using the dropdown list. This is the amount of money a worker receives for completing a single task.

4. (Optional) You can specify the Number of workers per dataset object under Additional configuration. For example, if you enter 3 in this field, each data object will be labeled by 3 workers.

5. (Optional) Specify the total amount of time workers have to complete a task using Task timeout.

6. (Optional) Specify the total amount of time a task remains available to workers in Task expiration. This is how long workers have to pick up a task before it fails.

7. Once you have created your human review workflow, you can use it to configure a human loop by providing its Amazon Resource Name (ARN) in the parameter FlowDefinitionArn. You configure a human loop using one of the API operations of a built-in task type, or the Amazon A2I runtime API operation, StartHumanLoop. To learn more, see Create and Start a Human Loop (p. 1129).

   When you configure your human loop, you must specify that your input data is free of personally identifiable information (PII) using the `FreeOfPersonallyIdentifiableInformation` content classifier in DataAttributes. If you use Mechanical Turk and do not specify that your input data is free of PII, your human review tasks will fail.
Use the `FreeOfAdultContent` flag to declare that your input data is free of adult content. SageMaker may restrict the Mechanical Turk workers that can view your task if it contains adult content.

**To use Mechanical Turk when you create a human review workflow (API):**

1. Use the following to create a human review workflow using the `CreateFlowDefinition` operation: [Create a Human Review Workflow (API)](p. 1112).
2. Use the following for the `WorkteamArn`. Replace `region` with the AWS Region you are using to create the labeling job.
   
   ```
   arn:aws:sagemaker:region:394669845002:workteam/public-crowd/default
   ```
3. Use `TaskTimeLimitInSeconds` to specify the total amount of time workers have to complete a task.
4. Use `TaskAvailabilityLifetimeInSeconds` to specify the total amount of time a task remains available to workers. This is how long workers have to pick up a task before it fails.
5. Use `TaskCount` to specify the number of workers per dataset object. For example, if you specify 3 for this parameter, each data object will be labeled by 3 workers.
6. Use `PublicWorkforceTaskPrice` to set the price per task. This is the amount of money a worker receives for completing a single task.
7. Once you have created your human review workflow, you can use it to configure a human loop by providing its Amazon Resource Name (ARN) in the parameter `FlowDefinitionArn`. You configure a human loop using one of the API operations of a built-in task type, or the Amazon A2I runtime API operation, `StartHumanLoop`. To learn more, see [Create and Start a Human Loop](p. 1129).

When you configure your human loop, you must specify that your input data is free of personally identifiable information (PII) using the `FreeOfPersonallyIdentifiableInformation` content classifier in `DataAttributes`. If you use Mechanical Turk and do not specify that your input data is free of PII, your human review tasks will fail.

Use the `FreeOfAdultContent` flag to declare that your input data is free of adult content. SageMaker may restrict the Mechanical Turk workers that can view your task if it contains adult content.

You can see examples of how to use this API in the following notebooks, found on GitHub: [Amazon A2I Jupyter Notebook Examples](#).

**When is Mechanical Turk Not Supported?**

This workforce is not supported under the following scenarios. In each scenario, you must use a private or vendor workforce.

- This workforce is not supported for Ground Truth video frame labeling jobs and 3D point cloud labeling jobs.
- You cannot use this workforce if your input data contains personally identifiable information (PII).
- Mechanical Turk is not available in some of the AWS special regions. If applicable, refer to the documentation for your special region for more information.

**Managing Vendor Workforces**

You can use a vendor-managed workforce to label your data using Amazon SageMaker Ground Truth (Ground Truth) and Amazon Augmented AI (Amazon A2I). Vendors have extensive experience in providing
data labeling services for the purpose of machine learning. Vendor workforces for these two services must be created and managed separately through the Amazon SageMaker console.

Vendors make their services available via the AWS Marketplace. You can find details of the vendor's services on their detail page, such as the number of workers and the hours that they work. You can use these details to make estimates of how much the labeling job will cost and the amount of time that you can expect the job to take. Once you have chosen a vendor you subscribe to their services using the AWS Marketplace.

A subscription is an agreement between you and the vendor. The agreement spells out the details of the agreement, such as price, schedule, or refund policy. You work directly with the vendor if there are any issues with your labeling job.

You can subscribe to any number of vendors to meet your data annotation needs. When you create a labeling job or human review workflow you can specify that the job be routed to a specific vendor.

**Important**
Before you send sensitive data to a vendor, check the vendor's security and compliance practices on their detail page and review the end user license agreement (EULA) that is part of your subscription agreement. You are responsible for ensuring that the vendor meets your compliance requirements for personal or confidential information. Do not share protected health information with this workforce.

You must use the console to subscribe to a vendor workforce. Once you have a subscription, you can use the `ListSubscribedWorkteams` operation to list your subscribed vendors.

**To subscribe to a vendor workforce**

2. Choose the appropriate page in the SageMaker console.
   - For Ground Truth labeling jobs, choose **Labeling workforces**, choose **Vendor**, and then choose **Find data labeling services**.
   - For Amazon A2I human review workflows, choose **Human review workforces**, choose **Vendor**, and then choose **Find human review services**.
3. The console opens the AWS Marketplace with:
   - data labeling services category selected for Ground Truth
   - human review services category selected for Amazon A2I

   Here you see a list of the vendor services available for this service.
4. Choose a vendor. The AWS Marketplace shows detailed information about the data labeling or human review service. Use this information to determine if the vendor meets your requirements for your task.
5. If the vendor meets your requirements, choose **Continue to subscribe**.
6. Review the details of the subscription. If you agree to the terms, choose **Subscribe** to complete your subscription to the service.

**Use a Private Workforce**

A **private workforce** is a group of workers that you choose. These can be employees of your company or a group of subject matter experts from your industry. For example, if the task is to label medical images, you could create a private workforce of people knowledgeable about the images in question.

Each AWS account has access to a single private workforce per region, and the owner has the ability to create multiple **private work teams** within that workforce. A single private work team is used to
complete a labeling job or human review task, or a job. You can assign each work team to a separate job or use a single team for multiple jobs. A single worker can be in more than one work team.

Your private workforce can either be created and managed using Amazon Cognito or your own private OpenID Connect (OIDC) Identity Provider (IdP).

If you are a new user of Amazon SageMaker Ground Truth or Amazon Augmented AI and do not require your workers to be managed with your own IdP, it is recommended that you use Amazon Cognito to create and manage your private workforce.

After you create a workforce, in addition to creating and managing work teams, you can do the following:

- Track worker performance
- Create and manage Amazon SNS topics to notify workers when labeling tasks are available
- Manage Private Workforce Access to Tasks Using IP Addresses

Note
Your private workforce is shared between Ground Truth and Amazon A2I. To create and manage private work teams used by Augmented AI, use the Ground Truth section of the SageMaker console.

Topics
- Create and Manage Amazon Cognito Workforce (p. 982)
- Create and Manage OIDC IdP Workforce (p. 989)
- Manage Private Workforce Using the Amazon SageMaker API (p. 999)
- Track Worker Performance (p. 1000)
- Create and manage Amazon SNS topics for your work teams (p. 1001)

Create and Manage Amazon Cognito Workforce

Create and manage your private workforce using Amazon Cognito when you want to create your workforce using the Amazon SageMaker console or you don’t want the overhead of managing worker credentials and authentication. When you create a private workforce with Amazon Cognito, it provides authentication, authorization, and user management for your private workers.

Topics
- Create a Private Workforce (Amazon Cognito) (p. 982)
- Manage a Private Workforce (Amazon Cognito) (p. 985)

Create a Private Workforce (Amazon Cognito)

When you use Amazon Cognito, you can create a private workforce in one of the following ways:

- Create a new workforce while you are creating your labeling job. To learn how, see Create an Amazon Cognito Workforce When Creating a Labeling Job (p. 983).
- Create a new workforce before you create your labeling job. To learn how, see Create an Amazon Cognito Workforce Using the Labeling Workforces Page (p. 984).
- Import an existing workforce after creating a user pool in the Amazon Cognito console. To learn how, see Create a Private Workforce (Amazon Cognito Console) (p. 984).
Once you create a private workforce, that workforce and all work teams and workers associated with it are available to use for all Ground Truth labeling job tasks and Amazon Augmented AI human review workflows tasks.

If you are new to Amazon SageMaker and want to test Ground Truth or Amazon A2I, we suggest that you create a private work team consisting of people from your organization using the console. Use this work team when creating labeling or human review workflows (flow definitions) to test your worker UI and job workflow.

**Topics**

- Create a Private Workforce (Amazon SageMaker Console) (p. 983)
- Create a Private Workforce (Amazon Cognito Console) (p. 984)

### Create a Private Workforce (Amazon SageMaker Console)

You can create a private workforce in the Amazon SageMaker console in one of two ways:

- When creating a labeling job in the **Labeling jobs** page of the Amazon SageMaker Ground Truth section.
- Using the **Labeling workforces** page of the Amazon SageMaker Ground Truth section. If you are creating a private workforce for an Amazon A2I human review workflow, use this method.

Both of these methods also create a default work team containing all of the members of the workforce. This private workforce is available to use for both Ground Truth and Amazon Augmented AI jobs.

When you create a private workforce using the console, SageMaker uses Amazon Cognito as an identity provider for your workforce. If you want to use your own OpenID Connect (OIDC) Identity Provider (IdP) to create and manage your private workforce, you must create a workforce using the SageMaker API operation `CreateWorkforce`. To learn more, see Create a Private Workforce (OIDC IdP) (p. 990).

### Create an Amazon Cognito Workforce When Creating a Labeling Job

If you haven't created a private workforce when you create your labeling job and you choose to use private workers, you are prompted to create a work team. This will create a private workforce using Amazon Cognito.

#### To create a workforce while creating a labeling job (console)

2. In the navigation pane, choose **Labeling jobs** and fill in all required fields. For instructions on how to start a labeling job, see **Getting started** (p. 641). Choose **Next**.
3. Choose **Private** for the workforce type.
4. In the **Workers** section, enter:
   a. The **Team name**.
   b. Email addresses for up to 100 workforce members. Email addresses are case sensitive. Your workers must log in using the same case used when the address was initially entered. You can add additional workforce members after the job has been created.
   c. The name of your organization. SageMaker uses this to customize the email sent to the workers.
   d. A contact email address for workers to report issues related to the task.

When you create the labeling job, an email is sent to each worker inviting them to join the workforce. After creating the workforce, you can add, delete, and disable workers using the SageMaker console or the Amazon Cognito console.
Create an Amazon Cognito Workforce Using the Labeling Workforces Page

To create and manage your private workforce using Amazon Cognito, you can use the Labeling workforces page. When following the instructions below, you have the option to create a private workforce by entering worker emails importing a pre-existing workforce from an Amazon Cognito user pool. To import a workforce, see Create a Private Workforce (Amazon Cognito Console) (p. 984).

To create a private workforce using worker emails

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose Labeling workforces.
3. Choose Private, then choose Create private team.
4. Choose Invite new workers by email.
5. Paste or type a list of up to 50 email addresses, separated by commas, into the email addresses box.
6. Enter an organization name and contact email.
7. Optionally, choose an SNS topic to which to subscribe the team so workers are notified by email when new Ground Truth labeling jobs become available. Amazon SNS notifications are supported by Ground Truth and are not supported by Augmented AI. If you subscribe workers to receive SNS notifications, they only receive notifications about Ground Truth labeling jobs. They do not receive notifications about Augmented AI tasks.
8. Click the Create private team button.

After you import your private workforce, refresh the page. On the Private workforce summary page, you can see information about the Amazon Cognito user pool for your workforce, a list of work teams for your workforce, and a list of all of the members of your private workforce.

Note
If you delete all of your private work teams, you have to repeat this process to use a private workforce in that region.

Create a Private Workforce (Amazon Cognito Console)

Amazon Cognito is used to define and manage your private workforce and your work teams. It is a service that you can use to create identities for your workers and authenticate these identities with identity providers. A private workforce corresponds to a single Amazon Cognito user pool. Private work teams correspond to Amazon Cognito user groups within that user pool.

Example identity providers supported by Amazon Cognito:

- Social sign-in providers such as Facebook and Google
- OpenID Connect (OIDC) providers
- Security Assertion Markup Language (SAML) providers such as Active Directory
- The Amazon Cognito built-in identity provider

For more information, see What Is Amazon Cognito?.

To create a private workforce using Amazon Cognito, you must have an existing Amazon Cognito user pool containing at least one user group. See Tutorial: Creating a User Pool to learn how to create a user pool. See Adding Groups to a User Pool to learn how to add a user group to a pool.

Once your user pool has been created, follow the steps below to create a private workforce by importing that user pool into Amazon SageMaker.

To create a private workforce by importing a Amazon Cognito user pool

2. In the navigation pane, choose Labeling workforces.
3. Choose **Private**.
4. Choose **Create private team**. This creates a private workforce and a work team.
5. Choose **Import workers from existing Amazon Cognito user groups**.
6. Choose a user pool that you have created. User pools require a domain and an existing user group. If you get an error that the domain is missing, set it in the **Domain name** options on the **App integration** page of the Amazon Cognito console for your group.
7. Choose an app client. We recommend using a client generated by SageMaker.
8. Choose a user group from your pool to import its members.
9. Optionally choose an Amazon Simple Notification Service (Amazon SNS) topic to which to subscribe the team so that workers are notified by email when new labeling jobs become available. Amazon SNS notifications are supported by Ground Truth and are not supported by Augmented AI. If you subscribe workers to receive SNS notifications, they only receive notifications about Ground Truth labeling jobs. They do not receive notifications about Augmented AI tasks.
10. Choose **Create private team**.

**Important**

After you create a workforce using an Amazon Cognito user pool, it should not be deleted without first deleting all work teams associated with that pool in the SageMaker console.

After you import your private workforce, refresh the page to see the **Private workforce summary** page. On this page, you can see information about the Amazon Cognito user pool for your workforce, a list of work teams for your workforce, and a list of all of the members of your private workforce. This workforce is now available to use in both Amazon Augmented AI and Amazon SageMaker Ground Truth for human review tasks and data labeling jobs respectively.

**Manage a Private Workforce (Amazon Cognito)**

After you have created a private workforce using Amazon Cognito, you can create and manage work teams using the Amazon SageMaker console and API operations.

You can do the following using either the [SageMaker console](https://console.aws.amazon.com/sagemaker) or [Amazon Cognito console](https://console.aws.amazon.com/cognito).  
- Add and delete work teams.
- Add workers to your workforce and one or more work teams.
- Disable or remove workers from your workforce and one or more work teams. If you add workers to a workforce using the Amazon Cognito console, you must use the same console to remove the worker from the workforce.

You can restrict access to tasks to workers at specific IP addresses using the SageMaker API. For more information, see [Manage Private Workforce Using the Amazon SageMaker API](https://docs.aws.amazon.com/sagemaker/latest/dg/private-workforce-using-sagemaker-api.html) (p. 999).

**Topics**
- [Manage a Private Workforce (Amazon Cognito Console)](https://docs.aws.amazon.com/sagemaker/latest/dg/private-workforce-cognito-console.html) (p. 988)

**Manage a Workforce (Amazon SageMaker Console)**

You can use the Amazon SageMaker console to create and manage the work teams and individual workers that make up a private workforce.

Use a work team to assign members of your private workforce to a labeling or human review job. When you create your workforce using the SageMaker console, there is a work team called **Everyone-in-private-workforce** that enables you to assign your entire workforce to a job. Because an imported
Amazon Cognito user pool may contain members that you don't want to include in your work teams, a similar work team is not created for Amazon Cognito user pools.

You have two choices to create a new work team:

- You can create a work team in the SageMaker console and add members from your workforce to the team.
- You can create a user group by using the Amazon Cognito console and then create a work team by importing the user group. You can import more than one user group into each work team. You manage the members of the work team by updating the user group in the Amazon Cognito console. See Manage a Private Workforce (Amazon Cognito Console) (p. 988) for more information.

Create a Work Team Using the SageMaker Console

You can create a new Amazon Cognito user group or import an existing user group using the SageMaker console, on the Labeling workforces page. For more information on creating a user group in the Amazon Cognito console, see Manage a Private Workforce (Amazon Cognito Console) (p. 988).

To create a work team using the SageMaker console

2. Choose Labeling workforces from the left menu.
3. Under Private, choose Create private team.
4. Under Team details, enter a Team name. The name must be unique in your account in an AWS Region.
5. Under Add workers, choose a method to add workers to the team using a user group.
   - If you chose Create a team by adding workers to a new Amazon Cognito user group, select the workers to add to the team.
   - If you chose Create a team by importing existing Amazon Cognito user groups, choose the user groups that are part of the new team.
6. If you select an SNS topic, all workers added to the team are subscribed to the Amazon SNS topic and notified when new work items are available to the team. Select from a list of your existing Ground Truth related Amazon SNS topics or select Create new topic to open a topic-creation dialog.

   Amazon SNS notifications are supported by Ground Truth and are not supported by Augmented AI. If you subscribe workers to receive SNS notifications, they only receive notifications about Ground Truth labeling jobs. They do not receive notifications about Augmented AI tasks.

   Workers in a workteam subscribed to a topic receive notifications when a new Ground Truth labeling job for that team becomes available and when one is about to expire.

   Read Create and manage Amazon SNS topics for your work teams (p. 1001) for more information about using Amazon SNS topic.

Subscriptions

After you have created a work team, you can see more information about the team and change or set the Amazon SNS topic to which its members are subscribed by visiting the Amazon Cognito console. If you added any team members before you subscribed the team to a topic, you need to manually subscribe those members to that topic. Read Create and manage Amazon SNS topics for your work teams for more information on creating and managing the Amazon SNS topic.
Add or Remove Workers

A work team is a group of workers within your workforce to whom you can assign jobs. A worker can be added to more than one work team. Once a worker has been added to a work team, that worker can be disabled or removed.

Add Workers to the Workforce

Adding a worker to the workforce enables you to add that worker to any work team within that workforce.

To add workers using the private workforce summary page

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Choose Labeling workforces to navigate to your private workforce summary page.
3. Choose Private.
5. Paste or type a list of email addresses, separated by commas, into the email addresses box. You can have up to 50 email addresses in this list.

Add a Worker to a Work Team

A worker must be added to the workforce before being added to a work team. To add a worker to a work team, first navigate to the Private workforce summary page using the steps above.

To add a worker to a work team from the private workforce summary page

1. In the Private teams section, choose the team to which you want to add the workers.
2. Choose the Workers tab.
3. Choose Add workers to team and choose the boxes next to the workers that you want to add.
4. Click Add workers to team.

Disable and Remove a Worker from the Workforce

Disabling a worker stops the worker from receiving a job. This action does not remove the worker from the workforce, or from any work team with which the worker is associated. To disable or remove a worker from a work team, first navigate to the private workforce summary page using the steps above.

To deactivate a worker using the private workforce summary page

1. In the Workers section, choose the worker that you would like to disable.
2. Choose Disable.

If desired, you can subsequently Enable a worker after they have been disabled.

You can remove workers from your private workforce directly in the SageMaker console if that worker was added in this console. If you added the worker (user) in the Amazon Cognito console, see Manage a Private Workforce (Amazon Cognito Console) (p. 988) to learn how to remove the worker in the Amazon Cognito console.

To remove a worker using the private workforce summary page

1. In the Workers section, choose the worker that you would like to delete.
2. If the worker has not been disabled, choose Disable.
3. Select the worker and choose **Delete**.

**Manage a Private Workforce (Amazon Cognito Console)**

A private workforce corresponds to a single **Amazon Cognito user pool**. Private work teams correspond to **Amazon Cognito user groups** within that user pool. Workers correspond to **Amazon Cognito users** within those groups.

After your workforce has been created, you can add work teams and individual workers through the Amazon Cognito console. You can also delete workers from your private workforce or remove them from individual teams in the Amazon Cognito console.

**Important**
You can't delete work teams from the Amazon Cognito console. Deleting a Amazon Cognito user group that is associated with an Amazon SageMaker work team will result in an error. To remove work teams, use the SageMaker console.

**Create Work Teams (Amazon Cognito Console)**

You can create a new work team to complete a job by adding a Amazon Cognito user group to the user pool associated with your private workforce. To add a Amazon Cognito user group to an existing worker pool, see **Adding groups to a User Pool**.

**To create a work team using an existing Amazon Cognito user group**

2. In the navigation pane, choose **Workforces**.
3. For **Private teams**, choose **Create private team**.
4. Under **Team details**, give the team a name. The name must be unique in your account in an AWS Region.
5. For **Add workers**, choose **Import existing Amazon Cognito user groups**, and choose one or more user groups that are part of the new team.
6. If you choose an **SNS topic**, all workers added to the team are subscribed to the Amazon Simple Notification Service (Amazon SNS) topic and notified when new work items are available to the team. Choose from a list of your existing SNS topics related to SageMaker Ground Truth or Amazon Augmented AI or choose **Create new topic** to create one.

**Note**
Amazon SNS notifications are supported by Ground Truth and are not supported by Augmented AI. If you subscribe workers to receive SNS notifications, they only receive notifications about Ground Truth labeling jobs. They do not receive notifications about Augmented AI tasks.

**Subscriptions**

After you have created a work team, you can see more information about the team and change or set the SNS topic to which its members are subscribed using the Amazon Cognito console. If you added any team members before you subscribed the team to a topic, you need to manually subscribe those members to that topic. For more information, see **Create and manage Amazon SNS topics for your work teams** (p. 1001).

**Add and Remove Workers (Amazon Cognito Console)**

When using the Amazon Cognito console to add workers to a work team, you must add a user to the user pool associated with the workforce before adding that user to a user group. Users can be added to a user pool in various ways. For more information, see **Signing Up and Confirming User Accounts**.
Add a Worker to a Work Team

After a user has been added to a pool, the user can be associated with user groups inside of that pool. After a user has been added to a user group, that user becomes a worker on any work team created using that user group.

**To add a user to a user group**

1. Open the Amazon Cognito console: [https://console.aws.amazon.com/cognito/](https://console.aws.amazon.com/cognito/).
2. Choose **Manage User Pools**.
3. Choose the user pool associated with your SageMaker workforce.
4. Under **General Settings**, choose **Users and Groups** and do one of the following:
   - Choose **Groups**, choose the group that you want to add the user to, and choose **Add users**. Choose the users that you want to add by choosing the plus-icon to the right of the user’s name.
   - Choose **Users**, choose the user that you want to add to the user group, and choose **Add to group**. From the dropdown menu, choose the group and choose **Add to group**.

Disable and Remove a Worker From a Work Team

Disabling a worker stops the worker from receiving jobs. This action doesn’t remove the worker from the workforce, or from any work team the worker is associated with. To remove a user from a work team in Amazon Cognito, you remove the user from the user group associated with that team.

**To deactivate a worker (Amazon Cognito console)**

1. Open the Amazon Cognito console: [https://console.aws.amazon.com/cognito/](https://console.aws.amazon.com/cognito/).
2. Choose **Manage User Pools**.
3. Choose the user pool associated with your SageMaker workforce.
4. Under **General Settings**, choose **Users and Groups**.
5. Choose the user that you want to disable.
6. Choose **Disable User**.

You can enable a disabled user by choosing **Enable User**.

**To remove a user from a user group (Amazon Cognito console)**

1. Open the Amazon Cognito console: [https://console.aws.amazon.com/cognito/](https://console.aws.amazon.com/cognito/).
2. Choose **Manage User Pools**.
3. Choose the user pool associated with your SageMaker workforce.
4. Under **General Settings**, choose **Users and Groups**.
5. For **User** tab, choose the X icon to the right of the group from which you want to remove the user.

Create and Manage OIDC IdP Workforce

Create a private workforce using an OpenID Connect (OIDC) Identity Provider (IdP) when you want to manage and authenticate your workers using your own OIDC IdP. Individual worker credentials and other data will be kept private. Ground Truth and Amazon A2I will only have visibility into worker information you provide through the claims that you send to these services. To create a workforce using an OIDC IdP, your IdP must support groups because Ground Truth and Amazon A2I map one or more groups in your IdP to a work team. To learn more, see **Send Required and Optional Claims to Ground Truth and Amazon A2I** (p. 990).
If you are a new user of Ground Truth or Amazon A2I, you can test your worker UI and job workflow by creating a private work team and adding yourself as a worker. Use this work team when you create a labeling job or human review workflow. First, create a private OIDC IdP workforce using the instructions in Create a Private Workforce (OIDC IdP) (p. 990). Next, refer to Manage a Private Workforce (OIDC IdP) (p. 996) to learn how to create a work team.

**Topics**
- Create a Private Workforce (OIDC IdP) (p. 990)
- Manage a Private Workforce (OIDC IdP) (p. 996)

### Create a Private Workforce (OIDC IdP)

Create a private workforce using an OpenID Connect (OIDC) Identity Provider (IdP) when you want to authenticate and manage workers using your own identity provider. Use this page to learn how to configure your IdP to communicate with Amazon SageMaker Ground Truth (Ground Truth) or Amazon Augmented AI (Amazon A2I) and to learn how to create a workforce using your own IdP.

To create a workforce using an OIDC IdP, your IdP must support *groups* because Ground Truth and Amazon A2I use one or more groups that you specify to create work teams. You use work teams to specify workers for your labeling jobs and human review tasks. Because groups are not a standard claim, your IdP may have a different naming convention for a group of users (workers). Therefore, you must identify one or more user groups to which a worker belongs using the custom claim `sagemaker:groups` that is sent to Ground Truth or Amazon A2I from your IdP. To learn more, see Send Required and Optional Claims to Ground Truth and Amazon A2I (p. 990).

You create an OIDC IdP workforce using the SageMaker API operation CreateWorkforce. Once you create a private workforce, that workforce and all work teams and workers associated with it are available to use for all Ground Truth labeling job tasks and Amazon A2I human review workflows tasks. To learn more, see Create an OIDC IdP Workforce (p. 992).

### Send Required and Optional Claims to Ground Truth and Amazon A2I

When you use your own IdP, Ground Truth and Amazon A2I use your Issuer, ClientId, and ClientSecret to authenticate workers by obtaining an authentication CODE from your AuthorizationEndpoint.

Ground Truth and Amazon A2I will use this CODE to obtain a custom claim from either your IdP's TokenEndpoint or UserInfoEndpoint. You can either configure TokenEndpoint to return a JSON web token (JWT) or UserInfoEndpoint to return a JSON object. The JWT or JSON object must contain required and optional claims that you specify. A claim is a key-value pair that contains information about a worker or metadata about the OIDC service. The following table lists the claims that must be included, and that can optionally be included in the JWT or JSON object that your IdP returns.

**Note**
Some of the parameters in the following table can be specified using a : or a -. For example, you can specify the groups a worker belongs to using `sagemaker:groups` or `sagemaker-groups` in your claim.

<table>
<thead>
<tr>
<th>Name</th>
<th>Required</th>
<th>Accepted Format and Values</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sagemaker:groups</code></td>
<td>Yes</td>
<td>Data type: string</td>
<td>Assigns a worker to one or more groups. Groups are used to map the worker into work teams.</td>
<td>Example of worker that belongs to a single group: &quot;work_team1&quot;</td>
</tr>
<tr>
<td><code>or sagemaker-groups</code></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Name</td>
<td>Required</td>
<td>Accepted Format and Values</td>
<td>Description</td>
<td>Example</td>
</tr>
<tr>
<td>---------------------</td>
<td>----------</td>
<td>-------------------------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>sagemaker:sub</td>
<td>Yes</td>
<td><strong>Data type:</strong> String</td>
<td>This is mandatory to track a worker identity inside the Ground Truth platform for auditing and to identify tasks worked on by that worker.</td>
<td>&quot;111011101-123456789-3687056437-1111&quot;</td>
</tr>
<tr>
<td>sagemaker:client_id</td>
<td></td>
<td><strong>Data type:</strong> String</td>
<td>A client ID. All tokens must be issued for this client ID.</td>
<td>&quot;00b600bb-1f00-05d0-bd00-00be00fb0e0&quot;</td>
</tr>
<tr>
<td>sagemaker:name</td>
<td>Yes</td>
<td><strong>Data type:</strong> String</td>
<td>The worker name to be displayed in the worker portal.</td>
<td>&quot;Jane Doe&quot;</td>
</tr>
</tbody>
</table>
Use a Private Workforce

<table>
<thead>
<tr>
<th>Name</th>
<th>Required</th>
<th>Accepted Format and Values</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>email</td>
<td>No</td>
<td>Data type: String</td>
<td>The worker email. Ground Truth uses this email to notify workers that they have been invited to work on labeling tasks. Ground Truth will also use this email to notify your workers when labeling tasks become available if you set up an Amazon SNS topic for a work team that this worker is on.</td>
<td>&quot;<a href="mailto:example-email@domain.com">example-email@domain.com</a>&quot;</td>
</tr>
<tr>
<td>email_verified</td>
<td>No</td>
<td>Data type: Bool</td>
<td>Indicates if the user email was verified or not.</td>
<td>True</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Accepted Values: True, False</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The following an example of the JSON object syntax your UserInfoEndpoint can return.

```json
{
    "sub":"122",
    "exp":10000,
    "sagemaker-groups":["group1","group2"],
    "sagemaker-name": "name",
    "sagemaker-sub": "122",
    "sagemaker-client_id": "123456"
}
```

Ground Truth or Amazon A2I compares the groups listed in `sagemaker-groups` or `sagemaker-groups` to verify that your worker belongs to the work team specified in the labeling job or human review task. After the work team has been verified, labeling or human review tasks are sent to that worker.

Create an OIDC IdP Workforce

You can create a workforce using the SageMaker API operation `CreateWorkforce` and associated language-specific SDKs. Specify a `WorkforceName` and information about your OIDC IDP in the parameter `OidcConfig`. It is recommended that you configure your OIDC with a place-holder redirect URI, and then update the URI with the worker portal URL after you create the workforce. To learn more, see Configure your OIDC IdP (p. 993).

The following shows an example of the request. See `CreateWorkforce` to learn more about each parameter in this request.

```json
CreateWorkforceRequest: {
    #required fields
    WorkforceName: "example-oidc-workforce",
    OidcConfig: {
        ClientId: "clientId",
```
Amazon SageMaker Developer Guide
Use a Private Workforce

ClientSecret: "secret",
Issuer: "https://example-oidc-idp.com/adfs",
TokenEndpoint: "https://example-oidc-idp.com/adfs/oauth2/token",
UserInfoEndpoint: "https://example-oidc-idp.com/adfs/oauth2/userInfo",
JwksUri: "https://example-oidc-idp.com/adfs/discovery/keys"
},
SourceIpConfig: {
  Cidrs: ["string", "string"]
}

Configure your OIDC IdP

How you configure your OIDC IdP depends on the IdP you use, and your business requirements.

When you configure your IdP, you must specify a callback or redirect URI. After Ground Truth or Amazon A2I authenticates a worker, this URI will redirect the worker to the worker portal where the workers can access labeling or human review tasks. To create a worker portal URL, you need to create a workforce with your OIDC IdP details using the CreateWorkforce API operation. Specifically, you must configure your OIDC IdP with required custom sagemaker claims (see the next section for more details). Therefore, it is recommended that you configure your OIDC with a place-holder redirect URI, and then update the URI after you create the workforce. See Create an OIDC IdP Workforce (p. 992) to learn how to create a workforce using this API.

You can view your worker portal URL in the SageMaker Ground Truth console, or using the SageMaker API operation, DescribeWorkforce. The worker portal URL is in the SubDomain parameter in the response.

Important
Make sure you add the workforce subdomain to your OIDC IdP allow list. When you add the subdomain to your allow list, it must end with /oauth2/idpresponse.

To view your worker portal URL after creating a private workforce (Console):

2. In the navigation pane, choose Labeling workforces.
3. Select the Private tab.
4. In Private workforce summary you will see Labeling portal sign-in URL. This is your worker portal URL.

To view your worker portal URL after creating a private workforce (API):

When you create a private workforce using CreateWorkforce, you specify a WorkforceName. Use this name to call DescribeWorkforce. The following table includes examples of requests using the AWS CLI and AWS SDK for Python (Boto3).

**SDK for Python (Boto3)**

```python
response = client.describe_workforce(WorkforceName='string')
print(f'The workforce subdomain is: {response['SubDomain']}')
```

**AWS CLI**

```
$ C:\> describe-workforce --workforce-name 'string'
```
Validate Your OIDC IdP Workforce Authentication Response

After you have created your OIDC IdP workforce, you can use the following procedure to validate its authentication workflow using cURL. This procedure assumes you have access to a terminal, and that you have cURL installed.

To validate your OIDC IdP authorization response:

1. Get an authorization code using a URI configured as follows:

   ```
   {AUTHORIZE ENDPOINT}?client_id={CLIENT ID}&redirect_uri={REDIRECT URI}&scope={SCOPE}&response_type=code
   ```

   a. Replace `{AUTHORIZE ENDPOINT}` with the authorize endpoint for your OIDC IdP.
   
   b. Replace `{CLIENT ID}` with the Client ID from your OAuth client.
   
   c. Replace `{REDIRECT URI}` with the worker portal URL. If it is not already present, you must add `/oauth2/idpresponse` to the end of the URL.
   
   d. If you have a custom scope, use it to replace `{SCOPE}`. If you do not have a custom scope, replace `{SCOPE}` with `openid`.

   The following is an example of a URI after the modifications above are made:

   ```
   ```

2. Copy and paste the modified URI from step 1 into your browser and press Enter on your keyboard.

3. Authenticate using your IdP.

4. Copy the authentication code query parameter in the URI. This parameter beings with `code=`.

   The following is an example of what the response might look like. In this example, copy `code=MCNYDB...` and everything thereafter.

   ```
   https://example.labeling.sagemaker.aws/oauth2/idpresponse?code=MCNYDB....
   ```

5. Open a terminal and enter the following command after making required modifications listed below:

   ```
   curl --request POST \
   --url '{TOKEN ENDPOINT}' \
   --header 'content-type: application/x-www-form-urlencoded' \
   --data grant_type=authorization_code \
   --data 'client_id={CLIENT ID}' \
   --data client_secret={CLIENT SECRET} \
   --data code={CODE} \
   --data 'redirect_uri={REDIRECT URI}'
   ```

   a. Replace `{TOKEN ENDPOINT}` with the token endpoint for your OIDC IdP.
   
   b. Replace `{CLIENT ID}` with the Client ID from your OAuth client.
   
   c. Replace `{CLIENT SECRET}` with the Client Secret from your OAuth client.
   
   d. Replace `{CODE}` with the authentication code query parameter you copied in step 4.
   
   e. Replace `{REDIRECT URI}` with the worker portal URL.

   The following is an example of the cURL request after making the modifications described above:
curl --request POST \
--url 'https://example.com/token' \
--header 'content-type: application/x-www-form-urlencoded' \
--data grant_type=authorization_code \
--data 'client_id=f490a907-9bf1-4471-97aa-6bf1d59f81ac' \
--data client_secret=client-secret \
--data code=MCNYDB... \
--data 'redirect_uri=https://example.labeling.sagemaker.aws/oauth2/idpresponse'

6. This step depends on the type of access_token your IdP returns, a plain text access token or a JWT access token.

   - If your IdP does not support JWT access tokens, access_token may be plain text (for example, a UUID). The response you see may look similar to the following. In this case, move to step 7.

   ```json
   {  
     "access_token":"179c144b-fccb-4d96-a28f-eea060f39c13",  
     "token_type":"Bearer",  
     "expires_in":3600,  
     "refresh_token":"ef43e52e-9b4f-410c-8d4c-d5c5ee57631a",  
     "scope":"openid"  
   }
   
   - If your IdP supports JWT access tokens, step 5 should generate an access token in JWT format. For example, the response may look similar to the following:

   ```json
   {  
     "access_token":"eyJ0eXAiOiJK9...JV_adQssw5c",  
     "refresh_token":"i6mapTIAVSp2oJkgUnCACKKFZxt_H5MBLiqcybBBd04",  
     "refresh_token_expires_in":6327,  
     "scope":"openid",  
     "id_token":"eyJ0eXAiOiJK9...-rDaQzUHl6cQQWNiDpWOl_lxXjQEvQ"
   }
   
   Copy the JWT and decode it. You can use python script or a third party website to decode it. For example, you can go to the website [https://jwt.io/](https://jwt.io/) and paste the JWT into the **Encoded** box to decode it.

   Make sure the decoded response contains the following:
   - The **Required** SageMaker claims in the table found in [Send Required and Optional Claims to Ground Truth and Amazon A2I](p. 990). If it does not, you must reconfigure your OIDC IdP to contain these claims.
   - The **Issuer** you specified when you set up the IdP workforce.

7. In a terminal and enter the following command after making required modifications listed below:

   ```bash
   curl -X POST -H 'Authorization: Bearer {ACCESS_TOKEN}' -d '' -k -v {USERINFO ENDPOINT}
   
a. Replace `{USERINFO ENDPOINT}` with the user info endpoint for your OIDC IdP.

b. Replace `{ACCESS_TOKEN}` with the access token in the response you received in step 7. This is the entry for the "access_token" parameter.

   The following is an example of the cURL request after making the modifications described above:

   ```bash
   curl -X POST -H 'Authorization: Bearer eyJ0eX...' -d '' -k -v https://example.com/userinfo
   ```
8. The response to the final step in the procedure above may look similar to the following code block.

If the access_token returned in step 6 was plain text, you must verify that this response contains required information. In this case, the response must contain the **Required** SageMaker claims in the table found in `Send Required and Optional Claims to Ground Truth and Amazon A2I` (p. 990). For example, `sagemaker-groups`, `sagemaker-name`.

```json
{
    "sub":"122",
    "exp":"10000",
    "sagemaker-groups":["group1","group2"]
    "sagemaker-name":"name",
    "sagemaker-sub":"122",
    "sagemaker-client_id":"123456"
}
```

**Next Steps**

Once you've created a private workforce using your IdP and verified your IdP authentication response, you can create work teams using your IdP groups. To learn more, see `Manage a Private Workforce (OIDC IdP)` (p. 996).

You can restrict worker access to tasks to specific IP addresses, and update or delete your workforce using the SageMaker API. To learn more, see `Manage Private Workforce Using the Amazon SageMaker API` (p. 999).

**Manage a Private Workforce (OIDC IdP)**

Once you've created a private workforce using your OpenID Connect (OIDC) Identity Provider (IdP), you can manage your workers using your IdP. For example, you can add, remove, and group workers directly through your IdP.

To add workers to an Amazon SageMaker Ground Truth (Ground Truth) labeling job or Amazon Augmented AI (Amazon A2I) human review task, you create work teams using 1-10 IdP groups and assign that work team to the job or task. You assign a work team to a job or task by specifying that work team when you create a labeling job (Ground Truth) or a human review workflow (Amazon A2I).

You can only assign one team to each labeling job or human review workflow. You can use the same team to create multiple labeling jobs or human review tasks. You can also create multiple work teams to work on different labeling jobs or human review tasks.

**Prerequisites**

To create and manage private work teams using your OIDC IdP groups, first you must create a workforce using the SageMaker API operation `CreateWorkforce`. To learn more, see `Create a Private Workforce (OIDC IdP)` (p. 990).

**Add work teams**

You can use the SageMaker console to create a private work team using your OIDC IdP workforce on the **Labeling workforces** page under **Ground Truth**. If you are creating a Ground Truth labeling job, you can also create a private work team while creating a labeling job.

**Note**

You create and manage work teams for Amazon A2I in the Ground Truth area of the SageMaker console.

You can also use the SageMaker API and associated language-specific SDKs to create a private work team.
Use the following procedures to learn how to create a private work team using the SageMaker console and API.

**To create a private work team on the Labeling workforces page (console)**

2. Select **Labeling workforces**.
3. Select **Private**.
4. In the **Private teams** section, select **Create private team**.
5. In the **Team details** section, enter a **Team name**.
6. In the **Add workers** section, enter the name of a single user group. All workers associated with this group in your IdP are added to this work team.
7. To add more than one user group, select **Add new user group** and enter the names of the user groups you want to add to this work team. Enter one user group per line.
8. (Optional) For Ground Truth labeling jobs, if you provide an email for workers in your JWT, Ground Truth notifies workers when a new labeling task is available if you select an SNS topic.
9. Select **Create private team**.

**To create a private work team while creating a Ground Truth labeling job (console)**

2. Select **Labeling jobs**.
3. Use the instructions in **Create a Labeling Job (Console)** (p. 820) to create a labeling job. Stop when you get to the **Workers** section on the second page.
4. Select **Private** for your worker type.
5. Enter a **Team name**.
6. In the **Add workers** section, enter the name of a single user group under **User groups**. All workers associated with this group in your IdP are added to this work team.

   **Important**
   The group names you specify for **User groups** must match the group names specified in your OIDC IdP.

7. To add more than one user group, select **Add new user group** and enter the names of the user groups you want to add to this work team. Enter one user group per line.
8. Complete all remaining steps to create your labeling job.

The private team that you create is used for this labeling job, and is listed in the **Labeling workforces** section of the SageMaker console.

**To create a private work team using the SageMaker API**

You can create a private work team using the SageMaker API operation **CreateWorkteam**.

When you use this operation, list all user groups that you want included in the work team in the **OidcMemberDefinition** parameter **Groups**.

**Important**
The group names you specify for **Groups** must match the group names specified in your OIDC IdP.
For example, if your user group names are group1, group2, and group3 in your OIDC IdP, configure OidcMemberDefinition as follows:

```
"OidcMemberDefinition": {
  "Groups": ["group1", "group2", "group3"]
}
```

Additionally, you must give the work team a name using the WorkteamName parameter.

**Add or remove IdP groups from work teams**

After you've created a work team, you can use the SageMaker API to manage that work team. Use the UpdateWorkteam operation to update the IdP user groups included in that work team.

- Use the WorkteamName parameter to identify the work team that you want to update.
- When you use this operation, list all user groups that you want included in the work team in the OidcMemberDefinition parameter Groups. If a user group is associated with a work team and you do not include it in this list, that user group is no longer associated with this work team.

**Delete a work team**

You can delete a work team using the SageMaker console and SageMaker API.

**To delete a private work team in the SageMaker console**

2. Select Labeling workforces.
3. Select Private.
4. In the Private teams section, select the work team that you want to delete.
5. Select Delete.

**To delete a private work team (API)**

You can delete a private work team using the SageMaker API operation DeleteWorkteam.

**Manage Individual Workers**

When you create a workforce using your own OIDC IdP, you cannot use Ground Truth or Amazon A2I to manage individual workers.

- To add a worker to a work team, add that worker to a group associated with that work team.
- To remove a worker from a work team, remove that worker from all user groups associated with that work team.

**Update, Delete, and Describe Your Workforce**

You can update, delete, and describe your OIDC IdP workforce using the SageMaker API. The following is a list of API operations that you can use to manage your workforce. For additional details, including how you can locate your workforce name, see Manage Private Workforce Using the Amazon SageMaker API (p. 999).

- **UpdateWorkforce** – You may want to update a workforce created using your own OIDC IdP to specify a different authorization endpoint, token endpoint, or issuer. You can update any parameter found in OidcConfig using this operation.
You can only update your OIDC IdP configuration when there are no work teams associated with your workforce. To learn how to delete work teams, see [Delete a work team](#)

- **DeleteWorkforce** – Use this operation to delete your private workforce. If you have any work teams associated with your workforce, you must delete those work teams before you delete your workforce. For more information, see [Delete a work team](#).
- **DescribeWorkforce** – Use this operation to list private workforce information, including workforce name, Amazon Resource Name (ARN), and, if applicable, allowed IP address ranges (CIDRs).

### Manage Private Workforce Using the Amazon SageMaker API

You can use Amazon SageMaker API operations to manage, update, and delete your private workforce. For each API operation linked on this page, you can find a list of supported language-specific SDKs and their documentation in the See Also section of the API documentation.

#### Find Your Workforce Name

Some of the SageMaker workforce-related API operations require your workforce name as input. You can see your Amazon Cognito or OIDC IdP private and vendor workforce names in an AWS Region using the ListWorkforces API operation in that AWS Region.

If you created your workforce using your own OIDC IdP, you can find your workforce name in the Ground Truth area of the SageMaker console.

**To find your workforce name in the SageMaker console**

2. Select Labeling workforces.
3. Select Private.
4. In the Private workforce summary section, locate your workforce ARN. Your workforce name is located at the end of this ARN. For example, if the ARN is `arn:aws:sagemaker:us-east-2:111122223333:workforce/example-workforce`, the workforce name is `example-workforce`.

#### Restrict Worker Access to Tasks to Allowable IP Addresses

By default, a workforce isn't restricted to specific IP addresses. You can use the UpdateWorkforce operation to require that workers use a specific range of IP addresses (CIDRs) to access tasks. If you specify one or more CIDRs, workers who attempt to access tasks using any IP address outside the specified ranges are denied and will get a HTTP 204 No Content error message on the worker portal. You can specify up to 10 CIDR values using UpdateWorkforce.

After you have restricted your workforce to one or more CIDRs, the output of UpdateWorkforce lists all allowable CIDRs. You can also use the DescribeWorkforce operation to view all allowable CIDRs for a workforce.

#### Update OIDC Identity Provider Workforce Configuration

You may want to update a workforce created using your own OIDC IdP to specify a different authorization endpoint, token endpoint, or issuer. You can update any parameter found in OidcConfig using the UpdateWorkforce operation.

**Important**

You can only update your OIDC IdP configuration when there are no work teams associated with your workforce. You can delete a private work team using the DeleteWorkteam operation.
Delete a Private Workforce

You can only have one private workforce in each AWS Region. You may want to delete your private workforce in an AWS Region when:

- You want to create a workforce using a new Amazon Cognito user pool.
- You have already created a private workforce using Amazon Cognito and you want to create a workforce using your own OpenID Connect (OIDC) Identity Provider (IdP).

To delete a private workforce, use the `DeleteWorkforce` API operation. If you have any work teams associated with your workforce, you must delete those work teams before you delete your workforce. You can delete a private work team using the `DeleteWorkteam` operation.

Track Worker Performance

Amazon SageMaker Ground Truth logs worker events to Amazon CloudWatch, such as when a worker starts or submits a task. Use Amazon CloudWatch metrics to measure and track throughput across a team or for individual workers.

**Important**
Worker event tracking is not available for Amazon Augmented AI human review workflows.

Enable Tracking

During the set-up process for a new work team, the permissions for Amazon CloudWatch logging of worker events are created. Since this feature was added in August 2019, work teams created prior to that may not have the correct permissions. If all of your work teams were created before August 2019, create a new work team. It does not need any members and may be deleted after creation, but by creating it, you establish the permissions and apply them to all of your work teams, regardless of when they were created.

Examine Logs

After tracking is enabled, the activity of your workers is logged. Open the Amazon CloudWatch console and choose Logs in the navigation pane. You should see a log group named `/aws/sagemaker/groundtruth/WorkerActivity`.

Each completed task is represented by a log entry, which contains information about the worker, their team, the job, when the task was accepted, and when it was submitted.

Example Log entry

```json
{
    "worker_id": "cd449a289e129409",
    "cognito_user_pool_id": "us-east-2_IpicJXXXX",
    "cognito_sub_id": "d6947abc-0250-447a-ab5d-894db61017fd",
    "task_accepted_time": "Wed Aug 14 16:00:59 UTC 2019",
    "task_submitted_time": "Wed Aug 14 16:01:04 UTC 2019",
    "task_returned_time": "",
    "task_declined_time": "",
    "work_requester_account_id": "1234567890",
    "job_reference_code": "1234567890",
    "job_type": "Private",
    "event_type": "TasksSubmitted",
    "event_timestamp": "1565798464"
}
```
A useful data point in each event is the cognito_sub_id. You can match that to an individual worker.

2. Under the **Ground Truth** section, choose **Workforces**.
3. Choose **Private**.
4. Choose the name of a team in the **Private teams** section.
5. In the **Team summary** section, choose the user group identified under **Amazon Cognito user group**. That will take you to the group in the Amazon Cognito console.
6. The **Group** page lists the users in the group. Choose any user's link in the **Username** column to see more information about the user, including a unique sub ID.

To get information about all of the team's members, use the ListUsers action (examples) in the Amazon Cognito API.

**Use Log Metrics**

If you don't want to write your own scripts to process and visualize the raw log information, Amazon CloudWatch metrics provide insights into worker activity for you.

**To view metrics**

2. In the navigation pane, choose **Metrics**.
3. Choose the AWS/SageMaker/Workteam name space, then explore the available metrics (p. 3577). For example, selecting the **Workteam** and **Workforce** metrics lets you calculate the average time per submitted task for a specific labeling job.

For more information, see [Using Amazon CloudWatch Metrics](https://docs.aws.amazon.com/AmazonSageMaker/latest/DG/using-cloudwatch-metrics.html).

**Create and manage Amazon SNS topics for your work teams**

Use the procedures in this topic when you want to:

- Create a topic to which you want an existing work team to subscribe.
- Create a topic before you've created a work team.
- Create or modify the work team with an API call, and specify a topic Amazon Resource Name (ARN).

If you create a work team using the console, the console provides an option to create a new topic for the team so that you don't have to perform these steps.

**Important**

The Amazon SNS feature is not supported by Amazon A2I. If you subscribe your work team to an Amazon SNS topic, workers will only receive notifications about Ground Truth labeling jobs. Workers will not receive notifications about new Amazon A2I human review tasks.

**Create the Amazon SNS topic**

The steps for creating Amazon SNS topics for work team notifications are similar to the steps in Getting Started in the Amazon SNS Developer Guide, with one significant addition—you must add an access policy so that Amazon SageMaker can publish messages to the topic on your behalf.
To add the policy when you create the topic

2. In Create topic, enter the name of your topic and then choose Next steps.
4. In the JSON editor, find the Resource property, which displays the topic's ARN.
5. Copy the Resource ARN value.
6. Before the final closing brace (}), add the following policy.

   ```json
   , {
       "Sid": "AwsSagemaker_SnsAccessPolicy",
       "Effect": "Allow",
       "Principal": {
         "Service": "sagemaker.amazonaws.com"
       },
       "Action": "sns:Publish",
       "Resource": "arn:partition:sns:region:111122223333:MyTopic", # ARN of the topic you copied in the previous step
       "Condition": {
         "ArnLike": {
           "aws:SourceArn": "arn:partition:sagemaker:region:111122223333:workteam/*" # Workteam ARN
         },
         "StringEquals": {
           "aws:SourceAccount": "111122223333" # SNS topic account
         }
       }
   }
   ```
7. Create the topic.

After you create the topic, it appears in your Topics summary screen. For more information about creating topics, see Creating a Topic in the Amazon SNS Developer Guide.

Manage worker subscriptions

If you subscribe a work team to a topic after you've already created the work team, the individual work team members who were added to the team when the work team was created are not automatically subscribed to the topic. For information about subscribing workers' email addresses to the topic, see Subscribing an Endpoint to an Amazon SNS Topic in the Amazon SNS Developer Guide.

The only situation in which workers are automatically subscribed to your topic is when you create or import an Amazon Cognito user group at the time that you create a work team and you set up the topic subscription when you create that work team. For more information about creating and managing your workteams with Amazon Cognito, see Create Work Teams (Amazon Cognito Console) (p. 988).

Crowd HTML Elements Reference

Crowd HTML Elements are web components, a web standard that abstracts HTML markup, CSS, and JavaScript functionality into an HTML tag or set of tags. Amazon SageMaker provides customers with the ability to design their own custom task templates in HTML.

As a starting point, you can use a template built using Crowd HTML Elements from one of the following GitHub repositories:
• Example task UIs for Amazon SageMaker Ground Truth
• Over 60 example task UIs for Amazon Augmented AI (A2I)

These repositories include templates designed for audio, image, text, video, and other types of data labeling and annotation tasks.

For more information about how to implement custom templates in Amazon SageMaker Ground Truth, see Creating Custom Labeling Workflows (p. 785). To learn more about custom templates in Amazon Augmented AI, see Create Custom Worker Task Templates (p. 1139).

SageMaker Crowd HTML Elements

The following is a list of Crowd HTML Elements that make building a custom template easier and provide a familiar UI for workers. These elements are supported in Ground Truth, Augmented AI, and Mechanical Turk.

Topics
• crowd-alert (p. 1004)
• crowd-badge (p. 1005)
• crowd-button (p. 1007)
• crowd-bounding-box (p. 1008)
• crowd-card (p. 1012)
• crowd-checkbox (p. 1014)
• crowd-classifier (p. 1016)
• crowd-classifier-multi-select (p. 1018)
• crowd-entity-annotation (p. 1020)
• crowd-fab (p. 1023)
• crowd-form (p. 1025)
• crowd-icon-button (p. 1026)
• crowd-image-classifier (p. 1027)
• crowd-image-classifier-multi-select (p. 1031)
• crowd-input (p. 1033)
• crowd-instance-segmentation (p. 1035)
• crowd-instructions (p. 1039)
• crowd-keypoint (p. 1041)
• crowd-line (p. 1045)
• crowd-modal (p. 1048)
• crowd-polygon (p. 1049)
• crowd-polyline (p. 1054)
• crowd-radio-button (p. 1058)
• crowd-radio-group (p. 1060)
• crowd-semantic-segmentation (p. 1062)
• crowd-slider (p. 1065)
• crowd-tab (p. 1067)
• crowd-tabs (p. 1068)
• crowd-text-area (p. 1070)
• **crowd-toast** *(p. 1072)*
• **crowd-toggle-button** *(p. 1073)*

**crowd-alert**

A message that alerts the worker to a current situation.

See an interactive example of an HTML template that uses this Crowd HTML Element in [CodePen](https://codepen.io).

The following is an example of a Liquid template that uses the `<crowd-alert>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <div id="errorBox"></div>

  <crowd-keypoint
    src="{{ task.input.taskObject | grant_read_access }}"
    labels="['Item A', 'Item B', 'Item C']"
    header="Please locate the centers of each item."
    name="annotatedResult">
    <short-instructions>
      Describe your task briefly here and give examples
    </short-instructions>
    <full-instructions>
      Give additional instructions and good/bad examples here
    </full-instructions>
  </crowd-keypoint>

  <script>
    var num_obj = 1;

    document.querySelector('crowd-form').onsubmit = function(e) {
      const keypoints = document.querySelector('crowd-keypoint').value.keypoints ||
        document.querySelector('crowd-keypoint')._submittableValue.keypoints;
      const labels = keypoints.map(function(p) {
        return p.label;
      });

      // 1. Make sure total number of keypoints is correct.
      var original_num_labels = document.getElementsByTagName("crowd-keypoint")
        [0].getAttribute("labels");
      original_num_labels = original_num_labels.substring(2, original_num_labels.length - 2).split("\","");
      var goalNumKeypoints = num_obj*original_num_labels.length;
      if (keypoints.length != goalNumKeypoints) {
        e.preventDefault();
        errorBox.innerHTML = '<crowd-alert type="error" dismissible>You must add all keypoint annotations and use each label only once.</crowd-alert>';
        errorBox.scrollIntoView();
        return;
      }

      // 2. Make sure all labels are unique.
      labelCounts = {};
      for (var i = 0; i < labels.length; i++) {
        if (!labelCounts[labels[i]]) {
          labelCounts[labels[i]] = 0;
        }
      }
    }
  </script>
</crowd-form>
```
} 

```javascript
labelCounts[labels[i]]++; 
}
const goalNumSingleLabel = num_obj;
const numLabels = Object.keys(labelCounts).length;
Object.entries(labelCounts).forEach(entry => {
    if (entry[1] != goalNumSingleLabel) {
        e.preventDefault();
        errorBox.innerHTML = '<crowd-alert type="error" dismissible>You must use each label only once.</crowd-alert>';
        errorBox.scrollIntoView();
    }
})
</script>

Attributes

The following attributes are supported by this element.

**dismissible**

A Boolean switch that, if present, allows the message to be closed by the worker.

**type**

A string that specifies the type of message to be displayed. The possible values are "info" (the default), "success", "error", and "warning".

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 1025)
- **Child elements**: none

See Also

For more information, see the following.

- Use Amazon SageMaker Ground Truth to Label Data (p. 640)
- Crowd HTML Elements Reference (p. 1002)

**crowd-badge**

An icon that floats over the top right corner of another element to which it is attached.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a template that uses the `<crowd-badge>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
  <crowd-image-classifier
    name="crowd-image-classifier"
    src="https://unsplash.com/photos/NLUkAA-nDdE"
    header="Choose the correct category for this image."
    categories="["Person", "Umbrella", "Chair", "Dolphin"]"
  >
    <full-instructions header="Classification Instructions">
      <p>Read the task carefully and inspect the image.</p>
      <p>Choose the appropriate label that best suits the image.</p>
    </full-instructions>
    <short-instructions id="short-instructions">
      <p>Read the task carefully and inspect the image.</p>
      <p>Choose the appropriate label that best suits the image.</p>
      <crowd-badge icon="star" for="short-instructions"/>
    </short-instructions>
  </crowd-image-classifier>
</crowd-form>

Attributes

The following attributes are supported by this element.

for

A string that specifies the ID of the element to which the badge is attached.

icon

A string that specifies the icon to be displayed in the badge. The string must be either the name of an icon from the open-source iron-icons set, which is pre-loaded, or the URL to a custom icon.

This attribute overrides the label attribute.

The following is an example of the syntax that you can use to add an iron-icon to a <crowd-badge> HTML element. Replace icon-name with the name of the icon you'd like to use from this Icons set.

<crowd-badge icon="icon-name" for="short-instructions"/>

label

The text to display in the badge. Three characters or less is recommended because text that is too large will overflow the badge area. An icon can be displayed instead of text by setting the icon attribute.

Element Hierarchy

This element has the following parent and child elements.

- Parent elements: crowd-form (p. 1025)
- Child elements: none

See Also

For more information, see the following.

- Use Amazon SageMaker Ground Truth to Label Data (p. 640)
• Crowd HTML Elements Reference (p. 1002)

crowd-button
A styled button that represents some action.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a template that uses the `<crowd-button>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <crowd-image-classifier
    name="crowd-image-classifier"
    src="https://unsplash.com/photos/NLUkAA-nDdE"
    header="Please select the correct category for this image"
    categories="["Person", "Umbrella", "Chair", "Dolphin"]"
  >
    <full-instructions header="Classification Instructions">
      <p>Read the task carefully and inspect the image.</p>
      <p>Choose the appropriate label that best suits the image.</p>
    </full-instructions>
    <short-instructions>
      <p>Read the task carefully and inspect the image.</p>
      <p>Choose the appropriate label that best suits the image.</p>
    </short-instructions>
    <crowd-button>
      <iron-icon icon="question-answer"/>
    </crowd-button>
  </crowd-image-classifier>
</crowd-form>
```

Attributes
The following attributes are supported by this element.

disabled
A Boolean switch that, if present, displays the button as disabled and prevents clicks.

form-action
A switch that either submits its parent `<crowd-form>` element, if set to "submit", or resets its parent `<crowd-form>` element, if set to "reset".

href
The URL to an online resource. Use this property if you need a link styled as a button.

icon
A string that specifies the icon to be displayed next to the button's text. The string must be the name of an icon from the open-source iron-icons set, which is pre-loaded. For example, to insert the search iron-icon, use the following:

```html
<crowd-button>
<iron-icon icon="search"/>
</crowd-button>
```
The icon is positioned to either the left or the right of the text, as specified by the `icon-align` attribute.

To use a custom icon see `icon-url`.

`icon-align`

The left or right position of the icon relative to the button's text. The default is "left".

`icon-url`

A URL to a custom image for the icon. A custom image can be used in place of a standard icon that is specified by the `icon` attribute.

`loading`

A Boolean switch that, if present, displays the button as being in a loading state. This attribute has precedence over the `disabled` attribute if both attributes are present.

`target`

When you use the `href` attribute to make the button act as a hyperlink to a specific URL, the `target` attribute optionally targets a frame or window where the linked URL should load.

`variant`

The general style of the button. Use "primary" for primary buttons, "normal" for secondary buttons, "link" for tertiary buttons, or "icon" to display only the icon without text.

**Element Hierarchy**

This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 1025)
- **Child elements**: none

**See Also**

For more information, see the following.

- Use Amazon SageMaker Ground Truth to Label Data (p. 640)
- Crowd HTML Elements Reference (p. 1002)

**crowd-bounding-box**

A widget for drawing rectangles on an image and assigning a label to the portion of the image that is enclosed in each rectangle.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that uses the `<crowd-bounding-box>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template. For more examples, see this GitHub repository.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
```
Attributes

The following attributes are supported by this element.

header

The text to display above the image. This is typically a question or simple instruction for the worker.

initial-value

An array of JSON objects, each of which sets a bounding box when the component is loaded. Each JSON object in the array contains the following properties. Bounding boxes set via the initial-value property can be adjusted and whether or not a worker answer was adjusted is tracked via an initialValueModified boolean in the worker answer output.

- **height** – The height of the box in pixels.
- **label** – The text assigned to the box as part of the labeling task. This text must match one of the labels defined in the *labels* attribute of the `<crowd-bounding-box>` element.
- **left** – Distance of the top-left corner of the box from the left side of the image, measured in pixels.
- **top** – Distance of the top-left corner of the box from the top of the image, measured in pixels.
- **width** – The width of the box in pixels.

You can extract the bounding box initial value from a manifest file of a previous job in a custom template using the Liquid templating language:

```html
initial-value="[ ]
```
labels

A JSON formatted array of strings, each of which is a label that a worker can assign to the image portion enclosed by a rectangle. **Limit:** 10 labels.

ame

The name of this widget. It's used as a key for the widget's input in the form output.

src

The URL of the image on which to draw bounding boxes.

**Element Hierarchy**

This element has the following parent and child elements.

- **Parent elements:** crowd-form (p. 1025)
- **Child elements:** full-instructions (p. 1010), short-instructions (p. 1010)

**Regions**

The following regions are required by this element.

full-instructions

General instructions about how to draw bounding boxes.

short-instructions

Important task-specific instructions that are displayed in a prominent place.

**Output**

The following output is supported by this element.

boundingBoxes

An array of JSON objects, each of which specifies a bounding box that has been created by the worker. Each JSON object in the array contains the following properties.

- **height** – The height of the box in pixels.
• **label** – The text assigned to the box as part of the labeling task. This text must match one of the labels defined in the `labels` attribute of the `<crowd-bounding-box>` element.
• **left** – Distance of the top-left corner of the box from the left side of the image, measured in pixels.
• **top** – Distance of the top-left corner of the box from the top of the image, measured in pixels.
• **width** – The width of the box in pixels.

**inputImageProperties**

A JSON object that specifies the dimensions of the image that is being annotated by the worker. This object contains the following properties.

• **height** – The height, in pixels, of the image.
• **width** – The width, in pixels, of the image.

**Example: Sample Element Outputs**

The following are samples of outputs from common use scenarios for this element.

**Single Label, Single Box / Multiple Label, Single Box**

```json
[
  {
    "annotatedResult": {
      "boundingBoxes": [
        {
          "height": 401,
          "label": "Dog",
          "left": 243,
          "top": 117,
          "width": 187
        }
      ],
      "inputImageProperties": {
        "height": 533,
        "width": 800
      }
    }
  }
]
```

**Single Label, Multiple Box**

```json
[
  {
    "annotatedResult": {
      "boundingBoxes": [
        {
          "height": 401,
          "label": "Dog",
          "left": 243,
          "top": 117,
          "width": 187
        },
        {
          "height": 283,
          "label": "Dog",
          "left": 684,
          "top": 120,
          "width": 116
        }
      ]
    }
  }
]
Multiple Label, Multiple Box

```
[
    {
        "annotatedResult": {
            "boundingBoxes": [
                {
                    "height": 395,
                    "label": "Dog",
                    "left": 241,
                    "top": 125,
                    "width": 158
                },
                {
                    "height": 298,
                    "label": "Cat",
                    "left": 699,
                    "top": 116,
                    "width": 101
                }
            ],
            "inputImageProperties": {
                "height": 533,
                "width": 800
            }
        }
    }
]
```

You could have many labels available, but only the ones that are used appear in the output.

**See Also**

For more information, see the following.

- Use Amazon SageMaker Ground Truth to Label Data (p. 640)
- Crowd HTML Elements Reference (p. 1002)

**crowd-card**

A box with an elevated appearance for displaying information.

See an interactive example of an HTML template that uses this Crowd HTML Element in [CodePen](https://codepen.io).

The following is an example of a template designed for sentiment analysis tasks that uses the `<crowd-card>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
```
<style>
  h3 {
    margin-top: 0;
  }

crowd-card {
  width: 100%;
}

card {
  margin: 10px;
}

.left {
  width: 70%;
  margin-right: 10px;
  display: inline-block;
  height: 200px;
}

.right {
  width: 20%;
  height: 200px;
  display: inline-block;
}
</style>

<crowd-form>
  <short-instructions>
    Your short instructions here.
  </short-instructions>

      <div class="card">
        Everything is great!
      </div>
    </crowd-card>
  </div>
</crowd-form>
<div class="right">
<h3>Select an option</h3>
<select name="sentiment2" style="font-size: large" required>
  <option value="">(Please select)</option>
  <option>Negative</option>
  <option>Neutral</option>
  <option>Positive</option>
  <option>Text is empty</option>
</select>
</div>
</crowd-form>

Attributes

The following attributes are supported by this element.

heading

The text displayed at the top of the box.

image

A URL to an image to be displayed within the box.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 1025)
- **Child elements**: none

See Also

For more information, see the following.

- Use Amazon SageMaker Ground Truth to Label Data (p. 640)
- Crowd HTML Elements Reference (p. 1002)

crowd-checkbox

A UI component that can be checked or unchecked allowing a user to select multiple options from a set.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that uses the <crowd-checkbox> element. Copy the following code and save it in a file with the extension .html. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<form>
  <p>Find the official website for: <strong>{{ task.input.company }}</strong></p>
  <p>Do not give Yelp pages, LinkedIn pages, etc.</p>
  <p>Include the http:// prefix from the website</p>
  <input type="text" name="website" placeholder="http://example.com">
</form>
```
Attributes

The following attributes are supported by this element.

checked

A Boolean switch that, if present, displays the check box as checked.

The following is an example of the syntax used to check a checkbox by default.

```html
<crowd-checkbox name="checkedBox" value="checked" checked>This box is checked</crowd-checkbox>
```

disabled

A Boolean switch that, if present, displays the check box as disabled and prevents it from being checked.

The following is an example of the syntax used to disable a checkbox.

```html
<crowd-checkbox name="disabledCheckBox" value="Disabled" disabled>Cannot be selected</crowd-checkbox>
```

name

A string that is used to identify the answer submitted by the worker. This value will match a key in the JSON object that specifies the answer.

required

A Boolean switch that, if present, requires the worker to provide input.

The following is an example of the syntax used to require a checkbox be selected.

```html
<crowd-checkbox name="work_verified" required>Instructions were clear</crowd-checkbox>
```

value

A string used as the name for the check box state in the output. Defaults to "on" if not specified.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 1025)
- **Child elements**: none

Output

Provides a JSON object. The name string is the object name and the value string is the property name for a Boolean value based on the check box state; true if checked, false if not checked.
Example: Sample Element Outputs

Using the same name value for multiple boxes.

```html
<!-- INPUT -->
<div><crowd-checkbox name="image_attributes" value="blurry"> Blurry </crowd-checkbox></div>
<div><crowd-checkbox name="image_attributes" value="dim"> Too Dim </crowd-checkbox></div>
<div><crowd-checkbox name="image_attributes" value="exposed"> Too Bright </crowd-checkbox></div>
```

//Output with "blurry" and "dim" checked
[
  {
    "image_attributes": {
      "blurry": true,
      "dim": true,
      "exposed": false
    }
  }
]

Note that all three color values are properties of a single object.

Using different name values for each box.

```html
<!-- INPUT -->
<div><crowd-checkbox name="Stop" value="Red"> Red </crowd-checkbox></div>
<div><crowd-checkbox name="Slow" value="Yellow"> Yellow </crowd-checkbox></div>
<div><crowd-checkbox name="Go" value="Green"> Green </crowd-checkbox></div>
```

//Output with "Red" checked
[
  {
    "Go": {
      "Green": false
    },
    "Slow": {
      "Yellow": false
    },
    "Stop": {
      "Red": true
    }
  }
]

See Also

For more information, see the following.

- Use Amazon SageMaker Ground Truth to Label Data (p. 640)
- Crowd HTML Elements Reference (p. 1002)

crowd-classifier

A widget for classifying non-image content, such as audio, video, or text.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.
The following is an example of an HTML worker task template built using crowd-classifier. This example uses the Liquid template language to automate:

- Label categories in the categories parameter
- The objects that are being classified in the classification-target parameter.

Copy the following code and save it in a file with the extension .html. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <crowd-classifier
    name="category"
    categories="{{ task.input.labels | to_json | escape }}"
    header="What type of a document is this?"
  >
    <classification-target>
      <iframe style="width: 100%; height: 600px;" src="{{ task.input.taskObject | grant_read_access }}" type="application/pdf"></iframe>
    </classification-target>
    <full-instructions header="Document Classification Instructions">
      <p>Read the task carefully and inspect the document.</p>
      <p>Choose the appropriate label that best suits the document.</p>
    </full-instructions>
    <short-instructions>
      Please choose the correct category for the document
    </short-instructions>
  </crowd-classifier>
</crowd-form>
```

**Attributes**

The following attributes are supported by this element.

- **categories**
  A JSON formatted array of strings, each of which is a category that a worker can assign to the text. You should include "other" as a category, otherwise the worker may not be able to provide an answer.

- **header**
  The text to display above the image. This is typically a question or simple instruction for the worker.

- **name**
  The name of this widget. It is used as a key for the widget's input in the form output.

**Element Hierarchy**

This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 1025)
- **Child elements**: classification-target (p. 1018), full-instructions (p. 1018), short-instructions (p. 1018)

**Regions**

The following regions are supported by this element.
classification-target

The content to be classified by the worker. This can be plain text or HTML. Examples of how the HTML can be used include but are not limited to embedding a video or audio player, embedding a PDF, or performing a comparison of two or more images.

full-instructions

General instructions about how to do text classification.

short-instructions

Important task-specific instructions that are displayed in a prominent place.

Output

The output of this element is an object using the specified name value as a property name, and a string from the categories as the property's value.

Example : Sample Element Outputs

The following is a sample of output from this element.

```
[{
  "<name>": {
    "label": "<value>"
  }
}
```

See Also

For more information, see the following.

- Use Amazon SageMaker Ground Truth to Label Data (p. 640)
- Crowd HTML Elements Reference (p. 1002)

crowd-classifier-multi-select

A widget for classifying various forms of content—such as audio, video, or text—into one or more categories. The content to classify is referred to as an object.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of an HTML worker task template built using this element. Copy the following code and save it in a file with the extension .html. Open the file in any browser to preview and interact with this template.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <crowd-classifier-multi-select
    name="category"
    categories="['Positive', 'Negative', 'Neutral']"
    header="Select the relevant categories"
    exclusion-category="{ text: 'None of the above' }"
  >
    <classification-target>
```
Attributes

The following attributes are supported by the crowd-classifier-multi-select element. Each attribute accepts a string value or string values.

**categories**

Required. A JSON-formatted array of strings, each of which is a category that a worker can assign to the object.

**header**

Required. The text to display above the image. This is typically a question or simple instruction for workers.

**name**

Required. The name of this widget. In the form output, the name is used as a key for the widget's input.

**exclusion-category**

Optional. A JSON-formatted string with the following format: "{ text: 'default-value' }". This attribute sets a default value that workers can choose if none of the labels applies to the object shown in the worker UI.

Element Hierarchy

This element has the following parent and child elements:

- **Parent elements**: crowd-form (p. 1025)
- **Child elements**: classification-target (p. 1018), full-instructions (p. 1018), short-instructions (p. 1018)

Regions

This element uses the following regions.

**classification-target**

The content to be classified by the worker. Content can be plain text or an object that you specify in the template using HTML. For example, you can use HTML elements to include a video or audio player, embedding a PDF file, or include a comparison of two or more images.
full-instructions

General instructions about how to classify text.

short-instructions

Important task-specific instructions. These instructions are displayed prominently.

Output

The output of this element is an object that uses the specified name value as a property name, and a string from categories as the property's value.

Example : Sample Element Outputs

The following is a sample of output from this element.

```
[ {
   "<name>": {
      labels: ["label_a", "label_b"]
   }
}
]
```

See Also

For more information, see the following:

- Text Classification (Multi-label) (p. 673)
- Use Amazon SageMaker Ground Truth to Label Data (p. 640)
- Crowd HTML Elements Reference (p. 1002)

crowd-entity-annotation

A widget for labeling words, phrases, or character strings within a longer text. Workers select a label, and highlight the text that the label applies to.

Important: Self-contained Widget

Do not use `<crowd-entity-annotation>` element with the `<crowd-form>` element. It contains its own form submission logic and Submit button.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a template that uses the `<crowd-entity-annotation>` element. Copy the following code and save it in a file with the extension .html. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-entity-annotation
   name="crowd-entity-annotation"
   header="Highlight parts of the text below"
   labels="[{
      'label': 'person', 'shortDisplayName': 'per', 'fullDisplayName': 'Person'},
      {
         'label': 'date', 'shortDisplayName': 'dat', 'fullDisplayName': 'Date'},
      {
         'label': 'company', 'shortDisplayName': 'com', 'fullDisplayName': 'Company'}]
   text="Amazon SageMaker Ground Truth helps you build highly accurate training datasets for machine learning quickly."
```
Attributes

The following attributes are supported by this element.

header

The text to display above the image. This is typically a question or simple instruction for the worker.

initial-value

A JSON formatted array of objects, each of which defines an annotation to apply to the text at initialization. Objects contain a label value that matches one in the labels attribute, an integer startOffset value for labeled span's starting unicode offset, and an integer endOffset value for the ending unicode offset.

Example

```
[
  { label: 'person',
```
labels

A JSON formatted array of objects, each of which contains:

- **label** (required): The name used to identify entities.
- **fullDisplayName** (optional): Used for the label list in the task widget. Defaults to the label value if not specified.
- **shortDisplayName** (optional): An abbreviation of 3-4 letters to display above selected entities. Defaults to the label value if not specified.

**shortDisplayName is highly recommended**

Values displayed above the selections can overlap and create difficulty managing labeled entities in the workspace. Providing a 3-4 character shortDisplayName for each label is highly recommended to prevent overlap and keep the workspace manageable for your workers.

Example

```json
[
  {
    label: 'person',
    shortDisplayName: 'per',
    fullDisplayName: 'person'
  }
]
```

name

Serves as the widget's name in the DOM. It is also used as the label attribute name in form output and the output manifest.

text

The text to be annotated. The templating system escapes quotes and HTML strings by default. If your code is already escaped or partially escaped, see Variable filters (p. 790) for more ways to control escaping.

Element Hierarchy

This element has the following parent and child elements.

- **Child elements**: full-instructions (p. 1022), short-instructions (p. 1023)

Regions

The following regions are supported by this element.

full-instructions

General instructions about how to work with the widget.
short-instructions

Important task-specific instructions that are displayed in a prominent place.

Output

The following output is supported by this element.

entities

A JSON object that specifies the start, end, and label of an annotation. This object contains the following properties.

- **label** – The assigned label.
- **startOffset** – The Unicode offset of the beginning of the selected text.
- **endOffset** – The Unicode offset of the first character after the selection.

Example : Sample Element Outputs

The following is a sample of the output from this element.

```json
{
   "myAnnotatedResult": {
      "entities": [
         {
            "endOffset": 54,
            "label": "person",
            "startOffset": 47
         },
         {
            "endOffset": 97,
            "label": "event",
            "startOffset": 93
         },
         {
            "endOffset": 219,
            "label": "date",
            "startOffset": 212
         },
         {
            "endOffset": 271,
            "label": "location",
            "startOffset": 260
         }
      ]
   }
}
```

See Also

For more information, see the following.

- Use Amazon SageMaker Ground Truth to Label Data (p. 640)
- Crowd HTML Elements Reference (p. 1002)

crowd-fab

A floating button with an image in its center.
See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template designed for image classification that uses the `<crowd-fab>` element. This template uses JavaScript to enable workers to report issues with the worker UI. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <crowd-image-classifier
    src="${image_url}"
    categories="[\'Cat\', \'Dog\', \'Bird\', \'None of the Above\']"
    header="Choose the correct category for the image"
    name="category">
      <short-instructions>
        <p>Read the task carefully and inspect the image.</p>
        <p>Choose the appropriate label that best suits the image.</p>
        <p>If there is an issue with the image or tools, please select <b>None of the Above</b>, describe the issue in the text box and click the button below.</p>
      </short-instructions>
      <full-instructions header="Classification Instructions">
        <p>Read the task carefully and inspect the image.</p>
        <p>Choose the appropriate label that best suits the image. Use the <b>None of the Above</b> option if none of the other labels suit the image.</p>
      </full-instructions>
  </crowd-image-classifier>

  <script>
    [button1,].forEach(function(button) {
      button.addEventListener('click', function() {
        document.querySelector('crowd-form').submit();
      });
    });
  </script>
</crowd-form>

Attributes

The following attributes are supported by this element.

**disabled**

A Boolean switch that, if present, displays the floating button as disabled and prevents clicks.

**icon**

A string that specifies the icon to be displayed in the center of the button. The string must be either the name of an icon from the open-source iron-icons set, which is pre-loaded, or the URL to a custom icon.

The following is an example of the syntax that you can use to add an iron-icon to a `<crowd-fab>` HTML element. Replace `icon-name` with the name of the icon you'd like to use from this icons set.
<crowd-fab id="button1" icon="icon-name" title="Issue"/>

**label**

A string consisting of a single character that can be used instead of an icon. Emojis or multiple characters may result in the button displaying an ellipsis instead.

**title**

A string that will display as a tool tip when the mouse hovers over the button.

### Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 1025)
- **Child elements**: none

### See Also

For more information, see the following.

- Use Amazon SageMaker Ground Truth to Label Data (p. 640)
- Crowd HTML Elements Reference (p. 1002)

### crowd-form

The form wrapper for all custom tasks. Sets and implements important actions for the proper submission of your form data.

If a crowd-button (p. 1007) of type "submit" is not included inside the <crowd-form> element, it will automatically be appended within the <crowd-form> element.

See an interactive example of an HTML template that uses this Crowd HTML Element in [CodePen](https://codepen.io).

The following is an example of an image classification template that uses the <crowd-form> element. Copy the following code and save it in a file with the extension .html. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <crowd-image-classifier
    src="${image_url}"
    categories="['Cat', 'Dog', 'Bird', 'None of the Above']"
    header="Choose the correct category for the image"
    name="category">
    <short-instructions>
      <p>Read the task carefully and inspect the image.</p>
      <p>Choose the appropriate label that best suits the image.</p>
    </short-instructions>

    <full-instructions header="Classification Instructions">
      <p>Read the task carefully and inspect the image.</p>
    </full-instructions>
  </crowd-image-classifier>
</crowd-form>
```
Choose the appropriate label that best suits the image. Use the "None of the Above" option if none of the other labels suit the image.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: none
- **Child elements**: Any of the UI Template (p. 1002) elements

Element Events

The crowd-form element extends the standard HTML form element and inherits its events, such as onclick and onsubmit.

See Also

For more information, see the following.

- Use Amazon SageMaker Ground Truth to Label Data (p. 640)
- Crowd HTML Elements Reference (p. 1002)

crowd-icon-button

A button with an image placed in the center. When the user touches the button, a ripple effect emanates from the center of the button.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template designed for image classification that uses the <crowd-icon-button> element. This template uses JavaScript to enable workers to report issues with the worker UI. Copy the following code and save it in a file with the extension .html. Open the file in any browser to preview and interact with this template.

```html
<p>Choose the appropriate label that best suits the image. Use the "None of the Above" option if none of the other labels suit the image.</p>
</full-instructions>
</crowd-image-classifier>
</crowd-form>

<short-instructions>
<p>Read the task carefully and inspect the image.</p>
<p>Choose the appropriate label that best suits the image.</p>
<p>If there is an issue with the image or tools, please select "None of the Above", describe the issue in the text box and click the button below.</p>
</short-instructions>

<crowd-input label="Report an Issue" name="template-issues"/>
<crowd-icon-button id="button1" icon="report-problem" title="Issue"/>
</short-instructions>
```
Attributes
The following attributes are supported by this element.

disabled
A Boolean switch that, if present, displays the button as disabled and prevents clicks.

icon
A string that specifies the icon to be displayed in the center of the button. The string must be either the name of an icon from the open-source iron-icons set, which is pre-loaded, or the URL to a custom icon.

The following is an example of the syntax that you can use to add an iron-icon to a <crowd-icon-button> HTML element. Replace icon-name with the name of the icon you’d like to use from this icons set.

```xml
<crowd-icon-button id="button1" icon="icon-name" title="Issue"/>
```

Element Hierarchy
This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 1025)
- **Child elements**: none

See Also
For more information, see the following.

- Use Amazon SageMaker Ground Truth to Label Data (p. 640)
- Crowd HTML Elements Reference (p. 1002)

crowd-image-classifier
A widget for classifying an image. Use one of the following supported image formats: APNG, BMP, GIF, ICO, JPEG, PNG, SVG. Images do not have a size limit.
See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of an image classification template that uses the `<crowd-image-classifier>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
  <crowd-image-classifier
    src="${image_url}"
    categories="['Cat', 'Dog', 'Bird', 'None of the Above']"
    header="Choose the correct category for the image"
    name="category">
    <short-instructions>
      <p>Read the task carefully and inspect the image.</p>
      <p>Choose the appropriate label that best suits the image.</p>
    </short-instructions>
    <full-instructions header="Classification Instructions">
      <p>Read the task carefully and inspect the image.</p>
      <p>Choose the appropriate label that best suits the image. Use the <b>None of the Above</b> option if none of the other labels suit the image.</p>
    </full-instructions>
  </crowd-image-classifier>
</crowd-form>
```

### Attributes

The following attributes are required by this element.

**categories**

A JSON formatted array of strings, each of which is a category that a worker can assign to the image. You should include “other” as a category, so that the worker can provide an answer. You can specify up to 10 categories.

**header**

The text to display above the image. This is typically a question or simple instruction for the worker.

**name**

The name of this widget. It is used as a key for the widget's input in the form output.

**overlay**

Information to be overlaid on the source image. This is for verification workflows of bounding-box, semantic-segmentation, and instance-segmentation tasks.

It is a JSON object containing an object with the name of the task-type in camelCase as the key. That key's value is an object that contains the labels and other necessary information from the previous task.

An example of a `<crowd-image-classifier>` element with attributes for verifying a bounding-box task follows:

```html
<crowd-image-classifier
```
name="boundingBoxClassification"
header="Rate the quality of the annotations based on the background section in the instructions on the left hand side."
src="https://i.imgur.com/CIPKVJo.jpg"
categories=["good", "bad", "okay"]
overlay={
  "boundingBox": {
    labels: ["bird", "cat"],
    value: [
      {
        height: 284,
        label: "bird",
        left: 230,
        top: 974,
        width: 223
      },
      {
        height: 69,
        label: "bird",
        left: 79,
        top: 889,
        width: 247
      }
    ]
  }
},
> ... </crowd-image-classifier>

A semantic segmentation verification task would use the overlay value as follows:

<crowd-image-classifier
name='crowd-image-classifier'
categories=["good", "bad"]
src='URL of image to be classified'
header='Please classify'
overlay=
  "semanticSegmentation": {
    "labels": ["Cat", "Dog", "Bird", "Cow"],
    "labelMappings": {
      "Bird": {
        "color": "#ff7f0e"
      },
      "Cat": {
        "color": "#2ca02c"
      },
      "Cow": {
        "color": "#d62728"
      },
      "Dog": {
        "color": "#2acf59"
      }
    },
    "src": "URL of overlay image",
  }
> ... </crowd-image-classifier>

An instance-segmentation task would use the overlay value as follows:

<crowd-image-classifier
name='crowd-image-classifier'
categories=["good", "bad"]
src='URL of image to be classified'
<pre>header='Please classify instances of each category'
overlay={
  "instanceSegmentation": {
    "labels": ["Cat", "Dog", "Bird", "Cow"],
    "instances": [
      { "color": "#2ca02c",
        "label": "Cat"
      },
      { "color": "#1f77b4",
        "label": "Cat"
      },
      { "color": "#d62728",
        "label": "Dog"
      }
    ],
    "src": "URL of overlay image",
  }
}</pre>

**src**

The URL of the image to be classified.

### Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 1025)
- **Child elements**: full-instructions (p. 1030), short-instructions (p. 1030), worker-comment (p. 1030)

### Regions

The following regions are used by this element.

**full-instructions**

General instructions for the worker on how to classify an image.

**short-instructions**

Important task-specific instructions that are displayed in a prominent place.

**worker-comment**

Use this in verification workflows when you need workers to explain why they made the choice they did. Use the text between the opening and closing tags to provide instructions for workers on what information should be included in the comment.

It uses the following attributes:

**header**

A phrase with a call to action for leaving a comment. Used as the title text for a modal window where the comment is added.

Optional. Defaults to "Add a comment."
This text appears below the categories in the widget. When clicked, it opens a modal window where the worker may add a comment.

Optional. Defaults to "Add a comment."

An example text in the comment text area that is overwritten when worker begins to type. This does not appear in output if the worker leaves the field blank.

Optional. Defaults to blank.

The output of this element is a string that specifies one of the values defined in the categories attribute of the <crowd-image-classifier> element.

Example : Sample Element Outputs

The following is a sample of output from this element.

```
[
  {
    "<name>": {
      "label": "<value>",
      "workerComment": "Comment - if no comment is provided, this field will not be present"
    }
  }
]
```

See Also

For more information, see the following.

- Use Amazon SageMaker Ground Truth to Label Data (p. 640)
- Crowd HTML Elements Reference (p. 1002)

crowd-image-classifier-multi-select

A widget for classifying an image into one or more categories. Use one of the following supported image formats: APNG, BMP, GIF, ICO, JPEG, PNG, SVG. Images do not have a size limit.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of an HTML worker task template built using this crowd element. Copy the following code and save it in a file with the extension .html. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
  <crowd-image-classifier-multi-select
    name="animals"
    categories="['Cat', 'Dog', 'Horse', 'Pig', 'Bird']"
  ></crowd-image-classifier-multi-select>
</crowd-form>
```
Attributes

The following attributes are supported by the `crowd-image-classifier-multi-select` element. Each attribute accepts a string value or string values.

**categories**

Required. A JSON-formatted array of strings, each of which is a category that a worker can assign to the image. A worker must choose at least one category and can choose all categories.

**header**

Required. The text to display above the image. This is typically a question or simple instruction for workers.

**name**

Required. The name of this widget. In the form output, the name is used as a key for the widget's input.

**src**

Required. The URL of the image to be classified.

**exclusion-category**

Optional. A JSON-formatted string with the following format: "{ text: 'default-value' }". This attribute sets a default value that workers can choose if none of the labels applies to the image shown in the worker UI.

Element Hierarchy

This element has the following parent and child elements:

- **Parent elements**: `crowd-form (p. 1025)`
- **Child elements**: `full-instructions (p. 1030), short-instructions (p. 1030), worker-comment (p. 1030)`

Regions

This element uses the following regions

**full-instructions**

General instructions for the worker on how to classify an image.
short-instructions

Important task-specific instructions. These instructions are displayed prominently.

Output

The output of this element is a string that specifies one or more of the values defined in the categories attribute of the `<crowd-image-classifier-multi-select>` element.

Example: Sample Element Outputs

The following is a sample of output from this element.

```
[
  {
    "<name>": {
      labels: ["label_a", "label_b"]
    }
  }
]
```

For more information, see the following:

- Image Classification (Multi-label) (p. 661)
- Use Amazon SageMaker Ground Truth to Label Data (p. 640)
- Crowd HTML Elements Reference (p. 1002)

crowd-input

A box that accepts input data.

**Cannot be self-closing**

Unlike the `input` element in the HTML standard, this element cannot be self-closed by putting a slash before the ending bracket, e.g. `<crowd-input ... />`. It must be followed with a `</crowd-input>` to close the element.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that uses the `<crowd-input>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <img style="max-width: 35vw; max-height: 50vh" src="{{ task.input.taskObject | grant_read_access }}"/>
  <crowd-input name="tag1" label="Word/phrase 1" required/>
  <crowd-input name="tag2" label="Word/phrase 2" required/>
  <crowd-input name="tag3" label="Word/phrase 3" required/>

  <short-instructions>
    Your custom quick instructions and examples
  </short-instructions>

  <full-instructions>
```

1033
Attributes

The following attributes are supported by this element.

allowed-pattern

A regular expression that is used with the auto-validate attribute to ignore non-matching characters as the worker types.

auto-focus

When the value is set to true, the browser places focus inside the input area after loading. This way, the worker can start typing without having to select it first.

auto-validate

A Boolean switch that, if present, turns on input validation. The behavior of the validator can be modified by the error-message and allowed-pattern attributes.

disabled

A Boolean switch that, if present, displays the input area as disabled.

error-message

The text to be displayed below the input field, on the left side, if validation fails.

label

A string that is displayed inside a text field.

This text shrinks and rises up above a text field when the worker starts typing in the field or when the value attribute is set.

max-length

A maximum number of characters the input will accept. Input beyond this limit is ignored.

min-length

A minimum length for the input in the field

name

Sets the name of the input to be used in the DOM and the output of the form.

placeholder

A string value that is used as placeholder text, displayed until the worker starts entering data into the input. It is not used as a default value.

required

A Boolean switch that, if present, requires the worker to provide input.
**type**

Takes a string to set the HTML5 input-type behavior for the input. Examples include file and date.

**value**

A preset that becomes the default if the worker does not provide input. The preset appears in a text field.

### Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 1025)
- **Child elements**: none

### Output

Provides a name string as the property name, and the text that was entered in the field as its value.

**Example: Sample JSON Output**

The values for multiple elements are output in the same object, with their name attribute value as their property name. Elements with no input do not appear in the output. For example, let's use three inputs:

```html
<crowd-input name="tag1" label="Word/phrase 1"></crowd-input>
<crowd-input name="tag2" label="Word/phrase 2"></crowd-input>
<crowd-input name="tag3" label="Word/phrase 3"></crowd-input>
```

This is the output if only two have input:

```json
[
    {
        "tag1": "blue",
        "tag2": "red"
    }
]
```

This means any code built to parse these results should be able to handle the presence or absence of each input in the answers.

### See Also

For more information, see the following.

- Use Amazon SageMaker Ground Truth to Label Data (p. 640)
- Crowd HTML Elements Reference (p. 1002)

**crowd-instance-segmentation**

A widget for identifying individual instances of specific objects within an image and creating a colored overlay for each labeled instance.

See an interactive example of an HTML template that uses this Crowd HTML Element in [CodePen](https://codepen.io).

The following is an example of a Liquid template that uses the `<crowd-instance-segmentation>`.

Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.
Use a template similar to the following to allow workers to add their own categories (labels).

```html
<crowd-instance-segmentation
 id="annotator"
 name="myTexts"
 src="{{ task.input.taskObject | grant_read_access }}"
 header="Click Instructions to add new labels."
 labels="['placeholder']">
 <short-instructions>
   <h3>Add a label to describe each type of object in this image.</h3>
   <h3>Cover each instance of each object with a segmentation mask.</h3>
   <br>
   <h3>Add new label</h3>
   <crowd-input name="_customLabel" id="customLabel"></crowd-input>
   <crowd-button id="addLabel">Add</crowd-button>
   <br><br><br>
   <h3>Manage labels</h3>
   <div id="labelsSection"></div>
 </short-instructions>
 <full-instructions>
   Describe your task in more detail here.
 </full-instructions>
</crowd-instance-segmentation>
```

```javascript
document.addEventListener('all-crowd-elements-ready', function(event) {
  document.querySelector('crowd-instance-segmentation').labels = [];
});

function populateLabelsSection() {
```
labelsSection.innerHTML = '';  
annotator.labels.forEach(function(label) {  
    const labelContainer = document.createElement('div');  
    labelContainer.innerHTML = label + ' <a href="javascript: void(0)">(Delete)</a>';  
    labelContainer.querySelector('a').onclick = function() {  
        annotator.labels = annotator.labels.filter(function(l) {  
            return l !== label;  
        });  
        populateLabelsSection();  
    };  
    labelsSection.appendChild(labelContainer);  
});
addLabel.onclick = function() {  
    annotator.labels = annotator.labels.concat([customLabel.value]);  
    customLabel.value = null;  
    populateLabelsSection();  
};
</script>

Attributes

The following attributes are supported by this element.

**header**

The text to display above the image. This is typically a question or simple instruction for the worker.

**labels**

A JSON formatted array of strings, each of which is a label that a worker can assign to an instance of an object in the image. Workers can generate different overlay colors for each relevant instance by selecting "add instance" under the label in the tool.

**name**

The name of this widget. It is used as a key for the labeling data in the form output.

**src**

The URL of the image that is to be labeled.

**initial-value**

A JSON object containing the color mappings of a prior instance segmentation job and a link to the overlay image output by the prior job. Include this when you want a human worker to verify the results of a prior labeling job and adjust it if necessary.

The attribute will appear as follows:

```
initial-value="{
    "instances": [
    {
        "color": "#2ca02c",
        "label": "Cat"
    },
    {
        "color": "#1f77b4",
        "label": "Cat"
    }
}"
```
Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 1025)
- **Child elements**: full-instructions (p. 1038), short-instructions (p. 1038)

Regions

The following regions are supported by this element.

full-instructions

General instructions about how to do image segmentation.

short-instructions

Important task-specific instructions that are displayed in a prominent place.

Output

The following output is supported by this element.

labeledImage

A JSON Object containing a Base64 encoded PNG of the labels.

instances

A JSON Array containing objects with the instance labels and colors.

- **color** – The hexadecimal value of the label's RGB color in the labeledImage PNG.
- **label** – The label given to overlay(s) using that color. This value may repeat, because the different instances of the label are identified by their unique color.

inputImageProperties

A JSON object that specifies the dimensions of the image that is being annotated by the worker. This object contains the following properties.

- **height** – The height, in pixels, of the image.
- **width** – The width, in pixels, of the image.

**Example : Sample Element Outputs**

The following is an example of output from this element.

```
{
  "color": "#d62728",
  "label": "Dog"
},
"src": {{ "S3 file URL for image" | grant_read_access }}
```
[{
  "annotatedResult": {
    "inputImageProperties": {
      "height": 533,
      "width": 800
    },
    "instances": [
      {
        "color": "#1f77b4",
        "label": "<Label 1>":
      },
      {
        "color": "#2ca02c",
        "label": "<Label 2>":
      },
      {
        "color": "#ff7f0e",
        "label": "<Label 3>":
      },
      "labeledImage": {
        "pngImageData": "<Base-64 Encoded Data>"
      }
    ]
  }
}]

**See Also**

For more information, see the following.

- [Use Amazon SageMaker Ground Truth to Label Data](p. 640)
- [Crowd HTML Elements Reference](p. 1002)

**crowd-instructions**

An element that displays instructions on three tabbed pages, **Summary**, **Detailed Instructions**, and **Examples**, when the worker clicks on a link or button.

See an interactive example of an HTML template that uses this Crowd HTML Element in [CodePen](https://codepen.io).

The following is an example of a Liquid template that used the `<crowd-instructions>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <crowd-instructions link-text="View instructions" link-type="button">
    <short-summary>
      <p>Given an image, write three words or short phrases that summarize its contents.</p>
    </short-summary>
    <detailed-instructions>
      <p>Imagine that you are describing an image to a friend or tagging it for a news website. Provide three specific words or short phrases that describe it.</p>
    </detailed-instructions>
    <positive-example>
    </positive-example>
  </crowd-instructions>
</crowd-form>
```
<p>
<ul>
<li>Highway</li>
<li>Cars</li>
<li>Gas station</li>
</ul>
</p>

</positive-example>

</negative-example>
</crowd-instructions>

<p><strong>Instructions: </strong>Given an image, write three words or short phrases that summarize its contents.</p>

<p>If someone were to see these three words or phrases, they should understand the subject and context of the image, as well as any important actions.</p>

<p>View the instructions for detailed instructions and examples.</p>

<p><img style="max-width: 100%; max-height: 100%" src="{{ task.input.taskObject | grant_read_access }}"></p>

</crowd-form>

Attributes

The following attributes are supported by this element.

link-text

The text to display for opening the instructions. The default is Click for instructions.

link-type

A string that specifies the type of trigger for the instructions. The possible values are "link" (default) and "button".

Element Hierarchy

This element has the following parent and child elements.

- Parent elements: crowd-form (p. 1025)
- Child elements: none

Regions

The following regions are supported by this element.

detailed-instructions

Content that provides specific instructions for a task. This appears on the page of the "Detailed Instructions" tab.
negative-example

Content that provides examples of inadequate task completion. This appears on the page of the "Examples" tab. More than one example may be provided within this element.

positive-example

Content that provides examples of proper task completion. This appears on the page of the "Examples" tab.

short-summary

A brief statement that summarizes the task to be completed. This appears on the page of the "Summary" tab. More than one example may be provided within this element.

See Also

For more information, see the following.

- Use Amazon SageMaker Ground Truth to Label Data (p. 640)
- Crowd HTML Elements Reference (p. 1002)

crowd-keypoint

Generates a tool to select and annotate key points on an image.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of an Liquid template that uses the `<crowd-keypoint>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<div id="errorBox"></div>

<crowd-keypoint
  src="{{ task.input.taskObject | grant_read_access }}"
  labels="['Item A', 'Item B', 'Item C']"
  header="Please locate the centers of each item."
  name="annotatedResult">
  <short-instructions>
    Describe your task briefly here and give examples
  </short-instructions>
  <full-instructions>
    Give additional instructions and good/bad examples here
  </full-instructions>
</crowd-keypoint>

<script>
  var num_obj = 1;

  document.querySelector('crowd-form').onsubmit = function(e) {
    const keypoints = document.querySelector('crowd-keypoint').value.keypoints ||
    document.querySelector('crowd-keypoint')._submittableValue.keypoints;
    const labels = keypoints.map(function(p) {
      return p.label;
    }
```
// 1. Make sure total number of keypoints is correct.
var original_num_labels = document.getElementsByTagName("crowd-keypoint")
[0].getAttribute("labels");
original_num_labels = original_num_labels.substring(2, original_num_labels.length - 2).split("","");
var goalNumKeypoints = num_obj*original_num_labels.length;
if (keypoints.length != goalNumKeypoints) {
  e.preventDefault();
  errorBox.innerHTML = '<crowd-alert type="error" dismissible>You must add all keypoint annotations and use each label only once.</crowd-alert>';
  errorBox.scrollIntoView();
  return;
}

// 2. Make sure all labels are unique.
labelCounts = {};
for (var i = 0; i < labels.length; i++) {
  if (!labelCounts[labels[i]]) {
    labelCounts[labels[i]] = 0;
  }
  labelCounts[labels[i]]++;
}
const goalNumSingleLabel = num_obj;
const numLabels = Object.keys(labelCounts).length;
Object.entries(labelCounts).forEach(entry => {
  if (entry[1] != goalNumSingleLabel) {
    e.preventDefault();
    errorBox.innerHTML = '<crowd-alert type="error" dismissible>You must use each label only once.</crowd-alert>';
    errorBox.scrollIntoView();
  }
});
</script>

Attributes

The following attributes are supported by this element.

header

The text to display above the image. This is typically a question or simple instruction for the worker.

initial-value

An array, in JSON format, of keypoints to be applied to the image on start. For example:

```json
initial-value="[
  {
    'label': 'Left Eye',
    'x': 1022,
    'y': 429
  },
  {
    'label': 'Beak',
    'x': 941,
    'y': 403
  }
]
```
Note
Please note that label values used in this attribute must have a matching value in the labels attribute or the point will not be rendered.

labels
An array, in JSON format, of strings to be used as keypoint annotation labels.

name
A string used to identify the answer submitted by the worker. This value will match a key in the JSON object that specifies the answer.

ds
The source URI of the image to be annotated.

Element Hierarchy
This element has the following parent and child elements.
- Parent elements: crowd-form (p. 1025)
- Child elements: full-instructions (p. 1043), short-instructions (p. 1043)

Regions
The following regions are required by this element.

full-instructions
General instructions about how to annotate the image.

short-instructions
Important task-specific instructions that are displayed in a prominent place.

Output
The following output is supported by this element.

inputImageProperties
A JSON object that specifies the dimensions of the image that is being annotated by the worker. This object contains the following properties.
- height – The height, in pixels, of the image.
- width – The width, in pixels, of the image.

keypoints
An array of JSON objects containing the coordinates and label of a keypoint. Each object contains the following properties.
- label – The assigned label for the keypoint.
• \( x \) – The X coordinate, in pixels, of the keypoint on the image.
• \( y \) – The Y coordinate, in pixels, of the keypoint on the image.

**Note**
X and Y coordinates are based on 0,0 being the top left corner of the image.

**Example: Sample Element Outputs**

The following is a sample output from using this element.

```json
[
   {
      "crowdKeypoint": {
         "inputImageProperties": {
            "height": 1314,
            "width": 962
         },
         "keypoints": [
            {
               "label": "dog",
               "x": 155,
               "y": 275
            },
            {
               "label": "cat",
               "x": 341,
               "y": 447
            },
            {
               "label": "cat",
               "x": 491,
               "y": 513
            },
            {
               "label": "dog",
               "x": 714,
               "y": 578
            },
            {
               "label": "cat",
               "x": 712,
               "y": 763
            },
            {
               "label": "cat",
               "x": 397,
               "y": 814
            }
         ]
      }
   }
]
```

You may have many labels available, but only the ones that are used appear in the output.

SageMaker Crowd HTML Elements

crowd-line
A widget for drawing lines on an image. Each line is associated with a label, and output data will report
the starting and ending points of each line.
See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.
The following is an example of a Liquid template that uses the <crowd-line> element. Copy the
following code and save it in a ﬁle with the extension .html. Open the ﬁle in any browser to preview
and interact with this template. For more examples, see this GitHub repository.
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
<crowd-line
name="crowdLine"
src="{{ task.input.taskObject | grant_read_access }}"
header="Add header here to describe the task"
labels="['car','pedestrian','street car']"
>
<short-instructions>
<p>Read the task carefully and inspect the image.</p>
<p>Choose the appropriate label that best suits the image.</p>
<p>Draw a line on each objects that the label applies to.</p>
</short-instructions>
<full-instructions>
<p>Read the task carefully and inspect the image.</p>
<p>Choose the appropriate label that best suits the image.
<p>Draw a line along each object that the image applies to.
Make sure that the line does not extend beyond the boundaries
of the object.
</p>
<p>Each line is defined by a starting and ending point. Carefully
place the starting and ending points on the boundaries of the object.</p>
</full-instructions>
</crowd-line>
</crowd-form>

Attributes
The following attributes are supported by this element.

header
Optional. The text to display above the image. This is typically a question or simple instruction for the
worker.

initial-value
Optional. An array of JSON objects, each of which sets a line when the component is loaded. Each JSON
object in the array contains the following properties:
• label – The text assigned to the line as part of the labeling task. This text must match one of the labels
deﬁned in the labels attribute of the <crowd-line> element.
• vertices – the x and y pixel corrdinates of the start point and end point of the line, relative to the topleft corner of the image.

initial-value="{

1045


Lines set via the initial-value property can be adjusted. Whether or not a worker answer was adjusted is tracked via an initialValueModified boolean in the worker answer output.

**labels**

Required. A JSON formatted array of strings, each of which is a label that a worker can assign to the line.

**Limit:** 10 labels

**label-colors**

Optional. An array of strings. Each string is a hexadecimal (hex) code for a label.

**name**

Required. The name of this widget. It's used as a key for the widget's input in the form output.

**src**

Required. The URL of the image on which to draw lines.

**Regions**

The following regions are required by this element.

**full-instructions**

General instructions about how to draw lines.

**short-instructions**

Important task-specific instructions that are displayed in a prominent place.
Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 1025)
- **Child elements**: short-instructions (p. 1046), full-instructions (p. 1046)

Output

inputImageProperties

A JSON object that specifies the dimensions of the image that is being annotated by the worker. This object contains the following properties.

- **height** – The height, in pixels, of the image.
- **width** – The width, in pixels, of the image.

lines

A JSON Array containing objects with the line labels and vertices.

- **label** – The label given to a line.
- **vertices** – the x and y pixel coordinates of the start point and end point of the line, relative to the top-left corner of the image.

Example : Sample Element Outputs

The following is an example of output from this element.

```
{
    "crowdLine": { //This is the name you set for the crowd-line
        "inputImageProperties": {
            "height": 1254,
            "width": 2048
        },
        "lines": [
            {
                "label": "yardline",
                "vertices": [
                    {
                        "x": 58,
                        "y": 295
                    },
                    {
                        "x": 1342,
                        "y": 398
                    }
                ]
            },
            {
                "label": "sideline",
                "vertices": [
                    {
                        "x": 472,
                        "y": 910
                    },
                    {
                        "x": 1480,
                        "y": 910
                    }
                ]
            }
        ]
    }
}
```

crowd-modal

A small window that pops up on the display when it is opened.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of the syntax that you can use with the `<crowd-modal>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-modal
  link-text = "See Examples"
  link-type = "button">
  Example Modal Text</crowd-modal>
```

Attributes

The following attributes are supported by this element.

- **link-text**

  The text to display for opening the modal. The default is "Click to open modal".

- **link-type**

  A string that specifies the type of trigger for the modal. The possible values are "link" (default) and "button".

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 1025)
- **Child elements**: none

See Also

For more information, see the following.
crowd-polygon

A widget for drawing polygons on an image and assigning a label to the portion of the image that is enclosed in each polygon.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that uses the `<crowd-polygon>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <crowd-polygon
    name="annotatedResult"
    src="{{ task.input.taskObject | grant_read_access }}"
    header="Draw a polygon around each of the requested target(s) of interest"
    labels="['Cat', 'Dog', 'Bird']"
  >
    <full-instructions header="Polygon instructions">
      <ul>
        <li>Make the polygon tight around the object</li>
        <li>You need to select a label before starting a polygon</li>
        <li>You will need to select a label again after completing a polygon</li>
        <li>To select a polygon, you can click on its borders</li>
        <li>You can start drawing a polygon from inside another polygon</li>
        <li>You can undo and redo while you're drawing a polygon to go back and forth between points you've placed</li>
        <li>You are prevented from drawing lines that overlap other lines from the same polygon</li>
      </ul>
    </full-instructions>
    <short-instructions>
      <p>Draw a polygon around each of the requested target(s) of interest</p>
      <p>Make the polygon tight around the object</p>
    </short-instructions>
  </crowd-polygon>
</crowd-form>
```

**Attributes**

The following attributes are supported by this element.

**header**

The text to display above the image. This is typically a question or simple instruction for the worker.

**labels**

A JSON formatted array of strings, each of which is a label that a worker can assign to the image portion enclosed by a polygon.

**name**

The name of this widget. It’s used as a key for the widget’s input in the form output.
src
The URL of the image on which to draw polygons.

initial-value
An array of JSON objects, each of which defines a polygon to be drawn when the component is loaded. Each JSON object in the array contains the following properties:

- **label** – The text assigned to the polygon as part of the labeling task. This text must match one of the labels defined in the `labels` attribute of the `<crowd-polygon>` element.
- **vertices** – An array of JSON objects. Each object contains an x and y coordinate value for a point in the polygon.

**Example**
An `initial-value` attribute might look something like this.

```json
initial-value = '
[
  {
    "label": "dog",
    "vertices": [
      {
        "x": 570,
        "y": 239
      },
      ...
      {
        "x": 759,
        "y": 281
      }
    ]
  }
]
```

Because this will be within an HTML element, the JSON array must be enclosed in single or double quotes. The example above uses single quotes to encapsulate the JSON and double quotes within the JSON itself. If you must mix single and double quotes inside your JSON, replace them with their HTML entity codes (" for double quote, &apos; for single) to safely escape them.

**Element Hierarchy**
This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 1025)
- **Child elements**: full-instructions (p. 1050), short-instructions (p. 1050)

**Regions**
The following regions are required.

full-instructions
General instructions about how to draw polygons.

short-instructions
Important task-specific instructions that are displayed in a prominent place.
Output

The following output is supported by this element.

*polygons*

An array of JSON objects, each of which describes a polygon that has been created by the worker. Each JSON object in the array contains the following properties.

- **label** – The text assigned to the polygon as part of the labeling task.
- **vertices** – An array of JSON objects. Each object contains an x and y coordinate value for a point in the polygon. The top left corner of the image is 0,0.

*inputImageProperties*

A JSON object that specifies the dimensions of the image that is being annotated by the worker. This object contains the following properties.

- **height** – The height, in pixels, of the image.
- **width** – The width, in pixels, of the image.

Example: Sample Element Outputs

The following are samples of outputs from common use scenarios for this element.

Single Label, Single Polygon

```json
{
  "annotatedResult": {
    "inputImageProperties": {
      "height": 853,
      "width": 1280
    },
    "polygons": [
      {
        "label": "dog",
        "vertices": [
          {
            "x": 570,
            "y": 239
          },
          {
            "x": 603,
            "y": 513
          },
          {
            "x": 823,
            "y": 645
          },
          {
            "x": 901,
            "y": 417
          },
          {
            "x": 759,
            "y": 281
          }
        ]
      }
    ]
  }
}
```
Single Label, Multiple Polygons

```json
[
  {
    "annotatedResult": {
      "inputImageProperties": {
        "height": 853,
        "width": 1280
      },
      "polygons": [
        {
          "label": "dog",
          "vertices": [
            {
              "x": 570,
              "y": 239
            },
            {
              "x": 603,
              "y": 513
            },
            {
              "x": 823,
              "y": 645
            },
            {
              "x": 901,
              "y": 417
            },
            {
              "x": 759,
              "y": 281
            }
          ]
        },
        {
          "label": "dog",
          "vertices": [
            {
              "x": 870,
              "y": 278
            },
            {
              "x": 908,
              "y": 446
            },
            {
              "x": 1009,
              "y": 602
            },
            {
              "x": 1116,
              "y": 519
            },
            {
              "x": 1174,
              "y": 498
            }
          ]
        }
      ]
    }
  }
]```
Multiple Labels, Multiple Polygons

[  
   "annotatedResult": {  
      "inputImageProperties": { 
         "height": 853,  
         "width": 1280  
      },  
      "polygons": [  
         {  
            "label": "dog",  
            "vertices": [  
               {  
                  "x": 570,  
                  "y": 239  
               },  
               {  
                  "x": 603,  
                  "y": 513  
               },  
               {  
                  "x": 823,  
                  "y": 645  
               },  
               {  
                  "x": 901,  
                  "y": 417  
               },  
               {  
                  "x": 759,  
                  "y": 281  
               }  
            ]  
         },  
         {  
            "label": "cat",  
            "vertices": [  
               {  
                  "x": 870,  
                  "y": 278  
               },  
               {  
                  "x": 908,  
                  "y": 446  
               }  
            ]  
         }  
      ]  
   }  
]
You could have many labels available, but only the ones that are used appear in the output.

**See Also**

For more information, see the following.

- Use Amazon SageMaker Ground Truth to Label Data (p. 640)
- Crowd HTML Elements Reference (p. 1002)

### crowd-polyline

A widget for drawing polylines or lines on an image. Each polyline is associated with a label and can include two or more vertices. A polyline can intersect itself and its starting and ending points can be placed anywhere on the image.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that uses the `<crowd-polyline>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template. For more examples, see this GitHub repository.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <crowd-polyline
    name="crowdPolyline"
    src="{{ task.input.taskObject | grant_read_access }}"
    header="Add header here to describe the task"
    labels="['car', 'pedestrian', 'street car']"
  >
    <full-instructions>
```
Attributes

The following attributes are supported by this element.

header

Optional. The text to display above the image. This is typically a question or simple instruction for the worker.

initial-value

Optional. An array of JSON objects, each of which sets a polyline when the component is loaded. Each JSON object in the array contains the following properties:

- label – The text assigned to the polyline as part of the labeling task. This text must match one of the labels defined in the labels attribute of the <crowd-polyline> element.
- vertices – the x and y pixel coordinates of the vertices of a polyline, relative to the top-left corner of the image.

```
initial-value= "{
  polylines: [
    {
      label: 'sideline', // label of this line annotation
      vertices:[        // an array of vertices which decide the position of the line
        { x: 84,
          y: 110
        },
        { x: 60,
          y: 100
        }
      ]
    },
    {
      label: 'yardline',
      vertices:[
        { x: 1055,
          y: 110
        }
      ]
    }
  ]
}
```
Polylines set via the `initial-value` property can be adjusted. Whether or not a worker answer was adjusted is tracked via an `initialValueModified` boolean in the worker answer output.

**labels**

Required. A JSON formatted array of strings, each of which is a label that a worker can assign to the line.

**Limit:** 10 labels

**label-colors**

Optional. An array of strings. Each string is a hexadecimal (hex) code for a label.

**name**

Required. The name of this widget. It's used as a key for the widget's input in the form output.

**src**

Required. The URL of the image on which to draw polylines.

**Regions**

The following regions are required by this element.

**full-instructions**

General instructions about how to draw polylines.

**short-instructions**

Important task-specific instructions that are displayed in a prominent place.

**Element Hierarchy**

This element has the following parent and child elements.

- **Parent elements:** crowd-form (p. 1025)
- **Child elements:** short-instructions (p. 1056), full-instructions (p. 1056)

**Output**

**inputImageProperties**

A JSON object that specifies the dimensions of the image that is being annotated by the worker. This object contains the following properties.
- **height** – The height, in pixels, of the image.
- **width** – The width, in pixels, of the image.

**polylines**

A JSON Array containing objects with polylines' labels and vertices.

- **label** – The label given to a line.
- **vertices** – the x and y pixel coordinates of the vertices of a polyline, relative to the top-left corner of the image.

**Example: Sample Element Outputs**

The following is an example of output from this element.

```
{
    "crowdPolyline": { //This is the name you set for the crowd-polyline
        "inputImageProperties": {
            "height": 1254,
            "width": 2048
        },
        "polylines": [
            {
                "label": "sideline",
                "vertices": [
                    {
                        "x": 651,
                        "y": 498
                    },
                    {
                        "x": 862,
                        "y": 869
                    },
                    {
                        "x": 1449,
                        "y": 611
                    }
                ]
            },
            {
                "label": "yardline",
                "vertices": [
                    {
                        "x": 1148,
                        "y": 322
                    },
                    {
                        "x": 1705,
                        "y": 474
                    },
                    {
                        "x": 1755,
                        "y": 474
                    }
                ]
            }
        ]
    }
}
```

• Use Amazon SageMaker Ground Truth to Label Data (p. 640)
• Crowd HTML Elements Reference (p. 1002)

crowd-radio-button
A button that can be either checked or unchecked. When radio buttons are inside a radio group, exactly
one radio button in the group can be checked at any time. The following is an example of how to
conﬁgure a crowd-radio-button element inside of a crowd-radio-group element.
See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.
The following is an example of the syntax that you can use with the <crowd-radio-button> element.
Copy the following code and save it in a ﬁle with the extension .html. Open the ﬁle in any browser to
preview and interact with this template.
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
<crowd-radio-group>
<crowd-radio-button name="tech" value="tech">Technology</crowd-radio-button>
<crowd-radio-button name="politics" value="politics">Politics</crowd-radio-button>
</crowd-radio-group>
</crowd-form>

The previous example can be seen in a custom worker task template in this GitHub example: entity
recognition labeling job custom template.
Crowd HTML Element radio buttons do not support the HTML tag, required. To make a radio button
selection required, use <input type="radio"> elements to create radio buttons and add the
required tag. The name attribute for all <input> elements that belong to the same group of radio
buttons must be the same. For example, the following template requires the user to select a radio button
in the animal-type group before submitting.
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
<p>Select an animal type:</p>
<img src="https://images.unsplash.com/photo-1537151608828-ea2b11777ee8?
ixlib=rb-1.2.1&ixid=eyJhcHBfaWQiOjEyMDd9&auto=format&fit=crop&w=1539&q=80" style="height:
500; width: 400;"/>
<br><br>
<div>
<input type="radio" id="cat" name="animal-type" value="cat" required>
<label for="cat">Cat</label>
</div>
<div>
<input type="radio" id="dog" name="animal-type" value="dog">
<label for="dog">Dog</label>
</div>
<div>
<input type="radio" id="unknown" name="animal-type" value="unknown">
<label for="unknown">Unknown</label>
</div>
<full-instructions header="Classification Instructions">
<p>Read the task carefully and inspect the image.</p>
<p>Choose the appropriate label that best suits the image.</p>
</full-instructions>

1058


**Attributes**

The following attributes are supported by this element.

- **checked**
  
  A Boolean switch that, if present, displays the radio button as checked.

- **disabled**
  
  A Boolean switch that, if present, displays the button as disabled and prevents it from being checked.

- **name**
  
  A string that is used to identify the answer submitted by the worker. This value will match a key in the JSON object that specifies the answer.

  **Note**
  
  If you use the buttons outside of a crowd-radio-group (p. 1060) element, but with the same name string and different value strings, the name object in the output will contain a Boolean value for each value string. To ensure that only one button in a group is selected, make them children of a crowd-radio-group (p. 1060) element and use different name values.

- **value**
  
  A property name for the element's boolean value. If not specified, it uses "on" as the default, e.g. 
  
  `{ "<name>": { "<value>": <true or false> } }.

**Element Hierarchy**

This element has the following parent and child elements.

- **Parent elements**: crowd-radio-group (p. 1060)
- **Child elements**: none

**Output**

Outputs an object with the following pattern: `{ "<name>": { "<value>": <true or false> } }`. If you use the buttons outside of a crowd-radio-group (p. 1060) element, but with the same name string and different value strings, the name object will contain a Boolean value for each value string. To ensure that only one button in a group is selected, make them children of a crowd-radio-group (p. 1060) element and use different name values.

**Example Sample output of this element**

```json
[  
  {  
    "btn1": {  
      "yes": true  
    },  
    "btn2": {  
      "no": false  
    }  
  } ]
```
crowd-radio-group

A group of radio buttons. Only one radio button within the group can be selected. Choosing one radio button clears any previously chosen radio button within the same group. For an example of a custom UI template that uses the crowd-radio-group element, see this entity recognition labeling job custom template.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of the syntax that you can use with the <crowd-radio-group> element. Copy the following code and save it in a file with the extension .html. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<style>
body {
  padding-left: 20px;
  margin-bottom: 20px;
}

#outer-container {
  display: flex;
  justify-content: space-around;
  max-width: 900px;
  margin-left: 100px;
}

.left-container {
  margin-right: auto;
  padding-right: 50px;
}

.right-container {
  margin-left: auto;
  padding-left: 50px;
}

#vertical-separator {
  border: solid 1px #d5dbdb;
}
</style>

<crowd-form>
  <div>
    <h1>Instructions</h1>
    Lorem ipsum...
  </div>
  <div>
    <h2>Background</h2>
    Lorem ipsum dolor sit amet, consectetur adipiscing elit, sed do eiusmod tempor incididunt ut labore et dolore magna aliqua. Ut enim ad minim veniam, quis nostrud exercitation ullamco laboris nisi ut aliquip ex ea commodo consequat.
  </div>
</crowd-form>
```
Attributes

No special attributes are supported by this element.

Element Hierarchy

This element has the following parent and child elements.

- Parent elements: crowd-form (p. 1025)
- Child elements: crowd-radio-button (p. 1058)

Output

Outputs an array of objects representing the crowd-radio-button (p. 1058) elements within it.

Example Sample of Element Output

```
[
  {
    "btn1": {
      "yes": true
    },
    "btn2": {
      "no": false
    }
  }
]
```

See Also

For more information, see the following.

- Use Amazon SageMaker Ground Truth to Label Data (p. 640)
- Crowd HTML Elements Reference (p. 1002)
**crowd-semantic-segmentation**

A widget for segmenting an image and assigning a label to each image segment.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that uses the `<crowd-semantic-segmentation>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <crowd-semantic-segmentation
    name="annotatedResult"
    src="{{ task.input.taskObject | grant_read_access }}"
    header="Please label each of the requested objects in this image"
    labels="['Cat', 'Dog', 'Bird']"
  >
    <full-instructions header="Segmentation Instructions">
      <ol>
        <li><strong>Read</strong> the task carefully and inspect the image.</li>
        <li><strong>Read</strong> the options and review the examples provided to understand more about the labels.</li>
        <li><strong>Choose</strong> the appropriate label that best suits the image.</li>
      </ol>
    </full-instructions>
    <short-instructions>
      <p>Use the tools to label the requested items in the image</p>
    </short-instructions>
  </crowd-semantic-segmentation>
</crowd-form>

**Attributes**

The following attributes are supported by this element.

**header**

The text to display above the image. This is typically a question or simple instruction for the worker.

**initial-value**

A JSON object containing the color mappings of a prior semantic segmentation job and a link to the overlay image output by the prior job. Include this when you want a human worker to verify the results of a prior labeling job and adjust it if necessary.

The attribute would appear as follows:

```json
initial-value='{
  "labelMappings": {
    "Bird": {
      "color": "#ff7f0e"
    },
    "Cat": {
      "color": "#2ca02c"
    },
    "Cow": {
      "color": "#d62728"
    }
  }
}
```
When using Ground Truth built in task types with annotation consolidation (where more than one worker labels a single image), label mappings are included in individual worker output records, however the overall result is represented as the internal-color-map in the consolidated results.

You can convert the internal-color-map to label-mappings in a custom template using the Liquid templating language:

```liquid
initial-value="{
    'src' : '{{ task.input.manifestLine.label-attribute-name-from-prior-job | grant_read_access }}',
    'labelMappings': {
        {% for box in task.input.manifestLine.label-attribute-name-from-prior-job-metadata.internal-color-map %}
            {% if box[1]['class-name'] != 'BACKGROUND' %}
                {{ box[1]['class-name'] | to_json }}: {
                    'color': {{ box[1]['hex-color'] | to_json }}
                },
            {% endif %}
        {% endfor %}
    }
}"'
```

**labels**

A JSON formatted array of strings, each of which is a label that a worker can assign to a segment of the image.

**name**

The name of this widget. It is used as a key for the widget's input in the form output.

**src**

The URL of the image that is to be segmented.

---

**Element Hierarchy**

This element has the following parent and child elements.

- **Parent elements:** crowd-form (p. 1025)
- **Child elements:** full-instructions (p. 1063), short-instructions (p. 1063)

---

**Regions**

The following regions are supported by this element.

**full-instructions**

General instructions about how to do image segmentation.

**short-instructions**

Important task-specific instructions that are displayed in a prominent place.
Output

The following output is supported by this element.

**labeledImage**

A JSON Object containing a Base64 encoded PNG of the labels.

**labelMappings**

A JSON Object containing objects with named with the segmentation labels.

- **color** – The hexadecimal value of the label's RGB color in the labeledImage PNG.

**initialValueModified**

A boolean representing whether the initial values have been modified. This is only included when the output is from an adjustment task.

**inputImageProperties**

A JSON object that specifies the dimensions of the image that is being annotated by the worker. This object contains the following properties.

- **height** – The height, in pixels, of the image.
- **width** – The width, in pixels, of the image.

**Example: Sample Element Outputs**

The following is a sample of output from this element.

```json
[
  {
    "annotatedResult": {
      "inputImageProperties": {
        "height": 533,
        "width": 800
      },
      "labelMappings": {
        "<Label 2>": {
          "color": "#ff7f0e"
        },
        "<label 3>": {
          "color": "#2ca02c"
        },
        "<label 1>": {
          "color": "#1f77b4"
        }
      },
      "labeledImage": {
        "pngImageData": "<Base-64 Encoded Data>"
      }
    }
  }
]
```

**See Also**

For more information, see the following.
crowd-slider

A bar with a sliding knob that allows a worker to select a value from a range of values by moving the knob. The slider makes it a great choice for settings that reflect intensity levels, such as volume, brightness, or color saturation.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a survey template that uses the `<crowd-slider>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.
Attributes

The following attributes are supported by this element.

disabled

A Boolean switch that, if present, displays the slider as disabled.

editable

A Boolean switch that, if present, displays an up/down button that can be chosen to select the value.

Selecting the value via the up/down button is an alternative to selecting the value by moving the knob on the slider. The knob on the slider will move synchronously with the up/down button choices.

max

A number that specifies the maximum value on the slider.

min

A number that specifies the minimum value on the slider.

name

A string that is used to identify the answer submitted by the worker. This value will match a key in the JSON object that specifies the answer.

pin

A Boolean switch that, if present, displays the current value above the knob as the knob is moved.

required

A Boolean switch that, if present, requires the worker to provide input.

secondary-progress

When used with a crowd-slider-secondary-color CSS attribute, the progress bar is colored to the point represented by the secondary-progress. For example, if this was representing the progress on a streaming video, the value would represent where the viewer was in the video timeline. The secondary-progress value would represent the point on the timeline to which the video had buffered.

step

A number that specifies the difference between selectable values on the slider.

value

A preset that becomes the default if the worker does not provide input.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 1025)
- **Child elements**: none
See Also

For more information, see the following.

- Use Amazon SageMaker Ground Truth to Label Data (p. 640)
- Crowd HTML Elements Reference (p. 1002)

crowd-tab

A component styled to look like a tab with information below.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example template that uses the `<crowd-tab>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <crowd-tabs>
    <crowd-tab header="Tab 1">
      <h2>Image</h2>
      <img src="https://images.unsplash.com/photo-1478382188900-5bb598fe27d3?ixlib=rb-1.2.1&ixid=eyJhcHBfaWQiOjEyMDd9&auto=format&fit=crop&w=1351&q=80" style="max-width: 40%" />
      <h2>Text</h2>
      <p>Lorem ipsum dolor sit amet, consectetur adipiscing elit, sed do eiusmod tempor incididunt ut labore et dolore magna aliqua.</p>
      <p>Sed risus ultricies tristique nulla aliquet enim tortor at auctor. Tempus egestas sed sed risus.</p>
    </crowd-tab>
    <crowd-tab header="Tab 2">
      <h2>Description</h2>
      <p>Sed risus ultricies tristique nulla aliquet enim tortor at auctor. Tempus egestas sed sed risus.</p>
    </crowd-tab>
    <crowd-tab header="Tab 3">
      <div style="width: 40%; display: inline-block">
        <img src="https://images.unsplash.com/photo-1472747459646-91fd6f13995f?ixlib=rb-1.2.1&ixid=eyJhcHBfaWQiOjEyMDd9&auto=format&fit=crop&w=1350&q=80" style="max-width: 80%" />
        <crowd-input label="Input inside tab" name="inputInsideTab"></crowd-input>
        <input type="checkbox" name="checkbox" value="foo">Foo
        <input type="checkbox" name="checkbox" value="bar">Bar
        <crowd-button>Some button</crowd-button>
      </div>
    </crowd-tab>
  </crowd-tabs>
</crowd-form>
```
Lorem ipsum dolor sit amet, lorem a wisi nibh, in pulvinar, consequat praesent vestibulum tellus ante felis auctor, vitae lobortis dictumst mauris. Pellentesque nulla ipsum ante quisque quam augue.

Attributes

The following attributes are supported by this element.

header

The text appearing on the tab. This is usually some short descriptive name indicative of the information contained below the tab.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-tabs (p. 1068)
- **Child elements**: none

See Also

      </div>
    </crowd-tab>
  </crowd-tabs>
</crowd-form>
```
Attributes

This element has no attributes.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements:** crowd-form (p. 1025)
- **Child elements:** crowd-tab (p. 1067)

See Also

For more information, see the following.

- Use Amazon SageMaker Ground Truth to Label Data (p. 640)
- Crowd HTML Elements Reference (p. 1002)

**crowd-text-area**

A field for text input.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template designed to transcribe audio clips that uses the `<crowd-text-area>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <audio controls>
    <source src="{{ task.input.taskObject | grant_read_access }}" type="audio/mpeg">
    Your browser does not support the audio element.
  </audio>
  <h3>Instructions</h3>
  <p>Transcribe the audio</p>
  <p>Ignore "umms", "hmms", "uhhs" and other non-textual phrases</p>
  <crowd-text-area name="transcription" rows="4"></crowd-text-area>
</crowd-form>
```
Attributes

The following attributes are supported by this element.

**allowed-pattern**

A regular expression that is used with the *auto-validate* attribute to ignore non-matching characters as the worker types.

**auto-focus**

A Boolean switch that, if present, puts the cursor in this element on-load so that users can immediately begin typing without having to click inside the element.

**auto-validate**

A Boolean switch that, if present, turns on input validation. The behavior of the validator can be modified by the *error-message* and *allowed-pattern* attributes.

**char-counter**

A Boolean switch that, if present, puts a small text field beneath the lower-right corner of the element, displaying the number of characters inside the element.

**disabled**

A Boolean switch that, if present, displays the input area as disabled.

**error-message**

The text to be displayed below the input field, on the left side, if validation fails.

**label**

A string that is displayed inside a text field.

This text shrinks and rises up above a text field when the worker starts typing in the field or when the *value* attribute is set.

**max-length**

An integer that specifies the maximum number of characters allowed by the element. Characters typed or pasted beyond the maximum are ignored.

**max-rows**

An integer that specifies the maximum number of rows of text that are allowed within a crowd-text-area. Normally the element expands to accommodate new rows. If this is set, after the number of rows exceeds it, content scrolls upward out of view and a scrollbar control appears.

**name**

A string used to represent the element's data in the output.

**placeholder**

A string presented to the user as placeholder text. It disappears after the user puts something in the input area.
rows
An integer that specifies the height of the element in rows of text.

value
A preset that becomes the default if the worker does not provide input. The preset appears in a text field.

Element Hierarchy
This element has the following parent and child elements.
- **Parent elements**: crowd-form (p. 1025)
- **Child elements**: none

Output
This element outputs the name as a property name and the element's text contents as the value. Carriage returns in the text are represented as \n.

Example Sample output for this element

```
[
  {
    "textInput1": "This is the text; the text that\nmakes the crowd go wild."
  }
]
```

See Also
For more information, see the following.
- Use Amazon SageMaker Ground Truth to Label Data (p. 640)
- Crowd HTML Elements Reference (p. 1002)

crowd-toast
A subtle notification that temporarily appears on the display. Only one crowd-toast is visible.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that uses the <crowd-toast> element. Copy the following code and save it in a file with the extension .html. Open the file in any browser to preview and interact with this template.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <p>Find the official website for: <strong>{{ task.input.company }}</strong></p>
  <p>Do not give Yelp pages, LinkedIn pages, etc.</p>
  <p>Include the http:// prefix from the website</p>
  <crowd-input name="website" placeholder="http://example.com"></crowd-input>
  <crowd-toast duration="10000" opened>
```

1072
This is a message that you want users to see when opening the template. This message will disappear in 10 seconds.
</crowd-toast>
</crowd-form>

Attributes

The following attributes are supported by this element.

duration
A number that specifies the duration, in milliseconds, that the notification appears on the screen.
text
The text to display in the notification.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 1025)
- **Child elements**: none

See Also

For more information, see the following.

- [Use Amazon SageMaker Ground Truth to Label Data (p. 640)](p. 640)
- [Crowd HTML Elements Reference (p. 1002)](p. 1002)

crowd-toggle-button

A button that acts as an ON/OFF switch, toggling a state.

See an interactive example of an HTML template that uses this Crowd HTML Element in [CodePen](https://codepen.io).

The following example shows different ways you can use to use the `<crowd-toggle-button>` HTML element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <!--Toggle button without value-->
  <crowd-toggle-button name="toggleButtonWithoutValue"></crowd-toggle-button>

  <!--Toggle button with value-->
  <crowd-toggle-button name="toggleButtonWithValue" value="someValue"></crowd-toggle-button>

  <!--Toggle button disabled-->
  <crowd-toggle-button name="toggleButtonDisabled" disabled></crowd-toggle-button>

  <!--Toggle button marked invalid-->
  <crowd-toggle-button name="toggleButtonInvalid" invalid></crowd-toggle-button>
</crowd-form>
```
<!--Toggle button marked required-->
<crowd-toggle-button name="toggleButtonRequired" required></crowd-toggle-button>
</crowd-form>

Attributes

The following attributes are supported by this element.

checked

A Boolean switch that, if present, displays the button switched to the ON position.

disabled

A Boolean switch that, if present, displays the button as disabled and prevents toggling.

invalid

When in an off position, a button using this attribute, will display in an alert color. The standard is red, but may be changed in CSS. When toggled on, the button will display in the same color as other buttons in the on position.

name

A string that is used to identify the answer submitted by the worker. This value matches a key in the JSON object that specifies the answer.

required

A Boolean switch that, if present, requires the worker to provide input.

value

A value used in the output as the property name for the element's Boolean state. Defaults to "on" if not provided.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form (p. 1025)
- **Child elements**: none

Output

This element outputs the name as the name of an object, containing the value as a property name and the element's state as Boolean value for the property. If no value for the element is specified, the property name defaults to "on."

Example Sample output for this element

```json
[
  {
    "theToggler": {
      "on": true
    }
  }
]```
Augmented AI Crowd HTML Elements

The following Crowd HTML Elements are only available for Amazon Augmented AI human workflow tasks.

Topics
  • crowd-textract-analyze-document (p. 1075)
  • crowd-rekognition-detect-moderation-labels (p. 1079)

crowd-textract-analyze-document

A widget to enable human review of a Amazon Textract document analysis result.

Attributes

The following attributes are supported by this element.

header

This is the text that is displayed as the header.

src

This is a link to the image to be analyzed by the worker.

initialValue

This sets initial values for attributes found in the worker UI.

The following is an example of an initialValue input:

```
[
  {
    "blockType": "KEY_VALUE_SET",
    "confidence": 38.4309020996094,
    "geometry": {
      "boundingBox": {
        "width": 0.32613086700439453,
        "weight": 0.0942094624042511,
        "left": 0.4833833575248718,
        "top": 0.5227989858358765
      },
      "polygon": [
        {"x": 0.123, "y": 0.345}, ...
      ]
    },
    "id": "8c97b240-0969-4678-834a-646c95da9cf4",
    "relationships": [
      {"type": "CHILD",
```
"ids": [
    "7ee7b7da-ee1b-428d-a567-55a3e3affa56",
    "4d6da730-ba43-467c-a9a5-c6137ba0c472"
],

"type": "VALUE",
"ids": [
    "6ee7b7da-ee1b-428d-a567-55a3e3affa54"
],

"entityTypes": ["KEY"],

"text": "Foo bar"
],

```
blockTypes
This determines the kind of analysis the workers can do. Only KEY_VALUE_SET is currently supported.

keys
This specifies new keys and the associated text value the worker can add. The input values for keys can include the following elements:

- `importantFormKey` accepts strings, and is used to specify a single key.
- `importantFormKeyAliases` can be used to specify aliases that are acceptable alternatives to the keys supplied. Use this element to identify alternative spellings or presentations of your keys. This parameter accepts a list of one or more strings.

The following is an example of an input for keys.

```
[
    {
        `importantFormKey`: 'Address',
        `importantFormKeyAliases`: [
            'address',
            'Addr.',
            'Add.'
        ]
    },
    {
        `importantFormKey`: 'Last name',
        `importantFormKeyAliases`: ['Surname']
    }
]
```

*no-key-edit*

This prevents the workers from editing the keys of annotations passed through `initialValue`. This prevents workers from editing the keys that have been detected on your documents. This is required.

*no-geometry-edit*

This prevents workers from editing the polygons of annotations passed through `initialValue`. For example, this would prevent the worker from editing the bounding box around a given key. This is required.
Element Hierarchy

This element has the following parent and child elements.

- Parent elements – crowd-form
- Child elements – full-instructions (p. 1077), short-instructions (p. 1077)

Regions

The following regions are supported by this element. You can use custom HTML and CSS code within these regions to format your instructions to workers. For example, use the short-instructions section to provide good and bad examples of how to complete a task.

full-instructions

General instructions about how to work with the widget.

short-instructions

Important task-specific instructions that are displayed in a prominent place.

Example of a Worker Template Using the crowd Element

An example of a worker template using this crowd element would look like the following.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
{% capture s3_uri %}http://s3.amazonaws.com/{{ task.input.aiServiceRequest.document.s3Object.bucket }}/\n{{ task.input.aiServiceRequest.document.s3Object.name }}{% endcapture %}

<crowd-form>
  <crowd-textract-analyze-document
    src="{{ s3_uri | grant_read_access }}"
    initial-value="{{ task.input.selectedAiServiceResponse.blocks }}"
    header="Review the key-value pairs listed on the right and correct them if they don't match the following document."
    no-key-edit
    no-geometry-edit
    keys="{{ task.input.humanLoopContext.importantFormKeys }}"
    block-types="["KEY_VALUE_SET"]"
  >
    <short-instructions header="Instructions">
      <style>
        .instructions {
          white-space: pre-wrap;
        }
        .instructionsImage {
          display: inline-block;
          max-width: 100%;
        }
      </style>
      <p class='instructions'>Click on a key-value block to highlight the corresponding key-value pair in the document.

      If it is a valid key-value pair, review the content for the value. If the content is incorrect, correct it.
      </p>
      <img class='instructionsImage' src="https://assets.crowd.aws/images/a2i-console/correct-value-text.png" />
    </short-instructions>

```
A wrong value is identified, correct it.

If it is not a valid key-value relationship, choose No.

If you can’t find the key in the document, choose Key not found.

If the content of a field is empty, choose Value is blank.

Examples:

Key and value are often displayed next or below to each other.

Key and value displayed in one line.

Key and value displayed in two lines.

If the content of the value has multiple lines, enter all the text without line break. Include all value text even if it extends beyond the highlight box.

Output

The following is a sample of the output from this element. You can find a detailed explanation of this output in the Amazon Textract AnalyzeDocument API documentation.
crowd-rekognition-detect-moderation-labels

A widget to enable human review of an Amazon Rekognition image moderation result.

Attributes

The following attributes are supported by this element.

header

This is the text that is displayed as the header.

src

This is a link to the image to be analyzed by the worker.

categories

This supports categories as an array of strings or an array of objects where each object has a name field.

If the categories come in as objects, the following applies:

• The displayed categories are the value of the name field.
• The returned answer contains the full objects of any selected categories.

If the categories come in as strings, the following applies:

• The returned answer is an array of all the strings that were selected.

eclusion-category

By setting this attribute you create a button underneath the categories in the UI.

• When a user chooses the button, all categories are deselected and disabled.
• Choosing the button again re-enables the categories so that users can choose them.
• If you submit after choosing the button, it returns an empty array.

Element Hierarchy

This element has the following parent and child elements.

• Parent elements – crowd-form
• Child elements – full-instructions (p. 1080), short-instructions (p. 1080)

AWS Regions

The following AWS Regions are supported by this element. You can use custom HTML and CSS code within these Regions to format your instructions to workers. For example, use the short-instructions section to provide good and bad examples of how to complete a task.
full-instructions

General instructions about how to work with the widget.

short-instructions

Important task-specific instructions that are displayed in a prominent place.

Example Worker Template with the crowd Element

An example of a worker template using the crowd element would look like the following.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
{% capture s3_uri %}http://s3.amazonaws.com/{{ task.input.aiServiceRequest.image.s3Object.bucket }}/{{ task.input.aiServiceRequest.image.s3Object.name }}{% endcapture %}

<crowd-form>
  <crowd-rekognition-detect-moderation-labels
    categories='[
      {% for label in task.input.selectedAiServiceResponse.moderationLabels %}
        {
          name: "{{ label.name }}",
          parentName: "{{ label.parentName }}",
        },
      {% endfor %}
    ]'
    src="{{ s3_uri | grant_read_access }}"
    header="Review the image and choose all applicable categories."
  >
  <short-instructions header="Instructions">
    <style>
      .instructions {
        white-space: pre-wrap;
      }
    </style>
    <p class='instructions'>Review the image and choose all applicable categories. If no categories apply, choose None.

    <b>Nudity</b>
    Visuals depicting nude male or female person or persons

    <b>Graphic Male Nudity</b>
    Visuals depicting full frontal male nudity, often close ups

    <b>Graphic Female Nudity</b>
    Visuals depicting full frontal female nudity, often close ups

    <b>Sexual Activity</b>
    Visuals depicting various types of explicit sexual activities and pornography

    <b>Illustrated Nudity or Sexual Activity</b>
    Visuals depicting animated or drawn sexual activity, nudity or pornography

    <b>Adult Toys</b>
    Visuals depicting adult toys, often in a marketing context

    <b>Female Swimwear or Underwear</b>
    Visuals depicting female person wearing only swimwear or underwear

    <b>Male Swimwear Or Underwear</b>
    Visuals depicting male person wearing only swimwear or underwear

    <b>Partial Nudity</b>
  </short-instructions>
</crowd-form>
```
Visuals depicting covered up nudity, for example using hands or pose

<b>Revealing Clothes</b>

Visuals depicting revealing clothes and poses, such as deep cut dresses

<b>Graphic Violence or Gore</b>

Visuals depicting prominent blood or bloody injuries

<b>Physical Violence</b>

Visuals depicting violent physical assault, such as kicking or punching

<b>Weapon Violence</b>

Visuals depicting violence using weapons like firearms or blades, such as shooting

<b>Weapons</b>

Visuals depicting weapons like firearms and blades

<b>Self Injury</b>

Visuals depicting self-inflicted cutting on the body, typically in distinctive patterns using sharp objects

<b>Emaciated Bodies</b>

Visuals depicting extremely malnourished human bodies

<b>Corpses</b>

Visuals depicting human dead bodies

<b>Hanging</b>

Visuals depicting death by hanging

Output

The following is a sample of the output from this element. For details about this output, see Amazon Rekognition DetectModerationLabels API documentation.

```json
{
  "AWS/Rekognition/DetectModerationLabels/Image/V3": {
    "ModerationLabels": [
      { name: 'Gore', parentName: 'Violence' },
      { name: 'Corpses', parentName: 'Violence' }
    ]
  }
}
```

Using Amazon Augmented AI for Human Review

When you use AI applications such as Amazon Rekognition, Amazon Textract, or your custom machine learning (ML) models, you can use Amazon Augmented AI to get human review of low-confidence predictions or random prediction samples.

What is Amazon Augmented AI?

Amazon Augmented AI (Amazon A2I) is a service that brings human review of ML predictions to all developers by removing the heavy lifting associated with building human review systems or managing large numbers of human reviewers.
Many ML applications require humans to review low-confidence predictions to ensure the results are correct. For example, extracting information from scanned mortgage application forms can require human review due to low-quality scans or poor handwriting. Building human review systems can be time-consuming and expensive because it involves implementing complex processes or workflows, writing custom software to manage review tasks and results, and managing large groups of reviewers.

Amazon A2I streamlines building and managing human reviews for ML applications. Amazon A2I provides built-in human review workflows for common ML use cases, such as content moderation and text extraction from documents. You can also create your own workflows for ML models built on SageMaker or any other tools. Using Amazon A2I, you can allow human reviewers to step in when a model is unable to make a high-confidence prediction or to audit its predictions on an ongoing basis.

Amazon A2I Use Case Examples

The following examples demonstrate how you can use Amazon A2I to integrate a human review loop into your ML application. For each of these examples, you can find a Jupyter Notebook that demonstrates that workflow in Use Cases and Examples Using Amazon A2I (p. 1102).

• Use Amazon A2I with Amazon Textract – Have humans review important key-value pairs in single-page documents or have Amazon Textract randomly sample and send documents from your dataset to humans for review.

• Use Amazon A2I with Amazon Rekognition – Have humans review unsafe images for explicit adult or violent content if Amazon Rekognition returns a low-confidence score, or have Amazon Rekognition randomly sample and send images from your dataset to humans for review.

• Use Amazon A2I to review real-time ML inferences – Use Amazon A2I to review real-time, low-confidence inferences made by a model deployed to a SageMaker hosted endpoint and incrementally train your model using Amazon A2I output data.

• Use Amazon A2I with Amazon Comprehend – Have humans review Amazon Comprehend inferences about text data such as sentiment analysis, text syntax, and entity detection.

• Use Amazon A2I with Amazon Transcribe – Have humans review Amazon Transcribe transcriptions of video or audio files. Use the results of transcription human review loops to create a custom vocabulary and improve future transcriptions of similar video or audio content.

• Use Amazon A2I with Amazon Translate – Have humans review low-confidence translations returned from Amazon Translate.

• Use Amazon A2I to review tabular data – Use Amazon A2I to integrate a human review loop into an ML application that uses tabular data.

Topics

• Get Started with Amazon Augmented AI (p. 1083)
• Use Cases and Examples Using Amazon A2I (p. 1102)
• Create a Human Review Workflow (p. 1110)
Get Started with Amazon Augmented AI

To get started using Amazon Augmented AI, review the Core Components of Amazon A2I (p. 1083) and Prerequisites to Using Augmented AI (p. 1086). Then, use the following documentation to learn how to use the Amazon A2I console and API.

- Tutorial: Get Started in the Amazon A2I Console (p. 1087)
- Tutorial: Get Started Using the Amazon A2I API (p. 1092)

You can also get started using the Amazon A2I API by following a Jupyter Notebook tutorial. See Use Cases and Examples Using Amazon A2I (p. 1102) for a list of notebooks and use cases.

Core Components of Amazon A2I

Review the following terms to familiarize yourself with the core components of Amazon A2I.

Task Types

The AI/ML workflow into which you integrate Amazon A2I defines an Amazon A2I task type.

Amazon A2I supports:

- Two built-in task types: Amazon Textract key-value pair extraction and Amazon Rekognition image moderation.
- A custom task type: Use a custom task type to integrate a human review loop into any machine learning workflow. You can use a custom task type to integrate Amazon A2I with other AWS services like Amazon Comprehend, Amazon Transcribe, and Amazon Translate, as well as your own custom machine learning workflows. To learn more, see Use Cases and Examples Using Amazon A2I (p. 1102).

Select a tab in the following table to see diagrams that illustrate how Amazon A2I works with each task type. Select the task type page using the links in the preceding list to learn more about that task type.

Amazon Textract – Key-value pair extraction

This image depicts the Amazon A2I built-in workflow with Amazon Textract. On the left, the resources that are required to create an Amazon Textract human review workflow are depicted: an Amazon S3 bucket, activation conditions, a worker task template, and a work team. These resources are used to create a human review workflow, or flow definition. An arrow points right to the next step in the workflow: using Amazon Textract to configure a human loop with the human review workflow. A second arrow points right from this step to the step in which activation conditions specified in the human review workflow are met. This initiates the creation of a human loop. On
the right of the image, the human loop is depicted in three steps: 1) the worker UI and tools are
generated and the task is made available to workers, 2) workers review input data, and finally, 3) results are saved in Amazon S3.

Amazon Rekognition – Image moderation

This image depicts the Amazon A2I built-in workflow with Amazon Rekognition. On the left, the
resources that are required to create an Amazon Rekognition human review workflow are depicted:
an Amazon S3 bucket, activation conditions, a worker task template, and a work team. These
resources are used to create a human review workflow, or flow definition. An arrow points right
to the next step in the workflow: using Amazon Rekognition to configure a human loop with the
human review workflow. A second arrow points right from this step to the step in which activation
conditions specified in the human review workflow are met. This initiates the creation of a human
loop. On the right of the image, the human loop is depicted in three steps: 1) the worker UI and
tools are generated and the task is made available to workers, 2) workers review input data, and
finally, 3) results are saved in Amazon S3.

Custom Task Type

The following image depicts the Amazon A2I custom workflow. A custom ML model is used to
generate predictions. The client application filters these predictions using user-defined criteria and
determines if a human review is required. If so, these predictions are sent to Amazon A2I for human
review. Amazon A2I collects the results of human review in Amazon S3, which can access by the
client application. If the filter determines that no human review is needed, predictions can be fed directly to the client application.

Human Review Workflow (Flow Definition)

You use a human review workflow to specify your human work team, to set up your worker UI using a worker task template, and to provide information about how workers should complete the review task.

For built-in task types, you also use the human review workflow to identify the conditions under which a human loop is initiated. For example, Amazon Rekognition can perform image content moderation using machine learning. You can use the human review workflow to specify that an image is sent to a human for content moderation review if Amazon Rekognition's confidence is too low.

You can use a human review workflow to create multiple human loops.

You can create a flow definition in the SageMaker console or with the SageMaker API. To learn more about both of these options, see Create a Human Review Workflow (p. 1110).

Work Team

A work team is a group of human workers to whom you send your human review tasks.

When you create a human review workflow, you specify a single work team.

Your work team can come from the Amazon Mechanical Turk workforce, a vendor-managed workforce, or your own private workforce. When you use the private workforce, you can create multiple work teams. Each work team can be used in multiple human review workflows. To learn how to create a workforce and work teams, see Create and Manage Workforces (p. 977).

Worker Task Template and Human Task UI

You use a worker task template to create a worker UI (a human task UI) for your human review tasks.

The human task UI displays your input data, such as documents or images, and instructions to workers. It also provides interactive tools that the worker uses to complete your tasks.

For built-in task types, you must use the Amazon A2I worker task template provided for that task type.

Human Loops

A human loop is used to create a single human review job. For each human review job, you can choose the number of workers that are sent a task to review a single data object. For example, if you set the
number of workers per object to 3 for an image classification labeling job, three workers classify each input image. Increasing the number of workers per object can improve label accuracy.

A human loop is created using a human review workflow as follows:

- For built-in task types, the conditions specified in the human review workflow determine when the human loop is created.
- Human review tasks are sent to the work team specified in the human review workflow.
- The worker task template specified in the human review workflow is used to render the human task UI.

**When do human loops get created?**

When you use one of the *built-in task types*, the corresponding AWS service creates and starts a human loop on your behalf when the conditions specified in your human review workflow are met. For example:

- When you use Augmented AI with Amazon Textract, you can integrate Amazon A2I into a document review task using the API operation `AnalyzeDocument`. A human loop is created every time Amazon Textract returns inferences about key-value pairs that meet the conditions you specify in your human review workflow.
- When you use Augmented AI with Amazon Rekognition, you can integrate Amazon A2I into an image moderation task using the API operation `DetectModerationLabels`. A human loop is created every time Amazon Rekognition returns inferences about image content that meet the conditions you specify in your human review workflow.

When using a *custom task type*, you start a human loop using the Amazon Augmented AI Runtime API. When you call `StartHumanLoop` in your custom application, a task is sent to human reviewers.

To learn how to create and start a human loop, see [Create and Start a Human Loop](p. 1129).

To generate these resources and create a human review workflow, Amazon A2I integrates multiple APIs, including the Amazon Augmented AI Runtime Model, the SageMaker APIs, and APIs associated with your task type. To learn more, see [Use APIs in Amazon Augmented AI](p. 1164).

**Note**

AWS Region availability may differ when you use Augmented AI with other AWS services, such as Amazon Textract. Create Augmented AI resources in the same AWS Region that you use to interact with those AWS services. For AWS Region availability for all services, see the Region Table.

**Prerequisites to Using Augmented AI**

Amazon A2I uses resources in IAM, SageMaker, and Amazon S3 to create and run your human review workflows. You can create some of these resources in the Amazon A2I console when you create a human review workflow. To learn how, see [Tutorial: Get Started in the Amazon A2I Console](p. 1087).

To use Amazon A2I, you need the following resources:

- One or more Amazon S3 buckets in the same AWS Region as the workflow for your input and output data. To create a bucket, follow the instructions in [Create a Bucket](the Amazon Simple Storage Service Console User Guide).
- An IAM role with required permissions to create a human review workflow and an IAM user or role with permission to access Augmented AI. For more information, see [Permissions and Security in Amazon Augmented AI](p. 1157).
- A public, private, or vendor workforce for your human review workflows. If you plan to use a private workforce, you need to set one up ahead of time in the same AWS Region as your Amazon A2I workflow. To learn more about these workforce types, see [Create and Manage Workforces](p. 977).
Important
To learn about the compliance programs that cover Amazon Augmented AI at this time, see AWS Services in Scope by Compliance Program. If you use Amazon Augmented AI in conjunction with other AWS services (such as Amazon Rekognition and Amazon Textract), note that Amazon Augmented AI may not be in scope for the same compliance programs as those other services. You are responsible for how you use Amazon Augmented AI, including understanding how the service processes or stores customer data and any impact on the compliance of your data environment. You should discuss your workload objectives and goals with your AWS account team; they can help you evaluate whether the service is a good fit for your proposed use case and architecture.

Tutorial: Get Started in the Amazon A2I Console

The following tutorial shows you how to get started using Amazon A2I in the Amazon A2I console.

The tutorial gives you the option to use Augmented AI with Amazon Textract for document review or Amazon Rekognition for image content review.

Prerequisites
To get started using Amazon A2I, complete the following prerequisites.

• Create an Amazon S3 bucket in the same AWS Region as the workflow for your input and output data. For example, if you are using Amazon A2I with Amazon Textract in us-east-1, create your bucket in us-east-1. To create a bucket, follow the instructions in Create a Bucket in the Amazon Simple Storage Service Console User Guide.

• Do one of the following:
  • If you want to complete the tutorial using Amazon Textract, download this sample document and place it in your Amazon S3 bucket.
  • If you want to complete the tutorial using Amazon Rekognition, download this image and place it in your Amazon S3 bucket.

Note
The Amazon A2I console is embedded in the SageMaker console.

Step 1: Create a Work Team

First, create a work team in the Amazon A2I console and add yourself as a worker so that you can preview the worker review task.

Important
This tutorial uses a private work team. The Amazon A2I private workforce is configured in the Ground Truth area of the SageMaker console and is shared between Amazon A2I and Ground Truth.

To create a private workforce using worker emails

2. In the navigation pane, choose Labeling workforces under Ground Truth.
3. Choose Private, then choose Create private team.
4. Choose Invite new workers by email.
5. For this tutorial, enter your email and any others that you want to be able to preview the human task UI. You can paste or type a list of up to 50 email addresses, separated by commas, into the email addresses box.
6. Enter an organization name and contact email.
7. Optionally, choose an Amazon SNS topic to which to subscribe the team so workers are notified by email when new Ground Truth labeling jobs become available. Amazon SNS notifications are supported by Ground Truth and are not supported by Augmented AI. If you subscribe workers to Amazon SNS notifications, they only receive notifications about Ground Truth labeling jobs. They do not receive notifications about Augmented AI tasks.

8. Choose Create private team.

If you add yourself to a private work team, you receive an email from no-reply@verificationemail.com with login information. Use the link in this email to reset your password and log in to your worker portal. This is where your human review tasks appear when you create a human loop.

**Step 2: Create a Human Review Workflow**

In this step, you create a human review workflow. Each human review workflow is created for a specific task type. This tutorial allows you to choose between the built-in task types: Amazon Rekognition and Amazon Textract.

**To create a human review workflow:**

1. Open the Augmented AI console at https://console.aws.amazon.com/a2i to access the Human review workflows page.
2. Select Create human review workflow.
3. In Workflow settings, enter a workflow Name, S3 bucket, and the IAM role that you created for this tutorial, with the AWS managed policy AmazonAugmentedAIIntegratedAPIAccess attached.
4. For Task type, select Textract – Key-value pair extraction or Rekognition – Image moderation.
5. Select the task type that you chose from the following table for instructions for that task type.

Amazon Textract – Key-value pair extraction

1. Select Trigger a human review for specific form keys based on the form key confidence score or when specific form keys are missing.
2. For Key name, enter Mail Address.
3. Set the identification confidence threshold between 0 and 99.
4. Set the qualification confidence threshold between 0 and 99.
5. Select Trigger a human review for all form keys identified by Amazon Textract with confidence scores in a specific range.
6. Set the identification confidence threshold between 0 and 90.
7. Set the qualification confidence threshold between 0 and 90.

This initiates a human review if Amazon Textract returns a confidence score that is less than 99 for Mail Address and its key, or if it returns a confidence score less than 90 for any key value pair detected in the document.

The following image shows the Amazon Textract form extraction - Conditions for invoking human review section of the Amazon A2I console. In the image, the check boxes for the two types of triggers explained in the proceeding paragraph are checked, and Mail Address is used as a Key name for the first trigger. The identification confidence threshold is defined using confidence scores for key-value pairs detect within the form and is set between 0 and 99. The qualification confidence threshold is defined using confidence scores for text contained within keys and values in a form and is set between 0 and 99.
Amazon Rekognition – Image moderation

1. Select **Trigger human review for labels identified by Amazon Rekognition based on label confidence score**.

2. Set the **Threshold** between 0 and 98.

This initiates a human review if Amazon Rekognition returns a confidence score that is less than 98 for an image moderation job.

The following image shows how you can select the **Trigger human review for labels identified by Amazon Rekognition based on label confidence score** option and enter a **Threshold** between 0 and 98 in the Amazon A2I console.
6. **Under Worker task template creation**, select **Create from a default template**.

7. Enter a **Template name**.

8. In **Task description** field, enter the following text:
   
   Read the instructions carefully and complete the task.

9. **Under Workers**, select **Private**.

10. Select the private team that you created.

11. Choose **Create**.

Once your human review workflow is created, it appears in the table on the **Human review workflows** page. When the **Status** is **Active**, copy and save the Workflow ARN. You need it for the next step.

**Step 3: Start a Human Loop**

You must use an API operation to start a human loop. There are a variety of language-specific SDKs that you can use to interact with these API operations. To see documentation for each of these SDKs, refer to the **See Also** section in the API documentation, as shown in the following image.

For this tutorial, you use one of the following APIs:

- If you chose the Amazon Textract task type, you use the **AnalyzeDocument** operation.
- If you chose the Amazon Rekognition task type, you use the **DetectModerationLabels** operation.
You can interact with these APIs using a SageMaker notebook instance (recommended for new users) or the AWS Command Line Interface (AWS CLI). Choose one of the following to learn more about these options:

- To learn more about and set up a notebook instance, see Amazon SageMaker Notebook Instances (p. 298).
- To learn more about and get started using the AWS CLI, see What Is the AWS Command Line Interface? in the AWS Command Line Interface User Guide.

Select your task type in the following table to see example requests for Amazon Textract and Amazon Rekognition using the AWS SDK for Python (Boto3).

**Amazon Textract – Key-value pair extraction**

The following example uses the AWS SDK for Python (Boto3) to call `analyze_document` in us-west-2. Replace the italicized red text with your resources. Include the `DataAttributes` parameter if you are using the Amazon Mechanical Turk workforce. For more information, see the `analyze_document` documentation in the AWS SDK for Python (Boto) API Reference.

```python
response = client.analyze_document(
    Document={
        "S3Object": {
            "Bucket": "AWSDOC-EXAMPLE-BUCKET",
            "Name": "document-name.pdf"
        }
    },
    HumanLoopConfig={
        "HumanLoopName": "human-loop-name",
        "DataAttributes": {
            "ContentClassifiers": [
                "FreeOfPersonallyIdentifiableInformation",
                "FreeOfAdultContent"
            ]
        }
    },
    FeatureTypes=['TABLES', 'FORMS'])
```

**Amazon Rekognition – Image moderation**

The following example uses the AWS SDK for Python (Boto3) to call `detect_moderation_labels` in us-west-2. Replace the italicized red text with your resources. Include the `DataAttributes` parameter if you are using the Amazon Mechanical Turk workforce. For more information, see the `detect_moderation_labels` documentation in the AWS SDK for Python (Boto) API Reference.

```python
response = client.detect_moderation_labels(
    Image={
        "S3Object": {
            "Bucket": "AWSDOC-EXAMPLE-BUCKET",
            "Name": "image-name.png"
        }
    },
    HumanLoopConfig={
        "HumanLoopName": "human-loop-name",
        "DataAttributes": {
            "ContentClassifiers": [
                "FreeOfPersonallyIdentifiableInformation",
                "FreeOfAdultContent"
            ]
        }
    }
)
```
Step 4: View Human Loop Status in Console

When you start a human loop, you can view its status in the Amazon A2I console.

To view your human loop status

1. Open the Augmented AI console at https://console.aws.amazon.com/a2i to access the **Human review workflows** page.
2. Select the human review workflow that you used to start your human loop.
3. In the **Human loops** section, you can see your human loop. View its status in the **Status** column.

Step 5: Download Output Data

Your output data is stored in the Amazon S3 bucket you specified when you created a human review workflow.

To view your Amazon A2I output data

1. Open the **Amazon S3 console**.
2. Select the Amazon S3 bucket you specified when you created your human review workflow in step 2 of this example.
3. Starting with the folder that is named after your human review workflow, navigate to your output data by selecting the folder with the following naming convention:

   s3://output-bucket-specified-in-human-review-workflow/human-review-workflow-name/YYYY/XX/mm/mm/human-loop-name/output.json

4. Select **output.json** and choose **Download**.

Tutorial: Get Started Using the Amazon A2I API

This tutorial explains the API operations you can use to get started using Amazon A2I.

To use a Jupyter Notebook to run these operations, select a Jupyter Notebook from **Use Cases and Examples Using Amazon A2I** (p. 1102) and use **Use SageMaker Notebook Instance with Amazon A2I Jupyter Notebook** (p. 1104) to learn how to use it in a SageMaker notebook instance.

To learn more about the API operations you can use with Amazon A2I, see **Use APIs in Amazon Augmented AI** (p. 1164).

Create a Private Work Team

You can create a private work team and add yourself as a worker so that you can preview Amazon A2I.

If you are not familiar with Amazon Cognito, we recommend that you use the SageMaker console to create a private workforce and add yourself as a private worker. For instructions, see **Step 1: Create a Work Team** (p. 1087).

If you are familiar with Amazon Cognito, you can use the following instructions to create a private work team using the SageMaker API. After you create a work team, note the work team ARN (WorkteamArn).

To learn more about the private workforce and other available configurations, see **Use a Private Workforce** (p. 981).
Create a private workforce

If you have not created a private workforce, you can do so using an Amazon Cognito user pool. Make sure that you have added yourself to this user pool. You can create a private work team using the AWS SDK for Python (Boto3) `create_workforce` function. For other language-specific SDKs, refer to the list in CreateWorkforce.

```python
response = client.create_workforce(
    CognitoConfig={
        "UserPool": "Pool_ID",
        "ClientId": "app-client-id"
    },
    WorkforceName="workforce-name"
)
```

Create a private work team

After you have created a private workforce in the AWS Region to configure and start your human loop, you can create a private work team using the AWS SDK for Python (Boto3) `create_workteam` function. For other language-specific SDKs, refer to the list in CreateWorkteam.

```python
response = client.create_workteam(
    WorkteamName="work-team-name",
    WorkforceName= "workforce-name",
    MemberDefinitions=[
        {
            "CognitoMemberDefinition": {
                "UserPool": "<aws-region>_ID",
                "UserGroup": "user-group",
                "ClientId": "app-client-id"
            },
        }
    ]
)
```

Access your work team ARN as follows:

```python
workteamArn = response["WorkteamArn"]
```

List private work teams in your account

If you have already created a private work team, you can list all work teams in a given AWS Region in your account using the AWS SDK for Python (Boto3) `list_workteams` function. For other language-specific SDKs, refer to the list in ListWorkteams.

```python
response = client.list_workteams()
```

If you have numerous work teams in your account, you may want to use MaxResults, SortBy, and NameContains to filter your results.

Create a Human Review Workflow

You can create a human review workflow using the Amazon A2I `CreateFlowDefinition` operation. Before you create your human review workflow, you need to create a human task UI. You can do this with the `CreateHumanTaskUi` operation.
If you are using Amazon A2I with the Amazon Textract or Amazon Rekognition integrations, you can specify activation conditions using a JSON.

Create a Human Task UI

If you are creating a human review workflow to be used with Amazon Textract or Amazon Rekognition integrations, you need to use and modify pre-made worker task template. For all custom integrations, you can use your own custom worker task template. Use the following table to learn how to create a human task UI using a worker task template for the two built-in integrations. Replace the template with your own to customize this request.

Amazon Textract – Key-value pair extraction

To learn more about this template, see [Custom Template Example for Amazon Textract (p. 1140)](Custom Template Example for Amazon Textract (p. 1140)).

```html
<template = r""
"% capture s3_uri %)http://s3.amazonaws.com/
{( task.input.aiServiceRequest.document.s3Object.bucket )}"
{( task.input.aiServiceRequest.document.s3Object.name )}%endcapture %}
<crowd-form>
  <crowd-textract-analyze-document
    src="{{ s3_uri | grant_read_access }}"
    initial-value="{{ task.input.selectedAiServiceResponse.blocks }}"
    header="Review the key-value pairs listed on the right and correct them if they
don't match the following document."
    no-key-edit=""
    no-geometry-edit=""
    keys="{{ task.input.humanLoopContext.importantFormKeys }}"
    block-types='"["KEY_VALUE_SET"]'">
    <short-instructions header="Instructions">
      <p>Click on a key-value block to highlight the corresponding key-value pair in
the document.</p>
      <p>If it is a valid key-value pair, review the content for the value. If the
content is incorrect, correct it.</p>
      <p>The text of the value is incorrect, correct it.</p>
      <p>A wrong value is identified, correct it.</p>
      <p>If it is not a valid key-value relationship, choose No.</p>
      <p>If you can't find the key in the document, choose Key not found.</p>
      <p>If the content of a field is empty, choose Value is blank.</p>
      <p>Key and value are often displayed next or below to each other.</p>
      <p>Key and value displayed in one line.</p>
      <p>Key and value displayed in two lines.</p>
    </short-instructions>
  </crowd-textract-analyze-document>
</crowd-form>
```
Amazon Rekognition – Image moderation

To learn more about this template, see [Custom Template Example for Amazon Rekognition (p. 1141)](https://amazon-rekognition-sagemaker-sample-code.readthedocs.io/en/latest/).

```python
template = r""
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
{% capture s3_uri %}http://s3.amazonaws.com/
{{ task.input.aiServiceRequest.image.s3Object.bucket }}/
{{ task.input.aiServiceRequest.image.s3Object.name }}{% endcapture %}

<crowd-form>
<crowd-rekognition-detect-moderation-labels

categories=[
    {% for label in task.input.selectedAiServiceResponse.moderationLabels %}
        name: "{{ label.name }}",
        parentName: "{{ label.parentName }}",
    {% endfor %}
]
src="{{ s3_uri | grant_read_access }}"
header="Review the image and choose all applicable categories."
>
<short-instructions header="Instructions">
<style>
.instructions {
    white-space: pre-wrap;
}
</style>
<p class="instructions">Review the image and choose all applicable categories. If no categories apply, choose None.
</p>
<b>Nudity</b>
Visuals depicting nude male or female person or persons

<b>Partial Nudity</b>
Visuals depicting covered up nudity, for example using hands or pose

<b>Revealing Clothes</b>
Visuals depicting revealing clothes and poses

<b>Physical Violence</b>
Visuals depicting violent physical assault, such as kicking or punching

<b>Weapon Violence</b>
Visuals depicting violence using weapons like firearms or blades, such as shooting

<b>Weapons</b>
Visuals depicting weapons like firearms and blades
</short-instructions>

<full-instructions header="Instructions"></full-instructions>
"""
Custom Integration

The following is an example template that can be used in a custom integration. This template is used in this notebook, demonstrating a custom integration with Amazon Comprehend.

```python
template = r""
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <crowd-classifier
    name="sentiment"
    categories='["Positive", "Negative", "Neutral", "Mixed"]'
    initial-value="{{ task.input.initialValue }}"
    header="What sentiment does this text convey?"
  >
    <classification-target>
      {{ task.input.taskObject }}
    </classification-target>

    <full-instructions header="Sentiment Analysis Instructions">
      <p><strong>Positive</strong> sentiment include: joy, excitement, delight</p>
      <p><strong>Negative</strong> sentiment include: anger, sarcasm, anxiety</p>
      <p><strong>Neutral</strong>: neither positive or negative, such as stating a fact</p>
      <p><strong>Mixed</strong>: when the sentiment is mixed</p>
    </full-instructions>

  <short-instructions>
    Choose the primary sentiment that is expressed by the text.
  </short-instructions>
</crowd-classifier>
""
```

Using the template specified above, you can create a template using the AWS SDK for Python (Boto3) `create_human_task_ui` function. For other language-specific SDKs, refer to the list in `CreateHumanTaskUI`.

```python
response = client.create_human_task_ui(
    HumanTaskUiName="human-task-ui-name",
    UiTemplate={
        "Content": template
    }
)
```

This response element contains the human task UI ARN. Save this as follows:

```python
humanTaskUiArn = response["HumanTaskUiArn"]
```

Create JSON to specify activation conditions

For Amazon Textract and Amazon Rekognition built-in integrations, you can save activation conditions in a JSON object and use this in your `CreateFlowDefinition` request.
Next, select a tab to see example activation conditions you can use for these built-in integrations. For additional information about activation condition options, see [JSON Schema for Human Loop Activation Conditions in Amazon Augmented AI](p. 1116).

**Amazon Textract – Key-value pair extraction**

This example specifies conditions for specific keys (such as `Mail address`) in the document. If Amazon Textract's confidence falls outside of the thresholds set here, the document is sent to a human for review, with the specific keys that initiated the human loop prompted to the worker.

```python
import json

humanLoopActivationConditions = json.dumps(
    {
        "Conditions": [
            {
                "Or": [
                    {
                        "ConditionType": "ImportantFormKeyConfidenceCheck",
                        "ConditionParameters": {
                            "ImportantFormKey": "Mail address",
                            "ImportantFormKeyAliases": ["Mail Address:","Mail address:","Mailing Add:","Mailing Addresses"],
                            "KeyValueBlockConfidenceLessThan": 100,
                            "WordBlockConfidenceLessThan": 100
                        }
                    },
                    {
                        "ConditionType": "MissingImportantFormKey",
                        "ConditionParameters": {
                            "ImportantFormKey": "Mail address",
                            "ImportantFormKeyAliases": ["Mail Address:","Mail address:","Mailing Add:","Mailing Addresses"]
                        }
                    }
                ],
                "ConditionType": "ImportantFormKeyConfidenceCheck",
                "ConditionParameters": {
                    "ImportantFormKey": "Phone Number",
                    "ImportantFormKeyAliases": ["Phone number:","Phone No.:","Number:"],
                    "KeyValueBlockConfidenceLessThan": 100,
                    "WordBlockConfidenceLessThan": 100
                }
            },
            {
                "ConditionType": "ImportantFormKeyConfidenceCheck",
                "ConditionParameters": {
                    "ImportantFormKey": "*",
                    "KeyValueBlockConfidenceLessThan": 100,
                    "WordBlockConfidenceLessThan": 100
                }
            },
            {
                "ConditionType": "ImportantFormKeyConfidenceCheck",
                "ConditionParameters": {
                    "ImportantFormKey": "*",
                    "KeyValueBlockConfidenceGreaterThan": 0,
                    "WordBlockConfidenceGreaterThan": 0
                }
            }
        ]
    }
)
Amazon Rekognition – Image moderation

The human loop activation conditions used here are tailored towards Amazon Rekognition content moderation; they are based on the confidence thresholds for the Suggestive and Female Swimwear Or Underwear moderation labels.

```python
import json

humanLoopActivationConditions = json.dumps(
    {
        "Conditions": [
            {
                "Or": [
                    {
                        "ConditionType": "ModerationLabelConfidenceCheck",
                        "ConditionParameters": {
                            "ModerationLabelName": "Suggestive",
                            "ConfidenceLessThan": 98
                        }
                    },
                    {
                        "ConditionType": "ModerationLabelConfidenceCheck",
                        "ConditionParameters": {
                            "ModerationLabelName": "Female Swimwear Or Underwear",
                            "ConfidenceGreaterThan": 98
                        }
                    }
                ]
            }
        ]
    }
)
```

Create a human review workflow

This section gives an example of the `create_flow_definition` AWS SDK for Python (Boto3) request using the resources created in the previous sections. For other language-specific SDKs, refer to the list in `create_flow_definition`. Use the tabs in the following table to see the requests to create a human review workflow for Amazon Textract and Amazon Rekognition built-in integrations.

Amazon Textract – Key-value pair extraction

If you use the built-in integration with Amazon Textract, you must specify "AWS/Textract/AnalyzeDocument/Forms/V1" for "AwsManagedHumanLoopRequestSource" in `HumanLoopRequestSource`.

```python
response = client.create_flow_definition(
    FlowDefinitionName="human-review-workflow-name",
    HumanLoopRequestSource={
        "AwsManagedHumanLoopRequestSource": "AWS/Textract/AnalyzeDocument/Forms/V1"
    },
    HumanLoopActivationConfig={
        "HumanLoopActivationConditionsConfig": {
            "HumanLoopActivationConditions": humanLoopActivationConditions
        }
    }
)
```
HumanLoopConfig={
    "WorkteamArn": workteamArn,
    "HumanTaskUiArn": humanTaskUiArn,
    "TaskTitle": "Document entry review",
    "TaskDescription": "Review the document and instructions. Complete the task",
    "TaskCount": 1,
    "TaskAvailabilityLifetimeInSeconds": 43200,
    "TaskTimeLimitInSeconds": 3600,
    "TaskKeywords": [
        "document review",
    ],
},
OutputConfig={
    "S3OutputPath": "s3://DOC-EXAMPLE-BUCKET/prefix/",
},
RoleArn="arn:aws:iam::<account-number>:role/<role-name>",
Tags=[
    {
        "Key": "string",
        "Value": "string"
    },
]
)

Amazon Rekognition – Image moderation

If you use the built-in integration with Amazon Rekognition, you must specify "AWS/Rekognition/DetectModerationLabels/Image/V3" for "AwsManagedHumanLoopRequestSource" in HumanLoopRequestSource.

response = client.create_flow_definition(
    FlowDefinitionName="human-review-workflow-name",
    HumanLoopRequestSource={
        "AwsManagedHumanLoopRequestSource": "AWS/Rekognition/DetectModerationLabels/Image/V3"
    },
    HumanLoopActivationConfig={
        "HumanLoopActivationConditionsConfig": {
            "humanLoopActivationConditions": humanLoopActivationConditions
        }
    },
    HumanLoopConfig={
        "WorkteamArn": workteamArn,
        "HumanTaskUiArn": humanTaskUiArn,
        "TaskTitle": "Image content moderation",
        "TaskDescription": "Review the image and instructions. Complete the task",
        "TaskCount": 1,
        "TaskAvailabilityLifetimeInSeconds": 43200,
        "TaskTimeLimitInSeconds": 3600,
        "TaskKeywords": [
            "content moderation",
        ],
    },
    OutputConfig={
        "S3OutputPath": "s3://DOC-EXAMPLE-BUCKET/prefix/",
    },
    RoleArn="arn:aws:iam::<account-number>:role/<role-name>",
    Tags=[
        {
            "Key": "string",
        }
    ]
)
Custom Integration

If you use a custom integration, exclude the following parameters: HumanLoopRequestSource, HumanLoopActivationConfig.

```python
response = client.create_flow_definition(
    FlowDefinitionName="human-review-workflow-name",
    HumanLoopConfig={
        "WorkteamArn": workteamArn,
        "HumanTaskUiArn": humanTaskUiArn,
        "TaskTitle": "Image content moderation",
        "TaskDescription": "Review the image and instructions. Complete the task",
        "TaskCount": 1,
        "TaskAvailabilityLifetimeInSeconds": 43200,
        "TaskTimeLimitInSeconds": 3600,
        "TaskKeywords": [
            "content moderation",
        ],
    },
    OutputConfig={
        "S3OutputPath": "s3://DOC-EXAMPLE-BUCKET/prefix/",
    },
    RoleArn="arn:aws:iam::<account-number>:role/<role-name>",
    Tags=[
        {
            "Key": "string",
            "Value": "string"
        },
    ]
)
```

After you create a human review workflow, you can retrieve the flow definition ARN from the response:

```python
humanReviewWorkflowArn = response["FlowDefinitionArn"]
```

Create a Human Loop

The API operation you use to start a human loop depends on the Amazon A2I integration you use.

- If you use the Amazon Textract built-in integration, you use the `AnalyzeDocument` operation.
- If you use the Amazon Rekognition built-in integration, you use the `DetectModerationLabels` operation.
- If you use a custom integration, you use the `StartHumanLoop` operation.

Select your task type in the following table to see example requests for Amazon Textract and Amazon Rekognition using the AWS SDK for Python (Boto3).

Amazon Textract – Key-value pair extraction

The following example uses the AWS SDK for Python (Boto3) to call `analyze_document` in `us-west-2`. Replace the italicized red text with your resources. Include the `DataAttributes`
parameter if you are using the Amazon Mechanical Turk workforce. For more information, see the `analyze_document` documentation in the AWS SDK for Python (Boto) API Reference.

```python
response = client.analyze_document(
    Document={"S3Object": {"Bucket": "AWSDOC-EXAMPLE-BUCKET", "Name": "document-name.pdf"},
              HumanLoopConfig={
                  "HumanLoopName": "human-loop-name",
                  "DataAttributes": {ContentClassifiers:
                      ["FreeOfPersonallyIdentifiableInformation" | "FreeOfAdultContent"]
                  }
              }
          FeatureTypes=["FORMS"]
      )

Human loops are only created if Amazon Textract’s confidence for document analysis task meets the activation conditions you specified in your human review workflow. You can check the `response` element to determine if a human loop has been created. To see everything included in this response, see `HumanLoopActivationOutput`.

```python
if "HumanLoopArn" in analyzeDocumentResponse["HumanLoopActivationOutput"]:
    # A human loop has been started!
    print(f"A human loop has been started with ARN: \
          {analyzeDocumentResponse["HumanLoopActivationOutput"]['HumanLoopArn']}")
```

Amazon Rekognition – Image moderation

The following example uses the AWS SDK for Python (Boto3) to call `detect_moderation_labels` in us-west-2. Replace the italicized red text with your resources. Include the `DataAttributes` parameter if you are using the Amazon Mechanical Turk workforce. For more information, see the `detect_moderation_labels` documentation in the AWS SDK for Python (Boto) API Reference.

```python
response = client.detect_moderation_labels(
    Image={"S3Object": {"Bucket": "AWSDOC-EXAMPLE-BUCKET", "Name": "image-name.png"},
           HumanLoopConfig={
               "HumanLoopName": "human-loop-name",
               "DataAttributes": {ContentClassifiers:
                   ["FreeOfPersonallyIdentifiableInformation" | "FreeOfAdultContent"]
                }
            }
        )

Human loops are only created if Amazon Rekognition’s confidence for an image moderation task meets the activation conditions you specified in your human review workflow. You can check the `response` element to determine if a human loop has been created. To see everything included in this response, see `HumanLoopActivationOutput`.

```python
if "HumanLoopArn" in response["HumanLoopActivationOutput"]:
    # A human loop has been started!
    print(f"A human loop has been started with ARN: \
          {response["HumanLoopActivationOutput"]['HumanLoopArn']}")
```
Custom Integration

The following example uses the AWS SDK for Python (Boto3) to call `start_human_loop` in `us-west-2`. Replace the italicized red text with your resources. Include the `DataAttributes` parameter if you are using the Amazon Mechanical Turk workforce. For more information, see the `start_human_loop` documentation in the AWS SDK for Python (Boto) API Reference.

```python
response = client.start_human_loop(
    HumanLoopName= "human-loop-name",
    HumanLoopInput={"InputContent": inputContentJson,
    DataAttributes={"ContentClassifiers": ["FreeOfPersonallyIdentifiableInformation"|"FreeOfAdultContent"]
)
```

This example stores input content in the variable `inputContentJson`. Assume that the input content contains two elements: a text blurb and sentiment (such as Positive, Negative, or Neutral), and it is formatted as follows:

```python
inputContent = {
    "initialValue": sentiment,
    "taskObject": blurb
}
```

The keys `initialValue` and `taskObject` must correspond to the keys used in the liquid elements of the worker task template. Refer to the custom template in Create a Human Task UI (p. 1094) to see an example.

To create `inputContentJson`, do the following:

```python
import json
inputContentJson = json.dumps(inputContent)
```

A human loop starts each time you call `start_human_loop`. To check the status of your human loop, use `describe_human_loop`:

```python
human_loop_info = a2i.describe_human_loop(HumanLoopName="human_loop_name")
print(f"HumanLoop Status: {resp["HumanLoopStatus"]}")
print(f"HumanLoop Output Destination: {resp["HumanLoopOutput"]}")
```

Use Cases and Examples Using Amazon A2I

You can use Amazon Augmented AI to incorporate a human review into your workflow for built-in task types, Amazon Textract and Amazon Rekognition, or your own custom tasks using a custom task type.

When you create a human review workflow using one of the built-in task types, you can specify conditions, such as confidence thresholds, that initiate a human review. The service (Amazon Rekognition or Amazon Textract) creates a human loop on your behalf when these conditions are met and supplies your input data directly to Amazon A2I to send to human reviewers. To learn more about the built-in task types, use the following:
When you use a custom task type, you create and start a human loop using the Amazon A2I Runtime API. Use the custom task type to incorporate a human review workflow with other AWS services or your own custom ML application.

- For more details, see Use Amazon Augmented AI with Custom Task Types (p. 1108)

The following table outlines a variety of Amazon A2I use cases that you can explore using SageMaker Jupyter Notebooks. To get started with a Jupyter Notebook, use the instructions in Use SageMaker Notebook Instance with Amazon A2I Jupyter Notebook (p. 1104). For more examples, see this GitHub repository.

- Use SageMaker Notebook Instance with Amazon A2I Jupyter Notebook (p. 1104)
- Use Amazon Augmented AI with Amazon Textract (p. 1104)
- Use Amazon Augmented AI with Amazon Rekognition (p. 1107)
- Use Amazon Augmented AI with Custom Task Types (p. 1108)

**Use SageMaker Notebook Instance with Amazon A2I Jupyter Notebook**

For an end-to-end example that demonstrates how to integrate an Amazon A2I human review loop into a machine learning workflow, you can use a Jupyter Notebook from this GitHub Repository in a SageMaker notebook instance.

**To use an Amazon A2I custom task type sample notebook in an Amazon SageMaker notebook instance:**

1. If you do not have an active SageMaker notebook instance, create one by following the instructions in Step 1: Create an Amazon SageMaker Notebook Instance (p. 299).
2. When your notebook instance is active, choose Open JupyterLab to the right of the notebook instance’s name. It may take a few moments for JupyterLab to load.
3. Choose the icon to clone a GitHub repository into your workspace.
4. Enter the amazon-a2i-sample-jupyter-notebooks repository HTTPS URL.
5. Choose CLONE.
6. Open the notebook that you would like to run.
7. Follow the instructions in the notebook to configure your human review workflow and human loop and run the cells.
8. To avoid incurring unnecessary charges, when you are done with the demo, stop and delete your notebook instance in addition to any Amazon S3 buckets, IAM roles, and CloudWatch Events resources created during the walkthrough.

**Use Amazon Augmented AI with Amazon Textract**

Amazon Textract enables you to add document text detection and analysis to your applications. Amazon Augmented AI (Amazon A2I) directly integrates with Amazon Textract’s AnalyzeDocument API operation. You can use AnalyzeDocument to analyze a document for relationships between detected items. When you add an Amazon A2I human review loop to an AnalyzeDocument request, Amazon A2I monitors the Amazon Textract results and sends a document to one or more human workers for review when the conditions specified in your flow definition are met. For example, if you want a human...
to review a specific key like \texttt{Full name}: and their associated input values, you can create an activation condition that starts a human review any time the \texttt{Full name}: key is detected or when the inference confidence for that key falls within a range that you specify.

The following image depicts the Amazon A2I built-in workflow with Amazon Textract. On the left, the resources that are required to create an Amazon Textract human review workflow are depicted: and Amazon S3 bucket, activation conditions, a worker task template, and a work team. These resources are used to create a human review workflow, or flow definition. An arrow points right to the next step in the workflow: using Amazon Textract to configure a human loop with the human review workflow. A second arrow points right from this step to the step in which activation conditions specified in the human review workflow are met. This initiates the creation of a human loop. On the right of the image, the human loop is depicted in three steps: 1) the worker UI and tools are generated and the task is made available to workers, 2) workers review input data, and finally, 3) results are saved in Amazon S3.

You can specify when Amazon Textract sends a task to a human worker for review when creating a human review workflow or flow definition by specifying \emph{activation conditions}.

You can set the following activation conditions when using the Amazon Textract task type:

- Initiate a human review for specific form keys based on the form key confidence score.
- Initiate a human review when specific form keys are missing.
- Initiate human review for all form keys identified by Amazon Textract with confidence scores in a specified range.
- Randomly send a sample of forms to humans for review.

When your activation condition depends on form key confidence scores, you can use two types of prediction confidence to initiate human loops:

- \textbf{Identification confidence} – The confidence score for key-value pairs detected within a form.
- \textbf{Qualification confidence} – The confidence score for text contained within key and value in a form.

In the image in the following section, \textbf{Full Name: Jane Doe} is the key-value pair, \textbf{Full Name} is the key, and \textbf{Jane Doe} is the value.

You can set these activation conditions using the Amazon SageMaker console when you create a human review workflow, or by creating a JSON for human loop activation conditions and specifying this as input in the HumanLoopActivationConditions parameter of \texttt{CreateFlowDefinition} API operation. To learn how specify activation conditions in JSON format, see \texttt{JSON Schema for Human Loop Activation}.
Get Started: Integrate a Human Review into an Amazon Textract Analyze Document Job

To integrate a human review into an Amazon Textract text detection and analysis job, you need to create a flow definition, and then use the Amazon Textract API to integrate that flow definition into your workflow. To learn how to create a flow definition using the SageMaker console or Augmented AI API, see the following topics:

- Create a Human Review Workflow (Console) (p. 1111)
- Create a Human Review Workflow (API) (p. 1112)

After you've created your flow definition, see Using Augmented AI with Amazon Textract to learn how to integrate your flow definition into your Amazon Textract task.

End-to-End Example Using Amazon Textract and Amazon A2I

For an end-to-end example that demonstrates how to use Amazon Textract with Amazon A2I using the console, see Tutorial: Get Started in the Amazon A2I Console (p. 1087).

To learn how to use the Amazon A2I API to create and start a human review, you can use Amazon Augmented AI (Amazon A2I) integration with Amazon Textract's Analyze Document [Example] in a SageMaker Notebook instance. To get started, see Use SageMaker Notebook Instance with Amazon A2I Jupyter Notebook (p. 1104).

A2I Textract Worker Console Preview

When they're assigned a review task in an Amazon Textract workflow, workers might see a user interface similar to the following:

You can customize this interface in the SageMaker console when you create your human review definition, or by creating and using a custom template. To learn more, see Create and Manage Worker Task Templates (p. 1136).
Use Amazon Augmented AI with Amazon Rekognition

Amazon Rekognition makes it easy to add image analysis to your applications. The Amazon Rekognition DetectModerationLabels API operation is directly integrated with Amazon A2I so that you can easily create a human loop to review unsafe images, such as explicit adult or violent content. You can use DetectModerationLabels to configure a human loop using a flow definition ARN. This enables Amazon A2I to analyze predictions made by Amazon Rekognition and send results to a human for review to ensure they meet the conditions set in your flow definition.

The following image depicts the Amazon A2I built-in workflow with Amazon Rekognition. On the left, the resources that are required to create an Amazon Rekognition human review workflow are depicted: an Amazon S3 bucket, activation conditions, a worker task template, and a work team. These resources are used to create a human review workflow, or flow definition. An arrow points right to the next step in the workflow: using Amazon Rekognition to configure a human loop with the human review workflow. A second arrow points right from this step to the step in which activation conditions specified in the human review workflow are met. This initiates the creation of a human loop. On the right of the image, the human loop is depicted in three steps: 1) the worker UI and tools are generated and the task is made available to workers, 2) workers review input data, and finally, 3) results are saved in Amazon S3.

You can set the following activation conditions when using the Amazon Rekognition task type:

- Initiate human review for labels identified by Amazon Rekognition based on the label confidence score.
- Randomly send a sample of images to humans for review.

You can set these activation conditions using the Amazon SageMaker console when you create a human review workflow, or by creating a JSON for human loop activation conditions and specifying this as input in the HumanLoopActivationConditions parameter of the CreateFlowDefinition API operation. To learn how specify activation conditions in JSON format, see JSON Schema for Human Loop Activation Conditions in Amazon Augmented AI (p. 1116) and Use Human Loop Activation Conditions JSON Schema with Amazon Rekognition (p. 1123).

Note
When using Augmented AI with Amazon Rekognition, create Augmented AI resources in the same AWS Region you use to call DetectModerationLabels.

Get Started: Integrate a Human Review into an Amazon Rekognition Image Moderation Job

To integrate a human review into an Amazon Rekognition, see the following topics:
• Create a Human Review Workflow (Console) (p. 1111)
• Create a Human Review Workflow (API) (p. 1112)

After you’ve created your flow definition, see Using Augmented AI with Amazon Rekognition to learn how to integrate your flow definition into your Amazon Rekognition task.

End-to-end Demo Using Amazon Rekognition and Amazon A2I

For an end-to-end example that demonstrates how to use Amazon Rekognition with Amazon A2I using the console, see Tutorial: Get Started in the Amazon A2I Console (p. 1087).

To learn how to use the Amazon A2I API to create and start a human review, you can use Amazon Augmented AI (Amazon A2I) integration with Amazon Rekognition [Example] in a SageMaker notebook instance. To get started, see Use SageMaker Notebook Instance with Amazon A2I Jupyter Notebook (p. 1104).

A2I Rekognition Worker Console Preview

When they’re assigned a review task in an Amazon Rekognition workflow, workers might see a user interface similar to the following:

You can customize this interface in the SageMaker console when you create your human review definition, or by creating and using a custom template. To learn more, see Create and Manage Worker Task Templates (p. 1136).

Use Amazon Augmented AI with Custom Task Types

You can use Amazon Augmented AI (Amazon A2I) to incorporate a human review (human loop) into any machine learning workflow using the custom task type. This option gives you the most flexibility to customize the conditions under which your data objects are sent to humans for review, as well as the look and feel of your worker user interface.

When you use a custom task type, you create a custom human review workflow and specify the conditions under which a data object is sent for human review directly in your application.

The following image depicts the Amazon A2I custom workflow. A custom ML model is used to generate predictions. The client application filters these predictions using user-defined criteria and determines if a
human review is required. If so, these predictions are sent to Amazon A2I for human review. Amazon A2I collects the results of human review in Amazon S3, which can access by the client application. If the filter determines that no human review is needed, predictions can be fed directly to the client application.

Use the procedures on this page to learn how to integrate Amazon A2I into any machine learning workflow using the custom task type.

Create a human loop using a flow definition, integrate it into your application, and monitor the results

1. Complete the Amazon A2I Prerequisites to Using Augmented AI (p. 1086). Note the following:
   - The path to the Amazon Simple Storage Service (Amazon S3) bucket or buckets where you store your input and output data.
   - The Amazon Resource Name (ARN) of an AWS Identity and Access Management (IAM) role with required permissions attached.
   - (Optional) The ARN of your private workforce, if you plan to use one.

2. Using HTML elements, create a custom worker template which Amazon A2I uses to generate your worker task UI. To learn how to create a custom template, see Create Custom Worker Task Templates (p. 1139).

3. Use the custom worker template from step 2 to generate a worker task template in the Amazon SageMaker console. To learn how, see Create a Worker Task Template (p. 1137).

In the next step, you create a flow definition:

   - If you want to create a flow definition using the SageMaker API, note the ARN of this worker task template for the next step.
   - If you are creating a flow definition using the console, your template automatically appears in Worker task template section when you choose Create human review workflow.

4. When creating your flow definition, provide the path to your S3 buckets, your IAM role ARN, and your worker template.
   - To learn how to create a flow definition using the SageMaker CreateFlowDefinition API, see Create a Human Review Workflow (API) (p. 1112).
   - To learn how to create a flow definition using the SageMaker console, see Create a Human Review Workflow (Console) (p. 1111).

5. Configure your human loop using the Amazon A2I Runtime API. To learn how, see Create and Start a Human Loop (p. 1129).
Create a Human Review Workflow

Use an Amazon Augmented AI (Amazon A2I) human review workflow, or flow definition, to specify the following:

- For the Amazon Textract and Amazon Rekognition built-in task types, the conditions under which your human loop is called
- The workforce to which your tasks are sent
- The set of instructions that your workforce receives, which is called a worker task template
- The configuration of your worker tasks, including the number of workers that receive a task and time limits to complete tasks
- Where your output data is stored

You can create a human review workflow in the SageMaker console or using the SageMaker CreateFlowDefinition operation. You can build a worker task template using the console for Amazon Textract and Amazon Rekognition task types while creating your flow definition.

**Important**
Human loop activation conditions, which initiate the human loop—for example, confidence thresholds—aren't available for Amazon A2I custom task types. When using the console to create a flow definition for a custom task type, you can't specify activation conditions. When using the Amazon A2I API to create a flow definition for a custom task type, you can't set the HumanLoopActivationConditions attribute of the HumanLoopActivationConditionsConfig parameter. To control when human reviews are initiated, specify conditions under which StartHumanLoop is called in your custom application. In this case, every StartHumanLoop invocation results in a human review. For more information, see Use Amazon Augmented AI with Custom Task Types (p. 1108).

**Prerequisites**
To create a human review workflow definition, you must have completed the prerequisites described in Prerequisites to Using Augmented AI (p. 1086).

If you use the API to create a flow definition for any task type, or if you use a custom task type when creating a flow definition in the console, first create a worker task template. For more information, see Create and Manage Worker Task Templates (p. 1136).

If you want to preview your worker task template while creating a flow definition for a built-in task type in the console, ensure that you grant the role that you use to create the flow definition permission to
access the Amazon S3 bucket that contains your template artifacts using a policy like the one described in Enable Worker Task Template Previews (p. 1161).

Topics

- Create a Human Review Workflow (Console) (p. 1111)
- Create a Human Review Workflow (API) (p. 1112)
- JSON Schema for Human Loop Activation Conditions in Amazon Augmented AI (p. 1116)

Create a Human Review Workflow (Console)

Use this procedure to create a Amazon Augmented AI (Amazon A2I) human review workflow using the SageMaker console. If you are new to Amazon A2I, we recommend that you create a private work team using people in your organization, and use this work team’s ARN when creating your flow definition. To learn how to set up a private workforce and create a work team, see Create a Private Workforce (Amazon SageMaker Console) (p. 983). If you have already set up a private workforce, see Create a Work Team Using the SageMaker Console (p. 986) to learn how to add a work team to that workforce.

If you are using Amazon A2I with one of the built-in task types, you can create worker instructions using a default worker task template provided by Augmented AI while creating a human review workflow in the console. To see samples of the default templates provided by Augmented AI, see the built-in task types in Use Cases and Examples Using Amazon A2I (p. 1102).

To create flow definition (console)

2. In the navigation pane, under the Augmented AI section, choose Human review workflows and then choose Create human review workflow.
3. In Overview, do the following:
   a. For Name, enter a unique workflow name. The name must be lowercase, unique within the AWS Region in your account, and can have up to 63 characters. Valid characters include: a-z, 0-9, and - (hyphen).
   b. For S3 location for output, enter the S3 bucket where you want to store the human review results. The bucket must be located in the same AWS Region as the workflow.
   c. For IAM role, choose the role that has the required permissions. If you choose a built-in task type and want to preview your worker template in the console, provide a role with the type of policy described in Enable Worker Task Template Previews (p. 1161) attached.
4. For Task type, choose the task type that you want the human worker to perform.
5. If you chose the Amazon Rekognition or Amazon Textract task type, specify the conditions that invoke human review.
   - For Amazon Rekognition image moderation tasks, choose an inference confidence score threshold interval that initiates human review.
   - For Amazon Textract tasks, you can initiate a human review when specific form keys are missing or when form key detection confidence is low. You can also initiate a human review if, after evaluating all of the form keys in the text, confidence is lower than your required threshold for any form key. Two variables specify your confidence thresholds: Identification confidence and Qualification confidence. To learn more about these variables, see Use Amazon Augmented AI with Amazon Textract (p. 1104).
   - For both task types, you can randomly send a percentage of data objects (images or forms) and their labels to humans for review.
6. Configure and specify your worker task template:
   a. If you are using the Amazon Rekognition or Amazon Textract task type:
Create a Human Review Workflow

In the **Create template** section:

- To create instructions for your workers using the Amazon A2I default template for Amazon Rekognition and Amazon Textract task types, choose **Build from a default template**.
- If you choose **Build from a default template**, create your instructions under **Worker task design**:
  - Provide a **Template name** that is unique in the AWS Region you are in.
  - In the **Instructions** section, provide detailed instructions on how to complete your task. To help workers achieve greater accuracy, provide good and bad examples.
  - (Optional) In **Additional instructions**, provide your workers with additional information and instructions. For information on creating effective instructions, see [Creating Good Worker Instructions](p. 1146).
- To select a custom template that you’ve created, choose it from the **Template** menu and provide a **Task description** to briefly describe the task for your workers. To learn how to create a custom template, see [Create a Worker Task Template](p. 1137).

b. If you are using the custom task type:

- In the **Worker task template** section, select your template from the list. All of the templates that you have created in the SageMaker console appear in this list. To learn how to create a template for custom task types, see [Create and Manage Worker Task Templates](p. 1136).

7. (Optional) Preview your worker template:

   For Amazon Rekognition and Amazon Textract task types, you have the option to choose **See a sample worker task** to preview your worker task UI.

   If you are creating a flow definition for a custom task type, you can preview your worker task UI using the RenderUiTemplate operation. For more information, see [Preview a Worker Task Template](p. 1145).

8. For **Workers**, choose a workforce type.

9. Choose **Create**.

**Next Steps**

After you've created a human review workflow, it appears in the console under **Human review workflows**. To see your flow definition's Amazon Resource Name (ARN) and configuration details, choose the workflow by selecting its name.

If you are using a built-in task type, you can use the flow definition ARN to start a human loop using that AWS service's API (for example, the Amazon Textract API). For custom task types, you can use the ARN to start a human loop using the Amazon Augmented AI Runtime API. To learn more about both options, see [Create and Start a Human Loop](p. 1129).

**Create a Human Review Workflow (API)**

To create a flow definition using the SageMaker API, you use the CreateFlowDefinition operation. After you complete the Prerequisites to Using Augmented AI (p. 1086), use the following procedure to learn how to use this API operation.

For an overview of the CreateFlowDefinition operation, and details about each parameter, see [CreateFlowDefinition](p. 1112).
To create a flow definition (API)

1. For FlowDefinitionName, enter a unique name. The name must be unique within the AWS Region in your account, and can have up to 63 characters. Valid characters include: a-z, 0-9, and - (hyphen).
2. For RoleArn, enter the ARN of the role that you configured to grant access to your data sources.
3. For HumanLoopConfig, enter information about the workers and what they should see. For information about each parameter in HumanLoopConfig, see HumanLoopConfig.
4. (Optional) If you are using a built-in task type, provide conditions that initiate a human loop in HumanLoopActivationConfig. To learn how to create the input required for the HumanLoopActivationConfig parameter, see JSON Schema for Human Loop Activation Conditions in Amazon Augmented AI (p. 1116). If you do not specify conditions here, when you provide a flow definition to the AWS service associated with a built-in task type (for example, Amazon Textract or Amazon Rekognition), that service sends every task to a human worker for review.

If you are using a custom task type, HumanLoopActivationConfig is disabled. To learn how to control when tasks are sent to human workers using a custom task type, see Use Amazon Augmented AI with Custom Task Types (p. 1108).

5. (Optional) If you are using a built-in task type, specify the integration source (for example, Amazon Rekognition or Amazon Textract) in the HumanLoopRequestSource parameter.
6. For OutputConfig, indicate where in Amazon Simple Storage Service (Amazon S3) to store the output of the human loop.
7. (Optional) Use Tags to enter key-value pairs to help you categorize and organize a flow definition. Each tag consists of a key and a value, both of which you define.

Amazon Textract – Key-value pair extraction

The following is an example of a request to create an Amazon Textract human review workflow (flow definition) using the AWS SDK for Python (Boto3). You must use 'AWS/Textract/AnalyzeDocument/Forms/V1' to create a Amazon Textract human loop. Only include PublicWorkforceTaskPrice if you are using the Mechanical Turk workforce.

sagemaker_client = boto3.client('sagemaker', aws_region)
response = sagemaker_client.create_flow_definition(
    FlowDefinitionName='ExampleFlowDefinition',
    HumanLoopRequestSource={
        'AwsManagedHumanLoopRequestSource': 'AWS/Textract/AnalyzeDocument/Forms/V1'
    },
    HumanLoopActivationConfig={[
        'HumanLoopActivationConditionsConfig': {
            'HumanLoopActivationConditions': '{...}'
        }
    ],
    HumanLoopConfig={[
        'TaskTitle': 'Example task title',
        'TaskDescription': 'Example task description.',
        'TaskCount': 123,
        'TaskAvailabilityLifetimeInSeconds': 123,
        'TaskTimeLimitInSeconds': 123,
        'TaskKeywords': [
            'Keyword1','Keyword2'
        ],
        'PublicWorkforceTaskPrice': {
            'AmountInUsd': {
                'Dollars': 123
            }
        }
    ]}
Amazon Rekognition – Image moderation

The following is an example of a request to create an Amazon Rekognition human review workflow (flow definition) using the AWS SDK for Python (Boto3). You must use 'AWS/Rekognition/DetectModerationLabels/Image/V3' to create an Amazon Rekognition flow definition. Only include PublicWorkforceTaskPrice if you are using the Mechanical Turk workforce.

```python
sagemaker_client = boto3.client('sagemaker', aws_region)
response = sagemaker_client.create_flow_definition(
    FlowDefinitionName='ExampleFlowDefinition',
    HumanLoopRequestSource={
        'AwsManagedHumanLoopRequestSource': 'AWS/Rekognition/DetectModerationLabels/Image/V3'
    },
    HumanLoopActivationConfig={
        'HumanLoopActivationConditionsConfig': {
            'HumanLoopActivationConditions': '{}'
        }
    },
    HumanLoopConfig={
        'TaskTitle': 'Example task title',
        'TaskDescription': 'Example task description.',
        'TaskCount': 123,
        'TaskAvailabilityLifetimeInSeconds': 123,
        'TaskTimeLimitInSeconds': 123,
        'TaskKeywords': ['Keyword1', 'Keyword2'],
        'PublicWorkforceTaskPrice': {
            'AmountInUsd': {
                'Dollars': 123,
                'Cents': 123,
                'TenthFractionsOfACent': 123
            }
        }
    },
    OutputConfig={
        'S3OutputPath': 's3://bucket/path/',
        'KmsKeyId': '1234abcd-12ab-34cd-56ef-1234567890ab'
    },
    RoleArn='arn:aws:iam::aws_account_number:role/role_name',
)
```

Amazon SageMaker Developer Guide
Create a Human Review Workflow
Tags=[
    {
        'Key': 'KeyName',
        'Value': 'ValueName'
    },
]

Custom Workflow

The following is an example of a request to create a human review workflow (flow definition) for a custom integration. To create this type of human review workflow, omit `HumanLoopRequestSource` from the flow definition request. You only need to include `PublicWorkforceTaskPrice` if you are using the Mechanical Turk workforce.

```python
sagemaker_client = boto3.client('sagemaker', aws_region)
response = sagemaker_client.create_flow_definition(
    FlowDefinitionName='ExampleFlowDefinition',
    HumanLoopActivationConfig={
        'HumanLoopActivationConditionsConfig': {
            'HumanLoopActivationConditions': '(...)
        },
    },
    HumanLoopConfig={
        'TaskTitle': 'Example task title',
        'TaskDescription': 'Example task description.',
        'TaskCount': 123,
        'TaskAvailabilityLifetimeInSeconds': 123,
        'TaskTimeLimitInSeconds': 123,
        'TaskKeywords': ['Keyword1', 'Keyword2'],
        'PublicWorkforceTaskPrice': {
            'AmountInUsd': {
                'Dollars': 123,
                'Cents': 123,
                'TenthFractionsOfACent': 123
            }
        },
    },
    OutputConfig={
        'S3OutputPath': 's3://bucket/path/',
        'KmsKeyId': '1234abcd-12ab-34cd-56ef-1234567890ab'
    },
    RoleArn='arn:aws:iam::account_number:role/role_name',
    Tags=[
        {
            'Key': 'KeyName',
            'Value': 'ValueName'
        },
    ]
)
```

Next Steps

The return value of a successful call of the `CreateFlowDefinition` API operation is a flow definition Amazon Resource Name (ARN).
If you are using a built-in task type, you can use the flow definition ARN to start a human loop using that AWS service's API (i.e. the Amazon Textract API). For custom task types, you can use the ARN to start a human loop using the Amazon Augmented AI Runtime API. To learn more about both of these options, see Create and Start a Human Loop (p. 1129).

**JSON Schema for Human Loop Activation Conditions in Amazon Augmented AI**

The HumanLoopActivationConditions is an input parameter of the `CreateFlowDefinition` API. This parameter is a JSON-formatted string. The JSON models the conditions under which a human loop is created when those conditions are evaluated against the response from an integrating AI service API (such as Rekognition.DetectModerationLabels or Textract.AnalyzeDocument). This response is referred to as an inference. For example, Amazon Rekognition sends an inference of a moderation label with an associated confidence score. In this example, the inference is the model’s best estimate of the appropriate label for an image. For Amazon Textract, inference is made on the association between blocks of text (key-value pairs), such as the association between Name: and Sue in a form as well as content within a block of text, or word block, such as 'Name'.

The following is the schema for the JSON. At the top level, the HumanLoopActivationConditions has a JSON array, Conditions. Each member of this array is an independent condition that, if evaluated to true, results in Amazon A2I creating a human loop. Each such independent condition can be a simple condition or a complex condition. A simple condition has the following attributes:

- **ConditionType**: This attribute identifies the type of condition. Each AWS AI service API that integrates with Amazon A2I defines its own set of allowed ConditionTypes.
  - Rekognition DetectModerationLabels – This API supports the moderation label confidence check and sampling ConditionType values.
  - Textract AnalyzeDocument – This API supports the ImportantFormKeyConfidenceCheck, MissingImportantFormKey, and Sampling ConditionType values.
- **ConditionParameters** – This is a JSON object that parameterizes the condition. The set of allowed attributes of this object is dependent on the value of the ConditionType. Each ConditionType defines its own set of ConditionParameters.

A member of the Conditions array can model a complex condition. This is accomplished by logically connecting simple conditions using the And and Or logical operators and nesting the underlying simple conditions. Up to two levels of nesting are supported.

**Note**

Human loop activation conditions aren't available for human review workflows that are integrated with custom task types. The HumanLoopActivationConditions parameter is disabled for custom task types.

**Topics**

- Use Human Loop Activation Conditions JSON Schema with Amazon Textract (p. 1117)
- Use Human Loop Activation Conditions JSON Schema with Amazon Rekognition (p. 1123)

**Use Human Loop Activation Conditions JSON Schema with Amazon Textract**

When used with Amazon A2I, the AnalyzeDocument operation supports the following inputs in the ConditionType parameter:

- **ImportantFormKeyConfidenceCheck** – Use this condition to create a human loop when inference confidence is within a specified range for document form keys and word blocks. A form key is any
word in a document that is associated with an input. The input is called a *value*. Together, form keys and values are referred to as *key-value pairs*. A *word block* refers to the words that Amazon Textract recognizes inside of a detected block of text. To learn more about Amazon Textract document blocks, see [Documents and Block Objects](https://docs.aws.amazon.com/textract/latest/dg/detect-document-blocks.html) in the *Amazon Textract Developer Guide*.

- **MissingImportantFormKey** – Use this condition to create a human loop when Amazon Textract did not identify the key or its associated aliases within the document.
- **Sampling** – Use this condition to specify a percentage of forms to send to humans for review, regardless of inference confidence scores. Use this condition to do the following:
  - Audit your ML model by randomly sampling all forms analyzed by your model and sending a specified percentage to humans for review.
  - Using the **ImportantFormKeyConfidenceCheck** condition, randomly sample a percentage of the inferences that met the conditions specified in **ImportantFormKeyConfidenceCheck** to start a human loop and send only the specified percentage to humans for review.

**Note**

If you send the same request to *AnalyzeDocument* multiple times, the result of **Sampling** does not change for the inference of that input. For example, if you make an *AnalyzeDocument* request once, and **Sampling** doesn't initiate a human loop, subsequent requests to *AnalyzeDocument* with the same configuration do not initiate a human loop.

**ImportantFormKeyConfidenceCheck Inputs and Results**

The **ImportantFormKeyConfidenceCheck** **ConditionType** supports the following **ConditionParameters**:

- **ImportantFormKey** – A string representing a key in a key-value pair detected by Amazon Textract that needs to be reviewed by human workers. If the value of this parameter is the special catch-all value (*), then all keys are considered to be matched to the condition. You can use this to model the case where any key-value pair satisfying certain confidence thresholds needs human review.
- **ImportantFormKeyAliases** – An array that represents alternate spellings or logical equivalents for the important form key.
- **KeyValueBlockConfidenceEquals**
- **KeyValueBlockConfidenceLessThan**
- **KeyValueBlockConfidenceLessThanEquals**
- **KeyValueBlockConfidenceGreaterThan**
- **KeyValueBlockConfidenceGreaterThanEquals**
- **WordBlockConfidenceEquals**
- **WordBlockConfidenceLessThan**
- **WordBlockConfidenceLessThanEquals**
- **WordBlockConfidenceGreaterThan**
- **WordBlockConfidenceGreaterThanEquals**

When you use the **ImportantFormKeyConfidenceCheck** **ConditionType**, Amazon A2I sends the key-value block and word block inferences of the key-value blocks and associated aliases that you specified in **ImportantFormKey** and **ImportantFormKeyAliases** for human review.

When creating a flow definition, if you use the default worker task template that is provided in the Human review workflows section of the Amazon SageMaker console, key-value and block inferences sent for human review by this activation condition are included in the worker UI. If you use a custom worker task template, you need to include the `{{ task.input.selectedAiServiceResponse.blocks }}` element to include initial-value input.
data (inferences) from Amazon Textract. For an example of a custom template that uses this input element, see Custom Template Example for Amazon Textract \(\text{(p. 1140)}\).

**MissingImportantFormKey Inputs and Results**

The MissingImportantFormKey ConditionType supports the following ConditionParameters:

- **ImportantFormKey** – A string representing a key in a key-value pair detected by Amazon Textract that needs to be reviewed by human workers.
- **ImportantFormKeyAliases** – An array that represents alternate spellings or logical equivalents for the important form key.

When you use the MissingImportantFormKey ConditionType, if the key in ImportantFormKey or aliases in ImportantFormKeyAliases are not included in the Amazon Textract inference, that form is sent to human for review and no predicted key-value pairs are included. For example, if Amazon Textract only identified Address and Phone in a form, but was missing the ImportantFormKey Name (in the MissingImportantFormKey condition type) that form would be sent to humans for review without any of the form keys detected (Address and Phone).

If you use the default worker task template that is provided in the SageMaker console, a task is created asking workers to identify the key in ImportantFormKey and associated value. If you use a custom worker task template, you need to include the `<task.input.humanLoopContext>` custom HTML element to configure this task.

**Sampling Inputs and Results**

The Sampling ConditionType supports the RandomSamplingPercentage ConditionParameters. The input for RandomSamplingPercentage must be a real number between 0.01 and 100. This number represents the percentage of data that qualifies for a human review and is sent to humans for review. If you use the Sampling condition without any other conditions, this number represents the percentage of all resulting inferences made by the AnalyzeDocument operation from a single request that is sent to humans for review.

If you specify the Sampling condition without any other condition type, all key-value and block inferences are sent to workers for review.

When creating a flow definition, if you use the default worker task template that is provided in the **Human review workflows** section of the SageMaker console, all key-value and block inferences sent for human review by this activation condition are included in the worker UI. If you use a custom worker task template, you need to include the `{{ task.input.selectedAiServiceResponse.blocks }}` element to include initial-value input data (inferences) from Amazon Textract. For an example of a custom template that uses this input element, see Custom Template Example for Amazon Textract \(\text{(p. 1140)}\).

**Examples**

While only one condition needs to evaluate to true to initiate a human loop, Amazon A2I evaluates all conditions for each object analyzed by Amazon Textract. The human reviewers are asked to review the important form keys for all the conditions that evaluated to true.

**Example 1: Detect important form keys with confidence scores in a specified range that initiate a human loop**

The following example shows a HumanLoopActivationConditions JSON that initiates a human loop if any one of the following three conditions is met:

- The Amazon Textract AnalyzeDocument API returns a key-value pair whose key is one of EmployeeName, Name, or EmployeeName, with the confidence of the key-value block being less than 60 and the confidences of each of the word blocks making up the key and value being less than 85.
The Amazon Textract AnalyzeDocument API returns a key-value pair whose key is one of Pay Date, PayDate, DateOfPay, or pay-date, with the confidence of the key-value block being less than 65 and the confidences of each of the word blocks making up the key and value being less than 85.

The Amazon Textract AnalyzeDocument API returns a key-value pair whose key is one of Gross Pay, GrossPay, or GrossAmount, with the confidence of the key-value block being less than 60 and the confidences of each of the word blocks making up the key and value being less than 85.

Example 2: Use ImportantFormKeyConfidenceCheck

In the following example, if Amazon Textract detects a key-value pair whose confidence for the key-value block is less than 60 and is less than 90 for any underlying word blocks, it creates a human loop. The human reviewers are asked to review all the form key-value pairs that matched the confidence value comparisons.
Example 3: Use Sampling

In the following example, 5% of inferences resulting from an Amazon Textract AnalyzeDocument request are sent to human workers for review. All detected key-value pairs returned by Amazon Textract are sent to workers for review.

```json
"Conditions": [ 
  { "ConditionType": "Sampling", 
    "ConditionParameters": { 
      "RandomSamplingPercentage": 5 
    } 
  } 
]
```

Example 4: Use MissingImportantFormKey

In the following example, if Mailing Address or its alias, Mailing Address:, is missing from keys detected by Amazon Textract, a human review is initiated. When using the default worker task template, the worker UI asks workers to identify the key Mailing Address or Mailing Address: and its associated value.

```json
"ConditionType": "MissingImportantFormKey", 
"ConditionParameters": { 
  "ImportantFormKey": "Mailing Address", 
  "ImportantFormKeyAliases": ["Mailing Address:"
}
```

Example 5: Use Sampling and ImportantFormKeyConfidenceCheck with the And operator

In this example, 5% of key-value pairs detected by Amazon Textract whose key is one of Pay Date, PayDate, DateOfPay, or pay-date, with the confidence of the key-value block less than 65 and the confidences of each of the word blocks making up the key and value less than 85, are sent to workers for review.

```json
"Conditions": [ 
  { 
    "And": [ 
      { 
        "ConditionType": "Sampling", 
        "ConditionParameters": { 
          "RandomSamplingPercentage": 5 
        } 
      }, 
      { 
        "ConditionType": "ImportantFormKeyConfidenceCheck", 
        "ConditionParameters": { 
```
Example 6: Use Sampling and ImportantFormKeyConfidenceCheck with the And operator

Use this example to configure your human review workflow to always send low confidence inferences of a specified key-value pair for human review and sample high confidence inference of a key-value pair at a specified rate.

In the following example, a human review is initiated in one of the following ways:

- Key-value pairs detected whose key is one of Pay Date, PayDate, DateOfPay, or pay-date, with key-value and word block confidences less than 60, are sent for human review. Only the Pay Date form key (and its aliases) and associated values are sent to workers to review.
- 5% of key-value pairs detected whose key is one of Pay Date, PayDate, DateOfPay, or pay-date, with key-value and word block confidences greater than 90, are sent for human review. Only the Pay Date form key (and its aliases) and associated values are sent to workers to review.
Example 7: Use Sampling and ImportantFormKeyConfidenceCheck with the Or operator

In the following example, the Amazon Textract AnalyzeDocument operation returns a key-value pair whose key is one of Pay Date, PayDate, DateOfPay, or pay-date, with the confidence of the key-value block less than 65 and the confidences of each of the word blocks making up the key and value less than 85. Additionally, 5% of all other forms initiate a human loop. For each form randomly chosen, all key-value pairs detected for that form are sent to humans for review.

```
{
  "Conditions": [
    { "Or": [
      { "ConditionType": "Sampling",
        "ConditionParameters": {
          "RandomSamplingPercentage": 5
        }
      },
      { "ConditionType": "ImportantFormKeyConfidenceCheck",
        "ConditionParameters": {
          "ImportantFormKey": "Pay Date",
          "ImportantFormKeyAliases": [
            "PayDate",
            "DateOfPay",
            "pay-date"
          ],
          "KeyValueBlockConfidenceLessThan": 65,
          "WordBlockConfidenceLessThan": 85
        }
      }
    ]
  }
}
```

Use Human Loop Activation Conditions JSON Schema with Amazon Rekognition

When used with Amazon A2I, the Amazon Rekognition DetectModerationLabels operation supports the following inputs in the ConditionType parameters:

- **ModerationLabelConfidenceCheck** – Use this condition type to create a human loop when inference confidence is low for one or more specified labels.
- **Sampling** – Use this condition to specify a percentage of all inferences to send to humans for review. Use this condition to do the following:
  - Audit your ML model by randomly sampling all of your model's inferences and sending a specified percentage to humans for review.
• Using the ModerationLabelConfidenceCheck condition, randomly sample a percentage of the inferences that met the conditions specified in ModerationLabelConfidenceCheck to start a human loop and send only the specified percentage to humans for review.

**Note**

If you send the same request to DetectModerationLabels multiple times, the result of Sampling does not change for the inference of that input. For example, if you make a DetectModerationLabels request once, and Sampling does not initiate a human loop, subsequent requests to DetectModerationLabels with the same configuration don't initiate a human loop.

When creating a flow definition, if you use the default worker task template that is provided in the **Human review workflows** section of the Amazon SageMaker console, inferences sent for human review by these activation conditions are included in the worker UI when a worker opens your task. If you use a custom worker task template, you need to include the `<task.input.selectedAiServiceResponse.blocks>` custom HTML element to access these inferences. For an example of a custom template that uses this HTML element, see **Custom Template Example for Amazon Rekognition** (p. 1141).

**ModerationLabelConfidenceCheck Inputs**

For the ModerationLabelConfidenceCheck ConditionType, the following ConditionParameters are supported:

- **ModerationLabelName** – The exact (case-sensitive) name of a ModerationLabel detected by the Amazon Rekognition DetectModerationLabels operation. You can specify the special catch-all value (*) to denote any moderation label.
- **ConfidenceEquals**
- **ConfidenceLessThan**
- **ConfidenceLessThanEquals**
- **ConfidenceGreaterThan**
- **ConfidenceGreaterThanEquals**

When you use the ModerationLabelConfidenceCheck ConditionType, Amazon A2I sends label inferences for the labels that you specified in ModerationLabelName for human review.

**Sampling Inputs**

The Sampling ConditionType supports the RandomSamplingPercentage ConditionParameters. The input for the RandomSamplingPercentage parameter should be a real number between 0.01 and 100. This number represents the percentage of inferences that qualifies for a human review that are sent to humans for review. If you use the Sampling condition without any other conditions, this number represents the percentage of all inferences that result from a single DetectModerationLabel request that are sent to humans for review.

**Examples**

**Example 1: Use ModerationLabelConfidenceCheck with the And operator**

The following example of a HumanLoopActivationConditions condition initiates a human loop when one or more of the following conditions are met:

- Amazon Rekognition detects the Graphic Male Nudity moderation label with a confidence between 90 and 99.
- Amazon Rekognition detects the Graphic Female Nudity moderation label with a confidence between 80 and 99.

Note the use of the Or and And logical operators to model this logic.

Although only one of the two conditions under the Or operator needs to evaluate to true for a human loop to be created, Amazon Augmented AI evaluates all conditions. Human reviewers are asked to review the moderation labels for all the conditions that evaluated to true.

```json
{
    "Conditions": [
        {
            "Or": [
                {
                    "And": [
                        {
                            "ConditionType": "ModerationLabelConfidenceCheck",
                            "ConditionParameters": {
                                "ModerationLabelName": "Graphic Male Nudity",
                                "ConfidenceLessThanEquals": 99
                            }
                        },
                        {
                            "ConditionType": "ModerationLabelConfidenceCheck",
                            "ConditionParameters": {
                                "ModerationLabelName": "Graphic Male Nudity",
                                "ConfidenceGreaterThanEquals": 90
                            }
                        }
                    ]
                },
                {
                    "And": [
                        {
                            "ConditionType": "ModerationLabelConfidenceCheck",
                            "ConditionParameters": {
                                "ModerationLabelName": "Graphic Female Nudity",
                                "ConfidenceLessThanEquals": 99
                            }
                        },
                        {
                            "ConditionType": "ModerationLabelConfidenceCheck",
                            "ConditionParameters": {
                                "ModerationLabelName": "Graphic Female Nudity",
                                "ConfidenceGreaterThanEquals": 80
                            }
                        }
                    ]
                }
            ]
        }
    ]
}
```

Example 2: Use ModerationLabelConfidenceCheck with the catch-all value (*)

In the following example, if any moderation label with a confidence greater than or equal to 75 is detected, a human loop is initiated. Human reviewers are asked to review all moderation labels with confidence scores greater than or equal to 75.

```json
{
    "Conditions": [
        {
            "ConditionType": "ModerationLabelConfidenceCheck",
            "ConditionParameters": {
                "ModerationLabelName": "*",
                "ConfidenceGreaterThanEquals": 75
            }
        }
    ]
}
```
Example 3: Use Sampling

In the following example, 5% of Amazon Rekognition inferences from a DetectModerationLabels request are sent to human workers. When using the default worker task template provided in the SageMaker console, all moderation labels returned by Amazon Rekognition are sent to workers for review.

```
{"Conditions": [
  {
    "ConditionType": "Sampling",
    "ConditionParameters": {
      "RandomSamplingPercentage": 5
    }
  }
]}
```

Example 4: Use Sampling and ModerationLabelConfidenceCheck with the And operator

In this example, 5% of Amazon Rekognition inferences of the Graphic Male Nudity moderation label with a confidence greater than 50 are sent workers for review. When using the default worker task template provided in the SageMaker console, only the inferences of the Graphic Male Nudity label are sent to workers for review.

```
{"Conditions": [
  {
    "And": [
      {
        "ConditionType": "Sampling",
        "ConditionParameters": {
          "RandomSamplingPercentage": 5
        }
      },
      {
        "ConditionType": "ModerationLabelConfidenceCheck",
        "ConditionParameters": {
          "ModerationLabelName": "Graphic Male Nudity",
          "ConfidenceGreaterThan": 50
        }
      }
    ]
  }
]}
```

Example 5: Use Sampling and ModerationLabelConfidenceCheck with the And operator

Use this example to configure your human review workflow to always send low-confidence inferences of a specified label for human review and sample high-confidence inferences of a label at a specified rate.

In the following example, a human review is initiated in one of the following ways:

- Inferences for the Graphic Male Nudity moderation label the with confidence scores less than 60 are always sent for human review. Only the Graphic Male Nudity label is sent to workers to review.
• 5% of all inferences for the Graphic Male Nudity moderation label the with confidence scores greater than 90 are sent for human review. Only the Graphic Male Nudity label is sent to workers to review.

```
{
   "Conditions": [
      {
         "Or": [
            {
               "ConditionType": "ModerationLabelConfidenceCheck",
               "ConditionParameters": {
                  "ModerationLabelName": "Graphic Male Nudity",
                  "ConfidenceLessThan": 60
               }
            },
            {
               "ConditionType": "Sampling",
               "ConditionParameters": {
                  "RandomSamplingPercentage": 5
               }
            },
            {
               "ConditionType": "ModerationLabelConfidenceCheck",
               "ConditionParameters": {
                  "ModerationLabelName": "Graphic Male Nudity",
                  "ConfidenceGreaterThan": 90
               }
            }
         ]
      }
   ]
}
```

**Example 6: Use Sampling and ModerationLabelConfidenceCheck with the Or operator**

In the following example, a human loop is created if the Amazon Rekognition inference response contains the 'Graphic Male Nudity' label with inference confidence greater than 50. Additionally, 5% of all other inferences initiate a human loop.

```
{
   "Conditions": [
      {
         "Or": [
            {
               "ConditionType": "Sampling",
               "ConditionParameters": {
                  "RandomSamplingPercentage": 5
               }
            },
            {
               "ConditionType": "ModerationLabelConfidenceCheck",
               "ConditionParameters": {
                  "ModerationLabelName": "Graphic Male Nudity",
                  "ConfidenceGreaterThan": 50
               }
            }
         ]
      }
   ]
}
```
Delete a Human Review Workflow

When you delete a human review workflow or you delete your AWS account while a human loop is in process, your human review workflow status changes to Deleting. Amazon A2I automatically stops and deletes all associated human loops if workers have not started tasks created by those human loops. If human workers are already working on a task, that task continues to be available until it is completed or expires. As long as workers are still working on a task, your human review workflow's status is Deleting. If these tasks are completed, the results are stored in the Amazon S3 bucket specified in your flow definition.

Deleting a flow definition does not remove any worker answers from your S3 bucket. If the tasks are completed, but you deleted your AWS account, the results are stored in the Augmented AI service bucket for 30 days and then permanently deleted.

After all human loops have been deleted, the human review workflow is permanently deleted. When a human review workflow has been deleted, you can reuse its name to create a new human review workflow.

You might want to delete a human review workflow for any of the following reasons:

- You have sent data to a set of human reviewers and you want to delete all non-started human loops because you do not want those workers to work on those tasks any longer.
- The worker task template used to generate your worker UI does not render correctly or is not functioning as expected.

After you delete a human review workflow, the following changes occur:

- The human review workflow no longer appears on the Human review workflows page in the Augmented AI area of the Amazon SageMaker console.
- When you use the human review workflow name as input to the API operations DescribeFlowDefinition or DeleteFlowDefinition, Augmented AI returns a ResourceNotFound error.
- When you use ListFlowDefinitions, deleted human review workflows aren't included in the results.
- When you use the human review workflow ARN as input to the Augmented AI Runtime API operation ListHumanLoops, Augmented AI returns a ResourceNotFoundException.

Delete a Flow Definition Using the Console or the SageMaker API

You can delete a human review workflow on the Human review workflows page in the Augmented AI area of the SageMaker console or by using the SageMaker API.

Flow definitions can only be deleted if their status is Active.

**Delete a human review workflow (console)**

1. Navigate to the Augmented AI console at [https://console.aws.amazon.com/a2i/](https://console.aws.amazon.com/a2i/).
2. In the navigation pane, under the Augmented AI section, choose Human review workflows.
3. Select the hyperlinked name of the human review workflow that you want to delete.
4. On the Summary page of your human review workflow, choose Delete.
5. In the dialog box asking you to confirm that you want to delete your human review workflow, choose **Delete**.

You're automatically redirected to the **Human review workflows** page. While your human review workflow is being deleted, the status **Deleting** appears in the status column for that workflow. After it's deleted, it doesn't appear in the list of workflows on this page.

**Delete a human review workflow (API)**

You can delete a human review workflow (flow definition) using the SageMaker **DeleteFlowDefinition** API operation. This API operation is supported through the **AWS CLI** and a **variety of language specific SDKs**. The following table shows example requests using SDK for Python (Boto3) and the AWS CLI to delete the human review workflow, `example-flow-definition`.

**AWS SDK for Python (Boto3)**

The following request example uses the SDK for Python (Boto3) to delete the human review workflow. For more information, see [delete_flow_definition](https://boto3.amazonaws.com/v1/documentation/api/latest/reference/services/sagemaker.html#Sagemaker.Client.delete_flow_definition) in the **AWS SDK for Python (Boto) API Reference**.

```python
import boto3
sagemaker_client = boto3.client('sagemaker')
response = sagemaker_client.delete_flow_definition(FlowDefinitionName='example-flow-definition')
```

**AWS CLI**

The following request example uses the AWS CLI to delete the human review workflow. For more information, see `delete-flow-definition` in the **AWS CLI Command Reference**.

```bash
$ aws sagemaker delete-flow-definition --flow-definition-name 'example-flow-definition'
```

If the action is successful, Augmented AI sends back an HTTP 200 response with an empty HTTP body.

**Create and Start a Human Loop**

A **human loop** starts your human review workflow and sends data review tasks to human workers. When you use one of the Amazon A2I built-in task types, the corresponding AWS service creates and starts a human loop on your behalf when the conditions specified in your flow definition are met. If no conditions are specified in your flow definition, a human loop is created for each object. When using Amazon A2I for a custom task, a human loop starts when your application calls `StartHumanLoop`.

Use the following instructions to configure a human loop with Amazon Rekognition or Amazon Textract built-in task types and custom task types.

**Prerequisites**

To create and start a human loop, you must attach the AmazonAugmentedAIFullAccess policy to the AWS Identity and Access Management (IAM) user or role that configures or starts the human loop. This is the identity that you use to configure the human loop using `HumanLoopConfig` for built-in task types. For custom task types, this is the identity that you use to call `StartHumanLoop`.

Additionally, when using a built-in task type, your user or role must have permission to invoke API operations of the AWS service associated with your task type. For example, if you are using Amazon Rekognition with Augmented AI, you must attach permissions required
to call DetectModerationLabels. For examples of identity-based policies you can use to grant these permissions, see Amazon Rekognition Identity-Based Policy Examples and Amazon Textract Identity-Based Policy Examples. You can also use the more general policy AmazonAugmentedAIIntegratedAPIAccess to grant these permissions. For more information, see Create a User With Permissions to Invoke Amazon A2I, Amazon Textract, and Amazon Rekognition API Operations (p. 1160).

To create and start a human loop, you need a flow definition ARN. To learn how to create a flow definition (or human review workflow), see Create a Human Review Workflow (p. 1110).

**Important**
Amazon A2I requires all S3 buckets that contain human loop input image data to have a CORS policy attached. To learn more about this change, see CORS Permission Requirement (p. 1158).

Create and Start a Human Loop for a Built-in Task Type

To start a human loop using a built-in task type, use the corresponding service's API to provide your input data and to configure the human loop. For Amazon Textract, you use the AnalyzeDocument API operation. For Amazon Rekognition, you use the DetectModerationLabels API operation. You can use the AWS CLI or a language-specific SDK to create requests using these API operations.

**Important**
When you create a human loop using a built-in task type, you can use DataAttributes to specify a set of ContentClassifiers related to the input provided to the StartHumanLoop operation. Use content classifiers to declare that your content is free of personally identifiable information or adult content.

<table>
<thead>
<tr>
<th>Important</th>
</tr>
</thead>
<tbody>
<tr>
<td>When using Amazon Mechanical Turk, ensure your data is free of personally identifiable information, including protected health information under HIPAA. Include the FreeOfPersonallyIdentifiableInformation content classifier. If you do not use this content classifier, SageMaker does not send your task to Mechanical Turk. If your data is free of adult content, also include the 'FreeOfAdultContent' classifier. If you do not use these content classifiers, SageMaker may restrict the Mechanical Turk workers that can view your task.</td>
</tr>
</tbody>
</table>

After you start your ML job using your built-in task type's AWS service API, Amazon A2I monitors the inference results of that service. For example, when running a job with Amazon Rekognition, Amazon A2I checks the inference confidence score for each image and compares it to the confidence thresholds specified in your flow definition. If the conditions to start a human review task are satisfied, or if you didn't specify conditions in your flow definition, a human review task is sent to workers.

Create an Amazon Textract Human Loop

Amazon A2I integrates with Amazon Textract so that you can configure and start a human loop using the Amazon Textract API. To send a document file to Amazon Textract for document analysis, you use the Amazon Textract AnalyzeDocument API operation. To add a human loop to this document analysis job, you must configure the parameter HumanLoopConfig.

When you configure your human loop, the flow definition you specify in FlowDefinitionArn of HumanLoopConfig must be located in the same AWS Region as the bucket identified in Bucket of the Document parameter.

The following table shows examples of how to use this operation with the AWS CLI and AWS SDK for Python (Boto3).

**AWS SDK for Python (Boto3)**

The following request example uses the SDK for Python (Boto3). For more information, see analyze_document in the AWS SDK for Python (Boto) API Reference.

```python
import boto3
```
$ aws textract analyze-document \  
--document '"bucket":"bucket_name","Name":"document_name"}' \  
--human-loop-config \  
{'HumanLoopName":"human_loop_name","FlowDefinitionArn":"arn:aws:sagemaker:aws-region:aws_account_number:flow-definition/flow_def_name","DataAttributes":{"ContentClassifiers":['FreeOfPersonallyIdentifiableInformation','FreeOfAdultContent']}'} \  
--feature-types ['TABLES', "FORMS"]

$ aws textract analyze-document \  
--document '"bucket":"bucket_name","Name":"document_name"}' \  
--human-loop-config \  
{'HumanLoopName":"human_loop_name","FlowDefinitionArn":"arn:aws:sagemaker:aws-region:aws_account_number:flow-definition/flow_def_name","DataAttributes":{"ContentClassifiers":['FreeOfPersonallyIdentifiableInformation','FreeOfAdultContent']}'} \  
--feature-types ['TABLES', "FORMS"]

After you run AnalyzeDocument with a human loop configured, Amazon A2I monitors the results from AnalyzeDocument and checks it against the flow definition's activation conditions. If the Amazon Textract inference confidence score for one or more key-value pairs meets the conditions for review, Amazon A2I starts a human review loop and includes the HumanLoopActivationOutput object in the AnalyzeDocument response.

Create an Amazon Rekognition Human Loop

Amazon A2I integrates with Amazon Rekognition so that you can configure and start a human loop using the Amazon Rekognition API. To send images to Amazon Rekognition for content moderation, you use the Amazon Rekognition DetectModerationLabels API operation. To configure a human loop, set the HumanLoopConfig parameter when you configure DetectModerationLabels.

When you configure your human loop, the flow definition you specify in FlowDefinitionArn of HumanLoopConfig must be located in the same AWS Region as the S3 bucket identified in Bucket of the Image parameter.

The following table shows examples of how to use this operation with the AWS CLI and AWS SDK for Python (Boto3).
AWS SDK for Python (Boto3)

The following request example uses the SDK for Python (Boto3). For more information, see `detect_moderation_labels` in the AWS SDK for Python (Boto) API Reference.

```python
import boto3
rekognition = boto3.client("rekognition", aws_region)
response = rekognition.detect_moderation_labels( 
    Image={'S3Object': {'Bucket': bucket_name, 'Name': image_name}}, 
    HumanLoopConfig={ 
        'HumanLoopName': human_loop_name, 
        'FlowDefinitionArn': "arn:aws:sagemaker:aws_region:aws_account_number:flow-definition/flow_def_name" 
    },
    "DataAttributes": {'ContentClassifiers': ['FreeOfPersonallyIdentifiableInformation','FreeOfAdultContent']}
)
```

AWS CLI

The following request example uses the AWS CLI. For more information, see `detect-moderation-labels` in the AWS CLI Command Reference.

```
$ aws rekognition detect-moderation-labels --human-loop-config
    "DataAttributes": {"ContentClassifiers": ["FreeOfPersonallyIdentifiableInformation","FreeOfAdultContent"]}
```

After you run DetectModerationLabels with a human loop configured, Amazon A2I monitors the results from DetectModerationLabels and checks it against the flow definition's activation conditions. If the Amazon Rekognition inference confidence score for an image meets the conditions for review, Amazon A2I starts a human review loop and includes the response element HumanLoopActivationOutput in the DetectModerationLabels response.

Create and Start a Human Loop for a Custom Task Type

To configure a human loop for a custom human review task, use the StartHumanLoop operation within your application. This section provides an example of a human loop request using the AWS SDK for Python (Boto3) and the AWS Command Line Interface (AWS CLI). For documentation on other language-specific SDKs that support StartHumanLoop, use the See Also section of StartHumanLoop in the Amazon Augmented AI Runtime API documentation. Refer to Use Cases and Examples Using Amazon A2I (p. 1102) to see examples that demonstrate how to use Amazon A2I with a custom task type.

Prerequisites
To complete this procedure, you need:

- Input data formatted as a string representation of a JSON-formatted file
- The Amazon Resource Name (ARN) of your flow definition

To configure the human loop

1. For DataAttributes, specify a set of ContentClassifiers related to the input provided to the StartHumanLoop operation. Use content classifiers to declare that your content is free of personally identifiable information or adult content.

   To use Amazon Mechanical Turk, ensure your data is free of personally identifiable information, including protected health information under HIPAA, and include the FreeOfPersonallyIdentifiableInformation content classifier. If you do not use this content classifier, SageMaker does not send your task to Mechanical Turk. If your data is free of adult content, also include the 'FreeOfAdultContent' classifier. If you do not use these content classifiers, SageMaker may restrict the Mechanical Turk workers that can view your task.

2. For FlowDefinitionArn, enter the Amazon Resource Name (ARN) of your flow definition.

3. For HumanLoopInput, enter your input data as a string representation of a JSON-formatted file. Structure your input data and custom worker task template so that your input data is properly displayed to human workers when you start your human loop. See Preview a Worker Task Template (p. 1145) to learn how to preview your custom worker task template.

4. For HumanLoopName, enter a name for the human loop. The name must be unique within the Region in your account and can have up to 63 characters. Valid characters are a-z, 0-9, and - (hyphen).

To start a human loop

- To start a human loop, submit a request similar to the following examples using your preferred language-specific SDK.

**AWS SDK for Python (Boto3)**

The following request example uses the SDK for Python (Boto3). For more information, see Boto 3 Augmented AI Runtime in the AWS SDK for Python (Boto) API Reference.

```python
import boto3

a2i_runtime_client = boto3.client('sagemaker-a2i-runtime')

response = a2i_runtime_client.start_human_loop(
    HumanLoopName='human_loop_name',
    HumanLoopInput={'InputContent': '{"InputContent": {"prompt": "What is the answer?"}}'},
    DataAttributes={'ContentClassifiers': ['FreeOfPersonallyIdentifiableInformation', 'FreeOfAdultContent']}
)
```

**AWS CLI**

The following request example uses the AWS CLI. For more information, see start-human-loop in the AWS CLI Command Reference.
Delete a Human Loop

When you successfully start a human loop by invoking `StartHumanLoop` directly, the response includes a `HumanLoopARN` and a `HumanLoopActivationResults` object which is set to NULL. You can use this the human loop name to monitor and manage your human loop.

Next Steps:

After starting a human loop, you can manage and monitor it with the Amazon Augmented AI Runtime API and Amazon CloudWatch Events. To learn more, see Monitor and Manage Your Human Loop (p. 1146).

Delete a Human Loop

When you delete a human loop, the status changes to Deleting. When the human loop is deleted, the associated human review task is no longer available to workers. You might want to delete a human loop in one of the following circumstances:

- The worker task template used to generate your worker user interface does not render correctly or is not functioning as expected.
- A single data object was accidentally sent to workers multiple times.
- You no longer need a data object reviewed by a human.

If the status of a human loop is InProgress, you must stop the human loop before deleting it. When you stop a human loop, the status changes to Stopping while it is being stopped. When the status changes to Stopped, you can delete the human loop.

If human workers are already working on a task when you stop the associated human loop, that task continues to be available until it is completed or expires. As long as workers are still working on a task, your human loop's status is Stopping. If these tasks are completed, the results are stored in the Amazon S3 bucket URI specified in your human review workflow. If the worker leaves the task without submitting work, it is stopped and the worker can't return to the task. If no worker has started working on the task, it is stopped immediately.

If you delete the AWS account used to create the human loop, it is stopped and deleted automatically.

Human Loop Data Retention and Deletion

When a human worker completes a human review task, the results are stored in the Amazon S3 output bucket you specified in the human review workflow used to create the human loop. Deleting or stopping a human loop does not remove any worker answers from your S3 bucket.

Additionally, Amazon A2I temporarily stores human loop input and output data internally for the following reasons:

- If you configure your human loops so that a single data object is sent to multiple workers for review, Amazon A2I does not write output data to your S3 bucket until all workers have completed the review.

```bash
$ aws sagemaker-a2i-runtime start-human-loop
    --human-loop-name 'human_loop_name'
    --human-loop-input '{"InputContent": "{prompt":"What is the answer?"}"
    --data-attributes
    ContentClassifiers="FreeOfPersonallyIdentifiableInformation","FreeOfAdultContent"
```
Delete a Human Loop

Amazon A2I stores partial answers—answers from individual workers—internally so that it can write full results to your S3 bucket.

- If you report a low-quality human review result, Amazon A2I can investigate and respond to your issue.
- If you lose access to or delete the output S3 bucket specified in the human review workflow used to create a human loop, and the task has already been sent to one or more workers, Amazon A2I needs a place to temporarily store human review results.

Amazon A2I deletes this data internally 30 days after a human loop's status changes to one of the following: Deleted, Stopped, or Completed. In other words, data is deleted 30 days after the human loop has been completed, stopped, or deleted. Additionally, this data is deleted after 30 days if you close the AWS account used to create associated human loops.

Stop and Delete a Flow Definition Using the Console or the Amazon A2I API

You can stop and delete a human loop in the Augmented AI console or by using the SageMaker API. When the human loop has been deleted, the status changes to Deleted.

Delete a human loop (console)

1. Navigate to the Augmented AI console at https://console.aws.amazon.com/a2i/.
2. In the navigation pane, under the Augmented AI section, choose Human review workflows.
3. Choose the hyperlinked name of the human review workflow you used to create the human loop you want to delete.
4. In the Human loops section at the bottom of the page, select the human loop you want to stop and delete.
5. If the human loop status is Completed, Stopped, or Failed, select Delete. If the human loop Status is InProgress, select Stop. When the status changes to Stopped, select Delete.

Delete a human loop (API)

1. Check the status of your human loop using the Augmented AI Runtime API operation DescribeHumanLoop. See examples using this operation in the following table.

AWS SDK for Python (Boto3)

The following example uses the SDK for Python (Boto3) to describe the human loop named example-human-loop. For more information, see describe_human_loop in the AWS SDK for Python (Boto) API Reference.

```python
import boto3

a2i_runtime_client = boto3.client('sagemaker-a2i-runtime')
response = a2i_runtime_client.describe_human_loop(HumanLoopName='example-human-loop')
human_loop_status = response['HumanLoopStatus']
print(f'example-human-loop status is: {human_loop_status}"
```

AWS CLI

The following example uses the AWS CLI to describe the human loop named example-human-loop. For more information, see describe-human-loop in the AWS CLI Command Reference.
Create and Manage Worker Task Templates

You can create a task user interface for your workers by creating a worker task template. A worker task template is an HTML file that is used to display your input data and instructions to help workers complete your task.

For Amazon Rekognition or Amazon Textract task types, you can customize a pre-made worker task template using a graphical user interface (GUI) and avoid interacting with HTML code. For this option,
Create and Manage Worker Task Templates

use the instructions in *Create a Human Review Workflow (Console)* (p. 1111) to create a human review workflow and customize your worker task template in the Amazon SageMaker console. Once you create a template using these instructions, it appears on the worker task templates page of the Augmented AI console.

If you are creating a human review workflow for a custom task type, you must create a custom worker task template using HTML code. For more information, see *Create Custom Worker Task Templates* (p. 1139).

If you create your template using HTML, you must use this template to generate an Amazon A2I human task UI Amazon Resource Name (ARN) in the Amazon A2I console. This ARN has the following format: `arn:aws:sagemaker:<aws-region>:<aws-account-number>:human-task-ui/<template-name>`. This ARN is associated with a worker task template resource that you can use in one or more human review workflows (flow definitions).

Generate a human task UI ARN using a worker task template by following the instructions found in *Create a Worker Task Template* (p. 1137) or by using the `CreateHumanTaskUi` API operation.

**Topics**
- Create and Delete Worker Task Templates (p. 1137)
- Create Custom Worker Task Templates (p. 1139)
- Creating Good Worker Instructions (p. 1146)

## Create and Delete Worker Task Templates

You can use a worker template to customize the interface and instructions that your workers see when working on your tasks. Use the instructions on this page to create a worker task template in the Augmented AI area of the Amazon SageMaker console. A starter template is provided for Amazon Textract and Amazon Rekognition tasks. To learn how to customize your template using HTML crowd elements, see *Create Custom Worker Task Templates* (p. 1139).

When you create a worker template in the worker task templates page of the Augmented AI area of the SageMaker console, a worker task template ARN is generated. Use this ARN as the input to `HumanTaskUiArn` when you create a flow definition using the API operation `CreateFlowDefinition`. You can choose this template when creating a human review workflow on the human review workflows page of the console.

If you are creating a worker task template resource for an Amazon Textract or Amazon Rekognition task type, you can preview the worker UI that is generated from your template on the worker task templates console page. You must attach the policy described in *Enable Worker Task Template Previews* (p. 1161) to the IAM role that you use to preview the template.

### Create a Worker Task Template

You can create a worker task template using the SageMaker console and using the SageMaker API operation `CreateHumanTaskUi`.

**Create a worker task template (console)**

1. Open the Amazon A2I console at `https://console.aws.amazon.com/a2i/`.
2. Under **Amazon Augmented AI** in the left navigation pane, choose **Worker task templates**.
3. Choose **Create template**.
4. In **Template name**, enter a unique name.
5. (Optional) Enter an **IAM role** that grants Amazon A2I the permissions necessary to call services on your behalf.
6. In **Template type**, choose a template type from the dropdown list. If you are creating a template for a **Textract-form extraction** or **Rekognition-image moderation** task, choose the appropriate option.

7. Enter your custom template elements as follows:
   - If you selected the Amazon Textract or Amazon Rekognition task template, the **Template editor** autopopulates with a default template that you can customize.
   - If you are using a custom template, enter your predefined template in the editor.

8. (Optional) To complete this step, you must provide an IAM role ARN with permission to read Amazon S3 objects that get rendered on your user interface in **Step 5**.

You can only preview your template if you are creating templates for Amazon Textract or Amazon Rekognition.

Choose **See preview** to preview the interface and instructions that workers see. This is an interactive preview. After you complete the sample task and choose **Submit**, you see the resulting output from the task that you just performed.

If you are creating a worker task template for a custom task type, you can preview your worker task UI using **RenderUiTemplate**. For more information, see [Preview a Worker Task Template](p. 1145).

9. When you're satisfied with your template, choose **Create**.

After you've created your template, you can select that template when you create a human review workflow in the console. Your template also appears in the **Amazon Augmented AI** section of the SageMaker console under **Worker task templates**. Choose your template to view its ARN. Use this ARN when using the **CreateFlowDefinition** API operation.

### Create a worker task template using a worker task template (API)

To generate a worker task template using the SageMaker API operation **CreateHumanTaskUi**, specify a name for your UI in **HumanTaskUiName** and input your HTML template in **Content** under **UiTemplate**. Find documentation on language-specific SDKs that support this API operation in the **See Also** section of the **CreateHumanTaskUi**.

### Delete a Worker Task Template

Once you have created a worker task template, you can delete it using the SageMaker console or the SageMaker API operation **DeleteHumanTaskUi**.

When you delete a worker task template, you are not able to use human review workflows (flow definitions) created using that template to start human loops. Any human loops that have already been created using the worker task template that you delete continue to be processed until completion and are not impacted.

### Delete a worker task template (console)

1. Open the Amazon A2I console at [https://console.aws.amazon.com/a2i/](https://console.aws.amazon.com/a2i/).
2. Under Amazon Augmented AI in the left navigation pane, choose **Worker task templates**.
3. Select the template that you want to delete.
4. Select **Delete**.
5. A modal appears to confirm your choice. Select **Delete**.

### Delete a worker task template (API)

To delete a worker task template using the SageMaker API operation **DeleteHumanTaskUi**, specify a name of your UI in **HumanTaskUiName**.
Create Custom Worker Task Templates

Crowd HTML Elements are web components that provide a number of task widgets and design elements that you can tailor to the question you want to ask. You can use these crowd elements to create a custom worker template and integrate it with an Amazon Augmented AI (Amazon A2I) human review workflow to customize the worker console and instructions.

For a list of all HTML crowd elements available to Amazon A2I users, see Crowd HTML Elements Reference (p. 1002). For examples of templates, see the AWS GitHub repository, which contains over 60 sample custom task templates.

Develop Templates Locally

When in the console to test how your template processes incoming data, you can test the look and feel of your template's HTML and custom elements in your browser by adding the following code to the top of your HTML file.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
```

This loads the necessary code to render the custom HTML elements. Use this code if you want to develop your template's look and feel in your preferred editor instead of in the console.

This code won't parse your variables. You might want to replace them with sample content while developing locally.

Use External Assets

Amazon Augmented AI custom templates enable you to embed external scripts and style sheets. For example, the following header embeds a text/css style sheet name stylesheet located at https://www.example.com/my-enhancement-styles.css into the custom template.

```
<script src="https://www.example.com/my-enhancement-script.js"></script>
<link rel="stylesheet" type="text/css" href="https://www.example.com/my-enhancement-styles.css">
```

If you encounter errors, ensure that your originating server is sending the correct MIME type and encoding headers with the assets.

For example, the MIME and encoding type for remote scripts is application/javascript;CHARSET=UTF-8.

The MIME and encoding type for remote stylesheets is text/css;CHARSET=UTF-8.

Track Your Variables

When building a custom template, you must add variables to it to represent the pieces of data that might change from task to task, or worker to worker. If you're starting with one of the sample templates, you need to make sure you're aware of the variables it already uses.

For example, for a custom template that integrates an Augmented AI human review loop with a Amazon Textract text review task, `{{ task.input.selectedAiServiceResponse.blocks }}` is used for initial-value input data. For Amazon Augmented AI (Amazon A2I) integration with Amazon Rekognition, `{{ task.input.selectedAiServiceResponse.moderationLabels }}` is used. For a custom task type, you need to determine the input parameter for your task type. Use `{{ task.input.customInputValuesForStartHumanLoop }}` where you specify `customInputValuesForStartHumanLoop`.

1139
Amazon SageMaker Developer Guide
Create and Manage Worker Task Templates

Custom Template Example for Amazon Textract
All custom templates begin and end with the <crowd-form> </crowd-form> elements. Like standard
HTML <form> elements, all of your form code should go between these elements.
For an Amazon Textract document analysis task, use the <crowd-textract-analyze-document>
element. It uses the following attributes:
• src – Speciﬁes the URL of the image ﬁle to be annotated.
• initialValue – Sets initial values for attributes found in the worker UI.
• blockTypes (required) – Determines the kind of analysis that the workers can do. Only
KEY_VALUE_SET is currently supported.
• keys (required) – Speciﬁes new keys and the associated text value that the worker can add.
• no-key-edit (required) – Prevents the workers from editing the keys of annotations passed through
initialValue.
• no-geometry-edit – Prevents workers from editing the polygons of annotations passed through
initialValue.
For children of the <crowd-textract-analyze-document> element, you must have two Regions. You
can use arbitrary HTML and CSS elements in these Regions.
• <full-instructions> – Instructions that are available from the View full instructions link in the
tool. You can leave this blank, but we recommend that you provide complete instructions to get better
results.
• <short-instructions> – A brief description of the task that appears in the tool's sidebar. You can
leave this blank, but we recommend that you provide complete instructions to get better results.
An Amazon Textract template would look similar to the following.

Example
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
{% capture s3_uri %}http://s3.amazonaws.com/
{{ task.input.aiServiceRequest.document.s3Object.bucket }}/
{{ task.input.aiServiceRequest.document.s3Object.name }}{% endcapture %}
<crowd-form>
<crowd-textract-analyze-document
src="{{ s3_uri | grant_read_access }}"
initial-value="{{ task.input.selectedAiServiceResponse.blocks }}"
header="Review the key-value pairs listed on the right and correct them if they don't
match the following document."
no-key-edit
no-geometry-edit
keys="{{ task.input.humanLoopContext.importantFormKeys }}"
block-types="['KEY_VALUE_SET']"
>
<short-instructions header="Instructions">
<style>
.instructions {
white-space: pre-wrap;
}
.instructionsImage {
display: inline-block;
max-width: 100%;
}
</style>

1140


Custom Template Example for Amazon Rekognition

All custom templates begin and end with the `<crowd-form>` elements. Like standard HTML `<form>` elements, all of your form code should go between these elements. For an Amazon Rekognition custom task template, use the `<crowd-rekognition-detect-moderation-labels>` element. This element supports the following attributes:

- **categories** – An array of strings or an array of objects where each object has a name field.
  - If the categories come in as objects, the following applies:
    - The displayed categories are the value of the name field.
    - The returned answer contains the **full** objects of any selected categories.
  - If the categories come in as strings, the following applies:
    - The returned answer is an array of all the strings that were selected.
- **exclusion-category** – By setting this attribute, you create a button underneath the categories in the UI. When a user selects the button, all categories are deselected and disabled. If the worker selects the button again, you re-enable users to choose categories. If the worker submits the task by selecting **Submit** after you select the button, that task returns an empty array.

For children of the `<crowd-rekognition-detect-moderation-labels>` element, you must have two Regions.
• **<full-instructions>** – Instructions that are available from the View full instructions link in the tool. You can leave this blank, but we recommend that you provide complete instructions to get better results.

• **<short-instructions>** – Brief description of the task that appears in the tool's sidebar. You can leave this blank, but we recommend that you provide complete instructions to get better results.

A template using these elements would look similar to the following.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
{% capture s3_uri %}http://s3.amazonaws.com/
{{ task.input.aiServiceRequest.image.s3Object.bucket }}/ {{ task.input.aiServiceRequest.image.s3Object.name }}{% endcapture %}
<crowd-form>
  <crowd-rekognition-detect-moderation-labels
    categories='[
    {% for label in task.input.selectedAiServiceResponse.moderationLabels %}
      {
        name: "{{ label.name }}",
        parentName: "{{ label.parentName }}",
      },
    {% endfor %}
  ]
    src="{{ s3_uri | grant_read_access }}"
    header="Review the image and choose all applicable categories."
  >
  <short-instructions header="Instructions"
    style=".instructions { white-space: pre-wrap; }">
    <p class='instructions'>Review the image and choose all applicable categories. If no categories apply, choose None.

    <b>Nudity</b>
    Visuals depicting nude male or female person or persons

    <b>Graphic Male Nudity</b>
    Visuals depicting full frontal male nudity, often close ups

    <b>Graphic Female Nudity</b>
    Visuals depicting full frontal female nudity, often close ups

    <b>Sexual Activity</b>
    Visuals depicting various types of explicit sexual activities and pornography

    <b>Illustrated Nudity or Sexual Activity</b>
    Visuals depicting animated or drawn sexual activity, nudity, or pornography

    <b>Adult Toys</b>
    Visuals depicting adult toys, often in a marketing context

    <b>Female Swimwear or Underwear</b>
    Visuals depicting female person wearing only swimwear or underwear

    <b>Male Swimwear Or Underwear</b>
    Visuals depicting male person wearing only swimwear or underwear

    <b>Partial Nudity</b>
    Visuals depicting covered up nudity, for example using hands or pose

    <b>Revealing Clothes</b>
```
Add Automation with Liquid

The custom template system uses Liquid for automation. Liquid is an open-source inline markup language. For more information and documentation, see the Liquid homepage.

In Liquid, the text between single curly braces and percent symbols is an instruction or tag that performs an operation like control flow or iteration. Text between double curly braces is a variable or object that outputs its value. The following list includes two types of liquid tags that you may find useful to automate template input data processing. If you select one of the following tag-types, you are redirected to the Liquid documentation.

- **Control flow**: Includes programming logic operators like if/else, unless, and case/when.
- **Iteration**: Enables you to run blocks of code repeatedly using statements like for loops.

For example, the following code example demonstrates how you can use the Liquid for tag to create a for loop. This example loops through the moderationLabels returned from Amazon Rekognition and displays the moderationLabels attributes name and parentName for workers to review:

```liquid
{% for label in task.input.selectedAiServiceResponse.moderationLabels %}
  { name: &quot;{{ label.name }}&quot;,
    parentName: &quot;{{ label.parentName }}&quot;,
  },
{% endfor %}
```
Use Variable Filters

In addition to the standard Liquid filters and actions, Amazon Augmented AI (Amazon A2I) offers additional filters. You apply filters by placing a pipe (|) character after the variable name, and then specifying a filter name. To chain filters, use the following format.

Example

```
{{ <content> | <filter> | <filter> }}
```

Autoescape and Explicit Escape

By default, inputs are HTML-escaped to prevent confusion between your variable text and HTML. You can explicitly add the escape filter to make it more obvious to someone reading the source of your template that escaping is being done.

escape_once

escape_once ensures that if you've already escaped your code, it doesn't get re-escaped again. For example, it ensures that & doesn't become &

skip_autoescape

skip_autoescape is useful when your content is meant to be used as HTML. For example, you might have a few paragraphs of text and some images in the full instructions for a bounding box.

Note

Use skip_autoescape sparingly. As a best practice for templates, avoid passing in functional code or markup with skip_autoescape unless you are absolutely sure that you have strict control over what's being passed. If you're passing user input, you could be opening your workers up to a cross-site scripting attack.

to_json

to_json encodes data that you provide to JavaScript Object Notation (JSON). If you provide an object, it serializes it.

grant_read_access

grant_read_access takes an Amazon Simple Storage Service (Amazon S3) URI and encodes it into an HTTPS URL with a short-lived access token for that resource. This makes it possible to display photo, audio, or video objects stored in S3 buckets that are not otherwise publicly accessible to workers.

Example Example of the to_json and grant_read_access filters

Input

```
auto-escape: {{ "Have you read 'James & the Giant Peach'?" }}
explicit escape: {{ "Have you read 'James & the Giant Peach'?" | escape }}
explicit escape_once: {{ "Have you read 'James &amp; the Giant Peach'?" | escape_once }}
skip_autoescape: {{ "Have you read 'James & the Giant Peach'?" | skip_autoescape }}
to_json: {{ jsObject | to_json }}
grant_read_access: {{ "s3://examplebucket/myphoto.png" | grant_read_access }}
```

Example

Output

```
auto-escape: Have you read 'James & the Giant Peach'?
explicit escape: Have you read 'James & the Giant Peach'?
explicit escape_once: Have you read 'James &amp; the Giant Peach'?
skip_autoescape: Have you read 'James & the Giant Peach'?
```
Example Example of an automated classification template.

To automate this simple text classification sample, include the Liquid tag {{ task.input.source }}. This example uses the crowd-classifier (p. 1016) element.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
  <crowd-classifier
    name="tweetFeeling"
    categories="["positive", "negative", "neutral", "cannot determine"]"
    header="Which term best describes this tweet?"
  >
    <classification-target>
      {{ task.input.source }}
    </classification-target>
    <full-instructions header="Analyzing a sentiment">
      Try to determine the feeling the author of the tweet is trying to express.
      If none seems to match, choose "other."
    </full-instructions>
    <short-instructions>
      Pick the term that best describes the sentiment of the tweet.
    </short-instructions>
  </crowd-classifier>
</crowd-form>
```

Preview a Worker Task Template

To preview a custom worker task template, use the SageMaker RenderUiTemplate operation. You can use the RenderUiTemplate operation with the AWS CLI or your preferred AWS SDK. For documentation on the supported language specific SDKs for this API operation, see the See Also section of the RenderUiTemplate.

Prerequisites

To preview your worker task template, the AWS Identity and Access Management (IAM) role Amazon Resource Name (ARN), or RoleArn, that you use must have permission to access to the S3 objects that are used by the template. To learn how to configure your role or user see Enable Worker Task Template Previews (p. 1161).

To preview your worker task template using the RenderUiTemplate operation:

1. Provide a RoleArn of the role with required policies attached to preview your custom template.
2. In the Input parameter of Task, provide a JSON object that contains values for the variables defined in the template. These are the variables that are substituted for the task.input.source variable. For example, if you define a task.input.text variable in your template, you can supply the variable in the JSON object as text: sample text.
3. In the Content parameter of UiTemplate, insert your template.

Once you've configured RenderUiTemplate, use your preferred SDK or the AWS CLI to submit a request to render your template. If your request was successful, the response includes RenderedContent, a Liquid template that renders the HTML for the worker UI.
Important
To preview your template, you need an IAM role with permissions to read Amazon S3 objects that get rendered on your user interface. For a sample policy that you can attach to your IAM role to grant these permissions, see Enable Worker Task Template Previews (p. 1161).

Creating Good Worker Instructions

Creating good instructions for your human review jobs improves your worker's accuracy in completing their task. You can modify the default instructions that are provided in the console when creating a human review workflow, or you can use the console to create a custom worker template and include your instructions in this template. The instructions are shown to the worker on the UI page where they complete their labeling task.

Create Good Worker Instructions

There are three kinds of instructions in the Amazon Augmented AI console:

- **Task Description** – The description should provide a succinct explanation of the task.
- **Instructions** – These instructions are shown on the same webpage where workers complete a task. These instructions should provide an easy reference to show the worker the correct way to complete the task.
- **Additional Instructions** – These instructions are shown in a dialog box that appears when a worker chooses View full instructions. We recommend that you provide detailed instructions for completing the task, and include several examples showing edge cases and other difficult situations for labeling objects.

Add Example Images to Your Instructions

Images provide useful examples for your workers. To add a publicly accessible image to your instructions, do the following:

1. Place the cursor where the image should go in the instructions editor.
2. Choose the image icon in the editor toolbar.
3. Enter the URL of your image.

If your instruction image is in an S3 bucket that isn't publicly accessible, do the following:

- For the image URL, enter: ```{{ 'https://s3.amazonaws.com/your-bucket-name/image-file-name' | grant_read_access }}```.

This renders the image URL with a short-lived, one-time access code that's appended so the worker's browser can display it. A broken image icon is displayed in the instructions editor, but previewing the tool displays the image in the rendered preview. See grant_read_access (p. 1144) for more information about the grant_read_access element.

Monitor and Manage Your Human Loop

Once you've started a human review loop, you can check the results of tasks sent to the loop and manage it using the Amazon Augmented AI Runtime API. Additionally, Amazon A2I integrates with Amazon EventBridge (also known as Amazon CloudWatch Events) to alert you when a human review loop status changes to Completed, Failed, or Stopped. This event delivery is guaranteed at least once, which means all events created when human loops finish are successfully delivered to EventBridge.
Use the procedures below to learn how to use the Amazon A2I Runtime API to monitor and manage your human loops. See [Use Amazon CloudWatch Events in Amazon Augmented AI](p. 1162) to learn how Amazon A2I integrates with Amazon EventBridge.

**To check your output data:**

1. Check the results of your human loop by calling the `DescribeHumanLoop` operation. The result of this API operation contains information about the reason for and outcome of the loop activation.
2. Check the output data from your human loop in Amazon Simple Storage Service (Amazon S3). In the path to the data, `YYYY/MM/DD/hh/mm/ss` represents the human loop creation date with year (YYYY), month (MM), and day (DD), and the creation time with hour (hh), minute (mm), and second (ss).

   s3://customer-output-bucket-specified-in-flow-definition/flow-definition-name/YYYY/MM/DD/hh/mm/ss/human-loop-name/output.json

You can integrate this structure with AWS Glue or Amazon Athena to partition and analyze your output data. For more information, see [Managing Partitions for ETL Output in AWS Glue](p. 1147).

To learn more about Amazon A2I output data format, see [Amazon A2I Output Data](p. 1147).

**To stop and delete your human loop:**

1. Once a human loop has been started, you can stop your human loop by calling the `StopHumanLoop` operation using the `HumanLoopName`. If a human loop was successfully stopped, the server sends back an HTTP 200 response.
2. To delete a human loop for which the status equals Failed, Completed, or Stopped, use the `DeleteHumanLoop` operation.

**To list human loops:**

1. You can list all active human loops by calling the `ListHumanLoops` operation. You can filter human loops by the creation date of the loop using the `CreationTimeAfter` and `CreateTimeBefore` parameters.
2. If successful, `ListHumanLoops` returns `HumanLoopSummaries` and NextToken objects in the response element. `HumanLoopSummaries` contains information about a single human loop. For example, it lists a loop's status and, if applicable, its failure reason.

   Use the string returned in NextToken as an input in a subsequent call to `ListHumanLoops` to see the next page of human loops.

**Amazon A2I Output Data**

When your machine learning workflow sends Amazon A2I a data object, a human loop is created and human reviewers receive a task to review that data object. The output data from each human review task is stored in the Amazon Simple Storage Service (Amazon S3) output bucket you specify in your human review workflow. In the path to the data, `YYYY/MM/DD/hh/mm/ss` represents the human loop creation date with year (YYYY), month (MM), and day (DD), and the creation time with hour (hh), minute (mm), and second (ss).

s3://customer-output-bucket-specified-in-flow-definition/flow-definition-name/YYYY/MM/DD/hh/mm/ss/human-loop-name/output.json

The content of your output data depends on the type of task type (built-in or custom) and the type of workforce you use. Your output data always includes the response from the human worker. Additionally,
output data may include metadata about the human loop, the human reviewer (worker), and the data object.

Use the following sections to learn more about Amazon A2I output data format for different task types and workforces.

**Output Data From Built-In Task Types**

Amazon A2I built-in task types include Amazon Textract and Amazon Rekognition. In addition to human responses, the output data from one of these tasks includes details about the reason the human loop was created and information about the integrated service used to create the human loop. Use the following table to learn more about the output data schema for all built-in task types. The value for each of these parameters depends on the service you use with Amazon A2I. Refer to the second table in this section for more information about these service-specific values.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value Type</th>
<th>Example Values</th>

</tbody>
</table>
Select a tab on the following table to learn about the task type–specific parameters and see an example output-data code block for each of the built-in task types.

Amazon Textract Task Type Output Data

When you use the Amazon Textract built-in integration, you see 'AWS/Textract/AnalyzeDocument/Forms/V1' as the value for awsManagedHumanLoopRequestSource in your output data.

The answerContent parameter contains a Block object that includes human responses for all blocks sent to Amazon A2I.

The aiServiceResponse parameter also includes a Block object with Amazon Textract's response to the original request sent using to AnalyzeDocument.

To learn more about the parameters you see in the block object, refer to Block in the Amazon Textract Developer Guide.

The following is an example of the output data from an Amazon A2I human review of Amazon Textract document analysis inferences.

```
{
    "awsManagedHumanLoopRequestSource": "AWS/Textract/AnalyzeDocument/Forms/V1",
    "humanAnswers": [
        {
            "answerContent": {
                "AWS/Textract/AnalyzeDocument/Forms/V1": {
                    "blocks": [...]
                }
            }
        }
    ],
    "submissionTime": "2020-09-28T19:17:59.880Z",
...
```

A JSON object in inputContent that contains the reason a human loop was created. This includes a list of the activation conditions (Conditions) included in your human review workflow (flow definition), and the evaluation result for each condition–this result is either true or false. To learn more about activation conditions, see JSON Schema for Human Loop Activation Conditions in Amazon Augmented AI (p. 1116).

            "EvaluationResult": true
          }
        ]
      }
    ]
  }
}
Amazon Rekognition Task Type Output Data

When you use the Amazon Textract built-in integration, you see the string 'AWS/Rekognition/DetectModerationLabels/Image/V3' as the value for awsManagedHumanLoopRequestSource in your output data.

The answerContent parameter contains a moderationLabels object that contains human responses for all moderation labels sent to Amazon A2I.

The aiServiceResponse parameter also includes a moderationLabels object with Amazon Rekognition's response to the original request sent to DetectModerationLabels.

To learn more about the parameters you see in the block object, refer to [ModerationLabel](#) in the Amazon Rekognition Developer Guide.

The following is an example of the output data from an Amazon A2I human review of Amazon Rekognition image moderation inferences.

```json
{
  "awsManagedHumanLoopRequestSource": "AWS/Rekognition/DetectModerationLabels/Image/V3",
  "humanAnswers": [
    {
      "answerContent": {
        "AWS/Rekognition/DetectModerationLabels/Image/V3": {
          "moderationLabels": [...]
        }
      },
      "submissionTime": "2020-09-28T19:22:35.508Z",
      "workerId": "ef7294f850a3d9d1",
      "workerMetadata": {
        "identityData": {
          "identityProviderType": "Cognito",
          "sub": "c6aa8eb7-9944-42e9-a6b9-111122223333"
        }
      }
    }
  ],
  "humanLoopName": "human-loop-name",
  "inputContent": {
    "aiServiceRequest": {
      "humanLoopConfig": {
        "..." // Additional human loop configuration details
      }
    }
  }
}
```
Output Data From Custom Task Types

When you add Amazon A2I to a custom human review workflow, you see the following parameters in the output data returned from human review tasks.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>flowDefinitionArn</td>
<td>String</td>
<td>The Amazon Resource Number (ARN) of the human review</td>
</tr>
<tr>
<td>humanLoopName</td>
<td></td>
<td></td>
</tr>
<tr>
<td>image</td>
<td></td>
<td></td>
</tr>
<tr>
<td>aiServiceResponse</td>
<td></td>
<td></td>
</tr>
<tr>
<td>moderationLabels</td>
<td></td>
<td></td>
</tr>
<tr>
<td>moderationModelVersion</td>
<td></td>
<td></td>
</tr>
<tr>
<td>humanTaskActivationConditionResults</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Parameter</td>
<td>Value Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>humanAnswers</td>
<td>List of JSON objects</td>
<td>A list of JSON objects that contain worker responses in answerContent. The value in this parameter is determined by the output received from your worker task template.</td>
</tr>
<tr>
<td>humanLoopName</td>
<td>String</td>
<td>The name of the human loop.</td>
</tr>
<tr>
<td>inputContent</td>
<td>JSON Object</td>
<td>The input content sent to Amazon A2I in the request to StartHumanLoop.</td>
</tr>
</tbody>
</table>

The following is an example of output data from a custom integration with Amazon A2I and Amazon Transcribe. In this example, the inputContent consists of:

- A path to an .mp4 file in Amazon S3 and the video title
- The transcription returned from Amazon Transcribe (parsed from Amazon Transcribe output data)
- A start and end time used by the worker task template to clip the .mp4 file and show workers a relevant portion of the video

```json

        "start_time": 948.51
    }
}
```
Track Worker Activity

Amazon A2I provides information that you can use to track individual workers in task output data. To identify the worker that worked on the human review task, use the following from the output data in Amazon S3:

- The `acceptanceTime` is the time that the worker accepted the task. The format of this date and time stamp is `YYYY-MM-DDTHH:MM:SS.mmmZ` for the year (`YYYY`), month (`MM`), day (`DD`), hour (`HH`), minute (`MM`), second (`SS`), and millisecond (`mmm`). The date and time are separated by a `T`.
- The `submissionTime` is the time that the worker submitted their annotations using the Submit button. The format of this date and time stamp is `YYYY-MM-DDTHH:MM:SS.mmmZ` for the year (`YYYY`), month (`MM`), day (`DD`), hour (`HH`), minute (`MM`), second (`SS`), and millisecond (`mmm`). The date and time are separated by a `T`.
- `timeSpentInSeconds` reports the total time, in seconds, that a worker actively worked on that task. This metric does not include time when a worker paused or took a break.
- The `workerId` is unique to each worker.
- If you use a private workforce, in `workerMetadata`, you see the following.
  - The `identityProviderType` is the service used to manage the private workforce.
  - The `issuer` is the Amazon Cognito user pool or OpenID Connect (OIDC) Identity Provider (IdP) issuer associated with the work team assigned to this human review task.
  - A unique sub identifier refers to the worker. If you create a workforce using Amazon Cognito, you can retrieve details about this worker (such as the name or user name) associated with this ID using Amazon Cognito. To learn how, see Managing and Searching for User Accounts in Amazon Cognito Developer Guide.

The following is an example of the output you may see if you use Amazon Cognito to create a private workforce. This is identified in the `identityProviderType`.

```json
"submissionTime": "2020-12-28T18:59:58.321Z",
"acceptanceTime": "2020-12-28T18:15:15.191Z",
"timeSpentInSeconds": 40.543,
"workerId": "a12b3cdefgh5i67",
"workerMetadata": {
  "identityData": {
    "identityProviderType": "Cognito",
    "sub": "aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee"
  }
}
```

The following is an example of the output you may see if you use your own OIDC IdP to create a private workforce:

```json
"workerMetadata": {
  "identityData": {
    "identityProviderType": "Oidc",
    "issuer": "https://example-oidc-ipd.com/adfs",
    "sub": "aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee"
  }
}
```
Permissions and Security in Amazon Augmented AI

When using Amazon Augmented AI (Amazon A2I) to create a human review workflow for your ML/AI application, you create and configure resources in Amazon SageMaker such as a human workforce and worker task templates. To configure and start a human loop, you either integrate Amazon A2I with other AWS services such as Amazon Textract or Amazon Rekognition, or use the Amazon Augmented AI Runtime API. To create a human review workflow and start a human loop, you must attach certain policies to your AWS Identity and Access Management (IAM) role or user. Specifically:

- When you start a human loop using image input data on or after January 12th, 2020, you must add a CORS header policy to the Amazon S3 bucket that contains your input data. See CORS Permission Requirement (p. 1158) to learn more.

- When you create a flow definition, you need to provide a role that grants Amazon A2I permission to access Amazon S3 both for reading objects that are rendered in a human task UI and for writing the results of the human review.

This role must also have a trust policy attached to give SageMaker permission to assume the role. This allows Amazon A2I to perform actions in accordance with permissions that you attach to the role.

See Add Permissions to the IAM Role Used to Create a Flow Definition (p. 1158) for example policies that you can modify and attach to the role you use to create a flow definition. These are the policies that are attached to the IAM role that is created in the Human review workflows section of the Amazon A2I area of the SageMaker console.

- To create and start human loops, you either use an API operation from a built-in task type (such as DetectModerationLabel or AnalyzeDocument) or the Amazon A2I Runtime API operation StartHumanLoop in a custom ML application. You need to attach the AmazonAugmentedAIFullAccess managed policy to the user that invokes these API operations to grant permission to these services to use Amazon A2I operations. To learn how, see Create a User That Can Invoke Amazon A2I API Operations (p. 1160).

This policy does not grant permission to invoke the API operations of the AWS service associated with built-in task types. For example, AmazonAugmentedAIFullAccess does not grant permission to call the Amazon Rekognition DetectModerationLabel API operation or Amazon Textract AnalyzeDocument API operation. You can use the more general policy, AmazonAugmentedAIIntegratedAPIAccess, to grant these permissions. For more information, see Create a User With Permissions to Invoke Amazon A2I, Amazon Textract, and Amazon Rekognition API Operations (p. 1160). This is a good option when you want to grant a user broad permissions to use Amazon A2I and integrated AWS services' API operations.

If you want to configure more granular permissions, see Amazon Rekognition Identity-Based Policy Examples and Amazon Textract Identity-Based Policy Examples for identity-based policies you can use to grant permission to use these individual services.

- To preview your custom worker task UI template, you need an IAM role with permissions to read Amazon S3 objects that get rendered on your user interface. See a policy example in Enable Worker Task Template Previews (p. 1161).

Topics

- CORS Permission Requirement (p. 1158)
- Add Permissions to the IAM Role Used to Create a Flow Definition (p. 1158)
- Create a User That Can Invoke Amazon A2I API Operations (p. 1160)
- Create a User With Permissions to Invoke Amazon A2I, Amazon Textract, and Amazon Rekognition API Operations (p. 1160)
CORS Permission Requirement

Earlier in 2020, widely used browsers like Chrome and Firefox changed their default behavior for rotating images based on image metadata, referred to as EXIF data. Previously, images would always display in browsers exactly how they are stored on disk, which is typically unrotated. After the change, images now rotate according to a piece of image metadata called orientation value. This has important implications for the entire machine learning (ML) community. For example, if the EXIF orientation is not considered, applications that are used to annotate images may display images in unexpected orientations and result in incorrect labels.

Starting with Chrome 89, AWS can no longer automatically prevent the rotation of images because the web standards group W3C has decided that the ability to control rotation of images violates the web’s Same-Origin Policy. Therefore, to ensure human workers annotate your input images in a predictable orientation when you submit requests to create a human loop, you must add a CORS header policy to the S3 buckets that contain your input images.

**Important**
If you do not add a CORS configuration to the S3 buckets that contains your input data, human review tasks for those input data objects fail.

You can add a CORS policy to an S3 bucket that contains input data in the Amazon S3 console. To set the required CORS headers on the S3 bucket that contains your input images in the S3 console, follow the directions detailed in [How do I add cross-domain resource sharing with CORS?](#). Use the following CORS configuration code for the buckets that host your images. If you use the Amazon S3 console to add the policy to your bucket, you must use the JSON format.

**JSON**

```json
[{
  "AllowedHeaders": [],
  "AllowedMethods": ["GET"],
  "AllowedOrigins": ["*"],
  "ExposeHeaders": []
}]
```

**XML**

```xml
<CORSConfiguration>
  <CORSRule>
    <AllowedOrigin>*</AllowedOrigin>
    <AllowedMethod>GET</AllowedMethod>
  </CORSRule>
</CORSConfiguration>
```

Add Permissions to the IAM Role Used to Create a Flow Definition

To create a flow definition, attach the policies in this section to the role that you use when creating a human review workflow in the SageMaker console, or when using the CreateFlowDefinition API operation.
If you are using the console to create a human review workflow, enter the role Amazon Resource Name (ARN) in the **IAM role** field when creating a human review workflow in the console.

When creating a flow definition using the API, attach these policies to the role that is passed to the `RoleArn` parameter of the `CreateFlowDefinition` operation.

When you create a human review workflow (flow definition), Amazon A2I invokes Amazon S3 to complete your task. To grant Amazon A2I permission to retrieve and store your files in your Amazon S3 bucket, create the following policy and attach it to your role. For example, if the images, documents, and other files that you are sending for human review are stored in an S3 bucket named `my_input_bucket`, and if you want the human reviews to be stored in a bucket named `my_output_bucket`, create the following policy.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["s3:GetObject"],
      "Resource": ["arn:aws:s3:::my_input_bucket/*"]
    },
    {
      "Effect": "Allow",
      "Action": ["s3:PutObject"],
      "Resource": ["arn:aws:s3:::my_output_bucket/*"]
    }
  ]
}
```

In addition, the IAM role must have the following trust policy to give SageMaker permission to assume the role. To learn more about IAM trust policies, see [Resource-Based Policies](https://docs.aws.amazon.com/IAM/latest/userguide/policies-and-permissions.html) section of **Policies and Permissions** in the **AWS Identity and Access Management** documentation.

```json
{
  "Version": "2012-10-17",
  "Statement": [  
    {
      "Sid": "AllowSageMakerToAssumeRole",
      "Effect": "Allow",
      "Principal": {
        "Service": "sagemaker.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

For more information about creating and managing IAM roles and policies, see the following topics in the **AWS Identity and Access Management User Guide**:

- To create an IAM role, see [Creating a Role to Delegate Permissions to an IAM User](https://docs.aws.amazon.com/IAM/latest/userguide/tutorial-create-role.html).
- To learn how to create IAM policies, see [Creating IAM Policies](https://docs.aws.amazon.com/IAM/latest/userguide/create-policy.html).
• To learn how to attach an IAM policy to a role, see Adding and Removing IAM Identity Permissions.

Create a User That Can Invoke Amazon A2I API Operations

To use Amazon A2I to create and start human loops for Amazon Rekognition, Amazon Textract, or the Amazon A2I runtime API, you must use a user that has permissions to invoke Amazon A2I operations. To do this, use the IAM console to attach the AmazonAugmentedAIFullAccess managed policy to a new or existing user.

This policy grants permission to a user to invoke API operations from the SageMaker API for flow definition creation and management and the Amazon Augmented AI Runtime API for human loop creation and management. To learn more about these API operations, see Use APIs in Amazon Augmented AI.

AmazonAugmentedAIFullAccess does not grant permissions to use Amazon Rekognition or Amazon Textract API operations.

Note
You can also attach the AmazonAugmentedAIFullAccess policy to an IAM role that is used to create and start a human loop.

To provide access, add permissions to your users, groups, or roles:

• Users and groups in AWS IAM Identity Center:
  Create a permission set. Follow the instructions in Create a permission set in the AWS IAM Identity Center User Guide.

• Users managed in IAM through an identity provider:
  Create a role for identity federation. Follow the instructions in Creating a role for a third-party identity provider (federation) in the IAM User Guide.

• IAM users:
  • Create a role that your user can assume. Follow the instructions in Creating a role for an IAM user in the IAM User Guide.
  • (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in Adding permissions to a user (console) in the IAM User Guide.

For more information, see Adding and Removing IAM Identity Permissions in the AWS Identity and Access Management User Guide.

Create a User With Permissions to Invoke Amazon A2I, Amazon Textract, and Amazon Rekognition API Operations

To create a user that has permission to invoke the API operations used by the built-in task types (that is, DetectModerationLabels for Amazon Rekognition and AnalyzeDocument for Amazon Textract) and permission to use all Amazon A2I API operations, attach the IAM managed policy, AmazonAugmentedAIIIntegratedAPIAccess. You may want to use this policy when you want to grant broad permissions to a user using Amazon A2I with more than one task type. To learn more about these API operations, see Use APIs in Amazon Augmented AI.

Note
You can also attach the AmazonAugmentedAIIIntegratedAPIAccess policy to an IAM role that is used to create and start a human loop.

To provide access, add permissions to your users, groups, or roles:
- Users and groups in AWS IAM Identity Center:
  
  Create a permission set. Follow the instructions in [Create a permission set](#) in the *AWS IAM Identity Center User Guide*.

- Users managed in IAM through an identity provider:
  
  Create a role for identity federation. Follow the instructions in [Creating a role for a third-party identity provider (federation)](#) in the *IAM User Guide*.

- IAM users:
  
  - Create a role that your user can assume. Follow the instructions in [Creating a role for an IAM user](#) in the *IAM User Guide*.
  
  - (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in [Adding permissions to a user (console)](#) in the *IAM User Guide*.

For more information, see [Adding and Removing IAM Identity Permissions](#) in the *AWS Identity and Access Management User Guide*.

## Enable Worker Task Template Previews

To customize the interface and instructions that your workers see when working on your tasks, you create a worker task template. You can create the template using the [CreateHumanTaskUi](#) operation or the SageMaker console.

To preview your template, you need an IAM role with the following permissions to read Amazon S3 objects that get rendered on your user interface.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject"
      ],
      "Resource": [
        "arn:aws:s3:::my_input_bucket/*"
      ]
    }
  ]
}
```

For Amazon Rekognition and Amazon Textract task types, you can preview your template using the Amazon Augmented AI section of the SageMaker console. For custom task types, you preview your template by invoking the [RenderUiTemplate](#) operation. To preview your template, follow the instructions for your task type:

- Amazon Rekognition and Amazon Textract task types – In the SageMaker console, use the role's Amazon Resource Name (ARN) in the procedure documented in [Create a Worker Task Template](#) (p. 1137).

- Custom task types – In the RenderUiTemplate operation, use the role's ARN in the RoleArn parameter.

## Using Amazon A2I with AWS KMS Encrypted Buckets

If you specify an AWS Key Management Service (AWS KMS) customer managed key to encrypt output data in OutputConfig of [CreateFlowDefinition](#), you must add an IAM policy similar to the
following to that key. This policy gives the IAM execution role that you use to create your human loops permission to use this key to perform all of the actions listed in "Action". To learn more about these actions, see AWS KMS permissions in the AWS Key Management Service Developer Guide.

To use this policy, replace the IAM service-role ARN in "Principal" with the ARN of the execution role you use to create the human review workflow (flow definition). When you create a labeling job using CreateFlowDefinition, this is the ARN you specify for RoleArn. Note that you cannot provide a KmsKeyId when you create a flow definition in the console.

```
{
    "Sid": "AllowUseOfKmsKey",
    "Effect": "Allow",
    "Principal": {
        "AWS": "arn:aws:iam::111122223333:role/service-role/example-role"
    },
    "Action": [
        "kms:Encrypt",
        "kms:Decrypt",
        "kms:ReEncrypt*",
        "kms:GenerateDataKey*",
        "kms:DescribeKey"
    ],
    "Resource": "*"
}
```

Additional Permissions and Security Resources

- the section called "Control Access to SageMaker Resources by Using Tags" (p. 3376).
- the section called "SageMaker Identity-Based Policies" (p. 3354)
- the section called "Control Creation of SageMaker Resources with Condition Keys" (p. 3366)
- the section called "Amazon SageMaker API Permissions Reference" (p. 3422)
- Configure security in Amazon SageMaker (p. 3341)

Use Amazon CloudWatch Events in Amazon Augmented AI

Amazon Augmented AI uses Amazon CloudWatch Events to alert you when a human review loop status changes to Completed, Failed, or Stopped. This event delivery is guaranteed at least once, which means all events created when human loops finish are successfully delivered to CloudWatch Events (Amazon EventBridge). When a review loop changes to one of these states, Augmented AI sends an event to CloudWatch Events similar to the following.

```
{
    "version":"0",
    "id":"12345678-1111-2222-3333-12345EXAMPLE",
    "detail-type":"SageMaker A2I HumanLoop Status Change",
    "source":"aws.sagemaker",
    "account":"111111111111",
    "time":"2019-11-14T17:49:25Z",
    "region":"us-east-1",
    "resources": ["arn:aws:sagemaker:us-east-1:111111111111:human-loop/humanloop-nov-14-1"],
    "detail": {
        "creationTime":"2019-11-14T17:37:36.740Z",
        "failureCode": null,
        "failureReason": null,
        "flowDefinitionArn": "arn:aws:sagemaker:us-east-1:111111111111:flow-definition/flowdef-nov-12",
        "status": "Completed"
    }
}
```
The details in the JSON output include the following:

- **creationTime**
  The timestamp when Augmented AI created the human loop.

- **failureCode**
  A failure code denoting a specific type of failure.

- **failureReason**
  The reason why a human loop has failed. The failure reason is only returned when the human review loop status is `failed`.

- **flowDefinitionArn**
  The Amazon Resource Name (ARN) of the flow definition, or *human review workflow*.

- **humanLoopArn**
  The Amazon Resource Name (ARN) of the human loop.

- **humanLoopName**
  The name of the human loop.

- **humanLoopOutput**
  An object containing information about the output of the human loop.

- **outputS3Uri**
  The location of the Amazon S3 object where Augmented AI stores your human loop output.

- **humanLoopStatus**
  The status of the human loop.

### Send Events from Your Human Loop to CloudWatch Events

To configure a CloudWatch Events rule to get status updates, or *events*, for your Amazon A2I human loops, use the AWS Command Line Interface (AWS CLI) `put-rule` command. When using the `put-rule` command, specify the following to receive human loop statuses:

- `%source%": ["aws.sagemaker"]`
- `%detail-type%": ["SageMaker A2I Human Loop Status Change"]`

To configure a CloudWatch Events rule to watch for all status changes, use the following command and replace the placeholder text. For example, replace "A2IHumanLoopStatusChanges" with a unique CloudWatch Events rule name and "arn:aws:iam::1111222333:role/MyRoleForThisRule" with the Amazon Resource Number (ARN) of an IAM role with an events.amazonaws.com trust policy attached. Replace `region` with the AWS Region in which you want to create the rule.
aws events put-rule --name "A2IHumanLoopStatusChanges"
  --event-pattern "{"source":["aws.sagemaker"],"detail-type":["SageMaker A2I HumanLoop Status Change"]}"  
  --role-arn "arn:aws:iam::111122223333:role/MyRoleForThisRule"
  --region "region"

To learn more about the put-rule request, see Event Patterns in CloudWatch Events in the Amazon CloudWatch Events User Guide.

Set Up a Target to Process Events

To process events, you need to set up a target. For example, if you want to receive an email when a human loop status changes, use a procedure in Setting Up Amazon SNS Notifications in the Amazon CloudWatch User Guide to set up an Amazon SNS topic and subscribe your email to it. Once you have created a topic, you can use it to create a target.

To add a target to your CloudWatch Events rule

1. Open the CloudWatch console: https://console.aws.amazon.com/cloudwatch/home
2. In the navigation pane, choose Rules.
3. Choose the rule to which you want to add a target.
4. Choose Actions, and then choose Edit.
5. Under Targets, choose Add Target and choose the AWS service you want to act when a human loop status change event is detected.
6. Configure your target. For instructions, see the topic for configuring a target in the AWS documentation for that service.
7. Choose Configure details.
8. For Name, enter a name and, optionally, provide details about the purpose of the rule in Description.
9. Make sure that the check box next to State is selected so that your rule is listed as Enabled.
10. Choose Update rule.

Use Human Review Output

After you receive human review results, you can analyze the results and compare them to machine learning predictions. The JSON that is stored in the Amazon S3 bucket contains both the machine learning predictions and the human review results.

More Information

Automating Amazon SageMaker with Amazon EventBridge (p. 3597)

Use APIs in Amazon Augmented AI

You can create a human review workflow or a worker task template programmatically. The APIs you use depend on whether you are creating a Amazon Rekognition, Amazon Textract, or custom task type. This topic provides links to API reference documentation for each task type and programming task.

The following APIs can be used with Augmented AI:

Amazon Augmented AI

Use the Augmented AI API to start, stop, and delete human review loops. You can also list all human review loops and return information about human review loops in your account.
Learn more about human review loop APIs in the Amazon Augmented AI Runtime API Reference.

**Amazon Rekognition**

Use the `HumanLoopConfig` parameter of the `DetectModerationLabels` API to initiate a human review workflow using Amazon Rekognition.

**Amazon SageMaker**

Use the Amazon SageMaker API to create a FlowDefinition, also known as a human review workflow. You can also create a HumanTaskUi or worker task template.

For more information, see the `CreateFlowDefinition` or the `CreateHumanTaskUi` API documentation.

**Amazon Textract**

Use the `HumanLoopConfig` parameter of the `AnalyzeDocument` API to initiate a human review workflow using Amazon Textract.

**Programmatic Tutorials**

The following tutorials provide example code and step-by-step instructions for creating human review workflows and worker task templates programmatically.

- Tutorial: Get Started Using the Amazon A2I API (p. 1092)
- Create a Human Review Workflow (API) (p. 1112)
- Create and Start a Human Loop (p. 1129)
- Using Amazon Augmented AI with Amazon Rekognition in the Amazon Rekognition Developer Guide
- Using Amazon Augmented AI with Amazon Textract AnalyzeDocument in the Amazon Textract Developer Guide
Prepare data

You can use Amazon SageMaker Data Wrangler to import, prepare, transform, visualize and analyze data. You can integrate Data Wrangler into your machine learning workflows to simplify and streamline data pre-processing and feature engineering using little to no coding. You can also add your own Python scripts and transformations to customize your data prep workflow.

Import data from Amazon S3, Amazon Redshift, Amazon Athena, and use Data Wrangler to create sophisticated machine learning data prep workflows with built-in and custom data transformations and analysis including feature target leakage and quick modeling.

After you have defined a data prep workflow, or data flow, you can integrate it with SageMaker Processing, SageMaker Pipelines, and SageMaker Feature Store, simplify the task of processing, sharing and storing ML training data. You can also export your data flow to a python script and create a custom ML data prep pipeline.

For more information, see Prepare ML Data with Amazon SageMaker Data Wrangler (p. 1167).

For fast data preparation at scale, Amazon SageMaker Studio provides a built-in integration with Amazon EMR. You can use SageMaker Studio to connect to, provision, or manage Amazon EMR clusters from your notebook interface for petabyte-scale data processing, interactive analytics, and machine learning. Amazon EMR uses open-source frameworks such as Apache Spark, Apache Hive, or Presto. For more information about using Amazon EMR within SageMaker Studio, see Prepare data using Amazon EMR (p. 1364).

Alternatively, you can use the Apache Spark-based serverless engine from an AWS Glue interactive sessions to aggregate and transform data from multiple sources. You can aggregate and transform data from your analytics and ETL (extract, transform, and load) pipelines without needing to manage infrastructure. For more information about using AWS Glue interactive sessions within SageMaker Studio, see Prepare data using AWS Glue Interactive Sessions (p. 1393).

The data that you’re using to train your machine learning model might contain bias. Bias can result in machine learning models that discriminate against certain individuals or groups. You can use Amazon SageMaker Clarify to determine whether the data that you’re using to train models or your resulting model encodes any bias. SageMaker Clarify can also help you explain models created with tabular, image or NLP data with partial dependence plots, feature importance and more. For more information about SageMaker Clarify, see Detect Pre-training Data Bias (p. 3208).

Topics
- Explore, Analyze, and Process Data (p. 1166)
- Prepare ML Data with Amazon SageMaker Data Wrangler (p. 1167)
- Scale data preparation using Apache Spark, Hive, or Presto on Amazon EMR or AWS Glue from Amazon SageMaker Studio notebooks (p. 1363)

Explore, Analyze, and Process Data

Before using a dataset to train a model, data scientists typically explore, analyze, and preprocess it.

Amazon SageMaker Processing enables running jobs to preprocess and postprocess data, perform feature engineering, and evaluate models on SageMaker easily and at scale. When combined with the other critical machine learning tasks provided by SageMaker, such as training and hosting, Processing provides you with the benefits of a fully managed machine learning environment, including all the security and compliance support built into SageMaker. With Processing, you have the flexibility to use
the built-in data processing containers or to bring your own containers and submit custom jobs to run on managed infrastructure. After you submit a job, SageMaker launches the compute instances, processes and analyzes the input data, and releases the resources upon completion. For more information, see Process data (p. 1399).

- For information about how to run your own data processing scripts, see Data Processing with scikit-learn (p. 1401).
- For information about how to build your own processing container to run scripts, see Build Your Own Processing Container (Advanced Scenario) (p. 1408).
- For information about how to perform exploratory data analysis (EDA) with a visual no-code interface, see Prepare ML Data with Amazon SageMaker Data Wrangler (p. 1167).

**Prepare ML Data with Amazon SageMaker Data Wrangler**

Amazon SageMaker Data Wrangler (Data Wrangler) is a feature of Amazon SageMaker Studio that provides an end-to-end solution to import, prepare, transform, featurize, and analyze data. You can integrate a Data Wrangler data preparation flow into your machine learning (ML) workflows to simplify and streamline data pre-processing and feature engineering using little to no coding. You can also add your own Python scripts and transformations to customize workflows.

Data Wrangler provides the following core functionalities to help you analyze and prepare data for machine learning applications.

- **Import** – Connect to and import data from Amazon Simple Storage Service (Amazon S3), Amazon Athena (Athena), Amazon Redshift, Snowflake, and Databricks.
- **Data Flow** – Create a data flow to define a series of ML data prep steps. You can use a flow to combine datasets from different data sources, identify the number and types of transformations you want to apply to datasets, and define a data prep workflow that can be integrated into an ML pipeline.
- **Transform** – Clean and transform your dataset using standard transforms like string, vector, and numeric data formatting tools. Featurize your data using transforms like text and date/time embedding and categorical encoding.
- **Generate Data Insights** – Automatically verify data quality and detect abnormalities in your data with Data Wrangler Data Insights and Quality Report.
- **Analyze** – Analyze features in your dataset at any point in your flow. Data Wrangler includes built-in data visualization tools like scatter plots and histograms, as well as data analysis tools like target leakage analysis and quick modeling to understand feature correlation.
- **Export** – Export your data preparation workflow to a different location. The following are example locations:
  - Amazon Simple Storage Service (Amazon S3) bucket
  - Amazon SageMaker Model Building Pipelines – Use SageMaker Pipelines to automate model deployment. You can export the data that you've transformed directly to the pipelines.
  - Amazon SageMaker Feature Store – Store the features and their data in a centralized store.
  - Python script – Store the data and their transformations in a Python script for your custom workflows.

To start using Data Wrangler, see Get Started with Data Wrangler (p. 1169).

**Important**

Data Wrangler no longer supports Jupyter Lab Version 1 (JL1). To access the latest features and updates, update to Jupyter Lab Version 3. For more information about upgrading, see View and update the JupyterLab version of an application from the console (p. 217).
Important
The information and procedures in this guide use the latest version of Amazon SageMaker Studio. For information about updating Studio to the latest version, see Amazon SageMaker Studio UI Overview (p. 205).

You must use Studio version 1.3.0 or later. Use the following procedure to open Amazon SageMaker Studio and see which version you're running.

To open Studio and check its version, see the following procedure.

1. Use the steps in Prerequisites (p. 1169) to access Data Wrangler through Amazon SageMaker Studio.
2. Next to the user you want to use to launch Studio, select Launch app.
3. Choose Studio.
4. After Studio loads, select File, then New, and then Terminal.
5. Once you have launched Studio, select File, then New, and then Terminal.
6. Enter cat /opt/conda/share/jupyter/lab/staging/yarn.lock | grep -A 1 "@amzn/sagemaker-ui-data-prep-plugin@" to print the version of your Studio instance. You must have Studio version 1.3.0 to use Snowflake.
You can update Amazon SageMaker Studio from within the AWS Management Console. For more information about updating Studio, see Amazon SageMaker Studio UI Overview (p. 205).

Get Started with Data Wrangler

Amazon SageMaker Data Wrangler is a feature in Amazon SageMaker Studio. Use this section to learn how to access and get started using Data Wrangler. Do the following:

1. Complete each step in Prerequisites (p. 1169).
2. Follow the procedure in Access Data Wrangler (p. 1170) to start using Data Wrangler.

Prerequisites

To use Data Wrangler, you must complete the following prerequisites.

1. To use Data Wrangler, you need access to an Amazon Elastic Compute Cloud (Amazon EC2) instance. For more information about the Amazon EC2 instances that you can use, see Instances (p. 1227). To learn how to view your quotas and, if necessary, request a quota increase, see AWS service quotas.
2. Configure the required permissions described in Security and Permissions (p. 1338).
3. If your organization is using a firewall that blocks internet traffic, you must have access to the following URLs:

   - https://ui.prod-1.data-wrangler.sagemaker.aws/
   - https://ui.prod-2.data-wrangler.sagemaker.aws/
   - https://ui.prod-4.data-wrangler.sagemaker.aws/

To use Data Wrangler, you need an active Studio instance. To learn how to launch a new instance, see Onboard to Amazon SageMaker Domain (p. 10). When your Studio instance is Ready, use the instructions in Access Data Wrangler (p. 1170).
Access Data Wrangler

The following procedure assumes you have completed the Prerequisites (p. 1169).

To access Data Wrangler in Studio, do the following.

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 10).
2. Choose Studio.
3. Choose Launch app.
4. From the dropdown list, select Studio.
5. Choose the Home icon.
6. Choose Data.
7. Choose Data Wrangler.
8. You can also create a Data Wrangler flow by doing the following.
   a. In the top navigation bar, select File.
   b. Select New.
   c. Select Data Wrangler Flow.
9. (Optional) Rename the new directory and the .flow file.
10. When you create a new .flow file in Studio, you might see a carousel that introduces you to Data Wrangler.

   This may take a few minutes.

   This messaging persists as long as the KernelGateway app on your User Details page is Pending. To see the status of this app, in the SageMaker console on the Amazon SageMaker Studio page, select the name of the user you are using to access Studio. On the User Details page, you see a KernelGateway app under Apps. Wait until this app status is Ready to start using Data Wrangler. This can take around 5 minutes the first time you launch Data Wrangler.
11. To get started, choose a data source and use it to import a dataset. See [Import](p. 1178) to learn more.

   When you import a dataset, it appears in your data flow. To learn more, see [Create and Use a Data Wrangler Flow](p. 1227).

12. After you import a dataset, Data Wrangler automatically infers the type of data in each column. Choose + next to the **Data types** step and select **Edit data types**.

   **Important**
   After you add transforms to the **Data types** step, you cannot bulk-update column types using **Update types**.

13. Use the data flow to add transforms and analyses. To learn more see [Transform Data](p. 1253) and [Analyze and Visualize](p. 1296).

14. To export a complete data flow, choose **Export** and choose an export option. To learn more, see [Export](p. 1311).

15. Finally, choose the **Components and registries** icon, and select **Data Wrangler** from the dropdown list to see all the .flow files that you've created. You can use this menu to find and move between data flows.

After you have launched Data Wrangler, you can use the following section to walk through how you might use Data Wrangler to create an ML data prep flow.

## Update Data Wrangler

We recommend that you periodically update the Data Wrangler Studio app to access the latest features and updates. The Data Wrangler app name starts with `sagemaker-data-wrang`. To learn how to update a Studio app, see [Shut down and Update Studio Apps](p. 293).

## Demo: Data Wrangler Titanic Dataset Walkthrough

The following sections provide a walkthrough to help you get started using Data Wrangler. This walkthrough assumes that you have already followed the steps in [Access Data Wrangler](p. 1170) and have a new data flow file open that you intend to use for the demo. You may want to rename this .flow file to something similar to `titanic-demo.flow`.

This walkthrough uses the `Titanic dataset`. It's a modified version of the `Titanic dataset` that you can import into your Data Wrangler flow more easily. This data set contains the survival status, age, gender, and class (which serves as a proxy for economic status) of passengers aboard the maiden voyage of the RMS Titanic in 1912.

In this tutorial, you perform the following steps.

1. Do one of the following:
   - Open your Data Wrangler flow and choose **Use Sample Dataset**.
   - Upload the [Titanic dataset](https://s3.amazonaws.com/titanic_datasets/Titanic.csv) to Amazon Simple Storage Service (Amazon S3), and then import this dataset into Data Wrangler.
2. Analyze this dataset using Data Wrangler analyses.
3. Define a data flow using Data Wrangler data transforms.
4. Export your flow to a Jupyter Notebook that you can use to create a Data Wrangler job.
5. Process your data, and kick off a SageMaker training job to train a XGBoost Binary Classifier.

Upload Dataset to S3 and Import

To get started, you can use one of the following methods to import the Titanic dataset into Data Wrangler:

- Importing the dataset directly from the Data Wrangler flow
- Uploading the dataset to Amazon S3 and then importing it into Data Wrangler

To import the dataset directly into Data Wrangler, open the flow and choose Use Sample Dataset.

Uploading the dataset to Amazon S3 and importing it into Data Wrangler is closer to the experience you have importing your own data. The following information tells you how to upload your dataset and import it.

Before you start importing the data into Data Wrangler, download the Titanic dataset and upload it to an Amazon S3 (Amazon S3) bucket in the AWS Region in which you want to complete this demo. If you are a new user of Amazon S3, you can do this using drag and drop in the Amazon S3 console. To learn how, see Uploading Files and Folders by Using Drag and Drop in the Amazon Simple Storage Service User Guide.

**Important**

Upload your dataset to an S3 bucket in the same AWS Region you want to use to complete this demo.

When your dataset has been successfully uploaded to Amazon S3, you can import it into Data Wrangler.

**Import the Titanic dataset to Data Wrangler**

1. Choose the Import data button in your Data flow tab or choose the Import tab.
2. Select Amazon S3.
3. Use the Import a dataset from S3 table to find the bucket to which you added the Titanic dataset. Choose the Titanic dataset CSV file to open the Details pane.
4. Under Details, the File type should be CSV. Check First row is header to specify that the first row of the dataset is a header. You can also name the dataset something more friendly, such as Titanic-train.
5. Choose the Import button.

When your dataset is imported into Data Wrangler, it appears in your Data Flow tab. You can double click on a node to enter the node detail view, which allows you to add transformations or analysis. You can use the plus icon for a quick access to the navigation. In the next section, you use this data flow to add analysis and transform steps.

**Data Flow**

In the data flow section, the only steps in the data flow are your recently imported dataset and a Data type step. After applying transformations, you can come back to this tab and see what the data flow looks like. Now, add some basic transformations under the Prepare and Analyze tabs.
Prepare and Visualize

Data Wrangler has built-in transformations and visualizations that you can use to analyze, clean, and transform your data.

The Data tab of the node detail view lists all built-in transformations in the right panel, which also contains an area in which you can add custom transformations. The following use case showcases how to use these transformations.

To get information that might help you with data exploration and feature engineering, create a data quality and insights report. The information from the report can help you clean and process your data. It gives you information such as the number of missing values and the number of outliers. If you have issues with your data, such as target leakage or imbalance, the insights report can bring those issues to your attention. For more information about creating a report, see Get Insights On Data and Data Quality (p. 1239).

Data Exploration

First, create a table summary of the data using an analysis. Do the following:

1. Choose the + next to the Data type step in your data flow and select Add analysis.
2. In the Analysis area, select Table summary from the dropdown list.
3. Give the table summary a Name.
4. Select Preview to preview the table that will be created.
5. Choose Save to save it to your data flow. It appears under All Analyses.

Using the statistics you see, you can make observations similar to the following about this dataset:

- Fare average (mean) is around $33, while the max is over $500. This column likely has outliers.
- This dataset uses ? to indicate missing values. A number of columns have missing values: cabin, embarked, and home.dest
- The age category is missing over 250 values.

Next, clean your data using the insights gained from these stats.

Drop Unused Columns

Using the analysis from the previous section, clean up the dataset to prepare it for training. To add a new transform to your data flow, choose + next to the Data type step in your data flow and choose Add transform.

First, drop columns that you don't want to use for training. You can use pandas data analysis library to do this, or you can use one of the built-in transforms.

Use the following procedure to drop the unused columns.

To drop the unused columns.

1. Open the Data Wrangler flow.
2. There are two nodes in your Data Wrangler flow. Choose the + to the right of the Data types node.
3. Choose Add transform.
4. In the All steps column, choose Add step.
5. In the Standard transform list, choose Manage Columns. The standard transformations are ready-made, built-in transformations. Make sure that Drop column is selected.
6. Under Columns to drop, check the following column names:
• cabin
• ticket
• name
• sibsp
• parch
• home.dest
• boat
• body

7. Choose **Preview**.
8. Verify that the columns have been dropped, then choose **Add**.

To do this using pandas, follow these steps.

1. In the **All steps** column, choose **Add step**.
2. In the **Custom** transform list, choose **Custom transform**.
3. Provide a name for your transformation, and choose **Python (Pandas)** from the dropdown list.
4. Enter the following Python script in the code box.

   ```python
   cols = ['name', 'ticket', 'cabin', 'sibsp', 'parch', 'home.dest', 'boat', 'body']
   df = df.drop(cols, axis=1)
   ```

5. Choose **Preview** to preview the change, and then choose **Add** to add the transformation.

**Clean up Missing Values**

Now, clean up missing values. You can do this with the **Handling missing values** transform group.

A number of columns have missing values. Of the remaining columns, **age** and **fare** contain missing values. Inspect this using a **Custom Transform**.

Using the **Python (Pandas)** option, use the following to quickly review the number of entries in each column:

```python
df.info()
```
To drop rows with missing values in the `age` category, do the following:

1. Choose **Handle missing**.
2. Choose **Drop missing** for the Transformer.
3. Choose `age` for the Input column.
4. Choose **Preview** to see the new data frame, and then choose **Add** to add the transform to your flow.
5. Repeat the same process for `fare`.

You can use `df.info()` in the **Custom transform** section to confirm that all rows now have 1,045 values.

**Custom Pandas: Encode**

Try flat encoding using Pandas. Encoding categorical data is the process of creating a numerical representation for categories. For example, if your categories are Dog and Cat, you may encode this information into two vectors: `[1, 0]` to represent Dog, and `[0, 1]` to represent Cat.

1. In the **Custom Transform** section, choose **Python (Pandas)** from the dropdown list.
2. Enter the following in the code box:

```python
import pandas as pd

dummies = []
cols = ['pclass', 'sex', 'embarked']
for col in cols:
    dummies.append(pd.get_dummies(df[col]))

encoded = pd.concat(dummies, axis=1)
```
df = pd.concat((df, encoded), axis=1)

3. Choose **Preview** to preview the change. The encoded version of each column is added to the dataset.
4. Choose **Add** to add the transformation.

### Custom SQL: SELECT Columns

Now, select the columns you want to keep using SQL. For this demo, select the columns listed in the following SELECT statement. Because `survived` is your target column for training, put that column first.

1. In the **Custom Transform** section, select **SQL (PySpark SQL)** from the dropdown list.
2. Enter the following in the code box.
   ```sql
   SELECT survived, age, fare, 1, 2, 3, female, male, C, Q, S FROM df;
   ```
3. Choose **Preview** to preview the change. The columns listed in your SELECT statement are the only remaining columns.
4. Choose **Add** to add the transformation.

### Export to a Data Wrangler Notebook

When you've finished creating a data flow, you have a number of export options. The following section explains how to export to a Data Wrangler job notebook. A Data Wrangler job is used to process your data using the steps defined in your data flow. To learn more about all export options, see **Export** (p. 1311).

#### Export to Data Wrangler Job Notebook

When you export your data flow using a Data Wrangler job, the process automatically creates a Jupyter Notebook. This notebook automatically opens in your Studio instance and is configured to run a SageMaker processing job to run your Data Wrangler data flow, which is referred to as a Data Wrangler job.

1. Save your data flow. Select **File** and then select **Save Data Wrangler Flow**.
2. Back to the **Data Flow** tab, select the last step in your data flow (SQL), then choose the + to open the navigation.
3. Choose **Export**, and **Amazon S3 (via Jupyter Notebook)**. This opens a Jupyter Notebook.
4. Choose any **Python 3 (Data Science)** kernel for the **Kernel**.

5. When the kernel starts, run the cells in the notebook book until **Kick off SageMaker Training Job (Optional)**.

6. Optionally, you can run the cells in **Kick off SageMaker Training Job (Optional)** if you want to create a SageMaker training job to train an XGBoost classifier. You can find the cost to run a SageMaker training job in **Amazon SageMaker Pricing**.

   Alternatively, you can add the code blocks found in Training XGBoost Classifier (p. 1177) to the notebook and run them to use the XGBoost open source library to train an XGBoost classifier.

7. Uncomment and run the cell under **Cleanup** and run it to revert the SageMaker Python SDK to its original version.

You can monitor your Data Wrangler job status in the SageMaker console in the **Processing** tab. Additionally, you can monitor your Data Wrangler job using Amazon CloudWatch. For additional information, see Monitor Amazon SageMaker Processing Jobs with CloudWatch Logs and Metrics.

If you kicked off a training job, you can monitor its status using the SageMaker console under **Training jobs** in the **Training section**.

**Training XGBoost Classifier**

You can train an XGBoost Binary Classifier using either a Jupyter notebook or a Amazon SageMaker Autopilot. You can use Autopilot to automatically train and tune models on the data that you've transformed directly from your Data Wrangler flow. For information about Autopilot, see Automatically Train Models on Your Data Flow (p. 1252).
In the same notebook that kicked off the Data Wrangler job, you can pull the data and train an XGBoost Binary Classifier using the prepared data with minimal data preparation.

1. First, upgrade necessary modules using pip and remove the _SUCCESS file (this last file is problematic when using awswrangler).
   
   ```
   ! pip install --upgrade awscli awswrangler boto sklearn
   ! aws s3 rm (output_path) --recursive --exclude "*" --include "*_SUCCESS*"
   ```

2. Read the data from Amazon S3. You can use awswrangler to recursively read all the CSV files in the S3 prefix. The data is then split into features and labels. The label is the first column of the dataframe.

   ```python
   import awswrangler as wr
   df = wr.s3.read_csv(path=output_path, dataset=True)
   X, y = df.iloc[:,:-1], df.iloc[:,-1]
   ```

   • Finally, create DMatrices (the XGBoost primitive structure for data) and do cross-validation using the XGBoost binary classification.

   ```python
   import xgboost as xgb
   dmatrix = xgb.DMatrix(data=X, label=y)
   params = {"objective":"binary:logistic","learning_rate": 0.1, 'max_depth': 5, 'alpha': 10}
   xgb.cv(
   dtrain=dmatrix,
   params=params,
   nfold=3,
   num_boost_round=50,
   early_stopping_rounds=10,
   metrics="rmse",
   as_pandas=True,
   seed=123)
   ```

Shut down Data Wrangler

When you are finished using Data Wrangler, we recommend that you shut down the instance it runs on to avoid incurring additional charges. To learn how to shut down the Data Wrangler app and associated instance, see Shut Down Data Wrangler (p. 1362).

**Import**

You can use Amazon SageMaker Data Wrangler to import data from the following *data sources*: Amazon Simple Storage Service (Amazon S3), Amazon Athena, Amazon Redshift, and Snowflake. The dataset that you import can include up to 1000 columns.

**Topics**

- Import data from Amazon S3 (p. 1180)
- Import data from Athena (p. 1183)
- Import data from Amazon Redshift (p. 1186)
- Import data from Amazon EMR (p. 1190)
- Import data from Databricks (JDBC) (p. 1198)
• Import data from Salesforce Data Cloud (p. 1200)
• Import data from Snowflake (p. 1207)
• Import Data From Software as a Service (SaaS) Platforms (p. 1223)
• Imported Data Storage (p. 1226)

Some data sources allow you to add multiple data connections:

• You can connect to multiple Amazon Redshift clusters. Each cluster becomes a data source.
• You can query any Athena database in your account to import data from that database.

When you import a dataset from a data source, it appears in your data flow. Data Wrangler automatically infers the data type of each column in your dataset. To modify these types, select the Data types step and select Edit data types.

When you import data from Athena or Amazon Redshift, the imported data is automatically stored in the default SageMaker S3 bucket for the AWS Region in which you are using Studio. Additionally, Athena stores data you preview in Data Wrangler in this bucket. To learn more, see Imported Data Storage (p. 1226).

Important
The default Amazon S3 bucket may not have the least permissive security settings, such as bucket policy and server-side encryption (SSE). We strongly recommend that you Add a Bucket Policy To Restrict Access to Datasets Imported to Data Wrangler.

Important
In addition, if you use the managed policy for SageMaker, we strongly recommend that you scope it down to the most restrictive policy that allows you to perform your use case. For more information, see Grant an IAM Role Permission to Use Data Wrangler (p. 1340).

All data sources except for Amazon Simple Storage Service (Amazon S3) require you to specify a SQL query to import your data. For each query, you must specify the following:

• Data catalog
• Database
• Table

You can specify the name of the database or the data catalog in either the drop down menus or within the query. The following are example queries:

• select * from example-data-catalog-name.example-database-name.example-table-name – The query doesn't use anything specified in the dropdown menus of the user-interface (UI) to run. It queries example-table-name within example-database-name within example-data-catalog-name.
• select * from example-database-name.example-table-name – The query uses the data catalog that you've specified in the Data catalog dropdown menu to run. It queries example-table-name within example-database-name within the data catalog that you've specified.
• select * from example-table-name – The query requires you to select fields for both the Data catalog and Database name dropdown menus. It queries example-table-name within the data catalog within the database and data catalog that you've specified.

The link between Data Wrangler and the data source is a connection. You use the connection to import data from your data source.
There are the following types of connections:

- Direct
- Cataloged

Data Wrangler always has access to the most recent data in a direct connection. If the data in the data source has been updated, you can use the connection to import the data. For example, if someone adds a file to one of your Amazon S3 buckets, you can import the file.

A cataloged connection is the result of a data transfer. The data in the cataloged connection doesn't necessarily have the most recent data. For example, you might set up a data transfer between Salesforce and Amazon S3. If there's an update to the Salesforce data, you must transfer the data again. You can automate the process of transferring data. For more information about data transfers, see Import Data From Software as a Service (SaaS) Platforms (p. 1223).

**Import data from Amazon S3**

You can use Amazon Simple Storage Service (Amazon S3) to store and retrieve any amount of data, at any time, from anywhere on the web. You can accomplish these tasks using the AWS Management Console, which is a simple and intuitive web interface, and the Amazon S3 API. If you've stored your dataset locally, we recommend that you add it to an S3 bucket for import into Data Wrangler. To learn how, see Uploading an object to a bucket in the Amazon Simple Storage Service User Guide.

Data Wrangler uses S3 Select to allow you to preview your Amazon S3 files in Data Wrangler. You incur standard charges for each file preview. To learn more about pricing, see the Requests & data retrievals tab on Amazon S3 pricing.

**Important**

If you plan to export a data flow and launch a Data Wrangler job, ingest data into a SageMaker feature store, or create a SageMaker pipeline, be aware that these integrations require Amazon S3 input data to be located in the same AWS region.

**Important**

If you're importing a CSV file, make sure it meets the following requirements:

- A record in your dataset can't be longer than one line.
- A backslash, \, is the only valid escape character.
- Your dataset must use one of the following delimiters:
  - Comma – ,
  - Colon – :
  - Semicolon – ;
  - Pipe – |
  - Tab – [TAB]

To save space, you can import compressed CSV files.

Data Wrangler gives you the ability to either import the entire dataset or sample a portion of it. For Amazon S3, it provides the following sampling options:

- None – Import the entire dataset.
- First K – Sample the first K rows of the dataset, where K is an integer that you specify.
- Randomized – Takes a random sample of a size that you specify.
- Stratified – Takes a stratified random sample. A stratified sample preserves the ratio of values in a column.
After you've imported your data, you can also use the sampling transformer to take one or more samples from your entire dataset. For more information about the sampling transformer, see Sampling (p. 1286).

You can use one of the following resource identifiers to import your data:

- An Amazon S3 URI that uses an Amazon S3 bucket or Amazon S3 access point
- An Amazon S3 access point alias
- An Amazon Resource Name (ARN) that uses an Amazon S3 access point or Amazon S3 bucket

Amazon S3 access points are named network endpoints that are attached to the buckets. Each access point has distinct permissions and network controls that you can configure. For more information about access points, see Managing data access with Amazon S3 access points.

Important
If you're using an Amazon Resource Name (ARN) to import your data, it must be for a resource located in the same AWS Region that you're using to access Amazon SageMaker Studio.

You can import either a single file or multiple files as a dataset. You can use the multfile import operation when you have a dataset that is partitioned into separate files. It takes all of the files from an Amazon S3 directory and imports them as a single dataset. For information on the types of files that you can import and how to import them, see the following sections.

Single File Import

You can import single files in the following formats:

- Comma Separated Values (CSV)
- Parquet
- Javascript Object Notation (JSON)
- Optimized Row Columnar (ORC)
- Image – Data Wrangler uses OpenCV to import images. For more information about supported image formats, see Image file reading and writing.

For files formatted in JSON, Data Wrangler supports both JSON lines (.jsonl) and JSON documents (.json). When you preview your data, it automatically shows the JSON in tabular format. For nested JSON documents that are larger than 5 MB, Data Wrangler shows the schema for the structure and the arrays as values in the dataset. Use the Flatten structured and Explode array operators to display the nested values in tabular format. For more information, see Unnest JSON Data (p. 1291) and Explode Array (p. 1292).

When you choose a dataset, you can rename it, specify the file type, and identify the first row as a header.

You can import a dataset that you've partitioned into multiple files in an Amazon S3 bucket in a single import step.

To import a dataset into Data Wrangler from a single file that you've stored in Amazon S3:

1. If you are not currently on the Import tab, choose Import.
2. Under Available, choose Amazon S3.
3. From the Import tabular, image, or time-series data from S3, do one of the following:
   - Choose an Amazon S3 bucket from the tabular view and navigate to the file that you're importing.
• For **S3 source**, specify an Amazon S3 bucket or an Amazon S3 URI and select **Go**. The Amazon S3 URIs can be in one of the following formats:
  - `s3://DOC-EXAMPLE-BUCKET/example-prefix/example-file`
  - `example-access-point-aqfqprnstdn7aefdfbarligizwgyfouse1a-s3alias/datasets/example-prefix/example-file`

4. Choose the dataset to open the **Import settings** pane.
5. If your CSV file has a header, select the checkbox next to **Add header to table**.
6. Use the **Preview** table to preview your dataset. This table shows up to 100 rows.
7. In the **Details** pane, verify or change the **Name** and **File Type** for your dataset. If you add a **Name** that contains spaces, these spaces are replaced with underscores when your dataset is imported.
8. Specify the sampling configuration that you'd like to use.
9. Choose **Import***.

### Multifile Import

The following are the requirements for importing multiple files:

- The files must be in the same folder of your Amazon S3 bucket.
- The files must either share the same header or have no header.

Each file must be in one of the following formats:

- CSV
- Parquet
- Optimized Row Columnar (ORC)
- Image – Data Wrangler uses OpenCV to import images. For more information about supported image formats, see [image file reading and writing](#).

Use the following procedure to import multiple files.

**To import a dataset into Data Wrangler from multiple files that you've stored in an Amazon S3 directory**

1. If you are not currently on the **Import** tab, choose **Import**.
2. Under **Available**, choose **Amazon S3**.
3. From the **Import tabular, image, or time-series data from S3**, do one of the following:
   - Choose an Amazon S3 bucket from the tabular view and navigate to the folder containing the files that you're importing.
   - **For S3 source**, specify the Amazon S3 bucket or an Amazon S3 URI with your files and select **Go**. The following are valid URIs:
     - `s3://DOC-EXAMPLE-BUCKET/example-prefix/example-prefix`
     - `example-access-point-aqfqprnstdn7aefdfbarligizwgyfouse1a-s3alias/example-prefix/`
     - `s3://arn:aws:s3:AWS-Region:111122223333:accesspoint/example-prefix`
4. Select the folder containing the files that you want to import. Each file must be in one of the supported formats. Your files must be the same data type.
5. If your folder contains CSV files with headers, select the checkbox next to **First row is header**.
6. If your files are nested within other folders, select the checkbox next to **Include nested directories**.
7. (Optional) Choose **Add filename column** add a column to the dataset that shows the filename for each observation.
8. (Optional) By default, Data Wrangler doesn't show you a preview of a folder. You can activate previewing by choosing the blue **Preview off** button. A preview shows the first 10 rows of the first 10 files in the folder.
9. In the **Details** pane, verify or change the **Name** and **File Type** for your dataset. If you add a **Name** that contains spaces, these spaces are replaced with underscores when your dataset is imported.
10. Specify the sampling configuration that you'd like to use.
11. Choose **Import dataset**.

You can also use parameters to import a subset of files that match a pattern. Parameters help you more selectively pick the files that you're importing. To start using parameters, edit the data source and apply them to the path that you're using to import the data. For more information, see [Reusing Data Flows for Different Datasets](p. 1304).

### Import data from Athena

Use Amazon Athena to import your data from Amazon Simple Storage Service (Amazon S3) into Data Wrangler. In Athena, you write standard SQL queries to select the data that you're importing from Amazon S3. For more information, see [What is Amazon Athena?](p.)

You can use the AWS Management Console to set up Amazon Athena. You must create at least one database in Athena before you start running queries. For more information about getting started with Athena, see [Getting started](p. 1185).

Athena is directly integrated with Data Wrangler. You can write Athena queries without having to leave the Data Wrangler UI.

In addition to writing simple Athena queries in Data Wrangler, you can also use:

- Athena workgroups for query result management. For more information about workgroups, see [Managing query results](p. 1185).
- Lifecycle configurations for setting data retention periods. For more information about data retention, see [Setting data retention periods](p. 1185).

### Query Athena within Data Wrangler

**Note**

Data Wrangler does not support federated queries.

If you use AWS Lake Formation with Athena, make sure your Lake Formation IAM permissions do not override IAM permissions for the database sagemaker_data wrangler.

Data Wrangler gives you the ability to either import the entire dataset or sample a portion of it. For Athena, it provides the following sampling options:

- None – Import the entire dataset.
- First K – Sample the first K rows of the dataset, where K is an integer that you specify.
- Randomized – Takes a random sample of a size that you specify.
• Stratified – Takes a stratified random sample. A stratified sample preserves the ratio of values in a column.

The following procedure shows how to import a dataset from Athena into Data Wrangler.

**To import a dataset into Data Wrangler from Athena**

1. Sign into [Amazon SageMaker Console](#).
2. Choose [Studio](#).
3. Choose [Launch app](#).
4. From the dropdown list, select [Studio](#).
5. Choose the Home icon.
6. Choose [Data](#).
7. Choose [Data Wrangler](#).
8. Choose [Import data](#).
10. For [Data Catalog](#), choose a data catalog.
11. Use the [Database](#) dropdown list to select the database that you want to query. When you select a database, you can preview all tables in your database using the [Tables](#) listed under [Details](#).
12. (Optional) Choose [Advanced configuration](#).
   a. Choose a [Workgroup](#).
   b. If your workgroup hasn't enforced the Amazon S3 output location or if you don't use a workgroup, specify a value for [Amazon S3 location of query results](#).
   c. (Optional) For [Data retention period](#), select the checkbox to set a data retention period and specify the number of days to store the data before it’s deleted.
   d. (Optional) By default, Data Wrangler saves the connection. You can choose to deselect the checkbox and not save the connection.
13. For [Sampling](#), choose a sampling method. Choose [None](#) to turn off sampling.
14. Enter your query in the query editor and use the [Run](#) button to run the query. After a successful query, you can preview your result under the editor.

**Note**

Salesforce data uses the `timestamptz` type. If you're querying the timestamp column that you've imported to Athena from Salesforce, cast the data in the column to the `timestamp` type. The following query casts the timestamp column to the correct type.

```
# cast column timestamptz_col as timestamp type, and name it as timestamp_col
select cast(timestamptz_col as timestamp) as timestamp_col from table
```

15. To import the results of your query, select [Import](#).

After you complete the preceding procedure, the dataset that you've queried and imported appears in the Data Wrangler flow.

By default, Data Wrangler saves the connection settings as a new connection. When you import your data, the query that you've already specified appears as a new connection. The saved connections store information about the Athena workgroups and Amazon S3 buckets that you’re using. When you're connecting to the data source again, you can choose the saved connection.
Managing query results

Data Wrangler supports using Athena workgroups to manage the query results within an AWS account. You can specify an Amazon S3 output location for each workgroup. You can also specify whether the output of the query can go to different Amazon S3 locations. For more information, see Using Workgroups to Control Query Access and Costs.

Your workgroup might be configured to enforce the Amazon S3 query output location. You can't change the output location of the query results for those workgroups.

If you don't use a workgroup or specify an output location for your queries, Data Wrangler uses the default Amazon S3 bucket in the same AWS Region in which your Studio instance is located to store Athena query results. It creates temporary tables in this database to move the query output to this Amazon S3 bucket. It deletes these tables after data has been imported; however the database, sagemaker_data_wrangler, persists. To learn more, see Imported Data Storage (p. 1226).

To use Athena workgroups, set up the IAM policy that gives access to workgroups. If you're using a SageMaker-Execution-Role, we recommend adding the policy to the role. For more information about IAM policies for workgroups, see IAM policies for accessing workgroups. For example workgroup policies, see Workgroup example policies.

Setting data retention periods

Data Wrangler automatically sets a data retention period for the query results. The results are deleted after the length of the retention period. For example, the default retention period is five days. The results of the query are deleted after five days. This configuration is designed to help you clean up data that you're no longer using. Cleaning up your data prevents unauthorized users from gaining access. It also helps control the costs of storing your data on Amazon S3.

If you don't set a retention period, the Amazon S3 lifecycle configuration determines the duration that the objects are stored. The data retention policy that you've specified for the lifecycle configuration removes any query results that are older than the lifecycle configuration that you've specified. For more information, see Setting lifecycle configuration on a bucket.

Data Wrangler uses Amazon S3 lifecycle configurations to manage data retention and expiration. You must give your Amazon SageMaker Studio IAM execution role permissions to manage bucket lifecycle configurations. Use the following procedure to give permissions.

To give permissions to manage the lifecycle configuration do the following.

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. Choose Roles.
3. In the search bar, specify the Amazon SageMaker execution role that Amazon SageMaker Studio is using.
4. Choose the role.
5. Choose Add permissions.
6. Choose Create inline policy.
7. For Service, specify S3 and choose it.
8. Under the Read section, choose GetLifecycleConfiguration.
9. Under the Write section, choose PutLifecycleConfiguration.
10. For Resources, choose Specific.
11. For Actions, select the arrow icon next to Permissions management.
13. For **Resources**, choose **Specific**.
14. Choose the checkbox next to **Any in this account**.
15. Choose **Review policy**.
16. For **Name**, specify a name.
17. Choose **Create policy**.

### Import data from Amazon Redshift

Amazon Redshift is a fully managed, petabyte-scale data warehouse service in the cloud. The first step to create a data warehouse is to launch a set of nodes, called an Amazon Redshift cluster. After you provision your cluster, you can upload your dataset and then perform data analysis queries.

You can connect to and query one or more Amazon Redshift clusters in Data Wrangler. To use this import option, you must create at least one cluster in Amazon Redshift. To learn how, see [Getting started with Amazon Redshift](#).

You can output the results of your Amazon Redshift query in one of the following locations:
- The default Amazon S3 bucket
- An Amazon S3 output location that you specify

You can either import the entire dataset or sample a portion of it. For Amazon Redshift, it provides the following sampling options:
- None – Import the entire dataset.
- First K – Sample the first K rows of the dataset, where K is an integer that you specify.
- Randomized – Takes a random sample of a size that you specify.
- Stratified – Takes a stratified random sample. A stratified sample preserves the ratio of values in a column.

The default Amazon S3 bucket is in the same AWS Region in which your Studio instance is located to store Amazon Redshift query results. For more information, see [Imported Data Storage](#).

For either the default Amazon S3 bucket or the bucket that you specify, you have the following encryption options:
- The default AWS service-side encryption with an Amazon S3 managed key (SSE-S3)
- An AWS Key Management Service (AWS KMS) key that you specify

An AWS KMS key is an encryption key that you create and manage. For more information on KMS keys, see [AWS Key Management Service](#).

You can specify an AWS KMS key using either the key ARN or the ARN of your AWS account.

If you use the IAM managed policy, `AmazonSageMakerFullAccess`, to grant a role permission to use Data Wrangler in Studio, your **Database User** name must have the prefix `sagemaker_access`.

Use the following procedures to learn how to add a new cluster.

**Note**

Data Wrangler uses the Amazon Redshift Data API with temporary credentials. To learn more about this API, refer to [Using the Amazon Redshift Data API](#) in the Amazon Redshift Management Guide.
To connect to a Amazon Redshift cluster

1. Sign into Amazon SageMaker Console.
2. Choose Studio.
3. Choose Launch app.
4. From the dropdown list, select Studio.
5. Choose the Home icon.
6. Choose Data.
7. Choose Data Wrangler.
8. Choose Import data.
10. Choose Amazon Redshift.
11. Choose Temporary credentials (IAM) for Type.
12. Enter a Connection Name. This is a name used by Data Wrangler to identify this connection.
13. Enter the Cluster Identifier to specify to which cluster you want to connect. Note: Enter only the cluster identifier and not the full endpoint of the Amazon Redshift cluster.
14. Enter the Database Name of the database to which you want to connect.
15. Enter a Database User to identify the user you want to use to connect to the database.
16. For UNLOAD IAM Role, enter the IAM role ARN of the role that the Amazon Redshift cluster should assume to move and write data to Amazon S3. For more information about this role, see Authorizing Amazon Redshift to access other AWS services on your behalf in the Amazon Redshift Management Guide.
17. Choose Connect.
18. (Optional) For Amazon S3 output location, specify the S3 URI to store the query results.
19. (Optional) For KMS key ID, specify the ARN of the AWS KMS key or alias. The following image shows you where you can find either key in the AWS Management Console.
General configuration

Alias

Alias name

ARN

arn:aws:kms:

Key policy

Cryptographic configuration

Aliases (1)
The following image shows all the fields from the preceding procedure.

![Add Amazon Redshift connection](image)

After your connection is successfully established, it appears as a data source under **Data Import**. Select this data source to query your database and import data.

**To query and import data from Amazon Redshift**

1. Select the connection that you want to query from **Data Sources**.
2. Select a **Schema**. To learn more about Amazon Redshift Schemas, see [Schemas](#) in the Amazon Redshift Database Developer Guide.
3. (Optional) Under **Advanced configuration**, specify the **Sampling** method that you'd like to use.
4. Enter your query in the query editor and choose **Run** to run the query. After a successful query, you can preview your result under the editor.
5. Select **Import dataset** to import the dataset that has been queried.
6. Enter a **Dataset name**. If you add a **Dataset name** that contains spaces, these spaces are replaced with underscores when your dataset is imported.
7. Choose **Add**.

To edit a dataset, do the following.
1. Navigate to your Data Wrangler flow.
2. Choose the + next to Source - Sampled.
3. Change the data that you're importing.
4. Choose Apply

**Import data from Amazon EMR**

You can use Amazon EMR as a data source for your Amazon SageMaker Data Wrangler flow. Amazon EMR is a managed cluster platform that you can use to process and analyze large amounts of data. For more information about Amazon EMR, see [What is Amazon EMR?](#). To import a dataset from EMR, you connect to it and query it.

**Important**
You must meet the following prerequisites to connect to an Amazon EMR cluster:

**Prerequisites**

- **Network configurations**
  - You have an Amazon VPC in the Region that you're using to launch Amazon SageMaker Studio and Amazon EMR.
  - Both Amazon EMR and Amazon SageMaker Studio must be launched in private subnets. They can be in the same subnet or in different ones.
  - Amazon SageMaker Studio must be in VPC-only mode.

  For more information about creating a VPC, see [Create a VPC](#).

  For more information about creating a VPC, see [Connect SageMaker Studio Notebooks in a VPC to External Resources](#).

  - The Amazon EMR clusters that you're running must be in the same Amazon VPC.
  - The Amazon EMR clusters and the Amazon VPC must be in the same AWS account.
  - Your Amazon EMR clusters are running Hive or Presto.
  - Hive clusters must allow inbound traffic from Studio security groups on port 10000.
  - Presto clusters must allow inbound traffic from Studio security groups on port 8889.

  **Note**
  The port number is different for Amazon EMR clusters using IAM roles. Navigate to the end of the prerequisites section for more information.

- **SageMaker Studio**
  - Amazon SageMaker Studio must run Jupyter Lab Version 3. For information about updating the Jupyter Lab Version, see [View and update the JupyterLab version of an application from the console](p. 217).
  - Amazon SageMaker Studio has an IAM role that controls user access. The default IAM role that you're using to run Amazon SageMaker Studio doesn't have policies that can give you access to Amazon EMR clusters. You must attach the policy granting permissions to the IAM role. For more information, see [Configure the discoverability of Amazon EMR clusters (for administrators)](p. 1378).
  - The IAM role must also have the following policy attached: `secretsmanager:PutResourcePolicy`.
  - If you're using a Studio domain that you've already created, make sure that its `AppNetworkAccessType` is in VPC-only mode. For information about updating a domain to use VPC-only mode, see [Shut down and Update SageMaker Studio](p. 292).
• **Amazon EMR clusters**
  - You must have Hive or Presto installed on your cluster.
  - The Amazon EMR release must be version 5.5.0 or later.

  **Note**
  Amazon EMR supports auto termination. Auto termination stops idle clusters from running and prevents you from incurring costs. The following are the releases that support auto termination:
  - For 6.x releases, version 6.1.0 or later.
  - For 5.x releases, version 5.30.0 or later.

• **Amazon EMR clusters using IAM runtime roles**
  - Use the following pages to set up IAM runtime roles for the Amazon EMR cluster. You must enable in-transit encryption when you're using runtime roles:
    - Prerequisites for launching an Amazon EMR cluster with a runtime role
    - Launch an Amazon EMR cluster with role-based access control
  - You must Lake Formation as a governance tool for the data within your databases. You must also use external data filtering for access control.
    - For more information about Lake Formation, see [What is AWS Lake Formation?](#)
    - For more information about integrating Lake Formation into Amazon EMR, see [Integrating third-party services with Lake Formation](#).
  - The version of your cluster must be 6.9.0 or later.
  - Access to AWS Secrets Manager. For more information about Secrets Manager see [What is AWS Secrets Manager?](#).
  - Hive clusters must allow inbound traffic from Studio security groups on port 10000.

An Amazon VPC is a virtual network that is logically isolated from other networks on the AWS cloud. Amazon SageMaker Studio and your Amazon EMR cluster only exist within the Amazon VPC.

Use the following procedure to launch Amazon SageMaker Studio in an Amazon VPC.

To launch Studio within a VPC, do the following.

2. Choose Launch SageMaker Studio.
3. Choose Standard setup.
4. For Default execution role, choose the IAM role to set up Studio.
5. Choose the VPC where you've launched the Amazon EMR clusters.
6. For Subnet, choose a private subnet.
7. For Security group(s), specify the security groups that you're using to control between your VPC.
9. (Optional) AWS uses a default encryption key. You can specify an AWS Key Management Service key to encrypt your data.
10. Choose Next.
11. Under Studio settings, choose the configurations that are best suited to you.
12. Choose Next to skip the SageMaker Canvas settings.
13. Choose Next to skip the RStudio settings.

If you don’t have an Amazon EMR cluster ready, you can use the following procedure to create one. For more information about Amazon EMR, see [What is Amazon EMR?](#)
To create a cluster, do the following.
1. Navigate to the AWS Management Console.
2. In the search bar, specify Amazon EMR.
3. Choose Create cluster.
4. For Cluster name, specify the name of your cluster.
5. For Release, select the release version of the cluster.

   **Note**
   Amazon EMR supports auto termination for the following releases:
   - For 6.x releases, releases 6.1.0 or later
   - For 5.x releases, releases 5.30.0 or later

   Auto termination stops idle clusters from running and prevents you from incurring costs.
6. (Optional) For Applications, choose Presto.
7. Choose the application that you're running on the cluster.
8. Under Networking, for Hardware configuration, specify the hardware configuration settings.

   **Important**
   For Networking, choose the VPC that is running Amazon SageMaker Studio and choose a private subnet.
9. Under Security and access, specify the security settings.
10. Choose Create.

For a tutorial about creating an Amazon EMR cluster, see Getting started with Amazon EMR. For information about best practices for configuring a cluster, see Considerations and best practices.

   **Note**
   For security best practices, Data Wrangler can only connect to VPCs on private subnets. You can't connect to the master node unless you use AWS Systems Manager for your Amazon EMR instances. For more information, see Securing access to EMR clusters using AWS Systems Manager.

You can currently use the following methods to access an Amazon EMR cluster:
- No authentication
- Lightweight Directory Access Protocol (LDAP)
- IAM (Runtime role)

Not using authentication or using LDAP can require you to create multiple clusters and Amazon EC2 instance profiles. If you're an administrator, you might need to provide groups of users with different levels of access to the data. These methods can result in administrative overhead that makes it more difficult to manage your users.

We recommend using an IAM runtime role that gives multiple users the ability to connect to the same Amazon EMR cluster. A runtime role is an IAM role that you can assign to a user who is connecting to an Amazon EMR cluster. You can configure the runtime IAM role to have permissions that are specific to each group of users.

Use the following sections to create a Presto or Hive Amazon EMR cluster with LDAP activated.
Presto

**Important**
To use AWS Glue as a metastore for Presto tables, select **Use for Presto table metadata** to store the results of your Amazon EMR queries in a AWS Glue data catalog when you're launching an EMR cluster. Storing the query results in a AWS Glue data catalog can save you from incurring charges.

To query large datasets on Amazon EMR clusters, you must add the following properties to the Presto configuration file on your Amazon EMR clusters:

```json
["classification":"presto-config","properties":{
  "http-server.max-request-header-size":"5MB",
  "http-server.max-response-header-size":"5MB"}]
```

You can also modify the configuration settings when you launch the Amazon EMR cluster. The configuration file for your Amazon EMR cluster is located under the following path: `/etc/presto/conf/config.properties`.

Use the following procedure to create a Presto cluster with LDAP activated.

To create a cluster, do the following.

1. Navigate to the AWS Management Console.
2. In the search bar, specify **Amazon EMR**.
3. Choose **Create cluster**.
4. For **Cluster name**, specify the name of your cluster.
5. For **Release**, select the release version of the cluster.

   **Note**
   Amazon EMR supports auto termination for the following releases:
   - For 6.x releases, releases 6.1.0 or later
   - For 5.x releases, releases 5.30.0 or later

   Auto termination stops idle clusters from running and prevent you from incurring costs.
6. Choose the application that you're running on the cluster.
7. Under **Networking**, for **Hardware configuration**, specify the hardware configuration settings.

   **Important**
   For **Networking**, choose the VPC that is running Amazon SageMaker Studio and choose a private subnet.
8. Under **Security and access**, specify the security settings.
9. Choose **Create**.

Hive

**Important**
To use AWS Glue as a metastore for Hive tables, select **Use for Hive table metadata** to store the results of your Amazon EMR queries in a AWS Glue data catalog when you're launching an EMR cluster. Storing the query results in a AWS Glue data catalog can save you from incurring charges.

To be able to query large datasets on Amazon EMR clusters, add the following properties to Hive configuration file on your Amazon EMR clusters:
You can also modify the configuration settings when you launch the Amazon EMR cluster. The configuration file for your Amazon EMR cluster is located under the following path: / etc/hive/conf/hive-site.xml. You can specify the following property and restart the cluster:

```
<property>
    <name>hive.resultset.use.unique.column.names</name>
    <value>false</value>
</property>
```

Use the following procedure to create a Hive cluster with LDAP activated.

To create a Hive cluster with LDAP activated, do the following.

1. Navigate to the AWS Management Console.
2. In the search bar, specify Amazon EMR.
3. Choose Create cluster.
4. Choose Go to advanced options.
5. For Release, select an Amazon EMR release version.
6. The Hive configuration option is selected by default. Make sure the Hive option has a checkbox next to it.
7. (Optional) You can also select Presto as a configuration option to activate both Hive and Presto on your cluster.
8. (Optional) Select Use for Hive table metadata to store the results of your Amazon EMR queries in a AWS Glue data catalog. Storing the query results in a AWS Glue catalog can save you from incurring charges. For more information, see Using the AWS Glue Data Catalog as the metastore for Hive.

   **Note**
   Storing the query results in a data catalog requires Amazon EMR version 5.8.0 or later.
9. Under Enter configuration, specify the following JSON:

```
[
  {
    "classification": "hive-site",
    "properties": {
      "hive.server2.authentication.ldap.baseDN": "dc=example,dc=org",
      "hive.server2.authentication": "LDAP",
      "hive.server2.authentication.ldap.url": "ldap://ldap-server-dns-name:389"
    }
  }
]
```

**Note**
As a security best practice, we recommend enabling SSL for HiveServer by adding a few properties in the preceding hive-site JSON. For more information, see Enable SSL on HiveServer2.
10. Specify the remaining cluster settings and create a cluster.

Use the following sections to use LDAP authentication for Amazon EMR clusters that you’ve already created.

LDAP for Presto

Using LDAP on a cluster running Presto requires access to the Presto coordinator through HTTPS. Do the following to provide access:

- Activate access on port 636
- Enable SSL for the Presto coordinator

Use the following template to configure Presto:

```
- Classification: presto-config
  ConfigurationProperties:
  http-server.authentication.type: 'PASSWORD'
  http-server.https.enabled: 'true'
  http-server.https.port: '8899'
  http-server.http.port: '8899'
  node-scheduler.include-coordinator: 'true'
  http-server.https.keystore.path: '/path/to/keystore/path/for/presto'
  http-server.https.keystore.key: 'keystore-key-password'
  discovery.uri: 'http://master-node-dns-name:8899'
- Classification: presto-password-authenticator
  ConfigurationProperties:
  password-authenticator.name: 'ldap'
  ldap.url: !Sub 'ldaps://ldap-server-dns-name:636'
  ldap.user-bind-pattern: "uid=${USER},dc=example,dc=org"
  internal-communication.authentication.ldap.user: "ldap-user-name"
  internal-communication.authentication.ldap.password: "ldap-password"
```

For information about setting up LDAP in Presto, see the following resources:

- [LDAP Authentication](#)
- [Using LDAP Authentication for Presto on Amazon EMR](#)

**Note**
As a security best practice, we recommend enabling SSL for Presto. For more information, see [Secure Internal Communication](#).

LDAP for Hive

To use LDAP for Hive for a cluster that you've created, use the following procedure [Reconfigure an instance group in the console](#).

You're specifying the name of the cluster to which you're connecting.
Use the following procedure to import data from a cluster.

To import data from a cluster, do the following.

1. Open a Data Wrangler flow.
2. Choose Create Connection.
3. Choose Amazon EMR.
4. Do one of the following.
   - (Optional) For Secrets ARN, specify the Amazon Resource Number (ARN) of the database within the cluster. Secrets provide additional security. For more information about secrets, see What is AWS Secrets Manager? For information about creating a secret for your cluster, see Creating a AWS Secrets Manager secret for your cluster (p. 1196).
     
     **Important**
     You must specify a secret if you're using an IAM runtime role for authentication.

   - From the dropdown table, choose a cluster.
5. Choose Next.
6. For Select an endpoint for example-cluster-name cluster, choose a query engine.
7. (Optional) Select Save connection.
8. Choose Next, select login and choose one of the following:
   - No authentication
   - LDAP
   - IAM
9. For Login into example-cluster-name cluster, specify the Username and Password for the cluster.
10. Choose Connect.
11. In the query editor specify a SQL query.
13. Choose Import.

**Creating a AWS Secrets Manager secret for your cluster**

If you're using an IAM runtime role to access your Amazon EMR cluster, you must store the credentials that you're using to access the Amazon EMR as a Secrets Manager secret. You store all the credentials that you use to access the cluster within the secret.

You must store the following information in the secret:

- JDBC endpoint – jdbc:hive2://
- DNS name – The DNS name of your Amazon EMR cluster. It's either the endpoint for the primary node or the hostname.
- Port – 8446

You can also store the following additional information within the secret:
• IAM role – The IAM role that you’re using to access the cluster. Data Wrangler uses your SageMaker execution role by default.

• Truststore path – By default, Data Wrangler creates a truststore path for you. You can also use your own truststore path. For more information about truststore paths, see In-transit encryption in HiveServer2.

• Truststore password – By default, Data Wrangler creates a truststore password for you. You can also use your own truststore path. For more information about truststore paths, see In-transit encryption in HiveServer2.

Use the following procedure to store the credentials within a Secrets Manager secret.

To store your credentials as a secret, do the following.

1. Navigate to the AWS Management Console.
2. In the search bar, specify Secrets Manager.
3. Choose AWS Secrets Manager.
4. Choose Store a new secret.
5. For Secret type, choose Other type of secret.
6. Under Key/value pairs, select Plaintext.
7. For clusters running Hive, you can use the following template for IAM authentication.

```json
{"jdbcURL": "",
"iam_auth": {
"endpoint": "jdbc:hive2://", #required
"dns": "ip-xx-xxx-xxx-xxx.ec2.internal", #required
"port": "10000", #required
"cluster_id": "j-xxxxxxxx", #required
"iam_role": "arn:aws:iam::xxxxxxxx:role/xxxxxxxxxxxx", #optional
"truststore_path": "/etc/alternatives/jre/lib/security/cacerts",
#optional
"truststore_password": "changeit" #optional
}
```

Note
After you import your data, you apply transformations to them. You then export the data that you’ve transformed to a specific location. If you’re using a Jupyter notebook to export your transformed data to Amazon S3, you must use the truststore path specified in the preceding example.

A Secrets Manager secret stores the JDBC URL of the Amazon EMR cluster as a secret. Using a secret is more secure than directly entering in your credentials.

Use the following procedure to store the JDBC URL as a secret.

To store the JDBC URL as a secret, do the following.

1. Navigate to the AWS Management Console.
2. In the search bar, specify Secrets Manager.
3. Choose AWS Secrets Manager.
4. Choose Store a new secret.
5. For Secret type, choose Other type of secret.
6. **For Key/value pairs**, specify `jdbcURL` as the key and a valid JDBC URL as the value.

The format of a valid JDBC URL depends on whether you use authentication and whether you use Hive or Presto as the query engine. The following list shows the valid JDBC URL formats for the different possible configurations.

- For Hive with SSL enabled, the JDBC URL format depends on whether you use a Java Keystore File for the TLS configuration. The Java Keystore File helps verify the identity of the master node of the Amazon EMR cluster. To use a Java Key Store File, generate it on an EMR cluster and upload it to Data Wrangler. To generate a file, use the following command on the Amazon EMR cluster, `keytool -genkey -alias hive -keyalg RSA -keystore hive.jks`. For information about running commands on an Amazon EMR cluster, see [Securing access to EMR clusters using AWS Systems Manager](#). To upload a file, choose the upward arrow on the left-hand navigation of the Data Wrangler UI.

The following are the valid JDBC URL formats for Hive with SSL enabled:

- Without a Java Keystore File – `jdbc:hive2://emr-cluster-master-public-dns:10000/;AuthMech=3;UID=user-name;PWD=password;SSL=1;AllowSelfSignedCerts=1;`
- With a Java Keystore File – `jdbc:hive2://emr-cluster-master-public-dns:10000/;AuthMech=3;UID=user-name;PWD=password;SSL=1;SSLKeyStore=/home/sagemaker-user/data/Java-keystore-file-name;SSLKeyStorePwd=Java-keystore-file-password;`

- For Presto with LDAP authentication and SSL enabled, the JDBC URL format depends on whether you use a Java Keystore File for the TLS configuration. The Java Keystore File helps verify the identity of the master node of the Amazon EMR cluster. To use a Java Key Store File, generate it on an EMR cluster and upload it to Data Wrangler. To upload a file, choose the upward arrow on the left-hand navigation of the Data Wrangler UI. For information about creating a Java Key Store File for Presto, see [Java Key Store File for TLS](#). For information about running commands on an Amazon EMR cluster, see [Securing access to EMR clusters using AWS Systems Manager](#).

- Without a Java Keystore File – `jdbc:presto://emr-cluster-master-public-dns:8889/;SSL=1;AuthenticationType=LDAP Authentication;UID=user-name;PWD=password;AllowSelfSignedServerCert=1;AllowHostNameCNMismatch=1;`
- With a Java Keystore File – `jdbc:presto://emr-cluster-master-public-dns:8889/;SSL=1;AuthenticationType=LDAP Authentication;SSLTrustStorePath=/home/sagemaker-user/data/Java-keystore-file-name;SSLTrustStorePwd=Java-keystore-file-password;UID=user-name;PWD=password;`

Throughout the process of importing data from an Amazon EMR cluster, you might run into issues. For information about troubleshooting them, see [Troubleshooting issues with Amazon EMR (p. 1355)](#).

**Import data from Databricks (JDBC)**

You can use Databricks as a data source for your Amazon SageMaker Data Wrangler flow. To import a dataset from Databricks, use the JDBC (Java Database Connectivity) import functionality to access to your Databricks database. After you access the database, specify a SQL query to get the data and import it.

We assume that you have a running Databricks cluster and that you've configured your JDBC driver to it. For more information, see the following Databricks documentation pages:
• **JDBC driver**
• **JDBC configuration and connection parameters**
• **Authentication parameters**

Data Wrangler stores your JDBC URL in AWS Secrets Manager. You must give your Amazon SageMaker Studio IAM execution role permissions to use Secrets Manager. Use the following procedure to give permissions.

To give permissions to Secrets Manager, do the following.

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. Choose **Roles**.
3. In the search bar, specify the Amazon SageMaker execution role that Amazon SageMaker Studio is using.
4. Choose the role.
5. Choose **Add permissions**.
6. Choose **Create inline policy**.
7. For **Service**, specify **Secrets Manager** and choose it.
8. For **Actions**, select the arrow icon next to **Permissions management**.
9. Choose **PutResourcePolicy**.
10. For **Resources**, choose **Specific**.
11. Choose the checkbox next to **Any in this account**.
12. Choose **Review policy**.
13. For **Name**, specify a name.
14. Choose **Create policy**.

You can use partitions to import your data more quickly. Partitions give Data Wrangler the ability to process the data in parallel. By default, Data Wrangler uses 2 partitions. For most use cases, 2 partitions give you near-optimal data processing speeds.

If you choose to specify more than 2 partitions, you can also specify a column to partition the data. The type of the values in the column must be numeric or date.

We recommend using partitions only if you understand the structure of the data and how it's processed.

You can either import the entire dataset or sample a portion of it. For a Databricks database, it provides the following sampling options:

• None – Import the entire dataset.
• First K – Sample the first K rows of the dataset, where K is an integer that you specify.
• Randomized – Takes a random sample of a size that you specify.
• Stratified – Takes a stratified random sample. A stratified sample preserves the ratio of values in a column.

Use the following procedure to import your data from a Databricks database.

To import data from Databricks, do the following.

1. Sign into [Amazon SageMaker Console](https://console.aws.amazon.com/).  
2. Choose **Studio**.
3. Choose **Launch app**.
4. From the dropdown list, select **Studio**.
5. From the **Import data** tab of your Data Wrangler flow, choose **Databricks**.
6. Specify the following fields:
   - **Dataset name** – A name that you want to use for the dataset in your Data Wrangler flow.
   - **Driver** – `com.simba.spark.jdbc.Driver`.
   - **JDBC URL** – The URL of the Databricks database. The URL formatting can vary between Databricks instances. For information about finding the URL and the specifying the parameters within it, see [JDBC configuration and connection parameters](#). The following is an example of how a URL can be formatted: `jdbc:spark://aws-sagemaker-datawrangler.cloud.databricks.com:443/default;transportMode=http;httpPath=sql/protocolv1/o/3122619508517275/0909-200301-cut318;AuthMech=3;UID=token;PWD=personal-access-token`.

   **Note**
   You can specify a secret ARN that contains the JDBC URL instead of specifying the JDBC URL itself. The secret must contain a key-value pair with the following format: `jdbcURL:JDBC-URL`. For more information, see [What is Secrets Manager?](#).

7. Specify a SQL SELECT statement.

   **Note**
   Data Wrangler doesn't support Common Table Expressions (CTE) or temporary tables within a query.

8. For **Sampling**, choose a sampling method.
9. Choose **Run**.
10. (Optional) For the **PREVIEW**, choose the gear to open the **Partition settings**. The gear for the additional settings is located to the far right of the **PREVIEW** title.

   - Specify the number of partitions. You can partition by column if you specify the number of partitions:
     - **Enter number of partitions** – Specify a value greater than 2.
     - (Optional) **Partition by column** – Specify the following fields. You can only partition by a column if you've specified a value for **Enter number of partitions**.
       - **Select column** – Select the column that you're using for the data partition. The data type of the column must be numeric or date.
       - **Upper bound** – From the values in the column that you've specified, the upper bound is the value that you're using in the partition. The value that you specify doesn't change the data that you're importing. It only affects the speed of the import. For the best performance, specify an upper bound that's close to the column's maximum.
       - **Lower bound** – From the values in the column that you've specified, the lower bound is the value that you're using in the partition. The value that you specify doesn't change the data that you're importing. It only affects the speed of the import. For the best performance, specify a lower bound that's close to the column's minimum.

11. Choose **Import**.

### Import data from Salesforce Data Cloud

You can use Salesforce Data Cloud as a data source in Amazon SageMaker Data Wrangler to prepare the data in your Salesforce Data Cloud for machine learning.

With Salesforce Data Cloud as a data source in Data Wrangler, you can quickly connect to your Salesforce data without writing a single line of code. You can join your Salesforce data with data from any other data source in Data Wrangler.
After you connect to the data cloud, you can do the following:

- Visualize your data with built-in visualizations
- Understand data and identify potential errors and extreme values
- Transform data with more than 300 built-in transformations
- Export the data that you've transformed

**Topics**

- Administrator setup (p. 1201)
- Data Scientist Guide (p. 1206)

**Administrator setup**

**Important**

Before you get started, make sure that your users are running Amazon SageMaker Studio version 1.3.0 or later. For information about checking the version of Studio and updating it, see Prepare ML Data with Amazon SageMaker Data Wrangler (p. 1167).

When you're setting up access to Salesforce Data Cloud, you must complete the following tasks:

- Getting your Salesforce Domain URL. Salesforce also refers to the Domain URL as your org's URL.
- Getting OAuth credentials from Salesforce.
- Getting the authorization URL and token URL for your Salesforce Domain.
- Creating a AWS Secrets Manager secret with the OAuth configuration.
- Creating a lifecycle configuration that Data Wrangler uses to read the credentials from the secret.
- Giving Data Wrangler permissions to read the secret.

After you perform the preceding tasks, your users can log into the Salesforce Data Cloud using OAuth.

**Note**

Your users might run into issues after you've set everything up. For information about troubleshooting, see Troubleshooting with Salesforce (p. 1356).

Use the following procedure to get the Domain URL.

1. Navigate to the Salesforce login page.
2. For Quick find, specify My Domain.
3. Copy the value of Current My Domain URL to a text file.
4. Add https:// to the beginning of the URL.

After you get the Salesforce Domain URL, you can use the following procedure to get the login credentials from Salesforce and allow Data Wrangler to access your Salesforce data.

To get the login credentials from Salesforce and provide access to Data Wrangler, do the following.

1. Navigate to your Salesforce Domain URL and log into your account.
2. Choose the gear icon.
3. In the search bar that appears, specify App Manager.
5. Specify the following fields:
- Connected App Name – You can specify any name, but we recommend choosing a name that includes Data Wrangler. For example, you can specify Salesforce Data Cloud Data Wrangler Integration.
- API name – Use the default value.
- Contact Email – Specify your email address.
- Under API heading (Enable OAuth Settings), select the checkbox to activate OAuth settings.
- For Callback URL specify the Amazon SageMaker Studio URL. To get the URL for Studio, access it from the AWS Management Console and copy the URL.

6. Under Selected OAuth Scopes, move the following from the Available OAuth Scopes to Selected OAuth Scopes:
   - Manage user data via APIs (api)
   - Perform requests at any time (refresh_token, offline_access)
   - Perform ANSI SQL queries on Salesforce Data Cloud data (cdp_query_api)
   - Manage Salesforce Customer Data Platform profile data (cdp_profile_api)

7. Choose Save. After you save your changes, Salesforce opens a new page.

8. Choose Continue

10. Choose Manage Consumer Details. Salesforce redirects you to a new page where you might have to pass two-factor authentication.

11. Important
    - Copy the Consumer Key and Consumer Secret to a text editor. You need this information to connect the data cloud to Data Wrangler.

13. Navigate to Connected App Name and the name of your application.

14. Choose Manage.
   a. Select Edit Policies.
   b. Change IP Relaxation to Relax IP restrictions.
   c. Choose Save.

After you provide access to your Salesforce Data Cloud, you need to provide permissions for your users. Use the following procedure to provide them with permissions.

To provide your users with permissions, do the following.

1. Navigate to the setup home page.
2. On the left-hand navigation, search for Users and choose the Users menu item.
3. Choose the hyperlink with your user name.
4. Navigate to Permission Set Assignments.
5. Choose Edit Assignments.
6. Add the following permissions:
   - Customer Data Platform Admin
   - Customer Data Platform Data Aware Specialist

7. Choose Save.

After you get the information for your Salesforce Domain, you must get the authorization URL and the token URL for the AWS Secrets Manager secret that you’re creating.
Use the following procedure to get the authorization URL and the token URL.

**To get the authorization URL and token URL**

1. Navigate to your Salesforce Domain URL.
2. Use one of the following methods to get the URLs. If you are on a Linux distribution with curl and jq installed, we recommend using the method that only works on Linux.
   - (Linux only) Specify the following command in your terminal.
     ```shell
     curl salesforce-domain-URL/.well-known/openid-configuration | \n     jq '. | { authorization_url: .authorization_endpoint, token_url: .token_endpoint }' | \n     jq ". += { identity_provider: "SALESFORCE", client_id: "example-client-id", client_secret: "example-client-secret" }
     ```
   - b. Copy the authorization_endpoint and token_endpoint to a text editor.
   - c. Create the following JSON object:
     ```json
     {
       "identity_provider": "SALESFORCE",
       "authorization_url": "example-authorization-endpoint",
       "token_url": "example-token-endpoint",
       "client_id": "example-consumer-key",
       "client_secret": "example-consumer-secret"
     }
     ```

After you create the OAuth configuration object, you can create a AWS Secrets Manager secret that stores it. Use the following procedure to create the secret.

To create a secret, do the following.

1. Navigate to the AWS Secrets Manager console.
2. Choose Store a secret.
3. Select Other type of secret.
4. Under Key/value pairs select Plaintext.
5. Replace the empty JSON with the following configuration settings.
   ```json
   {
     "identity_provider": "SALESFORCE",
     "authorization_url": "example-authorization-endpoint",
     "token_url": "example-token-endpoint",
     "client_id": "example-consumer-key",
     "client_secret": "example-consumer-secret"
   }
   ```
6. Choose Next.
7. For Secret Name, specify the name of the secret.
8. Under Tags, choose Add.
• For the Key, specify sagemaker:partner. For Value, we recommend specifying a value that might be useful for your use case. However, you can specify anything.

Important
You must create the key. You can't import your data from Salesforce if you don't create it.

9. Choose Next.
10. Choose Store.
11. Choose the secret you've created.
12. Make a note of the following fields:

• The Amazon Resource Number (ARN) of the secret
• The name of the secret

After you've created the secret, you must add permissions for Data Wrangler to read the secret. Use the following procedure to add permissions.

To add read permissions for Data Wrangler, do the following.

1. Navigate to the Amazon SageMaker console.
2. Choose Domains.
3. Choose the domain that you're using to access Data Wrangler.
4. Choose your User Profile.
5. Under Details, find the Execution role. Its ARN is in the following format: arn:aws:iam::111122223333:role/example-role. Make a note of the SageMaker execution role. Within the ARN, it's everything after role/.
6. Navigate to the IAM console.
7. In the Search IAM search bar, specify the name of the SageMaker execution role.
8. Choose the role.
9. Choose Add permissions.
10. Choose Create inline policy.
11. Choose the JSON tab.
12. Specify the following policy within the editor:

```json
{
"Version": "2012-10-17",
"Statement": [
{
"Effect": "Allow",
"Action": [
"secretsmanager:GetSecretValue",
"secretsmanager:PutSecretValue"
],
"Resource": "arn:aws:secretsmanager:*:*:secret:*",
"Condition": {
"ForAnyValue:StringLike": {
"aws:ResourceTag/sagemaker:partner": "*
}
}
},
{
"Effect": "Allow",
"Action": [
"sts:AssumeRole"  
]  
}
]
```  

After you've given Data Wrangler permissions to read the secret, you must add a Lifecycle Configuration that uses your Secrets Manager secret to your Amazon SageMaker Studio user profile.

Use the following procedure to create a lifecycle configuration and add it to the Studio profile.

To create a lifecycle configuration and add it to the Studio profile, do the following.

1. Navigate to the Amazon SageMaker console.
2. Choose Domains.
3. Choose the domain that you're using to access Data Wrangler.
4. Choose your User Profile.
5. If you see the following applications, delete them:
   - KernelGateway
   - JupyterKernel

   **Note**
   Deleting the applications updates Studio. It can take a while for the updates to happen.

6. While you're waiting for updates to happen, choose Lifecycle configurations.
7. Make sure the page you're on says Studio Lifecycle configurations.
8. Choose Create configuration.
9. Make sure Jupyter server app has been selected.
10. Choose Next.
11. For Name, specify a name for the configuration.
12. For Scripts, specify the following script:

```bash
#!/bin/bash
set -eux

cat > ~/.sfgenie_identity_provider_oauth_config <<EOL
{
  "secret_arn": "secrets-arn-containing-salesforce-credentials"
}
EOL
```

13. Choose Submit.
14. On the left hand navigation, choose Domains.
15. Choose your Domain.
16. Choose **Environment**.
17. Under **Lifecycle configurations for personal Studio apps**, choose **Attach**.
18. Select **Existing configuration**.
19. Under **Studio Lifecycle configurations** select the lifecycle configuration that you've created.
20. Choose **Attach to domain**.
21. Select the checkbox next to the lifecycle configuration that you've attached.
22. Select **Set as default**.

You might run into issues when you set up your lifecycle configuration. For information about debugging them, see **Debug lifecycle configurations** (p. 280).

### Data Scientist Guide

Use the following to connect Salesforce Data Cloud and access your data in Data Wrangler.

**Important**
Your administrator needs to use the information in the preceding sections to set up Salesforce Data Cloud. If you're running into issues, contact them for troubleshooting help.

To open Studio and check its version, see the following procedure.

1. Use the steps in **Prerequisites** (p. 1169) to access Data Wrangler through Amazon SageMaker Studio.
2. Next to the user you want to use to launch Studio, select **Launch app**.
3. Choose **Studio**.

**To create a dataset in Data Wrangler with data from the Salesforce Data Cloud**

1. Sign into **Amazon SageMaker Console**.
2. Choose **Studio**.
3. Choose **Launch app**.
4. From the dropdown list, select **Studio**.
5. Choose the Home icon.
6. Choose **Data**.
7. Choose **Data Wrangler**.
8. Choose **Import data**.
9. Under **Available**, choose **Salesforce Data Cloud**.
10. For **Connection name**, specify a name for your connection to the Salesforce Data Cloud.
11. For **Org URL**, specify the organization URL in your Salesforce account. You can get the URL from your administrator.s
12. Choose **Connect**.
13. Specify your credentials to log into Salesforce.

You can begin creating a dataset using data from Salesforce Data Cloud after you've connected to it.

After you select a table, you can write queries and run them. The output of your query shows under **Query results**.

After you have settled on the output of your query, you can then import the output of your query into a Data Wrangler flow to perform data transformations.
After you've created a dataset, navigate to the Data flow screen to start transforming your data.

**Import data from Snowflake**

You can use Snowflake as a data source in SageMaker Data Wrangler to prepare data in Snowflake for machine learning.

With Snowflake as a data source in Data Wrangler, you can quickly connect to Snowflake without writing a single line of code. You can join your data in Snowflake with data from any other data source in Data Wrangler.

Once connected, you can interactively query data stored in Snowflake, transform data with more than 300 preconfigured data transformations, understand data and identify potential errors and extreme values with a set of robust preconfigured visualization templates, quickly identify inconsistencies in your data preparation workflow, and diagnose issues before models are deployed into production. Finally, you can export your data preparation workflow to Amazon S3 for use with other SageMaker features such as Amazon SageMaker Autopilot, Amazon SageMaker Feature Store and Amazon SageMaker Model Building Pipelines.

You can encrypt the output of your queries using an AWS Key Management Service key that you've created. For more information about AWS KMS, see [AWS Key Management Service](#).

**Topics**

- Administrator Guide (p. 1207)
- Data Scientist Guide (p. 1220)

**Administrator Guide**

**Important**

To learn more about granular access control and best practices, see [Security Access Control](#).

This section is for Snowflake administrators who are setting up access to Snowflake from within SageMaker Data Wrangler.

**Important**

You are responsible for managing and monitoring the access control within Snowflake. Data Wrangler does not add a layer of access control with respect to Snowflake. Access control includes the following:

- The data that a user accesses
- (Optional) The storage integration that provides Snowflake the ability to write query results to an Amazon S3 bucket
- The queries that a user can run

(Optional) Configure Snowflake Data Import Permissions

By default, Data Wrangler queries the data in Snowflake without creating a copy of it in an Amazon S3 location. Use the following information if you're configuring a storage integration with Snowflake. Your users can use a storage integration to store their query results in an Amazon S3 location.

Your users might have different levels of access of sensitive data. For optimal data security, provide each user with their own storage integration. Each storage integration should have its own data governance policy.

This feature is currently not available in the opt-in Regions.
Snowflake requires the following permissions on an S3 bucket and directory to be able to access files in the directory:

- s3:GetObject
- s3:GetObjectVersion
- s3:ListBucket
- s3:ListObjects
- s3:GetBucketLocation

### Create an IAM policy

You must create an IAM policy to configure access permissions for Snowflake to load and unload data from an Amazon S3 bucket.

The following is the JSON policy document that you use to create the policy:

```json
# Example policy for S3 write access
# This needs to be updated
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:PutObject",
        "s3:GetObject",
        "s3:GetObjectVersion",
        "s3:DeleteObject",
        "s3:DeleteObjectVersion"
      ],
      "Resource": "arn:aws:s3:::bucket/prefix/*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:ListBucket"
      ],
      "Resource": "arn:aws:s3:::bucket/",
      "Condition": {
        "StringLike": {
          "s3:prefix": ["prefix/*"]
        }
      }
    }
  ]
}
```

For information and procedures about creating policies with policy documents, see [Creating IAM policies](#).

For documentation that provides an overview of using IAM permissions with Snowflake, see the following resources:

- [What is IAM?](#)
- [Create the IAM Role in AWS](#)
- [Create a Cloud Storage Integration in Snowflake](#)
- [Retrieve the AWS IAM User for your Snowflake Account](#)
- [Grant the IAM User Permissions to Access Bucket](#)
To grant the data scientist's Snowflake role usage permission to the storage integration, you must run
GRANT USAGE ON INTEGRATION integration_name TO snowflake_role;

- integration_name is the name of your storage integration.
- snowflake_role is the name of the default Snowflake role given to the data scientist user.

**Setting up Snowflake OAuth Access**

Instead of having your users directly enter their credentials into Data Wrangler, you can have them use an identity provider to access Snowflake. The following are links to the Snowflake documentation for the identity providers that Data Wrangler supports.

- Azure AD
- Okta
- Ping Federate

Use the documentation from the preceding links to set up access to your identity provider. The information and procedures in this section help you understand how to properly use the documentation to access Snowflake within Data Wrangler.

Your identity provider needs to recognize Data Wrangler as an application. Use the following procedure to register Data Wrangler as an application within the identity provider:

1. Select the configuration that starts the process of registering Data Wrangler as an application.
2. Provide the users within the identity provider access to Data Wrangler.
3. Turn on OAuth client authentication by storing the client credentials as an AWS Secrets Manager secret.
4. Specify a redirect URL using the following format: https://Domain-ID.studio.AWS Region.sagemaker.aws/jupyter/default/lab

   **Important**
   You're specifying the Amazon SageMaker Domain ID and AWS Region that you're using to run Data Wrangler.

   **Important**
   You must register a URL for each Amazon SageMaker Domain and AWS Region where you're running Data Wrangler. Users from a Domain and AWS Region that don't have redirect URLs set up for them won't be able to authenticate with the identity provider to access the Snowflake connection.

5. Make sure that the authorization code and refresh token grant types are allowed for the Data Wrangler application.

Within your identity provider, you must set up a server that sends OAuth tokens to Data Wrangler at the user level. The server sends the tokens with Snowflake as the audience.

Snowflake uses the concept of roles that are distinct role the IAM roles used in AWS. You must configure the identity provider to use any role to use the default role associated with the Snowflake account. For example, if a user has systems administrator as the default role in their Snowflake profile, the connection from Data Wrangler to Snowflake uses systems administrator as the role.

Use the following procedure to set up the server.

To set up the server, do the following. You're working within Snowflake for all steps except the last one.

1. Start setting up the server or API.
2. Configure the authorization server to use the authorization code and refresh token grant types.
3. Specify the lifetime of the access token.
4. Set the refresh token idle timeout. The idle timeout is the time that the refresh token expires if it's not used.
   
   **Note**
   
   If you’re scheduling jobs in Data Wrangler, we recommend making the idle timeout time greater than the frequency of the processing job. Otherwise, some processing jobs might fail because the refresh token expired before they could run. When the refresh token expires, the user must re-authenticate by accessing the connection that they've made to Snowflake through Data Wrangler.

5. Specify `session:role-any` as the new scope.
   
   **Note**
   
   For Azure AD, copy the unique identifier for the scope. Data Wrangler requires you to provide it with the identifier.

6. **Important**
   
   Within the External OAuth Security Integration for Snowflake, enable `external_oauth_any_role_mode`.

   **Important**
   
   Data Wrangler doesn’t support rotating refresh tokens. Using rotating refresh tokens might result in access failures or users needing to log in frequently.

   **Important**
   
   If the refresh token expires, your users must reauthenticate by accessing the connection that they've made to Snowflake through Data Wrangler.

After you've set up the OAuth provider, you provide Data Wrangler with the information it needs to connect to the provider. You can use the documentation from your identity provider to get values for the following fields:

- **Token URL** – The URL of the token that the identity provider sends to Data Wrangler.
- **Authorization URL** – The URL of the authorization server of the identity provider.
- **Client ID** – The ID of the identity provider.
- **Client secret** – The secret that only the authorization server or API recognizes.
- (Azure AD only) The OAuth scope credentials that you've copied.

You store the fields and values in a AWS Secrets Manager secret and add it to the Amazon SageMaker Studio lifecycle configuration that you're using for Data Wrangler. A Lifecycle Configuration is a shell script. Use it to make the Amazon Resource Name (ARN) of the secret accessible to Data Wrangler. For information about creating secrets see [Move hardcoded secrets to AWS Secrets Manager](#). For information about using lifecycle configurations in Studio, see [Use lifecycle configurations with Amazon SageMaker Studio](#).

**Important**

Before you create a Secrets Manager secret, make sure that the SageMaker execution role that you're using for Amazon SageMaker Studio has permissions to create and update secrets in Secrets Manager. For more information about adding permissions, see [Example: Permission to create secrets](#).

For Okta and Ping Federate, the following is the format of the secret:

```json
{
}
```
For Azure AD, the following is the format of the secret:

```
{
  "token_url": "https://identityprovider.com/oauth2/example-portion-of-URL-path/v2/token",
  "client_id": "example-client-id",
  "client_secret": "example-client-secret",
  "identity_provider": "AZURE_AD",
  "authorization_url": "https://identityprovider.com/oauth2/example-portion-of-URL-path/v2/authorize",
  "datasource_oauth_scope": "api://appuri/session:role-any"
}
```

You must have a lifecycle configuration that uses the Secrets Manager secret that you've created. You can either create the lifecycle configuration or modify one that has already been created. The configuration must use the following script.

```
#!/bin/bash
set -eux
## Script Body
  cat > ~/.snowflake_identity_provider_oauth_config <<EOL
  {
    "secret_arn": "example-secret-arn"
  }
EOL
```

For information about setting up lifecycle configurations, see Create and associate a lifecycle configuration (p. 271). When you're going through the process of setting up, do the following:

- Set the application type of the configuration to Jupyter Server.
- Attach the configuration to the Amazon SageMaker Domain that has your users.
- Have the configuration run by default. It must run every time a user logs into Studio. Otherwise, the credentials saved in the configuration won't be available to your users when they're using Data Wrangler.
- The lifecycle configuration creates a file with the name, `snowflake_identity_provider_oauth_config` in the user's home folder. The file contains the Secrets Manager secret. Make sure that it's in the user's home folder every time the Jupyter Server's instance is initialized.

Private Connectivity between Data Wrangler and Snowflake via AWS PrivateLink

This section explains how to use AWS PrivateLink to establish a private connection between Data Wrangler and Snowflake. The steps are explained in the following sections.
Create a VPC

If you do not have a VPC set up, then follow the Create a new VPC instructions to create one.

Once you have a chosen VPC you would like to use for establishing a private connection, provide the following credentials to your Snowflake Administrator to enable AWS PrivateLink:

- VPC ID
- AWS Account ID
- Your corresponding account URL you use to access Snowflake

Important
As described in Snowflake's documentation, enabling your Snowflake account can take up to two business days.

Set up Snowflake AWS PrivateLink Integration

After AWS PrivateLink is activated, retrieve the AWS PrivateLink configuration for your Region by running the following command in a Snowflake worksheet. Log into your Snowflake console and enter the following under Worksheets: select SYSTEM$GET_PRIVATELINK_CONFIG();

1. Retrieve the values for the following: privatelink-account-name, privatelink_ocsp-url, privatelink-account-url, and privatelink_ocsp-url from the resulting JSON object. Examples of each value are shown in the following snippet. Store these values for later use.

   privatelink-account-name: xxxxxxxx.region.privatelink
   privatelink-vpce-id: com.amazonaws.vpce.region.vpce-svc-xxxxxxxxxxxxxxxx
   privatelink-account-url: xxxxxxxx.region.privatelink.snowflakecomputing.com
   privatelink_ocsp-url: ocsp.xxxxxxxx.region.privatelink.snowflakecomputing.com

2. Switch to your AWS Console and navigate to the VPC menu.
3. From the left side panel, choose the Endpoints link to navigate to the VPC Endpoints setup.

   Once there, choose Create Endpoint.
4. Select the radio button for Find service by name, as shown in the following screenshot.

   Create Endpoint

   A VPC endpoint enables you to securely connect your VPC to another service.
   There are three types of VPC endpoints: Interface endpoints, Gateway Load Balancer endpoints, and gateway endpoints.
   Interface endpoints and Gateway Load Balancer endpoints are powered by AWS PrivateLink, and use an elastic network interface (ENI) as an entry point for traffic destined to the service.
   Interface endpoints are typically accessed using the public or private DNS name associated with the service, while gateway endpoints and Gateway Load Balancer endpoints serve as a target for a route in your route table for traffic destined for the service.

   Service category
   - AWS services
     - Find service by name
     - Your AWS Marketplace services

   Service Name
   Enter private service name and verify. 1
   e.g. com.privateexample.us-east-1

   Verify

5. In the Service Name field, paste in the value for privatelink-vpce-id that you retrieved in the preceding step and choose Verify.

   If the connection is successful, a green alert saying Service name found appears on your screen and the VPC and Subnet options automatically expand, as shown in the following screenshot. Depending on your targeted Region, your resulting screen may show another AWS Region name.
6. Select the same VPC ID that you sent to Snowflake from the VPC dropdown list.

7. If you have not yet created a subnet, then perform the following set of instructions on creating a subnet.

8. Select Subnets from the VPC dropdown list. Then select Create subnet and follow the prompts to create a subnet in your VPC. Ensure you select the VPC ID you have used in previous steps.

10. Provide a name for the new security group (such as datawrangler-doc-snowflake-privatelink-connection) and a description. Be sure to select the VPC ID you have used in previous steps.

11. Add two rules to allow traffic from within your VPC to this VPC endpoint. Navigate to your VPC under Your VPCs in a separate tab, and retrieve your CIDR block for your VPC. Then choose Add Rule in the Inbound Rules section. Select HTTPS for the type, leave the Source as Custom in the form, and paste in the value retrieved from the preceding describe-vpcs call (such as 10.0.0.0/16).

12. Choose Create Security Group. Retrieve the Security Group ID from the newly created security group (such as sg-xxxxxxxxxxxxxxxxx).

13. In the VPC Endpoint configuration screen, remove the default security group. Paste in the security group ID in the search field and select the checkbox.

15. If the endpoint creation is successful, you see a page that has a link to your VPC endpoint configuration, specified by the VPC ID. Select the link to view the configuration in full.
Retrieve the topmost record in the DNS names list. This can be differentiated from other DNS names because it only includes the Region name (such as `us-west-2`), and no Availability Zone letter notation (such as `us-west-2a`). Store this information for later use.

**Configure DNS for Snowflake Endpoints in your VPC**

This section explains how to configure DNS for Snowflake endpoints in your VPC. This allows your VPC to resolve requests to the Snowflake AWS PrivateLink endpoint.

1. Navigate to the Route 53 menu within your AWS console.
2. Select the Hosted Zones option (if necessary, expand the left-hand menu to find this option).
3. Choose Create Hosted Zone.
   a. In the Domain name field, reference the value that was stored for `privatelink-account-url` in the preceding steps. In this field, your Snowflake account ID is removed from the DNS name and only uses the value starting with the Region identifier. A Resource Record Set is also created later for the subdomain, such as, `region.privatelink.snowflakecomputing.com`.
   b. Select the radio button for Private Hosted Zone in the Type section. Your Region code may not be `us-west-2`. Reference the DNS name returned to you by Snowflake.

---

**Create hosted zone info**

**Hosted zone configuration**

A hosted zone is a container that holds information about how you want to route traffic for a domain, such as example.com, and its subdomains.

**Domain name info**

This is the name of the domain that you want to route traffic for.

```
us-west-2.privatelink.snowflakecomputing.com
```

Valid characters: a-z, 0-9, . - \* % & \* () + \* , - / ; : = > ? @ [ \{ ] \} \- \-

**Description - optional info**

This value lets you distinguish hosted zones that have the same name.

Private Hosted Zone that allows access to Snowflake via PrivateLink

The description can have up to 256 characters. 67/256

**Type info**

The type indicates whether you want to route traffic on the Internet or in an Amazon VPC.

- **Public hosted zone**
  A public hosted zone determines how traffic is routed on the Internet.

- **Private hosted zone**
  A private hosted zone determines how traffic is routed within an Amazon VPC.
c. In the **VPCs to associate with the hosted zone** section, select the Region in which your VPC is located and the VPC ID used in previous steps.

![VPCs to associate with the hosted zone](image)

For each VPC that you associate with a private hosted zone, you must set the Amazon VPC settings `enableDNSHostnames` and `enableDNSSupport` to `true`.

**Region**  
US West (Oregon) [us-west-2]  
VPC ID  
Search `vpc-XXXXXXXXXX`  
Remove VPC  
Add VPC

![Create hosted zone](image)

d. Choose **Create hosted zone**.

4. Next, create two records, one for `privatelink-account-url` and one for `privatelink_ocsp-url`.

   - In the **Hosted Zone** menu, choose **Create Record Set**.
     
     a. Under **Record name**, enter your Snowflake Account ID only (the first 8 characters in `privatelink-account-url`).
     
     b. Under **Record type**, select **CNAME**.
     
     c. Under **Value**, enter the DNS name for the regional VPC endpoint you retrieved in the last step of the **Set up the Snowflake AWS PrivateLink Integration** section.

![Create record](image)

d. Choose **Create records**.

   e. Repeat the preceding steps for the OCSP record we notated as `privatelink_ocsp-url`, starting with `ocsp` through the 8-character Snowflake ID for the record name (such as `ocsp.xxxxxxxx`).
Configure Route 53 Resolver Inbound Endpoint for your VPC

This section explains how to configure Route 53 resolvers inbound endpoints for your VPC.

1. Navigate to the Route 53 menu within your AWS console.
   - In the left hand panel in the Security section, select the Security Groups option.

   - Provide a name for your security group (such as datawranger-doc-route53-resolver-sg) and a description.
   - Select the VPC ID used in previous steps.
   - Create rules that allow for DNS over UDP and TCP from within the VPC CIDR block.
     - Choose Create Security Group. Note the Security Group ID because adds a rule to allow traffic to the VPC endpoint security group.

3. Navigate to the Route 53 menu within your AWS console.
   - In the Resolver section, select the Inbound Endpoint option.

4. Choose Create Inbound Endpoint.
   - Provide an endpoint name.
   - From the VPC in the Region dropdown list, select the VPC ID you have used in all previous steps.
   - In the Security group for this endpoint dropdown list, select the security group ID from Step 2 in this section.
In the IP Address section, select an Availability Zones, select a subnet, and leave the radio selector for Use an IP address that is selected automatically selected for each IP address.

Choose Submit.
5. Select the **Inbound endpoint** after it has been created.
6. Once the inbound endpoint is created, note the two IP addresses for the resolvers.

<table>
<thead>
<tr>
<th>IP addresses [2]</th>
<th>Remove from endpoint</th>
<th>Add IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP address</td>
<td>IP address ID</td>
<td>Status</td>
</tr>
<tr>
<td>10.0.1.0/25</td>
<td></td>
<td>Attached</td>
</tr>
<tr>
<td>10.0.1.0/25</td>
<td></td>
<td>Attached</td>
</tr>
</tbody>
</table>

**SageMaker VPC Endpoints**

This section explains how to create VPC endpoints for the following: Amazon SageMaker Studio, SageMaker Notebooks, the SageMaker API, SageMaker Runtime Runtime, and Amazon SageMaker Feature Store Runtime.

**Create a security group that is applied to all endpoints.**

1. Navigate to the [EC2 menu](#) in the AWS Console.
2. In the **Network & Security** section, select the **Security groups** option.
3. Choose **Create security group**.
4. Provide a security group name and description (such as `datawrangler-doc-sagemaker-vgpce-sg`). A rule is added later to allow traffic over HTTPS from SageMaker to this group.

**Creating the endpoints**

1. Navigate to the [VPC menu](#) in the AWS console.
2. Select the **Endpoints** option.
3. Choose **Create Endpoint**.
4. Search for the service by entering its name in the **Search** field.
5. From the **VPC** dropdown list, select the VPC in which your Snowflake AWS PrivateLink connection exists.
6. In the **Subnets** section, select the subnets which have access to the Snowflake PrivateLink connection.
7. Leave the **Enable DNS Name** checkbox selected.
8. In the **Security Groups** section, select the security group you created in the preceding section.
9. Choose **Create Endpoint**.

**Configure Studio and Data Wrangler**

This section explains how to configure Studio and Data Wrangler.

1. Configure the security group.
   a. Navigate to the Amazon EC2 menu in the AWS Console.
   b. Select the **Security Groups** option in the **Network & Security** section.
   c. Choose **Create Security Group**.
   d. Provide a name and description for your security group (such as `datawrangler-doc-sagemaker-studio`).
   e. Create the following inbound rules.
      - The HTTPS connection to the security group you provisioned for the Snowflake PrivateLink connection you created in the [Set up the Snowflake PrivateLink Integration](#) step.
- The HTTP connection to the security group you provisioned for the Snowflake PrivateLink connection you created in the *Set up the Snowflake PrivateLink Integration step*.
- The UDP and TCP for DNS (port 53) to Route 53 Resolver Inbound Endpoint security group you create in step 2 of *Configure Route 53 Resolver Inbound Endpoint for your VPC*.

f. Choose **Create Security Group** button in the lower right hand corner.

2. Configure Studio.
   - Navigate to the SageMaker menu in the AWS console.
   - From the left hand console, Select the **SageMaker Studio** option.
   - If you do not have any domains configured, the **Get Started** menu is present.
   - Select the **Standard Setup** option from the **Get Started** menu.
   - Under **Authentication method**, select **AWS Identity and Access Management (IAM)**.
     - From the **Permissions** menu, you can create a new role or use a pre-existing role, depending on your use case.
     - If you choose **Create a new role**, you are presented the option to provide an S3 bucket name, and a policy is generated for you.
     - If you already have a role created with permissions for the S3 buckets to which you require access, select the role from the dropdown list. This role should have the **AmazonSageMakerFullAccess** policy attached to it.
   - Select the **Network and Storage** dropdown list to configure the VPC, security, and subnets SageMaker uses.
     - Under **VPC**, select the VPC in which your Snowflake PrivateLink connection exists.
     - Under **Subnet(s)**, select the subnets which have access to the Snowflake PrivateLink connection.
     - Under **Network Access for Studio**, select **VPC Only**.
     - Under **Security Group(s)**, select the security group you created in step 1.
   - Choose **Submit**.

3. Edit the SageMaker security group.
   - Create the following inbound rules:
     - Port 2049 to the inbound and outbound NFS Security Groups created automatically by SageMaker in step 2 (the security group names contain the Studio domain ID).
     - Access to all TCP ports to itself (required for SageMaker for VPC Only).

4. Edit the VPC Endpoint Security Groups:
   - Navigate to the Amazon EC2 menu in the AWS console.
   - Locate the security group you created in a preceding step.
   - Add an inbound rule allowing for HTTPS traffic from the security group created in step 1.

5. Create a user profile.
   - From the **SageMaker Studio Control Panel**, choose **Add User**.
     - Provide a user name.
     - For the **Execution Role**, choose to create a new role or to use a pre-existing role.
       - If you choose **Create a new role**, you are presented the option to provide an Amazon S3 bucket name, and a policy is generated for you.
       - If you already have a role created with permissions to the Amazon S3 buckets to which you require access, select the role from the dropdown list. This role should have the **AmazonSageMakerFullAccess** policy attached to it.
   - Choose **Submit**.

6. Create a data flow (follow the data scientist guide outlined in a preceding section).
   - When adding a Snowflake connection, enter the value of `privatelink-account-name` (from the *Set up Snowflake PrivateLink Integration* step) into the **Snowflake account name (alphanumeric)** field, instead of the plain Snowflake account name. Everything else is left unchanged.
Provide information to the data scientist

Provide the data scientist with the information that they need to access Snowflake from Amazon SageMaker Data Wrangler.

**Important**
Your users need to run Amazon SageMaker Studio version 1.3.0 or later. For information about checking the version of Studio and updating it, see [Prepare ML Data with Amazon SageMaker Data Wrangler](p. 1167).

1. To allow your data scientist to access Snowflake from SageMaker Data Wrangler, provide them with one of the following:
   - For Basic Authentication, a Snowflake account name, user name, and password.
   - For OAuth, a user name and password in the identity provider.
   - For ARN, the Secrets Manager secret Amazon Resource Name (ARN).
   - A secret created with [AWS Secrets Manager](https://aws.amazon.com/secretsmanager) and the ARN of the secret. Use the following procedure below to create the secret for Snowflake if you choose this option.

      **Important**
      If your data scientists use the Snowflake Credentials (User name and Password) option to connect to Snowflake, you can use [Secrets Manager](https://aws.amazon.com/secretsmanager) to store the credentials in a secret. Secrets Manager rotates secrets as part of a best practice security plan. The secret created in Secrets Manager is only accessible with the Studio role configured when you set up a Studio user profile. This requires you to add this permission, `secretsmanager:PutResourcePolicy`, to the policy that is attached to your Studio role.

      We strongly recommend that you scope the role policy to use different roles for different groups of Studio users. You can add additional resource-based permissions for the Secrets Manager secrets. See [Manage Secret Policy](https://docs.aws.amazon.com/secretsmanager/latest/userguide/manage-policies.html) for condition keys you can use.
      For information about creating a secret, see [Create a secret](https://aws.amazon.com/secretsmanager). You're charged for the secrets that you create.

2. (Optional) Provide the data scientist with the name of the storage integration that you created using the following procedure [Create a Cloud Storage Integration in Snowflake](https://docs.snowflake.com/en/user-guide/storage-integrations-add_aws.html). This is the name of the new integration and is called `integration_name` in the `CREATE INTEGRATION` SQL command you ran, which is shown in the following snippet:

```
CREATE STORAGE INTEGRATION integration_name
TYPE = EXTERNAL_STAGE
STORAGE_PROVIDER = S3
ENABLED = TRUE
STORAGE_AWS_ROLE_ARN = 'iam_role'
STORAGE_AWS_OBJECT_ACL = 'bucket-owner-full-control'
STORAGE_ALLOWED_LOCATIONS = ('s3://bucket/path/', 's3://bucket/path/')
STORAGE_BLOCKED_LOCATIONS = ('s3://bucket/path/', 's3://bucket/path/')
```

**Data Scientist Guide**

Use the following to connect Snowflake and access your data in Data Wrangler.

**Important**
Your administrator needs to use the information in the preceding sections to set up Snowflake. If you're running into issues, contact them for troubleshooting help.

You can connect to Snowflake in one of the following ways:

- Specifying your Snowflake credentials (account name, user name, and password) in Data Wrangler.
• Providing an Amazon Resource Name (ARN) of a secret containing the credentials.
• Using an open standard for access delegation (OAuth) provider that connects to Snowflake. Your administrator can give you access to one of the following OAuth providers:
  • Azure AD
  • Okta
  • Ping Federate

Talk to your administrator about the method that you need to use to connect to Snowflake.

The following sections have information about how you can connect to Snowflake using the preceding methods.

Specifying your Snowflake Credentials

**To import a dataset into Data Wrangler from Snowflake using your credentials**

1. Sign into [Amazon SageMaker Console](https).
2. Choose Studio.
3. Choose Launch app.
4. From the dropdown list, select Studio.
5. Choose the Home icon.
6. Choose Data.
7. Choose Data Wrangler.
8. Choose Import data.
10. For *Connection name*, specify a name that uniquely identifies the connection.
11. For *Authentication method*, choose Basic Username-Password.
12. For *Snowflake account name (alphanumeric)*, specify the full name of the Snowflake account.
13. For *Username*, specify the username that you use to access the Snowflake account.
14. For *Password*, specify the password associated with the username.
15. (Optional) For *Advanced settings*, specify the following:
   - **Role** – A role within Snowflake. Some roles have access to different datasets. If you don’t specify a role, Data Wrangler uses the default role in your Snowflake account.
   - **Storage integration** – When you specify and run a query, Data Wrangler creates a temporary copy of the query results in memory. To store a permanent copy of the query results, specify the Amazon S3 location for the storage integration. Your administrator provided you with the S3 URI.
   - **KMS key ID** – A KMS key that you’ve created. You can specify its ARN to encrypt the output of the Snowflake query. Otherwise, Data Wrangler uses the default encryption.
16. Choose Connect.

Providing an Amazon Resource Name (ARN)

**To import a dataset into Data Wrangler from Snowflake using an ARN**

1. Sign into [Amazon SageMaker Console](https).
2. Choose Studio.
3. Choose Launch app.
4. From the dropdown list, select Studio.
5. Choose the Home icon.
6. Choose Data.
7. Choose Data Wrangler.
8. Choose Import data.
10. For Connection name, specify a name that uniquely identifies the connection.
11. For Authentication method, choose ARN.
12. Secrets Manager ARN – The ARN of the AWS Secrets Manager secret used to store the credentials used to connect to Snowflake.
13. (Optional) For Advanced settings, specify the following:
   - Role – A role within Snowflake. Some roles have access to different datasets. If you don’t specify a role, Data Wrangler uses the default role in your Snowflake account.
   - Storage integration – When you specify and run a query, Data Wrangler creates a temporary copy of the query results in memory. To store a permanent copy of the query results, specify the Amazon S3 location for the storage integration. Your administrator provided you with the S3 URI.
   - KMS key ID – A KMS key that you’ve created. You can specify its ARN to encrypt the output of the Snowflake query. Otherwise, Data Wrangler uses the default encryption.

Using an OAuth Connection

**Important**
Your administrator customized your Studio environment to provide the functionality you’re using to use an OAuth connection. You might need to restart the Jupyter server application to use the functionality.
Use the following procedure to update the Jupyter server application.

1. Within Studio, choose File
2. Choose Shut down.
3. Choose Shut down server.
4. Close the tab or window that you’re using to access Studio.
5. From the Amazon SageMaker console, open Studio.

To import a dataset into Data Wrangler from Snowflake using your credentials

1. Sign into Amazon SageMaker Console.
2. Choose Studio.
3. Choose Launch app.
4. From the dropdown list, select Studio.
5. Choose the Home icon.
6. Choose Data.
7. Choose Data Wrangler.
8. Choose Import data.
10. For Connection name, specify a name that uniquely identifies the connection.
11. For Authentication method, choose OAuth.
12. (Optional) For Advanced settings, specify the following:
• **Role** – A role within Snowflake. Some roles have access to different datasets. If you don’t specify a role, Data Wrangler uses the default role in your Snowflake account.

• **Storage integration** – When you specify and run a query, Data Wrangler creates a temporary copy of the query results in memory. To store a permanent copy of the query results, specify the Amazon S3 location for the storage integration. Your administrator provided you with the S3 URI.

• **KMS key ID** – A KMS key that you’ve created. You can specify its ARN to encrypt the output of the Snowflake query. Otherwise, Data Wrangler uses the default encryption.

13. **Choose Connect.**

You can begin the process of importing your data from Snowflake after you’ve connected to it.

Within Data Wrangler, you can view your data warehouses, databases, and schemas, along with the eye icon with which you can preview your table. After you select the **Preview Table** icon, the schema preview of that table is generated. You must select a warehouse before you can preview a table.

**Important**
If you're importing a dataset with columns of type `TIMESTAMP_TZ` or `TIMESTAMP_LTZ`, add `::string` to the column names of your query. For more information, see [How To: Unload TIMESTAMP_TZ and TIMESTAMP_LTZ data to a Parquet file](#).

After you select a data warehouse, database and schema, you can now write queries and run them. The output of your query shows under **Query results**.

After you have settled on the output of your query, you can then import the output of your query into a Data Wrangler flow to perform data transformations.

After you've imported your data, navigate to your Data Wrangler flow and start adding transformations to it. For a list of available transforms, see [Transform Data](#).

### Import Data From Software as a Service (SaaS) Platforms

You can use Data Wrangler to import data from more than forty software as a service (SaaS) platforms. To import your data from your SaaS platform, you or your administrator must use Amazon AppFlow to transfer the data from the platform to Amazon S3 or Amazon Redshift. For more information about Amazon AppFlow, see [What is Amazon AppFlow?](#) If you don't need to use Amazon Redshift, we recommend transferring the data to Amazon S3 for a simpler process.

Data Wrangler supports transferring data from the following SaaS platforms:

• **Amplitude**
• **Asana**
• **Braintree**
• **CircleCI**
• **DocuSign Monitor**
• **Delighted**
• **Domo**
• **Datadog**
• **Dynatrace**
• **Facebook Ads**
• **Facebook Page Insights**
• **Google Ads**
• Google Analytics 4
• Google Calendar
• Google Search Console
• GitHub
• GitLab
• Infor Nexus
• Instagram Ads
• Intercom
• JDBC (Sync)
• Jira Cloud
• LinkedIn Ads
• Mailchimp
• Marketo
• Microsoft Dynamics 365
• Microsoft Teams
• Mixpanel
• Okta
• Oracle HCM
• Paypal Checkout
• Pendo
• Salesforce
• Salesforce Marketing Cloud
• Salesforce Pardot
• SAP OData
• SendGrid
• ServiceNow
• Singular
• Slack
• Smartsheet
• Snapchat Ads
• Stripe
• Trend Micro
• Typeform
• Veeva
• WooCommerce
• Zendesk
• Zendesk Chat
• Zendesk Sell
• Zendesk Sunshine
• Zoho CRM
• Zoom Meetings

The preceding list has links to more information about setting up your data source. You or your administrator can refer to the preceding links after you've read the following information.
When you navigate to the **Import** tab of your Data Wrangler flow, you see data sources under the following sections:

- **Available**
- **Set up data sources**

You can connect to data sources under **Available** without needing additional configuration. You can choose the data source and import your data.

Data sources under **Set up data sources**, require you or your administrator to use Amazon AppFlow to transfer the data from the SaaS platform to Amazon S3 or Amazon Redshift. For information about performing a transfer, see *Using Amazon AppFlow to transfer your data* (p. 1225).

After you perform the data transfer, the SaaS platform appears as a data source under **Available**. You can choose it and import the data that you've transferred into Data Wrangler. The data that you've transferred appears as tables that you can query.

### Using Amazon AppFlow to transfer your data

Amazon AppFlow is a platform that you can use to transfer data from your SaaS platform to Amazon S3 or Amazon Redshift without having to write any code. To perform a data transfer, you use the AWS Management Console.

**Important**

You must make sure you've set up the permissions to perform a data transfer. For more information, see *Amazon AppFlow Permissions (p. 1346)*.

After you've added permissions, you can transfer the data. Within Amazon AppFlow, you create a **flow** to transfer the data. A flow is a series of configurations. You can use it to specify whether you're running the data transfer on a schedule or whether you're partitioning the data into separate files. After you've configured the flow, you run it to transfer the data.

For information about creating a flow, see *Creating flows in Amazon AppFlow*. For information about running a flow, see *Activate an Amazon AppFlow flow*.

After the data has been transferred, use the following procedure to access the data in Data Wrangler.

**Important**

Before you try to access your data, make sure your IAM role has the following policy:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "glue:SearchTables",
            "Resource": [
                "arn:aws:glue:*:*:table/*/*",
                "arn:aws:glue:*:*:database/*",
                "arn:aws:glue:*:*:catalog"
            ]
        }
    ]
}
```

By default, the IAM role that you use to access Data Wrangler is the SageMakerExecutionRole. For more information about adding policies, see *Adding IAM identity permissions (console)*.
To connect to a data source, do the following.

1. Sign into Amazon SageMaker Console.
2. Choose Studio.
3. Choose Launch app.
4. From the dropdown list, select Studio.
5. Choose the Home icon.
6. Choose Data.
7. Choose Data Wrangler.
8. Choose Import data.
9. Under Available, choose the data source.
10. For the Name field, specify the name of the connection.
11. (Optional) Choose Advanced configuration.
   a. Choose a Workgroup.
   b. If your workgroup hasn't enforced the Amazon S3 output location or if you don't use a workgroup, specify a value for Amazon S3 location of query results.
   c. (Optional) For Data retention period, select the checkbox to set a data retention period and specify the number of days to store the data before it's deleted.
   d. (Optional) By default, Data Wrangler saves the connection. You can choose to deselect the checkbox and not save the connection.
12. Choose Connect.
13. Specify a query.
   Note
   To help you specify a query, you can choose a table on the left-hand navigation panel. Data Wrangler shows the table name and a preview of the table. Choose the icon next to the table name to copy the name. You can use the table name in the query.
15. Choose Import query.
16. For Dataset name, specify the name of the dataset.
17. Choose Add.

When you navigate to the Import data screen, you can see the connection that you've created. You can use the connection to import more data.

Imported Data Storage

Important
We strongly recommend that you follow the best practices around protecting your Amazon S3 bucket by following Security best practices.

When you query data from Amazon Athena or Amazon Redshift, the queried dataset is automatically stored in Amazon S3. Data is stored in the default SageMaker S3 bucket for the AWS Region in which you are using Studio.

Default S3 buckets have the following naming convention: sagemaker-region-account number. For example, if your account number is 111122223333 and you are using Studio in us-east-1, your imported datasets are stored in sagemaker-us-east-1-111122223333.

Data Wrangler flows depend on this Amazon S3 dataset location, so you should not modify this dataset in Amazon S3 while you are using a dependent flow. If you do modify this S3 location, and you want to continue using your data flow, you must remove all objects in trained_parameters in your .flow file.
To do this, download the .flow file from Studio and for each instance of `trained_parameters`, delete all entries. When you are done, `trained_parameters` should be an empty JSON object:

```json
"trained_parameters": {}
```

When you export and use your data flow to process your data, the .flow file you export refers to this dataset in Amazon S3. Use the following sections to learn more.

**Amazon Redshift Import Storage**

Data Wrangler stores the datasets that result from your query in a Parquet file in your default SageMaker S3 bucket.

This file is stored under the following prefix (directory): `redshift/uuid/data/`, where `uuid` is a unique identifier that gets created for each query.

For example, if your default bucket is `sagemaker-us-east-1-111122223333`, a single dataset queried from Amazon Redshift is located in `s3://sagemaker-us-east-1-111122223333/redshift/uuid/data/`.

**Amazon Athena Import Storage**

When you query an Athena database and import a dataset, Data Wrangler stores the dataset, as well as a subset of that dataset, or preview files, in Amazon S3.

The dataset you import by selecting **Import dataset** is stored in Parquet format in Amazon S3.

Preview files are written in CSV format when you select **Run** on the Athena import screen, and contain up to 100 rows from your queried dataset.

The dataset you query is located under the prefix (directory): `athena/uuid/data/`, where `uuid` is a unique identifier that gets created for each query.

For example, if your default bucket is `sagemaker-us-east-1-111122223333`, a single dataset queried from Athena is located in `s3://sagemaker-us-east-1-111122223333/athena/uuid/data/example_dataset.parquet`.

The subset of the dataset that is stored to preview dataframes in Data Wrangler is stored under the prefix: `athena/`.

**Create and Use a Data Wrangler Flow**

Use an Amazon SageMaker Data Wrangler flow, or a data flow, to create and modify a data preparation pipeline. The data flow connects the datasets, transformations, and analyses, or steps, you create and can be used to define your pipeline.

**Instances**

When you create a Data Wrangler flow in Amazon SageMaker Studio, Data Wrangler uses an Amazon EC2 instance to run the analyses and transformations in your flow. By default, Data Wrangler uses the m5.4xlarge instance. m5 instances are general purpose instances that provide a balance between compute and memory. You can use m5 instances for a variety of compute workloads.

Data Wrangler also gives you the option of using r5 instances. r5 instances are designed to deliver fast performance that processes large datasets in memory.

We recommend that you choose an instance that is best optimized around your workloads. For example, the r5.8xlarge might have a higher price than the m5.4xlarge, but the r5.8xlarge might be better
optimized for your workloads. With better optimized instances, you can run your data flows in less time at lower cost.

The following table shows the instances that you can use to run your Data Wrangler flow.

<table>
<thead>
<tr>
<th>Standard Instances</th>
<th>vCPU</th>
<th>Memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>ml.m5.4xlarge</td>
<td>16</td>
<td>64 GiB</td>
</tr>
<tr>
<td>ml.m5.8xlarge</td>
<td>32</td>
<td>128 GiB</td>
</tr>
<tr>
<td>ml.m5.16xlarge</td>
<td>64</td>
<td>256 GiB</td>
</tr>
<tr>
<td>ml.m5.24xlarge</td>
<td>96</td>
<td>384 GiB</td>
</tr>
<tr>
<td>r5.4xlarge</td>
<td>16</td>
<td>128 GiB</td>
</tr>
<tr>
<td>r5.8xlarge</td>
<td>32</td>
<td>256 GiB</td>
</tr>
<tr>
<td>r5.24xlarge</td>
<td>96</td>
<td>768 GiB</td>
</tr>
</tbody>
</table>

For more information about r5 instances, see Amazon EC2 R5 Instances. For more information about m5 instances, see Amazon EC2 M5 Instances.

Each Data Wrangler flow has an Amazon EC2 instance associated with it. You might have multiple flows that are associated with a single instance.

For each flow file, you can seamlessly switch the instance type. If you switch the instance type, the instance that you used to run the flow continues to run.

To switch the instance type of your flow, do the following.

1. Choose the home icon, 🏡.
2. Navigate to the instance that you're using and choose it.
3. Choose the instance type that you want to use.
4. Choose **Save**.

You are charged for all running instances. To avoid incurring additional charges, shut down the instances that you aren't using manually. To shut down an instance that is running, use the following procedure.

To shut down a running instance.

1. Choose the instance icon. The following image shows you where to select the **RUNNING INSTANCES** icon.

![Image showing the instance icon](image)

2. Choose **Shut down** next to the instance that you want to shut down.

If you shut down an instance used to run a flow, you temporarily can't access the flow. If you get an error while attempting to open the flow running an instance you previously shut down, wait for 5 minutes and try opening it again.

When you export your data flow to a location such as Amazon Simple Storage Service or Amazon SageMaker Feature Store, Data Wrangler runs an Amazon SageMaker processing job. You can use one of the following instances for the processing job. For more information on exporting your data, see **Export** (p. 1311).

<table>
<thead>
<tr>
<th>Standard Instances</th>
<th>vCPU</th>
<th>Memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>ml.m5.4xlarge</td>
<td>16</td>
<td>64 GiB</td>
</tr>
<tr>
<td>ml.m5.12xlarge</td>
<td>48</td>
<td>192 GiB</td>
</tr>
<tr>
<td>ml.m5.24xlarge</td>
<td>96</td>
<td>384 GiB</td>
</tr>
</tbody>
</table>

For more information about the cost per hour for using the available instance types, see [SageMaker Pricing](https://aws.amazon.com/sagemaker/pricing/).

### The Data Flow UI

When you import a dataset, the original dataset appears on the data flow and is named **Source**. If you turned on sampling when you imported your data, this dataset is named **Source - sampled**. Data Wrangler automatically infers the types of each column in your dataset and creates a new dataframe named **Data types**. You can select this frame to update the inferred data types. You see results similar to those shown in the following image after you upload a single dataset:
Each time you add a transform step, you create a new dataframe. When multiple transform steps (other than Join or Concatenate) are added to the same dataset, they are stacked.

Join and Concatenate create standalone steps that contain the new joined or concatenated dataset.

The following diagram shows a data flow with a join between two datasets, as well as two stacks of steps. The first stack (Steps (2)) adds two transforms to the type inferred in the Data types dataset. The downstream stack, or the stack to the right, adds transforms to the dataset resulting from a join named demo-join.

The small, gray box in the bottom right corner of the data flow provides an overview of number of stacks and steps in the flow and the layout of the flow. The lighter box inside the gray box indicates the steps
that are within the UI view. You can use this box to see sections of your data flow that fall outside of the UI view. Use the fit screen icon ( ) to fit all steps and datasets into your UI view.

The bottom left navigation bar includes icons that you can use to zoom in ( ) and out ( ) of your data flow and resize the data flow to fit the screen. Use the lock icon ( ) to lock and unlock the location of each step on the screen.

Add a Step to Your Data Flow

Select + next to any dataset or previously added step and then select one of the following options:

- **Edit data types** (For a Data types step only): If you have not added any transforms to a Data types step, you can select Edit data types to update the data types Data Wrangler inferred when importing your dataset.
- **Add transform**: Adds a new transform step. See Transform Data (p. 1253) to learn more about the data transformations you can add.
- **Add analysis**: Adds an analysis. You can use this option to analyze your data at any point in the data flow. When you add one or more analyses to a step, an analysis icon ( ) appears on that step. See Analyze and Visualize (p. 1296) to learn more about the analyses you can add.
- **Join**: Joins two datasets and adds the resulting dataset to the data flow. To learn more, see Join Datasets (p. 1258).
- **Concatenate**: Concatenates two datasets and adds the resulting dataset to the data flow. To learn more, see Concatenate Datasets (p. 1258).

Delete a Step from Your Data Flow

To delete a step, select the step and select Delete. If the node is a node that has a single input, you delete only the step that you select. Deleting a step that has a single input doesn't delete the steps that
follow it. If you're deleting a step for a source, join, or concatenate node, all the steps that follow it are also deleted.

To delete a step from a stack of steps, select the stack and then select the step you want to delete.

You can use one of the following procedures to delete a step without deleting the downstream steps.

Delete a step in the Data Wrangler flow

You can delete an individual step for nodes in your data flow that have a single input. You can't delete individual steps for source, join, and concatenate nodes.

Use the following procedure to delete a step in the Data Wrangler flow.

1. Choose the group of steps that has the step that you're deleting.
2. Choose the icon next to the step.
3. Choose **Delete step**.
Data flow

Choose the plus sign to add a step to the flow. Select a step to modify.

Source - sampled

S3: titanic-train.csv
Delete a step in the table view

Use the following procedure to delete a step in the table view.

You can delete an individual step for nodes in your data flow that have a single input. You can't delete individual steps for source, join, and concatenate nodes.

1. Choose the step and open the table view for the step.
2. Move your cursor over the step so the ellipsis icon appears.
3. Choose the icon next to the step.
4. Choose Delete.

Edit a Step in Your Data Wrangler Flow

You can edit each step that you've added in your Data Wrangler flow. By editing steps, you can change the transformations or the data types of the columns. You can edit the steps to make changes with which you can perform better analyses.

There are many ways that you can edit a step. Some examples include changing the imputation method or changing the threshold for considering a value to be an outlier.

Use the following procedure to edit a step.

To edit a step, do the following.

1. Choose a step in the Data Wrangler flow to open the table view.
2. Choose a step in the data flow.
3. Edit the step.

The following image shows an example of editing a step.
You can use the shared spaces within your Amazon SageMaker Domain to work collaboratively on your Data Wrangler flows. Within a shared space, you and your collaborators can edit a flow file in real-time. However, neither you nor your collaborators can see the changes in real-time. When anyone makes a change to the Data Wrangler flow, they must save it immediately. When someone saves a file, a collaborator won't be able to see it unless the close the file and reopen.
it. Any changes that aren't saved by one person are overwritten by the person who saved their changes.

Get Insights On Data and Data Quality

Use the Data Quality and Insights Report to perform an analysis of the data that you've imported into Data Wrangler. We recommend that you create the report after you import your dataset. You can use the report to help you clean and process your data. It gives you information such as the number of missing values and the number of outliers. If you have issues with your data, such as target leakage or imbalance, the insights report can bring those issues to your attention.

Use the following procedure to create a Data Quality and Insights report. It assumes that you've already imported a dataset into your Data Wrangler flow.

To create a Data Quality and Insights report
1. Choose a + next to a node in your Data Wrangler flow.
2. Select Get data insights.
3. For Analysis name, specify a name for the insights report.
4. (Optional) For Target column, specify the target column.
5. For Problem type, specify Regression or Classification.
6. For Data size, specify one of the following:
   - 50 K – Uses the first 50000 rows of the dataset that you've imported to create the report.
   - Entire dataset – Uses the entire dataset that you've imported to create the report.

   Note
   Creating a Data Quality and Insights report on the entire dataset uses an Amazon SageMaker processing job. A SageMaker processing job provisions the additional compute resources required to get insights for all of your data. For more information about SageMaker processing jobs, see Process data (p. 1399).

7. Choose Create.

The following topics show the sections of the report:

Topics
- Summary (p. 1240)
- Target column (p. 1242)
- Quick model (p. 1245)
- Feature summary (p. 1247)
- Samples (p. 1249)
- Definitions (p. 1250)

You can either download the report or view it online. To download the report, choose the download button at the top right corner of the screen. The following image shows the button.
Summary

The insights report has a brief summary of the data that includes general information such as missing values, invalid values, feature types, outlier counts, and more. It can also include high severity warnings that point to probable issues with the data. We recommend that you investigate the warnings.

The following is an example of a report summary.
## SUMMARY

### High Priority Warnings

2 high severity warnings were detected. See the list below.

- **Skewed target** - High
  
The target column is skewed and contains outliers. Because the outliers induce low prediction quality for the non-outlier samples. In case you are interested in predicting the extreme values, there is no need for further action. However, if extreme values are not the point of interest, you can handle the outliers under **Handle outliers**.

- **Target leakage** - High
  
The feature `hoa_(BRL)` predicts the target extremely well on its own. A feature that predicts the target very well on its own indicates that the feature may be overfitting or not adding much value to the model. Alternatively, if the machine learning task is "easy", then a single feature can have a lot of power. However, you should not do anything further. However, if you think there's target leakage, we recommend taking steps to address it.
Target column

When you create the data quality and insights report, Data Wrangler gives you the option to select a target column. A target column is a column that you’re trying to predict. When you choose a target column, Data Wrangler automatically creates a target column analysis. It also ranks the features in the order of their predictive power. When you select a target column, you must specify whether you’re trying to solve a regression or a classification problem.

For classification, Data Wrangler shows a table and a histogram of the most common classes. A class is a category. It also presents observations, or rows, with a missing or invalid target value.

The following image shows an example target column analysis for a classification problem.
For regression, Data Wrangler shows a histogram of all the values in the target column. It also presents observations, or rows, with a missing, invalid, or outlier target value.

The following image shows an example target column analysis for a regression problem.
# Target Column

Quick model

The **Quick model** provides an estimate of the expected predicted quality of a model that you train on your data.

Data Wrangler splits your data into training and validation folds. It uses 80% of the samples for training and 20% of the values for validation. For classification, the sample is stratified split. For a stratified split, each data partition has the same ratio of labels. For classification problems, it's important to have the same ratio of labels between the training and classification folds. Data Wrangler trains the XGBoost model with the default hyperparameters. It applies early stopping on the validation data and performs minimal feature preprocessing.

For classification models, Data Wrangler returns both a model summary and a confusion matrix.

The following is an example of a classification model summary. To learn more about the information that it returns, see Definitions (p. 1250).

<table>

</tbody>
</table>

The following is an example of a confusion matrix that the quick model returns.
A confusion matrix gives you the following information:

- The number of times the predicted label matches the true label.
- The number of times the predicted label doesn't match the true label.

The true label represents an actual observation in your data. For example, if you're using a model to detect fraudulent transactions, the true label represents a transaction that is actually fraudulent or non-fraudulent. The predicted label represents the label that your model assigns to the data.

You can use the confusion matrix to see how well the model predicts the presence or the absence of a condition. If you're predicting fraudulent transactions, you can use the confusion matrix to get a sense of both the sensitivity and the specificity of the model. The sensitivity refers to the model's ability to detect fraudulent transactions. The specificity refers to the model's ability to avoid detecting non-fraudulent transactions as fraudulent.

The following is an example of the quick model outputs for a regression problem.
Feature summary

When you specify a target column, Data Wrangler orders the features by their prediction power. Prediction power is measured on the data after it was split into 80% training and 20% validation folds. Data Wrangler fits a model for each feature separately on the training fold. It applies minimal feature preprocessing and measures prediction performance on the validation data.

It normalizes the scores to the range [0,1]. Higher prediction scores indicate columns that are more useful for predicting the target on their own. Lower scores point to columns that aren't predictive of the target column.

It's uncommon for a column that isn't predictive on its own to be predictive when it's used in tandem with other columns. You can confidently use the prediction scores to determine whether a feature in your dataset is predictive.

A low score usually indicates the feature is redundant. A score of 1 implies perfect predictive abilities, which often indicates target leakage. Target leakage usually happens when the dataset contains a column that isn't available at the prediction time. For example, it could be a duplicate of the target column.

The following are examples of the table and the histogram that show the prediction value of each feature.
<table>

Samples

Data Wrangler provides information about whether your samples are anomalous or if there are duplicates in your dataset.

Data Wrangler detects anomalous samples using the isolation forest algorithm. The isolation forest associates an anomaly score with each sample (row) of the dataset. Low anomaly scores indicate anomalous samples. High scores are associated with non-anomalous samples. Samples with a negative anomaly score are usually considered anomalous and samples with positive anomaly score are considered non-anomalous.

When you look at a sample that might be anomalous, we recommend that you pay attention to unusual values. For example, you might have anomalous values that result from errors in gathering and processing the data. The following is an example of the most anomalous samples according to the Data Wrangler’s implementation of the isolation forest algorithm. We recommend using domain knowledge and business logic when you examine the anomalous samples.

Data Wrangler detects duplicate rows and calculates the ratio of duplicate rows in your data. Some data sources could include valid duplicates. Other data sources could have duplicates that point to problems in data collection. Duplicate samples that result from faulty data collection could interfere with machine learning processes that rely on splitting the data into independent training and validation folds.

The following are elements of the insights report that can be impacted by duplicated samples:

• Quick model
• Prediction power estimation
• Automatic hyperparameter tuning

You can remove duplicate samples from the dataset using the Drop duplicates transform under Manage rows. Data Wrangler shows you the most frequently duplicated rows.

Definitions

The following are definitions for the technical terms that are used in the data insights report.

Feature types

The following are the definitions for each of the feature types:

• **Numeric** – Numeric values can be either floats or integers, such as age or income. The machine learning models assume that numeric values are ordered and a distance is defined over them. For example, 3 is closer to 4 than to 10 and 3 < 4 < 10.

• **Categorical** – The column entries belong to a set of unique values, which is usually much smaller than the number of entries in the column. For example, a column of length 100 could contain the unique values Dog, Cat, and Mouse. The values could be numeric, text, or a combination of both. Horse, House, 8, Love, and 3.1 would all be valid values and could be found in the same categorical column. The machine learning model does not assume order or distance on the values of categorical features, as opposed to numeric features, even when all the values are numbers.

• **Binary** – Binary features are a special categorical feature type in which the cardinality of the set of unique values is 2.

• **Text** – A text column contains many non-numeric unique values. In extreme cases, all the elements of the column are unique. In an extreme case, no two entries are the same.

• **Datetime** – A datetime column contains information about the date or time. It can have information about both the date and time.

Feature statistics

The following are definitions for each of the feature statistics:

• **Prediction power** – Prediction power measures how useful the column is in predicting the target.

• **Outliers** (in numeric columns) – Data Wrangler detects outliers using two statistics that are robust to outliers: median and robust standard deviation (RSTD). RSTD is derived by clipping the feature values to the range [5 percentile, 95 percentile] and calculating the standard deviation of the clipped vector. All values larger than median + 5 * RSTD or smaller than median - 5 * RSTD are considered to be outliers.

• **Skew** (in numeric columns) – Skew measures the symmetry of the distribution and is defined as the third moment of the distribution divided by the third power of the standard deviation. The skewness of the normal distribution or any other symmetric distribution is zero. Positive values imply that the right tail of the distribution is longer than the left tail. Negative values imply that the left tail of the distribution is longer than the right tail. As a rule of thumb, a distribution is considered skewed when the absolute value of the skew is larger than 3.

• **Kurtosis** (in numeric columns) – Pearson's kurtosis measures the heaviness of the tail of the distribution. It's defined as the fourth moment of the distribution divided by the square of the second moment. The kurtosis of the normal distribution is 3. Kurtosis values lower than 3 imply that the distribution is concentrated around the mean and the tails are lighter than the tails of the normal distribution. Kurtosis values higher than 3 imply heavier tails or outliers.

• **Missing values** – Null-like objects, empty strings and strings composed of only white spaces are considered missing.
• **Valid values for numeric features or regression target** – All values that you can cast to finite floats are valid. Missing values are not valid.

• **Valid values for categorical, binary, or text features, or for classification target** – All values that are not missing are valid.

• **Datetime features** – All values that you can cast to a datetime object are valid. Missing values are not valid.

• **Invalid values** – Values that are either missing or you can't properly cast. For example, in a numeric column, you can't cast the string "six" or a null value.

Quick model metrics for regression

The following are the definitions for the quick model metrics:

• **R2 or coefficient of determination** – R2 is the proportion of the variation in the target that is predicted by the model. R2 is in the range of [-infty, 1]. 1 is the score of the model that predicts the target perfectly and 0 is the score of the trivial model that always predicts the target mean.

• **MSE or mean squared error** – MSE is in the range [0, infty]. 0 is the score of the model that predicts the target perfectly.

• **MAE or mean absolute error** – MAE is in the range [0, infty] where 0 is the score of the model that predicts the target perfectly.

• **RMSE or root mean square error** – RMSE is in the range [0, infty] where 0 is the score of the model that predicts the target perfectly.

• **Max error** – The maximum absolute value of the error over the dataset. Max error is in the range [0, infty]. 0 is the score of the model that predicts the target perfectly.

• **Median absolute error** – Median absolute error is in the range [0, infty]. 0 is the score of the model that predicts the target perfectly.

Quick model metrics for classification

The following are the definitions for the quick model metrics:

• **Accuracy** – Accuracy is the ratio of samples that are predicted accurately. Accuracy is in the range [0, 1]. 0 is the score of the model that predicts all samples incorrectly and 1 is the score of the perfect model.

• **Balanced accuracy** – Balanced accuracy is the ratio of samples that are predicted accurately when the class weights are adjusted to balance the data. All classes are given the same importance, regardless of their frequency. Balanced accuracy is in the range [0, 1]. 0 is the score of the model that predicts all samples wrong. 1 is the score of the perfect model.

• **AUC (binary classification)** – This is the area under the receiver operating characteristic curve. AUC is in the range [0, 1] where a random model returns a score of 0.5 and the perfect model returns a score of 1.

• **AUC (OVR)** – For multiclass classification, this is the area under the receiver operating characteristic curve calculated separately for each label using one versus rest. Data Wrangler reports the average of the areas. AUC is in the range [0, 1] where a random model returns a score of 0.5 and the perfect model returns a score of 1.

• **Precision** – Precision is defined for a specific class. Precision is the fraction of true positives out of all the instances that the model classified as that class. Precision is in the range [0, 1]. 1 is the score of the model that has no false positives for the class. For binary classification, Data Wrangler reports the precision of the positive class.

• **Recall** – Recall is defined for a specific class. Recall is the fraction of the relevant class instances that are successfully retrieved. Recall is in the range [0, 1]. 1 is the score of the model that classifies all the instances of the class correctly. For binary classification, Data Wrangler reports the recall of the positive class.
• **F1** – F1 is defined for a specific class. It’s the harmonic mean of the precision and recall. F1 is in the range \([0, 1]\). 1 is the score of the perfect model. For binary classification, Data Wrangler reports the F1 for classes with positive values.

**Textual patterns**

**Patterns** describe the textual format of a string using an easy to read format. The following are examples of textual patterns:

- "\{digits:4-7\}" describes a sequence of digits that have a length between 4 and 7.
- "\{alnum:5\}" describes an alpha-numeric string with a length of exactly 5.

Data Wrangler infers the patterns by looking at samples of non-empty strings from your data. It can describe many of the commonly used patterns. The **confidence** expressed as a percentage indicates how much of the data is estimated to match the pattern. Using the textual pattern, you can see which rows in your data you need to correct or drop.

The following describes the patterns that Data Wrangler can recognize:

<table>
<thead>
<tr>
<th>Pattern</th>
<th>Textual Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>{alnum}</td>
<td>Alphanumeric strings</td>
</tr>
<tr>
<td>{any}</td>
<td>Any string of word characters</td>
</tr>
<tr>
<td>{digits}</td>
<td>A sequence of digits</td>
</tr>
<tr>
<td>{lower}</td>
<td>A lowercase word</td>
</tr>
<tr>
<td>{mixed}</td>
<td>A mixed-case word</td>
</tr>
<tr>
<td>{name}</td>
<td>A word beginning with a capital letter</td>
</tr>
<tr>
<td>{upper}</td>
<td>An uppercase word</td>
</tr>
<tr>
<td>{whitespace}</td>
<td>whitespace characters</td>
</tr>
</tbody>
</table>

A word character is either an underscore or a character that might appear in a word in any language. For example, the strings 'Hello_word' and 'écoute' both consist of word characters. 'H' and 'é' are both examples of word characters.

**Automatically Train Models on Your Data Flow**

You can use Amazon SageMaker Autopilot to automatically train, tune, and deploy models on the data that you’ve transformed in your data flow. Amazon SageMaker Autopilot can go through several algorithms and use the one that works best with your data. For more information about Amazon SageMaker Autopilot, see [SageMaker Autopilot (p. 44)](https://docs.aws.amazon.com/sagemaker/latest/dg/autopilot.html).

When you train and tune a model, Data Wrangler exports your data to an Amazon S3 location where Amazon SageMaker Autopilot can access it.

You can prepare and deploy a model by choosing a node in your Data Wrangler flow and choosing **Export and Train** in the data preview. You can use this method to view your dataset before you choose to train a model on it.

You can also train and deploy a model directly from your data flow.
The following procedure prepares and deploys a model from the data flow. For Data Wrangler flows with multi-row transforms, you can't use the transforms from the Data Wrangler flow when you're deploying the model. You can use the following procedure to process the data before you use it to perform inference.

To train and deploy a model directly from your data flow, do the following.

1. Choose the + next to the node containing the training data.
2. Choose Train model.
3. (Optional) Specify an AWS KMS key or ID. For more information about creating and controlling cryptographic keys to protect your data, see AWS Key Management Service.
4. Choose Export and train.
5. After Amazon SageMaker Autopilot trains the model on the data that Data Wrangler exported, specify a name for Experiment name.
6. Under Input data, choose Preview to verify that Data Wrangler properly exported your data to Amazon SageMaker Autopilot.
7. For Target, choose the target column.
8. (Optional) For S3 location under Output data, specify an Amazon S3 location other than the default location.
10. Choose a training method. For more information, see Training modes (p. 62).
11. (Optional) For Auto deploy endpoint, specify a name for the endpoint.
12. For Deployment option, choose a deployment method. You can choose to deploy with or without the transformations that you've made to your data.
   Important
   You can't deploy an Amazon SageMaker Autopilot model with the transformations that you've made in your Data Wrangler flow. For more information about those transformations, see Export to an Inference Endpoint (p. 1320).
13. Choose Next: Review and create.
14. Choose Create experiment.

For more information about model training and deployment, see Create an Amazon SageMaker Autopilot experiment for tabular data (p. 46). Autopilot shows you analyses about the best model's performance. For more information about model performance, see View an Autopilot Model Performance Report (p. 83).

Transform Data

Amazon SageMaker Data Wrangler provides numerous ML data transforms to streamline cleaning, transforming, and featurizing your data. When you add a transform, it adds a step to the data flow. Each transform you add modifies your dataset and produces a new dataframe. All subsequent transforms apply to the resulting dataframe.

Data Wrangler includes built-in transforms, which you can use to transform columns without any code. You can also add custom transformations using PySpark, Python (User-Defined Function), pandas, and PySpark SQL. Some transforms operate in place, while others create a new output column in your dataset.

You can apply transforms to multiple columns at once. For example, you can delete multiple columns in a single step.

You can apply the Process numeric and Handle missing transforms only to a single column.

Use this page to learn more about these built-in and custom transforms.
Transform UI

Most of the built-in transforms are located in the Prepare tab of the Data Wrangler UI. You can access the join and concatenate transforms through the data flow view. Use the following table to preview these two views.

<table>
<thead>
<tr>
<th>Transform</th>
</tr>
</thead>
<tbody>
<tr>
<td>You can add a transform to any step in your data flow. Use the following procedure to add a transform to your data flow.</td>
</tr>
<tr>
<td>To add a step to your data flow, do the following.</td>
</tr>
<tr>
<td>1. Choose the + next to the step in the data flow.</td>
</tr>
<tr>
<td>2. Choose Add transform.</td>
</tr>
<tr>
<td>3. Choose Add step.</td>
</tr>
<tr>
<td>4. Choose a transform.</td>
</tr>
<tr>
<td>5. (Optional) You can search for the transform that you want to use. Data Wrangler highlights the query in the results.</td>
</tr>
</tbody>
</table>
To join two datasets, select the first dataset in your data flow and choose **Join**. When you choose **Join**, you see results similar to those shown in the following image. Your left and right datasets are displayed in the left panel. The main panel displays your data flow, with the newly joined dataset added.
When you choose **Configure** to configure your join, you see results similar to those shown in the following image. Your join configuration is displayed in the left panel. You can use this panel to choose the joined dataset name, join type, and columns to join. The main panel displays three tables. The top two tables display the left and right datasets on the left and right respectively. Under this table, you can preview the joined dataset.

See [Join Datasets](p. 1258) to learn more.

**Concatenate View**

To concatenate two datasets, you select the first dataset in your data flow and choose **Concatenate**. When you select **Concatenate**, you see results similar to those shown in the following image. Your
left and right datasets are displayed in the left panel. The main panel displays your data flow, with the newly concatenated dataset added.

When you choose **Configure** to configure your concatenation, you see results similar to those shown in the following image. Your concatenate configuration displays in the left panel. You can use this panel to choose the concatenated dataset's name, and choose to remove duplicates after concatenation and add columns to indicate the source dataframe. The main panel displays three tables. The top two tables display the left and right datasets on the left and right respectively. Under this table, you can preview the concatenated dataset.

See [Concatenate Datasets](p. 1258) to learn more.
Join Datasets

You join dataframes directly in your data flow. When you join two datasets, the resulting joined dataset appears in your flow. The following join types are supported by Data Wrangler.

- **Left Outer** – Include all rows from the left table. If the value for the column joined on a left table row does not match any right table row values, that row contains null values for all right table columns in the joined table.
- **Left Anti** – Include rows from the left table that do not contain values in the right table for the joined column.
- **Left semi** – Include a single row from the left table for all identical rows that satisfy the criteria in the join statement. This excludes duplicate rows from the left table that match the criteria of the join.
- **Right Outer** – Include all rows from the right table. If the value for the joined column in a right table row does not match any left table row values, that row contains null values for all left table columns in the joined table.
- **Inner** – Include rows from left and right tables that contain matching values in the joined column.
- **Full Outer** – Include all rows from the left and right tables. If the row value for the joined column in either table does not match, separate rows are created in the joined table. If a row doesn't contain a value for a column in the joined table, null is inserted for that column.
- **Cartesian Cross** – Include rows which combine each row from the first table with each row from the second table. This is a Cartesian product of rows from tables in the join. The result of this product is the size of the left table times the size of the right table. Therefore, we recommend caution in using this join between very large datasets.

Use the following procedure to join two dataframes.

1. Select + next to the left dataframe that you want to join. The first dataframe you select is always the left table in your join.
2. Choose Join.
3. Select the right dataframe. The second dataframe you select is always the right table in your join.
4. Choose Configure to configure your join.
5. Give your joined dataset a name using the Name field.
6. Select a Join type.
7. Select a column from the left and right tables to join.
8. Choose Apply to preview the joined dataset on the right.
9. To add the joined table to your data flow, choose Add.

Concatenate Datasets

**Concatenate two datasets:**

1. Choose + next to the left dataframe that you want to concatenate. The first dataframe you select is always the left table in your concatenate.
2. Choose Concatenate.
3. Select the right dataframe. The second dataframe you select is always the right table in your concatenate.
4. Choose Configure to configure your concatenate.
5. Give your concatenated dataset a name using the Name field.
6. (Optional) Select the checkbox next to **Remove duplicates after concatenation** to remove duplicate columns.

7. (Optional) Select the checkbox next to **Add column to indicate source dataframe** if, for each column in the new dataset, you want to add an indicator of the column's source.

8. Choose **Apply** to preview the new dataset.

9. Choose **Add** to add the new dataset to your data flow.

**Balance Data**

You can balance the data for datasets with an underrepresented category. Balancing a dataset can help you create better models for binary classification.

**Note**

You can't balance datasets containing column vectors.

You can use the **Balance data** operation to balance your data using one of the following operators:

- **Random oversampling** – Randomly duplicates samples in the minority category. For example, if you're trying to detect fraud, you might only have cases of fraud in 10% of your data. For an equal proportion of fraudulent and non-fraudulent cases, this operator randomly duplicates fraud cases within the dataset 8 times.

- **Random undersampling** – Roughly equivalent to random oversampling. Randomly removes samples from the overrepresented category to get the proportion of samples that you desire.

- **Synthetic Minority Oversampling Technique (SMOTE)** – Uses samples from the underrepresented category to interpolate new synthetic minority samples. For more information about SMOTE, see the following description.

You can use all transforms for datasets containing both numeric and non-numeric features. SMOTE interpolates values by using neighboring samples. Data Wrangler uses the R-squared distance to determine the neighborhood to interpolate the additional samples. Data Wrangler only uses numeric features to calculate the distances between samples in the underrepresented group.

For two real samples in the underrepresented group, Data Wrangler interpolates the numeric features by using a weighted average. It randomly assigns weights to those samples in the range of [0, 1]. For numeric features, Data Wrangler interpolates samples using a weighted average of the samples. For samples A and B, Data Wrangler could randomly assign a weight of 0.7 to A and 0.3 to B. The interpolated sample has a value of 0.7A + 0.3B.

Data Wrangler interpolates non-numeric features by copying from either of the interpolated real samples. It copies the samples with a probability that it randomly assigns to each sample. For samples A and B, it can assign probabilities 0.8 to A and 0.2 to B. For the probabilities it assigned, it copies A 80% of the time.

**Custom Transforms**

The **Custom Transforms** group allows you to use Python (User-Defined Function), PySpark, pandas, or PySpark (SQL) to define custom transformations. For all three options, you use the variable `df` to access the dataframe to which you want to apply the transform. To apply your custom code to your dataframe, assign the dataframe with the transformations that you've made to the `df` variable. If you're not using Python (User-Defined Function), you don't need to include a return statement. Choose **Preview** to preview the result of the custom transform. Choose **Add** to add the custom transform to your list of **Previous steps**.

You can import the popular libraries with an `import` statement in the custom transform code block, such as the following:
Important

Custom transform doesn't support columns with spaces or special characters in the name. We recommend that you specify column names that only have alphanumeric characters and underscores. You can use the Rename column transform in the Manage columns transform group to remove spaces from a column's name. You can also add a Python (Pandas) Custom transform similar to the following to remove spaces from multiple columns in a single step. This example changes columns named A column and B column to A_column and B_column respectively.

```python
df.rename(columns={"A column": "A_column", "B column": "B_column"})
```

If you include print statements in the code block, the result appears when you select Preview. You can resize the custom code transformer panel. Resizing the panel provides more space to write code. The following image shows the resizing of the panel.
Data flow

Choose the plus sign to add a step to the flow. Select a step to modify.

Source - sampled

S3: titanic.csv
The following sections provide additional context and examples for writing custom transform code.

**Python (User-Defined Function)**

The Python function gives you the ability to write custom transformations without needing to know Apache Spark or pandas. Data Wrangler is optimized to run your custom code quickly. You get similar performance using custom Python code and an Apache Spark plugin.

To use the Python (User-Defined Function) code block, you specify the following:

- **Input column** – The input column where you're applying the transform.
- **Mode** – The scripting mode, either pandas or Python.
- **Return type** – The data type of the value that you're returning.

Using the pandas mode gives better performance. The Python mode makes it easier for you to write transformations by using pure Python functions.

The following video shows an example of how to use custom code to create a transformation. It uses the Titanic dataset to create a column with the person's salutation.
Data flow

Choose the plus sign to add a step to the flow. Select a step to move it.
**PySpark**

The following example extracts date and time from a timestamp.

```python
from pyspark.sql.functions import from_unixtime, to_date, date_format
df = df.withColumn('DATE_TIME', from_unixtime('TIMESTAMP'))
df = df.withColumn('EVENT_DATE', to_date('DATE_TIME')).withColumn('EVENT_TIME', date_format('DATE_TIME', 'HH:mm:ss'))
```

**pandas**

The following example provides an overview of the dataframe to which you are adding transforms.

```python
df.info()
```

**PySpark (SQL)**

The following example creates a new dataframe with four columns: name, fare, pclass, survived.

```sql
SELECT name, fare, pclass, survived FROM df
```

If you don’t know how to use PySpark, you can use custom code snippets to help you get started.

Data Wrangler has a searchable collection of code snippets. You can use code snippets to perform tasks such as dropping columns, grouping by columns, or modelling.

To use a code snippet, choose **Search example snippets** and specify a query in the search bar. The text you specify in the query doesn’t have to match the name of the code snippet exactly.

The following example shows a **Drop duplicate rows** code snippet that can delete rows with similar data in your dataset. You can find the code snippet by searching for one of the following:

- Duplicates
- Identical
- Remove

The following snippet has comments to help you understand the changes that you need to make. For most snippets, you must specify the column names of your dataset in the code.

```python
# Specify the subset of columns
# all rows having identical values in these columns will be dropped
subset = ["col1", "col2", "col3"]
df = df.dropDuplicates(subset)
# to drop the full-duplicate rows run
# df = df.dropDuplicates()
```

To use a snippet, copy and paste its content into the **Custom transform** field. You can copy and paste multiple code snippets into the custom transform field.

**Custom Formula**

Use **Custom formula** to define a new column using a Spark SQL expression to query data in the current dataframe. The query must use the conventions of Spark SQL expressions.
Important

*Custom formula* doesn't support columns with spaces or special characters in the name. We recommend that you specify column names that only have alphanumeric characters and underscores. You can use the *Rename column* transform in the *Manage columns* transform group to remove spaces from a column's name. You can also add a *Python (Pandas) Custom transform* similar to the following to remove spaces from multiple columns in a single step. This example changes columns named *A column* and *B column* to *A_column* and *B_column* respectively.

```python
df.rename(columns={"A column": "A_column", "B column": "B_column"})
```

You can use this transform to perform operations on columns, referencing the columns by name. For example, assuming the current dataframe contains columns named *col_a* and *col_b*, you can use the following operation to produce an *Output column* that is the product of these two columns with the following code:

```python
col_a * col_b
```

Other common operations include the following, assuming a dataframe contains *col_a* and *col_b* columns:

- Concatenate two columns: `concat(col_a, col_b)`
- Add two columns: `col_a + col_b`
- Subtract two columns: `col_a - col_b`
- Divide two columns: `col_a / col_b`
- Take the absolute value of a column: `abs(col_a)`

For more information, see the [Spark documentation](https://spark.apache.org/docs/latest/ml-features.html) on selecting data.

### Reduce Dimensionality within a Dataset

Reduce the dimensionality in your data by using Principal Component Analysis (PCA). The dimensionality of your dataset corresponds to the number of features. When you use dimensionality reduction in Data Wrangler, you get a new set of features called components. Each component accounts for some variability in the data.

The first component accounts for the largest amount of variation in the data. The second component accounts for the second largest amount of variation in the data, and so on.

You can use dimensionality reduction to reduce the size of the data sets that you use to train models. Instead of using the features in your dataset, you can use the principal components instead.

To perform PCA, Data Wrangler creates axes for your data. An axis is an affine combination of columns in your dataset. The first principal component is the value on the axis that has the largest amount of variance. The second principal component is the value on the axis that has the second largest amount of variance. The nth principal component is the value on the axis that has the nth largest amount of variance.

You can configure the number of principal components that Data Wrangler returns. You can either specify the number of principal components directly or you can specify the variance threshold percentage. Each principal component explains an amount of variance in the data. For example, you might have a principal component with a value of 0.5. The component would explain 50% of the variation in the data. When you specify a variance threshold percentage, Data Wrangler returns the smallest number of components that meet the percentage that you specify.
The following are example principal components with the amount of variance that they explain in the data.

- Component 1 – 0.5
- Component 2 – 0.45
- Component 3 – 0.05

If you specify a variance threshold percentage of 94 or 95, Data Wrangler returns Component 1 and Component 2. If you specify a variance threshold percentage of 96, Data Wrangler returns all three principal components.

You can use the following procedure to run PCA on your dataset.

To run PCA on your dataset, do the following.

1. Open your Data Wrangler data flow.
2. Choose the +, and select Add transform.
3. Choose Add step.
4. Choose Dimensionality Reduction.
5. For Input Columns, choose the features that you're reducing into the principal components.
6. (Optional) For Number of principal components, choose the number of principal components that Data Wrangler returns in your dataset. If specify a value for the field, you can't specify a value for Variance threshold percentage.
7. (Optional) For Variance threshold percentage, specify the percentage of variation in the data that you want explained by the principal components. Data Wrangler uses the default value of 95 if you don't specify a value for the variance threshold. You can't specify a variance threshold percentage if you've specified a value for Number of principal components.
8. (Optional) Deselect Center to not use the mean of the columns as the center of the data. By default, Data Wrangler centers the data with the mean before scaling.
9. (Optional) Deselect Scale to not scale the data with the unit standard deviation.
10. (Optional) Choose Columns to output the components to separate columns. Choose Vector to output the components as a single vector.
11. (Optional) For Output column, specify a name for an output column. If you're outputting the components to separate columns, the name that you specify is a prefix. If you're outputting the components to a vector, the name that you specify is the name of the vector column.
12. (Optional) Select Keep input columns. We don't recommend selecting this option if you plan on only using the principal components to train your model.

**Encode Categorical**

Categorical data is usually composed of a finite number of categories, where each category is represented with a string. For example, if you have a table of customer data, a column that indicates the country a person lives in is categorical. The categories would be Afghanistan, Albania, Algeria, and so on. Categorical data can be nominal or ordinal. Ordinal categories have an inherent order, and nominal categories do not. The highest degree obtained (High school, Bachelors, Masters, and so on) is an example of ordinal categories.

Encoding categorical data is the process of creating a numerical representation for categories. For example, if your categories are Dog and Cat, you may encode this information into two vectors, [1, 0] to represent Dog, and [0, 1] to represent Cat.
When you encode ordinal categories, you may need to translate the natural order of categories into your encoding. For example, you can represent the highest degree obtained with the following map: \{"High school": 1, "Bachelors": 2, "Masters":3\}.

Use categorical encoding to encode categorical data that is in string format into arrays of integers.

The Data Wrangler categorical encoders create encodings for all categories that exist in a column at the time the step is defined. If new categories have been added to a column when you start a Data Wrangler job to process your dataset at time $t$, and this column was the input for a Data Wrangler categorical encoding transform at time $t-1$, these new categories are considered missing in the Data Wrangler job. The option you select for invalid handling strategy is applied to these missing values. Examples of when this can occur are:

- When you use a .flow file to create a Data Wrangler job to process a dataset that was updated after the creation of the data flow. For example, you may use a data flow to regularly process sales data each month. If that sales data is updated weekly, new categories may be introduced into columns for which an encode categorical step is defined.
- When you select Sampling when you import your dataset, some categories may be left out of the sample.

In these situations, these new categories are considered missing values in the Data Wrangler job.

You can choose from and configure an ordinal and a one-hot encode. Use the following sections to learn more about these options.

Both transforms create a new column named Output column name. You specify the output format of this column with Output style:

- Select Vector to produce a single column with a sparse vector.
- Select Columns to create a column for every category with an indicator variable for whether the text in the original column contains a value that is equal to that category.

**Ordinal Encode**

Select Ordinal encode to encode categories into an integer between 0 and the total number of categories in the Input column you select.

Invalid handling strategy: Select a method to handle invalid or missing values.

- Choose Skip if you want to omit the rows with missing values.
- Choose Keep to retain missing values as the last category.
- Choose Error if you want Data Wrangler to throw an error if missing values are encountered in the Input column.
- Choose Replace with NaN to replace missing with NaN. This option is recommended if your ML algorithm can handle missing values. Otherwise, the first three options in this list may produce better results.

**One-Hot Encode**

Select One-hot encode for Transform to use one-hot encoding. Configure this transform using the following:

- Drop last category: If True, the last category does not have a corresponding index in the one-hot encoding. When missing values are possible, a missing category is always the last one and setting this to True means that a missing value results in an all zero vector.
- **Invalid handling strategy**: Select a method to handle invalid or missing values.
  - Choose **Skip** if you want to omit the rows with missing values.
  - Choose **Keep** to retain missing values as the last category.
  - Choose **Error** if you want Data Wrangler to throw an error if missing values are encountered in the Input column.

- **Is input ordinal encoded**: Select this option if the input vector contains ordinal encoded data. This option requires that input data contain non-negative integers. If **True**, input $i$ is encoded as a vector with a non-zero in the $i$th location.

### Similarity encode

Use similarity encoding when you have the following:

- A large number of categorical variables
- Noisy data

The similarity encoder creates embeddings for columns with categorical data. An embedding is a mapping of discrete objects, such as words, to vectors of real numbers. It encodes similar strings to vectors containing similar values. For example, it creates very similar encodings for "California" and "Calfornia".

Data Wrangler converts each category in your dataset into a set of tokens using a 3-gram tokenizer. It converts the tokens into an embedding using min-hash encoding.

The following example shows how the similarity encoder creates vectors from strings.

![Example of similarity encoding](image-url)
The similarity encodings that Data Wrangler creates:

- Have low dimensionality
- Are scalable to a large number of categories
- Are robust and resistant to noise

For the preceding reasons, similarity encoding is more versatile than one-hot encoding.

To add the similarity encoding transform to your dataset, use the following procedure.

To use similarity encoding, do the following.

1. Sign in to the Amazon SageMaker Console.
2. Choose Open Studio.
3. Choose Launch app.
4. Choose Studio.
5. Specify your data flow.
6. Choose a step with a transformation.
7. Choose Add step.
8. Choose Encode categorical.
9. Specify the following:

   - **Transform** – Similarity encode
   - **Input column** – The column containing the categorical data that you’re encoding.
   - **Target dimension** – (Optional) The dimension of the categorical embedding vector. The default value is 30. We recommend using a larger target dimension if you have a large dataset with many categories.
   - **Output style** – Choose Vector for a single vector with all of the encoded values. Choose Column to have the encoded values in separate columns.
   - **Output column** – (Optional) The name of the output column for a vector encoded output. For a column-encoded output, this is the prefix of the column names followed by listed number.

### Featurize Text

Use the **Featurize Text** transform group to inspect string-typed columns and use text embedding to featurize these columns.
This feature group contains two features, Character statistics and Vectorize. Use the following sections to learn more about these transforms. For both options, the **Input column** must contain text data (string type).

**Character Statistics**

Use **Character statistics** to generate statistics for each row in a column containing text data.

This transform computes the following ratios and counts for each row, and creates a new column to report the result. The new column is named using the input column name as a prefix and a suffix that is specific to the ratio or count.

- **Number of words**: The total number of words in that row. The suffix for this output column is `-stats_word_count`.
- **Number of characters**: The total number of characters in that row. The suffix for this output column is `-stats_char_count`.
- **Ratio of upper**: The number of uppercase characters, from A to Z, divided by all characters in the column. The suffix for this output column is `-stats_capital_ratio`.
- **Ratio of lower**: The number of lowercase characters, from a to z, divided by all characters in the column. The suffix for this output column is `-stats_lower_ratio`.
- **Ratio of digits**: The ratio of digits in a single row over the sum of digits in the input column. The suffix for this output column is `-stats_digit_ratio`.
- **Special characters ratio**: The ratio of non-alphanumeric (characters like #$&%:@) characters to over the sum of all characters in the input column. The suffix for this output column is `-stats_special_ratio`.

**Vectorize**

Text embedding involves mapping words or phrases from a vocabulary to vectors of real numbers. Use the Data Wrangler text embedding transform to tokenize and vectorize text data into term frequency–inverse document frequency (TF-IDF) vectors.

When TF-IDF is calculated for a column of text data, each word in each sentence is converted to a real number that represents its semantic importance. Higher numbers are associated with less frequent words, which tend to be more meaningful.

When you define a Vectorize transform step, Data Wrangler uses the data in your dataset to define the count vectorizer and TF-IDF methods. Running a Data Wrangler job uses these same methods.

You configure this transform using the following:

- **Output column name**: This transform creates a new column with the text embedding. Use this field to specify a name for this output column.
- **Tokenizer**: A tokenizer converts the sentence into a list of words, or tokens.

Choose Standard to use a tokenizer that splits by white space and converts each word to lowercase. For example, "Good dog" is tokenized to ["good", "dog"].

Choose Custom to use a customized tokenizer. If you choose Custom, you can use the following fields to configure the tokenizer:

- **Minimum token length**: The minimum length, in characters, for a token to be valid. Defaults to 1. For example, if you specify 3 for minimum token length, words like a, at, in are dropped from the tokenized sentence.
- **Should regex split on gaps**: If selected, regex splits on gaps. Otherwise, it matches tokens. Defaults to True.
• **Regex pattern**: Regex pattern that defines the tokenization process. Defaults to `'\s+'`.

• **To lowercase**: If chosen, Data Wrangler converts all characters to lowercase before tokenization. Defaults to `True`.

To learn more, see the Spark documentation on [Tokenizer](https://spark.apache.org/docs/latest/ml-features.html).

• **Vectorizer**: The vectorizer converts the list of tokens into a sparse numeric vector. Each token corresponds to an index in the vector and a non-zero indicates the existence of the token in the input sentence. You can choose from two vectorizer options, **Count** and **Hashing**.

  • **Count vectorize** allows customizations that filter infrequent or too common tokens. **Count vectorize parameters** include the following:
    
    • **Minimum term frequency**: In each row, terms (tokens) with smaller frequency are filtered. If you specify an integer, this is an absolute threshold (inclusive). If you specify a fraction between 0 (inclusive) and 1, the threshold is relative to the total term count. Defaults to 1.
    
    • **Minimum document frequency**: Minimum number of rows in which a term (token) must appear to be included. If you specify an integer, this is an absolute threshold (inclusive). If you specify a fraction between 0 (inclusive) and 1, the threshold is relative to the total term count. Defaults to 1.
    
    • **Maximum document frequency**: Maximum number of documents (rows) in which a term (token) can appear to be included. If you specify an integer, this is an absolute threshold (inclusive). If you specify a fraction between 0 (inclusive) and 1, the threshold is relative to the total term count. Defaults to 0.999.
    
    • **Maximum vocabulary size**: Maximum size of the vocabulary. The vocabulary is made up of all terms (tokens) in all rows of the column. Defaults to 262144.

  • **Binary outputs**: If selected, the vector outputs do not include the number of appearances of a term in a document, but rather are a binary indicator of its appearance. Defaults to `False`.

To learn more about this option, see the Spark documentation on [CountVectorizer](https://spark.apache.org/docs/latest/ml-features.html).

• **Hashing** is computationally faster. **Hash vectorize parameters** includes the following:

  • **Number of features during hashing**: A hash vectorizer maps tokens to a vector index according to their hash value. This feature determines the number of possible hash values. Large values result in fewer collisions between hash values but a higher dimension output vector.

To learn more about this option, see the Spark documentation on [FeatureHasher](https://spark.apache.org/docs/latest/ml-features.html).

• **Apply IDF** applies an IDF transformation, which multiplies the term frequency with the standard inverse document frequency used for TF-IDF embedding. **IDF parameters** include the following:

  • **Minimum document frequency**: Minimum number of documents (rows) in which a term (token) must appear to be included. If **count_vectorize** is the chosen vectorizer, we recommend that you keep the default value and only modify the **min_doc_freq** field in **Count vectorize parameters**. Defaults to 5.

• **Output format**: The output format of each row.

  • Select **Vector** to produce a single column with a sparse vector.

  • Select **Flattened** to create a column for every category with an indicator variable for whether the text in the original column contains a value that is equal to that category. You can only choose flattened when **Vectorizer** is set as **Count vectorizer**.

### Transform Time Series

In Data Wrangler, you can transform time series data. The values in a time series dataset are indexed to specific time. For example, a dataset that shows the number of customers in a store for each hour in a day is a time series dataset. The following table shows an example of a time series dataset.
Hourly number of customers in a store

<table>
<thead>
<tr>
<th>Number of customers</th>
<th>Time (hour)</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>09:00</td>
</tr>
<tr>
<td>10</td>
<td>10:00</td>
</tr>
<tr>
<td>14</td>
<td>11:00</td>
</tr>
<tr>
<td>25</td>
<td>12:00</td>
</tr>
<tr>
<td>20</td>
<td>13:00</td>
</tr>
<tr>
<td>18</td>
<td>14:00</td>
</tr>
</tbody>
</table>

For the preceding table, the **Number of Customers** column contains the time series data. The time series data is indexed on the hourly data in the **Time (hour)** column.

You might need to perform a series of transformations on your data to get it in a format that you can use for your analysis. Use the **Time series** transform group to transform your time series data. For more information about the transformations that you can perform, see the following sections.

**Topics**

- [Group by a Time Series](#)
- [Resample Time Series Data](#)
- [Handle Missing Time Series Data](#)
- [Validate the Timestamp of Your Time Series Data](#)
- [Standardizing the Length of the Time Series](#)
- [Extract Features from Your Time Series Data](#)
- [Use Lagged Features from Your Time Series Data](#)
- [Create a Datetime Range In Your Time Series](#)
- [Use a Rolling Window In Your Time Series](#)

**Group by a Time Series**

You can use the group by operation to group time series data for specific values in a column.

For example, you have the following table that tracks the average daily electricity usage in a household.

**Average daily household electricity usage**

<table>
<thead>
<tr>
<th>Household ID</th>
<th>Daily timestamp</th>
<th>Electricity usage (kWh)</th>
<th>Number of household occupants</th>
</tr>
</thead>
<tbody>
<tr>
<td>household_0</td>
<td>1/1/2020</td>
<td>30</td>
<td>2</td>
</tr>
<tr>
<td>household_0</td>
<td>1/2/2020</td>
<td>40</td>
<td>2</td>
</tr>
<tr>
<td>household_0</td>
<td>1/4/2020</td>
<td>35</td>
<td>3</td>
</tr>
<tr>
<td>household_1</td>
<td>1/2/2020</td>
<td>45</td>
<td>3</td>
</tr>
<tr>
<td>household_1</td>
<td>1/3/2020</td>
<td>55</td>
<td>4</td>
</tr>
</tbody>
</table>
If you choose to group by ID, you get the following table.

**Electricity usage grouped by household ID**

<table>
<thead>
<tr>
<th>Household ID</th>
<th>Electricity usage series (kWh)</th>
<th>Number of household occupants series</th>
</tr>
</thead>
<tbody>
<tr>
<td>household_0</td>
<td>[30, 40, 35]</td>
<td>[2, 2, 3]</td>
</tr>
<tr>
<td>household_1</td>
<td>[45, 55]</td>
<td>[3, 4]</td>
</tr>
</tbody>
</table>

Each entry in the time series sequence is ordered by the corresponding timestamp. The first element of the sequence corresponds to the first timestamp of the series. For household_0, 30 is the first value of the *Electricity Usage Series*. The value of 30 corresponds to the first timestamp of 1/1/2020.

You can include the starting timestamp and ending timestamp. The following table shows how that information appears.

**Electricity usage grouped by household ID**

<table>
<thead>
<tr>
<th>Household ID</th>
<th>Electricity usage series (kWh)</th>
<th>Number of household occupants series</th>
<th>Start_time</th>
<th>End_time</th>
</tr>
</thead>
<tbody>
<tr>
<td>household_0</td>
<td>[30, 40, 35]</td>
<td>[2, 2, 3]</td>
<td>1/1/2020</td>
<td>1/4/2020</td>
</tr>
<tr>
<td>household_1</td>
<td>[45, 55]</td>
<td>[3, 4]</td>
<td>1/2/2020</td>
<td>1/3/2020</td>
</tr>
</tbody>
</table>

You can use the following procedure to group by a time series column.

1. Open your Data Wrangler data flow.
2. If you haven't imported your dataset, import it under the Import data tab.
3. In your data flow, under Data types, choose the +, and select Add transform.
5. Choose Time Series.
7. Specify a column in Group by this column.
8. For Apply to columns, specify a value.
9. Choose Preview to generate a preview of the transform.
10. Choose Add to add the transform to the Data Wrangler data flow.

**Resample Time Series Data**

Time series data usually has observations that aren't taken at regular intervals. For example, a dataset could have some observations that are recorded hourly and other observations that are recorded every two hours.

Many analyses, such as forecasting algorithms, require the observations to be taken at regular intervals. Resampling gives you the ability to establish regular intervals for the observations in your dataset.

You can either upsample or downsample a time series. Upsampling increases the interval between observations in the dataset. For example, if you downsample observations that are taken either
every hour or every two hours, each observation in your dataset is taken every two hours. The hourly observations are aggregated into a single value using an aggregation method such as the mean or median.

Upsampling reduces the interval between observations in the dataset. For example, if you upsample observations that are taken every two hours into hourly observations, you can use an interpolation method to infer hourly observations from the ones that have been taken every two hours. For information on interpolation methods, see pandas.DataFrame.interpolate.

You can resample both numeric and non-numeric data.

Use the Resample operation to resample your time series data. If you have multiple time series in your dataset, Data Wrangler standardizes the time interval for each time series.

The following table shows an example of downsampling time series data by using the mean as the aggregation method. The data is downsampled from every two hours to every hour.

### Hourly temperature readings over a day before downsampling

<table>
<thead>
<tr>
<th>Timestamp</th>
<th>Temperature (Celsius)</th>
</tr>
</thead>
<tbody>
<tr>
<td>12:00</td>
<td>30</td>
</tr>
<tr>
<td>1:00</td>
<td>32</td>
</tr>
<tr>
<td>2:00</td>
<td>35</td>
</tr>
<tr>
<td>3:00</td>
<td>32</td>
</tr>
<tr>
<td>4:00</td>
<td>30</td>
</tr>
</tbody>
</table>

### Temperature readings downsampled to every two hours

<table>
<thead>
<tr>
<th>Timestamp</th>
<th>Temperature (Celsius)</th>
</tr>
</thead>
<tbody>
<tr>
<td>12:00</td>
<td>30</td>
</tr>
<tr>
<td>2:00</td>
<td>33.5</td>
</tr>
<tr>
<td>4:00</td>
<td>35</td>
</tr>
</tbody>
</table>

You can use the following procedure to resample time series data.

1. Open your Data Wrangler data flow.
2. If you haven't imported your dataset, import it under the Import data tab.
3. In your data flow, under Data types, choose the +, and select Add transform.
5. Choose Resample.
6. For Timestamp, choose the timestamp column.
7. For Frequency unit, specify the frequency that you're resampling.
8. (Optional) Specify a value for Frequency quantity.
9. Configure the transform by specifying the remaining fields.
10. Choose Preview to generate a preview of the transform.
11. Choose Add to add the transform to the Data Wrangler data flow.
Handle Missing Time Series Data

If you have missing values in your dataset, you can do one of the following:

- For datasets that have multiple time series, drop the time series that have missing values that are greater than a threshold that you specify.
- Impute the missing values in a time series by using other values in the time series.

Imputing a missing value involves replacing the data by either specifying a value or by using an inferential method. The following are the methods that you can use for imputation:

- Constant value – Replace all the missing data in your dataset with a value that you specify.
- Most common value – Replace all the missing data with the value that has the highest frequency in the dataset.
- Forward fill – Use a forward fill to replace the missing values with the non-missing value that precedes the missing values. For the sequence: [2, 4, 7, NaN, NaN, NaN, 8], all of the missing values are replaced with 7. The sequence that results from using a forward fill is [2, 4, 7, 7, 7, 7, 8].
- Backward fill – Use a backward fill to replace the missing values with the non-missing value that follows the missing values. For the sequence: [2, 4, 7, NaN, NaN, NaN, 8], all of the missing values are replaced with 8. The sequence that results from using a backward fill is [2, 4, 7, 8, 8, 8, 8].
- Interpolate – Uses an interpolation function to impute the missing values. For more information on the functions that you can use for interpolation, see `pandas.DataFrame.interpolate`.

Some of the imputation methods might not be able to impute of all the missing value in your dataset. For example, a Forward fill can't impute a missing value that appears at the beginning of the time series. You can impute the values by using either a forward fill or a backward fill.

You can either impute missing values within a cell or within a column.

The following example shows how values are imputed within a cell.

**Electricity usage with missing values**

<table>
<thead>
<tr>
<th>Household ID</th>
<th>Electricity usage series (kWh)</th>
</tr>
</thead>
<tbody>
<tr>
<td>household_0</td>
<td>[30, 40, 35, NaN, NaN]</td>
</tr>
<tr>
<td>household_1</td>
<td>[45, NaN, 55]</td>
</tr>
</tbody>
</table>

**Electricity usage with values imputed using a forward fill**

<table>
<thead>
<tr>
<th>Household ID</th>
<th>Electricity usage series (kWh)</th>
</tr>
</thead>
<tbody>
<tr>
<td>household_0</td>
<td>[30, 40, 35, 35, 35]</td>
</tr>
<tr>
<td>household_1</td>
<td>[45, 45, 55]</td>
</tr>
</tbody>
</table>

The following example shows how values are imputed within a column.

**Average daily household electricity usage with missing values**

<table>
<thead>
<tr>
<th>Household ID</th>
<th>Electricity usage (kWh)</th>
</tr>
</thead>
<tbody>
<tr>
<td>household_0</td>
<td>30</td>
</tr>
</tbody>
</table>
You can use the following procedure to handle missing values.

1. Open your Data Wrangler data flow.
2. If you haven’t imported your dataset, import it under the Import data tab.
3. In your data flow, under Data types, choose the +, and select Add transform.
5. Choose Handle missing.
6. For Time series input type, choose whether you want to handle missing values inside of a cell or along a column.
7. For Impute missing values for this column, specify the column that has the missing values.
8. For Method for imputing values, select a method.
9. Configure the transform by specifying the remaining fields.
10. Choose Preview to generate a preview of the transform.
11. If you have missing values, you can specify a method for imputing them under Method for imputing values.
12. Choose Add to add the transform to the Data Wrangler data flow.

Validate the Timestamp of Your Time Series Data

You might have time stamp data that is invalid. You can use the Validate time stamp function to determine whether the timestamps in your dataset are valid. Your timestamp can be invalid for one or more of the following reasons:

- Your timestamp column has missing values.
- The values in your timestamp column are not formatted correctly.

If you have invalid timestamps in your dataset, you can’t perform your analysis successfully. You can use Data Wrangler to identify invalid timestamps and understand where you need to clean your data.
The time series validation works in one of the two ways:

You can configure Data Wrangler to do one of the following if it encounters missing values in your dataset:

• Drop the rows that have the missing or invalid values.
• Identify the rows that have the missing or invalid values.
• Throw an error if it finds any missing or invalid values in your dataset.

You can validate the timestamps on columns that either have the timestamp type or the string type. If the column has the string type, Data Wrangler converts the type of the column to timestamp and performs the validation.

You can use the following procedure to validate the timestamps in your dataset.

1. Open your Data Wrangler data flow.
2. If you haven't imported your dataset, import it under the Import data tab.
3. In your data flow, under Data types, choose the +, and select Add transform.
5. Choose Validate timestamps.
6. For Timestamp Column, choose the timestamp column.
7. For Policy, choose whether you want to handle missing timestamps.
8. (Optional) For Output column, specify a name for the output column.
9. If the date time column is formatted for the string type, choose Cast to datetime.
10. Choose Preview to generate a preview of the transform.
11. Choose Add to add the transform to the Data Wrangler data flow.

**Standardizing the Length of the Time Series**

If you have time series data stored as arrays, you can standardize each time series to the same length. Standardizing the length of the time series array might make it easier for you to perform your analysis on the data.

You can standardize your time series for data transformations that require the length of your data to be fixed.

Many ML algorithms require you to flatten your time series data before you use them. Flattening time series data is separating each value of the time series into its own column in a dataset. The number of columns in a dataset can't change, so the lengths of the time series need to be standardized between you flatten each array into a set of features.

Each time series is set to the length that you specify as a quantile or percentile of the time series set. For example, you can have three sequences that have the following lengths:

• 3
• 4
• 5

You can set the length of all of the sequences as the length of the sequence that has the 50th percentile length.
Time series arrays that are shorter than the length you've specified have missing values added. The following is an example format of standardizing the time series to a longer length: [2, 4, 5, NaN, NaN, NaN].

You can use different approaches to handle the missing values. For information on those approaches, see Handle Missing Time Series Data (p. 1275).

The time series arrays that are longer than the length that you specify are truncated.

You can use the following procedure to standardize the length of the time series.

1. Open your Data Wrangler data flow.
2. If you haven't imported your dataset, import it under the Import data tab.
3. In your data flow, under Data types, choose the +, and select Add transform.
5. Choose Standardize length.
6. For Standardize the time series length for the column, choose a column.
7. (Optional) For Output column, specify a name for the output column. If you don't specify a name, the transform is done in place.
8. If the datetime column is formatted for the string type, choose Cast to datetime.
9. Choose Cutoff quantile and specify a quantile to set the length of the sequence.
10. Choose Flatten the output to output the values of the time series into separate columns.
11. Choose Preview to generate a preview of the transform.
12. Choose Add to add the transform to the Data Wrangler data flow.

Extract Features from Your Time Series Data

If you're running a classification or a regression algorithm on your time series data, we recommend extracting features from the time series before running the algorithm. Extracting features might improve the performance of your algorithm.

Use the following options to choose how you want to extract features from your data:

- Use Minimal subset to specify extracting 8 features that you know are useful in downstream analyses. You can use a minimal subset when you need to perform computations quickly. You can also use it when your ML algorithm has a high risk of overfitting and you want to provide it with fewer features.
- Use Efficient subset to specify extracting the most features possible without extracting features that are computationally intensive in your analyses.
- Use All features to specify extracting all features from the time series.
- Use Manual subset to choose a list of features that you think explain the variation in your data well.

Use the following the procedure to extract features from your time series data.

1. Open your Data Wrangler data flow.
2. If you haven't imported your dataset, import it under the Import data tab.
3. In your data flow, under Data types, choose the +, and select Add transform.
5. Choose Extract features.
6. For Extract features for this column, choose a column.
7. (Optional) Select Flatten to output the features into separate columns.
8. For **Strategy**, choose a strategy to extract the features.
9. Choose **Preview** to generate a preview of the transform.
10. Choose **Add** to add the transform to the Data Wrangler data flow.

**Use Lagged Features from Your Time Series Data**

For many use cases, the best way to predict the future behavior of your time series is to use its most recent behavior.

The most common uses of lagged features are the following:

- Collecting a handful of past values. For example, for time, \( t + 1 \), you collect \( t, t - 1, t - 2, \) and \( t - 3 \).
- Collecting values that correspond to seasonal behavior in the data. For example, to predict the occupancy in a restaurant at 1:00 PM, you might want to use the features from 1:00 PM on the previous day. Using the features from 12:00 PM or 11:00 AM on the same day might not be as predictive as using the features from previous days.

1. Open your Data Wrangler data flow.
2. If you haven't imported your dataset, import it under the **Import data** tab.
3. In your data flow, under **Data types**, choose the +, and select **Add transform**.
4. Choose **Add step**.
5. Choose **Lag features**.
6. For **Generate lag features for this column**, choose a column.
7. For **Timestamp Column**, choose the column containing the timestamps.
8. For **Lag**, specify the duration of the lag.
9. **(Optional)** Configure the output using one of the following options:
   - **Include the entire lag window**
   - **Flatten the output**
   - **Drop rows without history**
10. Choose **Preview** to generate a preview of the transform.
11. Choose **Add** to add the transform to the Data Wrangler data flow.

**Create a Datetime Range In Your Time Series**

You might have time series data that don't have timestamps. If you know that the observations were taken at regular intervals, you can generate timestamps for the time series in a separate column. To generate timestamps, you specify the value for the start timestamp and the frequency of the timestamps.

For example, you might have the following time series data for the number of customers at a restaurant.

**Time series data on the number of customers at a restaurant**

<table>
<thead>
<tr>
<th>Number of customers</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
</tr>
<tr>
<td>14</td>
</tr>
<tr>
<td>24</td>
</tr>
</tbody>
</table>
If you know that the restaurant opened at 5:00 PM and that the observations are taken hourly, you can add a timestamp column that corresponds to the time series data. You can see the timestamp column in the following table.

<table>
<thead>
<tr>
<th>Number of customers</th>
<th>Timestamp</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>1:00 PM</td>
</tr>
<tr>
<td>14</td>
<td>2:00 PM</td>
</tr>
<tr>
<td>24</td>
<td>3:00 PM</td>
</tr>
<tr>
<td>40</td>
<td>4:00 PM</td>
</tr>
<tr>
<td>30</td>
<td>5:00 PM</td>
</tr>
<tr>
<td>20</td>
<td>6:00 PM</td>
</tr>
</tbody>
</table>

Use the following procedure to add a datetime range to your data.

1. Open your Data Wrangler data flow.
2. If you haven't imported your dataset, import it under the Import data tab.
3. In your data flow, under Data types, choose the +, and select Add transform.
5. Choose Datetime range.
6. For Frequency type, choose the unit used to measure the frequency of the timestamps.
7. For Starting timestamp, specify the start timestamp.
8. For Output column, specify a name for the output column.
9. (Optional) Configure the output using the remaining fields.
10. Choose Preview to generate a preview of the transform.
11. Choose Add to add the transform to the Data Wrangler data flow.

Use a Rolling Window In Your Time Series

You can extract features over a time period. For example, for time, \( t \), and a time window length of 3, and for the row that indicates the \( t \)th timestamp, we append the features that are extracted from the time series at times \( t - 3 \), \( t - 2 \), and \( t - 1 \). For information on extracting features, see Extract Features from Your Time Series Data (p. 1278).

You can use the following procedure to extract features over a time period.

1. Open your Data Wrangler data flow.
2. If you haven't imported your dataset, import it under the Import data tab.
3. In your data flow, under Data types, choose the +, and select Add transform.
5. Choose Rolling window features.
6. For Generate rolling window features for this column, choose a column.
7. For Timestamp Column, choose the column containing the timestamps.
8. (Optional) For Output Column, specify the name of the output column.
9. For Window size, specify the window size.
10. For Strategy, choose the extraction strategy.
11. Choose Preview to generate a preview of the transform.
12. Choose Add to add the transform to the Data Wrangler data flow.

Featurize Datetime

Use Featurize date/time to create a vector embedding representing a datetime field. To use this transform, your datetime data must be in one of the following formats:

- Strings describing datetime: For example, "January 1st, 2020, 12:44pm".
- A Unix timestamp: A Unix timestamp describes the number of seconds, milliseconds, microseconds, or nanoseconds from 1/1/1970.

You can choose to Infer datetime format and provide a Datetime format. If you provide a datetime format, you must use the codes described in the Python documentation. The options you select for these two configurations have implications for the speed of the operation and the final results.

- The most manual and computationally fastest option is to specify a Datetime format and select No for Infer datetime format.
- To reduce manual labor, you can choose Infer datetime format and not specify a datetime format. It is also a computationally fast operation; however, the first datetime format encountered in the input column is assumed to be the format for the entire column. If there are other formats in the column, these values are NaN in the final output. Inferring the datetime format can give you unparsed strings.
- If you don't specify a format and select No for Infer datetime format, you get the most robust results. All the valid datetime strings are parsed. However, this operation can be an order of magnitude slower than the first two options in this list.

When you use this transform, you specify an Input column which contains datetime data in one of the formats listed above. The transform creates an output column named Output column name. The format of the output column depends on your configuration using the following:

- **Vector**: Outputs a single column as a vector.
- **Columns**: Creates a new column for every feature. For example, if the output contains a year, month, and day, three separate columns are created for year, month, and day.

Additionally, you must choose an Embedding mode. For linear models and deep networks, we recommend choosing cyclic. For tree-based algorithms, we recommend choosing ordinal.

Format String

The Format string transforms contain standard string formatting operations. For example, you can use these operations to remove special characters, normalize string lengths, and update string casing.
This feature group contains the following transforms. All transforms return copies of the strings in the Input column and add the result to a new, output column.

<table>
<thead>
<tr>
<th>Name</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Left pad</td>
<td>Left-pad the string with a given Fill character to the given width. If the string is longer than width, the return value is shortened to width characters.</td>
</tr>
<tr>
<td>Right pad</td>
<td>Right-pad the string with a given Fill character to the given width. If the string is longer than width, the return value is shortened to width characters.</td>
</tr>
<tr>
<td>Center (pad on either side)</td>
<td>Center-pad the string (add padding on both sides of the string) with a given Fill character to the given width. If the string is longer than width, the return value is shortened to width characters.</td>
</tr>
<tr>
<td>Prepend zeros</td>
<td>Left-fill a numeric string with zeros, up to a given width. If the string is longer than width, the return value is shortened to width characters.</td>
</tr>
<tr>

</table>

Handle Outliers

Machine learning models are sensitive to the distribution and range of your feature values. Outliers, or rare values, can negatively impact model accuracy and lead to longer training times. Use this feature group to detect and update outliers in your dataset.

When you define a Handle outliers transform step, the statistics used to detect outliers are generated on the data available in Data Wrangler when defining this step. These same statistics are used when running a Data Wrangler job.

Use the following sections to learn more about the transforms this group contains. You specify an Output name and each of these transforms produces an output column with the resulting data.
Robust standard deviation numeric outliers

This transform detects and fixes outliers in numeric features using statistics that are robust to outliers.

You must define an **Upper quantile** and a **Lower quantile** for the statistics used to calculate outliers. You must also specify the number of **Standard deviations** from which a value must vary from the mean to be considered an outlier. For example, if you specify 3 for **Standard deviations**, a value must fall more than 3 standard deviations from the mean to be considered an outlier.

The **Fix method** is the method used to handle outliers when they are detected. You can choose from the following:

- **Clip**: Use this option to clip the outliers to the corresponding outlier detection bound.
- **Remove**: Use this option to remove rows with outliers from the dataframe.
- **Invalidate**: Use this option to replace outliers with invalid values.

Standard Deviation Numeric Outliers

This transform detects and fixes outliers in numeric features using the mean and standard deviation.

You specify the number of **Standard deviations** a value must vary from the mean to be considered an outlier. For example, if you specify 3 for **Standard deviations**, a value must fall more than 3 standard deviations from the mean to be considered an outlier.

The **Fix method** is the method used to handle outliers when they are detected. You can choose from the following:

- **Clip**: Use this option to clip the outliers to the corresponding outlier detection bound.
- **Remove**: Use this option to remove rows with outliers from the dataframe.
- **Invalidate**: Use this option to replace outliers with invalid values.

Quantile Numeric Outliers

Use this transform to detect and fix outliers in numeric features using quantiles. You can define an **Upper quantile** and a **Lower quantile**. All values that fall above the upper quantile or below the lower quantile are considered outliers.

The **Fix method** is the method used to handle outliers when they are detected. You can choose from the following:

- **Clip**: Use this option to clip the outliers to the corresponding outlier detection bound.
- **Remove**: Use this option to remove rows with outliers from the dataframe.
- **Invalidate**: Use this option to replace outliers with invalid values.

Min-Max Numeric Outliers

This transform detects and fixes outliers in numeric features using upper and lower thresholds. Use this method if you know threshold values that demark outliers.

You specify a **Upper threshold** and a **Lower threshold**, and if values fall above or below those thresholds respectively, they are considered outliers.

The **Fix method** is the method used to handle outliers when they are detected. You can choose from the following:
• **Clip**: Use this option to clip the outliers to the corresponding outlier detection bound.

• **Remove**: Use this option to remove rows with outliers from the dataframe.

• **Invalidate**: Use this option to replace outliers with invalid values.

### Replace Rare

When you use the **Replace rare** transform, you specify a threshold and Data Wrangler finds all values that meet that threshold and replaces them with a string that you specify. For example, you may want to use this transform to categorize all outliers in a column into an “Others” category.

- **Replacement string**: The string with which to replace outliers.

- **Absolute threshold**: A category is rare if the number of instances is less than or equal to this absolute threshold.

- **Fraction threshold**: A category is rare if the number of instances is less than or equal to this fraction threshold multiplied by the number of rows.

- **Max common categories**: Maximum not-rare categories that remain after the operation. If the threshold does not filter enough categories, those with the top number of appearances are classified as not rare. If set to 0 (default), there is no hard limit to the number of categories.

### Handle Missing Values

Missing values are a common occurrence in machine learning datasets. In some situations, it is appropriate to impute missing data with a calculated value, such as an average or categorically common value. You can process missing values using the **Handle missing values** transform group. This group contains the following transforms.

#### Fill Missing

Use the **Fill missing** transform to replace missing values with a **Fill value** you define.

#### Impute Missing

Use the **Impute missing** transform to create a new column that contains imputed values where missing values were found in input categorical and numerical data. The configuration depends on your data type.

For numeric data, choose an imputing strategy, the strategy used to determine the new value to impute. You can choose to impute the mean or the median over the values that are present in your dataset. Data Wrangler uses the value that it computes to impute the missing values.

For categorical data, Data Wrangler imputes missing values using the most frequent value in the column. To impute a custom string, use the **Fill missing** transform instead.

#### Add Indicator for Missing

Use the **Add indicator for missing** transform to create a new indicator column, which contains a Boolean “false” if a row contains a value, and “true” if a row contains a missing value.

#### Drop Missing

Use the **Drop missing** option to drop rows that contain missing values from the **Input column**.

### Manage Columns

You can use the following transforms to quickly update and manage columns in your dataset:
<table>
<thead>
<tr>
<th>Name</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Drop Column</td>
<td>Delete a column.</td>
</tr>
<tr>
<td>Duplicate Column</td>
<td>Duplicate a column.</td>
</tr>
<tr>
<td>Rename Column</td>
<td>Rename a column.</td>
</tr>
<tr>
<td>Move Column</td>
<td>Move a column's location in the dataset. Choose to move your column to</td>
</tr>
<tr>
<td></td>
<td>the start or end of the dataset, before or after a reference column, or</td>
</tr>
<tr>
<td></td>
<td>to a specific index.</td>
</tr>
</tbody>
</table>

### Manage Rows

Use this transform group to quickly perform sort and shuffle operations on rows. This group contains the following:

- **Sort**: Sort the entire dataframe by a given column. Select the check box next to Ascending order for this option; otherwise, deselect the check box and descending order is used for the sort.
- **Shuffle**: Randomly shuffle all rows in the dataset.

### Manage Vectors

Use this transform group to combine or flatten vector columns. This group contains the following transforms.

- **Assemble**: Use this transform to combine Spark vectors and numeric data into a single column. For example, you can combine three columns: two containing numeric data and one containing vectors. Add all the columns you want to combine in Input columns and specify a Output column name for the combined data.
- **Flatten**: Use this transform to flatten a single column containing vector data. The input column must contain PySpark vectors or array-like objects. You can control the number of columns created by specifying a Method to detect number of outputs. For example, if you select Length of first vector, the number of elements in the first valid vector or array found in the column determines the number of output columns that are created. All other input vectors with too many items are truncated. Inputs with too few items are filled with NaNs.

You also specify an Output prefix, which is used as the prefix for each output column.

### Process Numeric

Use the Process Numeric feature group to process numeric data. Each scalar in this group is defined using the Spark library. The following scalars are supported:

- **Standard Scaler**: Standardize the input column by subtracting the mean from each value and scaling to unit variance. To learn more, see the Spark documentation for StandardScaler.
- **Robust Scaler**: Scale the input column using statistics that are robust to outliers. To learn more, see the Spark documentation for RobustScaler.
- **Min Max Scaler**: Transform the input column by scaling each feature to a given range. To learn more, see the Spark documentation for MinMaxScaler.
- **Max Absolute Scaler**: Scale the input column by dividing each value by the maximum absolute value. To learn more, see the Spark documentation for MaxAbsScaler.
Sampling

After you've imported your data, you can use the Sampling transformer to take one or more samples of it. When you use the sampling transformer, Data Wrangler samples your original dataset.

You can choose one of the following sample methods:

- **Limit**: Samples the dataset starting from the first row up to the limit that you specify.
- **Randomized**: Takes a random sample of a size that you specify.
- **Stratified**: Takes a stratified random sample.

You can stratify a randomized sample to make sure that it represents the original distribution of the dataset.

You might be performing data preparation for multiple use cases. For each use case, you can take a different sample and apply a different set of transformations.

The following procedure describes the process of creating a random sample.

To take a random sample from your data.

1. Choose the + to the right of the dataset that you've imported. The name of your dataset is located below the +.
2. Choose Add transform.
3. Choose Sampling.
4. For Sampling method, choose the sampling method.
5. For Approximate sample size, choose the approximate number of observations that you want in your sample.
6. (Optional) Specify an integer for Random seed to create a reproducible sample.

The following procedure describes the process of creating a stratified sample.

To take a stratified sample from your data.

1. Choose the + to the right of the dataset that you've imported. The name of your dataset is located below the +.
2. Choose Add transform.
3. Choose Sampling.
4. For Sampling method, choose the sampling method.
5. For Approximate sample size, choose the approximate number of observations that you want in your sample.
6. For Stratify column, specify the name of the column that you want to stratify on.
7. (Optional) Specify an integer for Random seed to create a reproducible sample.

Search and Edit

Use this section to search for and edit specific patterns within strings. For example, you can find and update strings within sentences or documents, split strings by delimiters, and find occurrences of specific strings.

The following transforms are supported under Search and edit. All transforms return copies of the strings in the Input column and add the result to a new output column.
<table>
<thead>
<tr>
<th>Name</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Find substring</td>
<td>Returns the index of the first occurrence of the Substring for which you searched, You can start and end the search at Start and End respectively.</td>
</tr>
<tr>
<td>Find substring (from right)</td>
<td>Returns the index of the last occurrence of the Substring for which you searched, You can start and end the search at Start and End respectively.</td>
</tr>
<tr>
<td>Matches prefix</td>
<td>Returns a Boolean value if the string contains a given Pattern. A pattern can be a character sequence or regular expression. Optionally, you can make the pattern case sensitive.</td>
</tr>
<tr>
<td>Find all occurrences</td>
<td>Returns an array with all occurrences of a given pattern. A pattern can be a character sequence or regular expression.</td>
</tr>
<tr>
<td>Extract using regex</td>
<td>Returns a string that matches a given Regex pattern.</td>
</tr>
<tr>
<td>Extract between delimiters</td>
<td>Returns a string with all characters found between Left delimiter and Right delimiter.</td>
</tr>
<tr>
<td>Extract from position</td>
<td>Returns a string, starting from Start position in the input string, that contains all characters up to the start position plus Length.</td>
</tr>
<tr>
<td>Find and replace substring</td>
<td>Returns a string with all matches of a given Pattern (regular expression) replaced by Replacement string.</td>
</tr>
<tr>
<td>Replace between delimiters</td>
<td>Returns a string with the substring found between the first appearance of a Left delimiter and the last appearance of a Right delimiter replaced by Replacement string. If no match is found, nothing is replaced.</td>
</tr>
<tr>
<td>Replace from position</td>
<td>Returns a string with the substring between Start position and Start position plus Length replaced by Replacement string. If Start position plus Length is greater than the length of the replacement string, the output contains ...</td>
</tr>
<tr>
<td>Convert regex to missing</td>
<td>Converts a string to None if invalid and returns the result. Validity is defined with a regular expression in Pattern.</td>
</tr>
<tr>
<td>Split string by delimiter</td>
<td>Returns an array of strings from the input string, split by Delimiter, with up to Max number of splits (optional). The delimiter defaults to white space.</td>
</tr>
</tbody>
</table>

**Split data**

Use the **Split data** transform to split your dataset into two or three datasets. For example, you can split your dataset into a dataset used to train your model and a dataset used to test it. You can determine the
proportion of the dataset that goes into each split. For example, if you're splitting one dataset into two
datasets, the training dataset can have 80% of the data while the testing dataset has 20%.

Splitting your data into three datasets gives you the ability to create training, validation, and test
datasets. You can see how well the model performs on the test dataset by dropping the target column.

Your use case determines how much of the original dataset each of your datasets get and the method
you use to split the data. For example, you might want to use a stratified split to make sure that the
distribution of the observations in the target column are the same across datasets. You can use the
following split transforms:

- Randomized split — Each split is a random, non-overlapping sample of the original dataset. For larger
datasets, using a randomized split might be computationally expensive and take longer than an
ordered split.
- Ordered split – Splits the dataset based on the sequential order of the observations. For example, for
an 80/20 train-test split, the first observations that make up 80% of the dataset go to the training
dataset. The last 20% of the observations go to the testing dataset. Ordered splits are effective in
keeping the existing order of the data between splits.
- Stratified split – Splits the dataset to make sure that the number of observations in the input column
have proportional representation. For an input column that has the observations 1, 1, 1, 1, 1, 2, 2, 2,
2, 2, 2, 2, 3, 3, 3, 3, 3, 3, an 80/20 split on the column would mean that approximately 80% of the
1s, 80% of the 2s, and 80% of the 3s go to the training set. About 20% of each type of observation go
to the testing set.
- Split by key – Avoids data with the same key occurring in more than one split. For example, if you have
a dataset with the column 'customer_id' and you're using it as a key, no customer id is in more than
one split.

After you split the data, you can apply additional transformations to each dataset. For most use cases,
they aren't necessary.

Data Wrangler calculates the proportions of the splits for performance. You can choose an error
threshold to set the accuracy of the splits. Lower error thresholds more accurately reflect the proportions
that you specify for the splits. If you set a higher error threshold, you get better performance, but lower
accuracy.

For perfectly split data, set the error threshold to 0. You can specify a threshold between 0 and 1 for
better performance. If you specify a value greater than 1, Data Wrangler interprets that value as 1.

If you have 10000 rows in your dataset and you specify an 80/20 split with an error of 0.001, you would
get observations approximating one of the following results:

- 8010 observations in the training set and 1990 in the testing set
- 7990 observations in the training set and 2010 in the testing set

The number of observations for the testing set in the preceding example is in the interval between 8010
and 7990.

By default, Data Wrangler uses a random seed to make the splits reproducible. You can specify a
different value for the seed to create a different reproducible split.

Randomized split

Use the following procedure to perform a randomized split on your dataset.

To split your dataset randomly, do the following:

1. Choose the + next to the node containing the dataset that you're splitting.
2. Choose **Add transform**.
3. Choose **Split data**.
4. (Optional) For **Splits**, specify the names and proportions of each split. The proportions must sum to 1.
5. (Optional) Choose the + to create an additional split.
   - Specify the names and proportions of all the splits. The proportions must sum to 1.
6. (Optional) Specify a value for **Error threshold** other than the default value.
7. (Optional) Specify a value for **Random seed**.
8. Choose **Preview**.
9. Choose **Add**.

**Ordered split**

Use the following procedure to perform an ordered split on your dataset.

To make an ordered split in your dataset, do the following.

1. Choose the + next to the node containing the dataset that you're splitting.
2. Choose **Add transform**.
3. For **Transform**, choose **Ordered split**.
4. Choose **Split data**.
5. (Optional) For **Splits**, specify the names and proportions of each split. The proportions must sum to 1.
6. (Optional) Choose the + to create an additional split.
   - Specify the names and proportions of all the splits. The proportions must sum to 1.
7. (Optional) Specify a value for **Error threshold** other than the default value.
8. (Optional) For **Input column**, specify a column with numeric values. Uses the values of the columns to infer which records are in each split. The smaller values are in one split with the larger values in the other splits.
9. (Optional) Select **Handle duplicates** to add noise to duplicate values and create a dataset of entirely unique values.
10. (Optional) Specify a value for **Random seed**.
11. Choose **Preview**.
12. Choose **Add**.

**Stratified split**

Use the following procedure to perform a stratified split on your dataset.

To make a stratified split in your dataset, do the following.

1. Choose the + next to the node containing the dataset that you're splitting.
2. Choose **Add transform**.
3. Choose **Split data**.
4. For **Transform**, choose **Stratified split**.
5. (Optional) For **Splits**, specify the names and proportions of each split. The proportions must sum to 1.
6. (Optional) Choose the + to create an additional split.
   • Specify the names and proportions of all the splits. The proportions must sum to 1.
7. For **Input column**, specify a column with up to 100 unique values. Data Wrangler can't stratify a column with more than 100 unique values.
8. (Optional) Specify a value for **Error threshold** other than the default value.
9. (Optional) Specify a value for **Random seed** to specify a different seed.
10. Choose **Preview**.
11. Choose **Add**.

**Split by column keys**

Use the following procedure to split by the column keys in your dataset.

To split by the column keys in your dataset, do the following.

1. Choose the + next to the node containing the dataset that you're splitting.
2. Choose **Add transform**.
3. Choose **Split data**.
4. For **Transform**, choose **Split by key**.
5. (Optional) For **Splits**, specify the names and proportions of each split. The proportions must sum to 1.
6. (Optional) Choose the + to create an additional split.
   • Specify the names and proportions of all the splits. The proportions must sum to 1.
7. For **Key columns**, specify the columns with values that you don't want to appear in both datasets.
8. (Optional) Specify a value for **Error threshold** other than the default value.
9. Choose **Preview**.
10. Choose **Add**.

**Parse Value as Type**

Use this transform to cast a column to a new type. The supported Data Wrangler data types are:

- Long
- Float
- Boolean
- Date, in the format dd-MM-yyyy, representing day, month, and year respectively.
- String

**Validate String**

Use the **Validate string** transforms to create a new column that indicates that a row of text data meets a specified condition. For example, you can use a **Validate string** transform to verify that a string only contains lowercase characters. The following transforms are supported under **Validate string**.

The following transforms are included in this transform group. If a transform outputs a Boolean value, **True** is represented with a 1 and **False** is represented with a 0.
<table>
<thead>
<tr>
<th>Name</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>String length</td>
<td>Returns True if a string length equals specified length. Otherwise, returns False.</td>
</tr>
<tr>
<td>Starts with</td>
<td>Returns True if a string starts with a specified prefix. Otherwise, returns False.</td>
</tr>
<tr>
<td>Ends with</td>
<td>Returns True if a string length equals specified length. Otherwise, returns False.</td>
</tr>
<tr>
<td>Is alphanumeric</td>
<td>Returns True if a string only contains numbers and letters. Otherwise, returns False.</td>
</tr>
<tr>
<td>Is alpha (letters)</td>
<td>Returns True if a string only contains letters. Otherwise, returns False.</td>
</tr>
<tr>
<td>Is digit</td>
<td>Returns True if a string only contains digits. Otherwise, returns False.</td>
</tr>
<tr>
<td>Is space</td>
<td>Returns True if a string only contains numbers and letters. Otherwise, returns False.</td>
</tr>
<tr>
<td>Is title</td>
<td>Returns True if a string contains any white spaces. Otherwise, returns False.</td>
</tr>
<tr>
<td>Is lowercase</td>
<td>Returns True if a string only contains lower case letters. Otherwise, returns False.</td>
</tr>
<tr>
<td>Is uppercase</td>
<td>Returns True if a string only contains upper case letters. Otherwise, returns False.</td>
</tr>
<tr>
<td>Is numeric</td>
<td>Returns True if a string only contains numbers. Otherwise, returns False.</td>
</tr>
<tr>
<td>Is decimal</td>
<td>Returns True if a string only contains decimal numbers. Otherwise, returns False.</td>
</tr>
</tbody>
</table>

## Unnest JSON Data

If you have a .csv file, you might have values in your dataset that are JSON strings. Similarly, you might have nested data in columns of either a Parquet file or a JSON document.

Use the Flatten structured operator to separate the first level keys into separate columns. A first level key is a key that isn't nested within a value.

For example, you might have a dataset that has a person column with demographic information on each person stored as JSON strings. A JSON string might look like the following:

```
{"seq": 1,"name": {"first": "Nathaniel","last": "Ferguson"},"age": 59,"city": "Posbotno","state": "WV"}
```

The Flatten structured operator converts the following first level keys into additional columns in your dataset:

- seq
Amazon SageMaker Developer Guide
Transform Data

• name
• age
• city
• state
Data Wrangler puts the values of the keys as values under the columns. The following shows the column
names and values of the JSON.

seq, name,
age, city, state
1, {"first": "Nathaniel","last": "Ferguson"}, 59, Posbotno, WV

For each value in your dataset containing JSON, the Flatten structured operator creates columns for the
ﬁrst-level keys. To create columns for nested keys, call the operator again. For the preceding example,
calling the operator creates the columns:
• name_ﬁrst
• name_last
The following example shows the dataset that results from calling the operation again.

seq, name,
age, city, state, name_first, name_last
1, {"first": "Nathaniel","last": "Ferguson"}, 59, Posbotno, WV, Nathaniel, Ferguson

Choose Keys to ﬂatten on to specify the ﬁrst-level keys that want to extract as separate columns. If you
don't specify any keys, Data Wrangler extracts all the keys by default.

Explode Array
Use Explode array to expand the values of the array into separate output rows. For example, the
operation can take each value in the array, [[1, 2, 3,], [4, 5, 6], [7, 8, 9]] and create a new column with the
following rows:

[1, 2, 3]
[4, 5, 6]
[7, 8, 9]

Data Wrangler names the new column, input_column_name_ﬂatten.
You can call the Explode array operation multiple times to get the nested values of the array into
separate output columns. The following example shows the result of calling the operation multiple times
on a dataset with a nested array.

Putting the values of a nested array into separate columns

### Transform Image Data

Use Data Wrangler to import and transform the images that you're using for your machine learning (ML) pipelines. After you've prepared your image data, you can export it from your Data Wrangler flow to your ML pipeline.

You can use the information provided here to familiarize yourself with importing and transforming image data in Data Wrangler. Data Wrangler uses OpenCV to import images. For more information about supported image formats, see [Image file reading and writing](#).

After you've familiarized yourself with the concepts of transforming your image data, go through the following tutorial, [Prepare image data with Amazon SageMaker Data Wrangler](#).

The following industries and use cases are examples where applying machine learning to transformed image data can be useful:

- Manufacturing – Identifying defects in items from the assembly line
- Food – Identifying spoiled or rotten food
- Medicine – Identifying lesions in tissues

When you work with image data in Data Wrangler, you go through the following process:

1. Import – Select the images by choosing the directory containing them in your Amazon S3 bucket.
2. Transform – Use the built-in transformations to prepare the images for your machine learning pipeline.
3. Export – Export the images that you've transformed to a location that can be accessed from the pipeline.

Use the following procedure to import your image data.

**To import your image data**

1. Navigate to the Create connection page.
2. Choose Amazon S3.
3. Specify the Amazon S3 file path that contains the image data.
4. For File type, choose Image.
5. (Optional) Choose **Import nested directories** to import images from multiple Amazon S3 paths.
6. Choose **Import**.

Data Wrangler uses the open-source **imgaug** library for its built-in image transformations. You can use the following built-in transformations:

- ResizelImage
- EnhanceImage
- CorruptImage
- SplitImage
- DropCorruptedImages
- DropImageDuplicates
- Brightness
- ColorChannels
- Grayscale
- Rotate

Use the following procedure to transform your images without writing code.

**To transform the image data without writing code**

1. From your Data Wrangler flow, choose the + next to the node representing the images that you've imported.
2. Choose **Add transform**.
3. Choose **Add step**.
4. Choose the transform and configure it.
5. Choose **Preview**.
6. Choose **Add**.

In addition to using the transformations that Data Wrangler provides, you can also use your own custom code snippets. For more information about using custom code snippets, see **Custom Transforms** (p. 1259). You can import the OpenCV and imgaug libraries within your code snippets and use the transforms associated with them. The following is an example of a code snippet that detects edges within the images.

```python
# A table with your image data is stored in the `df` variable
import cv2
import numpy as np
from pyspark.sql.functions import column
from sagemaker_dataprep.compute.operators.transforms.image.constants import DEFAULT_IMAGE_COLUMN, IMAGE_COLUMN_TYPE
from sagemaker_dataprep.compute.operators.transforms.image.decorators import BasicImageOperationDecorator, PandasUDFOperationDecorator

@BasicImageOperationDecorator
def my_transform(image: np.ndarray) -> np.ndarray:
    # To use the code snippet on your image data, modify the following lines within the function
    HYST_THRLD_1, HYST_THRLD_2 = 100, 200
```
edges = cv2.Canny(image,HYST_THRLD_1,HYST_THRLD_2)
return edges

@PandasUDFOperationDecorator(IMAGE_COLUMN_TYPE)
def custom_image_udf(image_row):
    return my_transform(image_row)

df = df.withColumn(DEFAULT_IMAGE_COLUMN, custom_image_udf(column(DEFAULT_IMAGE_COLUMN)))

When apply transformations in your Data Wrangler flow, Data Wrangler only applies them to a sample of the images in your dataset. To optimize your experience with the application, Data Wrangler doesn't apply the transforms to all of your images.

To apply the transformations to all of your images, export your Data Wrangler flow to an Amazon S3 location. You can use the images that you've exported in your training or inference pipelines. Use a destination node or a Jupyter Notebook to export your data. You can access either method for exporting your data from the Data Wrangler flow. For information about using these methods, see Export to Amazon S3 (p. 1313).

Filter data

Use Data Wrangler to filter the data in your columns. When you filter the data in a column, you specify the following fields:

- **Column name** – The name of the column that you're using to filter the data.
- **Condition** – The type of filter that you're applying to values in the column.
- **Value** – The value or category in the column to which you're applying the filter.

You can filter on the following conditions:

- **=** – Returns values that match the value or category that you specify.
- **!=** – Returns values that don't match the value or category that you specify.
- **>=** – For Long or Float data, filters for values that are greater than or equal to the value that you specify.
- **<=** – For Long or Float data, filters for values that are less than or equal to the value that you specify.
- **>** – For Long or Float data, filters for values that are greater than the value that you specify.
- **<** – For Long or Float data, filters for values that are less than the value that you specify.

For a column that has the categories, male and female, you can filter out all the male values. You could also filter for all the female values. Because there are only male and female values in the column, the filter returns a column that only has female values.

You can also add multiple filters. The filters can be applied across multiple columns or the same column. For example, if you're creating a column that only has values within a certain range, you add two different filters. One filter specifies that the column must have values greater than the value that you provide. The other filter specifies that the column must have values less than the value that you provide.

Use the following procedure to add the filter transform to your data.

**To filter your data**

1. From your Data Wrangler flow, choose the + next to the node with the data that you're filtering.
2. Choose **Add transform**.
3. Choose **Add step**.
4. Choose **Filter data**.
5. Specify the following fields:
   - **Column name** – The column that you’re filtering.
   - **Condition** – The condition of the filter.
   - **Value** – The value or category in the column to which you’re applying the filter.
6. (Optional) Choose + following the filter that you’ve created.
7. Configure the filter.
8. Choose **Preview**.
9. Choose **Add**.

**Map Columns for Amazon Personalize**

Data Wrangler integrates with Amazon Personalize, a fully managed machine learning service that generates item recommendations and user segments. You can use the **Map columns for Amazon Personalize** transform to get your data into a format that Amazon Personalize can interpret. For more information about the transforms specific to Amazon Personalize, see **Importing data using Amazon SageMaker Data Wrangler**. For more information about Amazon Personalize see **What is Amazon Personalize?**

**Analyze and Visualize**

Amazon SageMaker Data Wrangler includes built-in analyses that help you generate visualizations and data analyses in a few clicks. You can also create custom analyses using your own code.

You add an analysis to a dataframe by selecting a step in your data flow, and then choosing **Add analysis**. To access an analysis you’ve created, select the step that contains the analysis, and select the analysis.

All analyses are generated using 100,000 rows of your dataset.

You can add the following analysis to a dataframe:

- Data visualizations, including histograms and scatter plots.
- A quick summary of your dataset, including number of entries, minimum and maximum values (for numeric data), and most and least frequent categories (for categorical data).
- A quick model of the dataset, which can be used to generate an importance score for each feature.
- A target leakage report, which you can use to determine if one or more features are strongly correlated with your target feature.
- A custom visualization using your own code.

Use the following sections to learn more about these options.

**Histogram**

Use histograms to see the counts of feature values for a specific feature. You can inspect the relationships between features using the **Color by** option. For example, the following histogram charts the distribution of user ratings of the best-selling books on Amazon from 2009–2019, colored by genre.
You can use the **Facet by** feature to create histograms of one column, for each value in another column. For example, the following diagram shows histograms of user reviews of best-selling books on Amazon if faceted by year.

**Scatter Plot**

Use the **Scatter Plot** feature to inspect the relationship between features. To create a scatter plot, select a feature to plot on the **X axis** and the **Y axis**. Both of these columns must be numeric typed columns.

You can color scatter plots by an additional column. For example, the following example shows a scatter plot comparing the number of reviews against user ratings of top-selling books on Amazon between 2009 and 2019. The scatter plot is colored by book genre.
Additionally, you can facet scatter plots by features. For example, the following image shows an example of the same review versus user rating scatter plot, faceted by year.

**Table Summary**

Use the **Table Summary** analysis to quickly summarize your data.

For columns with numerical data, including log and float data, a table summary reports the number of entries (count), minimum (min), maximum (max), mean, and standard deviation (stddev) for each column.

For columns with non-numerical data, including columns with string, Boolean, or date/time data, a table summary reports the number of entries (count), least frequent value (min), and most frequent value (max).
Quick Model

Use the **Quick Model** visualization to quickly evaluate your data and produce importance scores for each feature. A **feature importance score** score indicates how useful a feature is at predicting a target label. The feature importance score is between \([0, 1]\) and a higher number indicates that the feature is more important to the whole dataset. On the top of the quick model chart, there is a model score. A classification problem shows an F1 score. A regression problem has a mean squared error (MSE) score.

When you create a quick model chart, you select a dataset you want evaluated, and a target label against which you want feature importance to be compared. Data Wrangler does the following:

- Infers the data types for the target label and each feature in the dataset selected.
- Determines the problem type. Based on the number of distinct values in the label column, Data Wrangler determines if this is a regression or classification problem type. Data Wrangler sets a categorical threshold to 100. If there are more than 100 distinct values in the label column, Data Wrangler classifies it as a regression problem; otherwise, it is classified as a classification problem.
- Pre-processes features and label data for training. The algorithm used requires encoding features to vector type and encoding labels to double type.
- Trains a random forest algorithm with 70% of data. Spark's **RandomForestRegressor** is used to train a model for regression problems. The **RandomForestClassifier** is used to train a model for classification problems.
- Evaluates a random forest model with the remaining 30% of data. Data Wrangler evaluates classification models using an F1 score and evaluates regression models using an MSE score.
- Calculates feature importance for each feature using the Gini importance method.

The following image shows the user interface for the quick model feature.

---

Target Leakage

Target leakage occurs when there is data in a machine learning training dataset that is strongly correlated with the target label, but is not available in real-world data. For example, you may have a column in your dataset that serves as a proxy for the column you want to predict with your model.

When you use the **Target Leakage** analysis, you specify the following:

- **Target**: This is the feature about which you want your ML model to be able to make predictions.
• **Problem type**: This is the ML problem type on which you are working. Problem type can either be **classification** or **regression**.

• (Optional) **Max features**: This is the maximum number of features to present in the visualization, which shows features ranked by their risk of being target leakage.

For classification, the target leakage analysis uses the area under the receiver operating characteristic, or AUC - ROC curve for each column, up to **Max features**. For regression, it uses a coefficient of determination, or R2 metric.

The AUC - ROC curve provides a predictive metric, computed individually for each column using cross-validation, on a sample of up to around 1000 rows. A score of 1 indicates perfect predictive abilities, which often indicates target leakage. A score of 0.5 or lower indicates that the information on the column could not provide, on its own, any useful information towards predicting the target. Although it can happen that a column is uninformative on its own but is useful in predicting the target when used in tandem with other features, a low score could indicate the feature is redundant.

For example, the following image shows a target leakage report for a diabetes classification problem, that is, predicting if a person has diabetes or not. An AUC - ROC curve is used to calculate the predictive ability of five features, and all are determined to be safe from target leakage.

**Multicollinearity**

Multicollinearity is a circumstance where two or more predictor variables are related to each other. The predictor variables are the features in your dataset that you’re using to predict a target variable. When you have multicollinearity, the predictor variables are not only predictive of the target variable, but also predictive of each other.

You can use the **Variance Inflation Factor (VIF)**, **Principal Component Analysis (PCA)**, or **Lasso feature selection** as measures for the multicollinearity in your data. For more information, see the following.

**Variance Inflation Factor (VIF)**

The Variance Inflation Factor (VIF) is a measure of collinearity among variable pairs. Data Wrangler returns a VIF score as a measure of how closely the variables are related to each other. A VIF score is a positive number that is greater than or equal to 1.

A score of 1 means that the variable is uncorrelated with the other variables. Scores greater than 1 indicate higher correlation.
Theoretically, you can have a VIF score with a value of infinity. Data Wrangler clips high scores to 50. If you have a VIF score greater than 50, Data Wrangler sets the score to 50.

You can use the following guidelines to interpret your VIF scores:

- A VIF score less than or equal to 5 indicates that the variables are moderately correlated with the other variables.
- A VIF score greater than or equal to 5 indicates that the variables are highly correlated with the other variables.

**Principle Component Analysis (PCA)**

Principal Component Analysis (PCA) measures the variance of the data along different directions in the feature space. The feature space consists of all the predictor variables that you use to predict the target variable in your dataset.

For example, if you're trying to predict who survived on the *RMS Titanic* after it hit an iceberg, your feature space can include the passengers' age, gender, and the fare that they paid.

From the feature space, PCA generates an ordered list of variances. These variances are also known as singular values. The values in the list of variances are greater than or equal to 0. We can use them to determine how much multicollinearity there is in our data.

When the numbers are roughly uniform, the data has very few instances of multicollinearity. When there is a lot of variability among the values, we have many instances of multicollinearity. Before it performs PCA, Data Wrangler normalizes each feature to have a mean of 0 and a standard deviation of 1.

*Note*

PCA in this circumstance can also be referred to as Singular Value Decomposition (SVD).

**Lasso feature selection**

Lasso feature selection uses the L1 regularization technique to only include the most predictive features in your dataset.

For both classification and regression, the regularization technique generates a coefficient for each feature. The absolute value of the coefficient provides an importance score for the feature. A higher importance score indicates that it is more predictive of the target variable. A common feature selection method is to use all the features that have a non-zero lasso coefficient.

**Detect Anomalies In Time Series Data**

You can use the anomaly detection visualization to see outliers in your time series data. To understand what determines an anomaly, you need to understand that we decompose the time series into a predicted term and an error term. We treat the seasonality and trend of the time series as the predicted term. We treat the residuals as the error term.

For the error term, you specify a threshold as the number of standard of deviations the residual can be away from the mean for it to be considered an anomaly. For example, you can specify a threshold as being 3 standard deviations. Any residual greater than 3 standard deviations away from the mean is an anomaly.

You can use the following procedure to perform an Anomaly detection analysis.

1. Open your Data Wrangler data flow.
2. In your data flow, under Data types, choose the +, and select Add analysis.
3. For Analysis type, choose Time Series.
4. For Visualization, choose Anomaly detection.
5. For **Anomaly threshold**, choose the threshold that a value is considered an anomaly.
6. Choose **Preview** to generate a preview of the analysis.
7. Choose **Add** to add the transform to the Data Wrangler data flow.

### Seasonal Trend Decomposition In Time Series Data

You can determine whether there's seasonality in your time series data by using the Seasonal Trend Decomposition visualization. We use the STL (Seasonal Trend decomposition using LOESS) method to perform the decomposition. We decompose the time series into its seasonal, trend, and residual components. The trend reflects the long term progression of the series. The seasonal component is a signal that recurs in a time period. After removing the trend and the seasonal components from the time series, you have the residual.

You can use the following procedure to perform a **Seasonal-Trend decomposition** analysis.

1. Open your Data Wrangler data flow.
2. In your data flow, under **Data types**, choose the +, and select **Add analysis**.
3. For **Analysis type**, choose **Time Series**.
4. For **Visualization**, choose **Seasonal-Trend decomposition**.
5. For **Anomaly threshold**, choose the threshold that a value is considered an anomaly.
6. Choose **Preview** to generate a preview of the analysis.
7. Choose **Add** to add the transform to the Data Wrangler data flow.

### Bias Report

You can use the bias report in Data Wrangler to uncover potential biases in your data. To generate a bias report, you must specify the target column, or **Label**, that you want to predict and a **Facet**, or the column that you want to inspect for biases.

**Label**: The feature about which you want a model to make predictions. For example, if you are predicting customer conversion, you may select a column containing data on whether or not a customer has placed an order. You must also specify whether this feature is a label or a threshold. If you specify a label, you must specify what a **positive outcome** looks like in your data. In the customer conversion example, a positive outcome may be a 1 in the orders column, representing the positive outcome of a customer placing an order within the last three months. If you specify a threshold, you must specify a lower bound defining a positive outcome. For example, if your customer orders columns contains the number of orders placed in the last year, you may want to specify 1.

**Facet**: The column that you want to inspect for biases. For example, if you are trying to predict customer conversion, your facet may be the age of the customer. You may choose this facet because you believe that your data is biased toward a certain age group. You must identify whether the facet is measured as a value or threshold. For example, if you wanted to inspect one or more specific ages, you select **Value** and specify those ages. If you want to look at an age group, you select **Threshold** and specify the threshold of ages you want to inspect.

After you select your feature and label, you select the types of bias metrics you want to calculate.

To learn more, see [Generate reports for bias in pre-training data](#)

### Create Custom Visualizations

You can add an analysis to your Data Wrangler flow to create a custom visualization. Your dataset, with all the transformations you've applied, is available as a Pandas DataFrame. Data Wrangler uses the df variable to store the dataframe. You access the dataframe by calling the variable.
You must provide the output variable, chart, to store an Altair output chart. For example, you can use the following code block to create a custom histogram using the Titanic dataset.

```python
import altair as alt
df = df.iloc[:30]
df = df.rename(columns={"Age": "value"})
df = df.assign(count=df.groupby('value').value.transform('count'))
df = df[['value', 'count']]  
base = alt.Chart(df)
bar = base.mark_bar().encode(x=alt.X('value', bin=True, axis=None), y=alt.Y('count'))
rule = base.mark_rule(color='red').encode(  
    x='mean(value):Q',
    size=alt.value(5))
chart = bar + rule
```

To create a custom visualization:

1. Next to the node containing the transformation that you’d like to visualize, choose the +.
2. Choose Add analysis.
3. For Analysis type, choose Custom Visualization.
4. For Analysis name, specify a name.
5. Enter your code in the code box.
6. Choose Preview to preview your visualization.
7. Choose Save to add your visualization.

If you don’t know how to use the Altair visualization package in Python, you can use custom code snippets to help you get started.

Data Wrangler has a searchable collection of visualization snippets. To use a visualization snippet, choose Search example snippets and specify a query in the search bar.
The following example uses the Binned scatterplot code snippet. It plots a histogram for 2 dimensions. The snippets have comments to help you understand the changes that you need to make to the code. You usually need to specify the column names of your dataset in the code.

```python
import altair as alt

# Specify the number of top rows for plotting
rows_number = 1000
df = df.head(rows_number)
# You can also choose bottom rows or randomly sampled rows
# df = df.tail(rows_number)
# df = df.sample(rows_number)

chart = (alt.Chart(df)
    .mark_circle()
    .encode(
        x=alt.X("col1:Q", bin=alt.Bin(maxbins=20)),
        y=alt.Y("col2:Q", bin=alt.Bin(maxbins=20)),
        size="count()"
    )
)
```

# :Q specifies that label column has quantitative type.
# For more details on Altair typing refer to
# https://altair-viz.github.io/user_guide/encoding.html#encoding-data-types

Reusing Data Flows for Different Datasets

For Amazon Simple Storage Service (Amazon S3) data sources, you can create and use parameters. A parameter is a variable that you've saved in your Data Wrangler flow. Its value can be any portion of the data source's Amazon S3 path. Use parameters to quickly change the data that you're importing into a Data Wrangler flow or exporting to a processing job. You can also use parameters to select and import a specific subset of your data.

After you created a Data Wrangler flow, you might have trained a model on the data that you've transformed. For datasets that have the same schema, you can use parameters to apply the same transformations on a different dataset and train a different model. You can use the new datasets to perform inference with your model or you could be using them to retrain your model.

In general, parameters have the following attributes:

- Name – The name you specify for the parameter
- Type – The type of value that the parameter represents
- Default value – The value of the parameter when you don't specify a new value

**Note**

Datet ime parameters have a time range attribute that they use as the default value.

Data Wrangler uses curly braces, {{}}, to indicate that a parameter is being used in the Amazon S3 path. For example, you can have a URL such as s3://DOC-EXAMPLE-BUCKET1/{{example_parameter_name}}/example-dataset.csv.
You create a parameter when you're editing the Amazon S3 data source that you've imported. You can set any portion of the file path to a parameter value. You can set the parameter value to either a value or a pattern. The following are the available parameter value types in the Data Wrangler flow:

- Number
- String
- Pattern
- Datetime

**Note**

You can't create a pattern parameter or a datetime parameter for the name of the bucket in the Amazon S3 path.

You must set a number as the default value of a number parameter. You can change the value of the parameter to a different number when you're editing a parameter or when you're launching a processing job. For example, in the S3 path, `s3://DOC-EXAMPLE-BUCKET/example-prefix/example-file-1.csv`, you can create a number parameter named `number_parameter` in the place of 1. Your S3 path now appears as `s3://DOC-EXAMPLE-BUCKET/example-prefix/example-file-{{number_parameter}}.csv`. The path continues to point to the example-file-1.csv dataset until you change the value of the parameter. If you change the value of `number_parameter` to 2 the path is now `s3://DOC-EXAMPLE-BUCKET/example-prefix/example-file-2.csv`. You can import example-file-2.csv into Data Wrangler if you've uploaded the file to that Amazon S3 location.

A string parameter stores a string as its default value. For example, in the S3 path, `s3://DOC-EXAMPLE-BUCKET/example-prefix/example-file-1.csv`, you can create a string parameter named `string_parameter` in the place of the filename, example-file-1.csv. The path now appears as `s3://DOC-EXAMPLE-BUCKET/example-prefix/{{string_parameter}}`. It continues to match `s3://DOC-EXAMPLE-BUCKET/example-prefix/example-file-1.csv`, until you change the value of the parameter.

Instead of specifying the filename as a string parameter, you can create a string parameter using the entire Amazon S3 path. You can specify a dataset from any Amazon S3 location in the string parameter.

A pattern parameter stores a regular expression (Python REGEX) string as its default value. You can use a pattern parameter to import multiple data files at the same time. To import more than one object at a time, specify a parameter value that matches the Amazon S3 objects that you're importing.

You can also create a pattern parameter for the following datasets:

- `s3://DOC-EXAMPLE-BUCKET1/example-prefix/example-file-1.csv`
- `s3://DOC-EXAMPLE-BUCKET1/example-prefix/example-file-2.csv`
- `s3://DOC-EXAMPLE-BUCKET1/example-prefix/example-file-10.csv`
- `s3://DOC-EXAMPLE-BUCKET/example-prefix/example-file-0123.csv`

For `s3://DOC-EXAMPLE-BUCKET1/example-prefix/example-file-1.csv`, you can create a pattern parameter in the place of 1, and set the default value of the parameter to \d+. The `\d` + REGEX string matches any one or more decimal digits. If you create a pattern parameter named `pattern_parameter`, your S3 path appears as `s3://DOC-EXAMPLE-BUCKET1/example-prefix/example-file-{{pattern_parameter}}.csv`.

You can also use pattern parameters to match all CSV objects within your bucket. To match all objects in a bucket, create a pattern parameter with the default value of . * and set the path to `s3://DOC-EXAMPLE-BUCKET/{{pattern_parameter}}.csv`. The . * character matches any string character in the path.
The s3://DOC-EXAMPLE-BUCKET/{{pattern_parameter}}.csv path can match the following datasets.

- example-file-1.csv
- other-example-file.csv
- example-file-a.csv

A datetime parameter stores the format with the following information:

- A format for parsing strings inside an Amazon S3 path.
- A relative time range to limit the datetime values that match

For example, in the Amazon S3 file path, s3://DOC-EXAMPLE-BUCKET/2020/01/01/example-dataset.csv, 2020/01/01 represents a datetime in the format of year/month/day. You can set the parameter's time range to an interval such as 1 years or 24 hours. An interval of 1 year matches all S3 paths with datetimes that fall between the current time and the time exactly a year before the current time. The current time is the time when you start exporting the transformations that you've made to the data. For more information about exporting data, see Export (p. 1311). If the current date is 2022/01/01 and the time range is 1 year, the S3 path matches datasets such as the following:

- s3://DOC-EXAMPLE-BUCKET/2021/01/01/example-dataset.csv
- s3://DOC-EXAMPLE-BUCKET/2021/06/30/example-dataset.csv
- s3://DOC-EXAMPLE-BUCKET/2021/12/31/example-dataset.csv

The datetime values within a relative time range change as time passes. The S3 paths that fall within the relative time range might also differ.

For the Amazon S3 file path, s3://DOC-EXAMPLE-BUCKET/2020/01/01/example-dataset.csv, 20200101 is an example of a path that can become a datetime parameter.

To view a table of all parameters that you've created in Data Wrangler flow, choose the `{{}}` to the right of the text box containing the Amazon S3 path. If you no longer need a parameter that you've created, you can edit or delete. To edit or delete a parameter, choose icons to the right of the parameter.

**Important**
Before you delete a parameter, make sure that you haven't used it anywhere in your Data Wrangler flow. Deleted parameters that are still within the flow cause errors.

You can create parameters for any step of your Data Wrangler flow. You can edit or delete any parameter that you create. If you're applying transformations to data that is no longer relevant to your use case, you can modify the values of parameters. Modifying the values of the parameters changes the data that you're importing.

The following sections provide additional examples and general guidance on using parameters. You can use the sections to understand the parameters that work best for you.

**Note**
The following sections contain procedures that use the Data Wrangler interface to override the parameters and create a processing job. You can also override the parameters by using the following procedures.

To export your Data Wrangler flow and override the value of a parameter, do the following:

1. Choose the + next to the node that you want to export.
2. Choose Export to.
3. Choose the location where you're exporting the data.
4. Under parameter_overrides, specify different values for the parameters that you’ve created.
5. Run the Jupyter Notebook.

Applying a Data Wrangler flow to files using patterns

You can use parameters to apply transformations in your Data Wrangler flow to different files that match a pattern in the Amazon S3 URI path. This helps you specify the files in your S3 bucket that you want to transform with high specificity. For example, you might have a dataset with the path `s3://DOC-EXAMPLE-BUCKET1/example-prefix-0/example-prefix-1/example-prefix-2/example-dataset.csv`. Different datasets named `example-dataset.csv` are stored under many different example prefixes. The prefixes might also be numbered sequentially. You can create patterns for the numbers in the Amazon S3 URI. Pattern parameters use REGEX to select any number of files that match the pattern of the expression. The following are REGEX patterns that might be useful:

- `.*` – Matches zero or more of any character, except newline characters
- `.+` – Matches one or more of any character, excluding newline characters
- `\d+` – Matches one or more of any decimal digit
- `\w+` – Matches one or more of any alphanumeric character
- `[abc-_]{2,4}` – Matches a string two, three, or four characters composed of the set of characters provided within a set of brackets
- `abc|def` – Matches one string or another. For example, the operation matches either abc or def

You can replace each number in the following paths with a single parameter that has a value of `\d+`.

- `s3://DOC-EXAMPLE-BUCKET1/example-prefix-3/example-prefix-4/example-prefix-5/example-dataset.csv`
- `s3://DOC-EXAMPLE-BUCKET1/example-prefix-8/example-prefix-12/example-prefix-13/example-dataset.csv`
- `s3://DOC-EXAMPLE-BUCKET1/example-prefix-4/example-prefix-9/example-prefix-137/example-dataset.csv`

The following procedure creates a pattern parameter for a dataset with the path `s3://DOC-EXAMPLE-BUCKET1/example-prefix-0/example-prefix-1/example-prefix-2/example-dataset.csv`.

To create a pattern parameter, do the following.

1. Next to the dataset that you’ve imported, choose **Edit dataset**.
2. Highlight the `0` in `example-prefix-0`.
3. Specify values for the following fields:
   - **Name** – A name for parameter
   - **Type** – Pattern
   - **Value** – `\d+` a regular expression that corresponds to one or more digits
4. Choose **Create**.
5. Replace the `1` and the `2` in S3 URI path with the parameter. The path should have the following format: `s3://DOC-EXAMPLE-BUCKET1/example-prefix-{{example_parameter_name}}/example-prefix-{{example_parameter_name}}/example-prefix-{{example_parameter_name}}/example-dataset.csv`

The following is a general procedure for creating a pattern parameter.
1. Navigate to your Data Wrangler flow.
2. Next to the dataset that you've imported, choose **Edit dataset**.
3. Highlight the portion of the URI that you're using as the value of the pattern parameter.
4. Choose **Create custom parameter**.
5. Specify values for the following fields:
   - **Name** – A name for parameter
   - **Type** – Pattern
   - **Value** – A regular expression containing the pattern that you'd like to store.
6. Choose **Create**.

### Applying a Data Wrangler flow to files using numeric values

You can use parameters to apply transformations in your Data Wrangler flow to different files that have similar paths. For example, you might have a dataset with the path `s3://DOC-EXAMPLE-BUCKET1/example-prefix-0/example-prefix-1/example-prefix-2/example-dataset.csv`.

You might have the transformations from your Data Wrangler flow that you've applied to datasets under `example-prefix-1`. You might want to apply the same transformations to `example-dataset.csv` that falls under `example-prefix-10` or `example-prefix-20`.

You can create a parameter that stores the value 1. If you want to apply the transformations to different datasets, you can create processing jobs that replace the value of the parameter with a different value. The parameter acts as a placeholder for you to change when you want to apply the transformations from your Data Wrangler flow to new data. You can override the value of the parameter when you create a Data Wrangler processing job to apply the transformations in your Data Wrangler flow to different datasets.

Use the following procedure to create numeric parameters for `s3://DOC-EXAMPLE-BUCKET1/example-prefix-0/example-prefix-1/example-prefix-2/example-dataset.csv`.

To create parameters for the preceding S3 URI path, do the following.

1. Navigate to your Data Wrangler flow.
2. Next to the dataset that you've imported, choose **Edit dataset**.
3. Highlight the number in an example prefix of `example-prefix-number`.
4. Choose **Create custom parameter**.
5. For **Name**, specify a name for the parameter.
6. For **Type**, choose **Integer**.
7. For **Value**, specify the number.
8. Create parameters for the remaining numbers by repeating the procedure.

After you've created the parameters, apply the transforms to your dataset and create a destination node for them. For more information about destination nodes, see **Export** (p. 1311).

Use the following procedure to apply the transformations from your Data Wrangler flow to a different time range. It assumes that you've created a destination node for the transformations in your flow.

To change the value of a numeric parameter in a Data Wrangler processing job, do the following.

1. From your Data Wrangler flow, choose **Create job**
2. Select only the destination node that contains the transformations to the dataset containing the datetime parameters.
3. Choose **Configure job**.
4. Choose **Parameters**.
5. Choose the name of a parameter that you've created.
6. Change the value of the parameter.
7. Repeat the procedure for the other parameters.
8. Choose **Run**.

### Applying a Data Wrangler flow to files using strings

You can use parameters to apply transformations in your Data Wrangler flow to different files that have similar paths. For example, you might have a dataset with the path `s3://DOC-EXAMPLE-BUCKET1/example-prefix/example-dataset.csv`

You might have transformations from your Data Wrangler flow that you've applied to datasets under `example-prefix`. You might want to apply the same transformations to `example-dataset.csv` under another `example-prefix` or `example-prefix-20`.

You can create a parameter that stores the value `example-prefix`. If you want to apply the transformations to different datasets, you can create processing jobs that replace the value of the parameter with a different value. The parameter acts as a placeholder for you to change when you want to apply the transformations from your Data Wrangler flow to new data. You can override the value of the parameter when you create a Data Wrangler processing job to apply the transformations in your Data Wrangler flow to different datasets.

Use the following procedure to create a string parameter for `s3://DOC-EXAMPLE-BUCKET1/example-prefix/example-dataset.csv`.

To create a parameter for the preceding S3 URI path, do the following.

1. Navigate to your Data Wrangler flow.
2. Next to the dataset that you've imported, choose **Edit dataset**.
3. Highlight the example prefix, `example-prefix`.
4. Choose **Create custom parameter**.
5. For **Name**, specify a name for the parameter.
6. For **Type**, choose **String**.
7. For **Value**, specify the prefix.

After you've created the parameter, apply the transforms to your dataset and create a destination node for them. For more information about destination nodes, see **Export** (p. 1311).

Use the following procedure to apply the transformations from your Data Wrangler flow to a different time range. It assumes that you've created a destination node for the transformations in your flow.

To change the value of a numeric parameter in a Data Wrangler processing job, do the following:

1. From your Data Wrangler flow, choose **Create job**
2. Select only the destination node that contains the transformations to the dataset containing the datetime parameters.
3. Choose **Configure job**.
4. Choose **Parameters**.
5. Choose the name of a parameter that you've created.
6. Change the value of the parameter.
7. Repeat the procedure for the other parameters.
8. Choose **Run**.
Applying a Data Wrangler flow to different datetime ranges

Use datetime parameters to apply transformations in your Data Wrangler flow to different time ranges. Highlight the portion of the Amazon S3 URI that has a timestamp and create a parameter for it. When you create a parameter, you specify a time range from the current time to a time in the past. For example, you might have an Amazon S3 URI that looks like the following: s3://DOC-EXAMPLE-BUCKET1/example-prefix/2022/05/15/example-dataset.csv. You can save 2022/05/15 as a datetime parameter. If you specify a year as the time range, the time range includes the moment that you run the processing job containing the datetime parameter and the time exactly one year ago. If the moment you're running the processing job is September 6th, 2022 or 2022/09/06, the time ranges can include the following:

- s3://DOC-EXAMPLE-BUCKET1/example-prefix/2022/03/15/example-dataset.csv
- s3://DOC-EXAMPLE-BUCKET1/example-prefix/2022/01/08/example-dataset.csv
- s3://DOC-EXAMPLE-BUCKET1/example-prefix/2022/07/31/example-dataset.csv
- s3://DOC-EXAMPLE-BUCKET1/example-prefix/2021/09/07/example-dataset.csv

The transformations in the Data Wrangler flow apply to all of the preceding prefixes. Changing the value of the parameter in the processing job doesn't change the value of the parameter in the Data Wrangler flow. To apply the transformations to datasets within a different time range, do the following:

1. Create a destination node containing all the transformations that you'd like to use.
2. Create a Data Wrangler job.
3. Configure the job to use a different time range for the parameter. Changing the value of the parameter in the processing job doesn't change the value of the parameter in the Data Wrangler flow.

For more information about destination nodes and Data Wrangler jobs, see Export (p. 1311).

The following procedure creates a datetime parameter for the Amazon S3 path: s3://DOC-EXAMPLE-BUCKET1/example-prefix/2022/05/15/example-dataset.csv.

To create a datetime parameter for the preceding S3 URI path, do the following.

1. Navigate to your Data Wrangler flow.
2. Next to the dataset that you've imported, choose Edit dataset.
3. Highlight the portion of the URI that you're using as the value of the datetime parameter.
4. Choose Create custom parameter.
5. For Name, specify a name for the parameter.
6. For Type, choose Datetime.
   
   **Note**
   By default, Data Wrangler selects Predefined, which provides a dropdown menu for you to select a date format. However, the timestamp format that you're using might not be available. Instead of using Predefined as the default option, you can choose Custom and specify the timestamp format manually.
7. For Date format, open the dropdown menu following Predefined and choose yyyy/MM/dd. The format, yyyy/MM/dd, corresponds to the year/month/day of the timestamp.
8. For Timezone, choose a time zone.
   
   **Note**
   The data that you're analyzing might have time stamps taken in a different time zone from your time zone. Make sure that the time zone that you select matches the time zone of the data.
9. For Time range, specify the time range for the parameter.
10. (Optional) Enter a description to describe how you're using the parameter.
11. Choose Create.

After you've created the datetime parameters, apply the transforms to your dataset and create a destination node for them. For more information about destination nodes, see Export (p. 1311).

Use the following procedure to apply the transformations from your Data Wrangler flow to a different time range. It assumes that you've created a destination node for the transformations in your flow.

To change the value of a datetime parameter in a Data Wrangler processing job, do the following:

1. From your Data Wrangler flow, choose Create job
2. Select only the destination node that contains the transformations to the dataset containing the datetime parameters.
3. Choose Configure job.
4. Choose Parameters.
5. Choose the name of the datetime parameter that you've created.
6. For Time range, change the time range for the datasets.
7. Choose Run.

Export

In your Data Wrangler flow, you can export some or all of the transformations that you've made to your data processing pipelines.

A Data Wrangler flow is the series of data preparation steps that you've performed on your data. In your data preparation, you perform one or more transformations to your data. Each transformation is done using a transform step. The flow has a series of nodes that represent the import of your data and the transformations that you've performed. For an example of nodes, see the following image.
The preceding image shows a Data Wrangler flow with two nodes. The **Source - sampled** node shows the data source from which you've imported your data. The **Data types** node indicates that Data Wrangler has performed a transformation to convert the dataset into a usable format.

Each transformation that you add to the Data Wrangler flow appears as an additional node. For information on the transforms that you can add, see **Transform Data** (p. 1253). The following image shows a Data Wrangler flow that has a **Rename-column** node to change the name of a column in a dataset.

You can export your data transformations to the following:

- Amazon S3
- SageMaker Pipelines
- Amazon SageMaker Feature Store
- Python Code

**Important**
We recommend that you use the IAM AmazonSageMakerFullAccess managed policy to grant AWS permission to use Data Wrangler. If you don't use the managed policy, you can use an IAM policy that gives Data Wrangler access to an Amazon S3 bucket. For more information on the policy, see **Security and Permissions** (p. 1338).

When you export your data flow, you're charged for the AWS resources that you use. You can use cost allocation tags to organize and manage the costs of those resources. You create these tags for your user-profile and Data Wrangler automatically applies them to the resources used to export the data flow. For more information, see **Using Cost Allocation Tags**.
Export to Amazon S3

Data Wrangler gives you the ability to export your data to a location within an Amazon S3 bucket. You can specify the location using one of the following methods:

- **Destination node** – Where Data Wrangler stores the data after it has processed it.
- **Export to** – Exports the data resulting from a transformation to Amazon S3.
- **Export data** – For small datasets, can quickly export the data that you’ve transformed.

Use the following sections to learn more about each of these methods.

Destination Node

If you want to output a series of data processing steps that you've performed to Amazon S3, you create a destination node. A destination node tells Data Wrangler where to store the data after you've processed it. After you create a destination node, you create a processing job to output the data. A processing job is an Amazon SageMaker processing job. When you're using a destination node, it runs the computational resources needed to output the data that you've transformed to Amazon S3.

You can use a destination node to export some of the transformations or all of the transformations that you've made in your Data Wrangler flow.

You can use multiple destination nodes to export different transformations or sets of transformations. The following example shows two destination nodes in a single Data Wrangler flow.

You can use the following procedure to create destination nodes and export them to an Amazon S3 bucket.

To export your data flow, you create destination nodes and a Data Wrangler job to export the data. Creating a Data Wrangler job starts a SageMaker processing job to export your flow. You can choose the destination nodes that you want to export after you've created them.
Note
You can choose **Create job** in the Data Wrangler flow to view the instructions to use a processing job.

Use the following procedure to create destination nodes.

1. Choose the + next to the nodes that represent the transformations that you want to export.
2. Choose **Add destination**.
3. Choose **Amazon S3**.
4. Specify the following fields.

- **Dataset name** – The name that you specify for the dataset that you're exporting.
- **File type** – The format of the file that you're exporting.
- **Delimiter** (CSV and Parquet files only) – The value used to separate other values.
- **Compression** (CSV and Parquet files only) – The compression method used to reduce the file size. You can use the following compression methods:
  - bzip2
  - deflate
  - gzip
- (Optional) **Amazon S3 location** – The S3 location that you're using to output the files.
- (Optional) **Number of partitions** – The number of datasets that you're writing as the output of the processing job.
- (Optional) **Partition by column** – Writes all data with the same unique value from the column.
- (Optional) **Inference Parameters** – Selecting **Generate inference artifact** applies all of the transformations you've used in the Data Wrangler flow to data coming into your inference pipeline. The model in your pipeline makes predictions on the transformed data.

5. Choose **Add destination**.

Use the following procedure to create a processing job.

Create a job from the **Data flow** page and choose the destination nodes that you want to export.

**Note**

You can choose **Create job** in the Data Wrangler flow to view the instructions for creating a processing job.

1. Choose **Create job**. The following image shows the pane that appears after you select **Create job**.

2. For **Job name**, specify the name of the export job.
3. Choose the destination nodes that you want to export.

4. (Optional) Specify an AWS KMS key ARN. An AWS KMS key is a cryptographic key that you can use to protect your data. For more information about AWS KMS keys, see AWS Key Management Service.

5. (Optional) Under Trained parameters, choose Refit if you've done the following:
   - Sampled your dataset
   - Applied a transform that uses your data to create a new column in the dataset

   For more information about refitting the transformations you've made to an entire dataset, see Refit Transforms to The Entire Dataset and Export Them (p. 1329).

   **Note**
   For image data, Data Wrangler exports the transformations that you've made to all of the images. Refitting the transformations isn't applicable to your use case.

6. Choose Configure job. The following image shows the Configure job page.

   ![Configure job configuration](image)

   7. (Optional) Configure the Data Wrangler job. You can make the following configurations:
      - Job configuration
      - Spark memory configuration
• Network configuration
• Tags
• Parameters
• Associate Schedules

Export to

As an alternative to using a destination node, you can use the Export to option to export your Data Wrangler flow to Amazon S3 using a Jupyter notebook. You can choose any data node in your Data Wrangler flow and export it. Exporting the data node exports the transformation that the node represents and the transformations that precede it.

Use the following procedure to generate a Jupyter notebook and run it to export your Data Wrangler flow to Amazon S3.

1. Choose the + next to the node that you want to export.
2. Choose Export to.
3. Choose Amazon S3 (via Jupyter Notebook).
4. Run the Jupyter notebook.

When you run the notebook, it exports your data flow (.flow file) in the same AWS Region as the Data Wrangler flow.

The notebook provides options that you can use to configure the processing job and the data that it outputs.

Important
We provide you with job configurations to configure the output of your data. For the partitioning and driver memory options, we strongly recommend that you don't specify a configuration unless you already have knowledge about them.

Under Job Configurations, you can configure the following:

• output_content_type – The content type of the output file. Uses CSV as the default format, but you can specify Parquet.
• delimiter – The character used to separate values in the dataset when writing to a CSV file.
• compression – If set, compresses the output file. Uses gzip as the default compression format.
• num_partitions – The number of partitions or files that Data Wrangler writes as the output.
• partition_by – The names of the columns that you use to partition the output.

To change the output file format from CSV to Parquet, change the value from "CSV" to "Parquet".
For the rest of the preceding fields, uncomment the lines containing the fields that you want to specify.

Under (Optional) Configure Spark Cluster Driver Memory you can configure Spark properties for the job, such as the Spark driver memory, in the config dictionary.

The following shows the config dictionary.

```python
config = json.dumps({
    "Classification": "spark-defaults",
    "Properties": {
        "spark.driver.memory": f"{driver_memory_in_mb}m",
    }
})
```

To apply the configuration to the processing job, uncomment the following lines:

```python
# data_sources.append(ProcessingInput(
#     source=config_s3_uri,
#     destination="/opt/ml/processing/input/conf",
#     input_name="spark-config",
#     s3_data_type="S3Prefix",
#     s3_input_mode="File",
#     s3_data_distribution_type="FullyReplicated"
# ))
```

Export data

If you have a transformation on a small dataset that you want to export quickly, you can use the Export data method. When you start choose Export data, Data Wrangler works synchronously to export the data that you've transformed to Amazon S3. You can't use Data Wrangler until either it finishes exporting your data or you cancel the operation.

For information on using the Export data method in your Data Wrangler flow, see the following procedure.

To use the Export data method:

1. Choose a node in your Data Wrangler flow by opening (double-clicking on) it.
2. Configure how you want to export the data.
3. Choose Export data.

When you export your data flow to an Amazon S3 bucket, Data Wrangler stores a copy of the flow file in the S3 bucket. It stores the flow file under the data_wrangler_flows prefix. If you use the default Amazon S3 bucket to store your flow files, it uses the following naming convention: sagemaker-region-account_number. For example, if your account number is 111122223333 and you are using Studio in us-east-1, your imported datasets are stored in sagemaker-us-east-1-111122223333. In this example, your .flow files created in us-east-1 are stored in s3://sagemaker-region-account_number/data_wrangler_flows/.

Export to SageMaker Pipelines

When you want to build and deploy large-scale machine learning (ML) workflows, you can use SageMaker Pipelines to create workflows that manage and deploy SageMaker jobs. With SageMaker Pipelines, you can build workflows that manage your SageMaker data preparation, model training, and model deployment jobs. You can use the first-party algorithms that SageMaker offers by using SageMaker Pipelines. For more information on SageMaker Pipelines, see SageMaker Pipelines.

When you export one or more steps from your data flow to SageMaker Pipelines, Data Wrangler creates a Jupyter notebook that you can use to define, instantiate, run, and manage a pipeline.

Use a Jupyter Notebook to Create a Pipeline

Use the following procedure to create a Jupyter notebook to export your Data Wrangler flow to SageMaker Pipelines.

Use the following procedure to generate a Jupyter notebook and run it to export your Data Wrangler flow to SageMaker Pipelines.

1. Choose the + next to the node that you want to export.
2. Choose Export to.
4. Run the Jupyter notebook.
You can use the Jupyter notebook that Data Wrangler produces to define a pipeline. The pipeline includes the data processing steps that are defined by your Data Wrangler flow.

You can add additional steps to your pipeline by adding steps to the `steps` list in the following code in the notebook:

```python
pipeline = Pipeline(
    name=pipeline_name,
    parameters=[instance_type, instance_count],
    steps=[step_process],  #Add more steps to this list to run in your Pipeline
)
```

For more information on defining pipelines, see [Define SageMaker Pipeline](#).

### Export to an Inference Endpoint

Use your Data Wrangler flow to process data at the time of inference by creating a SageMaker serial inference pipeline from your Data Wrangler flow. An inference pipeline is a series of steps that results in a trained model making predictions on new data. A serial inference pipeline within Data Wrangler transforms the raw data and provides it to the machine learning model for a prediction. You create, run, and manage the inference pipeline from a Jupyter notebook within Studio. For more information about accessing the notebook, see [Use a Jupyter Notebook to create an inference endpoint (p. 1322)](#).

Within the notebook, you can either train a machine learning model or specify one that you've already trained. You can either use Amazon SageMaker Autopilot or XGBoost to train the model using the data that you've transformed in your Data Wrangler flow.

The pipeline provides the ability to perform either batch or real-time inference. You can also add the Data Wrangler flow to SageMaker Model Registry. For more information about hosting models, see [Host multiple models in one container behind one endpoint (p. 2399)](#).

**Important**

You can't export your Data Wrangler flow to an inference endpoint if it has the following transformations:

- Join
• Concatenate
• Group by

If you must use the preceding transforms to prepare your data, use the following procedure.

**To prepare your data for inference with unsupported transforms**

1. Create a Data Wrangler flow.
2. Apply the preceding transforms that aren't supported.
3. Export the data to an Amazon S3 bucket.
4. Create a separate Data Wrangler flow.
5. Import the data that you've exported from the preceding flow.
6. Apply the remaining transforms.
7. Create a serial inference pipeline using the Jupyter notebook that we provide.

For information about exporting your data to an Amazon S3 bucket see [Export to Amazon S3](p. 1313). For information about opening the Jupyter notebook used to create the serial inference pipeline, see [Use a Jupyter Notebook to create an inference endpoint](p. 1322).

Data Wrangler ignores transforms that remove data at the time of inference. For example, Data Wrangler ignores the [Handle Missing Values](p. 1284) transform if you use the **Drop missing** configuration.

If you've refit transforms to your entire dataset, the transforms carry over to your inference pipeline. For example, if you used the median value to impute missing values, the median value from refitting the transform is applied to your inference requests. You can either refit the transforms from your Data Wrangler flow when you're using the Jupyter notebook or when you're exporting your data to an inference pipeline. For information about refitting transforms, see [Refit Transforms to The Entire Dataset and Export Them](p. 1329).

The serial inference pipeline supports the following data types for the input and output strings. Each data type has a set of requirements.

**Supported datatypes**

- **text/csv** – the datatype for CSV strings
  - The string can't have a header.
  - Features used for the inference pipeline must be in the same order as features in the training dataset.
  - There must be a comma delimiter between features.
  - Records must be delimited by a newline character.

  The following is an example of a validly formatted CSV string that you can provide in an inference request.

  abc,0.0,"Doe, John",12345\ndef,1.1,"Doe, Jane",67890

- **application/json** – the datatype for JSON strings
  - The features used in the dataset for the inference pipeline must be in the same order as the features in the training dataset.
  - The data must have a specific schema. You define schema as a single **instances** object that has a set of **features**. Each **features** object represents an observation.
The following is an example of a validly formatted JSON string that you can provide in an inference request.

```
{
  "instances": [
    {
      "features": ["abc", 0.0, "Doe, John", 12345]
    },
    {
      "features": ["def", 1.1, "Doe, Jane", 67890]
    }
  ]
}
```

**Use a Jupyter Notebook to create an inference endpoint**

Use the following procedure to export your Data Wrangler flow to create an inference pipeline.

To create an inference pipeline using a Jupyter notebook, do the following.

1. Choose the + next to the node that you want to export.
2. Choose Export to.
4. Run the Jupyter notebook.

When you run the Jupyter notebook, it creates an inference flow artifact. An inference flow artifact is a Data Wrangler flow file with additional metadata used to create the serial inference pipeline. The node that you're exporting encompasses all of the transforms from the preceding nodes.

**Important**

Data Wrangler needs the inference flow artifact to run the inference pipeline. You can't use your own flow file as the artifact. You must create it by using the preceding procedure.

**Export to Python Code**

To export all steps in your data flow to a Python file that you can manually integrate into any data processing workflow, use the following procedure.

Use the following procedure to generate a Jupyter notebook and run it to export your Data Wrangler flow to Python Code.

1. Choose the + next to the node that you want to export.
2. Choose Export to.
4. Run the Jupyter notebook.
You might need to configure the Python script to make it run in your pipeline. For example, if you’re running a Spark environment, make sure that you are running the script from an environment that has permission to access AWS resources.

Export to Amazon SageMaker Feature Store

You can use Data Wrangler to export features you’ve created to Amazon SageMaker Feature Store. A feature is a column in your dataset. Feature Store is a centralized store for features and their associated metadata. You can use Feature Store to create, share, and manage curated data for machine learning (ML) development. Centralized stores make your data more discoverable and reusable. For more information about Feature Store, see Amazon SageMaker Feature Store.

A core concept in Feature Store is a feature group. A feature group is a collection of features, their records (observations), and associated metadata. It’s similar to a table in a database.

You can use Data Wrangler to do one of the following:

- Update an existing feature group with new records. A record is an observation in the dataset.
- Create a new feature group from a node in your Data Wrangler flow. Data Wrangler adds the observations from your datasets as records in your feature group.

If you’re updating an existing feature group, your dataset’s schema must match the schema of the feature group. All the records in the feature group are replaced with the observations in your dataset.

You can use either a Jupyter notebook or a destination node to update your feature group with the observations in the dataset.

If your feature groups with the Iceberg table format have a custom offline store encryption key, make sure you grant the IAM that you’re using for the Amazon SageMaker Processing job permissions to use it. At a minimum, you must grant it permissions to encrypt the data that you’re writing to Amazon S3. To grant the permissions, give the IAM role the ability to use the GenerateDataKey. For more information about granting IAM roles permissions to use AWS KMS keys see https://docs.aws.amazon.com/kms/latest/developerguide/key-policies.html
Destination Node

If you want to output a series of data processing steps that you've performed to a feature group, you can create a destination node. When you create and run a destination node, Data Wrangler updates a feature group with your data. You can also create a new feature group from the destination node UI. After you create a destination node, you create a processing job to output the data. A processing job is an Amazon SageMaker processing job. When you're using a destination node, it runs the computational resources needed to output the data that you've transformed to the feature group.

You can use a destination node to export some of the transformations or all of the transformations that you've made in your Data Wrangler flow.

Use the following procedure to create a destination node to update a feature group with the observations from your dataset.

To update a feature group using a destination node, do the following.

**Note**
You can choose **Create job** in the Data Wrangler flow to view the instructions for using a processing job to update the feature group.

1. Choose the + symbol next to the node containing the dataset that you'd like to export.
2. Under **Add destination**, choose **SageMaker Feature Store**.
3. Choose (double-click) the feature group. Data Wrangler checks whether the schema of the feature group matches the schema of the data that you're using to update the feature group.
4. (Optional) Select **Export to offline store only** for feature groups that have both an online store and an offline store. This option only updates the offline store with observations from your dataset.
5. After Data Wrangler validates the schema of your dataset, choose **Add**.

Use the following procedure to create a new feature group with data from your dataset.

You can store your feature group in one of the following ways:

- **Online** – Low-latency, high-availability cache for a feature group that provides real-time lookup of records. The online store allows quick access to the latest value for a record in a feature group.
- **Offline** – Stores data for your feature group in an Amazon S3 bucket. You can store your data offline when you don't need low-latency (sub-second) reads. You can use an offline store for features used in data exploration, model training, and batch inference.
- **Both online and offline** – Stores your data in both an online store and an offline store.
To create a feature group using a destination node, do the following.

1. Choose the + symbol next to the node containing the dataset that you'd like to export.
2. Under Add destination, choose SageMaker Feature Store.
3. Choose Create Feature Group.
4. In the following dialog box, if your dataset doesn't have an event time column, select Create "EventTime" column.
5. Choose Next.
6. Choose Copy JSON Schema. When you create a feature group, you paste the schema into the feature definitions.
7. Choose Create.
8. For Feature group name, specify a name for your feature group.
9. For Description (optional), specify a description to make your feature group more discoverable.
10. To create a feature group for an online store, do the following.
   a. Select Enable storage online.
   b. For Online store encryption key, specify an AWS managed encryption key or an encryption key of your own.
11. To create a feature group for an offline store, do the following.
   a. Select Enable storage offline. Specify values for the following fields:
      • S3 bucket name – The name of the Amazon S3 bucket that stores the feature group.
      • (Optional) Dataset directory name – The Amazon S3 prefix that you're using to store the feature group.
      • IAM Role ARN – The IAM role that has access to Feature Store.
      • Table Format – Table format of your offline store. You can specify Glue or Iceberg. Glue is the default format.
      • Offline store encryption key – By default, Feature Store uses an AWS Key Management Service managed key, but you can use the field to specify a key of your own.
   b. Specify values for the following fields:
      • S3 bucket name – The name of the bucket storing the feature group.
      • (Optional) Dataset directory name – The Amazon S3 prefix that you're using to store the feature group.
      • IAM Role ARN – The IAM role that has access to feature store.
      • Offline store encryption key – By default, Feature Store uses an AWS managed key, but you can use the field to specify a key of your own.
12. Choose Continue.
13. Choose JSON.
14. Remove the placeholder brackets in the window.
15. Paste the JSON text from Step 6.
16. Choose Continue.
17. For RECORD IDENTIFIER FEATURE NAME, choose the column in your dataset that has unique identifiers for each record in your dataset.
18. For EVENT TIME FEATURE NAME, choose the column with the timestamp values.
19. Choose Continue.
20. (Optional) Add tags to make your feature group more discoverable.
21. Choose Continue.
22. Choose Create feature group.
23. Navigate back to your Data Wrangler flow and choose the refresh icon next to the Feature Group search bar.

**Note**
If you've already created a destination node for a feature group within a flow, you can't create another destination node for the same feature group. If you want to create another destination node for the same feature group, you must create another flow file.

Use the following procedure to create a Data Wrangler job.

Create a job from the Data flow page and choose the destination nodes that you want to export.

1. Choose Create job. The following image shows the pane that appears after you select Create job.
2. For Job name, specify the name of the export job.
3. Choose the destination nodes that you want to export.
4. (Optional) For Output KMS Key, specify an ARN, ID, or alias of an AWS KMS key. A KMS key is a cryptographic key. You can use the key to encrypt the output data from the job. For more information about AWS KMS keys, see AWS Key Management Service.
5. The following image shows the Configure job page with the Job configuration tab open.
(Optional) Under **Trained parameters**, choose **Refit** if you've done the following:

- Sampled your dataset
- Applied a transform that uses your data to create a new column in the dataset

For more information about refitting the transformations you've made to an entire dataset, see [Refit Transforms to The Entire Dataset and Export Them](p. 1329).

6. Choose **Configure job**.
7. (Optional) Configure the Data Wrangler job. You can make the following configurations:
   - **Job configuration**
   - **Spark memory configuration**
   - **Network configuration**
   - **Tags**
   - **Parameters**
   - **Associate Schedules**
8. Choose **Run**.

Jupyter notebook

Use the following procedure to a Jupyter notebook to export to Amazon SageMaker Feature Store.

Use the following procedure to generate a Jupyter notebook and run it to export your Data Wrangler flow to Feature Store.

1. Choose the + next to the node that you want to export.
2. Choose **Export to**.
3. Choose **Amazon SageMaker Feature Store (via Jupyter Notebook)**.
4. Run the Jupyter notebook.
Running a Jupyter notebook runs a Data Wrangler job. Running a Data Wrangler job starts a SageMaker processing job. The processing job ingests the flow into an online and offline feature store.

**Important**
The IAM role you use to run this notebook must have the following AWS managed policies attached: AmazonSageMakerFullAccess and AmazonSageMakerFeatureStoreAccess.

You only need to enable one online or offline feature store when you create a feature group. You can also enable both. To disable online store creation, set `EnableOnlineStore` to `False`:

```python
# Online Store Configuration
online_store_config = {
    "EnableOnlineStore": False
}
```

The notebook uses the column names and types of the dataframe you export to create a feature group schema, which is used to create a feature group. A feature group is a group of features defined in the feature store to describe a record. The feature group defines the schema and features contained in the feature group. A feature group definition is composed of a list of features, a record identifier feature name, an event time feature name, and configurations for its online store and offline store.

Each feature in a feature group can have one of the following types: `String`, `Fractional`, or `Integral`. If a column in your exported dataframe is not one of these types, it defaults to `String`.

The following is an example of a feature group schema.

```json
column_schema = [
    {
        "name": "Height",
        "type": "long"
    },
    {
        "name": "Input",
        "type": "string"
    },
    {
        "name": "Output",
        "type": "string"
    },
    {
        "name": "Sum",
        "type": "string"
    },
    {
        "name": "Time",
        "type": "string"
    }
]
```

Additionally, you must specify a record identifier name and event time feature name:

- The **record identifier name** is the name of the feature whose value uniquely identifies a record defined in the feature store. Only the latest record per identifier value is stored in the online store. The record identifier feature name must be one of feature definitions' names.
- The **event time feature name** is the name of the feature that stores the `EventTime` of a record in a feature group. An `EventTime` is a point in time when a new event occurs that corresponds
to the creation or update of a record in a feature. All records in the feature group must have a corresponding EventTime.

The notebook uses these configurations to create a feature group, process your data at scale, and then ingest the processed data into your online and offline feature stores. To learn more, see Data Sources and Ingestion.

The notebook uses these configurations to create a feature group, process your data at scale, and then ingest the processed data into your online and offline feature stores. To learn more, see Data Sources and Ingestion.

**Refit Transforms to The Entire Dataset and Export Them**

When you import data, Data Wrangler uses a sample of the data to apply the encodings. By default, Data Wrangler uses the first 50,000 rows as a sample, but you can import the entire dataset or use a different sampling method. For more information, see Import (p. 1178).

The following transformations use your data to create a column in the dataset:

- [Encode Categorical](p. 1266)
- [Featurize Text](p. 1269)
- [Handle Outliers](p. 1282)
- [Handle Missing Values](p. 1284)

If you used sampling to import your data, the preceding transforms only use the data from the sample to create the column. The transform might not have used all of the relevant data. For example, if you use the Encode Categorical transform, there might have been a category in the entire dataset that wasn’t present in the sample.

You can either use a destination node or a Jupyter notebook to refit the transformations to the entire dataset. When Data Wrangler exports the transformations in the flow, it creates a SageMaker processing job. When the processing job finishes, Data Wrangler saves the following files in either the default Amazon S3 location or an S3 location that you specify:

- The Data Wrangler flow file that specifies the transformations that are refit to the dataset
- The dataset with the refit transformations applied to it

You can open a Data Wrangler flow file within Data Wrangler and apply the transformations to a different dataset. For example, if you've applied the transformations to a training dataset, you can open and use the Data Wrangler flow file to apply the transformations to a dataset used for inference.

For a information about using destination nodes to refit transforms and export see the following pages:

- [Export to Amazon S3](p. 1313)
- [Export to Amazon SageMaker Feature Store](p. 1323)

Use the following procedure to run a Jupyter notebook to refit the transformations and export the data.

To run a Jupyter notebook and to refit the transformations and export your Data Wrangler flow, do the following.

1. Choose the + next to the node that you want to export.
2. Choose Export to.
3. Choose the location to which you're exporting the data.
4. For the `refit_trained_params` object, set `refit` to `True`.
5. For the `output_flow` field, specify the name of the output flow file with the refit transformations.
6. Run the Jupyter notebook.

### Create a Schedule to Automatically Process New Data

If you're processing data periodically, you can create a schedule to run the processing job automatically. For example, you can create a schedule that runs a processing job automatically when you get new data. For more information about processing jobs, see [Export to Amazon S3](p. 1313) and [Export to Amazon SageMaker Feature Store](p. 1323).

When you create a job you must specify an IAM role that has permissions to create the job. By default, the IAM role that you use to access Data Wrangler is the `SageMakerExecutionRole`.

The following permissions allow Data Wrangler to access EventBridge and allow EventBridge to run processing jobs:

- Add the following AWS Managed policy to the Amazon SageMaker Studio execution role that provides Data Wrangler with permissions to use EventBridge:

  ```
  arn:aws:iam::aws:policy/AmazonEventBridgeFullAccess
  ```

  For more information about the policy, see [AWS managed policies for EventBridge](.)

- Add the following policy to the IAM role that you specify when you create a job in Data Wrangler:

  ```
  { 
  "Version": "2012-10-17",
  "Statement": [
  {
  "Effect": "Allow",
  "Action": "sagemaker:StartPipelineExecution",
  }
  ]
  }
  ```

  If you're using the default IAM role, you add the preceding policy to the Amazon SageMaker Studio execution role.

  Add the following trust policy to the role to allow EventBridge to assume it.

  ```
  { 
  "Effect": "Allow",
  "Principal": {
  "Service": "events.amazonaws.com"
  },
  "Action": "sts:AssumeRole"
  }
  ```
When you create a schedule, Data Wrangler creates an eventRule in EventBridge. You incur charges for both the event rules that you create and the instances used to run the processing job.

For information about EventBridge pricing, see Amazon EventBridge pricing. For information about processing job pricing, see Amazon SageMaker Pricing.

You can set a schedule using one of the following methods:

- **CRON expressions**
  - **Note**
    - Data Wrangler doesn't support the following expressions:
      - LW#
      - Abbreviations for days
      - Abbreviations for months
  - **RATE expressions**
  - Recurring – Set an hourly or daily interval to run the job.
  - Specific time – Set specific days and times to run the job.

The following sections provide procedures on creating jobs.

**CRON**

Use the following procedure to create a schedule with a CRON expression.

To specify a schedule with a CRON expression, do the following.

1. Open your Data Wrangler flow.
2. Choose **Create job**.
3. (Optional) For **Output KMS key**, specify an AWS KMS key to configure the output of the job.
4. Choose **Next, 2. Configure job**.
5. Select **Associate Schedules**.
6. Choose **Create a new schedule**.
7. For **Schedule Name**, specify the name of the schedule.
8. For **Run Frequency**, choose **CRON**.
9. Specify a valid CRON expression.
10. Choose **Create**.
11. (Optional) Choose **Add another schedule** to run the job on an additional schedule.

- **Note**
  - You can associate a maximum of two schedules. The schedules are independent and don’t affect each other unless the times overlap.

12. Choose one of the following:

   - **Schedule and run now** – Data Wrangler the job runs immediately and subsequently runs on the schedules.
   - **Schedule only** – Data Wrangler the job only runs on the schedules that you specify.

13. Choose **Run**

**RATE**

Use the following procedure to create a schedule with a RATE expression.
To specify a schedule with a RATE expression, do the following.

1. Open your Data Wrangler flow.
2. Choose Create job.
3. (Optional) For Output KMS key, specify an AWS KMS key to configure the output of the job.
5. Select Associate Schedules.
6. Choose Create a new schedule.
7. For Schedule Name, specify the name of the schedule.
8. For Run Frequency, choose Rate.
9. For Value, specify an integer.
10. For Unit, select one of the following:
    - Minutes
    - Hours
    - Days
11. Choose Create.
12. (Optional) Choose Add another schedule to run the job on an additional schedule.

    **Note**
    You can associate a maximum of two schedules. The schedules are independent and don't affect each other unless the times overlap.

13. Choose one of the following:
    - Schedule and run now – Data Wrangler the job runs immediately and subsequently runs on the schedules.
    - Schedule only – Data Wrangler the job only runs on the schedules that you specify.
14. Choose Run

Recurring

Use the following procedure to create a schedule that runs a job on a recurring basis.

To specify a schedule with a CRON expression, do the following.

1. Open your Data Wrangler flow.
2. Choose Create job.
3. (Optional) For Output KMS key, specify an AWS KMS key to configure the output of the job.
5. Select Associate Schedules.
6. Choose Create a new schedule.
7. For Schedule Name, specify the name of the schedule.
8. For Run Frequency, make sure Recurring is selected by default.
9. For Every x hours, specify the hourly frequency that the job runs during the day. Valid values are integers in the inclusive range of 1 and 23.
10. For On days, select one of the following options:
    - Every Day
    - Weekends
    - Weekdays
• Select Days

• (Optional) If you've selected Select Days, choose the days of the week to run the job.

**Note**
The schedule resets every day. If you schedule a job to run every five hours, it runs at the following times during the day:

• 00:00
• 05:00
• 10:00
• 15:00
• 20:00

11. Choose Create.
12. (Optional) Choose Add another schedule to run the job on an additional schedule.

**Note**
You can associate a maximum of two schedules. The schedules are independent and don't affect each other unless the times overlap.

13. Choose one of the following:

• **Schedule and run now** – Data Wrangler the job runs immediately and subsequently runs on the schedules.

• **Schedule only** – Data Wrangler the job only runs on the schedules that you specify.

14. Choose Run

**Specific time**

Use the following procedure to create a schedule that runs a job at specific times.

To specify a schedule with a CRON expression, do the following.

1. Open your Data Wrangler flow.
2. Choose Create job.
3. (Optional) For Output KMS key, specify an AWS KMS key to configure the output of the job.
5. Select Associate Schedules.
6. Choose Create a new schedule.
7. For Schedule Name, specify the name of the schedule.
8. Choose Create.
9. (Optional) Choose Add another schedule to run the job on an additional schedule.

**Note**
You can associate a maximum of two schedules. The schedules are independent and don't affect each other unless the times overlap.

10. Choose one of the following:

• **Schedule and run now** – Data Wrangler the job runs immediately and subsequently runs on the schedules.

• **Schedule only** – Data Wrangler the job only runs on the schedules that you specify.

11. Choose Run
You can use Amazon SageMaker Studio view the jobs that are scheduled to run. Your processing jobs run within SageMaker Pipelines. Each processing job has its own pipeline. It runs as a processing step within the pipeline. You can view the schedules that you've created within a pipeline. For information about viewing a pipeline, see View a Pipeline (p. 2876).

Use the following procedure to view the jobs that you've scheduled.

To view the jobs you've scheduled, do the following.

1. Open Amazon SageMaker Studio.
2. Open SageMaker Pipelines
3. View the pipelines for the jobs that you've created.
   - The pipeline running the job uses the job name as a prefix. For example, if you've created a job named housing-data-feature-engineering, the name of the pipeline is data-wrangler-housing-data-feature-engineering.
4. Choose the pipeline containing your job.
5. View the status of the pipelines. Pipelines with a Status of Succeeded have run the processing job successfully.

To stop the processing job from running, do the following:

To stop a processing job from running, delete the event rule that specifies the schedule. Deleting an event rule stops all the jobs associated with the schedule from running. For information about deleting a rule, see Disabling or deleting an Amazon EventBridge rule.

You can stop and delete the pipelines associated with the schedules as well. For information about stopping a pipeline, see StopPipelineExecution. For information about deleting a pipeline, see DeletePipeline.

Use an Interactive Data Preparation Widget in an Amazon SageMaker Studio Notebook to Get Data Insights

Use the Data Wrangler data preparation widget to interact with your data, get visualizations, explore actionable insights, and fix data quality issues.

You can access the data preparation widget from an Amazon SageMaker Studio notebook. For each column, the widget creates a visualization that helps you better understand its distribution. If a column has data quality issues, a warning appears in its header.

To see the data quality issues, select the column header showing the warning. You can use the information that you get from the insights and the visualizations to apply the widget's built-in transformations to help you fix the issues.

For example, the widget might detect that you have a column that only has one unique value and show you a warning. The warning provides the option to drop the column from the dataset.

Getting started with running the widget

Use the following information to help you get started with running a notebook.

Open a notebook in Amazon SageMaker Studio. For information about opening a notebook, see Create or Open an Amazon SageMaker Studio Notebook (p. 225).
Important
To run the widget, the notebook must use one of the following images:

- Python 3 (Data Science) with Python 3.7
- Python 3 (Data Science 2.0) with Python 3.8
- Python 3 (Data Science 3.0) with Python 3.10
- SparkAnalytics 1.0
- SparkAnalytics 2.0

For more information about images, see Available Amazon SageMaker Images (p. 244).

Use the following code to import the data preparation widget and pandas. The widget uses pandas dataframes to analyze your data.

```python
import pandas as pd
import sagemaker_datawrangler
```

The following example code loads a file into the dataframe called `df`.

```python
df = pd.read_csv("example-dataset.csv")
```

You can use a dataset in any format that you can load as a pandas dataframe object. For more information about pandas formats, see IO tools (text, CSV, HDF5, ...).

The following cell runs the `df` variable to start the widget.

```python
df
```

The top of the dataframe has the following options:

- **View the Pandas table**  Switches between the interactive visualization and a pandas table.
- **Use all of the rows in your dataset to compute the insights. Using the entire dataset might increase the time it takes to generate the insights.**  – If you don’t select the option, Data Wrangler computes the insights for the first 10,000 rows of the dataset.

The dataframe shows the first 1000 rows of the dataset. Each column header has a stacked bar chart that shows the column’s characteristics. It shows the proportion of valid values, invalid values, and missing values. You can hover over the different portions of the stacked bar chart to get the calculated percentages.

Each column has a visualization in the header. The following shows the types of visualizations the columns can have:

- Categorical – Bar chart
- Numeric – Histogram
- Datetime – Bar chart
- Text – Bar chart

For each visualization, the data preparation widget highlights outliers in orange.

When you choose a column, it opens a side panel. The side panel shows you the **Insights** tab. The pane provides a count for the following types of values:

- Invalid values – Values whose type doesn’t match the column type.
• Missing values – Values that are missing, such as NaN or None.
• Valid values – Values that are neither missing nor invalid.

For numeric columns, the **Insights** tab shows the following summary statistics:

• Minimum – The smallest value.
• Maximum – The largest value.
• Mean – The mean of the values.
• Mode – The value that appears most frequently.
• Standard deviation – The standard deviation of the values.

For categorical columns, the **Insights** tab shows the following summary statistics:

• Unique values – The number of unique values in the column.
• Top – The value that appears most frequently.

The columns that have warning icons in their headers have data quality issues. Choosing a column opens a **Data quality** tab that you can use to find transforms to help you fix the issue. A warning has one of the following severity levels:

• Low – Issues that might not affect your analysis, but can be useful to fix.
• Medium – Issues that are likely to affect your analysis, but are likely not critical to fix.
• High – Severe issues that we strongly recommend fixing.

**Note**
The widget sorts the column to show the values that have data quality issues at the top of the dataframe. It also highlights the values that are causing the issues. The color of the highlighting corresponds to the severity level.

Under **SUGGESTED TRANSFORMS**, you can choose a transform to fix the data quality issue. The widget can offer multiple transforms that can fix the issue. It can offer recommendations for the transforms that are best suited to the problem. You can move your cursor over the transform to get more information about it.

To apply a transform to the dataset, choose **Apply and export code**. The transform modifies the dataset and updates the visualization with modified values. The code for the transform appears in the following cell of the notebook. If you apply additional transforms to the dataset, the widget appends the transforms to the cell. You can use the code that the widget generates to do the following:

• Customize it to better fit your needs.
• Use it in your own workflows.

You can reproduce all the transforms you've made by rerunning all of the cells in the notebook.

The widget can provide insights and warnings for the target column. The target column is the column that you're trying to predict. Use the following procedure to get target column insights.

To get target column insights, do the following.

1. Choose the column that you're using as the target column.
2. Choose **Select as target column**.
3. Choose the problem type. The widget’s insights and warnings are tailored to the problem types. The following are the problem types:
• **Classification** – The target column has categorical data.
• **Regression** – The target column has numeric data.

5. (Optional) Under **Target Column Insights**, choose one of the suggested transforms.

**Reference for the insights and transforms in the widget**

For feature columns (columns that aren't the target column), you can get the following insights to warn you about issues with your dataset.

• **Missing values** – The column has missing values such as None, NaN (not a number), or NaT (not a timestamp). Many machine learning algorithms don't support missing values in the input data. Filling them in or dropping the rows with missing data is therefore a crucial data preparation step. If you see the missing values warning, you can use one of the following transforms to correct the issue.
  • **Drop missing** – Drops rows with missing values. We recommend dropping rows when the percentage of rows with missing data is small and imputing the missing values isn't appropriate.
  • **Replace with new value** – Replaces textual missing values with Other. You can change Other to a different value in the output code. Replaces numeric missing values with 0.
  • **Replace with mean** – Replaces missing values with the mean of the column.
  • **Replace with median** – Replaces missing values with the median of the column.
  • **Drop column** – Drops the column with missing values from the dataset. We recommend dropping the entire column when there's a high percentage of rows with missing data.

• **Disguised missing values** – The column has disguised missing values. A disguised missing value is a value that isn't explicitly encoded as a missing value. For example, instead of using a NaN to indicate a missing value, the value could be Placeholder. You can use one of the following transforms to handle the missing values:
  • **Drop missing** – Drops rows with missing values
  • **Replace with new value** – Replaces textual missing values with Other. You can change Other to a different value in the output code. Replaces numeric missing values with 0.

• **Constant column** – The column only has one value. It therefore has no predictive power. We strongly recommend using the **Drop column** transform to drop the column from the dataset.

• **ID column** – The column has no repeating values. All of the values in the column are unique. They might be either IDs or database keys. Without additional information, the column has no predictive power. We strongly recommend using the **Drop column** transform to drop the column from the dataset.

• **High cardinality** – The column has a high percentage of unique values. High cardinality limits the predictive power of categorical columns. Examine the importance of the column in your analysis and consider using the **Drop column** transform to drop it.

For the target column, you can get the following insights to warn you about issues with your dataset. You can use the suggested transformation provided with the warning to correct the issue.

• **Mixed data types in target (Regression)** – There are some non-numeric values in the target column. There might be data entry errors. We recommend removing the rows that have the values that can't be converted.

• **Frequent label** – Certain values in the target column appear more frequently than what would be normal in the context of regression. There might be an error in data collection or processing. A frequently appearing category might indicate that either the value is used as a default value or that it's a placeholder for missing values. We recommend using the **Replace with new value** transform to replace the missing values with Other.
• **Too few instances per class** – The target column has categories that appear rarely. Some of the categories don't have enough rows for the target column to be useful. You can use one of the following transforms:
  • **Drop rare target** – Drops unique values with fewer than ten observations. For example, drops the value `cat` if it appears nine times in the column.
  • **Replace rare target** – Replaces categories that appear rarely in the dataset with the value `Other`.
  • **Classes too imbalanced (multi-class classification)** – There are categories in the dataset that appear much more frequently than the other categories. The class imbalance might affect prediction accuracy. For the most accurate predictions possible, we recommend updating the dataset with rows that have the categories that currently appear less frequently.

• **Large amount of classes/too many classes** – There's a large number of classes in the target column. Having many classes might result in longer training times or poor predictive quality. We recommend doing one of the following:
  • Grouping some of the categories into their own category. For example, if six categories are closely related, we recommend using a single category for them.
  • Using an ML algorithm that's resilient to multiple categories.

**Security and Permissions**

When you query data from Athena or Amazon Redshift, the queried dataset is automatically stored in the default SageMaker S3 bucket for the AWS Region in which you are using Studio. Additionally, when you export a Jupyter Notebook from Amazon SageMaker Data Wrangler and run it, your data flows, or .flow files, are saved to the same default bucket, under the prefix `data_wrangler_flows`.

For high-level security needs, you can configure a bucket policy that restricts the AWS roles that have access to this default SageMaker S3 bucket. Use the following section to add this type of policy to an S3 bucket. To follow the instructions on this page, use the AWS Command Line Interface (AWS CLI). To learn how, see [Configuring the AWS CLI](#) in the IAM User Guide.

Additionally, you need to grant each IAM role that uses Data Wrangler permissions to access required resources. If you do not require granular permissions for the IAM role you use to access Data Wrangler, you can add the IAM managed policy, `AmazonSageMakerFullAccess`, to an IAM role that you use to create your Studio user. This policy grants you full permission to use Data Wrangler. If you require more granular permissions, refer to the section, [Grant an IAM Role Permission to Use Data Wrangler (p. 1340)](#).

**Add a Bucket Policy To Restrict Access to Datasets Imported to Data Wrangler**

You can add a policy to the S3 bucket that contains your Data Wrangler resources using an Amazon S3 bucket policy. Resources that Data Wrangler uploads to your default SageMaker S3 bucket in the AWS Region you are using Studio in include the following:

• Queried Amazon Redshift results. These are stored under the `redshift/` prefix.
• Queried Athena results. These are stored under the `athena/` prefix.
• The .flow files uploaded to Amazon S3 when you run an exported Jupyter Notebook Data Wrangler produces. These are stored under the `data_wrangler_flows/` prefix.

Use the following procedure to create an S3 bucket policy that you can add to restrict IAM role access to that bucket. To learn how to add a policy to an S3 bucket, see [How do I add an S3 Bucket policy?](#).

**To set up a bucket policy on the S3 bucket that stores your Data Wrangler resources:**

1. Configure one or more IAM roles that you want to be able to access Data Wrangler.
2. Open a command prompt or shell. For each role that you create, replace `role-name` with the name of the role and run the following:

```
$ aws iam get-role --role-name role-name
```

In the response, you see a `RoleId` string which begins with AROA. Copy this string.

3. Add the following policy to the SageMaker default bucket in the AWS Region in which you are using Data Wrangler. Replace `region` with the AWS Region in which the bucket is located, and `account-id` with your AWS account ID. Replace `userIds` starting with `AROAEXAMPLEID` with the IDs of an AWS roles to which you want to grant permission to use Data Wrangler.

```
{
    "Version": "2012-10-17",
    "Statement": [  
        {
            "Effect": "Deny",
            "Principal": "*",
            "Action": "s3:*",
            "Resource": [  
                "arn:aws:s3:::sagemaker-region-account-id/data_wrangler_flows/",
                "arn:aws:s3:::sagemaker-region-account-id/data_wrangler_flows/*",
                "arn:aws:s3:::sagemaker-region-account-id/athena",
                "arn:aws:s3:::sagemaker-region-account-id/athena/*",
                "arn:aws:s3:::sagemaker-region-account-id/redshift",
                "arn:aws:s3:::sagemaker-region-account-id/redshift/*"
            ],
            "Condition": {  
                "StringNotLike": {  
                    "aws:userId": [  
                        "AROAEXAMPLEID_1:*",
                        "AROAEXAMPLEID_2:*"
                    ]  
                }
            }
        }
    ]
}
```

Create an Allowlist for Data Wrangler

Whenever a user starts running Data Wrangler from the Amazon SageMaker Studio user interface, they make call to the SageMaker application programming interface (API) to create a Data Wrangler application.

Your organization might not provide your users with permissions to make those API calls by default. To provide permissions, you must create and attach a policy to the user's IAM roles using the following policy template: Data Wrangler Allow List Example.

**Note**

The preceding policy example only gives your users access to the Data Wrangler application.

For information about creating a policy, see Creating policies on the JSON tab. When you're creating a policy, copy and paste the JSON policy from Data Wrangler Allow List Example in the JSON tab.

**Important**

Delete any IAM policies that prevent users from running the following operations:

- CreateApp
- DescribeApp
If you don’t delete the policies, your users could still be affected by them.

After you've creating the policy using the template, attach it to the IAM roles of your users. For information about attaching a policy, see Adding IAM identity permissions (console).

**Grant an IAM Role Permission to Use Data Wrangler**

You can grant an IAM role permission to use Data Wrangler with the general IAM managed policy, AmazonSageMakerFullAccess. This is a general policy that includes permissions required to use all SageMaker services. This policy grants an IAM role full access to Data Wrangler. You should be aware of the following when using AmazonSageMakerFullAccess to grant access to Data Wrangler:

- If you import data from Amazon Redshift, the **Database User** name must have the prefix sagemaker_access.
- This managed policy only grants permission to access buckets with one of the following in the name: SageMaker, SageMaker, sagemaker, or aws-glue. If you want to use Data Wrangler to import from an S3 bucket without these phrases in the name, refer to the last section on this page to learn how to grant permission to an IAM entity to access your S3 buckets.

If you have high-security needs, you can attach the policies in this section to an IAM entity to grant permissions required to use Data Wrangler.

If you have datasets in Amazon Redshift or Athena that an IAM role needs to import from Data Wrangler, you must add a policy to that entity to access these resources. The following policies are the most restrictive policies you can use to give an IAM role permission to import data from Amazon Redshift and Athena.

To learn how to attach a custom policy to an IAM role, refer to Managing IAM policies in the IAM User Guide.

**Policy example to grant access to an Athena dataset import**

The following policy assumes that the IAM role has permission to access the underlying S3 bucket where data is stored through a separate IAM policy.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "athena:ListDataCatalogs",
        "athena:ListDatabases",
        "athena:ListTableMetadata",
        "athena:GetQueryExecution",
        "athena:GetQueryResults",
        "athena:StartQueryExecution",
        "athena:StopQueryExecution"
      ],
      "Resource": [
        "*"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
        "glue:CreateTable"
      ],
      "Resource": [
        "arn:aws:glue:*:*:table/*/sagemaker_tmp_*",
        "arn:aws:glue:*:*:table/sagemaker_featurestore/*"
      ]
    }
  ]
}
```
Policy example to grant access to an Amazon Redshift dataset import

The following policy grants permission to set up an Amazon Redshift connection to Data Wrangler using database users that have the prefix `sagemaker_access` in the name. To grant permission to connect using additional database users, add additional entries under "Resources" in the following policy. The following policy assumes that the IAM role has permission to access the underlying S3 bucket where data is stored through a separate IAM policy, if applicable.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "redshift-data:ExecuteStatement",
                "redshift-data:DescribeStatement",
                "redshift-data:CancelStatement",
                "redshift-data:GetStatementResult",
                "redshift-data:ListSchemas"
            ],
            "Resource": [
                "arn:aws:s3:::bucket/your-bucket-name",
                "arn:aws:s3:::bucket/your-other-bucket-name"
            ]
        }
    ]
}
```
Policy to grant access to an S3 bucket

If your dataset is stored in Amazon S3, you can grant an IAM role permission to access this bucket with a policy similar to the following. This example grants programmatic read-write access to the bucket named `test`.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["s3:ListBucket"],
      "Resource": ["arn:aws:s3:::test"]
    },
    {
      "Effect": "Allow",
      "Action": ["s3:PutObject", "s3:GetObject", "s3:DeleteObject"],
      "Resource": ["arn:aws:s3:::test/\*"]
    }
  ]
}
```

To import data from Athena and Amazon Redshift, you must grant an IAM role permission to access the following prefixes under the default Amazon S3 bucket in the AWS Region Data Wrangler in which is being used: `athena/`, `redshift/`. If a default Amazon S3 bucket does not already exist in the AWS Region, you must also give the IAM role permission to create a bucket in this region.

Additionally, if you want the IAM role to be able to use the Amazon SageMaker Feature Store, SageMaker Pipelines, and Data Wrangler job export options, you must grant access to the prefix `data_wrangler_flows/` in this bucket.

Data Wrangler uses the `athena/` and `redshift/` prefixes to store preview files and imported datasets. To learn more, see `Imported Data Storage (p. 1226)`.

Data Wrangler uses the `data_wrangler_flows/` prefix to store .flow files when you run a Jupyter Notebook exported from Data Wrangler. To learn more, see `Export (p. 1311)`.

Use a policy similar to the following to grant the permissions described in the preceding paragraphs.

```json
{
  "redshift-data:ListTables"
}
```
You can also access data in your Amazon S3 bucket from another AWS account by specifying the Amazon S3 bucket URI. To do this, the IAM policy that grants access to the Amazon S3 bucket in the other account should use a policy similar to the following example, where BucketFolder is the specific directory in the user's bucket UserBucket. This policy should be added to the user granting access to their bucket for another user.

```json
{
    "Version": "2012-10-17",
    "Statement": [
    {
        "Effect": "Allow",
        "Action": [
            "s3:GetObject",
            "s3:PutObject",
            "s3:PutObjectAcl"
        ],
        "Resource": "arn:aws:s3:::UserBucket/BucketFolder/**"
    },
    {
        "Effect": "Allow",
        "Action": [
            "s3:ListBucket"
        ],
        "Resource": "arn:aws:s3:::UserBucket",
        "Condition": {
            "StringLike": {
                "s3:prefix": [
                    "BucketFolder/**"
                ]
            }
        }
    }
]
}
The user that is accessing the bucket (not the bucket owner) must add a policy similar to the following example to their user. Note that `AccountX` and `TestUser` below refers to the bucket owner and their user respectively.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::AccountX:user/TestUser"
      },
      "Action": [
        "s3:GetObject",
        "s3:PutObject",
        "s3:PutObjectAcl"
      ],
      "Resource": [
        "arn:aws:s3:::UserBucket/BucketFolder/**"
      ]
    },
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::AccountX:user/TestUser"
      },
      "Action": [
        "s3:ListBucket"
      ],
      "Resource": [
        "arn:aws:s3:::UserBucket"
      ]
    }
  ]
}
```

**Policy example to grant access to use SageMaker Studio**

Use a policy like to the following to create an IAM execution role that can be used to set up a Studio instance.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "sagemaker:CreatePresignedDomainUrl",
        "sagemaker:DescribeDomain",
        "sagemaker:ListDomains",
        "sagemaker:DescribeUserProfile",
        "sagemaker:ListUserProfiles",
        "sagemaker:*App",
        "sagemaker:ListApps"
      ],
      "Resource": "*"
    }
  ]
}
```
Snowflake and Data Wrangler

All permissions for AWS resources are managed via your IAM role attached to your Studio instance. The Snowflake administrator manages Snowflake-specific permissions, as they can grant granular permissions and privileges to each Snowflake user. This includes databases, schemas, tables, warehouses, and storage integration objects. You must ensure that the correct permissions are set up outside of Data Wrangler.

Note that the Snowflake COPY INTO Amazon S3 command moves data from Snowflake to Amazon S3 over the public internet by default, but data in transit is secured using SSL. Data at rest in Amazon S3 is encrypted with SSE-KMS using the default AWS KMS key.

With respect to Snowflake credentials storage, Data Wrangler does not store customer credentials. Data Wrangler uses Secrets Manager to store the credentials in a secret and rotates secrets as part of a best practice security plan. The Snowflake or Studio administrator needs to ensure that the data scientist’s Studio execution role is granted permission to perform GetSecretValue on the secret storing the credentials. If already attached to the Studio execution role, the AmazonSageMakerFullAccess policy has the necessary permissions to read secrets created by Data Wrangler and secrets created by following the naming and tagging convention in the instructions above. Secrets that do not follow the conventions must be separately granted access. We recommend using Secrets Manager to prevent sharing credentials over unsecured channels; however, note that a logged-in user can retrieve the plain-text password by launching a terminal or Python notebook in Studio and then invoking API calls from the Secrets Manager API.

Data Encryption with AWS KMS

Within Data Wrangler, you can decrypt encrypted files and add them to your Data Wrangler flow. You can also encrypt the output of the transforms using either a default AWS KMS key or one that you provide.

You can import files if they have the following:

- server-side encryption
- SSE-KMS as the encryption type

To decrypt the file and import to a Data Wrangler flow, you must add the SageMaker Studio user that you’re using as a key user.

The following screenshot shows a Studio user role added as a key user. See IAM Roles to access users under the left panel to make this change.

<table>
<thead>
<tr>
<th>Key users</th>
</tr>

<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>Admin</td>
</tr>
</tbody>
</table>

AmazonSageMaker-ExecutionRole-20210409T160134
Amazon S3 customer managed key setup for Data Wrangler imported data storage

By default, Data Wrangler uses Amazon S3 buckets that have the following naming convention: `sagemaker-region-account number`. For example, if your account number is 111122223333 and you are using Studio in us-east-1, your imported datasets are stored with the following naming convention: `sagemaker-us-east-1-111122223333`.

The following instructions explain how to set up a customer managed key for your default Amazon S3 bucket.

1. To enable server-side encryption and setup a customer managed key for your default S3 bucket, see Using KMS Encryption.
2. After following step 1, navigate to AWS KMS in your AWS Management Console. Find the customer managed key you selected in step 1 of the previous step and add the Studio role as the key user. To do this, follow the instructions in Allows key users to use a customer managed key.

Encrypting the Data That You Export

You can encrypt the data that you export using one of the following methods:

- Specifying that your Amazon S3 bucket has object use SSE-KMS encryption.
- Specifying an AWS KMS key to encrypt the data that you export from Data Wrangler.

On the Export data page, specify a value for the AWS KMS key ID or ARN.

For more information on using AWS KMS keys, see Protecting Data Using Server-Side Encryption with AWS KMS keys Stored in AWS Key Management Service (SSE-KMS).

Amazon AppFlow Permissions

When you're performing a transfer, you must specify an IAM role that has permissions to perform the transfer. You can use the same IAM role that has permissions to use Data Wrangler. By default, the IAM role that you use to access Data Wrangler is the SageMakerExecutionRole.

The IAM role must have the following permissions:

- Permissions to Amazon AppFlow
- Permissions to the AWS Glue Data Catalog
- Permissions for AWS Glue to discover the data sources that are available

When you run a transfer, Amazon AppFlow stores metadata from the transfer in the AWS Glue Data Catalog. Data Wrangler uses the metadata from the catalog to determine whether it's available for you to query and import.

To add permissions to Amazon AppFlow, add the AmazonAppFlowFullAccess AWS managed policy to the IAM role. For more information about adding policies, see Adding or removing IAM identity permissions.

If you're transferring data to Amazon S3, you must also attach the following policy.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
```
To add AWS Glue permissions, add the AWSGlueConsoleFullAccess managed policy to the IAM role. For more information about AWS Glue permissions with Amazon AppFlow, see [link-to-appflow-page].

Amazon AppFlow needs to access AWS Glue and Data Wrangler for you to import the data that you’ve transferred. To grant Amazon AppFlow access, add the following trust policy to the IAM role:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::<123456789012>:root",
                "Service": [
                    "appflow.amazonaws.com"
                ]
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

To display the Amazon AppFlow data in Data Wrangler, add the following policy to the IAM role:
Using Lifecycle Configurations in Data Wrangler

You might have an Amazon EC2 instance that is configured to run Kernel Gateway applications, but not the Data Wrangler application. Kernel Gateway applications provide access to the environment and the kernels that you use to run Studio notebooks and terminals. The Data Wrangler application is the UI application that runs Data Wrangler. Amazon EC2 instances that aren’t Data Wrangler instances require a modification to their lifecycle configurations to run Data Wrangler. Lifecycle configurations are shell scripts that automate the customization of your Amazon SageMaker Studio environment.

For more information about lifecycle configurations, see Use lifecycle configurations with Amazon SageMaker Studio (p. 271).

The default lifecycle configuration for your instance doesn’t support using Data Wrangler. You can make the following modifications to the default configuration to use Data Wrangler with your instance.

```bash
#!/bin/bash
set -eux
STATUS=$((
    python3 -c "import sagemaker_dataprep"
    echo $?
))
if [ "$STATUS" -eq 0 ]; then
echo 'Instance is of Type Data Wrangler'
else
echo 'Instance is not of Type Data Wrangler'
fi

# Replace this with the URL of your git repository
export REPOSITORY_URL="https://github.com/aws-samples/sagemaker-studio-lifecycle-config-examples.git"
git -C /root clone $REPOSITORY_URL
fi

You can save the script as lifecycle_configuration.sh.

You attach the lifecycle configuration to your Studio domain or user profile. For more information about creating and attaching a lifecycle configuration, see Create and associate a lifecycle configuration (p. 271).

The following instructions show you how to attach a lifecycle configuration to a Studio domain or user profile.
You might run into errors when you're creating or attaching a lifecycle configuration. For information about debugging lifecycle configuration errors, KernelGateway app failure (p. 281).

## Release Notes

Data Wrangler is regularly updated with new features and bug fixes. To upgrade the version of Data Wrangler you are using in Studio, follow the instructions in Shut down and Update Studio Apps (p. 293).

<table>
<thead>
<tr>
<th>Date</th>
<th>New functionality</th>
</tr>
</thead>
<tbody>
<tr>
<td>8/31/2023</td>
<td>You can now create a Data Quality and Insights report on your entire dataset. For more information, see Get Insights On Data and Data Quality (p. 1239).</td>
</tr>
<tr>
<td>5/20/2023</td>
<td>You can now import your data from Salesforce Data Cloud. For more information, see Import data from Salesforce Data Cloud (p. 1200).</td>
</tr>
<tr>
<td>4/18/2023</td>
<td>You can now get your data in a format that Amazon Personalize can interpret. For more information, see Map Columns for Amazon Personalize (p. 1296).</td>
</tr>
<tr>
<td>3/1/2023</td>
<td>You can now use Hive to import your data from Amazon EMR. For more information, see Import data from Amazon EMR (p. 1190).</td>
</tr>
<tr>
<td>12/10/2022</td>
<td>You can now export your Data Wrangler flow to an inference endpoint. For more information, see Export to an Inference Endpoint (p. 1320).</td>
</tr>
<tr>
<td>10/12/2022</td>
<td>You can now import data from SaaS platforms. For more information, see Import Data From Software as a Service (SaaS) Platforms (p. 1223).</td>
</tr>
</tbody>
</table>
Release Notes
You can now reuse data flows for different data sets. For more information, see Reusing Data Flows for Different Datasets (p. 1304).

10/05/2022
New functionality:
You can now use Principal Component Analysis (PCA) as a transform. For more information, see Reduce Dimensionality within a Dataset (p. 1265).

10/05/2022
New functionality:
You can now refit parameters in your Data Wrangler flow. For more information, see Export (p. 1311).

10/03/2022
New functionality:
You can now deploy models from your Data Wrangler flow. For more information, see Automatically Train Models on Your Data Flow (p. 1252).

9/20/2022
New functionality:
You can now set data retention periods in Athena. For more information, see Import data from Athena (p. 1183).

6/9/2022
New functionality:
You can now use Amazon SageMaker Autopilot to train a model directly from your Data Wrangler flow. For more information, see Automatically Train Models on Your Data Flow (p. 1252).

5/6/2022
New functionality:
You can now use additional m5 and r5 instances. For more information, see Instances (p. 1227).

4/27/2022
New functionalities:
• You can now get a data quality report. For more information, see Get Insights On Data and Data Quality (p. 1239)
• You can now perform random sampling and stratified sampling. For more information, see Sampling (p. 1286).

4/1/2022
New functionality:
You can now use Databricks as a data source. For more information, see Import data from Databricks (JDBC) (p. 1198).
Release Notes

2/2/2022

New functionalities:

- You can now export using destination nodes. For more information, see Export (p. 1311).
- You can import ORC and JSON files. For more information about file types, see Import (p. 1178).
- Data Wrangler now supports using the SMOTE transform. For more information, see Balance Data (p. 1259).
- Data Wrangler now supports similarity encoding for categorical data. For more information, see Similarity encode (p. 1268).
- Data Wrangler now supports unnesting JSON data. For more information, see Unnest JSON Data (p. 1291).
- Data Wrangler now supports expanding the values of an array into separate columns. For more information, see Explode Array (p. 1292).
- Data Wrangler now supports reaching out to the service team when you're having issues. For more information, see Troubleshoot (p. 1353).
- Data Wrangler supports editing and deleting steps in your data flow. For more information, see Delete a Step from Your Data Flow (p. 1231) and Edit a Step in Your Data Wrangler Flow (p. 1236).
- You can now perform transformations on multiple columns. For more information, see Transform Data (p. 1253).
- Data Wrangler now supports cost allocation tags. For more information, see Using Cost Allocation Tags.

10/16/2021

New functionality:

Data Wrangler now supports Athena workgroups. For more information, see Import data from Athena (p. 1183).

10/6/2021

New functionality:

Data Wrangler now supports transforming time series data. For more information, see Transform Time Series (p. 1271).

7/15/2021

New functionalities:

- Snowflake and Data Wrangler (p. 1345) is now supported. You can use Snowflake as a data source in Data Wrangler.
- Added support for custom field delimiter in CSV. Now comma, colon, semicolon, pipe (|) and Tab are supported.
- Now you can export results directly to Amazon S3.
- Added a few new multicollinearity analyzers: Variance Inflation Factors, Principal Component Analysis and Lasso feature selection.

Enhancements:

- The analyze charts can no longer be could be packed with overlapping labels.
## Release Notes

### Bug Fixes:
- One-hot encoder handles empty string gracefully.
- Fixed crashes that occurred when a dataframe column name contained dots.

### 4/26/2021

### Enhancements:
- Added support for distributed processing Jobs. You can use multiple instances when running a processing job.
- Data Wrangler Processing job now automatically coalesces small outputs when estimated result size is less than 1 gigabytes.
- Feature Store Notebook: Improved feature store ingestion performance
- Data Wrangler Processing jobs now use 1.x as the authoritative container tag for future releases.

### Bug Fixes:
- Fixed rendering issues for faceted histogram.
- Fixed **Export to Processing Job** to support vector type columns.
- Fixed **Extract using regex operator** to return the first captured group if one or more exists in the regular expression or regex.

### 2/8/2021

### New Functionalities:
- Data Wrangler Flows supports multiple instances.
- Updated Export to Data Wrangler Job Notebook to use SageMaker SDK 2.20.0.
- Updated Export to Pipeline Notebook to use SageMaker SDK 2.20.0.
- Updated Export to Pipeline Notebook to add XGBoost training example as an optional step.

### Enhancements:
- To improve performance, importing CSV files that contain multiple lines in a single field is no longer supported.

### Bug Fixes:
- Fixed type inference issue in Quick model.
- Fixed the bias metric bug in bias reports.
- Fixed the Featurize text transform to work with columns with missing values.
- Fixed Histogram and Scatter plot built-in visualizations to work with datasets that contain array-like columns.
- Athena query now re-runs if the query execution ID has expired.
Troubleshoot

If an issue arises when using Amazon SageMaker Data Wrangler, we recommend you do the following:

- If an error message is provided, read the message and resolve the issue it reports if possible.
- Make sure the IAM role of your Studio user has the required permissions to perform the action. For more information, see Security and Permissions (p. 1338).
- If the issue occurs when you are trying to import from another AWS service, such as Amazon Redshift or Athena, make sure that you have configured the necessary permissions and resources to perform the data import. For more information, see Import (p. 1178).
- If you’re still having issues, choose Get help at the top right of your screen to reach out to the Data Wrangler team. For more information, see the following images.
As a last resort, you can try restarting the kernel on which Data Wrangler is running.

1. Save and exit the .flow file for which you want to restart the kernel.
2. Select the **Running Terminals and Kernels** icon, as shown in the following image.

![Running Terminals and Kernels](image.png)

3. Select the **Stop** icon to the right of the .flow file for which you want to terminate the kernel, as shown in the following image.
4. Refresh the browser.
5. Reopen the .flow file on which you were working.

**Troubleshooting issues with Amazon EMR**

Use the following information to help you troubleshoot errors that might come up when you're using Amazon EMR.

- **Connection failure** – If the connection fails with the following message The IP address of the EMR cluster isn’t private error message, your Amazon EMR cluster might not have been launched in a private subnet. As a security best practice, Data Wrangler only supports connecting to private Amazon EMR clusters. Choose a private EC2 subnet you launch an EMR cluster.

- **Connection hanging and timing out** – The issue is most likely due to a network connectivity issue. After you start connecting to the cluster, the screen doesn't refresh. After about 2 minutes, you might see the following error JdbcAddConnectionError: An error occurred when trying to connect to presto: xxx: Connect to xxx failed: Connection timed out (Connection timed out) will display on top of the screen.
The errors might have two root causes:

- The Amazon EMR and Amazon SageMaker Studio are in different VPCs. We recommend launching both Amazon EMR and Studio in the same VPC. You can also use VPC peering. For more information, see What is VPC peering?
- The Amazon EMR master security group lacks the inbound traffic rule for the security group of Amazon SageMaker Studio on the port used for Presto. To resolve the issue, allow inbound traffic on port 8889.
- Connection fails due to the connection type being misconfigured – You might see the following error message: Data Wrangler couldn't create a connection to {connection_source} successfully. Try connecting to {connection_source} again. For more information, see Troubleshoot. If you're still experiencing issues, contact support.

Check the authentication method. The authentication method that you've specified in Data Wrangler should match the authentication method that you're using on the cluster.
- You don’t have HDFS permissions for LDAP authentication – Use the following guidance to resolve the issue: Set up HDFS Permissions using Linux Credentials. You can log into the cluster using the following commands:

  ```bash
  hdfs dfs -mkdir /user/USERNAME
  hdfs dfs -chown USERNAME:USERNAME /user/USERNAME
  ```

- LDAP authentication missing connection key error – You might see the following error message: Data Wrangler couldn't connect to EMR hive successfully. JDBC connection is missing required connection key(s): PWD.

  For LDAP authentication, you must specify both a username and a password. The JDBC URL stored in Secrets Manager is missing property PWD.
- When you're troubleshooting the LDAP configuration: We recommend making sure that the LDAP authenticator (LDAP server) is correctly configured to connect to the Amazon EMR cluster. Use the `ldapwhoami` command to help you resolve the configuration issue. The following are example commands that you can run:
  - For LDAPS: `ldapwhoami -x -H ldaps://ldap-server`
  - For LDAP: `ldapwhoami -x -H ldap://ldap-server`

  Either command should return Anonymous if you've configured the authenticator successfully.

## Troubleshooting with Salesforce

### Lifecycle configuration error

When your user opens Studio for the first time, they might get an error saying that there's something wrong with their lifecycle configuration. Use Amazon CloudWatch to access the logs written by your lifecycle configuration script. For more information about debugging lifecycle configurations, see Debug lifecycle configurations (p. 280).

If you aren't able to debug the error, you can create the configuration file manually. You must create the file every time you delete or restart the Jupyter server. Use the following procedure to create the file manually.

### To create a configuration file

1. Navigate to Studio.
2. Choose File, then New, then Terminal.
4. Open the file in a text editor.
5. Add a JSON object containing the Amazon Resource Name (ARN) of the Secrets Manager secret to
   the file. You can use the following template to create the object.

   ```json
   {
   "secret_arn": "example-secret-ARN"
   }
   ```

   6. Save your changes to the file.

**Unable to access Salesforce Data Cloud from the Data Wrangler flow**

After your user chooses Salesforce Data Cloud from your Data Wrangler flow, they might get an error
indicating the prerequisites to set up the connection haven't been met. It might be caused by following
errors:

- The Salesforce secret in Secrets Manager hasn't been created.
- The Salesforce secret in Secrets Manager has been created, but it's missing the Salesforce tag.
- The Salesforce secret in Secrets Manager has been created in the wrong AWS Region. For example,
your user won't be able to access the Salesforce Data Cloud in ca-central-1 because you've created
the secret in us-east-1. You can either replicate the secret to ca-central-1 or create a new secret
with the same credentials in ca-central-1. For information about replicating secrets, see Replicate
an AWS Secrets Manager secret to other AWS Regions.
- The policy that your users are using to access Amazon SageMaker Studio are missing permissions for
AWS Secrets Manager
- There's a typo in the Secrets Manager ARN of the JSON object that you've specified through your
lifecycle configuration.
- There's a typo in the Secrets Manager secret containing your Salesforce OAuth configuration

**Blank page showing redirect_uri_mismatch**

After your users choose Save and Connect, they might get redirected to a page that shows
redirect_uri_mismatch. The callback URI that you've registered in your Salesforce Connected App
settings is either missing or incorrect.

Use the following URL to check that your Studio URL is correctly registered in your Salesforce
org's Connected App settings: https://EXAMPLE_SALESFORCE_ORG/lightning/setup/
NavigationMenus/home/. For more information about using the connected app settings, navigate to
the following URL: https://EXAMPLE_SALESFORCE_ORG/lightning/setup/NavigationMenus/
home/.

**Note**

It takes roughly ten minutes to propagate the URI within Salesforce's systems.

**Shared spaces**

Shared spaces doesn't currently work with the Salesforce Data Cloud integration. You can either delete
the shared spaces in the Amazon SageMaker Domain that you intend to use, or you can use another
Domain that doesn't have shared spaces set up.
OAuth Redirect Error

Your users should be able to import their data from the Salesforce Data Cloud after they choose Connect. If they’re running into an error, we recommend asking them to do the following:

• Tell them to be patient – When they get redirected back to Amazon SageMaker Studio, it can take up to a minute to complete the authentication process. While they’re getting redirected, we recommend telling them to avoid interacting with the browser. For example, they shouldn’t close the browser tab, switch to another tab, or interact with the Data Wrangler flow. Interacting with the browser might remove the authorization code required to connect to the data cloud.

• Have your users reconnect to the data cloud – There are transient issues that can cause a connection to the Salesforce Data Cloud to fail. Have your users create a new Data Wrangler flow and try connecting to the Salesforce Data Cloud again.

• Make sure your users close all other tabs with Amazon SageMaker Studio – Having Studio open in multiple tabs can cause the Salesforce Data Cloud connection to fail. Make sure your users only have one Studio tab open.

• Multiple users accessing Studio at the same time – Only one user should access an Amazon SageMaker Domain at a time. If multiple users access the same Domain, the connection that a user is trying to create to the Salesforce Data Cloud might fail.

Updating both Data Wrangler and Studio might also fix their error. For information about updating Data Wrangler, see Update Data Wrangler (p. 1361). For information about updating Studio, see Shut down and Update SageMaker Studio (p. 292).

If none of the preceding troubleshooting steps work, you might find an error message from Salesforce with a corresponding description embedded in the Studio URL. The following is an example of a message you could find: error=invalid_client_id&error_description=client%20identifier%20invalid.

You can look at the error message in the URL and try to address the issues it presents. If the error message or description is unclear, we recommend searching the Salesforce Knowledge Base. If searching the knowledge base doesn’t work, you can reach out to the Salesforce help desk for more assistance.

Data Wrangler takes a long time to load

When your users are getting redirected back to Data Wrangler from the Salesforce Data Cloud, they might experience long load times.

If this is the user’s first time using Data Wrangler or they’ve deleted the kernel, it might take about 5 minutes to provision the new Amazon EC2 instance to use Data Wrangler.

If this isn’t the user’s first time using Data Wrangler and they haven’t deleted the kernel, you can ask them to refresh the page or close as many browser tabs as possible.

If none of the preceding interventions work, have them set up a new connection to the Salesforce Data Cloud.

User fails to export their data with an Invalid batch Id error

When your user exports the transformations that they’ve made to their Salesforce data, the SageMaker processing job that Data Wrangler uses on the backend might fail. The Salesforce Data Cloud might be temporarily unavailable or there could be a caching issue.

To address the issue, we recommend having your users go back to the step where they’re importing the data and changing the order of the columns that they’re querying. For example, they can change the following query:
SELECT col_A, col_B FROM table

To the following query:

SELECT col_B, col_A FROM table

After they've changed the order of the columns and made sure that the subsequent transformations they've made are still valid, they can start exporting their data again.

**Users can't export a very large dataset**

If your users imported a very large dataset from the Salesforce Data Cloud, they might not be able to export the transformations that they've made. A large dataset might have too many rows, or it can result from a complex query.

We recommend having your users take the following actions:

- Simplifying their SQL query
- Sampling their data

The following are some strategies that they can use to simplify their queries:

- Specify column names instead of using the * operator
- Finding a subset of the data that they'd like to import instead of using a larger subset
- Minimizing joins between very large datasets

They can use sampling to reduce the number of rows in their dataset. For information about sampling methods, your users can refer to [Sampling](p. 1286).

**Users can't export data due to invalid refresh token**

Data Wrangler uses a JDBC driver to integrate with the Salesforce Data Cloud. The method for authentication is OAuth. For OAuth, the refresh token and the access token are two different pieces of data that are used to authorize access to resources within your Salesforce Data Cloud.

The access token, or core token, is what allows you to access your Salesforce data and run queries directly through Data Wrangler. It's short lived and designed to expire quickly. To maintain access to your Salesforce data, Data Wrangler uses the refresh token to get a new access token from Salesforce.

You might have set the refresh to expire too quickly to get a new access token for your users. You might have to revisit your refresh token policy to make sure that it can accommodate queries that take a long time to run for your users. For information about configuring your refresh token policy, see [https://EXAMPLE_SALESFORCE_ORG_URL/lightning/setup/ConnectedApplication/home/](https://EXAMPLE_SALESFORCE_ORG_URL/lightning/setup/ConnectedApplication/home/).

**Queries failing or tables not loading**

Salesforce experiences service outages. Even if you've configured everything correctly, your users might not be able to import their data for periods of time.

Service outages can happen for maintenance reasons. We recommend checking in the following day to see if the issue has been resolved.

If you're experiencing issues for more than a day, we recommend contacting Salesforce's help desk for further assistance. For information about contacting Salesforce, see [How would you like to contact Salesforce?](https://example.com/how-to-contact-salesforce)
OAuth_APP_BLOCKED during Studio redirect

When your user gets redirected back to Amazon SageMaker Studio, they might notice the query parameter error=OAuth_APP_BLOCKED within the URL. They're might be experiencing a transient issue that should resolve itself within a day.

It's possible that you've blocked their access to the Connected App as well. For information about resolving the issue, see https://EXAMPLE_SALESFORCE_ORG_URL/lightning/setup/ConnectedApplication/home/.

OAuth_APP_DENIED during Studio redirect

When your user gets redirected back to Amazon SageMaker Studio, they might notice the query parameter error=OAuth_APP_ACCESS_DENIED within the URL. You haven't given their profile type permissions to access the Connected App associated with Data Wrangler.

To resolve their access issue, navigate to https://EXAMPLE_SALESFORCE_ORG_URL/lightning/setup/ManageUsers/home/ and check whether the user is assigned to the correct profile.

Increase Amazon EC2 Instance Limit

You might see the following error message when you're using Data Wrangler: The following instance type is not available: ml.m5.4xlarge. Try selecting a different instance below.

The message can indicate that you need to select a different instance type, but it can also indicate that you don't have enough Amazon EC2 instances to successfully run Data Wrangler on your workflow. You can increase the number of instances by using the following procedure.

To increase the number of instances, do the following.

1. Open the AWS Management Console.
2. In the search bar, specify Services Quotas.
3. Choose Service Quotas.
4. Choose AWS services.
5. In the search bar, specify Amazon SageMaker.
6. Choose Amazon SageMaker.
7. Under Service quotas, specify Studio KernelGateway Apps running on ml.m5.4xlarge instance.
   
   Note
   
   ml.m5.4xlarge is the default instance type for Data Wrangler. You can use other instance types and request quota increases for them. For more information, see Instances (p. 1227).

8. Select Studio KernelGateway Apps running on ml.m5.4xlarge instance.
9. Choose Request quota increase.
10. For Change quota value, specify a value greater than Applied quota value.
11. Choose Request.

If your request is approved, AWS sends a notification to the email address associated with your account. You can also check the status of your request by choosing Quota request history on the Service Quotas page. Processed requests have a Status of Closed.
Update Data Wrangler

To update Data Wrangler to the latest release, first shut down the corresponding KernelGateway app from the Amazon SageMaker Studio control panel. After the KernelGateway app is shut down, restart it by opening a new or existing Data Wrangler flow in Studio. When you open a new or existing Data Wrangler flow, the kernel that starts contains the latest version of Data Wrangler.

**Update your Studio and Data Wrangler instance**

1. Navigate to your [SageMaker Console](#).
2. Choose SageMaker and then Studio.
3. Choose your user name.
4. Under Apps, in the row displaying the App name, choose Delete app for the app that starts with sagemaker-data-wrang, and for the JupyterServer app.
5. Choose Yes, delete app.
6. Type delete in the confirmation box.
7. Choose Delete.
8. Reopen your Studio instance. When you begin to create a Data Wrangler flow, your instance now uses the latest version of Data Wrangler.

Alternatively, if you are using a Data Wrangler application version that is not the latest version, and you have an existing Data Wrangler flow open, you are prompted to update your Data Wrangler application version in the Studio UI. The following screenshot shows this prompt.

**Important**
This updates the Data Wrangler kernel gateway app only. You still need to shut down the JupyterServer app in your user account. To do this, follow the preceding steps.

You can also choose **Remind me later**, in which case an **Update** button appears in the top-right corner of the screen.
Shut Down Data Wrangler

When you are not using Data Wrangler, it is important to shut down the instance on which it runs to avoid incurring additional fees.

To avoid losing work, save your data flow before shutting Data Wrangler down. To save your data flow in Studio, choose **File** and then choose **Save Data Wrangler Flow**. Data Wrangler automatically saves your data flow every 60 seconds.
To shut down the Data Wrangler instance in Studio

1. In Studio, select the Running Instances and Kernels icon.

2. Under RUNNING APPS is the sagemaker-data-wrangler-1.0 app. Select the shutdown icon next to this app.

Data Wrangler runs on an ml.m5.4xlarge instance. This instance disappears from RUNNING INSTANCES when you shut down the Data Wrangler app.

After you shut down the Data Wrangler app, it has to restart the next time you open a Data Wrangler flow file. This can take a few minutes.

Scale data preparation using Apache Spark, Hive, or Presto on Amazon EMR or AWS Glue from Amazon SageMaker Studio notebooks

Amazon SageMaker Studio provides data scientists, machine learning (ML) engineers, and general practitioners with tools to perform data analytics and data preparation at scale. Analyzing, transforming, and preparing large amounts of data is a foundational step of any data science and ML workflow. SageMaker Studio comes with built-in integration of Amazon EMR and AWS Glue Interactive Sessions.
Prepare data using Amazon EMR

Amazon SageMaker Developer Guide
Prepare data using Amazon EMR

to handle your large-scale interactive data preparation and machine learning workflows, all within your Studio notebook.

Amazon EMR is a managed big data platform with resources to help you run petabyte-scale distributed data processing jobs using open-source analytics frameworks on AWS such as Apache Spark, Apache Hive, Presto, HBase, Flink, and Hudi among others. Data engineers and data scientists use Amazon EMR for a wide variety of use cases, including big data analytics, what-if analyses, real-time analytics, and data preparation for machine learning. With Studio integration with Amazon EMR, you can create, browse, discover, and connect to Amazon EMR clusters without leaving your Studio notebook. You can also monitor and debug your Spark workloads with one-click access to the Spark UI from within the notebook. You should consider Amazon EMR for your data preparation workloads if you want maximum control over hardware and software versions, containers, and big data processing applications.

AWS Glue Interactive Sessions is a serverless service that you can enlist to collect, transform, cleanse, and prepare data for storage in your data lakes and data pipelines. AWS Glue Interactive Sessions provides an on-demand, serverless Apache Spark runtime environment that you can initialize in seconds on a dedicated Data Processing Unit (DPU) without having to worry about provisioning and managing complex compute cluster infrastructure. After initialization, you can quickly browse the AWS Glue data catalog, run large queries, access data governed by AWS Lake Formation, and interactively analyze and prepare data using Spark, right in your Studio notebook. You can then use the prepared data to train, tune, and deploy models using the purpose-built ML tools within SageMaker Studio. You should consider AWS Glue Interactive Sessions for your data preparation workloads when you want a serverless Spark service with moderate control of configurability and flexibility.

Content

- Prepare data using Amazon EMR (p. 1364)
- Prepare data using AWS Glue Interactive Sessions (p. 1393)

Prepare data using Amazon EMR

Amazon SageMaker Studio comes with built-in integration of Amazon EMR, with which data scientists and data engineers can perform petabyte-scale interactive data preparation and machine learning (ML) right from their Studio notebook. Within a notebook, they can discover and connect to existing Amazon EMR clusters, then interactively explore, visualize, and prepare large-scale data for machine learning using Apache Spark, Apache Hive, Presto. Additionally, users can access Spark UI with a single click to monitor their Spark jobs from their Studio notebooks.

Administrators can use the AWS Service Catalog to define AWS CloudFormation templates of Amazon EMR clusters accessible to Studio users. Data scientists can then choose a predefined template to self-provision an Amazon EMR cluster directly from Amazon SageMaker Studio notebooks. Administrators can further parameterize the templates to let users choose aspects of the cluster to match their workloads within predefined values. For example, a data scientist or data engineer may want to specify the number of core nodes of the cluster up to a predetermined maximum value, or select the instance type of a node from a dropdown menu.

- If you are an administrator, make sure that you have enabled communication between Amazon SageMaker Studio notebooks and Amazon EMR clusters. For instructions, see the Configure networking (for administrators) (p. 1365) section. Once this communication is enabled, you have the option to:
  - Define cluster templates in AWS Service Catalog and ensure the availability of these templates through Studio's notebooks: Configure Amazon EMR templates in AWS Service Catalog (for administrators) (p. 1369).
  - Configure the discoverability of existing Amazon EMR clusters directly from Studio's notebooks: Configure the discoverability of Amazon EMR clusters (for administrators) (p. 1378).
  - If you are a data scientist or data engineer looking to self-provision an Amazon EMR cluster, see Launch an Amazon EMR cluster from Studio (p. 1375).
• If you are a data scientist or data engineer looking to discover and connect to existing Amazon EMR clusters from Studio, see Use Amazon EMR clusters from Studio notebooks (p. 1377).

List of topics

Configure networking (for administrators)

This section provides information about how administrators can configure their network to allow communication between Amazon SageMaker Studio notebooks and an Amazon EMR cluster.

The networking instructions vary based on whether SageMaker Studio and Amazon EMR are deployed within a private Amazon Virtual Private Cloud (VPC) or communicate over the internet.

By default, SageMaker Studio runs in an AWS managed VPC with internet access. When using an internet connection, Studio accesses AWS resources, such as Amazon S3 buckets, over the internet. However, if you have security requirements to control access to your data and job containers, we recommend that you configure SageMaker Studio and Amazon EMR so that your data and containers aren't accessible over the internet. To control access to your resources or run SageMaker Studio without public internet access, you can specify the VPC only network access type when you onboard to Amazon SageMaker Domain (p. 10). In this scenario, SageMaker Studio establishes connections with other AWS services via private VPC endpoints. For information about configuring SageMaker Studio in VPC only mode, see Connect SageMaker Studio notebooks in a VPC to external resources.

The first two sections describe how to ensure communication between SageMaker Studio and an Amazon EMR cluster in VPCs without public internet access. The last section covers how to ensure communication between SageMaker Studio and Amazon EMR using an internet connection. Prior to connecting SageMaker Studio and Amazon EMR without internet access, make sure to establish endpoints for Amazon Simple Storage Service (data storage), Amazon CloudWatch (logging and monitoring), and Amazon SageMaker Runtime (fine-grained role-based access control (RBAC)).

• If your Amazon SageMaker Studio and Amazon EMR cluster are set up in different VPCs in the same AWS account or in different accounts, see Studio and Amazon EMR are deployed in separate VPCs (p. 1365).
• If your Amazon SageMaker Studio and Amazon EMR cluster are set up in the same VPC, see Amazon SageMaker Studio and Amazon EMR are in the same VPC (p. 1367).
• If you chose to connect Amazon SageMaker Studio and Amazon EMR cluster over public internet, see Amazon SageMaker Studio and Amazon EMR communicate over public internet (p. 1368).

Studio and Amazon EMR are deployed in separate VPCs

To allow communication between SageMaker Studio and an Amazon EMR cluster when they are deployed in different VPCs:

1. Start by connecting your VPCs through a VPC peering connection.
2. Update your routing tables in each VPC to route the network traffic between Studio subnets and Amazon EMR subnets both ways.
3. Configure your security groups to allow inbound and outbound traffic.

The steps are similar, regardless of whether Amazon SageMaker Studio and the Amazon EMR cluster are deployed within the same AWS account (Single account use case) or different AWS accounts (Cross accounts use case).

1. **VPC peering**

   Create a [VPC peering connection](https://docs.aws.amazon.com/sagemaker/latest/dg/setup-emr-cluster-peering.html) to facilitate the networking between the two VPCs (SageMaker Studio and Amazon EMR).

   a. From your SageMaker Studio account, on the VPC dashboard, choose **Peering connections**, then **Create peering connection**.

   b. Create your request to peer the Studio VPC within the Amazon EMR VPC. When requesting peering in another AWS account, choose **Another account** in **Select another VPC to peer with**.

      For cross accounts peering, the administrator must accept the request from the Amazon EMR account.

      When peering private subnets, you should enable private IP DNS resolution at the VPC peering connection level.

2. **Routing tables**

   Send the network traffic between SageMaker Studio subnets and Amazon EMR subnets both ways.

   After you establish the peering connection, the administrator (on each account for cross-account access) can add routes to the private subnet route tables to route the traffic between the notebooks and the cluster subnets. You can define those routes by going to the **Route Tables** section of each VPC in the VPC dashboard.

   The following illustration of the route table of a Studio VPC subnet shows an example of an outbound route from the Studio account to the Amazon EMR VPC IP range (here 2.0.1.0/24) through the peering connection.

   ![Route Table Example](image1.png)

   The following illustration of a route table of an Amazon EMR VPC subnet shows an example of return routes from the Amazon EMR VPC to Studio VPC IP range (here 10.0.20.0/24) through the peering connection.

   ![Route Table Example](image2.png)
3. **Security groups**

Lastly, the security group of your Studio domain must allow outbound traffic, and the security group of the Amazon EMR primary node must allow inbound traffic on Apache Livy, Hive, or Presto TCP ports (respectively 8998, 10000, and 8889) from the Studio instance security group. Apache Livy is a service that enables interaction with a Amazon EMR cluster over a REST interface.

The following image shows an example of an Amazon VPC setup that enables SageMaker Studio notebooks to provision Amazon EMR clusters from AWS CloudFormation templates and then connect to an Amazon EMR cluster within the same AWS account. The diagram provides an additional illustration of the required endpoints for a direct connection to various AWS services, such as Amazon S3 or Amazon CloudWatch, when the VPCs have no internet access. Alternatively, a **NAT gateway** must be used to allow instances in private subnets of multiple VPCs to share a single public IP address provided by the **internet gateway** when accessing the internet.

**Amazon SageMaker Studio and Amazon EMR are in the same VPC**

If Amazon SageMaker Studio and the cluster are in different subnets, add routes to each private subnet route table to route the traffic between the notebooks and the cluster subnets. You can define those routes by going to the **Route Tables** section of each VPC in the VPC dashboard. If you deployed Amazon SageMaker Studio and an Amazon EMR cluster in the same VPC and the same subnet, you do not need to route the traffic between the notebooks and the cluster.
Whether or not you needed to update your routing tables, the security group of your Studio domain must allow outbound traffic, and the security group of the Amazon EMR primary node must allow inbound traffic on Apache Livy, Hive, or Presto TCP ports (respectively 8998, 10000, and 8889) from the Studio instance security group. **Apache Livy** is a service that enables interaction with an Amazon EMR cluster over a REST interface.

**Amazon SageMaker Studio and Amazon EMR communicate over public internet**

By default, SageMaker Studio provides a network interface that allows communication with the internet through an internet gateway in the VPC associated with the SageMaker Domain. If you choose to connect to Amazon EMR through the public internet, your Amazon EMR cluster needs to accept inbound traffic on **Apache Livy**, **Hive**, or **Presto** TCP ports (respectively 8998, 10000, and 8889) from its internet gateway. **Apache Livy** is a service that enables interaction with an Amazon EMR cluster over a REST interface.

Keep in mind that any port on which you allow inbound traffic represents a potential security vulnerability. Carefully review custom security groups to ensure that you minimize vulnerabilities. For more information, see [Control network traffic with security groups](#).

Alternatively, see [Walkthroughs and whitepapers](#) for a detailed walkthrough of how to enable Kerberos on Amazon EMR, set the cluster in a private subnet, and access the cluster using a **Network Load Balancer (NLB)** to expose only specific ports, which are access-controlled via security groups.

**Note**

When connecting to your Apache Livy endpoint through the public internet, we recommend that you secure communications between Amazon SageMaker Studio and your Amazon EMR cluster using TLS. For information on setting up HTTPS with Apache Livy, see [Enabling HTTPS with Apache Livy](#). For information on setting an Amazon EMR cluster with transit encryption enabled, see [Providing certificates for encrypting data in transit with Amazon EMR encryption](#). Additionally, you need to configure Studio to access your certificate key as specified in [Connect to an Amazon EMR cluster over HTTPS](#).

**Create an Amazon EMR cluster from Studio notebooks**

Administrators can use AWS Service Catalog to define AWS CloudFormation templates of Amazon EMR clusters as products of a portfolio, then make them available to selected users. Using the Service Catalog, administrators can fully control the organizational, security, and networking setup of Amazon EMR clusters. Data scientists and data engineers can then view, select, and customize those templates for their specific workloads to create on-demand Amazon EMR clusters directly from their SageMaker Studio notebooks. This can be done without manually setting up complex configurations. Users can also terminate Amazon EMR clusters from Studio notebooks after use.

* If you are an administrator looking to configure AWS CloudFormation templates as AWS Service Catalog products so users can create Amazon EMR clusters from Studio, see [Configure Amazon EMR templates in AWS Service Catalog (for administrators)](#).

* If you are a data scientist or data engineer looking to self-provision an Amazon EMR cluster to process data at scale using open-source frameworks such as Apache Spark, Apache Hive, or Presto, see [Launch an Amazon EMR cluster from Studio](#).

* If you are looking to discover and connect to existing Amazon EMR clusters from Studio, see [Use Amazon EMR clusters from Studio notebooks](#).

**Topics**

* [Configure Amazon EMR templates in AWS Service Catalog (for administrators)](#)

* [Launch an Amazon EMR cluster from Studio](#)
Configure Amazon EMR templates in AWS Service Catalog (for administrators)

This section provides details about how administrators can configure an AWS Service Catalog product so users can independently self-provision Amazon EMR clusters from Amazon SageMaker Studio notebooks. Additionally, administrators can configure the Amazon EMR cluster templates in a way so end-users can customize various aspects of the cluster to suit their specific requirements. For example, the administrator can define a list of permissible instance types from which users can choose when creating cluster.

This topic assumes that you are familiar with the creation of portfolios and products in AWS Service Catalog as well as Amazon EMR, and AWS CloudFormation.

**Note**
You can refer to the AWS CloudFormation templates in [aws-samples/sagemaker-studio-emr](https://github.com/aws-samples/sagemaker-studio-emr) GitHub repository as examples of CloudFormation stacks to deploy IAM roles, Amazon VPCs, a sandbox Studio Domain, a user profile, as well as a CloudFormation template to launch an Amazon EMR cluster. Several options are available depending on your authentication method between Studio and the Amazon EMR cluster. In these examples, a parent CloudFormation template passes the SageMaker VPC ID, security group, and subnet ID parameters to the CloudFormation template of an Amazon EMR cluster. You can access various examples of CloudFormation Amazon EMR templates in the nested repository [sagemaker-studio-emr/cloudformation/emr_servicecatalog_templates](https://github.com/aws-samples/sagemaker-studio-emr/cloudformation/emr_servicecatalog_templates) and further choose from a single account deployment to cross accounts.

For more information about the authentication methods available when connecting to an Amazon EMR cluster, see [Use Amazon EMR clusters from Studio notebooks](p. 1377).

To simplify the creation of Amazon EMR clusters, administrators can register the CloudFormation template of an Amazon EMR cluster as a product in the portfolio of the AWS Service Catalog. Then they associate the Service Catalog portfolio with the Studio execution role to ensure the availability of the template in Studio. Furthermore, to make sure that data scientists can discover those templates, provision Amazon EMR clusters, and connect to Amazon EMR clusters from their Studio notebooks, administrators need to set the proper access permissions.

The following list provides the additional settings that administrators need to apply to a baseline CloudFormation stack to enable Studio to access the Service Catalog products and provision Amazon EMR clusters. Those settings must be applied at multiple levels:

- In the Service Catalog portfolio
- In the Service Catalog product
- In the CloudFormation Amazon EMR template declared as the Service Catalog product

Finally, administrators must assign the required permissions to both the Studio execution role accessing the clusters and the account where Amazon EMR is deployed, based on whether Studio and Amazon EMR are in the same or different AWS accounts.

- **Pre-requisites: Networking and authentication requirements**
  
  As a prerequisite, ensure that you have reviewed the networking and security requirements in [Configure networking (for administrators)](p. 1365) and that you have created a baseline CloudFormation stack supporting the authentication method of your choice. You can find examples of CloudFormation templates in [aws-samples/sagemaker-studio-emr](https://github.com/aws-samples/sagemaker-studio-emr).

- **In your Service Catalog portfolio:**
  
  Add the following section to your portfolio CloudFormation template (see the example in YAML format) to associate your portfolio with the Studio execution role accessing your cluster.

  ```yaml
  SageMakerStudioEMRProductPortfolioPrincipalAssociation:
    Type: AWS::ServiceCatalog::PortfolioPrincipalAssociation
  ```
Properties:
PrincipalARN: SageMakerExecutionRole.Arn
PortfolioId: SageMakerStudioEMRProductPortfolio ID
PrincipalType: IAM

- **In your Service Catalog product:**

  Add the following tag key "sagemaker:studio-visibility:emr" and set to the value "true" (here in YAML) to the Service Catalog product referencing the Amazon EMR template resource. This ensures the visibility of the template in Studio.

  
  SMStudioEMRNoAuthProduct:
  
  Type: AWS::ServiceCatalog::CloudFormationProduct
  Properties:
  Owner: AWS
  Name: SageMaker Studio Domain No Auth EMR
  ProvisioningArtifactParameters:
  - Name: SageMaker Studio Domain No Auth EMR
    Description: Provisions a SageMaker domain and No Auth EMR Cluster
    Info:
    LoadTemplateFromURL: 
    Link to your CloudFormation template. For example, https://aws-ml-blog.s3.amazonaws.com/artifacts/astra-m4-sagemaker/end-to-end/CFN-EMR-NoStudioNoAuthTemplate-v3.yaml
    Tags:
    - Key: "sagemaker:studio-visibility:emr"
      Value: "true"

  - **In the CloudFormation template of the Amazon EMR cluster** within your Service Catalog product:

    Add the following mandatory stack parameters as a placeholder. This section is populated with the Studio project name and identifier used by the user when provisioning a cluster from Studio.

    
    SageMakerProjectName:
    Type: String
    Description: Name of the project

    SageMakerProjectId:
    Type: String
    Description: Service generated ID of the project.

    Administrators can specify Default and AllowedValues to include choices in the parameters section of a template, letting users input or select custom values when creating a cluster. The following example illustrates additional input parameters that administrators can set when creating an Amazon EMR template.

    "Parameters": {
    "EmrClusterName": {
      "Type": "String",
      "Description": "EMR cluster Name."
    },
    "MasterInstanceType": {
      "Type": "String",
      "Description": "Instance type of the EMR master node."
      "Default": "m5.xlarge",
      "AllowedValues": [
        "m5.xlarge",
        "m5.2xlarge",
        "m5.4xlarge"
      ]
    },
    "CoreInstanceType": {
      "Type": "String",
      "Description": "Instance type of the EMR core nodes."
      "Default": "m5.xlarge",
      "AllowedValues": [
        "m5.xlarge",
        "m5.2xlarge",
        "m5.4xlarge"
      ]
    }
  }
Last, attach the required IAM policies to enable the visibility of CloudFormation Amazon EMR templates and the self-provisioning of Amazon EMR clusters from the Studio notebooks. The role to which you must add those policies depends on whether Studio and Amazon EMR are deployed in the same account (single account) or in different accounts (cross accounts).

- If your Amazon EMR cluster is deployed in the same AWS account as the Studio account, refer to the Single Account tab.
- If your Amazon EMR cluster is deployed in a different AWS account than the Studio account, refer to the Cross Accounts tab.

For more information on cross-account access using roles, see Cross account resource access in IAM or Cross-account policy evaluation logic.

Single account

Attach the following permissions to the Studio execution role accessing your cluster.

The following list provides a breakdown of the permissions required.

- AllowEMRTemplateDiscovery allows the discoverability for Amazon EMR templates.
- AllowSagemakerProjectManagement enables the creation of SageMaker projects. In Studio, access to the AWS Service Catalog is granted through Projects.
- AllowClusterDetailsDiscovery and AllowClusterDiscovery allow the discovery and connection to Amazon EMR clusters.
- AllowPresignedUrl allows the creation of pre-signed URLs to access Spark UI.

The following is a comprehensive JSON that includes these permissions.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "*",
            "Resource": "*"
        }
    ]
}
```
Cross accounts

If your Amazon EMR clusters and Studio are deployed in separate AWS accounts, you configure the permissions in multiple steps.

- On the trusting account (the account in which Amazon EMR is deployed), create a custom IAM role (referred to as ASSUMABLE-ROLE in this page) with the following permissions and trust relationship.
For information about creating a role on an AWS account, see Creating an IAM role (console).

1. Add an IAM policy defining the following permissions.
   - AllowClusterDetailsDiscovery and AllowClusterDiscovery to allow the discovery and connection to Amazon EMR clusters.
   - AllowPresignedUrl to allow the creation of pre-signed URLs to access Spark UI.

   The following is a comprehensive JSON that includes these permissions.

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Sid": "AllowPresignedUrl",
         "Effect": "Allow",
         "Action": [
           "elasticmapreduce:DescribeCluster",
           "elasticmapreduce:ListInstanceGroups",
           "elasticmapreduce:CreatePersistentAppUI",
           "elasticmapreduce:DescribePersistentAppUI",
           "elasticmapreduce:GetPersistentAppUIPresignedURL",
           "elasticmapreduce:GetOnClusterAppUIPresignedURL"
         ],
         "Resource": [
         ]
       },
       {
         "Sid": "AllowClusterDetailsDiscovery",
         "Effect": "Allow",
         "Action": [
           "elasticmapreduce:DescribeCluster",
           "elasticmapreduce:ListInstances",
           "elasticmapreduce:ListInstanceGroups",
           "elasticmapreduce:DescribeSecurityConfiguration"
         ],
         "Resource": [
         ]
       },
       {
         "Sid": "AllowClusterDiscovery",
         "Effect": "Allow",
         "Action": [
           "elasticmapreduce:ListClusters"
         ],
         "Resource": "*"
       }
     ]
   }
   ```

2. To grant the trusted account (the account in which Studio is deployed) the permission to assume a role in the trusting account, include the following trust relationship.

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Principal": {
           "AWS": "arn:aws:iam::studio-account:root"
         },
         "Action": "sts:AssumeRole"
       }
     ]
   }
   ```
On the trusted account (the account in which Studio is deployed), add the following permissions and trust relationship to the Studio execution role.

1. Add an IAM policy defining the following permissions.
   - AllowSagemakerProjectManagement to allow the creation of SageMaker projects. In Studio, access to the AWS Service Catalog is granted through Projects.
   - AllowEMRTemplateDiscovery to allow the discoverability of Amazon EMR templates.

   The following is a comprehensive JSON that includes these permissions.

   ```json
   {
   "Version": "2012-10-17",
   "Statement": [
   {
   "Sid": "AllowSagemakerProjectManagement",
   "Effect": "Allow",
   "Action": [
   "sagemaker:CreateProject",
   "sagemaker:DeleteProject"
   ],
   "Resource": "arn:aws:sagemaker:::project/*"
   },
   {
   "Sid": "AllowEMRTemplateDiscovery",
   "Effect": "Allow",
   "Action": [
   "servicecatalog:SearchProducts"
   ],
   "Resource": "*"
   }
   ]
   }
   ```

2. To grant the Studio execution role the permission to assume the ASSUMABLE-ROLE in the trusting account, include the following trust relationship.

   ```json
   {
   "Version": "2012-10-17",
   "Statement": [
   {
   "Sid": "AllowRoleAssumptionForCrossAccountDiscovery",
   "Effect": "Allow",
   "Action": "sts:AssumeRole",
   "Resource": ["arn:aws:iam::emr-account:role/ASSUMABLE-ROLE"]
   }
   ]
   }
   ```

   Last, see Additional Configuration for cross accounts use cases (for administrators) (p. 1391) to learn how to provide the ARN of the ASSUMABLE-ROLE to the Studio execution role. The ARN is loaded by the Studio Jupyter server at launch. The Studio execution role assumes that cross-account role to discover and connect to Amazon EMR clusters in the trusting account.

Once the CloudFormation templates are available in Amazon SageMaker Studio, data scientists can use them to self-provision Amazon EMR clusters. Each of the "Parameters" specified in the template becomes an input box in the cluster creation form of Studio, with the corresponding "AllowedValues" appearing in a dropdown menu.
The following illustration shows the dynamic form assembled from a CloudFormation Amazon EMR template to create an Amazon EMR cluster in SageMaker Studio.

Visit [Launch an Amazon EMR cluster from Studio (p. 1375)](Launch an Amazon EMR cluster from Studio (p. 1375)) to learn about how to launch a cluster from Studio using those Amazon EMR templates.

**Launch an Amazon EMR cluster from Studio**

Data scientists and data engineers can self-provision Amazon EMR clusters from Studio using AWS CloudFormation templates configured by their administrators. If you are an administrator looking to configure CloudFormation templates as AWS Service Catalog products so users can create Amazon
EMR clusters from Studio, see Configure Amazon EMR templates in AWS Service Catalog (for administrators) (p. 1369).

To provision a new Amazon EMR cluster from Studio:

1. Select the **Home** ( ) icon in the Studio UI's left-side panel, then select the **Data** node in the navigation menu. Navigate down to the **Clusters** node. This opens up a page listing the Amazon EMR clusters that you can access from SageMaker Studio.

2. Choose **Create cluster**. This opens up a page, in the main working area, listing the cluster templates available to you.

3. Select a cluster configuration template by choosing a template name. The selection of a template activates the **Select template** button. Choose **Select template**. This opens up a cluster creation form.

4. Enter the cluster's details, such as a cluster name and any specific configurable parameter set by your administrator, then choose **Create cluster**. The creation of the cluster might take a couple of minutes.
Once the cluster is provisioned, the Studio UI displays a The cluster has been successfully created message.

To connect to your cluster, see Use Amazon EMR clusters from Studio notebooks (p. 1377)

Use Amazon EMR clusters from Studio notebooks

In this section, you learn about how to discover, connect to, or terminate an Amazon EMR cluster from SageMaker Studio notebooks.

- If you are an administrator, see Configure the discoverability of Amazon EMR clusters (for administrators) (p. 1378) to configure the discoverability of Amazon EMR clusters from SageMaker Studio notebooks.
- If you are a data scientist or data engineer looking to discover Amazon EMR clusters from your Studio notebooks, see Discover Amazon EMR clusters from SageMaker Studio (p. 1381).
- If you are a data scientist or data engineer looking to connect to existing Amazon EMR clusters from your Studio notebooks, see Connect to an Amazon EMR cluster from SageMaker Studio (p. 1381).

When connecting to your Amazon EMR cluster from SageMaker Studio, you can authenticate to your cluster with Kerberos, Lightweight Directory Access Protocol (LDAP), or use runtime IAM role authentication. Your authentication method depends on your cluster configuration. You can refer to this example Access Apache Livy using a Network Load Balancer on a Kerberos-enabled Amazon EMR cluster to set up an Amazon EMR cluster that uses Kerberos. Alternatively, you can look at the CloudFormation example templates using Kerberos or LDAP in the aws-samples/sagemaker-studio-emr GitHub repository.

Find the list of available connection commands to an Amazon EMR cluster per authentication method in Enter the connection command to an Amazon EMR cluster manually (p. 1382) to connect to your Amazon EMR cluster.

Supported images and kernels to connect to an Amazon EMR cluster from SageMaker Studio

SageMaker Studio provides built-in support to connect to Amazon EMR clusters in the following images and kernels:

- DataScience – Python 3 kernel
- DataScience 2.0 – Python 3 kernel
- DataScience 3.0 – Python 3 kernel
- SparkAnalytics 1.0 – SparkMagic and PySpark kernels
- SparkAnalytics 2.0 – SparkMagic and PySpark kernels
- SparkMagic – SparkMagic and PySpark kernels
- PyTorch 1.8 – Python 3 kernels
- TensorFlow 2.6 – Python 3 kernel
- TensorFlow 2.11 – Python 3 kernel

Those images and kernels come with sagemaker-studio-analytics-extension, a notebook extension that enables connection to a remote Spark (Amazon EMR) cluster via the SparkMagic library using Apache Livy.

To connect to Amazon EMR clusters using another built-in image or your own image, follow the instructions in Bring your own image (p. 1378).
Bring your own image

To bring your own image in SageMaker Studio and allow your notebooks to connect to Amazon EMR clusters, install the following `sagemaker-studio-analytics-extension` extension to your kernel. It supports connecting SageMaker Studio notebooks to Spark(Amazon EMR) clusters through the SparkMagic library.

```
pip install sparkmagic
pip install sagemaker-studio-sparkmagic-lib
pip install sagemaker-studio-analytics-extension
```

Additionally, to connect to Amazon EMR with Kerberos authentication, you must install the kinit client. Depending on your OS, the command to install the kinit client can vary. To bring an Ubuntu (Debian based) image, use the `apt-get install -y -qq krb5-user` command.

For more information on bringing your own image in SageMaker Studio, see [Bring your own SageMaker image](#).

Configure the discoverability of Amazon EMR clusters (for administrators)

This section provides details about how administrators can configure the discoverability of existing Amazon EMR clusters from SageMaker Studio. The clusters can be deployed in the same AWS account as Studio (Single Account tab) or in separate accounts (Cross Accounts tab).

**Single Account**

Attach the following permissions to the SageMaker Studio execution role accessing your cluster.

The following list provides a breakdown of the permissions required.

- **AllowSagemakerProjectManagement** enables the creation of [SageMaker projects](#). In Studio, access to the AWS Service Catalog is granted through Projects.
- **AllowClusterDetailsDiscovery** and **AllowClusterDiscovery** allow the discovery and connection to Amazon EMR clusters.
- **AllowPresignedUrl** allows the creation of pre-signed URLs to access Spark UI.

The following is a comprehensive JSON that includes these permissions.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowPresignedUrl",
            "Effect": "Allow",
            "Action": [
                "elasticmapreduce:DescribeCluster",
                "elasticmapreduce:ListInstanceGroups",
                "elasticmapreduce:CreatePersistentAppUI",
                "elasticmapreduce:DescribePersistentAppUI",
                "elasticmapreduce:GetPersistentAppUIPresignedURL",
                "elasticmapreduce:GetOnClusterAppUIPresignedURL"
            ],
            "Resource": [
                "arn:aws:elasticmapreduce:region:account-id:cluster/**"
            ]
        },
        {
            "Sid": "AllowClusterDetailsDiscovery",
            "Effect": "Allow",
            "Action": [
```
Cross Accounts

If your Amazon EMR clusters and SageMaker Studio are deployed in separate AWS accounts, you configure the permissions in multiple steps.

- On the trusting account (the account in which Amazon EMR is deployed), create a custom IAM role (referred to as ASSUMABLE-ROLE in this page) with the following permissions and trust relationship.

For information about creating a role on an AWS account, see Creating an IAM role (console).

1. Add a policy defining the following permissions.
   - AllowClusterDetailsDiscovery and AllowClusterDiscovery to allow the discovery and connection to Amazon EMR clusters.
   - AllowPresignedUrl to allow the creation of pre-signed URLs to access Spark UI.

The following is a comprehensive JSON that includes these permissions.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowPresignedUrl",
      "Effect": "Allow",
      "Action": [
        "elasticmapreduce:DescribeCluster",
        "elasticmapreduce:ListInstanceGroups",
        "elasticmapreduce:CreatePersistentAppUI",
        "elasticmapreduce:DescribePersistentAppUI",
        "elasticmapreduce:GetPersistentAppUIPresignedURL",
        "elasticmapreduce:GetOnClusterAppUIPresignedURL"
      ],
      "Resource": [
      ]
    }
  ]
}
```
2. To grant the trusted account (the account in which SageMaker Studio’s account is deployed) the permission to assume a role in the trusting account, add the following trust relationship.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::studio-account:root"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

- On the trusted account (the account in which SageMaker Studio is deployed), add the following trust relationship to the Studio execution role.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowRoleAssumptionForCrossAccountDiscovery",
      "Effect": "Allow",
      "Action": "sts:AssumeRole",
      "Resource": ["arn:aws:iam::emr-account:role/ASSUMABLE-ROLE"]
    }
  ]
}
```

- Last, see Additional Configuration for cross accounts use cases (for administrators) (p. 1391) to learn how to provide the ARN of the ASSUMABLE-ROLE to the Studio execution role. The ARN is loaded by the Studio Jupyter server at launch. The Studio execution role assumes that cross-account role to discover and connect to Amazon EMR clusters in the trusting account.
Visit Discover Amazon EMR clusters from SageMaker Studio (p. 1381) to learn how to discover and connect to Amazon EMR clusters from Studio notebooks.

**Discover Amazon EMR clusters from SageMaker Studio**

Data scientists and data engineers can discover, connect to, and manage Amazon EMR clusters from Amazon SageMaker Studio. The Amazon EMR clusters may be in the same AWS account as Amazon SageMaker Studio or in a different AWS account.

If your administrator configured the cross accounts discovery of Amazon EMR clusters, you can see a consolidated list of clusters in the AWS account used by SageMaker Studio as well as in the remote accounts.

If you are an administrator looking to set up the discoverability of Amazon EMR clusters from SageMaker Studio, see Configure the discoverability of Amazon EMR clusters (for administrators) (p. 1378).

To view the list of available Amazon EMR clusters from SageMaker Studio:

1. Select the Home (🏠) icon in Studio UI's left-side panel, then select the Data node in the navigation menu.
2. Navigate down to the Clusters node. This opens up a page listing the Amazon EMR clusters that you can access from SageMaker Studio.

The list displays the status of each cluster. A cluster status can be Starting, Bootstrapping, Running/Walking, Terminating, Terminated, and Terminated with error. You can filter clusters by status by selecting the filter icon. The following image shows an example of a list of clusters.

3. To connect to a particular Running/Walking cluster, see Connect to an Amazon EMR cluster from SageMaker Studio (p. 1381).

**Connect to an Amazon EMR cluster from SageMaker Studio**

This section explains how you can connect to an Amazon EMR cluster from a Studio notebook when you use any of the supported kernels.

**Connect to an Amazon EMR cluster automatically**

To connect to your cluster using the Studio UI, you can either initiate a connection from the list of clusters accessed in Discover Amazon EMR clusters from SageMaker Studio (p. 1381), or from a notebook in SageMaker Studio.

**To connect to a particular cluster from your list of clusters**

1. Choose the name of the cluster in your list. This activates the Attach to new notebook button.
2. Choose Attach to new notebook. This opens up the images and kernels selection box.
3. Select your image and kernel, then choose **Select**. For a list of supported images, see **Supported images and kernels to connect to an Amazon EMR cluster from SageMaker Studio** (p. 1377) or refer to **Bring your own image** (p. 1378).

4. If the cluster you select does not use Kerberos, LDAP, or runtime role authentication, Studio prompts you to select the credential type. Choose from **Http basic authentication** or **No credentials**, then enter your credentials, if applicable. A connection command populates the first cell of your notebook and initiates the connection with the Amazon EMR cluster.

Once the connection succeeds, a message confirms the connection and the start of the Spark application.

**Alternatively, you can connect to a cluster from a notebook.**

1. Choose **Cluster** at the top of your notebook.

   **Cluster** is only visible when you use a kernel from **Supported images and kernels to connect to an Amazon EMR cluster from SageMaker Studio** (p. 1377) or from **Bring your own image** (p. 1378). If you cannot see **Cluster** at the top of your notebook, ensure that your administrator has configured the discoverability of your clusters and switch to a supported kernel.

   ![Cluster dropdown menu](image_url)

   This opens up a list of available clusters.

2. Select the cluster to which you want to connect, then choose **Connect**.

3. If you configured your Amazon EMR clusters to support runtime IAM roles and your administrator preloaded your roles in an execution role configuration JSON, you can select your Amazon EMR access role from the **Amazon EMR execution role** drop down menu. If your roles are not preloaded, Studio uses your Studio execution role by default. For information about using runtime roles with Amazon EMR, see **Connect to an Amazon EMR cluster from Studio using runtime IAM roles** (p. 1384). When you connect to a cluster, Studio adds a code block to an active cell to establish the connection.

   Otherwise, if the cluster you choose does not use Kerberos, LDAP, or runtime role authentication, Studio prompts you to select the credential type. You can choose **HTTP basic authentication** or **No credential**.

4. An active cell populates and runs. This cell contains the connection command to connect to your Amazon EMR cluster.

   Once the connection succeeds, a message confirm the connection and the start of the Spark application.

**Enter the connection command to an Amazon EMR cluster manually**

You can manually connect to your Amazon EMR cluster from a Studio notebook whether or not your Studio application and cluster reside in the same AWS account.

For each of the following authentication types, use the specified command to manually connect to your cluster from your Studio notebook.

- **Kerberos**

  Append the `--assumable-role-arn` argument if you need cross-account Amazon EMR access.
  Append the `--verify-certificate` argument if you connect to your cluster with HTTPS.

```bash
%load_ext sagemaker_studio_analytics_extension.magics
```
%sm_analytics emr connect --cluster-id cluster_id \
--auth-type Kerberos --language python 
[--assumable-role-arn EMR_access_role_ARN ] 
[--verify-certificate /home/user/certificateKey.pem]

- **LDAP**

Append the --assumable-role-arn argument if you need cross-account Amazon EMR access. Append the --verify-certificate argument if you connect to your cluster with HTTPS.

%load_ext sagemaker_studio_analytics_extension.magics 
%sm_analytics emr connect --cluster-id cluster_id \
--auth-type Basic_Access --language python 
[--assumable-role-arn EMR_access_role_ARN ] 
[--verify-certificate /home/user/certificateKey.pem]

- **NoAuth**

Append the --assumable-role-arn argument if you need cross-account Amazon EMR access. Append the --verify-certificate argument if you connect to your cluster with HTTPS.

%load_ext sagemaker_studio_analytics_extension.magics 
%sm_analytics emr connect --cluster-id cluster_id \
--auth-type None --language python 
[--assumable-role-arn EMR_access_role_ARN ] 
[--verify-certificate /home/user/certificateKey.pem]

- **Runtime IAM roles**

Append the --assumable-role-arn argument if you need cross-account Amazon EMR access. Append the --verify-certificate argument if you connect to your cluster with HTTPS.

For more information on connecting to an Amazon EMR cluster using runtime IAM roles, see [Connect to an Amazon EMR cluster from Studio using runtime IAM roles (p. 1384)](#).

%load_ext sagemaker_studio_analytics_extension.magics 
%sm_analytics emr connect --cluster-id cluster_id \
--auth-type Basic_Access \
--emr-execution-role-arn arn:aws:iam::studio_account_id:role/emr-execution-role-name 
[--assumable-role-arn EMR_access_role_ARN] 
[--verify-certificate /home/user/certificateKey.pem]

**Connect to an Amazon EMR cluster over HTTPS**

If you have configured your Amazon EMR cluster with transit encryption enabled and Apache Livy server for HTTPS and would like Studio to communicate with Amazon EMR using HTTPS, you need to configure Studio to access your certificate key.

For self-signed or local Certificate Authority (CA) signed certificates, you can do this in two steps:

1. Download the PEM file of your certificate to your local file system using one of the following options:
   - Jupyter's built-in file upload function.
   - A notebook cell.
   - A lifecycle configuration (LCC) script.

   For information on how to use an LCC script, see [Customize a Notebook Instance Using a Lifecycle Configuration Script](#).
2. Enable the validation of the certificate by providing the path to your certificate in the `--verify-certificate` argument of your connection command.

```bash
%sm_analytics emr connect --cluster-id cluster_id \
  --verify-certificate /home/user/certificateKey.pem ...
```

For public CA issued certificates, set the certificate validation by setting the `--verify-certificate` parameter as `true`.

Alternatively, you can disable the certificate validation by setting the `--verify-certificate` parameter as `false`.

You can find the list of available connection commands to an Amazon EMR cluster in the [Enter the connection command to an Amazon EMR cluster manually](#) (p. 1382).

**Connect to an Amazon EMR cluster from Studio using runtime IAM roles**

When you connect to an Amazon EMR cluster from your Amazon SageMaker Studio notebook, you can visually browse a list of IAM roles, known as runtime roles, and select one on the fly. Subsequently, all your Apache Spark, Apache Hive, or Presto jobs created from your Studio notebook access only the data and resources permitted by policies attached to the runtime role. Also, when data is accessed from data lakes managed with AWS Lake Formation, you can enforce table-level and column-level access using policies attached to the runtime role.

With this capability, you and your teammates can connect to the same cluster, each using a runtime role scoped with permissions matching your individual level of access to data. Your sessions are also isolated from one another on the shared cluster. With this ability to control fine-grained access to data on the same shared cluster, you can simplify provisioning of Amazon EMR clusters, reducing operational overhead and saving costs.

To try out this new feature, see [Apply fine-grained data access controls with AWS Lake Formation and Amazon EMR from Amazon SageMaker Studio](#). This blog post helps you set up a demo environment where you can try using preconfigured runtime roles to connect to Amazon EMR clusters.

**Prerequisites**

Before you get started, make sure you meet the following prerequisites:

- Use Amazon EMR version 6.9 or above.
- Use JupyterLab version 3 in the Studio Jupyter server application configuration. This version supports Studio connection to Amazon EMR clusters using runtime roles.
- Allow the use of runtime roles in your cluster's security configuration. For more information, see [Runtime roles for Amazon EMR steps](#).
- Create a notebook with any of the kernels listed in [Use Amazon EMR clusters from Studio notebooks](#) (p. 1377).
- Make sure you review the instructions in [Set up Studio to use runtime IAM roles](#) (p. 1385) to configure runtime roles with Studio.

**Cross-account connection scenarios**

Runtime role authentication supports a variety of cross-account connection scenarios when your data resides outside of your Studio account. The following image shows three different ways you can assign your Amazon EMR cluster, data, and even Amazon EMR execution role between your Studio and data accounts:
In option 1, your Amazon EMR cluster and Amazon EMR execution role are in a separate data account from your Studio account. You define a separate Amazon EMR access role permission policy which grants permission to your Studio execution role to assume the Amazon EMR access role. The Amazon EMR access role then calls the Amazon EMR API GetClusterSessionCredentials on behalf of your Studio execution role, giving you access to the cluster.

In option 2, your Amazon EMR cluster and Amazon EMR execution role are in your Studio account. Your Studio execution role has permission to use the Amazon EMR API GetClusterSessionCredentials to gain access to your cluster. To access the Amazon S3 bucket, give the Amazon EMR execution role cross-account Amazon S3 bucket access permissions — you grant these permissions within your Amazon S3 bucket policy.

In option 3, your Amazon EMR clusters are in your Studio account, and the Amazon EMR execution role is in the data account. Your Studio execution role has permission to use the Amazon EMR API GetClusterSessionCredentials to gain access to your cluster. Add the Amazon EMR execution role into the execution role configuration JSON. Then you can select the role in the UI when you choose your cluster. For details about how to set up your execution role configuration JSON file, see Preload your execution roles into Studio (p. 1388).

**Set up Studio to use runtime IAM roles**

To establish runtime role authentication for your Amazon EMR clusters, configure the required IAM policies, network, and usability enhancements. Your setup depends on whether you handle any cross-account arrangements if your Amazon EMR clusters, Amazon EMR execution role, or both, reside outside of your Amazon SageMaker Studio account. The following discussion guides you through the policies to install, how to configure the network to allow traffic between cross-accounts, and the local configuration file to set up to automate your Amazon EMR connection.

**Configure runtime role authentication when your Amazon EMR cluster and Studio are in the same account**

If your Amazon EMR cluster resides in your Studio account, add the basic policy to connect to your Amazon EMR cluster and set permissions to call the Amazon EMR API GetClusterSessionCredentials, which gives you access to the cluster. Complete the following steps to add necessary permissions to your Studio execution policy:
1. Add the required IAM policy to connect to Amazon EMR clusters. For details, see Discover Amazon EMR clusters from SageMaker Studio (p. 1381).

2. Grant permission to call the Amazon EMR API GetClusterSessionCredentials when you pass one or more permitted Amazon EMR execution roles specified in the policy.

3. (Optional) Grant permission to pass IAM roles that follow any user-defined naming conventions.

4. (Optional) Grant permission to access Amazon EMR clusters that are tagged with specific user-defined strings.

5. If you don’t want to manually call the Amazon EMR connection command, install a SageMaker configuration file in your local Amazon EFS and select the role to use when you select your Amazon EMR cluster. For details about how to preload your IAM roles, see Preload your execution roles into Studio (p. 1388).

The following example policy permits Amazon EMR execution roles belonging to the modeling and training groups to call GetClusterSessionCredentials. In addition, the policyholder can access Amazon EMR clusters tagged with the strings modeling or training.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "VisualEditor0",
         "Effect": "Allow",
         "Action": "elasticmapreduce:GetClusterSessionCredentials",
         "Resource": "*",
         "Condition": {
            "StringLike": {
               "elasticmapreduce:ExecutionRoleArn": [
                  "arn:aws:iam::123456780910:role/emr-execution-role-ml-modeling",
                  "arn:aws:iam::123456780910:role/emr-execution-role-ml-training"
               ],
               "elasticmapreduce:ResourceTag/group": [
                  "modeling",
                  "training"
               ]
            }
         }
      }
   ]
}
```

Configure runtime role authentication when your cluster and Studio are in different accounts

If your Amazon EMR cluster is not in your Studio account, allow your Studio execution role to assume the cross-account Amazon EMR access role so you can connect to the cluster. Complete the following steps to set up your cross-account configuration:

1. Create your Studio execution role permission policy so that the execution role can assume the Amazon EMR access role. The following policy is an example:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "AllowAssumeCrossAccountEMRAccessRole",
         "Effect": "Allow",
         "Action": "sts:AssumeRole",
         "Resource": "arn:aws:iam::emr_account_id:role/emr-access-role-name"
      }
   ]
}
```
2. Create the trust policy to specify which Studio account IDs are trusted to assume the Amazon EMR access role. The following policy is an example:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowCrossAccountSageMakerExecutionRoleToAssumeThisRole",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::studio_account_id:role/studio_execution_role"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

3. Create the Amazon EMR access role permission policy, which grants the Amazon EMR execution role the needed permissions to carry out the intended tasks on the cluster. Configure the Amazon EMR access role to call the API `GetClusterSessionCredentials` with the Amazon EMR execution roles specified in the access role permission policy. The following policy is an example:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowCallingEmrGetClusterSessionCredentialsAPI",
            "Effect": "Allow",
            "Action": "elasticmapreduce:GetClusterSessionCredentials",
            "Resource": 
            "Condition": { 
                "StringLike": { 
                    "elasticmapreduce:ExecutionRoleArn": [ 
                        "arn:aws:iam::emr_account_id:role/emr-execution-role-name"
                    ]
                }
            }
        }
    ]
}
```

4. Set up the cross-account network so that traffic can move back and forth between your accounts. For guided instruction, see Set up the network in the blog post Create and manage Amazon EMR Clusters from SageMaker Studio to run interactive Spark and ML workloads – Part 2. The steps in the blog post help you complete the following tasks:
   a. VPC-peer your Studio account and your Amazon EMR account to establish a connection.
   b. Manually add routes to the private subnet route tables in both accounts. This permits creation and connection of Amazon EMR clusters from the Studio account to the remote account's private subnet.
   c. Set up the security group attached to your Studio domain to allow outbound traffic and the security group of the Amazon EMR primary node to allow inbound TCP traffic from the Studio instance security group.
5. If you don't want to manually call the Amazon EMR connection command, install a SageMaker configuration file in your local Amazon EFS so you can select the role to use when you choose your Amazon EMR cluster. For details about how to preload your IAM roles, see Preload your execution roles into Studio (p. 1388).
Configure Lake Formation access

When you access data from data lakes managed by AWS Lake Formation, you can enforce table-level and column-level access using policies attached to your runtime role. To configure permission for Lake Formation access, see [Integrate Amazon EMR with AWS Lake Formation](https://docs.aws.amazon.com/sagemaker/latest/dg/emr-lf.html).

Preload your execution roles into Studio

If you don’t want to manually call the Amazon EMR connection command, you can install a SageMaker configuration file in your local Amazon EFS so you can select the execution role to use when you choose your Amazon EMR cluster.

To write a configuration file for the Amazon EMR execution roles, associate a [Use lifecycle configurations with Amazon SageMaker Studio (p. 271)](https://docs.aws.amazon.com/sagemaker/latest/dg/lifecycle-configurations.html) (LCC) to the Jupyter server application. Alternatively, you can write or update the configuration file and restart the Jupyter server with the command: `restart-jupyter-server`.

The following snippet is an example LCC bash script you can apply if your Studio application and cluster are in the same account:

```bash
#!/bin/bash
set -eux
FILE_DIRECTORY="/home/sagemaker-user/.sagemaker-analytics-configuration-DO_NOT_DELETE"
FILE_NAME="emr-configurations-DO_NOT_DELETE.json"
FILE="${FILE_DIRECTORY}/${FILE_NAME}"
mkdir -p $FILE_DIRECTORY
cat << 'EOF' > "$FILE"
{
  "emr-execution-role-arns":
  {
    "123456789012": [
      "arn:aws:iam::123456789012:role/emr-execution-role-1",
      "arn:aws:iam::123456789012:role/emr-execution-role-2"
    ]
  }
} EOF
```

If your Studio application and clusters are in different accounts, specify the Amazon EMR access roles that can use the cluster. In the following example policy, `123456789012` is the ARN for the Amazon EMR cluster account, and `212121212121` and `434343434343` are the ARNs for the permitted Amazon EMR access roles.

```bash
#!/bin/bash
set -eux
FILE_DIRECTORY="/home/sagemaker-user/.sagemaker-analytics-configuration-DO_NOT_DELETE"
FILE_NAME="emr-configurations-DO_NOT_DELETE.json"
FILE="${FILE_DIRECTORY}/${FILE_NAME}"
mkdir -p $FILE_DIRECTORY
cat << 'EOF' > "$FILE"
{
  "emr-execution-role-arns":
  {
    "123456789012": [
      "arn:aws:iam::123456789012:role/emr-execution-role-1",
      "arn:aws:iam::123456789012:role/emr-execution-role-2"
    ]
  }
} EOF
```

1388
Terminate an Amazon EMR cluster from Studio

The following procedure shows how to terminate an Amazon EMR cluster from a Studio notebook.

To terminate a cluster in a Running state, navigate to the list of available Amazon EMR clusters.

1. In SageMaker Studio, select the Home icon in Studio UI's left-side panel, then select the Data node in the navigation menu.
2. Navigate down to the Clusters node. This opens up a page listing the Amazon EMR clusters that you can access from SageMaker Studio.
3. Select the name of the cluster that you want to terminate, then choose Terminate.
4. This opens up a confirmation window informing you that any pending work or data on your cluster will be lost permanently after termination. Confirm by choosing Terminate again.

Access Spark UI from Studio

The following sections give instructions for accessing the Spark UI from SageMaker Studio notebooks. The Spark UI allows you to monitor and debug your Spark Jobs submitted to run on Amazon EMR from Studio notebooks. SSH tunneling and presigned URLs are two ways for accessing the Spark UI.

Set up SSH tunneling for Spark UI access

To set up SSH tunneling to access the Spark UI, follow one of the two options in this section.

Options for setting up SSH tunneling:

- Option 1: Set up an SSH tunnel to the master node using local port forwarding
- Option 2, part 1: Set up an SSH tunnel to the master node using dynamic port forwarding
  
  Option 2, part 2: Configure proxy settings to view websites hosted on the master node

For information about viewing web interfaces hosted on Amazon EMR clusters, see View web interfaces hosted on Amazon EMR Clusters. You can also visit your Amazon EMR console to get access to the Spark UI.

Note

You can set up an SSH tunnel even if presigned URLs are not available to you.
Presigned URLs

To create one-click URLs that can access Spark UI on Amazon EMR from SageMaker Studio notebooks, you must enable the following IAM permissions. Choose the option that applies to you:

- For Amazon EMR clusters that are in the same account as the SageMaker Studio notebook: Add the following permissions to the SageMaker Studio IAM execution role.
- For Amazon EMR clusters that are in a different account (not SageMaker Studio notebook): Add the following permissions to the cross-account role that you created for Discover Amazon EMR clusters from SageMaker Studio (p. 1381).

**Note**

You can access presigned URLs from the console in the following regions:

- US East (N. Virginia) Region
- US West (N. California) Region
- Canada (Central) Region
- Europe (Frankfurt) Region
- Europe (Stockholm) Region
- Europe (Ireland) Region
- Europe (London) Region
- Europe (Paris) Region
- Asia Pacific (Tokyo) Region
- Asia Pacific (Seoul) Region
- Asia Pacific (Sydney) Region
- Asia Pacific (Mumbai) Region
- Asia Pacific (Singapore) Region
- South America (São Paulo)

The following policy gives access to presigned URLs for your execution role.

```json
{
   "Sid": "AllowPresignedUrl",
   "Effect": "Allow",
   "Action": [
      "elasticmapreduce:DescribeCluster",
      "elasticmapreduce:ListInstanceGroups",
      "elasticmapreduce:CreatePersistentAppUI",
      "elasticmapreduce:DescribePersistentAppUI",
      "elasticmapreduce:GetPersistentAppUIPresignedURL",
      "elasticmapreduce:GetOnClusterAppUIPresignedURL"
   ],
   "Resource": [
      "arn:aws:elasticmapreduce:region:account-id:cluster/*"
   ]
}
```

Walkthroughs and whitepapers

The following blogs use a case study of sentiment prediction for a movie review to illustrate the process of executing a complete machine learning workflow. This includes data preparation, monitoring Spark jobs, and training and deploying a ML model to get predictions directly from your Studio notebook.
• Create and manage Amazon EMR clusters from SageMaker Studio to run interactive Spark and ML workloads.

• To extend the use case to a cross-account configuration where SageMaker Studio and your Amazon EMR cluster are deployed in separate AWS accounts, see Create and manage Amazon EMR clusters from SageMaker Studio to run interactive Spark and ML workloads - Part 2.

See also:

• A walkthrough of the configuration of Access Apache Livy using a Network Load Balancer on a Kerberos-enabled Amazon EMR cluster.

• AWS whitepapers for SageMaker Studio best practices.

Additional Configuration for cross accounts use cases (for administrators)

To enable cluster discovery across accounts, administrators need to provide the ARN of a cross-account IAM role to the execution role of SageMaker Studio. SageMaker Studio's execution role assumes that remote role to discover and connect to Amazon EMR clusters in the trusting account. The ARN of this role is loaded by the Studio's Jupyter server at launch.

You can specify this information in two ways.

• Write this remote role in a file named `emr-discovery-iam-role-arns-DO_NOT_DELETE.json` placed in the directory `.cross-account-configuration-DO_NOT_DELETE` in your home directory located in the Amazon EFS storage volume used by SageMaker Studio.

• Alternatively, you can automate this process by using Lifecycle Configuration (LCC) scripts. You can attach the LCC to your Domain or a specific user profile. The LCC script that you use must be a JupyterServer configuration. For more information on how to create an LCC script, see Use Lifecycle Configurations with Studio.

The following is an example LCC script. To modify the script, replace `ASSUMABLE-ROLE` and `emr-account` with your role name and remote account ID, respectively. The number of cross accounts is limited to five.

```bash
#!/bin/bash
set -eux

FILE_DIRECTORY="/home/sagemaker-user/.cross-account-configuration-DO_NOT_DELETE"
FILE_NAME="emr-discovery-iam-role-arns-DO_NOT_DELETE.json"
FILE="$FILE_DIRECTORY/$FILE_NAME"

mkdir -p $FILE_DIRECTORY

cat > "$FILE" <<- "EOF"
{
  "emr-cross-account1": "arn:aws:iam::emr-cross-account1:role/ASSUMABLE-ROLE",
  "emr-cross-account2": "arn:aws:iam::emr-cross-account2:role/ASSUMABLE-ROLE"
}
EOF
```
After the LCC runs and the files are written, the server reads the file /home/sagemaker-user/.cross-account-configuration-DO_NOT_DELETE/emr-discovery-iam-role-arns-DO_NOT_DELETE.json and stores the cross-account ARN.

Troubleshooting

The following are common errors that might occur while connecting or using Amazon EMR clusters from Studio notebooks.

Troubleshoot Livy connections hanging or failing

The following are Livy connectivity issues that might occur while using Amazon EMR clusters from Studio notebooks.

• Your Amazon EMR cluster encountered an out-of-memory error.

A possible reason for a Livy connection via sparkmagic hanging or failing is if your Amazon EMR cluster encountered an out-of-memory error.

By default, the Java configuration parameter of the Apache Spark driver, spark.driver.defaultJavaOptions, is set to -XX:OnOutOfMemoryError='kill -9 %p'. This means that the default action taken when the driver program encounters an OutOfMemoryError is to terminate the driver program by sending a SIGKILL signal. When the Apache Spark driver is terminated, any Livy connection via sparkmagic that depends on that driver hangs or fails. This is because the Spark driver is responsible for managing the Spark application's resources, including task scheduling and execution. Without the driver, the Spark application cannot function, and any attempts to interact with it fails.

If you suspect that your Spark cluster is experiencing memory issues, you can check Amazon EMR logs. Containers killed due to out-of-memory errors typically exit with a code of 137. In such cases, you need to restart the Spark application and establish a new Livy connection to resume interaction with the Spark cluster.

You can refer to the knowledge base article How do I resolve the error “Container killed by YARN for exceeding memory limits” in Spark on Amazon EMR? on AWS re:Post to learn about various strategies and parameters that can be used to address an out-of-memory issue.

We recommend reviewing the Amazon EMR Best Practices Guides for best practices and tuning guidance on running Apache Spark workloads on your Amazon EMR clusters.

• Your Livy session times out when connecting to an Amazon EMR cluster for the first time.

When you initially connect to an Amazon EMR cluster using sagemaker-studio-analytics-extension, which enables connection to a remote Spark (Amazon EMR) cluster via the SparkMagic library using Apache Livy, you may encounter a connection timeout error:

An error was encountered: Session 0 did not start up in 60 seconds.

If your Amazon EMR cluster requires the initialization of a Spark application upon establishing a connection, there is an increased chance of seeing connection timeout errors.

To reduce the chances of getting timeouts when connecting to an Amazon EMR cluster using Livy through the analytics extension, sagemaker-studio-analytics-extension version 0.0.19 and later override the default server session timeout to 120 seconds instead of sparkmagic's default of 60 seconds.

We recommend upgrading your extension 0.0.18 and sooner by running the following upgrade command.
pip install --upgrade sagemaker-studio-analytics-extension

Note that when providing a custom timeout configuration in sparkmagic, sagemaker-studio-analytics-extension honors this override. However, setting the session timeout to 60 seconds automatically triggers the default server session timeout of 120 seconds in sagemaker-studio-analytics-extension.

Prepare data using AWS Glue Interactive Sessions

AWS Glue Interactive Sessions is an on-demand, serverless, Apache Spark runtime environment that data scientists and engineers can use to rapidly build, test, and run data preparation and analytics applications.

You can initiate an AWS Glue interactive session by starting a SageMaker Studio notebook. When creating your Studio notebook, choose the built-in Glue PySpark or Glue Spark kernel. This automatically starts an interactive, serverless Spark session. You do not need to provision or manage any compute cluster or infrastructure. After initialization, you can explore the AWS Glue Data Catalog, execute complex queries, and interactively analyze and prepare data using Spark within your Studio notebook. You can then use the prepared data to build, train, tune, and deploy models using the purpose-built ML tools within SageMaker Studio.

Before starting your AWS Glue interactive session in SageMaker Studio, you need to set the appropriate roles and policies. Additionally, you may need to provide access to additional resources, such as a storage Amazon S3 bucket, which might require additional policies. For more information about required and additional IAM policies, see Permissions for AWS Glue Interactive Sessions in SageMaker Studio (p. 1394).

SageMaker Studio provides a default configuration for your AWS Glue interactive session, however, you can use AWS Glue’s full catalog of Jupyter magic commands to further customize your environment. For information about the default and additional Jupyter magics that you can use in your AWS Glue interactive session, see Configure your AWS Glue interactive session in SageMaker Studio (p. 1397).

The supported images and kernels for connecting to a AWS Glue interactive session are as follows:

- Images: SparkAnalytics 1.0, SparkAnalytics 2.0
- Kernel: Glue Python [PySpark and Ray] and Glue Spark

Prerequisites:

The SparkAnalytics image that you select to launch your AWS Glue session in Studio is a combination of two frameworks - the SparkMagic framework (used with Amazon EMR), and AWS Glue. For this reason, the prerequisites for both frameworks apply. However, you do not have to set up the Amazon EMR cluster if you only plan to use AWS Glue Interactive Sessions. Before you start your first AWS Glue interactive session in Studio, complete the following:

- Complete the prerequisites required to use the SparkMagic image. For a list of the prerequisites, see the Prerequisites section in Prepare Data at Scale with Studio Notebooks.
- Create an execution role with permissions for both AWS Glue and SageMaker Studio. Add the managed policy AwsGlueSessionUserRestrictedServiceRole, and create a custom policy that includes permissions sts:GetCallerIdentity, iam:GetRole, and IAM:Passrole. For instructions about how to create the necessary permissions, see Permissions for AWS Glue Interactive Sessions in SageMaker Studio (p. 1394).
- Create a SageMaker Domain with the execution role you created. For instructions about how to create a Domain, see Onboard using IAM (p. 39).
Get Started with AWS Glue Interactive Sessions

In this guide, you learn how to initiate an AWS Glue interactive session in SageMaker Studio, and manage your environment with Jupyter magics.

Permissions for AWS Glue Interactive Sessions in SageMaker Studio

This section lists the required policies to run AWS Glue interactive sessions in Studio and explains how to set them up. In particular, it details how to:

- Attach the AwsGlueSessionUserRestrictedServiceRole managed policy to your SageMaker execution role.
- Create an inline custom policy on your SageMaker execution role.
- Modify the trust relationship of your SageMaker execution role.

To attach the AwsGlueSessionUserRestrictedServiceRole managed policy to your execution role

1. Open the IAM console.
2. Select Roles in the left-side panel.
3. Find your Studio execution role. Choose the role name to access the role summary page.
4. Under the Permissions tab, select Attach policies from the Add Permissions dropdown menu.
5. Select the checkbox next to the managed policy AwsGlueSessionUserRestrictedServiceRole.
6. Choose Attach policies.

   The summary page shows your newly-added managed policies.

To create the inline custom policy on your execution role

1. Select Create inline policy in the Add Permissions dropdown menu.
2. Select the JSON tab.
3. Copy and paste in the following policy.

   ```json
   {
   "Version": "2012-10-17",
   "Statement": [
   {
   "Sid": "unique_statement_id",
   "Effect": "Allow",
   "Action": [
   "iam:GetRole",
   "iam:PassRole",
   "sts:GetCallerIdentity"
   ],
   "Resource": "*"
   }
   ]
   }
   
   
   5. Enter a Name and choose Create policy.

   The summary page shows your newly-added custom policy.
To modify the trust relationship of your execution role

1. Select the Trust relationships tab.
2. Choose Edit trust policy.
3. Copy and paste in the following policy.

```json
{
"Version": "2012-10-17",
"Statement": [
{
"Effect": "Allow",
"Principal": {
"Service": [
"glue.amazonaws.com",
"sagemaker.amazonaws.com"
]
},
"Action": "sts:AssumeRole"
}
]
}
```
4. Choose Update policy.

You can add additional roles and policies if you need to access other AWS resources. For a description of the additional roles and policies you can include, see Interactive sessions with IAM in the AWS Glue documentation.

Tag propagation

Tags are commonly used to track and allocate costs, control access to your session, isolate your resources, and more. To learn about adding metadata to your AWS resources using tagging, or for details on common use cases, see Additional information (p. 1397).

You can enable the automatic propagation of AWS tags to new AWS Glue interactive sessions created from within the Studio UI. When an AWS Glue interactive session is created from SageMaker Studio, any user-defined tags attached to the user profile or shared space are carried over to the new AWS Glue interactive session. Additionally, SageMaker Studio automatically adds two AWS-generated internal tags ((sagemaker:user-profile-arn and sagemaker:domain-arn) or (sagemaker:shared-space-arn and sagemaker:domain-arn)) to new AWS Glue interactive sessions created from the Studio UI. You can use these tags to aggregate costs across individual Domains, user profiles, or spaces.

Enable tag propagation

To enable the automatic propagation of tags to new AWS Glue interactive sessions, set the following permissions for your SageMaker execution role and the IAM role associated with your AWS Glue session:

**Note**

By default, the role associated with the AWS Glue interactive session is the same as the SageMaker execution role. You can specify a different execution role for the AWS Glue interactive session by using the %iam_role magic command. For information on the available Jupyter magic commands to configure AWS Glue interactive sessions, see Configure your AWS Glue interactive session in SageMaker Studio (p. 1397).

- **On your SageMaker execution role**: Create a new inline policy, and paste the following JSON file. The policy grants the execution role permission to describe (DescribeUserProfile, DescribeSpace, DescribeDomain) and list the tags (ListTag) set on the user profiles, shared spaces, and SageMaker Domain.
• On the IAM role of your AWS Glue session: Create a new inline policy, and paste the following JSON file. The policy grants your role permission to attach tags (TagResource) to your session, or retrieve its list of tags (GetTags).

```json
{
  "Effect": "Allow",
  "Action": [
    "sagemaker:ListTags",
    "sagemaker:DescribeUserProfile",
    "sagemaker:DescribeSpace",
    "sagemaker:DescribeDomain"
  ],
  "Resource": [
    "arn:aws:sagemaker:*:*:user-profile/*",
    "arn:aws:sagemaker:*:*:space/*",
    "arn:aws:sagemaker:*:*:space/*",
    "arn:aws:sagemaker:*:*:domain/*"
  ]
}
```

Note

• Failures occurring while applying those permissions do not prevent the creation of AWS Glue interactive sessions. You can find details about the reason of the failure in SageMaker Studio CloudWatch logs.
• You must restart the kernel of your AWS Glue interactive session to propagate the update of a tag’s value.
It is important to note the following points:

- Once a tag is attached to a session, it cannot be removed by propagation.

You can remove tags from an AWS Glue interactive session directly through the AWS CLI, the AWS Glue API, or the [console.aws.amazon.com/sagemaker/](https://console.aws.amazon.com/sagemaker/). For example, using the AWS CLI, you can remove a tag by providing the session's ARN and the tag keys you want to remove as follows:

```bash
aws glue untag-resource
--tags-to-remove tag-key1,tag-key2
```

- SageMaker Studio adds two AWS-generated internal tags (`sagemaker:user-profile-arn` and `sagemaker:domain-arn`) or (`sagemaker:shared-space-arn` and `sagemaker:domain-arn`) to new AWS Glue interactive sessions created from the Studio UI. Those tags count against the limit of 50 tags set on all AWS resources. Both `sagemaker:user-profile-arn` and `sagemaker:shared-space-arn` contain the Domain ID to which they belong.

- Tags keys starting with `aws:`, `AWS:`, or any combination of upper and lowercase letters as a prefix for keys are not propagated and are reserved for AWS use.

Additional information

For more information on tagging, refer to the following resources.

- To learn about adding metadata to your AWS resources with tagging, see [Tagging AWS resources](#).
- For information on tracking costs using tags, see [Cost analysis](#) in SageMaker Studio Administration Best Practices.
- For information on controlling access to AWS Glue based on tag keys, see [ABAC with AWS Glue](#).

Launch your AWS Glue interactive session on SageMaker Studio

After you create the roles, policies, and SageMaker Domain, you can launch your AWS Glue interactive session in SageMaker Studio.

To launch AWS Glue in SageMaker Studio

1. Create a SageMaker Domain. For instructions on how to create a new Domain, see [Onboard to Amazon SageMaker Domain (p. 10)](#).
3. Select Control Panel in the left-side panel.
4. In the Launch App dropdown menu next to the user name, select Studio.
5. In the Jupyter view, choose File, then New, then Notebook.
6. In the Image dropdown menu, select SparkAnalytics 1.0 or SparkAnalytics 2.0. In the kernel dropdown menu, select Glue Spark or Glue Python [PySpark and Ray]. Choose Select.
7. (optional) Use Jupyter magics to customize your environment. For more information about Jupyter magics, see [Configure your AWS Glue interactive session in SageMaker Studio (p. 1397)](#).
8. Start writing your Spark data processing scripts.

Configure your AWS Glue interactive session in SageMaker Studio

**Note**

All magic configurations are carried over to subsequent sessions for the lifetime of the AWS Glue kernel.
You can use Jupyter magics in your AWS Glue interactive session to modify your session and configuration parameters. Magics are short commands prefixed with `%` at the start of Jupyter cells that provide a quick and easy way to help you control your environment. In your AWS Glue interactive session, the following magics are set for you by default:

<table>
<thead>
<tr>
<th>Magic</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>%glue_version</td>
<td>3.0</td>
</tr>
<tr>
<td>%iam_role</td>
<td>execution role attached to your SageMaker Domain</td>
</tr>
<tr>
<td>%region</td>
<td>your region</td>
</tr>
</tbody>
</table>

You can use magics to further customize your environment. For example, if you want to change the number of workers allocated to your job from the default five to 10, you can specify `%number_of_workers 10`. If you want to configure your session to stop after 10 minutes of idle time instead of the default 2880, you can specify `%idle_timeout 10`.

All of the Jupyter magics currently available in AWS Glue are also available in SageMaker Studio. For the complete list of AWS Glue magics available, see Configuring AWS Glue interactive sessions for Jupyter and AWS Glue Studio notebooks.

**AWS Glue Interactive Session Pricing**

When you use AWS Glue Interactive Sessions on SageMaker Studio notebooks, you are charged separately for resource usage on AWS Glue and Studio notebooks.

AWS charges for AWS Glue Interactive Sessions based on how long the session is active and the number of Data Processing Units (DPU) used. You are charged an hourly rate for the number of DPUs used to run your workloads, billed in increments of one second. AWS Glue Interactive Sessions assigns a default of five DPUs and requires a minimum of two DPUs. There is also a one-minute minimum billing duration for each interactive session. To see the AWS Glue rates and pricing examples, or to estimate your costs using the AWS Pricing Calculator, see AWS Glue pricing.

Your SageMaker Studio notebook runs on an Amazon EC2 instance and you are charged for the instance type you choose, based on the duration of use. Studio assigns you a default EC2 instance type of `ml-t3-medium` when you select the SparkAnalytics image and associated kernel. You can change the instance type for of your Studio notebook to suit your workload. For information about SageMaker Studio pricing, see Amazon SageMaker Pricing.
Process data

To analyze data and evaluate machine learning models on Amazon SageMaker, use Amazon SageMaker Processing. With Processing, you can use a simplified, managed experience on SageMaker to run your data processing workloads, such as feature engineering, data validation, model evaluation, and model interpretation. You can also use the Amazon SageMaker Processing APIs during the experimentation phase and after the code is deployed in production to evaluate performance.

The preceding diagram shows how Amazon SageMaker spins up a Processing job. Amazon SageMaker takes your script, copies your data from Amazon Simple Storage Service (Amazon S3), and then pulls a processing container. The processing container image can either be an Amazon SageMaker built-in image or a custom image that you provide. The underlying infrastructure for a Processing job is fully managed by Amazon SageMaker. Cluster resources are provisioned for the duration of your job, and cleaned up when a job completes. The output of the Processing job is stored in the Amazon S3 bucket you specified.

Note
Your input data must be stored in an Amazon S3 bucket. Alternatively, you can use Amazon Athena or Amazon Redshift as input sources.

Tip
To learn best practices for distributed computing of machine learning (ML) training and processing jobs in general, see Distributed computing with SageMaker best practices (p. 2225).

Use Amazon SageMaker Processing Sample Notebooks

We provide two sample Jupyter notebooks that show how to perform data preprocessing, model evaluation, or both.

For a sample notebook that shows how to run scikit-learn scripts to perform data preprocessing and model training and evaluation with the SageMaker Python SDK for Processing, see scikit-learn Processing. This notebook also shows how to use your own custom container to run processing workloads with your Python libraries and other specific dependencies.

For a sample notebook that shows how to use Amazon SageMaker Processing to perform distributed data preprocessing with Spark, see Distributed Processing (Spark). This notebook also shows how to train a regression model using XGBoost on the preprocessed dataset.

For instructions on how to create and access Jupyter notebook instances that you can use to run these samples in SageMaker, see Amazon SageMaker Notebook Instances (p. 298). After you have created a
notebook instance and opened it, choose the SageMaker Examples tab to see a list of all the SageMaker samples. To open a notebook, choose its Use tab and choose Create copy.

Monitor Amazon SageMaker Processing Jobs with CloudWatch Logs and Metrics

Amazon SageMaker Processing provides Amazon CloudWatch logs and metrics to monitor processing jobs. CloudWatch provides CPU, GPU, memory, GPU memory, and disk metrics, and event logging. For more information, see Monitor Amazon SageMaker with Amazon CloudWatch (p. 3577) and Log Amazon SageMaker Events with Amazon CloudWatch (p. 3591).

Data Processing with Apache Spark

Apache Spark is a unified analytics engine for large-scale data processing. Amazon SageMaker provides prebuilt Docker images that include Apache Spark and other dependencies needed to run distributed data processing jobs. With the Amazon SageMaker Python SDK, you can easily apply data transformations and extract features (feature engineering) using the Spark framework. For information about using the SageMaker Python SDK to run Spark processing jobs, see Data Processing with Spark in the Amazon SageMaker Python SDK.

A code repository that contains the source code and Dockerfiles for the Spark images is available on GitHub.

Running a Spark Processing Job

You can use the sagemaker.spark.PySparkProcessor or sagemaker.spark.SparkJarProcessor class to run your Spark application inside of a processing job. Note you can set MaxRuntimeInSeconds to a maximum runtime limit of 5 days. With respect to execution time, and number of instances used, simple spark workloads see a near linear relationship between the number of instances vs. time to completion.

The following code example shows how to run a processing job that invokes your PySpark script preprocess.py.

```python
from sagemaker.spark.processing import PySparkProcessor

spark_processor = PySparkProcessor(
    base_job_name="spark-preprocessor",
    framework_version="2.4",
    role=role,
    instance_count=2,
    instance_type="ml.m5.xlarge",
    max_runtime_in_seconds=1200,
)

spark_processor.run(
    submit_app="preprocess.py",
    arguments=['s3_input_bucket', bucket,
              's3_input_key_prefix', input_prefix,
              's3_output_bucket', bucket,
              's3_output_key_prefix', output_prefix]
)
```
For an in-depth look, see the Distributed Data Processing with Apache Spark and SageMaker Processing example notebook.

If you are not using the Amazon SageMaker Python SDK and one of its Processor classes to retrieve the pre-built images, you can retrieve these images yourself. The SageMaker prebuilt Docker images are stored in Amazon Elastic Container Registry (Amazon ECR). For a complete list of the available pre-built Docker images, see the available images document.

To learn more about using the SageMaker Python SDK with Processing containers, see Amazon SageMaker Python SDK.

Data Processing with scikit-learn

For a sample notebook that shows how to run scikit-learn scripts using a Docker image provided and maintained by SageMaker to preprocess data and evaluate models, see scikit-learn Processing. To use this notebook, you need to install the SageMaker Python SDK for Processing.

This notebook runs a processing job using SKLearnProcessor class from the the SageMaker Python SDK to run a scikit-learn script that you provide. The script preprocesses data, trains a model using a SageMaker training job, and then runs a processing job to evaluate the trained model. The processing job estimates how the model is expected to perform in production.

To learn more about using the SageMaker Python SDK with Processing containers, see the SageMaker Python SDK. For a complete list of pre-built Docker images available for processing jobs, see Docker Registry Paths and Example Code.

The following code example shows how the notebook uses SKLearnProcessor to run your own scikit-learn script using a Docker image provided and maintained by SageMaker, instead of your own Docker image.

```python
from sagemaker.sklearn.processing import SKLearnProcessor
from sagemaker.processing import ProcessingInput, ProcessingOutput

sklearn_processor = SKLearnProcessor(framework_version='0.20.0',
                                       role=role,
                                       instance_type='ml.m5.xlarge',
                                       instance_count=1)

sklearn_processor.run(code='preprocessing.py',
                       inputs=[ProcessingInput(
                               source='s3://path/to/my/input-data.csv',
                               destination='/opt/ml/processing/input')],
                       outputs=[ProcessingOutput(source='/opt/ml/processing/output/train'),
                                ProcessingOutput(source='/opt/ml/processing/output/validation'),
                                ProcessingOutput(source='/opt/ml/processing/output/test')])
```

To process data in parallel using Scikit-Learn on Amazon SageMaker Processing, you can shard input objects by S3 key by setting `s3_data_distribution_type='ShardedByS3Key'` inside a ProcessingInput so that each instance receives about the same number of input objects.

Data Processing with Framework Processors

A FrameworkProcessor can run Processing jobs with a specified machine learning framework, providing you with an Amazon SageMaker–managed container for whichever machine learning
framework you choose. FrameworkProcessor provides premade containers for the following machine learning frameworks: Hugging Face, MXNet, PyTorch, TensorFlow, and XGBoost.

The FrameworkProcessor class also provides you with customization over the container configuration. The FrameworkProcessor class supports specifying a source directory source_dir for your processing scripts and dependencies. With this capability, you can give the processor access to multiple scripts in a directory instead of only specifying one script. FrameworkProcessor also supports including a requirements.txt file in the source_dir for customizing the Python libraries to install in the container.

For more information on the FrameworkProcessor class and its methods and parameters, see FrameworkProcessor in the Amazon SageMaker Python SDK.

To see examples of using a FrameworkProcessor for each of the supported machine learning frameworks, see the following topics.

Topics
- Hugging Face Framework Processor (p. 1402)
- MXNet Framework Processor (p. 1403)
- PyTorch Framework Processor (p. 1404)
- TensorFlow Framework Processor (p. 1405)
- XGBoost Framework Processor (p. 1406)

Hugging Face Framework Processor

Hugging Face is an open-source provider of natural language processing (NLP) models. The HuggingFaceProcessor in the Amazon SageMaker Python SDK provides you with the ability to run processing jobs with Hugging Face scripts. When you use the HuggingFaceProcessor, you can leverage an Amazon-built Docker container with a managed Hugging Face environment so that you don't need to bring your own container.

The following code example shows how you can use the HuggingFaceProcessor to run your Processing job using a Docker image provided and maintained by SageMaker. Note that when you run the job, you can specify a directory containing your scripts and dependencies in the source_dir argument, and you can have a requirements.txt file located inside your source_dir directory that specifies the dependencies for your processing script(s). SageMaker Processing installs the dependencies in requirements.txt in the container for you.

```python
from sagemaker.huggingface import HuggingFaceProcessor
from sagemaker.processing import ProcessingInput, ProcessingOutput
from sagemaker import get_execution_role

#Initialize the HuggingFaceProcessor
hfp = HuggingFaceProcessor(
    role=get_execution_role(),
    instance_count=1,
    instance_type='ml.g4dn.xlarge',
    transformers_version='4.4.2',
    pytorch_version='1.6.0',
    base_job_name='frameworkprocessor-hf'
)

#Run the processing job
hfp.run(
    code='processing-script.py',
    source_dir='scripts',
    inputs=[]
)
```
If you have a requirements.txt file, it should be a list of libraries you want to install in the container. The path for source_dir can be a relative, absolute, or Amazon S3 URI path. However, if you use an Amazon S3 URI, then it must point to a tar.gz file. You can have multiple scripts in the directory you specify for source_dir. To learn more about the HuggingFaceProcessor class, see Hugging Face Estimator in the Amazon SageMaker Python SDK.

### MXNet Framework Processor

Apache MXNet is an open-source deep learning framework commonly used for training and deploying neural networks. The MXNetProcessor in the Amazon SageMaker Python SDK provides you with the ability to run processing jobs with MXNet scripts. When you use the MXNetProcessor, you can leverage an Amazon-built Docker container with a managed MXNet environment so that you don’t need to bring your own container.

The following code example shows how you can use the MXNetProcessor to run your Processing job using a Docker image provided and maintained by SageMaker. Note that when you run the job, you can specify a directory containing your scripts and dependencies in the source_dir argument, and you can have a requirements.txt file located inside your source_dir directory that specifies the dependencies for your processing script(s). SageMaker Processing installs the dependencies in requirements.txt in the container for you.

```python
from sagemaker.mxnet import MXNetProcessor
from sagemaker.processing import ProcessingInput, ProcessingOutput
from sagemaker import get_execution_role

#Initialize the MXNetProcessor
mxp = MXNetProcessor(
    framework_version='1.8.0',
    py_version='py37',
    role=get_execution_role(),
    instance_count=1,
    instance_type='ml.c5.xlarge',
    base_job_name='frameworkprocessor-mxnet'
)

#Run the processing job
mxp.run(
    code='processing-script.py',
    source_dir='scripts',
    inputs=[
        ProcessingInput(  
            input_name='data',
            source='s3://(BUCKET)/(S3_INPUT_PATH)',
            destination='/opt/ml/processing/input/data/
        )
    ],
    outputs=[
        ProcessingOutput(output_name='train', source='/opt/ml/processing/output/train/',
                         destination='s3://(BUCKET)/(S3_OUTPUT_PATH)'),
        ProcessingOutput(output_name='test', source='/opt/ml/processing/output/test/',
                         destination='s3://(BUCKET)/(S3_OUTPUT_PATH)'),
        ProcessingOutput(output_name='val', source='/opt/ml/processing/output/val/',
                         destination='s3://(BUCKET)/(S3_OUTPUT_PATH)')
    ]
)
```
If you have a requirements.txt file, it should be a list of libraries you want to install in the container. The path for source_dir can be a relative, absolute, or Amazon S3 URI path. However, if you use an Amazon S3 URI, then it must point to a tar.gz file. You can have multiple scripts in the directory you specify for source_dir. To learn more about the MXNetProcessor class, see MXNet Estimator in the Amazon SageMaker Python SDK.

**PyTorch Framework Processor**

PyTorch is an open-source machine learning framework. The PyTorchProcessor in the Amazon SageMaker Python SDK provides you with the ability to run processing jobs with PyTorch scripts. When you use the PyTorchProcessor, you can leverage an Amazon-built Docker container with a managed PyTorch environment so that you don't need to bring your own container.

The following code example shows how you can use the PyTorchProcessor to run your Processing job using a Docker image provided and maintained by SageMaker. Note that when you run the job, you can specify a directory containing your scripts and dependencies in the source_dir argument, and you can have a requirements.txt file located inside your source_dir directory that specifies the dependencies for your processing script(s). SageMaker Processing installs the dependencies in requirements.txt in the container for you.

```python
from sagemaker.pytorch.processing import PyTorchProcessor
from sagemaker.processing import ProcessingInput, ProcessingOutput
from sagemaker import get_execution_role

# Initialize the PyTorchProcessor
pytorch_processor = PyTorchProcessor(
    framework_version='1.8',
    role=get_execution_role(),
    instance_type='ml.m5.xlarge',
    instance_count=1,
    base_job_name='frameworkprocessor-PT'
)

# Run the processing job
pytorch_processor.run(
    code='processing-script.py',
    source_dir='scripts',
    inputs=[
        ProcessingInput(
            input_name='data',
            source=f's3://{BUCKET}/{S3_INPUT_PATH}',
            destination='/opt/ml/processing/input'
        )
    ],
    outputs=[
        ProcessingOutput(output_name='data_structured', source='/opt/ml/processing/tmp/data_structured', destination=f's3://{BUCKET}/{S3_OUTPUT_PATH}'),
        ProcessingOutput(output_name='train', source='/opt/ml/processing/output/train', destination=f's3://{BUCKET}/{S3_OUTPUT_PATH}'),
        ProcessingOutput(output_name='validation', source='/opt/ml/processing/output/val', destination=f's3://{BUCKET}/{S3_OUTPUT_PATH}')
    ]
)
```
TensorFlow Framework Processor

TensorFlow is an open-source machine learning and artificial intelligence library. The TensorFlowProcessor in the Amazon SageMaker Python SDK provides you with the ability to run processing jobs with TensorFlow scripts. When you use the TensorFlowProcessor, you can leverage an Amazon-built Docker container with a managed TensorFlow environment so that you don’t need to bring your own container.

The following code example shows how you can use the TensorFlowProcessor to run your Processing job using a Docker image provided and maintained by SageMaker. Note that when you run the job, you can specify a directory containing your scripts and dependencies in the source_dir argument, and you can have a requirements.txt file located inside your source_dir directory that specifies the dependencies for your processing script(s). SageMaker Processing installs the dependencies in requirements.txt in the container for you.

```python
from sagemaker.tensorflow import TensorFlowProcessor
from sagemaker.processing import ProcessingInput, ProcessingOutput
from sagemaker import get_execution_role

#Initialize the TensorFlowProcessor
tp = TensorFlowProcessor(
    framework_version='2.3',
    role=get_execution_role(),
    instance_type='ml.m5.xlarge',
    instance_count=1,
    base_job_name='frameworkprocessor-TF',
    py_version='py37'
)

#Run the processing job
tp.run(
    code='processing-script.py',
    source_dir='scripts',
    inputs=[
        ProcessingInput(
            input_name='data',
            source=f's3://{BUCKET}/{S3_INPUT_PATH}',
            destination='/opt/ml/processing/input/data'
        ),
        ProcessingInput(
            input_name='model',
            source=f's3://{BUCKET}/{S3_PATH_TO_MODEL}',
            destination='/opt/ml/processing/input/model'
        )
    ],
    outputs=[
        ProcessingOutput(
            output_name='predictions',
        )
    ]
)
```

If you have a requirements.txt file, it should be a list of libraries you want to install in the container. The path for source_dir can be a relative, absolute, or Amazon S3 URI path. However, if you use an Amazon S3 URI, then it must point to a tar.gz file. You can have multiple scripts in the directory you specify for source_dir. To learn more about the PyTorchProcessor class, see PyTorch Estimator in the Amazon SageMaker Python SDK.
If you have a requirements.txt file, it should be a list of libraries you want to install in the container. The path for source_dir can be a relative, absolute, or Amazon S3 URI path. However, if you use an Amazon S3 URI, then it must point to a tar.gz file. You can have multiple scripts in the directory you specify for source_dir. To learn more about the TensorFlowProcessor class, see TensorFlow Estimator in the Amazon SageMaker Python SDK.

**XGBoost Framework Processor**

XGBoost is an open-source machine learning framework. The XGBoostProcessor in the Amazon SageMaker Python SDK provides you with the ability to run processing jobs with XGBoost scripts. When you use the XGBoostProcessor, you can leverage an Amazon-built Docker container with a managed XGBoost environment so that you don’t need to bring your own container.

The following code example shows how you can use the XGBoostProcessor to run your Processing job using a Docker image provided and maintained by SageMaker. Note that when you run the job, you can specify a directory containing your scripts and dependencies in the source_dir argument, and you can have a requirements.txt file located inside your source_dir directory that specifies the dependencies for your processing script(s). SageMaker Processing installs the dependencies in requirements.txt in the container for you.

```python
from sagemaker.xgboost import XGBoostProcessor
from sagemaker.processing import ProcessingInput, ProcessingOutput
from sagemaker import get_execution_role

#Initialize the XGBoostProcessor
xgb = XGBoostProcessor(
    framework_version='1.2-2',
    role=get_execution_role(),
    instance_type='ml.m5.xlarge',
    instance_count=1,
    base_job_name='frameworkprocessor-XGB',
)

#Run the processing job
xgb.run(
    code='processing-script.py',
    source_dir='scripts',
    inputs=[
        ProcessingInput(
            input_name='data',
            source=f's3://{BUCKET}/{S3_INPUT_PATH}',
            destination='/opt/ml/processing/input/data'
        ),
    ],
    outputs=[
        ProcessingOutput(
            output_name='processed_data',
            source='/opt/ml/processing/output/',
            destination=f's3://{BUCKET}/{S3_OUTPUT_PATH}'
        ),
    ]
)
```

If you have a requirements.txt file, it should be a list of libraries you want to install in the container. The path for source_dir can be a relative, absolute, or Amazon S3 URI path. However, if you use an
Amazon S3 URI, then it must point to a tar.gz file. You can have multiple scripts in the directory you specify for source_dir. To learn more about the XGBoostProcessor class, see XGBoost Estimator in the Amazon SageMaker Python SDK.

Use Your Own Processing Code

You can install libraries to run your scripts in your own processing container or, in a more advanced scenario, you can build your own processing container that satisfies the contract to run in Amazon SageMaker. For more information about containers in SageMaker, see Use Docker containers to build models (p. 3281). For a formal specification that defines the contract for an Amazon SageMaker Processing container, see Build Your Own Processing Container (Advanced Scenario) (p. 1408).

Topics

- Run Scripts with Your Own Processing Container (p. 1407)
- Build Your Own Processing Container (Advanced Scenario) (p. 1408)

Run Scripts with Your Own Processing Container

You can use scikit-learn scripts to preprocess data and evaluate your models. To see how to run scikit-learn scripts to perform these tasks, see the scikit-learn Processing sample notebook. This notebook uses the ScriptProcessor class from the Amazon SageMaker Python SDK for Processing.

The following example shows a general workflow for using a ScriptProcessor class with your own processing container. The workflow shows how to create your own image, build your container, and use a ScriptProcessor class to run a Python preprocessing script with the container. The processing job processes your input data and saves the processed data in Amazon Simple Storage Service (Amazon S3).

Before using the following examples, you need to have your own input data and a Python script prepared to process your data. For an end-to-end, guided example of this process, refer back to the scikit-learn Processing sample notebook.

1. Create a Docker directory and add the Dockerfile used to create the processing container. Install pandas and scikit-learn into it. (You could also install your own dependencies with a similar RUN command.)

```
mkdir docker

%%writefile docker/Dockerfile

FROM python:3.7-slim-buster

RUN pip3 install pandas==0.25.3 scikit-learn==0.21.3

ENV PYTHONUNBUFFERED=TRUE

ENTRYPOINT ["python3"]
```

2. Build the container using the docker command, create an Amazon Elastic Container Registry (Amazon ECR) repository, and push the image to Amazon ECR.

```
import boto3

account_id = boto3.client('sts').get_caller_identity().get('Account')
region = boto3.Session().region_name
ecr_repository = 'sagemaker-processing-container'
```
3. Set up the ScriptProcessor from the SageMaker Python SDK to run the script. Replace `image_uri` with the URI for the image you created, and replace `role_arn` with the ARN for an AWS Identity and Access Management role that has access to your target Amazon S3 bucket.

```python
from sagemaker.processing import ScriptProcessor, ProcessingInput, ProcessingOutput
script_processor = ScriptProcessor(command=['python3'],
                                  image_uri='image_uri',
                                  role='role_arn',
                                  instance_count=1,
                                  instance_type='ml.m5.xlarge')
```

4. Run the script. Replace `preprocessing.py` with the name of your own Python processing script, and replace `s3://path/to/my/input-data.csv` with the Amazon S3 path to your input data.

```python
script_processor.run(code='preprocessing.py',
                     inputs=[ProcessingInput(
                              source='s3://path/to/my/input-data.csv',
                              destination='/opt/ml/processing/input')],
                     outputs=[ProcessingOutput(source='/opt/ml/processing/output/
                                                  train'),
                              ProcessingOutput(source='/opt/ml/processing/output/
                                                  validation'),
                              ProcessingOutput(source='/opt/ml/processing/output/
                                                  test')])
```

You can use the same procedure with any other library or system dependencies. You can also use existing Docker images. This includes images that you run on other platforms such as Kubernetes.

### Build Your Own Processing Container (Advanced Scenario)

You can provide Amazon SageMaker Processing with a Docker image that has your own code and dependencies to run your data processing, feature engineering, and model evaluation workloads.

The following example of a Dockerfile builds a container with the Python libraries scikit-learn and pandas, which you can run as a processing job.

```Dockerfile
FROM python:3.7-slim-buster
# Install scikit-learn and pandas
RUN pip3 install scikit-learn==0.25.3

# Add a Python script and configure Docker to run it
ADD processing_script.py /
ENTRYPOINT ["python3", "/processing_script.py"]
```
For an example of a processing script, see the [Get started with SageMaker Processing](https://docs.aws.amazon.com/sagemaker/latest/dg/get-started-processing.html).

Build and push this Docker image to an Amazon Elastic Container Registry (Amazon ECR) repository and ensure that your SageMaker IAM role can pull the image from Amazon ECR. Then you can run this image on Amazon SageMaker Processing.

**How Amazon SageMaker Processing Runs Your Processing Container Image**

Amazon SageMaker Processing runs your processing container image in a similar way as the following command, where `AppSpecification.ImageUri` is the Amazon ECR image URI that you specify in a `CreateProcessingJob` operation.

```
docker run [AppSpecification.ImageUri]
```

This command runs the `ENTRYPOINT` command configured in your Docker image.

You can also override the entrypoint command in the image or give command-line arguments to your entrypoint command using the `AppSpecification.ContainerEntrypoint` and `AppSpecification.ContainerArgument` parameters in your `CreateProcessingJob` request. Specifying these parameters configures Amazon SageMaker Processing to run the container similar to the way that the following command does.

```
```

For example, if you specify the `ContainerEntrypoint` to be `[python3, -v, /processing_script.py]` in your `CreateProcessingJob` request, and `ContainerArguments` to be `[data-format, csv]`, Amazon SageMaker Processing runs your container with the following command.

```
python3 -v /processing_script.py data-format csv
```

When building your processing container, consider the following details:

- Amazon SageMaker Processing decides whether the job completes or fails depending on the exit code of the command run. A processing job completes if all of the processing containers exit successfully with an exit code of 0, and fails if any of the containers exit with a non-zero exit code.

- Amazon SageMaker Processing lets you override the processing container's entrypoint and set command-line arguments just like you can with the Docker API. Docker images can also configure the entrypoint and command-line arguments using the `ENTRYPOINT` and `CMD` instructions. The way `CreateProcessingJob`'s `ContainerEntrypoint` and `ContainerArgument` parameters configure a Docker image's entrypoint and arguments mirrors how Docker overrides the entrypoint and arguments through the Docker API:
  - If neither `ContainerEntrypoint` nor `ContainerArguments` are provided, Processing uses the default `ENTRYPOINT` or `CMD` in the image.
  - If `ContainerEntrypoint` is provided, but not `ContainerArguments`, Processing runs the image with the given entrypoint, and ignores the `ENTRYPOINT` and `CMD` in the image.
  - If `ContainerArguments` is provided, but not `ContainerEntrypoint`, Processing runs the image with the default `ENTRYPOINT` in the image and with the provided arguments.
  - If both `ContainerEntrypoint` and `ContainerArguments` are provided, Processing runs the image with the given entrypoint and arguments, and ignores the `ENTRYPOINT` and `CMD` in the image.
• You must use the exec form of the ENTRYPOINT instruction in your Dockerfile (ENTRYPOINT ["executable", "param1", "param2"])) instead of the shell form (ENTRYPOINT command param1 param2). This lets your processing container receive SIGINT and SIGKILL signals, which Processing uses to stop processing jobs with the StopProcessingJob API.

• /opt/ml and all its subdirectories are reserved by SageMaker. When building your Processing Docker image, don't place any data required by your processing container in these directories.

• If you plan to use GPU devices, make sure that your containers are nvidia-docker compatible. Include only the CUDA toolkit in containers. Don't bundle NVIDIA drivers with the image. For more information about nvidia-docker, see NVIDIA/nvidia-docker.

How Amazon SageMaker Processing Configures Input and Output For Your Processing Container

When you create a processing job using the CreateProcessingJob operation, you can specify multiple ProcessingInput and ProcessingOutput values.

You use the ProcessingInput parameter to specify an Amazon Simple Storage Service (Amazon S3) URI to download data from, and a path in your processing container to download the data to. The ProcessingOutput parameter configures a path in your processing container from which to upload data, and where in Amazon S3 to upload that data to. For both ProcessingInput and ProcessingOutput, the path in the processing container must begin with /opt/ml/processing/.

For example, you might create a processing job with one ProcessingInput parameter that downloads data from s3://your-data-bucket/path/to/input/csv/data into /opt/ml/processing/csv in your processing container, and a ProcessingOutput parameter that uploads data from /opt/ml/processing/processed_csv to s3://your-data-bucket/path/to/output/csv/data. Your processing job would read the input data, and write output data to /opt/ml/processing/processed_csv. Then it uploads the data written to this path to the specified Amazon S3 output location.

Important
Symbolic links (symlinks) can not be used to upload output data to Amazon S3. Symlinks are not followed when uploading output data.

How Amazon SageMaker Processing Provides Logs and Metrics for Your Processing Container

When your processing container writes to stdout or stderr, Amazon SageMaker Processing saves the output from each processing container and puts it in Amazon CloudWatch logs. For information about logging, see Log Amazon SageMaker Events with Amazon CloudWatch (p. 3591).

Amazon SageMaker Processing also provides CloudWatch metrics for each instance running your processing container. For information about metrics, see Monitor Amazon SageMaker with Amazon CloudWatch (p. 3577).

How Amazon SageMaker Processing Configures Your Processing Container

Amazon SageMaker Processing provides configuration information to your processing container through environment variables and two JSON files—/opt/ml/config/processingjobconfig.json and /opt/ml/config/resourceconfig.json—at predefined locations in the container.

When a processing job starts, it uses the environment variables that you specified with the Environment map in the CreateProcessingJob request. The /opt/ml/config/
processingjobconfig.json file contains information about the hostnames of your processing containers, and is also specified in the CreateProcessingJob request.

The following example shows the format of the /opt/ml/config/processingjobconfig.json file.

```json
{
    "ProcessingJobArn": ":<processing_job_arn>",
    "ProcessingJobName": ":<processing_job_name>",
    "AppSpecification": {
        "ImageUri": ":<image_uri>",
        "ContainerEntrypoint": null,
        "ContainerArguments": null
    },
    "Environment": {
        "KEY": "VALUE"
    },
    "ProcessingInputs": [
        {
            "InputName": "input-1",
            "S3Input": {
                "LocalPath": ":/opt/ml/processing/input/dataset",
                "S3Uri": "<s3_uri>",
                "S3DataDistributionType": "FullyReplicated",
                "S3DataType": "S3Prefix",
                "S3InputMode": "File",
                "S3CompressionType": "None",
                "S3DownloadMode": "StartOfJob"
            }
        }
    ],
    "ProcessingOutputConfig": {
        "Outputs": [
            {
                "OutputName": "output-1",
                "S3Output": {
                    "LocalPath": ":/opt/ml/processing/output/dataset",
                    "S3Uri": "<s3_uri>",
                    "S3UploadMode": "EndOfJob"
                }
            }
        ],
        "KmsKeyId": null
    },
    "ProcessingResources": {
        "ClusterConfig": {
            "InstanceCount": 1,
            "InstanceType": "ml.m5.xlarge",
            "VolumeSizeInGB": 30,
            "VolumeKmsKeyId": null
        },
        "RoleArn": ":<IAM role>",
        "StoppingCondition": {
            "MaxRuntimeInSeconds": 86400
        }
    }
}
```

The /opt/ml/config/resourceconfig.json file contains information about the hostnames of your processing containers. Use the following hostnames when creating or running distributed processing code.

```json
{
    "current_host": "algo-1",
}
```
"hosts": ["algo-1","algo-2","algo-3"]
}

Don't use the information about hostnames contained in /etc/hostname or /etc/hosts because it might be inaccurate.

Hostname information might not be immediately available to the processing container. We recommend adding a retry policy on hostname resolution operations as nodes become available in the cluster.

**Save and Access Metadata Information About Your Processing Job**

To save metadata from the processing container after exiting it, containers can write UTF-8 encoded text to the /opt/ml/output/message file. After the processing job enters any terminal status ("Completed", "Stopped", or "Failed"), the "ExitMessage" field in DescribeProcessingJob contains the first 1 KB of this file. Access that initial part of file with a call to DescribeProcessingJob, which returns it through the ExitMessage parameter. For failed processing jobs, you can use this field to communicate information about why the processing container failed.

**Important**

Don't write sensitive data to the /opt/ml/output/message file.

If the data in this file isn't UTF-8 encoded, the job fails and returns a ClientError. If multiple containers exit with an ExitMessage, the content of the ExitMessage from each processing container is concatenated, then truncated to 1 KB.

**Run Your Processing Container Using the SageMaker Python SDK**

You can use the SageMaker Python SDK to run your own processing image by using the Processor class. The following example shows how to run your own processing container with one input from Amazon Simple Storage Service (Amazon S3) and one output to Amazon S3.

```python
from sagemaker.processing import Processor, ProcessingInput, ProcessingOutput

processor = Processor(image_uri='<your_ecr_image_uri>',
                       role=role,
                       instance_count=1,
                       instance_type="ml.m5.xlarge")

processor.run(inputs=[ProcessingInput(
    source='<s3_uri or local path>',
    destination='/opt/ml/processing/input_data')],
               outputs=[ProcessingOutput(
    source='/opt/ml/processing/processed_data',
    destination='<s3_uri>')],
)
```

Instead of building your processing code into your processing image, you can provide a ScriptProcessor with your image and the command that you want to run, along with the code that you want to run inside that container. For an example, see [Run Scripts with Your Own Processing Container](p. 1407).

You can also use the scikit-learn image that Amazon SageMaker Processing provides through SKLearnProcessor to run scikit-learn scripts. For an example, see [Data Processing with scikit-learn](p. 1401).
Create, store, and share features with Amazon SageMaker Feature Store

The machine learning (ML) development process often begins with extracting data signals also known as features from data to train ML models. Amazon SageMaker Feature Store makes it easy for data scientists, machine learning engineers, and general practitioners to create, share, and manage features for ML development. Feature Store accelerates this process by reducing repetitive data processing and curation work required to convert raw data into features for training an ML algorithm.

Further, the processing logic for your data is authored only once, and features generated are used for both training and inference, reducing the training-serving skew. Feature Store is a centralized store for features and associated metadata so features can be easily discovered and reused. You can create an online or an offline store. The online store is used for low latency real-time inference use cases, and the offline store is used for training and batch inference.

The following diagram shows how you can use Feature Store as part of your machine learning pipeline. First, you read in your raw data and process it. You can ingest data via streaming to the online and offline store, or in batches directly to the offline store. You first create a FeatureGroup and configure it to an online or offline store, or both. Then, you can ingest data into your FeatureGroup and store it in your store. A FeatureGroup is a group of features that is defined via a schema in Feature Store to describe a record.

Online store is primarily designed for supporting real-time predictions that need low millisecond latency reads and high throughput writes. Offline store is primarily intended for batch predictions and model training. Offline store is an append only store and can be used to store and access historical feature data. The offline store can help you store and serve features for exploration and model training. The online store retains only the latest feature data. Feature Groups are mutable and can evolve their schema after creation.

How Feature Store works

In Feature Store, features are stored in a collection called a feature group. You can visualize a feature group as a table in which each column is a feature, with a unique identifier for each row. In principle, a
feature group is composed of features and values specific to each feature. A Record is a collection of values for features that correspond to a unique RecordIdentifier. Altogether, a FeatureGroup is a group of features defined in your FeatureStore to describe a Record.

You can use Feature Store in the following modes:

- **Online** – In online mode, features are read with low latency (milliseconds) reads and used for high throughput predictions. This mode requires a feature group to be stored in an online store.
- **Offline** – In offline mode, large streams of data are fed to an offline store, which can be used for training and batch inference. This mode requires a feature group to be stored in an offline store. The offline store uses your S3 bucket for storage and can also fetch data using Athena queries.
- **Online and Offline** – This includes both online and offline modes.

You can ingest data into feature groups in Feature Store in two ways: streaming or in batches. When you ingest data through streaming, a collection of records are pushed to Feature Store by calling a synchronous PutRecord API call. This API enables you to maintain the latest feature values in Feature Store and to push new feature values as soon an update is detected.

Alternatively, Feature Store can process and ingest data in batches. You can author features using Amazon SageMaker Data Wrangler, create feature groups in Feature Store and ingest features in batches using a SageMaker Processing job with a notebook exported from Data Wrangler. This mode allows for batch ingestion into the offline store. It also supports ingestion into the online store if the feature group is configured for both online and offline use.

### Create feature groups

To ingest features into Feature Store, you must first define the feature group and the feature definitions (feature name and data type) for all features that belong to the feature group. After they are created, feature groups are mutable and can evolve their schema. Feature group names are unique within an AWS Region and AWS account. When creating a feature group, you can also create the metadata for the feature group, such as a short description, storage configuration, features for identifying each record, and the event time, as well as tags to store information such as the author, data source, version, and more.

**Important**

FeatureGroup names or associated metadata such as description or tags should not contain any personal identifiable information (PII) or confidential information.

### Find, discover, and share features

After you create a feature group in Feature Store, other authorized users of the feature store can share and discover it. Users can browse through a list of all feature groups in Feature Store or discover existing feature groups by searching by feature group name, description, record identifier name, creation date, and tags.

### Real-time inference for features stored in the online store

With Feature Store, you can enrich your features stored in the online store in real time with data from a streaming source (clean stream data from another application) and serve the features with low millisecond latency for real-time inference.
You can also perform joins across different FeatureGroups for real-time inference by querying two different FeatureGroups in the client application.

Offline store for model training and batch inference

Feature Store provides offline storage for feature values in your S3 bucket. Your data is stored in your S3 bucket using a prefixing scheme based on event time. The offline store is an append-only store, enabling Feature Store to maintain a historical record of all feature values. Data is stored in the offline store in Parquet format for optimized storage and query access.

You can query, explore, and visualize features using Data Wrangler from Amazon SageMaker Studio. Feature Store supports combining data to produce, train, validate, and test data sets, and allows you to extract data at different points in time.

Feature data ingestion

Feature generation pipelines can be created to process large batches (1 million rows of data or more) or small batches, and to write feature data to the offline or online store. Streaming sources such as Amazon Managed Streaming for Apache Kafka or Amazon Kinesis can also be used as data sources from which features are extracted and directly fed to the online store for training, inference, or feature creation.

You can push records to Feature Store by calling the synchronous PutRecord API call. Since this is a synchronous API call, it allows small batches of updates to be pushed in a single API call. This enables you to maintain high freshness of the feature values and publish values as soon as an update is detected. These are also called streaming features.

When feature data is ingested and updated, Feature Store stores historical data for all features in the offline store. For batch ingest, you can pull feature values from your S3 bucket or use Athena to query. You can also use Data Wrangler to process and engineer new features that can then be exported to a chosen S3 bucket to be accessed by Feature Store. For batch ingestion, you can configure a processing job to batch ingest your data into Feature Store, or you can pull feature values from your S3 bucket using Athena.

To remove a Record from your online store, use the DeleteRecord API call. This will also add the deleted record to the offline store.

Resilience in Feature Store

Feature Store is distributed across multiple Availability Zones (AZs). An AZ is an isolated location within an AWS Region. If some AZs fail, Feature Store can use other AZs. For more information about AZs, see Resilience in Amazon SageMaker (p. 3520).

Get started with Amazon SageMaker Feature Store

The following topics give information about using Amazon SageMaker Feature Store. First learn the Feature Store concepts, how to manage permissions to use Feature Store, how to create and use feature groups using a Amazon SageMaker Studio Jupyter or JupyterLab notebook, how to use Feature Store in the Studio User Interface, and how to delete feature groups using SDK for Python and Studio.
Feature Store concepts

We list common terms used in Amazon SageMaker Feature Store, followed by example diagrams to visualize a few concepts:

- **Feature Store**: Storage and data management layer for machine learning (ML) features. Serves as the single source of truth to store, retrieve, remove, track, share, discover, and control access to features. In the following example diagram, the Feature Store is a store for your feature groups, which contains your ML data, and provides additional services.

- **Online store**: Low latency, high availability store for a feature group that enables real-time lookup of records. The online store allows quick access to the latest record via the GetRecord API.

- **Offline store**: Stores historical data in your Amazon S3 bucket. The offline store is used when low (sub-second) latency reads are not needed. For example, the offline store can be used when you want to store and serve features for exploration, model training, and batch inference.

- **Feature group**: The main resource of Feature Store that contains the data and metadata used for training or predicting with a ML model. A feature group is a logical grouping of features used to describe records. In the following example diagram, a feature group contains your ML data.

- **Feature**: A property that is used as one of the inputs to train or predict using your ML model. In the Feature Store API a feature is an attribute of a record. In the following example diagram, a feature describes a column in your ML data table.

- **Feature definition**: Consists of a name and one of the data types: integral, string or fractional. A feature group contains a list of feature definitions. For more information on Feature Store data types, see Data types (p. 1511).

- **Record**: Collection of values for features for a single record identifier. A combination of record identifier and event time values uniquely identify a record within a feature group. In the following example diagram, a record is a row in your ML data table.

- **Record identifier name**: The record identifier name is the name of the feature that identifies the records. It must refer to one of the names of a feature defined in the feature group’s feature definitions. Each feature group is defined with a record identifier name.

- **Event time**: Timestamp that you provide corresponding to when the record event occurred. All records in a feature group must have a corresponding event time. The online store only contains the record corresponding to the latest event time, whereas the offline store contains all historic records. For more information on event time formats, see Data types (p. 1511).

- **Ingestion**: Adding new records to a feature group. Ingestion is typically achieved via the PutRecord API.

**Topics**
- Concepts overview diagram (p. 1416)
- Ingestion diagrams (p. 1417)
The Feature Store contains your feature groups and a feature group contains your ML data. In the example diagram, the original feature group contains a data table that has three features (each describing a column) and two records (rows).

- A feature's definition describes the feature name and data type of the feature values that are associated with records.
- A record contains the feature values and is uniquely identified by its record identifier and must include the event time.

**Ingestion diagrams**

Ingestion is the action of adding a record or records to an existing feature group. The way that the online and offline stores are updated is different.

**Ingestion to the online store example**

The online store acts as a real-time look-up of records and only keeps the most up-to-date records. After a new record is ingested into an existing online store, the updated online store will only keep the record with the latest event time.

In the following example diagram, the original online store contains your ML data table with one record. A new record is added with the same record ID as the original record, but the new record has its event time earlier than the original record. The updated online store only contains the record with the latest event time.
Ingestion to the offline store example

The offline store acts as a historical look-up of records and keeps all records. After a new record is ingested into an existing offline store, the updated offline store will keep the new record.

In the following example diagram, the original offline store contains your ML data table with one record. A new record is ingested with the same record ID as the original record, but the new record has it’s event time earlier than the original record. The updated offline store contains all of the records.
To get started with Amazon SageMaker Feature Store you must have a role and add the required policy to your role, AmazonSageMakerFeatureStoreAccess. The following is a walkthrough on how to view the policies attached to a role and how to add a policy to your role. For information on how to
create a role, see SageMaker Roles (p. 3387). For information on how to get your execution role, see Get execution role (p. 3390).

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane on the left of the IAM console, choose Roles.
3. In the search bar enter the role you are using for Amazon SageMaker Feature Store.

   For examples on how to find your execution role ARN for a notebook within SageMaker (from the SageMaker console or Amazon SageMaker Studio), see Get execution role (p. 3390). The role is at the end of the execution role ARN.
4. After you enter the role in the search bar, choose the role.

   Under Permissions policies you can view the policies attached to the role.
5. After you choose the role, choose Add permissions, then choose Attach policies.
6. In the search bar under Other permissions policies enter AmazonSageMakerFeatureStoreAccess and press enter. If the policy does not show, you may already have the policy attached, listed under your Current permissions policies.
7. After you press enter, select the check box next to the policy and then choose Add permissions.
8. After you have attached the policy to your role, the policy will appear under Permissions policies for your IAM role.

Use Feature Store with SDK for Python (Boto3)

The feature group is the main Feature Store resource that contains your machine learning (ML) data and metadata stored in Amazon SageMaker Feature Store. A feature group is a logical grouping of features and records. A feature group’s definition is composed of a configurations for its online and offline store and a list of feature definitions that are used to describe the values of your records. The feature definitions must include a record identifier name and an event time name. For more information on feature store concepts, see Feature Store concepts (p. 1416).

Prior to using a feature store you typically load your dataset, run transformations, and set up your features for ingestion. This process has a lot of variation and is highly dependent on your data. The example code in the following topics refer to the Introduction to Feature Store and Fraud Detection with Amazon SageMaker Feature Store example notebooks, respectively. Both use the AWS SDK for Python (Boto3). We recommend that you clone and run these notebook in Amazon SageMaker Studio.

Feature Store supports the following feature types: String, Fractional (IEEE 64-bit floating point value), and Integral (Int64 - 64 bit signed integral value). The default type is set to String. This means that, if a column in your dataset is not of a float or long feature type, it defaults to String in your feature store.

You may use a schema to describe your data’s columns and data types. You pass this schema into FeatureDefinitions, a required parameter for a FeatureGroup. You can use the SDK for Python (Boto3), which has automatic data type detection when you use the load_feature_definitions function.

The default behavior when a new feature record is added with an already existing record ID is as follows. In the offline store, the new record will be appended. In the online store, if the event time of the new record is less than the existing event time then nothing will happen, but if the event time of the new record is greater than or equal to the existing event time, the record will be overwritten.

When you create a new feature group you can choose one of the following table formats:

- AWS Glue (Default)
- Apache Iceberg
Ingesting data, especially when streaming, can result in a large number of small files deposited into the offline store. This can negatively impact query performance due the higher number of file operations required. To avoid potential performance issues, use the Apache Iceberg table format when creating new feature groups. With Iceberg you can compact the small data files into fewer large files in the partition, resulting in significantly faster queries. This compaction operation is concurrent and does not affect ongoing read and write operations on the feature group. If you choose the Iceberg option when creating new feature groups, Amazon SageMaker Feature Store will create the Iceberg tables using Parquet file format, and register the tables with the AWS Glue Data Catalog.

**Important**

Note that for feature groups in Iceberg table format, you must specify `String` as the value for the event time. If you specify any other type, you can’t create the feature group successfully.

In the following we list some available Feature Store managed resources.

**Topics**

- [Introduction to Feature Store example notebook](#)
- [Fraud detection with Feature Store example notebook](#)

## Introduction to Feature Store example notebook

The example code on this page refers to the [Introduction to Feature Store example notebook](#). It is recommended that you run this notebook in Amazon SageMaker Studio, Jupyter, and JupyterLab because the code in this guide is conceptual and not fully functional if copied. To open the notebook in Studio, first clone the [aws/amazon-sagemaker-examples](#) GitHub repository to Studio by following the steps in [Clone a Git Repository in SageMaker Studio](#), then navigate to the amazon-sagemaker-examples/sagemaker-featurestore directory and choose the file.

### Step 1: Set up

To start using Feature Store, create a SageMaker session and set up the Amazon S3 bucket you want to use for your features. The Amazon S3 bucket is your offline store. The following code uses the SageMaker default bucket and adds a custom prefix to it.

**Note**

The role that you use to run the notebook must have the following managed policies attached to it: AmazonS3FullAccess and AmazonSageMakerFeatureStoreAccess. For information on adding policies to your IAM role, see [Adding policies to your IAM role](#).

```python
# SageMaker Python SDK version 2.x is required
import sagemaker
import sys
import boto3
import pandas as pd
import numpy as np
import io
from sagemaker.session import Session
from sagemaker import get_execution_role

prefix = 'sagemaker-featurestore-introduction'
role = get_execution_role()
sagemaker_session = sagemaker.Session()
region = sagemaker_session.boto_region_name
s3_bucket_name = sagemaker_session.default_bucket()
```
Step 2: Inspect your data

In this notebook example we ingest synthetic data from the Github repository that hosts the full notebook.

```python
customer_data = pd.read_csv("data/feature_store_introduction_customer.csv")
orders_data = pd.read_csv("data/feature_store_introduction_orders.csv")
print(customer_data.head())
print(orders_data.head())
```

The following diagram illustrates the steps the data goes through before it is ingested into Feature Store. In this notebook, we illustrate the use-case where you have data from multiple sources and want to store them independently in a Feature Store. Our example considers data from a data warehouse (customer data), and data from a real-time streaming service (order data).
Step 3: Create feature groups

We first start by creating feature group names for customer_data and orders_data. Following this, we create two Feature Groups, one for customer_data and another for orders_data.

```python
import time
from time import strftime, gmtime

customers_feature_group_name = 'customers-feature-group-\' + strftime('%d-%H-%M-%S', gmtime())
orders_feature_group_name = 'orders-feature-group-\' + strftime('%d-%H-%M-%S', gmtime())
```

Instantiate a FeatureGroup object for customers_data and orders_data.

```python
from sagemaker.feature_store.feature_group import FeatureGroup

customers_feature_group = FeatureGroup(
    name=customers_feature_group_name, sagemaker_session=sagemaker_session
)

orders_feature_group = FeatureGroup(
    name=orders_feature_group_name, sagemaker_session=sagemaker_session
)
```

```python
import time
current_time_sec = int(round(time.time()))
record_identifier_feature_name = "customer_id"
```

Append EventTime feature to your data frame. This parameter is required, and time stamps each data point.

```python
customer_data["EventTime"] = pd.Series([current_time_sec]*len(customer_data), dtype="float64")
orders_data["EventTime"] = pd.Series([current_time_sec]*len(orders_data), dtype="float64")
```

Load feature definitions to your feature group.

```python
customers_feature_group.load_feature_definitions(data_frame=customer_data)
orders_feature_group.load_feature_definitions(data_frame=orders_data)
```

Below we call create to create two feature groups, customers_feature_group and orders_feature_group respectively.

```python
customers_feature_group.create(
    s3_uri=f"s3://{s3_bucket_name}/{prefix}",
    record_identifier_name=record_identifier_feature_name,
    event_time_feature_name="EventTime",
    role_arn=role,
    enable_online_store=True
)

orders_feature_group.create(
    s3_uri=f"s3://{s3_bucket_name}/{prefix}",
    record_identifier_name=record_identifier_feature_name,
    event_time_feature_name="EventTime",
    role_arn=role,
    enable_online_store=True
)
```
To confirm that your feature group has been created we use DescribeFeatureGroup and ListFeatureGroups APIs to display the created feature group.

```python
customers_feature_group.describe()
orders_feature_group.describe()
sagemaker_session.boto_session.client('sagemaker', region_name=region).list_feature_groups() # We use the boto client to list FeatureGroups
```

### Step 4: Ingest data into a feature group

After the FeatureGroups have been created, we can put data into the FeatureGroups. If you are using the SageMaker Python SDK, use the `ingest` API call. If you are using boto3 then use the PutRecord API. It will take less than 1 minute to ingest data both of these options. This example uses the SageMaker Python SDK, so it uses the `ingest` API call.

```python
def check_feature_group_status(feature_group):
    status = feature_group.describe().get("FeatureGroupStatus")
    while status == "Creating":
        print("Waiting for Feature Group to be Created")
        time.sleep(5)
        status = feature_group.describe().get("FeatureGroupStatus")
        print(f"FeatureGroup {feature_group.name} successfully created.")
check_feature_group_status(customers_feature_group)
check_feature_group_status(orders_feature_group)

customers_feature_group.ingest(
    data_frame=customer_data, max_workers=3, wait=True
)

others_feature_group.ingest(
    data_frame=orders_data, max_workers=3, wait=True
)
```

Using an arbitrary customer record id, 573291 we use `get_record` to check that the data has been ingested into the feature group.

```python
customer_id = 573291
sample_record = sagemaker_session.boto_session.client('sagemaker-featurestore-runtime', region_name=region).get_record(FeatureGroupName=customers_feature_group_name, RecordIdentifierValueAsString=str(customer_id))

print(sample_record)
```

Below demonstrates how to use the `batch_get_record` to get a batch of records.

```python
all_records = sagemaker_session.boto_session.client(
    "sagemaker-featurestore-runtime", region_name=region
).batch_get_record(
    Identifiers=[
        {
            "FeatureGroupName": customers_feature_group_name,
            "RecordIdentifiersValueAsString": ["573291", "109382", "828400", "124013"],
```
Step 5: Clean up

Here we remove the Feature Groups we created.

```python
customers_feature_group.delete()
orders_feature_group.delete()
```

Step 6: Next steps

In this example notebook, you learned how to quickly get started with Feature Store, create feature groups, and ingest data into them.

For an advanced example on how to use Feature Store for a Fraud Detection use-case, see [Fraud Detection with Feature Store](#).

Step 7: Programmers note

In this notebook we used a variety of different API calls. Most of them are accessible through the Python SDK, however some only exist within boto3. You can invoke the Python SDK API calls directly on your Feature Store objects, whereas to invoke API calls that exist within boto3, you must first access a boto3 client through your boto3 and SageMaker sessions: for example, `sagemaker_session.boto_session.client()`.

Below we list API calls used in this notebook that exist within the Python SDK and ones that exist in boto3 for your reference.

**Python SDK API Calls**

- `describe()`
- `ingest()`
- `delete()`
- `create()`
- `load_feature_definitions()`

**Boto3 API Calls**

- `list_feature_groups()`
- `get_record()`

**Fraud detection with Feature Store example notebook**

The example code on this page refers to the [Fraud Detection with Amazon SageMaker Feature Store](#) example notebook. To open the notebook in Studio, first clone the [aws/amazon-sagemaker-examples](#) GitHub repository to Studio by following the steps in [Clone a Git Repository in SageMaker Studio](#), then navigate to the `amazon-sagemaker-examples/sagemaker-featurestore` directory and choose the file.
Step 1: Set up Feature Store

To start using Feature Store, create a SageMaker session, boto3 session, and a Feature Store session. Also, set up the Amazon S3 bucket you want to use for your features. This is your offline store. The following code uses the SageMaker default bucket and adds a custom prefix to it.

**Note**
The role that you use to run the notebook must have the following managed policies attached to it: AmazonSageMakerFullAccess and AmazonSageMakerFeatureStoreAccess. For information on adding policies to your IAM role, see Adding policies to your IAM role (p. 1419).

```python
import boto3
import sagemaker
from sagemaker.session import Session

sagemaker_session = sagemaker.Session()
region = sagemaker_session.boto_region_name
boto_session = boto3.Session(region_name=region)
role = sagemaker.get_execution_role()
default_bucket = sagemaker_session.default_bucket()
prefix = 'sagemaker-featurestore'
offline_feature_store_bucket = 's3://{}/{}'.format(default_bucket, prefix)

sagemaker_client = boto_session.client(service_name='sagemaker', region_name=region)
featurestore_runtime = boto_session.client(service_name='sagemaker-featurestore-runtime',
                                         region_name=region)

feature_store_session = Session(
    boto_session=boto_session,
    sagemaker_client=sagemaker_client,
    sagemaker_featurestore_runtime_client=featurestore_runtime
)
```

Step 2: Load datasets and partition data into feature groups

Load your data into data frames for each of your features. You use these data frames after you set up the feature group. In the fraud detection example, you can see these steps in the following code.

```python
import numpy as np
import pandas as pd
import matplotlib.pyplot as plt
import io

s3_client = boto3.client(service_name='s3', region_name=region)

fraud_detection_bucket_name = 'sagemaker-featurestore-fraud-detection'
identity_file_key = 'sampled_identity.csv'
transaction_file_key = 'sampled_transactions.csv'

identity_data_object = s3_client.get_object(Bucket=fraud_detection_bucket_name,
                                         Key=identity_file_key)
transaction_data_object = s3_client.get_object(Bucket=fraud_detection_bucket_name,
                                         Key=transaction_file_key)

identity_data = pd.read_csv(io.BytesIO(identity_data_object['Body'].read()))
transaction_data = pd.read_csv(io.BytesIO(transaction_data_object['Body'].read()))

identity_data = identity_data.round(5)
transaction_data = transaction_data.round(5)

identity_data = identity_data.fillna(0)
transaction_data = transaction_data.fillna(0)
```
# Feature transformations for this dataset are applied before ingestion into FeatureStore.
# One hot encode card4, card6
encoded_card_bank = pd.get_dummies(transaction_data['card4'], prefix = 'card_bank')
encoded_card_type = pd.get_dummies(transaction_data['card6'], prefix = 'card_type')

transformed_transaction_data = pd.concat([transaction_data, encoded_card_type, 
enabled_card_bank], axis=1)
transformed_transaction_data = transformed_transaction_data.rename(columns={"card_bank_american express": "card_bank_american_express")

### Step 3: Set up feature groups

When you set up your feature groups, you need to customize the feature names with a unique name and set up each feature group with the FeatureGroup class.

```python
from sagemaker.feature_store.feature_group import FeatureGroup
feature_group_name = "some string for a name"
feature_group = FeatureGroup(name=feature_group_name, 
sagemaker_session=feature_store_session)
```

For example, in the fraud detection example, the two feature groups are identity and transaction. In the following code you can see how the names are customized with a timestamp, and then each group is set up by passing in the name and the session.

```python
import time
from time import gmtime, strftime, sleep
from sagemaker.feature_store.feature_group import FeatureGroup

identity_feature_group_name = 'identity-feature-group-' + strftime('%d-%H-%M-%S', gmtime())
transaction_feature_group_name = 'transaction-feature-group-' + strftime('%d-%H-%M-%S', gmtime())

identity_feature_group = FeatureGroup(name=identity_feature_group_name, 
sagemaker_session=feature_store_session)

transaction_feature_group = FeatureGroup(name=transaction_feature_group_name, 
sagemaker_session=feature_store_session)
```

### Step 4: Set up record identifier and event time features

In this step, you specify a record identifier name and an event time feature name. This name maps to the column of the corresponding features in your data. For example, in the fraud detection example, the column of interest is TransactionID. EventTime can be appended to your data when no timestamp is available. In the following code, you can see how these variables are set, and then EventTime is appended to both feature's data.

```python
record_identifier_name = "TransactionID"
event_time_feature_name = "EventTime"
current_time_sec = int(round(time.time()))

identity_data[event_time_feature_name] = pd.Series([current_time_sec]*len(identity_data), 
dtype="float64")
transformed_transaction_data[event_time_feature_name] = 

pd.Series([current_time_sec]*len(transaction_data), dtype="float64")
```

### Step 5: Load feature definitions

You can now load the feature definitions by passing a data frame containing the feature data. In the following code for the fraud detection example, the identity feature and transaction feature are each loaded by using load_feature_definitions, and this function automatically detects the data type.
of each column of data. For developers using a schema rather than automatic detection, see the Export Feature Groups from Data Wrangler example for code that shows how to load the schema, map it, and add it as a FeatureDefinition that you can use to create the FeatureGroup. This example also covers a boto3 implementation, which you can use instead of the SageMaker Python SDK.

```python
identity_feature_group.load_feature_definitions(data_frame=identity_data); # output is suppressed
transaction_feature_group.load_feature_definitions(data_frame=transformed_transaction_data);
# output is suppressed
```

### Step 6: Create a feature group

In this step, you use the create function to create the feature group. The following code shows all of the available parameters. The online store is not created by default, so you must set this as True if you want to enable it. The s3_uri is the S3 bucket location of your offline store.

```python
# create a FeatureGroup
feature_group.create(
    description = "Some info about the feature group",
    feature_group_name = feature_group_name,
    record_identifier_name = record_identifier_name,
    event_time_feature_name = event_time_feature_name,
    feature_definitions = feature_definitions,
    role_arn = role,
    s3_uri = offline_feature_store_bucket,
    enable_online_store = True,
    online_store_kms_key_id = None,
    offline_store_kms_key_id = None,
    disable_glue_table_creation = False,
    data_catalog_config = None,
    tags = ["tag1","tag2"])
```

The following code from the fraud detection example shows a minimal create call for each of the two features groups being created.

```python
identity_feature_group.create(
    s3_uri=offline_feature_store_bucket,
    record_identifier_name=record_identifier_name,
    event_time_feature_name=event_time_feature_name,
    role_arn=role,
    enable_online_store=True
)

transaction_feature_group.create(
    s3_uri=offline_feature_store_bucket,
    record_identifier_name=record_identifier_name,
    event_time_feature_name=event_time_feature_name,
    role_arn=role,
    enable_online_store=True
)
```

When you create a feature group, it takes time to load the data, and you need to wait until the feature group is created before you can use it. You can check status using the following method.

```python
status = feature_group.describe().get("FeatureGroupStatus")
```

While the feature group is being created, you receive Creating as a response. When this step has finished successfully, the response is Created. Other possible statuses are CreateFailed, Deleting, or DeleteFailed.
Step 7: Work with feature groups

Now that you've set up your feature group, you can perform any of the following tasks:

**Topics**
- Describe a feature group (p. 1430)
- List feature groups (p. 1430)
- Put records in a feature group (p. 1430)
- Get records from a feature group (p. 1430)
- Generate hive DDL commands (p. 1431)
- Build a training dataset (p. 1431)
- Write and execute an Athena query (p. 1431)
- Delete a feature group (p. 1432)

Describe a feature group

You can retrieve information about your feature group with the `describe` function.

```python
feature_group.describe()
```

List feature groups

You can list all of your feature groups with the `list_feature_groups` function.

```python
sagemaker_client.list_feature_groups()
```

Put records in a feature group

You can use the `ingest` function to load your feature data. You pass in a data frame of feature data, set the number of workers, and choose to wait for it to return or not. The following example demonstrates using the `ingest` function.

```python
feature_group.ingest(
    data_frame=feature_data, max_workers=3, wait=True
)
```

For each feature group you have, run the `ingest` function on the feature data you want to load.

Get records from a feature group

You can use the `get_record` function to retrieve the data for a specific feature by its record identifier. The following example uses an example identifier to retrieve the record.

```python
record_identifier_value = str(2990130)
featurestore_runtime.get_record(FeatureGroupName=transaction_feature_group_name,
    RecordIdentifierValueAsString=record_identifier_value)
```

An example response from the fraud detection example:

```json
...
'Record': [{'FeatureName': 'TransactionID', 'ValueAsString': '2990130'},
  {'FeatureName': 'isFraud', 'ValueAsString': '0'},
  {'FeatureName': 'TransactionDT', 'ValueAsString': '152647'},
...
Generate hive DDL commands

The SageMaker Python SDK’s `FeatureStore` class also provides the functionality to generate Hive DDL commands. The schema of the table is generated based on the feature definitions. Columns are named after feature name and data-type are inferred based on feature type.

```python
print(feature_group.as_hive_ddl())
```

Example output:

```sql
CREATE EXTERNAL TABLE IF NOT EXISTS sagemaker_featurestore.identity-feature-group-27-19-33-00 (
  TransactionID INT
  id_01 FLOAT
  id_02 FLOAT
  id_03 FLOAT
  id_04 FLOAT
  ...
```

Build a training dataset

Feature Store automatically builds an AWS Glue data catalog when you create feature groups and you can turn this off if you want. The following describes how to create a single training dataset with feature values from both identity and transaction feature groups created earlier in this topic. Also, the following describes how to run an Amazon Athena query to join data stored in the offline store from both identity and transaction feature groups.

To start, create an Athena query using `athena_query()` for both identity and transaction feature groups. The `table_name` is the AWS Glue table that is autogenerated by Feature Store.

```python
identity_query = identity_feature_group.athena_query()
transaction_query = transaction_feature_group.athena_query()

identity_table = identity_query.table_name
transaction_table = transaction_query.table_name
```

Write and execute an Athena query

You write your query using SQL on these feature groups, and then execute the query with the `.run()` command and specify your Amazon S3 bucket location for the data set to be saved there.

```python
# Athena query
query_string = 'SELECT * FROM "'+transaction_table+'" LEFT JOIN "'+identity_table+'" ON "'+transaction_table+'".transactionid = "'+identity_table+'".transactionid

# run Athena query. The output is loaded to a Pandas dataframe.
dataset = pd.DataFrame()
identity_query.run(query_string=query_string,
output_location='s3://'+default_s3_bucket_name+'/query_results/)
identity_query.wait()
dataset = identity_query.as_dataframe()
```

From here you can train a model using this data set and then perform inference.
Delete a feature group

You can delete a feature group with the delete function.

```
feature_group.delete()
```

The following code example is from the fraud detection example.

```
identity_feature_group.delete()
transaction_feature_group.delete()
```

For more information, see the [Delete a feature group API](#).

Use Amazon SageMaker Feature Store with Amazon SageMaker Studio

You can use Amazon SageMaker Studio to create and view details about your feature groups.

Topics

- Create a feature group in Studio (p. 1432)
- View feature group details in Studio (p. 1434)
- Update feature group in Studio (p. 1434)
- View pipeline executions in Studio (p. 1435)
- View lineage in Studio (p. 1435)

Create a feature group in Studio

The create feature group process has four steps:

1. Enter feature group information.
2. Enter feature definitions.
3. Enter required features.
4. Enter feature group tags.

Consider which of the following options best fits your use case:

- Create an online store, an offline store, or both. For more information on the differences between online and offline stores, see [Feature Store concepts (p. 1416)](#).
- Use a default AWS Key Management Service key or your own KMS key. The default key is [AWS KMS key (SSE-KMS)](#). You can reduce AWS KMS request costs by configuring use of Amazon S3 Bucket Keys on the offline store Amazon S3 bucket. The Amazon S3 Bucket Key needs to be enabled before using the bucket for your feature groups. For more information about reducing the cost by using Amazon S3 bucket keys, see [Reducing the cost of SSE-KMS with Amazon S3 Bucket Keys](#).

You can use the same key for both online and offline stores, or have a unique key for each. For more information on AWS KMS, see [AWS Key Management Service](#).

- If you create an offline store:
  - Decide if you want to create an Amazon S3 bucket or use an existing one. When using an existing one, you need to know the Amazon S3 bucket URL or Amazon S3 bucket name and dataset directory name, if applicable.
• Choose which IAM role ARN to use. For more information on how to find your role and attached policies, see Adding policies to your IAM role (p. 1419).

• Decide whether to use the AWS Glue (default) or Apache Iceberg table format. In most use cases, you use the Apache Iceberg table format. For more information on table formats, see Use Feature Store with SDK for Python (Boto3) (p. 1420).

Steps to create a feature group using Studio

1. Open Studio. For more information, see Launch Amazon SageMaker Studio (p. 209).
2. Choose the Home icon ( ) on the left panel.
3. Choose Data.
4. From the dropdown list, choose Feature Store.
5. Choose Create feature group.
6. Under Feature group details, enter a feature group name.
7. (Optional) Enter a description of the feature group.
8. Under Feature group storage configuration, choose a storage type from the Storage type dropdown list.

If you choose offline storage:

a. From the Amazon S3 bucket name dropdown list, choose an existing Amazon S3 bucket name, enter a new bucket name, or choose Enter bucket URL manually and enter the URL under Amazon S3 bucket address.

b. (Optional) If you have a specified directory name for your dataset, choose from the Dataset directory name dropdown list.

c. From the Table format dropdown list, choose the table format. In most use cases, you should use the Apache Iceberg table format. For more information on table formats, see Use Feature Store with SDK for Python (Boto3) (p. 1420).

d. Under IAM role ARN, choose the IAM role ARN you want to attach to this feature group. For more information on how to find your role and attached policies, see Adding policies to your IAM role (p. 1419).

9. Under the Online store encryption key or Offline store encryption key dropdown list, choose Use AWS managed AWS KMS key (default) or Enter a AWS KMS key ARN and enter your AWS KMS key ARN under Offline store encryption key ARN. For more information about AWS KMS, see AWS Key Management Service.

10. (Optional) If you have chosen the online storage Storage type, you can choose to apply Time to Live (TTL) by toggling the switch to On and specifying the Time to Live duration value and unit. This will update the default TTL duration for all records added to the feature group after the feature group is created.

11. If you have chosen the offline storage Table format and AWS Glue (default) Table format, under Data catalog, you have the option to choose Use default values for your AWS Glue data catalog or provide your existing data catalog name, table name, and database name to extend your existing AWS Glue catalog.

12. Once all of the required information has been specified, the Continue button is available. Choose Continue.

13. Under Specify feature definitions, you have two options for providing a schema for your features: a JSON editor, or a table editor. In the JSON tab, type in or copy and paste your feature definitions in the JSON format. For the table editor, type in the name and choose the corresponding data type for each feature in your feature group. Choose + Add feature definitions to include more features. Be aware that you cannot remove feature definitions from your feature groups, but you can add and update feature definitions after the feature group is created.
There must be at least two features in a feature group representing the record identifier and event time:

- The record Type can be a string, fractional, or an integral.
- The event time Type must be a string or a fractional. However, if you chose the Iceberg table format, the event time must be a string.

14. Once all of the features are included, choose Continue.
15. Under Select required features you must specify the record identifier and event time features by choosing the feature name under Record identifier feature name and Event time feature name dropdown lists, respectively.
16. Once the record identifier and event time features are chosen, choose Continue.
17. (Optional) Add tags for the feature group by first choosing Add new tag and then entering a tag key and corresponding value under Key and Value, respectively.
18. Choose Continue.
19. Under Review feature group, review the feature group information. You may edit any step by choosing the Edit button that corresponds to that step. This brings you to the corresponding step for editing. To return to step 5, choose Continue until you return to step 5.
20. Once you have finalized the setup for your feature group, choose Create feature group.

If there are any issues with the setup, there is a red alert pop-up message that appears at the bottom of the page with tips on solving the issue. You can return to previous steps to fix them.

If the feature group has been successfully created, a green pop-up message appears at the bottom of the page. When the feature group is successfully created, it appears in your feature groups catalog.

**View feature group details in Studio**

You can view details of your feature groups once a feature group has successfully been created in the Feature Store.

1. Open Studio. For more information, see Launch Amazon SageMaker Studio (p. 209).
2. Choose the Home icon (🏠) on the left panel.
3. Choose Data.
4. From the dropdown list, choose Feature Store.
5. Under the Feature group catalog tab, choose your feature group name from the list. This opens the feature group page.
6. Under the Details tab and the Information sub-tab, you can review your feature group information, including and not limited to Latest execution, Offline storage settings, and Online storage settings.
7. Under the Details tab and the Tags sub-tab, you can review your feature group tags. Choose Add new tag to add a new tag or Remove to remove a tag.
8. On the Features tab, you can find a list of all of the features. Use the filter to refine your list. Choose a feature to view its details.

**Update feature group in Studio**

You can update your feature groups once a feature group has successfully been created in the Feature Store.
1. Open Studio. For more information, see Launch Amazon SageMaker Studio (p. 209).
2. Choose the Home icon (🏠) on the left panel.
3. Choose Data.
4. From the dropdown list, choose Feature Store.
5. Under the Feature group catalog tab, search for and choose your feature group name from the list. This opens the feature group page.
6. Choose Update feature group.
7. (Optional) If your feature group uses the online store, you can update the default Time to Live (TTL). If TTL hasn’t been enabled for the feature group, toggle the switch button under Time to Live (TTL) to On. You can specify the TTL value and unit under Time to Live duration. This will update the default TTL duration for all records added to the feature group after the feature group is updated.
8. (Optional) You can add feature definitions to your feature group but be aware that you cannot remove feature definitions from your feature groups. To add a feature definition, choose + Add feature definition and then specify the new feature definition name under the Name column and select the feature type under the Type column.
9. Choose Save changes.
10. To confirm your changes choose Confirm.

View pipeline executions in Studio

You can view the latest pipeline execution information for a feature or feature group under Pipeline executions, including quick links to pipelines, executions, code, and other useful execution information.

1. Open Studio. For more information, see Launch Amazon SageMaker Studio (p. 209).
2. Choose the Home icon (🏠) on the left panel.
3. Choose Data.
4. From the dropdown list, choose Feature Store.
5. Choose a feature group or feature you wish to see the pipeline execution for.
6. Choose the Pipeline executions tab.
7. Search for a pipeline from the Select a pipeline dropdown list.
8. You can view the links for the pipeline, execution, and code details as well as view the execution owner, status, date, and duration.

View lineage in Studio

You can view the lineage of a feature group. The lineage includes the information about the execution code of your feature processing workflow, what data sources were used, and how they are ingested to the feature group or feature.

1. Open Studio. For more information, see Launch Amazon SageMaker Studio (p. 209).
2. Choose the Home icon (🏠) on the left panel.
3. Choose Data.
4. From the dropdown list, choose Feature Store.
5. Choose a feature group or feature you wish to see the lineage for.
6. Choose the Lineage tab.
7. Choose a feature group or pipeline node to expand the node. This contains more information about a feature group or pipeline.
8. You can zoom in, zoom out, or recenter the lineage graph by using the buttons on the bottom left of the screen.
9. You can navigate the lineage map when you press Tab or Shift+Tab to switch between nodes, when you choose nodes, or when you choose and drag the screen.
10. If applicable, you can navigate the lineage upstream (left, earlier) or downstream (right, most recent) by choosing a node and then choosing Query upstream lineage or Query downstream lineage.

Delete a feature group

You can use Amazon SageMaker Studio or the Amazon SageMaker Feature Store API to delete your feature group.

The following sections provide an overview of using both to delete a feature group.

Topics
- Delete a feature group using Studio (p. 1436)
- Delete feature group example Python code (p. 1436)

Delete a feature group using Studio

1. Open Studio. For more information, see Launch Amazon SageMaker Studio (p. 209).
2. Choose the Home icon (🏠) on the left panel.
3. Choose Data.
4. From the dropdown list, choose Feature Store.
5. In the Feature Group Catalog tab choose the feature group you wish to delete under Feature group name.
6. Choose Delete feature group.
7. In the popup window confirm deletion by typing “delete” in the field, then choose Delete.

Delete feature group example Python code

The following code uses the DeleteFeatureGroup API operation to delete your feature group using the AWS SDK for Python (Boto3). It assumes that you've set up Feature Store and created a feature group. For more information about getting started, see Introduction to Feature Store example notebook (p. 1421).

```python
import sagemaker
from sagemaker.feature_store.feature_group import FeatureGroup

sagemaker_session = sagemaker.Session()
fg_name = 'your-feature-group-name'
my_fg = FeatureGroup(name=fg_name, sagemaker_session=sagemaker_session)
my_fg.delete()
```
Data sources and ingestion

Records are added to your feature groups through ingestion. Depending on your desired use case, the ingested records may be kept within the feature group or not. This depends on the storage configuration, if your feature group uses the offline or online store. The offline store is used as a historical database, that is typically used for data exploration, machine learning (ML) model training, and batch inference. The online store is used as a real-time lookup of records, that is typically used for ML model serving. For more information on Feature Store concepts and ingestion, see Feature Store concepts (p. 1416).

There are multiple ways to bring your data into Amazon SageMaker Feature Store. Feature Store offers a single API call for data ingestion called PutRecord that enables you to ingest data in batches or from streaming sources. You can use Amazon SageMaker Data Wrangler to engineer features and then ingest your features into your Feature Store. You can also use Amazon EMR for batch data ingestion through a Spark connector.

In the following topics we will discuss the difference between:

Topics
- Stream ingestion (p. 1437)
- Data Wrangler with Feature Store (p. 1437)
- Batch ingestion with Amazon SageMaker Feature Store Spark (p. 1438)

Stream ingestion

You can use streaming sources such as Kafka or Kinesis as a data source, where records are extracted from, and directly feed records to the online store for training, inference or feature creation. Records can be ingested into your feature group by using the synchronous PutRecord API call. Since this is a synchronous API call it allows small batches of updates to be pushed in a single API call. This enables you to maintain high freshness of the feature values and publish values as soon an update is detected. These are also called streaming features.

Data Wrangler with Feature Store

Data Wrangler is a feature of Studio that provides an end-to-end solution to import, prepare, transform, featurize, and analyze data. Data Wrangler enables you to engineer your features and ingest them into your online or offline store groups.

After using with Data Wrangler in Studio, choose the Export tab, choose Export Step, and the choose Feature Store, as shown in the following screenshot. This exports a Jupyter notebook that contains all of the source code needed to create a Feature Store feature group that adds your features from Data Wrangler to an online or offline store.
After the feature group has been created, you can also select and join data across multiple feature groups to create new engineered features in Data Wrangler and then export your data set to an Amazon S3 bucket.

For more information on how to export to Feature Store, see [Export to SageMaker Feature Store](#).

**Batch ingestion with Amazon SageMaker Feature Store Spark**

Amazon SageMaker Feature Store Spark is a Spark connector that connects the Spark library to Feature Store. Feature Store Spark simplifies data ingestion from Spark DataFrames to feature groups. Feature Store supports batch data ingestion with Spark, using your existing ETL pipeline, on Amazon EMR, GIS, an AWS Glue job, an Amazon SageMaker Processing job, or a SageMaker notebook.

Methods for installing and implementing batch data ingestion are provided for Python and Scala developers. Python developers can use the open-source sagemaker-feature-store-pyspark Python library for local development, installation on Amazon EMR, and for Jupyter Notebooks by following the instructions in the [Amazon SageMaker Feature Store Spark GitHub repository](#). Scala developers can use the Feature Store Spark connector available in the [Amazon SageMaker Feature Store Spark SDK Maven central repository](#).

You can use the Spark connector to ingest data in the following ways, depending on if the online store, offline store, or both are enabled.

1. Ingest by default – If the online store is enabled, Spark connector first ingests your dataframe into the online store using the `PutRecord` API. Only the record with the largest event time remains in the online
store. If the offline store is enabled, within 15 minutes Feature Store ingests your dataframe into the offline store. For more information about how the online and offline stores work, see Feature Store concepts (p. 1416).

You can accomplish this by not specifying target_stores in the .ingest_data(...) method.

2. Offline store direct ingestion – If offline store is enabled, Spark connector batch ingests your dataframe directly into the offline store. Ingesting the dataframe directly into the offline store doesn't update the online store.

You can accomplish this by setting target_stores=["OfflineStore"] in the .ingest_data(...) method.

3. Online store only – If online store is enabled, Spark connector ingests your dataframe into the online store using the PutRecord API. Ingesting the dataframe directly into the online store doesn't update the offline store.

You can accomplish this by setting target_stores=["OnlineStore"] in the .ingest_data(...) method.

For information about using the different ingestion methods, see Example implementations (p. 1443).

Topics
- Feature Store Spark installation (p. 1439)
- Retrieving the JAR for Feature Store Spark (p. 1442)
- Example implementations (p. 1443)

Feature Store Spark installation

Scala users

The Feature Store Spark SDK is available in the Amazon SageMaker Feature Store Spark SDK Maven central repository for Scala users.

Requirements
- Spark >= 3.0.0 and <= 3.3.0
- iceberg-spark-runtime >= 0.14.0
- Scala >= 2.12.x
- Amazon EMR >= 6.1.0 (only if you are using Amazon EMR)

Declare the dependency in POM.xml

The Feature Store Spark connector has a dependency on the iceberg-spark-runtime library. You must therefore add corresponding version of the iceberg-spark-runtime library to the dependency if you're ingesting data into a feature group that you've auto-created with the Iceberg table format. For example, if you're using Spark 3.1, you must declare the following in your project's POM.xml:

```xml
<dependency>
  <groupId>software.amazon.sagemaker.featurestore</groupId>
  <artifactId>sagemaker-feature-store-spark-sdk_2.12</artifactId>
  <version>1.0.0</version>
</dependency>

<dependency>
  <groupId>org.apache.iceberg</groupId>
  <artifactId>iceberg-spark-runtime-3.1.2_2.12</artifactId>
</dependency>
```
Python users

The Feature Store Spark SDK is available in the open-source Amazon SageMaker Feature Store Spark GitHub repository.

Requirements

- Spark >= 3.0.0 and <= 3.3.0
- Amazon EMR >= 6.1.0 (only if you are using Amazon EMR)
- Kernel = conda_python3

We recommend setting the $SPARK_HOME to the directory where you have Spark installed. During installation, Feature Store uploads the required JAR to SPARK_HOME, so that the dependencies load automatically. Spark starting a JVM is required to make this PySpark library work.

Local installation

To find more info about the installation, enable verbose mode by appending --verbose to the following installation command.

```bash
pip3 install sagemaker-feature-store-pyspark-3.1 --no-binary :all:
```

Installation on Amazon EMR

Create an Amazon EMR cluster with the release version 6.1.0 or later. Enable SSH to help you troubleshoot any issues.

You can do one of the following to install the library:

- Create a custom step within Amazon EMR.
- Connect to your cluster using SSH and install the library from there.

**Note**

The following information uses Spark version 3.1, but you can specify any version that meets the requirements.

```bash
export SPARK_HOME=/usr/lib/spark
sudo -E pip3 install sagemaker-feature-store-pyspark-3.1 --no-binary :all: --verbose
```

**Note**

If you want to install the dependent JARs automatically to SPARK_HOME, do not use the bootstrap step.

Installation on a SageMaker notebook instance

Install a version of PySpark that's compatible with the Spark connector using the following commands:

```bash
!pip3 install pyspark==3.1.1
!pip3 install sagemaker-feature-store-pyspark-3.1 --no-binary :all:
```
If you're performing batch ingestion to the offline store, the dependencies aren't within the notebook instance environment.

```python
from pyspark.sql import SparkSession
import feature_store_pyspark
extra_jars = ','.join(feature_store_pyspark.classpath_jars())
spark = SparkSession.builder 
    .config("spark.jars", extra_jars) 
    .config("spark.jars.packages", "org.apache.hadoop:hadoop-aws:3.2.1,org.apache.hadoop:hadoop-common:3.2.1") 
    .getOrCreate()
```

### Installation on notebooks with GIS

**Important**

You must use AWS Glue Version 2.0 or later.

Use the following information to help you install the PySpark connector in an AWS Glue Interactive Session (GIS).

Amazon SageMaker Feature Store Spark requires a specific Spark connector JAR during the initialization of the session to be uploaded to your Amazon S3 bucket. For more information on uploading the required JAR to your S3 bucket, see [Retrieving the JAR for Feature Store Spark](p. 1442).

After you've uploaded the JAR, you must provide the GIS sessions with the JAR using the following command.

```bash
%extra_jars s3:/<YOUR_BUCKET>/spark-connector-jars/sagemaker-feature-store-spark-sdk.jar
```

To install Feature Store Spark in the AWS Glue runtime, use the `%additional_python_modules` magic command within the GIS notebook. AWS Glue runs `pip` to the modules that you've specified under `%additional_python_modules`.

```bash
%additional_python_modules sagemaker-feature-store-pyspark-3.1
```

Before you start the AWS Glue session, you must use both of the preceding magic commands.

### Installation on an AWS Glue job

**Important**

You must use AWS Glue Version 2.0 or later.

To install the Spark connector on a AWS Glue job, use the `--extra-jars` argument to provide the necessary JARs and `--additional-python-modules` to install the Spark Connector as job parameters when you create the AWS Glue job as shown in the following example. For more information on uploading the required JAR to your S3 bucket, see [Retrieving the JAR for Feature Store Spark](p. 1442).

```python
glue_client = boto3.client('glue', region_name=region)
response = glue_client.create_job( 
    Name=pipeline_id, 
    Description='Feature Store Compute Job', 
    Role=glue_role_arn, 
    ExecutionProperty={'MaxConcurrentRuns': max_concurrent_run}, 
    Command={
        'Name': 'glueetl', 
        'ScriptLocation': script_location_uri, 
        'PythonVersion': '3'
    },
)
DefaultArguments={
    '--TempDir': temp_dir_location_uri,
    '--additional-python-modules': 'sagemaker-feature-store-pyspark-3.1',
    '--extra-jars': "s3://<YOUR_BUCKET>/spark-connector-jars/sagemaker-feature-store-
    spark-sdk.jar",
    ...
},
MaxRetries=3,
NumberOfWorkers=149,
Timeout=2880,
GlueVersion='3.0',
WorkerType='G.2X'
)

Installation on an Amazon SageMaker Processing job

To use Feature Store Spark with Amazon SageMaker Processing jobs, bring your own image. For more information about bringing your image, see Bring your own SageMaker image (p. 257). Add the installation step to a Dockerfile. After you’ve pushed the Docker image to an Amazon ECR repository, you can use the PySparkProcessor to create the processing job. For more information about creating a processing job with the PySpark processor, see Data Processing with Apache Spark (p. 1400).

The following is an example of adding an installation step to the Dockerfile.

FROM <ACCOUNT_ID>.dkr.ecr.<AWS_REGION>.amazonaws.com/sagemaker-spark-processing:3.1-cpu-
py38-v1.0
RUN /usr/bin/python3 -m pip install sagemaker-feature-store-pyspark-3.1 --no-binary :all:
    --verbose

Retrieving the JAR for Feature Store Spark

To retrieve the Feature Store Spark dependency JAR, you must install the Spark connector from the Python Package Index (PyPI) repository using pip in any Python environment with network access. A SageMaker Jupyter Notebook is an example of a Python environment with network access.

The following command installs the Spark connector.

!pip install sagemaker-feature-store-pyspark-3.1

After you've installed Feature Store Spark, you can retrieve the JAR location and upload the JAR to Amazon S3.

The feature-store-pyspark-dependency-jars command provides the location of the necessary dependency JAR that Feature Store Spark added. You can use the command to retrieve the JAR and upload it to Amazon S3.

jar_location = !feature-store-pyspark-dependency-jars
jar_location = jar_location[0]
s3_client = boto3.client("s3")
s3_client.upload_file(jar_location, "<YOUR_BUCKET>","spark-connector-jars/sagemaker-
    feature-store-spark-sdk.jar")
Example implementations

Example Python script

`FeatureStoreBatchIngestion.py`

```python
from pyspark.sql import SparkSession
from feature_store_pyspark.FeatureStoreManager import FeatureStoreManager
import feature_store_pyspark

spark = SparkSession.builder.getOrCreate()

# Construct test DataFrame
columns = ['RecordIdentifier', 'EventTime']
df = spark.createDataFrame(data).toDF(*columns)

# Initialize FeatureStoreManager with a role arn if your feature group is created by another account
feature_store_manager = FeatureStoreManager("arn:aws:iam::111122223333:role/role-arn")

# Load the feature definitions from input schema. The feature definitions can be used to create a feature group
feature_definitions = feature_store_manager.load_feature_definitions_from_schema(df)

feature_group_arn = "arn:aws:sagemaker:<AWS_REGION>:<ACCOUNT_ID>:feature-group/<YOUR_FEATURE_GROUP_NAME>"

# Ingest by default. The connector will leverage PutRecord API to ingest your data in stream
# https://docs.aws.amazon.com/sagemaker/latest/APIReference/API_feature_store_PutRecord.html
feature_store_manager.ingest_data(input_data_frame=df, feature_group_arn=feature_group_arn)

# To select the target stores for ingestion, you can specify the target store as the parameter
# If OnlineStore is selected, the connector will leverage PutRecord API to ingest your data in stream
feature_store_manager.ingest_data(input_data_frame=df,
                                    feature_group_arn=feature_group_arn, target_stores=['OfflineStore', 'OnlineStore'])

# If only OfflineStore is selected, the connector will batch write the data to offline store directly
feature_store_manager.ingest_data(input_data_frame=df,
                                    feature_group_arn=feature_group_arn, target_stores=['OfflineStore'])

# To retrieve the records failed to be ingested by spark connector
failed_records_df = feature_store_manager.get_failed_stream_ingestion_data_frame()
```

Submit a Spark job with example Python script

The PySpark version requires an extra dependent JAR to be imported, so extra steps are needed to run the Spark application.

If you did not specify SPARK_HOME during installation, then you have to load required JARs in JVM when running spark-submit. feature-store-pyspark-dependency-jars is a Python script installed by the Spark library to automatically fetch the path to all JARs for you.
spark-submit --jars `feature-store-pyspark-dependency-jars` FeatureStoreBatchIngestion.py

If you are running this application on Amazon EMR, we recommended that you run the application in client mode, so that you do not need to distribute the dependent JARs to other task nodes. Add one more step in Amazon EMR cluster with Spark argument similar to the following:

```
spark-submit --deploy-mode client --master yarn s3://<PATH_TO_SCRIPT>/FeatureStoreBatchIngestion.py
```

Example Scala script

```
FeatureStoreBatchIngestion.scala
```

```scala
import software.amazon.sagemaker.featurestore.sparksdk.FeatureStoreManager
import org.apache.spark.sql.types.{StringType, StructField, StructType}
import org.apache.spark.sql.{Row, SparkSession}

object TestSparkApp {
  def main(args: Array[String]): Unit = {
    val spark = SparkSession.builder().getOrCreate()

    // Construct test DataFrame

    val schema = StructType(List(      StructField("RecordIdentifier", StringType),      StructField("EventTime", StringType))
    )

    val df = spark.createDataFrame(spark.sparkContext.parallelize(data), schema)

    // Initialize FeatureStoreManager with a role arn if your feature group is created
    // by another account
    val featureStoreManager = new FeatureStoreManager("arn:aws:iam::111122223333:role/role-arn")

    // Load the feature definitions from input schema. The feature definitions can
    // be used to create a feature group
    val featureDefinitions = featureStoreManager.loadFeatureDefinitionsFromSchema(df)

    // Ingest by default. The connector will leverage PutRecord API to ingest your data
    // in stream
    featureStoreManager.ingestData(df, featureGroupArn)

    // To select the target stores for ingestion, you can specify the target store as
    // the parameter
    // If OnlineStore is selected, the connector will leverage PutRecord API to ingest
    // your data in stream
```
Submit a Spark job

Scala

You should be able to use Feature Store Spark as a normal dependency. No extra instruction is needed to run the application on all platforms.

Feature Processing

Amazon SageMaker Feature Store Feature Processing is a capability with which you can transform raw data into machine learning (ML) features. It provides you with a Feature Processor SDK with which you can transform and ingest data from batch data sources into your feature groups. With this capability, Feature Store takes care of the underlying infrastructure including provisioning the compute environments and creating and maintaining SageMaker Pipelines to load and ingest data. This way you can focus on your feature processor definitions that includes a transformation function (for example, count of product views, mean of transaction value), sources (where to apply this transformation on), and sinks (where to write the computed feature values to).

Feature Processor pipeline is a SageMaker Pipelines pipeline. As a SageMaker Pipelines, you can also track scheduled Feature Processor pipelines with SageMaker lineage in Amazon SageMaker Studio. For more information on SageMaker Lineage, see Amazon SageMaker ML Lineage Tracking (p. 2973). This includes tracking scheduled executions, visualizing lineage to trace features back to their data sources, and viewing shared feature processors in a single environment. For information on using Feature Store with Studio, see View pipeline executions in Studio (p. 1435).

Topics

- Running Feature Store Feature Processor remotely (p. 1447)
- Creating and running Feature Store Feature Processor pipelines (p. 1448)
- Scheduled and event based executions for Feature Processor pipelines (p. 1449)
- Monitor Amazon SageMaker Feature Store Feature Processor pipelines (p. 1451)
- IAM permissions and execution roles (p. 1452)
- Feature Processor restrictions, limits, and quotas (p. 1452)
- Data sources (p. 1453)
- Example Feature Processing code for common use cases (p. 1463)

Feature Store Feature Processor SDK

Declare a Feature Store Feature Processor definition by decorating your transformation functions with the @feature_processor decorator. The SageMaker SDK for Python (Boto3) automatically loads data
from the configured input data sources, applies the decorated transformation function, and then ingests the transformed data to a target feature group. Decorated transformation functions must conform to the expected signature of the @feature_processor decorator. For more information about the @feature_processor decorator, see @feature_processor Decorator in the Amazon SageMaker Feature Store Read the Docs.

With the @feature_processor decorator, your transformation function runs in a Spark runtime environment where the input arguments provided to your function and its return value are Spark DataFrames. The number of input parameters in your transformation function must match the number of inputs configured in the @feature_processor decorator.

For more information on the @feature_processor decorator, see the Feature Processor Feature Store SDK for Python (Boto3).

The following code are basic examples on how to use the @feature_processor decorator. For more specific example usage cases, see Example Feature Processing code for common use cases (p. 1463).

The Feature Processor SDK can be installed from the SageMaker Python SDK and its extras using the following command.

```bash
pip install sagemaker[feature-processor]
```

In the following examples, us-east-1 is the region of the resource, 111122223333 is the resource owner account ID, and your-feature-group-name is the feature group name.

The following is a basic feature processor definition, where the @feature_processor decorator configures a CSV input from Amazon S3 to be loaded and provided to your transformation function (for example, transform), and prepares it for ingestion to a feature group. The last line runs it.

```python
from sagemaker.feature_store.feature_processor import CSVDataSource, feature_processor
CSV_DATA_SOURCE = CSVDataSource('s3://your-bucket/prefix-to-csv/')
@feature_processor(inputs=[CSV_DATA_SOURCE], output=OUTPUT_FG)
def transform(csv_input_df):
    return csv_input_df
transform()
```

The @feature_processor parameters include:

- **inputs (List[str]):** A list of data sources that are used in your Feature Store Feature Processor. If your data sources are feature groups or stored in Amazon S3 you may be able to use Feature Store provided data source definitions for feature processor. For a full list of Feature Store provided data source definitions, see the Feature Processor Data Source in the Amazon SageMaker Feature Store Read the Docs.
- **output (str):** The ARN of the feature group to ingest the output of the decorated function.
- **target_stores (Optional[List[str]]):** A list of stores (for example, OnlineStore or OfflineStore) to ingest to the output. If unspecified, data is ingested to all of the output feature group’s enabled stores.
- **parameters (Dict[str, Any]):** A dictionary to be provided to your transformation function.
- **enable_ingestion (bool):** A flag to indicate whether the transformation function’s outputs are ingested to the output feature group. This flag is useful during the development phase. If unspecified, ingestion is enabled.
Optional wrapped function parameters (provided as an argument if provided in the function signature) include:

- **params (Dict[str, Any]):** The dictionary defined in the @feature_processor parameters. It also contains system configured parameters that can be referenced with the key `system`, such as the `scheduled_time` parameter.
- **spark (SparkSession):** A reference to the SparkSession instance initialized for the Spark Application.

The following code is an example of using the `params` and `spark` parameters.

```python
from sagemaker.feature_store.feature_processor import CSVDataSource, feature_processor

CSV_DATA_SOURCE = CSVDataSource('s3://your-bucket/prefix-to-csv/)
OUTPUT_FG = 'arn:aws:sagemaker:us-east-1:111122233333:feature-group/your-feature-group-name'

@feature_processor(inputs=[CSV_DATA_SOURCE], output=OUTPUT_FG)
def transform(csv_input_df, params, spark):
    scheduled_time = params['system']['scheduled_time']
    csv_input_df.createOrReplaceTempView('csv_input_df')
    return spark.sql(f'''
        SELECT *
        FROM csv_input_df
        WHERE date_add(event_time, 1) >= {scheduled_time}
    ''')
    transform()
```

The `scheduled_time` system parameter (provided in the `params` argument to your function) is an important value to support retrying each execution. The value can help to uniquely identify the Feature Processor’s execution and can be used as a reference point for daterange–based inputs (for example, only loading the last 24 hours worth of data) to guarantee the input range independent of the code’s actual execution time. If the Feature Processor runs on a schedule (see Scheduled and event based executions for Feature Processor pipelines (p. 1449)) then its value is fixed to the time it is scheduled to run. The argument can be overridden during synchronous execution using the SDK’s execute API to support use cases such as data backfills or re-running a missed past execution. Its value is the current time if the Feature Processor runs any other way.

For information about authoring Spark code, see the Spark SQL Programming Guide.

For more code samples for common use-cases, see the Example Feature Processing code for common use cases (p. 1463).

Note that transformation functions decorated with `@feature_processor` do not return a value. To programmatically test your function, you can remove or monkey patch the `@feature_processor` decorator such that it acts as a pass-through to the wrapped function. For more details on the `@feature_processor` decorator, see Amazon SageMaker Feature Store Python SDK.

### Running Feature Store Feature Processor remotely

To run your Feature Processors on large data sets that require hardware more powerful than what is locally available, you can decorate your code with the `@remote` decorator to run your local Python code as a single or multi-node distributed SageMaker training job. For more information on running your code as a SageMaker training job, see Run your local code as a SageMaker training job (p. 1813).

The following is a usage example of the `@remote` decorator along with the `@feature_processor` decorator.
Creating and running Feature Store Feature Processor pipelines

The spark_config parameter indicates that the remote job runs as a Spark application. The SparkConfig instance can be used to configure the Spark Configuration and provide additional dependencies to the Spark application such as Python files, JARs, and files.

For faster iterations when developing your feature processing code, you can specify the keep_alive_period_in_seconds argument in the @remote decorator to retain configured resources in a warm pool for subsequent training jobs. For more information on warm pools, see KeepAlivePeriodInSeconds in the API Reference guide.

The following code is an example of local requirements.txt:

```
sagemaker>=2.167.0
```

This will install the corresponding SageMaker SDK version in remote job which is required for executing the method annotated by @feature-processor.

Creating and running Feature Store Feature Processor pipelines

The Feature Processor SDK provides APIs to promote your Feature Processor Definitions into a fully managed SageMaker Pipeline. For more information on SageMaker Pipelines, see SageMaker Pipelines Overview (p. 2806). To convert your Feature Processor Definitions into a SageMaker Pipeline, use the to_pipeline API with your Feature Processor definition. You can schedule executions of your Feature Processor Definition can be scheduled, operationally monitor them with CloudWatch metrics, and integrate them with EventBridge to act as event sources or subscribers. For more information about monitoring pipelines created with SageMaker Pipelines, see Monitor Amazon SageMaker Feature Store Feature Processor pipelines (p. 1451).

To view your Feature Processor pipelines, see View pipeline executions in Studio (p. 1435).

If your function is also decorated with the @remote decorator, then its configurations is carried over to the Feature Processor pipeline. You can specify advanced configurations such as compute instance type and count, runtime dependencies, network and security configurations using the @remote decorator.

The following example uses the to_pipeline and execute APIs.
from sagemaker.feature_store.feature_processor import (  
    execute, to_pipeline, describe, TransformationCode  
)

pipeline_name="feature-processor-pipeline"
pipeline_arn = to_pipeline(  
    pipeline_name=pipeline_name,
    step=transform,
    transformation_code=TransformationCode(s3_uri="s3:///bucket/prefix"),
)

pipeline_execution_arn = execute(  
    pipeline_name=pipeline_name
)

The to_pipeline API is semantically an upsert operation. It updates the pipeline if it already exists; otherwise, it creates a pipeline.

The to_pipeline API optionally accepts an Amazon S3 URI that references a file containing the Feature Processor definition to associate it with the Feature Processor pipeline to track the transformation function and its versions in its SageMaker machine learning lineage.

To retrieve a list of every Feature Processor pipeline in your account, you can use the list_pipelines API. A subsequent request to the describe API returns details related to the Feature Processor pipeline including, but not limited to, SageMaker Pipelines and schedule details.

The following example uses the list_pipelines and describe APIs.

from sagemaker.feature_store.feature_processor import list_pipelines, describe

feature_processor_pipelines = list_pipelines()
pipeline_description = describe(  
    pipeline_name = feature_processor_pipelines[0]
)

Scheduled and event based executions for Feature Processor pipelines

Amazon SageMaker Feature Store Feature Processing pipeline executions can be configured to start automatically and asynchronously based on a preconfigured schedule or as a result of another AWS service event. For example, you can schedule Feature Processing pipelines to execute on the first of every month or chain two pipelines together so that a target pipeline is executed automatically after a source pipeline execution completes.

Topics

- Schedule based executions (p. 1449)
- Event based executions (p. 1450)

Schedule based executions

The Feature Processor SDK provides a schedule API to run Feature Processor pipelines on a recurring basis with Amazon EventBridge Scheduler integration. The schedule can be specified with an at, rate, or cron expression using the ScheduleExpression parameter with the same expressions supported by Amazon EventBridge. The schedule API is semantically an upsert operation in that it updates the
Scheduled and event based executions

for Feature Processor pipelines

schedule if it already exists; otherwise, it creates it. For more information on the EventBridge expressions and examples, see Schedule types on EventBridge Scheduler in the EventBridge Scheduler User Guide.

The following examples use the Feature Processor schedule API, using the at, rate, and cron expressions.

```python
from sagemaker.feature_store.feature_processor import schedule
pipeline_name='feature-processor-pipeline'

event_bridge_schedule_arn = schedule(
    pipeline_name=pipeline_name,
    schedule_expression="at(2020-11-30T00:00:00)"
)

event_bridge_schedule_arn = schedule(
    pipeline_name=pipeline_name,
    schedule_expression="rate(24 hours)"
)

event_bridge_schedule_arn = schedule(
    pipeline_name=pipeline_name,
    schedule_expression="cron(0 0-23/1 ? * * 2023-2024)"
)
```

The default timezone for date and time inputs in the schedule API are in UTC. For more information about EventBridge Scheduler schedule expressions, see ScheduleExpression in the EventBridge Scheduler API Reference documentation.

Scheduled Feature Processor pipeline executions provide your transformation function with the scheduled execution time, to be used as an idempotency token or a fixed reference point for date range-based inputs. To disable (i.e., pause) or re-enable a schedule, use the state parameter of the schedule API with ‘DISABLED’ or ‘ENABLED’, respectively.

For information about Feature Processor, see Feature Processor SDK data sources (p. 1453).

Event based executions

A Feature Processing pipeline can be configured to automatically execute when an AWS event occurs. The Feature Processing SDK provides a put_trigger function that accepts a list of source events and a target pipeline. The source events must be instances of FeatureProcessorPipelineEvent that specifies a pipeline and execution status events.

The put_trigger function configures an Amazon EventBridge rule and target to route events and allows you to specify an EventBridge event pattern to respond to any AWS event. For information on these concepts, see Amazon EventBridge rules, targets, and event patterns.

Triggers can be enabled or disabled. EventBridge will start a target pipeline execution using the role provided in the role_arn parameter of the put_trigger API. The execution role is used by default if the SDK is used in a Amazon SageMaker Studio or Notebook environment. For information on how to get your execution role, see Get execution role (p. 3390).

The following example sets up:

- A SageMaker Pipeline using the to_pipeline API, that takes in your target pipeline name (target-pipeline) and your transformation function (transform). For information on your Feature Processor and transform function, see Feature Processor SDK data sources (p. 1453).
- A trigger using the put_trigger API, that takes in FeatureProcessorPipelineEvent for the event and your target pipeline name (target-pipeline).
The FeatureProcessorPipelineEvent defines the trigger for when the status of your source pipeline (source-pipeline) becomes Succeeded. For information on the Feature Processor Pipeline event function, see FeatureProcessorPipelineEvent in the Feature Store Read the Docs.

```python
from sagemaker.feature_store.feature_processor import put_trigger, to_pipeline,
FeatureProcessorPipelineEvent
to_pipeline(pipeline_name="target-pipeline", step=transform)
put_trigger(
    source_pipeline_events=[
        FeatureProcessorPipelineEvent(
            pipeline_name="source-pipeline",
            status=["Succeeded"]
        ),
    ],
    target_pipeline="target-pipeline"
)
```

For an example of using event based triggers to create continuous executions and automatic retries for your Feature Processor pipeline, see Continuous executions and automatic retries using event based triggers (p. 1465).

For an example of using event based triggers to create continuous streaming and automatic retries using event based triggers, see Streaming custom data source examples (p. 1460).

**Monitor Amazon SageMaker Feature Store Feature Processor pipelines**

AWS provides monitoring tools to watch your Amazon SageMaker resources and applications in real time, report when something goes wrong, and take automatic actions when appropriate. Feature Store Feature Processor pipelines are SageMaker Pipelines, so the standard monitoring mechanisms and integrations are available. Operational metrics such as execution failures can be monitored via Amazon CloudWatch metrics and Amazon EventBridge events.

For more information on how to monitor and operationalize Feature Store Feature Processor, see the following resources:

- Monitor AWS resources provisioned while using Amazon SageMaker (p. 3577) - General guidance on monitoring and auditing activity for SageMaker resources.
- SageMaker Pipelines Metrics (p. 3589) - CloudWatch Metrics emitted by SageMaker Pipelines.
- Pipeline execution state change (p. 3604) - EventBridge events emitted for SageMaker Pipelines and executions.
- Troubleshooting Amazon SageMaker Model Building Pipelines (p. 2859) - General debugging and troubleshooting tips for SageMaker Pipelines.

Feature Store Feature Processor execution logs can be found in Amazon CloudWatch Logs under the /aws/sagemaker/TrainingJobs log group, where you can find the execution log streams using lookup conventions. For executions created by directly invoking the @feature_processor decorated function, you can find logs in your local execution environment's console. For @remote decorated executions, the CloudWatch Logs stream name contains the name of the function and the execution timestamp. For Feature Processor pipeline executions, the CloudWatch Logs stream for the step contains the feature-processor string and the pipeline execution ID.
Feature Store Feature Processor pipelines and recent execution statuses can be found in Amazon SageMaker Studio for a given feature group in the Feature Store UI. Feature groups related to the Feature Processor pipelines as either inputs or outputs are displayed in the UI. In addition, the lineage view can provide context into upstream executions, such as data producing Feature Processor pipelines and data sources, for further debugging. For more information on using the lineage view using Studio, see View lineage in Studio (p. 1435).

IAM permissions and execution roles

To use the Amazon SageMaker Python SDK requires permissions to interact with AWS services. The following policies are required for full Feature Processor functionality. You can attach the AmazonSageMakerFullAccess and AmazonEventBridgeSchedulerFullAccess AWS Managed Policies attached to your IAM role. For information on attaching policies to your IAM role, see Adding policies to your IAM role (p. 1419). See the following examples for details.

The trust policy of the role to which this policy is applied must allow the "scheduler.amazonaws.com", "sagemaker.amazonaws.com", and "glue.amazonaws.com" principles.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "scheduler.amazonaws.com",
          "sagemaker.amazonaws.com",
          "glue.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

Feature Processor restrictions, limits, and quotas

Amazon SageMaker Feature Store Feature Processing relies on SageMaker machine learning (ML) lineage tracking. The Feature Store Feature Processor uses lineage contexts to represent and track Feature Processing Pipelines and Pipeline versions. Each Feature Store Feature Processor consumes at least two lineage contexts (one for the Feature Processing Pipeline and another for the version). If the input or output data source of a Feature Processing Pipeline changes, an additional lineage context is created. You can update SageMaker ML lineage limits by reaching out to AWS support for a limit increase. Default limits for resources used by Feature Store Feature Processor are as follows. For information on SageMaker ML lineage tracking, see Amazon SageMaker ML Lineage Tracking (p. 2973).

For more information on SageMaker quotas, see Amazon SageMaker endpoints and quotas.

Lineage limits per Region

- Contexts – 500 (soft limit)
- Artifacts – 6,000 (soft limit)
- Associations – 6,000 (soft limit)

Training Limits per Region

- Longest run time for a training job – 432,000 seconds
Data sources

Amazon SageMaker Feature Store Feature Processing supports multiple data sources. The Feature Processor SDK for Python (Boto3) provides constructs to load data from feature groups or objects stored in Amazon S3. In addition, you can author custom data sources to load data from other data sources. For information about Feature Store provided data sources, see Feature Processor data source Feature Store Python SDK.

Topics

- Feature Processor SDK data sources (p. 1453)
- Custom data sources (p. 1453)
- Custom data source examples (p. 1454)

Feature Processor SDK data sources

The Amazon SageMaker Feature Store Feature Processor SDK for Python (Boto3) provides constructs to load data from feature groups or objects stored in Amazon S3. For a full list of Feature Store provided data source definitions, see the Feature Processor data source Feature Store Python SDK.

For examples on how to use the Feature Store Python SDK data source definitions, see Example Feature Processing code for common use cases (p. 1463).

FeatureGroupDataSource

The FeatureGroupDataSource is used to specify a feature group as an input data source for a Feature Processor. Data can be loaded from an offline store feature group. Attempting to load your data from an online store feature group will result in a validation error. You can specify start and end offsets to limit the data that is loaded to a specific time range. For example, you can specify a start offset of ‘14 days’ to load only the last two weeks of data, and you can additionally specify an end offset of ‘7 days’ to limit the input to the previous week of data.

Feature Store provided data source definitions

The Feature Store Python SDK contain data source definitions that can be used to specify various input data sources for a Feature Processor. These include CSV, Parquet, and Iceberg table sources. For a full list of Feature Store provided data source definitions, see the Feature Processor data source Feature Store Python SDK.

Custom data sources

On this page we will describe how to create a custom data source class and show some usage examples. With custom data sources, you can use the SageMaker SDK for Python (Boto3) provided APIs in the same way as if you are using Amazon SageMaker Feature Store provided data sources.
To use a custom data source to transform and ingest data into a feature group using Feature Processing, you will need to extend the `PySparkDataSource` class with the following class members and function.

- `data_source_name` (str): an arbitrary name for the data source. For example, Amazon Redshift, Snowflake, or a Glue Catalog ARN.
- `data_source_unique_id` (str): a unique identifier that refers to the specific resource being accessed. For example, table name, DDB Table ARN, Amazon S3 prefix. All usage of the same `data_source_unique_id` in custom data sources will be associated to the same data source in the lineage view. Lineage includes information about the execution code of a feature processing workflow, what data sources were used, and how they are ingested into the feature group or feature. For information about viewing lineage of a feature group in Studio, see [View lineage in Studio](p. 1435).
- `read_data` (func): a method used to connect with the feature processor. Returns a Spark data frame. For examples, see [Custom data source examples](p. 1454).

Both `data_source_name` and `data_source_unique_id` are used to uniquely identify your lineage entity. The following is an example for a custom data source class named `CustomDataSource`.

```python
from sagemaker.feature_store.feature_processor import PySparkDataSource
from pyspark.sql import DataFrame

class CustomDataSource(PySparkDataSource):
    data_source_name = "custom-data-source-name"
    data_source_unique_id = "custom-data-source-unique-id"

    def read_data(self, parameter, spark) -> DataFrame:
        your own code here to read data into a Spark dataframe
        return dataframe
```

### Custom data source examples

This section provides examples of custom data sources implementations for Feature Processors. For more information on custom data sources, see [Custom data sources](p. 1453).

Security is a shared responsibility between AWS and our customers. AWS is responsible for protecting the infrastructure that runs the services in the AWS Cloud. Customers are responsible for all of their necessary security configuration and management tasks. For example, secrets such as access credentials to data stores should not be hard coded in your custom data sources. You can use AWS Secrets Manager to manage these credentials. For information about Secrets Manager, see [What is AWS Secrets Manager?](in the AWS Secrets Manager user guide. The following examples will use Secrets Manager for your credentials.

#### Topics

- [Amazon Redshift Clusters (JDBC) custom data source examples](p. 1454)
- [Snowflake custom data source examples](p. 1456)
- [Databricks (JDBC) custom data source examples](p. 1458)
- [Streaming custom data source examples](p. 1460)

#### Amazon Redshift Clusters (JDBC) custom data source examples

Amazon Redshift offers a JDBC driver that can be used to read data with Spark. For information about how to download the Amazon Redshift JDBC driver, see [Download the Amazon Redshift JDBC driver, version 2.1](in the AWS Secrets Manager user guide. The following examples will use Secrets Manager for your credentials.

To create the custom Amazon Redshift data source class, you will need to overwrite the `read_data` method from the [Custom data sources](p. 1453).
To connect with an Amazon Redshift cluster you need your:

- Amazon Redshift JDBC URL (\textit{jdbc-url})

  For information about obtaining your Amazon Redshift JDBC URL, see Getting the JDBC URL in the Amazon Redshift Database Developer Guide.

- Amazon Redshift user name (\textit{redshift-user}) and password (\textit{redshift-password})

  For information about how to create and manage database users using the Amazon Redshift SQL commands, see Users in the Amazon Redshift Database Developer Guide.

- Amazon Redshift table name (\textit{redshift-table-name})

  For information about how to create a table with some examples, see CREATE TABLE in the Amazon Redshift Database Developer Guide.

- (Optional) If using Secrets Manager, you'll need the secret name (\textit{secret-redshift-account-info}) where you store your Amazon Redshift access username and password on Secrets Manager.

  For information about Secrets Manager, see Find secrets in AWS Secrets Manager in the AWS Secrets Manager User Guide.

- AWS Region (\textit{your-region})

  For information about obtaining your current session's region name using SDK for Python (Boto3), see region_name in the Boto3 documentation.

The following example demonstrates how to retrieve the JDBC URL and personal access token from Secrets Manager and override the read_data for your custom data source class, DatabricksDataSource.

```python
from sagemaker.feature_store.feature_processor import PySparkDataSource
import json
import boto3

class RedshiftDataSource(PySparkDataSource):
    data_source_name = "Redshift"
    data_source_unique_id = "redshift-resource-arn"

    def read_data(self, spark, params):
        url = "$\textit{jdbc-url}\?user=\textit{redshift-user}\&password=\textit{redshift-password}\$"
        aws_iam_role_arn = "\textit{redshift-command-access-role}\$"
        secret_name = "\textit{secret-redshift-account-info}\$
        region_name = "\textit{your-region}\$

        session = boto3.session.Session()
        sm_client = session.client(
            service_name='secretsmanager',
            region_name=region_name,
        )

        secrets = json.loads(sm_client.get_secret_value(SecretId=secret_name)['SecretString'])
        jdbc_url = url.replace("$\textit{jdbc-url}$", secrets['jdbcurl']).replace("\textit{redshift-user}\$, secrets['username']).replace("\textit{redshift-password}\$, secrets['password'])

        return spark.read \\
            .format("jdbc") \\
            .option("url", url) \\
            .option("driver", "com.amazon.redshift.Driver") \\
            .option("dbtable", "\textit{redshift-table-name}\") \\
```

1455
The following example shows how to connect RedshiftDataSource to your feature_processor decorator.

```python
from sagemaker.feature_store.feature_processor import feature_processor
@feature_processor(
    inputs=[RedshiftDataSource()],
    output="feature-group-arn",
    target_stores=['OfflineStore'],
    spark_config={'spark.jars.packages': 'com.amazon.redshift:redshift-jdbc42:2.1.0.16'}
)
def transform(input_df):
    return input_df
```

To run the feature processor job remotely, you need to provide the jdbc driver by defining SparkConfig and pass it to the @remote decorator.

```python
from sagemaker.remote_function import remote
from sagemaker.remote_function.spark_config import SparkConfig
config = {
    "Classification": "spark-defaults",
    "Properties": {
        "spark.jars.packages": "com.amazon.redshift:redshift-jdbc42:2.1.0.16"
    }
}
@remote(
    spark_config=SparkConfig(configuration=config),
    instance_type="ml.m5.2xlarge",
)
@feature_processor(
    inputs=[RedshiftDataSource()],
    output="feature-group-arn",
    target_stores=['OfflineStore'],
)
def transform(input_df):
    return input_df
```

### Snowflake custom data source examples

Snowflake provides a Spark connector that can be used for your feature_processor decorator. For information about Snowflake connector for Spark, see [Snowflake Connector for Spark](snowflake documentation).

To create the custom Snowflake data source class, you will need to override the read_data method from the Custom data sources (p. 1453) and add the Spark connector packages to the Spark classpath.

To connect with a Snowflake data source you need:

- Snowflake URL (sf-url)
  For information about URLs for accessing Snowflake web interfaces, see [Account Identifiers](snowflake documentation).
- Snowflake database (sf-database)
For information about obtaining the name of your database using Snowflake, see `CURRENT_DATABASE` in the Snowflake documentation.

- Snowflake database schema (sf-schema)
  
  For information about obtaining the name of your schema using Snowflake, see `CURRENT_SCHEMA` in the Snowflake documentation.

- Snowflake warehouse (sf-warehouse)
  
  For information about obtaining the name of your warehouse using Snowflake, see `CURRENT_WAREHOUSE` in the Snowflake documentation.

- Snowflake table name (sf-table-name)

- (Optional) If using Secrets Manager, you’ll need the secret name (secret-snowflake-account-info) where you store your Snowflake access username and password on Secrets Manager.

  For information about Secrets Manager, see Find secrets in AWS Secrets Manager in the AWS Secrets Manager User Guide.

- AWS Region (your-region)
  
  For information about obtaining your current session’s region name using SDK for Python (Boto3), see `region_name` in the Boto3 documentation.

The following example demonstrates how to retrieve the Snowflake user name and password from Secrets Manager and override the read_data function for your custom data source class SnowflakeDataSource.

```python
from sagemaker.feature_store.feature_processor import PySparkDataSource
from sagemaker.feature_store.feature_processor import feature_processor
import json
import boto3

class SnowflakeDataSource(PySparkDataSource):
    sf_options = {
        "sfUrl" : "sf-url",
        "sfDatabase" : "sf-database",
        "sfSchema" : "sf-schema",
        "sfWarehouse" : "sf-warehouse",
    }

data_source_name = "Snowflake"
data_source_unique_id = "sf-url"

def read_data(self, spark, params):
    secret_name = "secret-snowflake-account-info"
    region_name = "your-region"

    session = boto3.session.Session()
    sm_client = session.client(
        service_name='secretsmanager',
        region_name=region_name,
    )

    secrets = json.loads(sm_client.get_secret_value(SecretId=secret_name)["SecretString"])
    self.sf_options["sfUser"] = secrets.get("username")
    self.sf_options["sfPassword"] = secrets.get("password")

    return spark.read.format("net.snowflake.spark.snowflake")
```
The following example shows how to connect SnowflakeDataSource to your feature_processor decorator.

```python
from sagemaker.feature_store.feature_processor import feature_processor

@feature_processor(
    inputs=[SnowflakeDataSource()],
    output="feature-group-arn",
    target_stores="OfflineStore",
    spark_config="spark.jars.packages": "net.snowflake:spark-snowflake_2.12:2.12.0-spark_3.3"
)
def transform(input_df):
    return input_df
```

To run the feature processor job remotely, you need to provide the packages via defining SparkConfig and pass it to @remote decorator. The Spark packages in the following example are such that spark-snowflake_2.12 is the Feature Processor Scala version, 2.12.0 is the Snowflake version you wish to use, and spark_3.3 is the Feature Processor Spark version.

```python
from sagemaker.remote_function import remote
from sagemaker.remote_function.spark_config import SparkConfig

config = {
    "Classification": "spark-defaults",
    "Properties": {
        "spark.jars.packages": "net.snowflake:spark-snowflake_2.12:2.12.0-spark_3.3"
    }
}

@remote(
    spark_config=SparkConfig(configuration=config),
    instance_type="ml.m5.2xlarge",
)
@feature_processor(
    inputs=[SnowflakeDataSource()],
    output="feature-group-arn",
    target_stores="OfflineStore",
)
def transform(input_df):
    return input_df
```

### Databricks (JDBC) custom data source examples

Spark can read data from Databricks by using the Databricks JDBC driver. For information about the Databricks JDBC driver, see Configure the Databricks ODBC and JDBC drivers in the Databricks documentation.

**Note**

You can read data from any other database by including the corresponding JDBC driver in Spark classpath. For more information, see JDBC To Other Databases in the Spark SQL Guide.

To create the custom Databricks data source class, you will need to override the `read_data` method from the Custom data sources (p. 1453) and add the JDBC jar to the Spark classpath.

To connect with a Databricks data source you need:

- Databricks URL (`databricks-url`)
For information about your Databricks URL, see Building the connection URL for the Databricks driver in the Databricks documentation.

- Databricks personal access token (personal-access-token)

For information about your Databricks access token, see Databricks personal access token authentication in the Databricks documentation.

- Data catalog name (db-catalog)

For information about your Databricks catalog name, see Catalog name in the Databricks documentation.

- Schema name (db-schema)

For information about your Databricks schema name, see Schema name in the Databricks documentation.

- Table name (db-table-name)

For information about your Databricks table name, see Table name in the Databricks documentation.

- (Optional) If using Secrets Manager, you’ll need the secret name (secret-databricks-account-info) where you store your Databricks access username and password on Secrets Manager.

For information about Secrets Manager, see Find secrets in AWS Secrets Manager in the AWS Secrets Manager User Guide.

- AWS Region (your-region)

For information about obtaining your current session’s region name using SDK for Python (Boto3), see region_name in the Boto3 documentation.

The following example demonstrates how to retrieve the JDBC URL and personal access token from Secrets Manager and overwrite the read_data for your custom data source class, DatabricksDataSource.

```python
from sagemaker.feature_store.feature_processor import PySparkDataSource
import json
import boto3

class DatabricksDataSource(PySparkDataSource):
    data_source_name = "Databricks"
    data_source_unique_id = "databricks-url"

    def read_data(self, spark, params):
        secret_name = "secret-databricks-account-info"
        region_name = "your-region"

        session = boto3.session.Session()
        sm_client = session.client(
            service_name='secretsmanager',
            region_name=region_name,
        )

        secrets = json.loads(sm_client.get_secret_value(SecretId=secret_name)['SecretString'])
        jdbc_url = secrets["jdbcurl"].replace("personal-access-token", secrets["pwd"])

        return spark.read.format("jdbc")
            .option("url", jdbc_url) \
            .option("dbtable","`{}``.`{}``.`{}`") \
```

1459
The following example shows how to upload the JDBC driver jar, `jdbc-jar-file-name.jar`, to Amazon S3 in order to add it to the Spark classpath. For information about downloading the Spark JDBC driver (`jdbc-jar-file-name.jar`) from Databricks, see Download JDBC Driver in the Databricks website.

```python
from sagemaker.feature_store.feature_processor import feature_processor

@feature_processor(
    inputs=[DatabricksDataSource()],
    output="feature-group-arn",
    target_stores=["OfflineStore"],
    spark_config={"spark.jars": "s3://your-bucket-name/your-bucket-prefix/jdbc-jar-file-name.jar"}
)
def transform(input_df):
    return input_df
```

To run the feature processor job remotely, you need to provide the jars by defining SparkConfig and pass it to the `@remote` decorator.

```python
from sagemaker.remote_function import remote
from sagemaker.remote_function.spark_config import SparkConfig
config = {
    "Classification": "spark-defaults",
    "Properties": {
        "spark.jars": "s3://your-bucket-name/your-bucket-prefix/jdbc-jar-file-name.jar"
    }
}

@remote(
    spark_config=SparkConfig(configuration=config),
    instance_type="ml.m5.2xlarge",
)
@feature_processor(
    inputs=[DatabricksDataSource()],
    output="feature-group-arn",
    target_stores=["OfflineStore"],
)
def transform(input_df):
    return input_df
```

### Streaming custom data source examples

You can connect to streaming data sources like Amazon Kinesis, and author transforms with Spark Structured Streaming to read from streaming data sources. For information about the Kinesis connector, see Kinesis Connector for Spark Structured Streaming in GitHub. For information about Amazon Kinesis, see What Is Amazon Kinesis Data Streams? in the Amazon Kinesis Developer Guide.

To create the custom Amazon Kinesis data source class, you will need to extend the `BaseDataSource` class and override the `read_data` method from Custom data sources (p. 1453).

To connect to an Amazon Kinesis data stream you need:

- **Kinesis ARN (`kinesis-resource-arn`)**

  For information on Kinesis data stream ARNs, see Amazon Resource Names (ARNs) for Kinesis Data Streams in the Amazon Kinesis Developer Guide.
• Kinesis data stream name (*kinesis-stream-name*)
• AWS Region (*your-region*)

For information about obtaining your current session’s region name using SDK for Python (Boto3), see *region_name* in the Boto3 documentation.

```python
from sagemaker.feature_store.feature_processor import BaseDataSource
from sagemaker.feature_store.feature_processor import feature_processor

class KinesisDataSource(BaseDataSource):
    data_source_name = "Kinesis"
    data_source_unique_id = "kinesis-resource-arn"

    def read_data(self, spark, params):
        return spark.readStream.format("kinesis")
            .option("streamName", "kinesis-stream-name")
            .option("awsUseInstanceProfile", "false")
            .option("endpointUrl", "https://kinesis.your-region.amazonaws.com")
            .load()

The following example demonstrates how to connect KinesisDataSource to your feature_processor decorator.

```python
from sagemaker.remote_function import remote
from sagemaker.remote_function.spark_config import SparkConfig
import feature_store_pyspark.FeatureStoreManager as fsm

defingest_micro_batch_into_fg(input_df, epoch_id):
    feature_group_arn = "feature-group-arn"
    fsm.FeatureStoreManager().ingest_data(
        input_data_frame = input_df,
        feature_group_arn = feature_group_arn
    )

@remote(
    spark_config=SparkConfig(
        configuration={
            "Classification": "spark-defaults",
            "Properties":{
                "spark.sql.streaming.schemaInference": "true",
                "spark.jars.packages": "com.roncemer.spark/spark-sql-kinesis_2.13/1.2.2_spark-3.2"
            }
        },
        instance_type="ml.m5.2xlarge",
        max_runtime_in_seconds=2419200 # 28 days
    )
)
@feature_processor(
    inputs=[KinesisDataSource()],
    output="feature-group-arn"
)
def transform(input_df):
    output_stream = (input_df.selectExpr("CAST(rand() AS STRING) as partitionKey", "CAST(data AS STRING)")
         .writeStream.foreachBatch(ingest_micro_batch_into_fg)
         .trigger(processingTime="1 minute")
         .option("checkpointLocation", "s3a://checkpoint-path")
         .start()"
```
output_stream.awaitTermination()

In the example code above we use a few Spark Structured Streaming options while streaming micro-batches into your feature group. For a full list of options, see the Structured Streaming Programming Guide in the Apache Spark documentation.

- The foreachBatch sink mode is a feature that allows you to apply operations and write logic on the output data of each micro-batch of a streaming query.

  For information on foreachBatch, see Using Foreach and ForeachBatch in the Apache Spark Structured Streaming Programming Guide.

- The checkpointLocation option periodically saves the state of the streaming application. The streaming log is saved in checkpoint location s3a://checkpoint-path.

  For information on the checkpointLocation option, see Recovering from Failures with Checkpointing in the Apache Spark Structured Streaming Programming Guide.

- The trigger setting defines how often the micro-batch processing is triggered in a streaming application. In the example, the processing time trigger type is used with one-minute micro-batch intervals, specified by trigger(processingTime="1 minute"). To backfill from a stream source, you can use the available-now trigger type, specified by trigger(availableNow=True).

  For a full list of trigger types, see Triggers in the Apache Spark Structured Streaming Programming Guide.

Continuous streaming and automatic retries using event based triggers

The Feature Processor uses SageMaker Training as compute infrastructure and it has a maximum runtime limit of 28 days. You can use event based triggers to extend your continuous streaming for a longer period of time and recover from transient failures. For more information on schedule and event based executions, see Scheduled and event based executions for Feature Processor pipelines (p. 1449).

The following is an example of setting up an event based trigger to keep the streaming Feature Processor pipeline running continuously. This uses the streaming transform function defined in the previous example. A target pipeline can be configured to be triggered when a STOPPED or FAILED event occurs for a source pipeline execution. Note that the same pipeline is used as the source and target so that it run continuously.

```python
import sagemaker.feature_store.feature_processor as fp
from sagemaker.feature_store.feature_processor import FeatureProcessorPipelineEvent
from sagemaker.feature_store.feature_processor import FeatureProcessorPipelineExecutionStatus

streaming_pipeline_name = "streaming-pipeline"
streaming_pipeline_arn = fp.to_pipeline(
    pipeline_name = streaming_pipeline_name,
    step = transform # defined in previous section
)

fp.put_trigger(
    source_pipeline_events=FeatureProcessorPipelineEvents(
        pipeline_name=source_pipeline_name,
        pipeline_execution_status=[
            FeatureProcessorPipelineExecutionStatus.STOPPED,
            FeatureProcessorPipelineExecutionStatus.FAILED
        ]
    ),
    target_pipeline=target_pipeline_name
)```
Example Feature Processing code for common use cases

The following examples provide sample Feature Processing code for common use cases. For a more detailed example notebook showcasing specific use cases, see Amazon SageMaker Feature Store Feature Processing notebook.

In the following examples, `us-east-1` is the region of the resource, `111122223333` is the resource owner account ID, and `your-feature-group-name` is the feature group name.

The transactions data set used in the following examples has the following schema:

```json
'FeatureDefinitions': [  
  {'FeatureName': 'txn_id', 'FeatureType': 'String'},  
  {'FeatureName': 'txn_time', 'FeatureType': 'String'},  
  {'FeatureName': 'credit_card_num', 'FeatureType': 'String'},  
  {'FeatureName': 'txn_amount', 'FeatureType': 'Fractional'}  
]
```

Topics

- Joining data from multiple data sources (p. 1463)
- Sliding window aggregates (p. 1463)
- Tumbling window aggregates (p. 1464)
- Promotion from the offline store to online store (p. 1464)
- Transformations with the Pandas library (p. 1464)
- Continuous executions and automatic retries using event based triggers (p. 1465)

**Joining data from multiple data sources**

```python
@feature_processor(  
    inputs=[  
        CSVDataSource('s3://bucket/customer'),  
        FeatureGroupDataSource('transactions')  
    ],  
    output='arn:aws:sagemaker:us-east-1:111122223333:feature-group/your-feature-group-name'  
)
def join(transactions_df, customer_df):  
    '''Combine two data sources with an inner join on a common column'''  
    return transactions_df.join(  
        customer_df, transactions_df.customer_id == customer_df.customer_id, "inner"  
)
```

**Sliding window aggregates**

```python
@feature_processor(  
    inputs=[FeatureGroupDataSource('transactions')],  
    output='arn:aws:sagemaker:us-east-1:111122223333:feature-group/your-feature-group-name'  
)
def sliding_window_aggregates(transactions_df):  
    '''Aggregates over 1-week windows, across 1-day sliding windows.'''  
    from pyspark.sql.functions import import_window, avg, count
```
Example Feature Processing code for common use cases

```python
return (  
    transactions_df  
    .groupBy("credit_card_num", window("txn_time", "1 week", "1 day"))  
    .agg(avg("txn_amount").alias("avg_week"), count("*").alias("count_week"))  
    .orderBy("window.start")  
    .select("credit_card_num", "window.start", "avg_week", "count_week")
)
```

### Tumbling window aggregates

@feature_processor(  
    inputs=[FeatureGroupDataSource('transactions')],  
    output='arn:aws:sagemaker:us-east-1:111122223333:feature-group/your-feature-group-name'
)  

def tumbling_window_aggregates(transactions_df, spark):
    '''Aggregates over 1-week windows, across 1-day tumbling windows, as a SQL query.'''

    transactions_df.createOrReplaceTempView('transactions')
    return spark.sql(f'''
    SELECT credit_card_num, window.start, AVG(amount) AS avg, COUNT(*) AS count
    FROM transactions
    GROUP BY credit_card_num, window(txn_time, "1 week")
    ORDER BY window.start
    ''')

### Promotion from the offline store to online store

@feature_processor(  
    inputs=[FeatureGroupDataSource('transactions')],  
    target_stores=['OnlineStore'],  
    output='arn:aws:sagemaker:us-east-1:111122223333:feature-group/transactions'
)  

def offline_to_online():
    '''Move data from the offline store to the online store of the same feature group.'''

    transactions_df.createOrReplaceTempView('transactions')
    return spark.sql(f'''
    SELECT txn_id, txn_time, credit_card_num, amount
    FROM
    (SELECT *,
    row_number()
    OVER
    (PARTITION BY txn_id
    ORDER BY "txn_time" DESC, Api_Invocation_Time DESC, write_time DESC)
    AS row_number
    FROM transactions)
    WHERE row_number = 1
    ''')

### Transformations with the Pandas library

#### Transformations with the Pandas library

@feature_processor(  
    inputs=[FeatureGroupDataSource('transactions')],  
    target_stores=['OnlineStore'],  
    output='arn:aws:sagemaker:us-east-1:111122223333:feature-group/transactions'
)  

def pandas(transactions_df):
    '''Author transformations using the Pandas interface.'''
Time to live (TTL) duration for records

Amazon SageMaker Feature Store provides the option for records to be hard deleted from the online store after a time duration is reached, with time to live (TTL) duration (TtlDuration). The record will expire after the record's EventTime plus the TtlDuration is reached, or ExpiresAt = EventTime + TtlDuration. The TtlDuration can be applied at a feature group level, where all records within the feature group will have the TtlDuration by default, or at an individual record level. If TtlDuration is unspecified, the default value is null and the record will remain in the online store until it is overwritten.

A record deleted using TtlDuration is hard deleted, or completely removed from the online store, and the deleted record is added to the offline store. For more information on hard delete and deletion
modes, see `DeleteRecord` in the Amazon SageMaker API Reference guide. When a record is hard deleted it immediately becomes inaccessible using Feature Store APIs, but it may take up to 48 hours to be physically deleted from Amazon DynamoDB, the database service used by Feature Store. For more information on how items are deleted from a DynamoDB table, see [How it works: DynamoDB Time to Live (TTL)](https://docs.aws.amazon.com/AmazonDynamoDB/latest/developerguide/DynamoDB-TTL.html).

TtlDuration must be a dictionary containing a `Unit` and a `Value`, where the `Unit` must be a string with values "Seconds", "Minutes", "Hours", "Days", or "Weeks" and `Value` must be an integer greater than or equal to 1. `TtlDuration` can be applied while using the `CreateFeatureGroup`, `UpdateFeatureGroup`, and `PutRecord` APIs. See the request and response syntax in the SDK for Python (Boto3) documentation for `CreateFeatureGroup`, `UpdateFeatureGroup`, and `PutRecord` APIs.

- When `TtlDuration` is applied at a feature group level (using the `CreateFeatureGroup` or `UpdateFeatureGroup` APIs), the applied `TtlDuration` becomes the default `TtlDuration` for all records that are added to the feature group from the point in time that the API is called. When applying `TtlDuration` with the `UpdateFeatureGroup` API, this will not become the default `TtlDuration` for records that were created before the API is called.
- When `TtlDuration` is applied at a record level (for example, using `PutRecord` API), the `TtlDuration` duration applies to that record and is used instead of the feature group level default `TtlDuration`.
- When `TtlDuration` is applied on a feature group level it may take a few minutes for `TtlDuration` to come into effect.
- If `TtlDuration` is used when there is no online store, you will receive a `Validation Exception (400)` error.

The following example code shows how to apply `TtlDuration` while updating a feature group, such that the records added to the feature group after running the API will by default expire four weeks after their event times.

```python
import boto3

sagemaker_client = boto3.client("sagemaker")
feature_group_name = '<YOUR_FEATURE_GROUP_NAME>'

sagemaker_client.update_feature_group(
    FeatureGroupName=feature_group_name,
    OnlineStoreConfig={
        TtlDuration:{
            "Unit": "Weeks",
            "Value": 4
        }
    }
)
```

You can use the `DescribeFeatureGroup` API to view the default `TtlDuration`.

To view the expiration times, `ExpiresAt` (in UTC time ISO-8601 format), while using the `GetRecord` or `BatchGetRecord` APIs you must set `ExpirationTimeResponse` to `ENABLED`. See the request and response syntax in the SDK for Python (Boto3) documentation for `DescribeFeatureGroup`, `GetRecord`, and `BatchGetRecord` APIs.
Cross account feature group discoverability and access

Data scientists and data engineers can benefit from exploring and accessing features that span multiple accounts, in order to promote data consistency, streamline collaboration, and reduce duplication of effort.

With Amazon SageMaker Feature Store, you can share feature group resources across accounts. The resources that can be shared in Feature Store are feature group entities or the feature group catalog, where the feature group catalog contains all of the feature group entities on your account. The resource owner account shares resources with the resource consumer accounts. There are two distinct categories of permissions associated with sharing resources:

- **Discoverability permission**: Discoverability means being able to see feature group names and metadata. When you share the feature group catalog and grant the discoverability permission, all feature group entities in the account that you share from (resource owner account) become discoverable by the accounts that you are sharing with (resource consumer account). For example, if you make the feature group catalog in the resource owner account discoverable to a resource consumer account, then principals of the resource consumer account can see all feature groups contained in the resource owner account. It means discoverability is “all or nothing” at the account level (regionalized). This permission is granted to resource consumer accounts by using the feature group catalog resource type.

- **Access permissions**: When you grant an access permission, you do so at a feature group resource level (not at account level). This gives you more granular control over granting access to data. The type of access permissions that can be granted are: read-only, read-write, and admin. For example, you can select only certain feature groups from the resource owner account to be accessible by principals of the resource consumer account, depending on your business needs. This permission is granted to resource consumer accounts by using the feature group resource type and specifying feature group entities.

The distinction between discoverability and access is important to keep in mind when you set up cross account sharing. Also, the methods of sharing resources differ depending on whether you are sharing online or offline feature groups. For information about online and offline feature groups, see Feature Store concepts (p. 1416). In the following topics, you can learn how to apply discoverability and access permissions to your shared resources.

The following example diagram visualizes the feature group catalog resource versus a feature group resource entity. The feature group catalog contains all of your feature group entities and can be shared using the discoverability permission. When granted a discoverability permission, the resource consumer account can search and discover all feature group entities within the resource owner account. A feature group entity contains your machine learning data and can be shared using the access permission. When granted an access permission, the resource consumer account can access the feature group data, with access determined by the relevant access permission.
Enabling cross account discoverability

With AWS Resource Access Manager (AWS RAM) you can securely share the feature group catalog, which contains all of your feature group and feature resources, with other AWS accounts. This lets members of your team search and discover feature groups and features that span multiple accounts, promoting data consistency, streamlining collaboration, and reducing duplication of effort.

The resource owner account can share resources with other individual AWS accounts by granting permissions using AWS RAM. The resource consumer account is the AWS account with whom a resource is shared, limited by the permissions granted from the resource owner account. If you are an organization, you may want to take advantage of AWS Organizations, with which you can share resources with individual AWS accounts, with all accounts in your organization, or in an Organization Unit (OU), without having to apply permissions to each account. For instructional videos and more information about AWS RAM concepts and benefits, see What is AWS Resource Access Manager? in the AWS RAM User Guide.

This section covers how the resource owner account can choose the feature group catalog and grant discoverability privilege to resource consumer accounts, and then how the resource consumer accounts with the discoverability privilege can use search and discover the feature groups within the resource owner account. The discoverability permission does not grant access permissions (read-only, read-write, or admin). Access permissions are granted at a resource level and not at the account level. For information about granting access permissions, see Enabling cross account access (p. 1471).
The following topics discuss how to share the feature group catalog and how to search for shared resources with discoverability permissions applied.

Topics

- Share your feature group catalog (p. 1469)
- Search discoverable resources (p. 1470)

Share your feature group catalog

The feature group catalog, DefaultFeatureGroupCatalog, contains all feature group entities owned by the resource owner account. The catalog can be shared by the resource owner account to grant discoverability to a single or multiple resource consumer accounts, by creating a resource share in AWS Resource Access Manager (AWS RAM). A feature group is the main resource in Amazon SageMaker Feature Store and is composed of feature definitions and records that are managed by Feature Store. For more information about feature groups, see Feature Store concepts (p. 1416).

Discoverability means that the resource consumer accounts can search for the discoverable resources and view them as if they were in their own account (excluding tags). When allowing the feature group catalog to be discoverable, the resource consumer accounts by default are not granted access permissions (read-only, read-write, or admin). Access permissions are granted at a resource level and not at the account level. For information about granting access permissions, see Enabling cross account access (p. 1471).

In order to enable cross account discoverability you will need to specify the SageMaker Resource Catalog and the feature group catalog while using the AWS RAM Create a resources share instructions in the AWS RAM developer guide. In the following we give the specifications for using the AWS RAM console instructions.

1. Specify resource share details:
   - Resource type: Choose SageMaker Resource Catalogs.
   - ARN: Choose the feature group catalog ARN with the format: arn:aws:sagemaker:us-east-1:111122223333:sagemaker-catalog/DefaultFeatureGroupCatalog
     - us-east-1 is the region of the resource and 111122223333 is the resource owner account ID.
   - Resource ID: Choose DefaultFeatureGroupCatalog.

2. Associate managed permissions:
   - Managed permission: Choose AWSRAMPermissionSageMakerCatalogResourceSearch.

3. Grant access to principals:
   - Choose the principal types (AWS account, Organization, or Organizational unit) and enter the appropriate ID.

   If you are an organization, you may want to take advantage of AWS Organizations, with which you can share resources with individual AWS accounts, with all accounts in your organization, or with an Organization Unit (OU), without having to apply permissions to each account. For more information about sharing your resources and granting permissions within AWS, see Enable resource sharing within AWS Organizations in the AWS Resource Access Manager Developer Guide.

4. Review and create:
   - Review then choose Create resource share.

It may take a few minutes for the resource share and principal, or resource consumer account, associations to complete. Once the resource share and principal associations are set, the specified resource consumer accounts receive an invitation to join the resource share. The resource consumer
accounts can view and accept the invitations by opening the Shared with me: Resource shares page in the AWS RAM console. For more information on accepting and viewing resources in AWS RAM, see Access AWS resources shared with you. Invitations are not sent in these cases:

- If you are part of an organization in AWS Organizations and sharing in your organization is enabled, then principals in the organization automatically get access to the shared resources without invitations.
- If you share with the AWS account that owns the resource, then the principals in that account automatically get access to the shared resources without invitations.

For more information about accepting and using a resource share, see Search discoverable resources (p. 1470).

Share the feature group catalog using the AWS SDK for Python (Boto3)

You can use the AWS SDK for Python (Boto3) for AWS RAM APIs to create a resource share. The following code is an example of a resource owner account ID 111122223333 within the region us-east-1 creating a resource share named test-cross-account-catalog, sharing the feature group catalog with the resource consumer account ID 444455556666. To use the Python SDK for AWS RAM APIs, attach the AWSRAMPermissionSageMakerCatalogResourceSearch policy with the execution role. See AWS RAM APIs for more details.

```python
# Call list resource catalogs as a prerequisite for RAM share
sagemaker_client.list_resource_catalogs()

# Share DefaultFeatureGroupCatalog with other account
ram_client = boto3.client("ram")
response = ram_client.create_resource_share(
    name='test-cross-account-catalog', # Change to your custom resource share name
    resourceArns=[
        'arn:aws:sagemaker:us-east-1:111122223333:sagemaker-catalog/' +
            'DefaultFeatureGroupCatalog', # Change 111122223333 to the resource owner account ID
    ],
    principals=[
        '444455556666', # Change 444455556666 to the resource consumer account ID
    ],
    permissionArns = ['arn:aws:ram::aws:permission/AWSRAMPermissionSageMakerCatalogResourceSearch'] # AWSRAMPermissionSageMakerCatalogResourceSearch is the only policy allowed for SageMaker Catalog
)
```

Principals are actors in a security system. In a resource-based policy, the allowed principals are IAM users, IAM roles, the root account, or another AWS service.

Search discoverable resources

The resource owner account must grant permissions to resource consumer accounts to allow for discoverability or access (read-only, read-write, or admin) privileges with a shared resource. In the following sections, we provide instructions on how to accept an invitation to shared resources and examples showing how to search for discoverable feature groups.

Accept an invitation to shared resources

As the resource consumer account, you receive an invitation to join a resource share once the resource owner account has granted permission. To accept the invitation to any shared resources, open the Shared with me: Resource shares page in the AWS RAM console to view and respond to invitations. Invitations are not sent in these cases:
• If you are part of an organization in AWS Organizations and sharing in your organization is enabled, then principals in the organization automatically get access to the shared resources without invitations.
• If you share with the AWS account that owns the resource, then the principals in that account automatically get access to the shared resources without invitations.

For more information about accepting and using a resource share in AWS RAM, see Respond to the resource share invitation.

Search discoverable feature groups example

Once resources are shared with a resource consumer account with the discoverability permission applied, the resource consumer account can search for and discover the shared resources in Amazon SageMaker Feature Store using the Amazon SageMaker Studio UI and the Feature Store SDK. Note that you cannot search on tags for cross account resources. The maximum number of feature group catalogs viewable is 1000. For more information about granting discoverability permissions, see Enabling cross account discoverability (p. 1468). For details about viewing shared feature groups in Studio, see Find feature groups in your Feature Store (p. 1487).

In the following example, the resource consumer account uses SageMaker search to search for resources made discoverable to them when CrossAccountFilterOption is set to "CrossAccount":

```python
from sagemaker.session import Session
sagemaker_session = Session(boto_session=boto_session)
sagemaker_session.search(
    resource="FeatureGroup",
    search_expression={
        "Filters": [
            {
                "Name": "FeatureGroupName",
                "Value": "MyFeatureGroup",
                "Operator": "Contains",
            }
        ],
        "Operator": "And",
    },
    sort_by="Name",
    sort_order="Ascending",
    next_token="token",
    max_results=50,
    CrossAccountFilterOption="CrossAccount"
)
```

For more information about SageMaker search and the request parameters, see Search in the Amazon SageMaker API Reference.

Enabling cross account access

The access permissions are read-only, read-write, and admin permissions. The permission name, description, and list of specific APIs available for each permission are listed in the following:

• Read-only permission (AWSRAMPermissionFeatureGroupReadOnly): The read privilege allows resource consumer accounts to read records in the shared feature groups and view details and metadata.
• DescribeFeatureGroup: Retrieves details about a feature group and its configuration
• DescribeFeatureMetadata: Shows the metadata for a feature within a feature group
• BatchGetRecord: Retrieves a batch of records from a feature group
• GetRecord: Retrieves a record from a feature group
• Read-write permission (AWSRAMPermissionSagemakerFeatureGroupReadWrite): The read-write privilege allows resource consumer accounts to write records to, and delete records from, the shared feature groups, in addition to read permissions.
• PutRecord: Writes a record to a feature group
• DeleteRecord: Removes a record from a feature group
• APIs listed in AWSRAMPermissionFeatureGroupReadOnly
• Admin permission (AWSRAMPermissionSagemakerFeatureGroupAdmin): The admin privilege allows the resource consumer accounts to update the description and parameters of features within the shared feature groups, update the configuration of the shared feature groups, in addition to read-write permissions.
• DescribeFeatureMetadata: Shows the metadata for a feature within a feature group
• UpdateFeatureGroup: Updates a feature group configuration
• UpdateFeatureMetadata: Updates description and parameters of a feature in the feature group
• APIs listed in AWSRAMPermissionSagemakerFeatureGroupReadWrite

In the following topics you can learn how to share online store and offline feature groups—there are differences between the two when it comes to sharing.

Topics
• Share online feature groups with AWS Resource Access Manager (p. 1472)
• Cross account offline store access (p. 1476)

Share online feature groups with AWS Resource Access Manager

With AWS Resource Access Manager (AWS RAM) you can securely share Amazon SageMaker Feature Store online feature groups with other AWS accounts. Members of your team can explore and access feature groups that span multiple accounts, promoting data consistency, streamlining collaboration, and reducing duplication of effort.

The resource owner account can share resources with other individual AWS accounts by granting permissions using AWS RAM. The resource consumer account is the AWS account with whom a resource is shared, limited by the permissions granted from the resource owner account. If you are an organization, you may want to take advantage of AWS Organizations, with which you can share resources with individual AWS accounts, with all accounts in your organization, or in an Organization Unit (OU), without having to apply permissions to each account. For instructional videos and more information about AWS RAM concepts and benefits, see What is AWS Resource Access Manager? in the AWS RAM User Guide.

Note that there is a soft maximum limit to the transactions per second (TPS) per API per AWS account. The maximum TPS limit applies to all transactions on the resources within the resource owner account, so transactions from the resource consumer accounts also count towards this maximum limit. For information about service quotas and how to request a quota increase, see AWS service quotas.

This section covers how the resource owner account can choose feature groups and grant access privileges (read-only, read-write, and admin) to resource consumer accounts, and then how the resource consumer accounts with access privileges can use those feature groups. The access permissions do not allow for the resource consumer accounts to search and discover feature groups. To allow for resource consumer accounts to search and discover feature groups from the resource owner account, the resource owner account must grant discoverability permission to the resource consumer accounts, where all of the feature groups within the resource owner account are discoverable by the resource consumer.
accounts. For more information about granting the discoverability permission, see Enabling cross account discoverability (p. 1468).

The following topics show how to share Feature Store online store resources using the AWS RAM console. For information about sharing your resources and granting permissions within AWS using the AWS RAM console or AWS Command Line Interface (AWS CLI), see Sharing your AWS resources.

Topics
• Share your feature group entities (p. 1473)
• Use online store shared resources with access permissions (p. 1474)

Share your feature group entities

As the resource owner account you can use the feature group resource type for Amazon SageMaker Feature Store to share feature group entities, by creating a resource share in AWS Resource Access Manager (AWS RAM).

Use the following instructions along with the Sharing your AWS resources instructions in the AWS RAM User Guide.

When sharing the feature group resource type using the AWS RAM console, you need to make the following choices.

1. Specify resource share details:
   • Resource type: Choose SageMaker Feature Groups.
   • ARN: Choose your feature group ARN with the format: arn:aws:sagemaker:us-east-1:11112223333:feature-group/your-feature-group-name.
     us-east-1 is the region of the resource, 11112223333 is the resource owner account ID, and your-feature-group-name is the feature group you are sharing.
   • Resource ID: Choose the feature group, your-feature-group-name, to which you want to grant access permissions.

2. Associate managed permissions:
   • Managed permission: Choose the access permission. For more information about access permissions, see Enabling cross account access (p. 1471).

3. Grant access to principals:
   • Choose the principal type (AWS account, Organization, Organizational unit, IAM role, or IAM user) and enter the appropriate ID or ARN.

4. Review and create:
   • Review then choose Create resource share.

Granting any access permission does not grant resource consumer accounts the discoverability permission, so the resource consumer accounts with access permissions cannot search and discover those feature groups. To allow for resource consumer accounts to search and discover feature groups from the resource owner account, the resource owner account must grant the discoverability permission to the resource consumer accounts, where all of the feature groups within the resource owner account are discoverable by the resource consumer accounts. For more information about granting the discoverability permission, see Enabling cross account discoverability (p. 1468).

If the resource consumer accounts are only granted access permissions, the feature group entities can still be viewed on AWS RAM. To view resources on AWS RAM, see Access AWS resources shared with you in the AWS RAM User Guide.
Enabling cross account access

It may take a few minutes for the resource share and principal, or resource consumer account, associations to complete. Once the resource share and principal associations are set, the specified resource consumer accounts receive an invitation to join the resource share. The resource consumer accounts can view and accept the invitations by opening the Shared with me: Resource shares page in the AWS RAM console. Invitations are not sent in these cases:

- If you are part of an organization in AWS Organizations and sharing in your organization is enabled, then principals in the organization automatically get access to the shared resources without invitations.
- If you share with the AWS account that owns the resource, then the principals in that account automatically get access to the shared resources without invitations.

For more information about accepting and using a resource share in AWS RAM, see Using shared AWS resources in the AWS RAM User Guide.

Share online store feature groups using the AWS SDK for Python (Boto3)

You can use the AWS SDK for Python (Boto3) for AWS RAM APIs to create a resource share. The following code is an example of a resource owner account ID 111122223333 creating a resource share named 'test-cross-account-fg', sharing the feature group named 'my-feature-group' with the resource consumer account ID 444455556666 while granting the AWSRAMPermissionSageMakerFeatureGroupReadOnly permission. For more information about access permissions, see Enabling cross account access (p. 1471). To use the Python SDK for AWS RAM APIs, you need to attach AWS RAM full access managed policy with execution role. See create_resource_share AWS RAM API for more details.

```python
import boto3

# Choose feature group name
feature_group_name = 'my-feature-group' # Change to your feature group name

# Share 'my-feature-group' with other account
ram_client = boto3.client("ram")
response = ram_client.create_resource_share(
    name='test-cross-account-fg', # Change to your custom resource share name
    resourceArns=[
        'arn:aws:sagemaker:us-east-1:111122223333:feature-group/' + feature_group_name, # Change 111122223333 to the resource owner account ID
    ],
    principals=[
        '444455556666', # Change 444455556666 to the resource consumer account ID
    ],
    permissionArns = ["arn:aws:ram::aws:permission/AWSRAMPermissionSageMakerFeatureGroupReadOnly"]
)
```

Principals are actors in a security system. In a resource-based policy, the allowed principals are IAM users, IAM roles, the root account, or another AWS service.

Use online store shared resources with access permissions

The resource owner account must grant permissions to resource consumer accounts to allow for discoverability, read-only, write, or admin privileges with a shared resource. In the following sections, we provide instructions on how to accept an invitation to access shared resources and provide examples showing how to view and interact with shared feature groups.

Accept an invitation to access shared resources using AWS RAM

As the resource consumer account, you will receive an invitation to join a resource share once the resource owner account has granted permission. To accept the invitation to any shared resources, open
Enabling cross account access

the [Shared with me: Resource shares](#) page in the AWS RAM console to view and respond to invitations. Invitations are not sent in these cases:

- If you are part of an organization in AWS Organizations and sharing in your organization is enabled, then principals in the organization automatically get access to the shared resources without invitations.
- If you share with the AWS account that owns the resource, then the principals in that account automatically get access to the shared resources without invitations.

For more information about accepting and using a resource share in AWS RAM, see [Using shared AWS resources](#) in the AWS RAM User Guide.

**View shared resources on the AWS RAM console**

Granting any access permissions does not grant resource consumer accounts the discoverability permission, so the resource consumer accounts with access permissions cannot search and discover those feature groups. To allow for resource consumer accounts to search and discover feature groups from the resource owner account, the resource owner account must grant the discoverability permission to the resource consumer accounts, where all of the feature groups within the resource owner account are discoverable by the resource consumer accounts. For more information about granting the discoverability permission, see [Enabling cross account discoverability](p. 1468).

To view the shared resources on the AWS RAM console, open the [Shared with me: Resource shares](#) page in the AWS RAM console.

**Read and write actions with a shared feature groups example**

Once your resource consumer account is granted the appropriate permissions by the resource owner account, you can perform actions on the shared resources using the Feature Store SDK. You can do this by providing the resource ARN as the FeatureGroupName. To obtain the Feature Group ARN, you can use the AWS SDK for Python (Boto3) [DescribeFeatureGroup](#) function or use the Studio UI. For information about using the Studio UI to view feature group details, see [View feature group details in Studio](p. 1434).

The following examples use [PutRecord](#) and [GetRecord](#) with a shared feature group entity. See the request and response syntax in the AWS SDK for Python (Boto3) documentation for [PutRecord](#) and [GetRecordAPIs](#).

```python
import boto3

sagemaker_featurestore_runtime = boto3.client('sagemaker-featurestore-runtime')

# Put record into feature group named 'test-fg' within the resource owner account ID 111122223333
featurestore_runtime.put_record(
    Record=[value.to_dict() for value in record] # You will need to define record prior to calling PutRecord
)

import boto3

sagemaker_featurestore_runtime = boto3.client('sagemaker-featurestore-runtime')

# Choose record identifier
record_identifier_value = str(2990130)

# Get record from feature group named 'test-fg' within the resource owner account ID 111122223333
```
featurestore_runtime.get_record(
    RecordIdentifierValueAsString=record_identifier_value
)

For more information about granting permissions to feature group entities, see Share your feature group entities (p. 1473).

Cross account offline store access

Amazon SageMaker Feature Store allows users to create a feature group in one account (Account A) and configure it with an offline store using an Amazon S3 bucket in another account (Account B). You can set this up using the steps in the following section.

Topics

• **Step 1: Set up the offline store access role in Account A** (p. 1476)
• **Step 2: Set up an offline store Amazon S3 bucket in Account B** (p. 1477)
• **Step 3: Set up an offline store AWS KMS encryption key in Account A** (p. 1477)
• **Step 4: Create a feature group in Account A** (p. 1479)

Step 1: Set up the offline store access role in Account A

First, set up a role for Amazon SageMaker Feature Store to write the data into the offline store. The simplest way to accomplish this is to create a new role using the AmazonSageMakerFeatureStoreAccess policy or to use an existing role that already has the AmazonSageMakerFeatureStoreAccess policy attached. This document refers to this policy as Account-A-Offline-Feature-Store-Role-ARN.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:PutObject",
                "s3:GetBucketAcl",
                "s3:PutObjectAcl"
            ],
            "Resource": [
                "arn:aws:s3:::*SageMaker*",
                "arn:aws:s3:::*Sagemaker*",
                "arn:aws:s3:::*sagemaker*"
            ]
        }
    ]
}
```

The preceding code snippet shows the AmazonSageMakerFeatureStoreAccess policy. The Resource section of the policy is scoped down by default to S3 buckets with names that contain SageMaker, Sagemaker, or sagemaker. This means the offline store Amazon S3 bucket being used must follow this naming convention. If this is not your case, or if you want to further scope down the resource, you can copy and paste the policy to your Amazon S3 bucket policy in the console, customize the Resource section to be `arn:aws:s3:::your-offline-store-bucket-name`, and then attach to the role.

Additionally, this role must have AWS KMS permissions attached. At a minimum, it requires the kms:GenerateDataKey permission to be able to write to the offline store using your customer managed key. See Step 3 to learn about why a customer managed key is needed for the cross account scenario and how to set it up. The following example shows an inline policy:
Amazon SageMaker Developer Guide

Enabling cross account access

The Resource section of this policy is scoped to any key in Account A. To further scope this down, after setting up the offline store KMS key in Step 3, return to this policy and replace it with the key ARN.

Step 2: Set up an offline store Amazon S3 bucket in Account B

Create an Amazon S3 bucket in Account B. If you are using the default AmazonSageMakerFeatureStoreAccess policy, the bucket name must include SageMaker, Sagemaker, or sagemaker. Edit the bucket policy as shown in the following example to allow Account A to read and write objects.

This document refers to the following example bucket policy as Account-B-Offline-Feature-Store-Bucket.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "S3CrossAccountBucketAccess",
            "Effect": "Allow",
            "Action": [
                "s3:PutObject",
                "s3:PutObjectAcl",
                "s3:GetBucketAcl"
            ],
            "Principal": {
                "AWS": [
                    "*Account-A-Offline-Feature-Store-Role-ARN*"
                ],
            },
            "Resource": [
                "arn:aws:s3:::offline-store-bucket-name/*",
                "arn:aws:s3:::offline-store-bucket-name"
            ]
        }
    ]
}
```

In the preceding policy, the principal is Account-A-Offline-Feature-Store-Role-ARN, which is the role created in Account A in Step 1 and provided to Amazon SageMaker Feature Store to write to the offline store. You can provide multiple ARN roles under Principal.

Step 3: Set up an offline store AWS KMS encryption key in Account A

Amazon SageMaker Feature Store ensures that server-side encryption is always enabled for Amazon S3 objects in the offline store. For cross account use cases, you must provide a customer managed key so that you are in control of who can write to the offline store (in this case, Account-A-Offline-
Enabling cross account access

Feature-Store-Role-ARN from Account A) and who can read from the offline store (in this case, identities from Account B).

This document refers to the following example key policy as Account-A-Offline-Feature-Store-KMS-Key-ARN.

```json
{
    "Version": "2012-10-17",
    "Id": "key-consolepolicy-3",
    "Statement": [
        {
            "Sid": "Enable IAM User Permissions",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::Account-A-Account-Id:root"
            },
            "Action": "kms:*",
            "Resource": "*"
        },
        {
            "Sid": "Allow access for Key Administrators",
            "Effect": "Allow",
            "Principal": {
                "AWS": [
                    "arn:aws:iam::Account-A-Account-Id:role/Administrator"
                ]
            },
            "Action": [
                "kms:Create*",

}
```
Feature Store storage configurations

Amazon SageMaker Feature Store consists of an online store and an offline store. The online store enables real-time lookup of features for inference, while the offline store contains historical data for model training and batch inference. When creating a feature group, you have the option of enabling either the online store, offline store, or both. When you enable both, they sync to avoid discrepancies between training and serving data. For more information about the online and offline stores and other Feature Store concepts, see Feature Store concepts (p. 1416).

The following topics discuss online store storage types and offline store table formats.

Topics
- Online store (p. 1479)
- Offline store (p. 1480)

Online store

The online store is a low-latency, high-availability data store that provides real-time lookup of features. It is typically used for machine learning (ML) model serving. You can choose between the standard online store (Standard) or an in-memory tier online store (InMemory), at the point when you create a feature group. In this way, you can select the storage type that best matches the read and write patterns for a particular application, while considering performance and cost. For more details on pricing, see Amazon SageMaker Pricing.
The online store contains the following StorageType options. For more information on the online store contents, see OnlineStoreConfig.

**Standard tier storage type**

The Standard tier is a managed low-latency data store for online store feature groups. It provides fast data retrieval for ML model service for your applications. Standard is the default storage type.

**In-memory tier storage type**

The InMemory tier is a managed data store for online store feature groups that supports very low-latency retrieval. It provides large-scale real-time data retrieval for ML model serving used for high throughput applications. The InMemory tier is powered by Amazon ElastiCache for Redis. For more information, see What is Amazon ElastiCache for Redis?

The online store InMemory tier supports collection types, namely list, set, and vector. For more information on the InMemory collection types, see Collection types (p. 1481).

Feature Store provides low latency read and writes to the online store. The application latency is primarily made up of two primary components: infrastructure or network latency and Feature Store API latency. Reduction of network latency helps with getting the lowest latency reads and writes to Feature Store. You can reduce the network latency to Feature Store by deploying AWS PrivateLink to Feature Store Runtime endpoint. With AWS PrivateLink, you can privately access all Feature Store Runtime API operations from your Amazon Virtual Private Cloud (VPC) in a scalable manner by using interface VPC endpoints. An AWS PrivateLink deployment with the privateDNSEnabled option set as true:

- It keeps all Feature Store read/write traffic within your VPC.
- It keeps traffic in the same AZ as the client that originated it when using Feature Store. This avoids the "hops" between AZs reducing the network latency.

Follow the steps in Access an AWS service using an interface VPC endpoint to setup AWS PrivateLink to Feature Store. The service name for Feature Store Runtime in AWS PrivateLink is com.amazonaws.region.sagemaker.featurestore-runtime.

The InMemory tier online store scales automatically based on storage usage and requests. The automated scaling can take a few minutes to adapt to a new usage pattern if it changes rapidly. During automated scaling:

- Write operations to the feature group may receive throttling errors. You should retry your requests a few minutes later.
- Read operations to the feature group may receive throttling errors. Standard retry strategies are suitable in this case.
- Read operations may see elevated latency.

The default InMemory tier feature group maximum size is 50 GiB.

Note that the InMemory tier currently supports online feature groups only, not online+offline feature groups, so there is not replication between online and offline stores for the InMemory tier. Also, the InMemory tier does not currently support customer managed KMS keys.

**Offline store**

The offline store is used for historical data when sub-second retrieval is not needed. It is typically used for data exploration, model training, and batch inference.
When you enable both the online and offline stores for your feature group, both stores sync to avoid discrepancies between training and serving data. Please note that an online store feature group with the InMemory storage type enabled does not currently support a corresponding feature group in the offline store (no online to offline replication). For more information on ML model serving in Amazon SageMaker Feature Store, see Online store (p. 1479).

The offline store contains the following TableFormat options. For information on the offline store contents, see OfflineStoreConfig in the Amazon SageMaker API Reference.

**Glue table format**

The Glue format (default) is a standard Hive type table format for AWS Glue. With AWS Glue, you can discover, prepare, move, and integrate data from multiple sources. It also includes additional productivity and data ops tooling for authoring, running jobs, and implementing business workflows. For more information on AWS Glue, see What is AWS Glue?

**Iceberg table format**

The Iceberg format (recommended) is an open table format for very large analytic tables. With Iceberg, you can compact the small data files into fewer large files in the partition, resulting in significantly faster queries. This compaction operation is concurrent and does not affect ongoing read and write operations on the feature group. For more information on compaction, see Optimizing Iceberg tables in the Amazon Athena User Guide.

Iceberg manages large collections of files as tables and supports modern analytical data lake operations. If you choose the Iceberg option when creating new feature groups, Amazon SageMaker Feature Store creates the Iceberg tables using Parquet file format, and registers the tables with the AWS Glue Data Catalog. For more information on Iceberg table formats, see Using Apache Iceberg tables.

**Important**

Note that for feature groups in Iceberg table format, you must specify String as the feature type for the event time. If you specify any other type, you can't create the feature group successfully.

**Collection types**

Collection types provide a way to organize and structure data for efficient retrieval and analysis. They are used in ML databases to define the schema of a dataset and its elements. In Amazon SageMaker Feature Store, the supported collection types include list, set, and vector.

Collections are a grouping of elements in which each element within the collection must have the same feature type (String, Integral, or Fractional). For example, a collection can contain elements with all of the element feature types as Fractional, but a collection cannot contain elements with some feature types as Fractional and some feature types as String.

Only InMemory online store feature groups currently support collection types. The following list describes the collection type options.

**List:** An ordered collection of elements.

- The length of the list is determined by how many elements are in the collection.
- Example: You can have a list such as ['a', 'b', 'a'], because the list preserves the order and can have repeat elements.
Add features and records to a feature group

You can use the Amazon SageMaker Feature Store API or Amazon SageMaker Studio to update and describe your feature group as well as add features and records to your feature group. A feature group is an object that contains your data and a feature describes a column in the table. When you add a feature to the feature group you are effectively adding a column to the table. When you add a new record to the feature group you are filling in values for features associated with a specific record identifier. For more information on Feature Store concepts, see Feature Store concepts (p. 1416).

After you successfully add features to a feature group, you cannot remove those features. The features that you have added do not add any data to your records. You can add new records to the feature group or overwrite them using the PutRecord API. For examples on updating, describing, and putting records into a feature group, see Example code (p. 1483).

You can use Studio to add features to a feature group. For more information on how to update your feature groups using Studio, see Update feature group in Studio (p. 1434).

The following sections provide an overview of using Feature Store APIs to add features to a feature group followed by examples. With the API, you can also add or overwrite records after you've updated the feature group.

Topics
- API (p. 1482)
- Example code (p. 1483)

API

Use the UpdateFeatureGroup operation to add features to a feature group.

You can use the DescribeFeatureGroup operation to see if you've added the features successfully.

To add or overwrite records, use the PutRecord operation.
To see the updates that you've made to a record, use the `GetRecord` operation. To see the updates that you've made to multiple records, use the `BatchGetRecord` operation. It can take up to five minutes for the updates that you've made to appear.

You can use the example code in the following section to walk through adding features and records using the AWS SDK for Python (Boto3).

**Example code**

The example code walks you through the following process:

1. Adding features to the feature group
2. Verifying that you've added them successfully
3. Adding a record to the feature group
4. Verifying that you've added it successfully

### Step 1: Add features to a feature group

The following code uses the `UpdateFeatureGroup` operation to add new features to the feature group. It assumes that you've set up Feature Store and created a feature group. For more information about getting started, see [Introduction to Feature Store example notebook](p. 1421).

```python
import boto3
sagemaker_client = boto3.client("sagemaker")

sagemaker_client.update_feature_group(
    FeatureGroupName=feature_group_name,
    FeatureAdditions=[
        {"FeatureName": "new-feature-1", "FeatureType": "Integral"},
        {"FeatureName": "new-feature-2", "FeatureType": "Fractional"},
        {"FeatureName": "new-feature-3", "FeatureType": "String"}
    ]
)
```

The following code uses the `DescribeFeatureGroup` operation to check the status of the update. If the `LastUpdateStatus` field is **Successful**, you've added the features successfully.

```python
sagemaker_client.describe_feature_group(
    FeatureGroupName=feature_group_name
)
```

### Step 2: Add a new record to the feature group

The following code uses the `PutRecord` operation to add records to the feature group that you've created.

```python
record_identifier_value = 'new_record'
sagemaker_featurestore_runtime_client = boto3.client("sagemaker-featurestore-runtime")
```
sagemaker_runtime_client.put_record(  
    FeatureGroupName=feature_group_name,  
    Record=[  
        {  
            'FeatureName': "record-identifier-feature-name",  
            'ValueAsString': record_identifier_value  
        },  
        {  
            'FeatureName': "event-time-feature",  
            'ValueAsString': "timestamp-that-feature-store-returns"  
        },  
        {  
            'FeatureName': "new-feature-1",  
            'ValueAsString': "value-as-string"  
        },  
        {  
            'FeatureName': "new-feature-2",  
            'ValueAsString': "value-as-string"  
        },  
        {  
            'FeatureName': "new-feature-3",  
            'ValueAsString': "value-as-string"  
        }  
    ]  
)

Use the GetRecord operation to see which records in your feature group don't have data for the features that you've added. You can use the PutRecord operation to overwrite the records that don't have data for the features that you've added.

Find features in your feature groups

With Amazon SageMaker Feature Store, you can search for the features that you've created in your feature groups. You can search through all of your features without needing to first select a feature group. You can use the search functionality to quickly find the features that are relevant to your use case.

**Note**
To search for features in your feature groups, the feature groups that you're searching for must be within your AWS Region and AWS account, or shared with and made discoverable to your AWS account. For more information on how to share the feature group catalog and grant discoverability, see [Share your feature group catalog](p. 1469).

**Important**
Use the latest version of Amazon SageMaker Studio to make sure that you're using the most recent version of the search functionality. For information on updating Studio, see [Shut down and Update SageMaker Studio](p. 292).

If you're on a team, you might have teammates that are looking for features to use in their models, they can search through all the features in all of the feature groups.

You can add searchable parameters and descriptions to make your features more discoverable. For more information, see [Adding searchable metadata to your features](p. 1492).

The following are the types of metadata that you can use in your search.

You can search for features using either Amazon SageMaker Studio or the Search operation in the SageMaker API. The following table lists all of the searchable metadata and whether you can search for it in Studio.
Find features in your feature groups

<table>
<thead>
<tr>
<th>Searchable metadata</th>

</tr>
</tbody>
</table>

The following sections show you how to search for your features.

Studio

Use the following procedure to search through all the features that you've created.

To search through your features, proceed with the following.

1. Launch Studio. For more information, see [Launch Amazon SageMaker Studio](p. 209).
2. Choose the **Home** icon on the left panel.
3. Choose **Data**.
4. From the dropdown list, choose **Feature Store**.
5. Under the **Feature Catalog** tab you can choose **My account** to view your feature groups.
6. Under the **Feature Catalog** tab you can choose **Cross account** to view feature groups that are made discoverable to you. The resource owner account ID of the feature group can be seen under **Created by**.
7. You can search for your feature in the **Search** dropdown list.
   - (Optional) If you would like to filter your search choose the filter icon next to the **Search** dropdown list. You can use filters to specify parameters or date ranges in your search results. If you're searching for a parameter, specify both its key and value. To find your features more easily, you can specify time ranges or deselect columns that you do not want to query.
   - For shared resources you can only edit feature group metadata or feature definitions if you have the proper access permission granted from the resource owner account. Having the discoverability permission alone will not allow you to edit metadata or feature definitions. For more information on granting access permissions, see [Enabling cross account access](p. 1471).

SDK for Python (Boto3)

The example uses the **Search** operation in the AWS SDK for Python (Boto3) to run the search query. For information about the other languages to submit a query, see **See Also** in the Amazon SageMaker API Reference.

The following code shows different example search queries using the API.

---

1485
# Return all features in your feature groups
sagemaker_client.search(
    Resource="FeatureMetadata",
)

# Search for all features that belong to a feature group that contain the "ver" substring
sagemaker_client.search(
    Resource="FeatureMetadata",
    SearchExpression={
        'Filters': [
            {
                'Name': 'FeatureGroupName',
                'Operator': 'Contains',
                'Value': 'ver'
            }
        ]
    }
)

# Search for all features that belong to a feature group that have the EXACT name "airport"
sagemaker_client.search(
    Resource="FeatureMetadata",
    SearchExpression={
        'Filters': [
            {
                'Name': 'FeatureGroupName',
                'Operator': 'Equals',
                'Value': 'airport'
            }
        ]
    }
)

# Search for all features that belong to a feature group that contains the name "ver" AND have a name that contains "wha" AND have a parameter (key or value) that contains "hea"
sagemaker_client.search(
    Resource="FeatureMetadata",
    SearchExpression={
        'Filters': [
            {
                'Name': 'FeatureGroupName',
                'Operator': 'Contains',
                'Value': 'ver'
            },
            {
                'Name': 'FeatureName',
                'Operator': 'Contains',
                'Value': 'wha'
            },
            {
                'Name': 'AllParameters',
                'Operator': 'Contains',
                'Value': 'hea'
            }
        ]
    }
)

# Search for all features that belong to a feature group with substring "ver" in its name OR features that have a name that contain "wha" OR features that have a parameter (key or value) that contains "hea"
Find feature groups in your Feature Store

With Amazon SageMaker Feature Store, you can search for the feature groups using either Amazon SageMaker Studio or the `Search` operation. You can use the search functionality to find features and
feature groups that are relevant to the models that you're creating. You can use the search functionality to quickly find the feature groups that are relevant to your use case.

**Note**
The feature groups that you're searching for must be within your AWS Region and AWS account, or shared with and made discoverable to your AWS account. For more information on how to share the feature group catalog and grant discoverability, see [Share your feature group catalog](p. 1469).

**Important**
Use the latest version of Amazon SageMaker Studio to make sure that you're using the most recent version of the search functionality. For information on updating Studio, see [Shut down and Update SageMaker Studio](p. 292).

The following table shows the searchable fields and whether you can use Studio to search for a specific field.

You can search for features using either Amazon SageMaker Studio or the **Search** operation in the SageMaker API. The following table lists all of the searchable metadata and whether you can search for it in Studio. Tags are searchable for your own feature groups but are not searchable for feature groups made discoverable to you.

The following sections show you how to search for your features.

**Search for feature groups in Studio**

To search through your feature groups, proceed with the following.
Find feature groups in your Feature Store

1. Launch Studio. For more information, see Launch Amazon SageMaker Studio (p. 209).
2. Choose the Home icon (🏠) on the left panel.
3. Choose Data.
4. From the dropdown list, choose Feature Store.
5. Under the Feature Group Catalog tab you can choose My account to view your feature groups.
6. Under the Feature Group Catalog tab you can choose Cross account to view feature groups that are made discoverable to you. The resource owner account ID of the feature group can be seen under Created by.
7. You can search for your feature groups in the Search dropdown list.
   • (Optional) If you would like to filter your search choose the filter icon next to the Search dropdown list. You can use filters to specify parameters or date ranges in your search results. If you're searching for a parameter, specify both its key and value. To find your feature groups more easily, you can specify time ranges, deselect columns that you do not want to query, choose which stores to search, or search by status.
   • For shared resources you can only edit feature group metadata or feature definitions if you have the proper access permission granted from the resource owner account. Having the discoverability permission alone will not allow you to edit metadata or feature definitions. For more information on granting access permissions, see Enabling cross account access (p. 1471).

SDK for Python (Boto3)

The example uses the Search operation in the AWS SDK for Python (Boto3) to run the search query. For information about the other languages to submit a query, see See Also in the Amazon SageMaker API Reference.

The following code shows different example search queries using the API.

```python
# Return all feature groups
sagemaker_client.search(
    Resource="FeatureGroups",
)

# Search for feature groups that are shared with your account
sagemaker_session.search(
    resource="FeatureGroup",
    search_expression={
        "Filters": [
            {
                "Name": "FeatureGroupName",
                "Value": "MyFeatureGroup",
                "Operator": "Contains",
            }
        ],
        "Operator": "And",
    },
    sort_by="Name",
    sort_order="Ascending",
    next_token="token",
    max_results=50,
    CrossAccountFilterOption="SameAccount"
)

# Search for all feature groups with a name that contains the "ver" substring
sagemaker_client.search(
    Resource="FeatureGroups",
)
```

1489
SearchExpression={
    'Filters': [
        {
            'Name': 'FeatureGroupName',
            'Operator': 'Contains',
            'Value': 'ver'
        },
    ]
}

# Search for all feature groups that have the EXACT name "airport"
sagemaker_client.search(
    Resource="FeatureGroups",
    SearchExpression={
        'Filters': [
            {
                'Name': 'FeatureGroupName',
                'Operator': 'Equals',
                'Value': 'airport'
            }
        ]
    }
)

# Search for all feature groups that contains the name "ver"
# AND have a record identifier feature name that contains "wha"
# AND have a tag (key or value) that contains "hea"
sagemaker_client.search(
    Resource="FeatureGroups",
    SearchExpression={
        'Filters': [
            {
                'Name': 'FeatureGroupName',
                'Operator': 'Contains',
                'Value': 'ver'
            },
            {
                'Name': 'RecordIdentifierFeatureName',
                'Operator': 'Contains',
                'Value': 'wha'
            },
            {
                'Name': 'AllTags',
                'Operator': 'Contains',
                'Value': 'hea'
            }
        ]
    }
)

# Search for all feature groups with substring "ver" in its name
# OR feature groups that have a record identifier feature name that contains "wha"
# OR feature groups that have a tag (key or value) that contains "hea"
sagemaker_client.search(
    Resource="FeatureGroups",
    SearchExpression={
        'Filters': [
            {
                'Name': 'FeatureGroupName',
                'Operator': 'Contains',
                'Value': 'ver'
            },
            {
                'Name': 'RecordIdentifierFeatureName',
                'Operator': 'Contains',
                'Value': 'wha'
            },
            {
                'Name': 'AllTags',
                'Operator': 'Contains',
                'Value': 'hea'
            }
        ]
    }
)
'Value': 'wha'
},
{
    'Name': 'AllTags',
    'Operator': 'Contains',
    'Value': 'hea'
},
'Operator': 'Or' # note that this is explicitly set to "Or"- the default is "And"
)}

# Search for all feature groups with substring "ver" in its name
# OR feature groups that have a record identifier feature name that contains "wha"
# OR tags with the value 'Sage' for the 'org' key
sagemaker_client.search(
    Resource="FeatureGroups",
    SearchExpression={
        'Filters': [
            {
                'Name': 'FeatureGroupName',
                'Operator': 'Contains',
                'Value': 'ver'
            },
            {
                'Name': 'RecordIdentifierFeatureName',
                'Operator': 'Contains',
                'Value': 'wha'
            },
            {
                'Name': 'Tags.org',
                'Operator': 'Contains',
                'Value': 'Sage'
            }
        ],
        'Operator': 'Or' # note that this is explicitly set to "Or"- the default is "And"
    }
)

# Search for all offline only feature groups
sagemaker_client.search(
    Resource="FeatureGroups",
    SearchExpression={
        'Filters': [
            {
                'Name': 'OnlineStoreConfig.EnableOnlineStore',
                'Operator': 'NotEquals',
                'Value': 'true'
            }
        ]
    }
)

# Search for all online only feature groups
sagemaker_client.search(
    Resource="FeatureGroups",
    SearchExpression={
        'Filters': [
            {
                'Name': 'OfflineStoreConfig.S3StorageConfig.S3Uri',
                'Operator': 'Exists'
            }
        ]
    }
)
Adding searchable metadata to your features

In Amazon SageMaker Feature Store, you can search through all of your features. To make your features more discoverable, you can add metadata to them. You can add the following types of metadata:

```python
response = client.create_resource_share(
    name='string',
    resourceArns=[
        'string',
    ],
    principals=[
        'string',
    ],
    tags=[
        {'key': 'string',
         'value': 'string'}
    ],
    allowExternalPrincipals=True|False,
    clientToken='string',
    permissionArns=[
        'string',
    ]
)
```

You can also use python SDK of AWS RAM APIs to create resource share. The API signature is given below. To use python SDK of AWS RAM API, you need attach AWS RAM full access managed policy with execution Role.

You can also use python SDK of AWS RAM APIs to create resource share. The API signature is given below. To use python SDK of AWS RAM API, you need attach AWS RAM full access managed policy with execution Role.

```python
response = client.create_resource_share(
    name='string',
    resourceArns=[
        'string',
    ],
    principals=[
        'string',
    ],
    tags=[
        {'key': 'string',
         'value': 'string'}
    ],
    allowExternalPrincipals=True|False,
    clientToken='string',
    permissionArns=[
        'string',
    ]
)
```

---

Adding searchable metadata to your features

In Amazon SageMaker Feature Store, you can search through all of your features. To make your features more discoverable, you can add metadata to them. You can add the following types of metadata:
• Description – A searchable description of the feature.
• Parameters – Searchable key-value pairs.

The description can have up to 255 characters.

For parameters, you must specify a key-value pair in your search. You can add up to 25 parameters.

To update the metadata of a feature, you can use either Amazon SageMaker Studio or the UpdateFeatureMetadata operation.

Use the following procedure to update the metadata using Studio.

To update the feature metadata with Studio, proceed with the following.

1. Launch Studio. For more information, see Launch Amazon SageMaker Studio (p. 209).
2. Choose the Home icon (🏠) on the left panel.
3. Choose Data.
4. From the dropdown list, choose Feature Store.
5. Under the Feature Catalog tab you can choose My account to view your feature groups.
6. Under the Feature Catalog tab you can choose Cross account to view feature groups that are made discoverable to you. The resource owner account ID of the feature group can be seen under Created by.
7. You can search for your feature in the Search dropdown list.
   • (Optional) If you would like to filter your search choose the filter icon next to the Search dropdown list. You can use filters to specify parameters or date ranges in your search results. If you’re searching for a parameter, specify both its key and value. To find your features more easily, you can specify time ranges or deselect columns that you do not want to query.
   • For shared resources you can only edit feature group metadata or feature definitions if you have the proper access permission granted from the resource owner account. Having the discoverability permission alone will not allow you to edit metadata or feature definitions. For more information on granting access permissions, see Enabling cross account access (p. 1471).
8. Choose your feature.
9. Choose Edit metadata.
10. In the Description field, add or update the description.
11. In the Parameters field under Parameters, specify a key-value pair for the parameter.
12. (Optional) Choose Add new parameter to add another parameter.
13. Choose Save changes.

You can also use the AWS SDK for Python (Boto3) to edit feature metadata. The following describes how you can use the UpdateFeatureMetadata operation for different scenarios.

Add a list of parameters to a feature

To add a list of parameters to a feature, specify values for the following fields:

• FeatureGroupName
• Feature
• Parameters
The following example code uses the AWS SDK for Python (Boto3) to add two parameters.

```python
sagemaker_client.update_feature_metadata(
    FeatureGroupName="feature_group_name",
    FeatureName="feature-name",
    ParameterAdditions=[
        {"Key": "example-key-0", "Value": "example-value-0"},
        {"Key": "example-key-1", "Value": "example-value-1"},
    ]
)
```

Add a description to a feature

To add a description to a feature, specify values for the following fields:

- FeatureGroupName
- Feature
- Description

```python
sagemaker_client.update_feature_metadata(
    FeatureGroupName="feature-group-name",
    FeatureName="feature-name",
    Description="description"
)
```

Remove parameters for a feature

To remove all parameters for a feature, do the following.

Specify values for the following fields:

- FeatureGroupName
- Feature

Specify the keys for the parameters that you're removing under ParameterRemovals.

```python
sagemaker_client.update_feature_metadata(
    FeatureGroupName="feature_group_name",
    FeatureName="feature-name",
    ParameterRemovals=[
        {"Key": "example-key-0"},
        {"Key": "example-key-1"},
    ]
)
```

Remove the description for a feature

To remove the description for a feature, do the following.

Specify values for the following fields:

- FeatureGroupName
• Feature

Specify an empty string for Description.

```python
sagemaker_client.update_feature_metadata(
    FeatureGroupName="feature-group-name",
    FeatureName="feature-name",
    Description="",
)
```

After you've updated the metadata for a feature, you can use the `DescribeFeatureMetadata` operation to see the updates that you've made.

The following code goes through an example workflow using the AWS SDK for Python (Boto3).

**Example code**

The example code does the following:

1. Sets up your SageMaker environment.
2. Creates a feature group.
3. Adds features to the group.
4. Adds metadata to the features.

**Step 1: Setup**

To start using Feature Store, create SageMaker, boto3 and Feature Store sessions. Then set up the S3 bucket you want to use for your features. This is your offline store. The following code uses the SageMaker default bucket and adds a custom prefix to it.

**Note**

The role that you use must have the following managed policies attached to it: AmazonS3FullAccess and AmazonSageMakerFeatureStoreAccess.

```python
# SageMaker Python SDK version 2.x is required
%pip install 'sagemaker>=2.0.0'
import sagemaker
import sys
import boto3
import pandas as pd
import numpy as np
import io
from sagemaker.session import Session
from sagemaker import get_execution_role
from botocore.exceptions import ClientError

prefix = 'sagemaker-featurestore-introduction'
role = get_execution_role()
sagemaker_session = sagemaker.Session()
region = sagemaker_session.boto_region_name
s3_bucket_name = sagemaker_session.default_bucket()
```
Example code

```python
sagemaker_client = boto_session.client(service_name='sagemaker', region_name=region)

Step 2: Create a feature group and add features

The following code is an example of creating a feature group with feature definitions.

```python
feature_group_name = "test-for-feature-metadata"
feature_definitions = [
    {"FeatureName": "feature-1", "FeatureType": "String"},
    {"FeatureName": "feature-2", "FeatureType": "String"},
    {"FeatureName": "feature-3", "FeatureType": "String"},
    {"FeatureName": "feature-4", "FeatureType": "String"},
    {"FeatureName": "feature-5", "FeatureType": "String"}
]
try:
    sagemaker_client.create_feature_group(
        FeatureGroupName=feature_group_name,
        RecordIdentifierFeatureName="feature-1",
        EventTimeFeatureName="feature-2",
        FeatureDefinitions=feature_definitions,
        OnlineStoreConfig={"EnableOnlineStore": True}
    )
except ClientError as e:
    if e.response["Error"]["Code"] == "ResourceInUse":
        pass
    else:
        raise e
```

Step 3: Add metadata

Before you add metadata, use the `DescribeFeatureGroup` operation to make sure that the status of the feature group is Created.

```python
sagemaker_client.describe_feature_group(
    FeatureGroupName=feature_group_name
)
```

Add a description to the feature.

```python
sagemaker_client.update_feature_metadata(
    FeatureGroupName=feature_group_name,
    FeatureName="feature-1",
    Description="new description"
)
```

You can use the `DescribeFeatureMetadata` operation to see if you have successfully updated the description for the feature group.

```python
sagemaker_client.describe_feature_metadata(
    FeatureGroupName=feature_group_name,
    FeatureName="feature-1"
)
```
Create a dataset from your feature groups

You can use the Feature Store APIs to create a dataset from your feature groups. Data scientists create ML datasets for training by retrieving ML feature data from one or more feature groups in the offline store. You can also join the feature groups to a single pandas dataframe. You can use Amazon Athena to write and execute SQL queries.

Using the Amazon SageMaker Python SDK to get your data from your feature groups

You can use the Feature Store APIs to create a dataset from your feature groups. Data scientists create ML datasets for training by retrieving ML feature data from one or more feature groups in the offline store.
store. Use the create_dataset() function to create the dataset. You can use the SDK to do the following:

- Create a dataset from multiple feature groups.
- Create a dataset from the feature groups and a pandas data frame.

By default, Feature Store doesn't include records that you've deleted from the dataset. It also doesn't include duplicated records. A duplicate record has the record ID and timestamp value in the event time column.

Before you use the SDK to create a dataset, you must start a SageMaker session. Use the following code to start the session.

```python
import boto3
from sagemaker.session import Session
from sagemaker.feature_store.feature_store import FeatureStore

region = boto3.Session().region_name
boto_session = boto3.Session(region_name=region)
sagemaker_client = boto_session.client(
    service_name="sagemaker", region_name=region
)  
featurestore_runtime = boto_session.client(
    service_name="sagemaker-featurestore-runtime", region_name=region
)

feature_store_session = Session(
    boto_session=boto_session,
    sagemaker_client=sagemaker_client,
    sagemaker_featurestore_runtime_client=featurestore_runtime,
)

feature_store = FeatureStore(feature_store_session)
```

The following code shows an example of creating a dataset from multiple feature groups. The following code snippet uses the example feature groups "base_fg_name", "first_fg_name", and "second_fg_name", which may not exist or have the same schema within your Feature Store. It is recommended to replace these feature groups with feature groups that exist within your Feature Store. For information on how to create a feature group, see Step 3: Create feature groups (p. 1424).

```python
from sagemaker.feature_store.feature_group import FeatureGroup

s3_bucket_name = "offline-store-sdk-test"

base_fg_name = "base_fg_name"
base_fg = FeatureGroup(name=base_fg_name, sagemaker_session=feature_store_session)

first_fg_name = "first_fg_name"
first_fg = FeatureGroup(name=first_fg_name, sagemaker_session=feature_store_session)

second_fg_name = "second_fg_name"
second_fg = FeatureGroup(name=second_fg_name, sagemaker_session=feature_store_session)

feature_store = FeatureStore(feature_store_session)
builder = feature_store.create_dataset(
    base=base_fg,
    output_path=f"s3://{s3_bucket_name}/[DOC-EXAMPLE-BUCKET1]",
).with_feature_group(first_fg)
.with_feature_group(second_fg, "base_id", ["base_feature_1"])```
The following code shows an example of creating a dataset from multiple feature groups and a pandas dataframe.

```python
base_data = [[1, 187512346.0, 123, 128],
              [2, 187512347.0, 168, 258],
              [3, 187512348.0, 125, 184],
              [1, 187512349.0, 195, 206]]
base_data_df = pd.DataFrame(base_data,
                            columns=["base_id", "base_time", "base_feature_1", "base_feature_2"]
                      )
builder = feature_store.create_dataset(
    base=base_data_df,
    event_time_identifier_feature_name='base_time',
    record_identifier_feature_name='base_id',
    output_path=f"s3://{s3_bucket_name}"
).with_feature_group(first_fg)
                      .with_feature_group(second_fg, "base_id", ["base_feature_1"])
```

The Feature Store APIs provides you with helper methods for the `create_dataset` function. You can use them to do the following:

- Create a dataset from multiple feature groups.
- Create a dataset from multiple feature groups and a pandas dataframe.
- Create a dataset from a single feature group and a pandas dataframe.
- Create a dataset using a point in time accurate join where records in the joined feature group follow sequentially.
- Create a dataset with the duplicated records, instead of following the default behavior of the function.
- Create a dataset with the deleted records, instead of following the default behavior of the function.
- Create a dataset for time periods that you specify.
- Save the dataset as a CSV file.
- Save the dataset as a pandas dataframe.

The base feature group is an important concept for joins. The base feature group is the feature group that has other feature groups or the pandas dataframe joined to it. For each dataset

You can add the following optional methods to the `create_dataset` function to configure how you're creating dataset:

- `with_feature_group` – Performs an inner join between the base feature group and another feature group using the record identifier and the target feature name in the base feature group. The following provides information about the parameters that you specify:
  - `feature_group` – The feature group that you're joining.
  - `target_feature_name_in_base` – The name of the feature in the base feature group that you're using as a key in the join. The record identifier in the other feature groups are the other keys that Feature Store uses in the join.
  - `included_feature_names` – A list of strings representing the feature names of the base feature group. You can use the field to specify the features that you want to include in the dataset.
  - `feature_name_in_target` – Optional string representing the feature in the target feature group that will be compared to the target feature in the base feature group.
  - `join_comparator` – Optional `JoinComparatorEnum` representing the comparator used when joining the target feature in the base feature group and the feature in the target feature group.
These JoinComparatorEnum values can be GREATER_THAN, GREATER_THAN_OR_EQUAL_TO, LESS_THAN, LESS_THAN_OR_EQUAL_TO, NOT_EQUAL_TO or EQUALS by default.

- **join_type** – Optional JoinTypeEnum representing the type of join between the base and target feature groups. These JoinTypeEnum values can be LEFT_JOIN, RIGHT_JOIN, FULL_JOIN, CROSS_JOIN or INNER_JOIN by default.

- **with_event_time_range** – Creates a dataset using the event time range that you specify.
- **as_of** – Creates a dataset up to a timestamp that you specify. For example, if you specify datetime(2021, 11, 28, 23, 55, 59, 342380) as the value, creates a dataset up to November 28th, 2021.

- **point_time_accurate_join** – Creates a dataset where all of the event time values of the base feature group is less than all the event time values of the feature group or pandas dataframe that you're joining.

- **include_duplicated_records** – Keeps duplicated values in the feature groups.
- **include_deleted_records** – Keeps deleted values in the feature groups.
- **with_number_of_recent_records_by_record_identifier** – An integer that you specify to determine how many of the most recent records appear in the dataset.
- **with_number_of_records_by_record_identifier** – An integer that represents how many records appear in the dataset.

After you've configured the dataset, you can specify the output using one of the following methods:

- **to_csv_file** – Saves the dataset as a CSV file.
- **to_dataframe** – Saves the dataset as a pandas dataframe.

You can retrieve data that comes after a specific period in time. The following code retrieves data after a timestamp.

```python
fg1 = FeatureGroup("example-feature-group-1")
feature_store.create_dataset(
    base=fg1,
    output_path="s3://example-S3-path"
).with_number_of_records_from_query_results(5).to_csv_file()
```

You can also retrieve data from a specific time period. You can use the following code to get data for a specific time range:

```python
fg1 = FeatureGroup("fg1")
feature_store.create_dataset(
    base=fg1,
    output_path="example-S3-path"
).with_event_time_range(
    datetime(2021, 11, 28, 23, 55, 59, 342380),
    datetime(2020, 11, 28, 23, 55, 59, 342380)
).to_csv_file() #example time range specified in datetime functions
```

You might want to join multiple feature groups to a pandas dataframe where the event time values of the feature group happen no later than the event time of the data frame. Use the following code as a template to help you perform the join.

```python
fg1 = FeatureGroup("fg1")
fg2 = FeatureGroup("fg2")
events = [['2020-02-01T08:30:00Z', 6, 1],
         ['2020-02-02T10:15:30Z', 5, 2],
         ['2020-02-03T13:20:59Z', 1, 3],
         ...
]```
Sample Amazon Athena queries

You can write queries in Amazon Athena to create a dataset from your feature groups. You can also write queries that create a dataset from feature groups and a single pandas dataframe.

**Interactive Exploration**

This query selects the first 1000 records.

```sql
SELECT * 
FROM <FeatureGroup.DataCatalogConfig.DatabaseName>.<FeatureGroup.DataCatalogConfig.TableName> 
LIMIT 1000
```

**Latest snapshot without duplicates**

This query selects the latest non-duplicate records.

```sql
SELECT * 
FROM (SELECT *, 
    row_number() 
    OVER (PARTITION BY <RecordIdentifierFeatureName> 
    ORDER BY <EventTimeFeatureName> DESC, Api_Invocation_Time DESC, write_time DESC) AS row_num 
FROM <FeatureGroup.DataCatalogConfig.DatabaseName>.<FeatureGroup.DataCatalogConfig.TableName>) 
WHERE row_num = 1;
```

**Latest snapshot without duplicates and deleted records in the offline store**

This query filters out any deleted records and selects non-duplicate records from the offline store.

```sql
SELECT * 
FROM (SELECT *, 
    row_number() 
```
Delete records from your feature groups

You can use the Amazon SageMaker Feature Store API to delete records from your feature groups. A feature group is an object that contains your machine learning (ML) data, where the columns of your data are described by features and your data are contained in records. A record contains values for features that are associated with a specific record identifier.

There are two storage configurations for your feature groups: online store and offline store. The online store only keeps the record with the latest event time and is typically used for real-time lookup for ML inference. The offline store keeps all records and acts as a historical database and is typically used for feature exploration, ML training, and batch inference.

For more information on Feature Store concepts, see Ingestion diagrams (p. 1417).

There are two ways to delete records from your feature groups, and the behavior is different depending on the storage configuration. In the following topics we will describe how to soft and hard delete records from the online and offline stores and provide examples.

Topics

- Delete records from the online store (p. 1502)
- Delete records from the offline store (p. 1504)

Delete records from the online store

You can soft or hard delete a record from the online store using the DeleteRecord API by using the DeletionMode request parameter to specify SoftDelete (default) or HardDelete. For more information on the DeleteRecord API, see DeleteRecord in the Amazon SageMaker API Reference.
With the online store:

- When you soft delete (default), the record is no longer retrievable by GetRecord or BatchGetRecord and the feature column values are set to null, except for the RecordIdentifier and EventTime feature values.
- When you hard delete, the record is completely removed from the online store.

In both cases Feature Store appends the deleted record marker to the OfflineStore. The deleted record marker is a record with the same RecordIdentifier as the original, but with is_deleted value set to True, EventTime set to the delete input EventTime, and other feature values set to null.

Note that the EventTime specified in DeleteRecord should be set later than the EventTime of the existing record in the OnlineStore for that same RecordIdentifier. If it is not, the deletion does not occur:

- For SoftDelete, the existing (not deleted) record remains in the OnlineStore, though the delete record marker is still written to the OfflineStore.
- HardDelete returns EventTime: 400 ValidationException to indicate that the delete operation failed. No delete record marker is written to the OfflineStore.

The following examples use the SDK for Python (Boto3) `delete_record` operation to delete a record from a feature group. To delete a record from a feature group, you will need:

- Feature group name (`feature-group-name`
- Record identifier value as a string (`record-identifier-value`)  
- Deletion event time (`deletion-event-time`)  

The deletion event time should be later than the event time of the record you wish to delete.

### Online store soft delete example

For soft delete you will need use the DeleteRecord API and can use the default DeletionMode or set the DeletionMode to SoftDelete.

```python
import boto3
client = boto3.client('sagemaker-featurestore-runtime')

client.delete_record(
    FeatureGroupName='feature-group-name',
    RecordIdentifierValueAsString='record-identifier-value',
    EventTime='deletion-event-time',
    TargetStores=['OnlineStore'],
    DeletionMode='SoftDelete'
)
```

### Online store hard delete example

For hard delete you will need use the DeleteRecord API and set the DeletionMode to HardDelete.

```python
import boto3
client = boto3.client('sagemaker-featurestore-runtime')

client.delete_record(
    FeatureGroupName='feature-group-name',
    RecordIdentifierValueAsString='record-identifier-value',
    EventTime='deletion-event-time',
    TargetStores=['OnlineStore'],
    DeletionMode='HardDelete'
)
```
Delete records from the offline store

With Amazon SageMaker Feature Store you can soft and hard delete a record from the OfflineStore Iceberg table format. With the OfflineStore Iceberg table format:

- When you soft delete a record the latest version of the Iceberg table file will not contain the record, but previous versions will still contain the record and can be accessed using time travel. For information on time travel, see Querying Iceberg table data and performing time travel in the Athena user guide.
- When you hard delete a record you are removing previous versions of the Iceberg table that contain the record. In this case you should specify which versions of the Iceberg table you wish to delete.

Obtain your Iceberg table name

To soft and hard delete from your OfflineStore Iceberg table, you will need to obtain your Iceberg table name, *iceberg-table-name*. The following instructions assumes you have already used Feature Store to create a feature group using the offline store storage configuration using the Iceberg table format, with `DisableGlueTableCreation = False` (default). For more information on creating feature groups, see Get started with Amazon SageMaker Feature Store (p. 1415).

To obtain your *iceberg-table-name*, use the DescribeFeatureGroup API to obtain `DataCatalogConfig`. This contains the metadata of the Glue table which serves as data catalog for the OfflineStore. The `TableName` within the `DataCatalogConfig` is your *iceberg-table-name*.

Amazon Athena offline store soft and hard delete example

The following instructions use Amazon Athena to soft delete then hard delete a record from the OfflineStore Iceberg table. This assumes that the record you intend to delete in your OfflineStore is a deleted record marker. For information on the deleted record marker in yourOfflineStore, see Delete records from the online store (p. 1502).

1. Obtain your Iceberg table name, *iceberg-table-name*. For information on how to obtain your Iceberg table name, see Obtain your Iceberg table name (p. 1504).
2. Run the DELETE command to soft delete the records on the OfflineStore, such that the latest version (or snapshot) of the Iceberg table will not contain the records. The following example deletes the records where `is_deleted` is 'True' and the previous event-time versions of the those records. You may add additional conditions based on other features to restrict the deletion. For more information on using DELETE with Athena, see DELETE in the Athena user guide.

```sql
DELETE FROM iceberg-table-name WHERE record-id-feature-name IS IN ( SELECT record-id-feature-name FROM iceberg-table-name WHERE is_deleted = 'True')
```

The soft deleted records are still viewable on previous file versions by performing time travel. For information on performing time travel, see Querying Iceberg table data and performing time travel in the Athena user guide.

```python
client.delete_record(
    FeatureGroupName='feature-group-name',
    RecordIdentifierValueAsString='record-identifier-value',
    EventTime='deletion-event-timestamp',
    TargetStores=[
        'OnlineStore',
    ],
    DeletionMode='HardDelete'
)
```
3. Remove the record from previous versions of your Iceberg tables to hard delete the record from OfflineStore:
   
a. Run the OPTIMIZE command to rewrite the data files into a more optimized layout, based on their size and number of associated delete files. For more information on optimizing Iceberg tables and the syntax, see Optimizing Iceberg tables in the Athena user guide.

   ```sql
   OPTIMIZE iceberg-table-name REWRITE DATA USING BIN_PACK
   ```

   b. (Optional, only need to run once) Run the ALTER TABLE command to alter the Iceberg table set values, and set when previous file versions are to be hard deleted according to your specifications. This can be done by assigning values to vacuum_min_snapshots_to_keep and vacuum_max_snapshot_age_seconds properties. For more information on altering your Iceberg table set properties, see ALTER TABLE SET PROPERTIES in the Athena user guide. For more information on Iceberg table property key-value pairs, see Table properties in the Athena user guide.

   ```sql
   ALTER TABLE iceberg-table-name SET TBLPROPERTIES (    'vacuum_min_snapshots_to_keep'='your-specified-value',    'vacuum_max_snapshot_age_seconds'='your-specified-value'  )
   ```

   c. Run the VACUUM command to remove no longer needed data files for your Iceberg tables, not referenced by the current version. The VACUUM command should run after the deleted record is no longer referenced in the current snapshot. For example, vacuum_max_snapshot_age_seconds after the deletion. For more information on VACUUM with Athena and the syntax, see VACUUM.

   ```sql
   VACUUM iceberg-table-name
   ```

### Apache Spark offline store soft and hard delete example

To soft and then hard delete a record from the OfflineStore Iceberg table using Apache Spark, you can follow the same instructions as in the Amazon Athena offline store soft and hard delete example (p. 1504) above, but using Spark procedures. For a full list of procedures, see Spark Procedures in the Apache Iceberg documentation.

- When soft deleting from the OfflineStore: instead of using the DELETE command in Athena, use the DELETE FROM command in Apache Spark.
- To remove the record from previous versions of your Iceberg tables to hard delete the record from OfflineStore:
  - When changing your Iceberg table configuration: instead of using the ALTER TABLE command from Athena, use expire_snapshots procedure.
  - To remove no longer needed data files from your Iceberg tables: instead of using the VACUUM command in Athena, use the remove_orphan_files procedure.

### Logging Feature Store operations by using AWS CloudTrail

Amazon SageMaker Feature Store is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in Feature Store. CloudTrail captures all of the API calls for Feature Store listed on this page. The logged events include API calls from Feature Store resource
management and data operations. When you create a trail, you activate continuous delivery of CloudTrail events from Feature Store to an Amazon S3 bucket. Using the information collected by CloudTrail, you can determine the request that was made to Feature Store, the IP address from which the request was made, who made the request, when it was made, and additional details.

To learn more about CloudTrail, see the AWS CloudTrail User Guide.

Management events

Management events capture operations performed on Feature Store resources in your AWS account. For example, the log generated from the management events provides visibility if a user creates or deletes a Feature Store. The following APIs log management events with Amazon SageMaker Feature Store.

- CreateFeatureGroup
- DeleteFeatureGroup
- DescribeFeatureGroup
- UpdateFeatureGroup

Amazon SageMaker API calls and management events are logged by default when you create the account, as described in Log Amazon SageMaker API Calls with AWS CloudTrail (p. 3592). For more information, see Logging management events for trails.

Data events

Data events capture data plane operations performed using the Feature Store resources in your AWS account. For example, the log generated from the data events provides visibility if a user adds or deletes a record within a feature group. The following APIs log data events with Amazon SageMaker Feature Store.

- BatchGetRecord
- DeleteRecord
- GetRecord
- PutRecord

Data events are not logged by CloudTrail trails by default. To activate logging of data events, turn on logging of data plane API activity in CloudTrail. For more information, see CloudTrail’s Logging data events for trails.

The following is an example CloudTrail event for a PutRecord API call:

```json
{
   "eventVersion": "1.08",
   "userIdentity": {
      "type": "IAMUser",
      "principalId": "USERPRINCIPALID",
      "arn": "arn:aws:iam::123456789012:user/user",
      "accountId": "123456789012",
      "accessKeyId": "USERACCESSKEYID",
      "userName": "your-user-name"
   },
   "eventTime": "2023-01-01T01:00:00Z",
   "eventSource": "sagemaker.amazonaws.com",
   "eventName": "PutRecord",
   "awsRegion": "us-east-1",
   "sourceIPAddress": "192.0.2.0",
}```
Security and access control

Amazon SageMaker Feature Store enables you to create two types of stores: an online store or offline store. The online store is used for low latency real-time inference use cases whereas the offline store is used for training and batch inference use cases. When you create a feature group for online or offline use you can provide an AWS Key Management Service customer managed key to encrypt all your data at rest. In case you do not provide an AWS KMS key then we ensure that your data is encrypted on the server side using an AWS owned AWS KMS key or AWS managed AWS KMS key. While creating a feature group, you can select storage type and optionally provide an AWS KMS key for encrypting data, then you can call various APIs for data management such as PutRecord, GetRecord, DeleteRecord.

Feature Store allows you to grant or deny access to individuals at the feature group-level and enables cross-account access to Feature Store. For example, you can set up developer accounts to access the offline store for model training and exploration that do not have write access to production accounts. You can set up production accounts to access both online and offline stores. Feature Store uses unique customer AWS KMS keys for offline and online store data at-rest encryption. Access control is enabled through both API and AWS KMS key access. You can also create feature group-level access control.

For more information about customer managed key, see customer managed keys. For more information about AWS KMS, see AWS KMS.

Using AWS KMS permissions for Amazon SageMaker Feature Store

Encryption at rest protects Feature Store under an AWS KMS customer managed key. By default, it uses an AWS owned customer managed key for OnlineStore and AWS managed customer managed key for OfflineStore. Feature Store supports an option to encrypt your online or offline store under customer managed key. You can select the customer managed key for Feature Store when you create your online or offline store, and they can be different for each store.

Feature Store supports only symmetric customer managed keys. You cannot use an asymmetric customer managed key to encrypt your data in your online or offline store. For help determining whether a
customer managed key is symmetric or asymmetric, see Identifying symmetric and asymmetric customer managed keys.

When you use a customer managed key, you can take advantage of the following features:

- You create and manage the customer managed key, including setting the key policies, IAM policies and grants to control access to the customer managed key. You can enable and disable the customer managed key, enable and disable automatic key rotation, and delete the customer managed key when it is no longer in use.
- You can use a customer managed key with imported key material or a customer managed key in a custom key store that you own and manage.
- You can audit the encryption and decryption of your online or offline store by examining the API calls to AWS KMS in AWS CloudTrail logs.

You do not pay a monthly fee for AWS owned customer managed keys. Customer managed keys will incur a charge for each API call and AWS Key Management Service quotas apply to each customer managed key.

Authorizing use of a customer managed Key for your online store

If you use a customer managed key to protect your online store, the policies on that customer managed key must give Feature Store permission to use it on your behalf. You have full control over the policies and grants on a customer managed key.

Feature Store does not need additional authorization to use the default AWS owned KMS key to protect your online or offline stores in your AWS account.

Customer managed key policy

When you select a customer managed key to protect your Online Store, Feature Store must have permission to use the customer managed key on behalf of the principal who makes the selection. That principal, a user or role, must have the permissions on the customer managed key that Feature Store requires. You can provide these permissions in a key policy, an IAM policy, or a grant. At a minimum, Feature Store requires the following permissions on a customer managed key:

For example, the following example key policy provides only the required permissions. The policy has the following effects:

- Allows Feature Store to use the customer managed key in cryptographic operations and create grants, but only when it is acting on behalf of principals in the account who have permission to use your Feature Store. If the principals specified in the policy statement don't have permission to use your Feature Store, the call fails, even when it comes from the Feature Store service.
- The kms:ViaService condition key allows the permissions only when the request comes from FeatureStore on behalf of the principals listed in the policy statement. These principals can't call these operations directly. The value for kms:ViaService should be sagemaker.*.amazonaws.com.

Note
The kms:ViaService condition key can only be used for the online store customer managed AWS KMS key, and cannot be used for the offline store. If you add this special condition to
Using grants to authorize Feature Store

In addition to key policies, Feature Store uses grants to set permissions on the customer managed key. To view the grants on a customer managed key in your account, use the `ListGrants` operation. Feature Store does not need grants, or any additional permissions, to use the AWS owned customer managed key to protect your online store.

```json
{"Id": "key-policy-feature-store",
 "Version": "2012-10-17",
 "Statement": [
  {
    "Sid": "Allow access through Amazon SageMaker Feature Store for all principals in the account that are authorized to use Amazon SageMaker Feature Store",
    "Effect": "Allow",
    "Principal": {
      "AWS": "arn:aws:iam::111122223333:user/featurestore-user",
      "Action": [
        "kms:Encrypt",
        "kms:Decrypt",
        "kms:DescribeKey",
        "kms:CreateGrant",
        "kms:RetireGrant",
        "kms:ReEncryptFrom",
        "kms:ReEncryptTo",
        "kms:GenerateDataKey",
        "kms:ListAliases",
        "kms:ListGrants"
      ],
      "Resource": "*",
      "Condition": {
        "StringLike": {
          "kms:ViaService": "sagemaker.*.amazonaws.com"
        }
      }
    },
    "Effect": "Allow",
    "Principal": {
      "AWS": "arn:aws:iam::111122223333:role/featurestore-admin"
    },
    "Action": [
      "kms:Describe*",
      "kms:Get*",
      "kms:List*",
      "kms:RevokeGrant"
    ],
    "Resource": "*"
  },
  {
    "Sid": "Enable IAM User Permissions",
    "Effect": "Allow",
    "Principal": {
      "AWS": "arn:aws:iam::123456789:root"
    },
    "Action": "kms:*",
    "Resource": "*"
  }
 ]
}
```

Before using an example key policy, replace the example principals with actual principals from your AWS account.
Feature Store uses the grant permissions when it performs background system maintenance and continuous data protection tasks.

Each grant is specific to an online store. If the account includes multiple stores encrypted under the same customer managed key, there will be unique grants per FeatureGroup using the same customer managed key.

The key policy can also allow the account to revoke the grant on the customer managed key. However, if you revoke the grant on an active encrypted online store, Feature Store won't be able to protect and maintain the store.

**Monitoring Feature Store interaction with AWS KMS**

If you use a customer managed key to protect your online or offline store, you can use AWS CloudTrail logs to track the requests that Feature Store sends to AWS KMS on your behalf.

**Accessing data in your online store**

The caller (either user or role) to ALL DataPlane operations (Put, Get, DeleteRecord) must have below permissions on the customer managed key:

```
"kms:Decrypt"
```

**Authorizing use of a customer managed key for your offline store**

The roleArn that is passed as a parameter to createFeatureGroup must have below permissions to the OfflineStore KmsKeyId:

```
"kms:GenerateDataKey"
```

**Note**

The key policy for the online store also works for the offline store, only when the kms:ViaService condition is not specified.

**Important**

You can specify a AWS KMS encryption key to encrypt the Amazon S3 location used for your offline feature store when you create a feature group. If AWS KMS encryption key is not specified, by default we encrypt all data at rest using AWS KMS key. By defining your bucket-level key for SSE, you can reduce AWS KMS requests costs by up to 99 percent.

**Quotas, naming rules and data types**

**Quota terminologies**

- **Read Request Unit (RRU):** Measure of read throughput, where the number of RRUs per read request is equal to the ceiling of read record's size divided into 4KB chunks. The minimum RRU per request is 0.
- **Write Request Unit (WRU):** Measure of write throughput, where the number of WRUs per write request is equal to the ceiling of the written record's size divided into 1KB chunks. The minimum WRU per request is 1 (including delete operations).
Limits and quotas

Note
Soft limits can be increased based on your needs.

- **Maximum number of feature groups per AWS account**: Soft limit of 100.
- **Maximum number of feature definitions per feature group**: 2500.
- **Maximum number of RRU per record identifier**: 2400 RRU per second.
- **Maximum number of WRU per record identifier**: 500 WRU per second.
- **Maximum Transactions per second (TPS) per API per AWS account**: Soft limit of 10000 TPS per API excluding the BatchGetRecord API call, which has a soft limit of 500 TPS.
- **Maximum size of a record**: 350KB.
- **Maximum size of a record identifier**: 2KB.
- **Maximum size of a feature value**: 350KB.
- **Maximum number of concurrent feature group creation workflows**: 4.
- **BatchGetRecord API**: Can contain as many as 100 records and can query up to 10 feature groups.

For information about service quotas and how to request a quota increase, see [AWS service quotas](https://aws.amazon.com/service-quotas/).

Naming rules

- **Reserved Words**: The following are reserved words and cannot be used as feature names in feature definitions: `is_deleted`, `write_time`, and `api_invocation_time`.

Data types

- **String Feature Type**: Strings are Unicode with UTF-8 binary encoding. The minimum length of a string can be zero, the maximum length is constrained by the maximum size of a record.
- **Fractional Feature Type**: Fractional feature values must conform to a double precision floating point number as defined by the [IEEE 754 standard](https://en.wikipedia.org/wiki/IEEE_754).
- **Integral Feature Type**: Feature Store supports integral values in the range of a 64-bit signed integer. Minimum value of \(-2^{63}\) and a maximum value: \(2^{63} - 1\).
- **Event Time Features**: All feature groups have an event time feature with nanosecond precision. Any event time with lower than nanosecond precision will lead to backwards incompatibility. The feature can have a feature type of either String or Fractional.
  - A string event time is accepted in ISO-8601 format, in UTC time, conforming to the pattern(s): `[yyyy-MM-dd'T'HH:mm:ssZ, yyyy-MM-dd'T'HH:mm:ss.SSSSSSSSZ]`.
  - A fractional event time value is accepted as seconds from unix epoch. Event times must be in the range of `[0000-01-01T00:00:00.000000000Z, 9999-12-31T23:59:59.999999999Z]`. For feature groups in the Iceberg table format, you can only use String type for the event time.

Amazon SageMaker Feature Store offline store data format

Amazon SageMaker Feature Store supports the AWS Glue and Apache Iceberg table formats for the offline store. You can choose the table format when you're creating a new feature group. AWS Glue is the default format.
Amazon SageMaker Feature Store offline store data is stored in an Amazon S3 bucket within your account. When you call `PutRecord`, your data is buffered, batched, and written into Amazon S3 within 15 minutes. Feature Store only supports the Parquet file format when writing your data to your offline store. Specifically, when your data is written to your offline store, the data can be retrieved from your Amazon S3 bucket in Parquet format. Each file can contain multiple Records.

For the Iceberg format, Feature Store saves the table’s metadata in the same Amazon S3 bucket that you’re using to store the offline store data. You can find it under the metadata prefix.

Feature Store also exposes the `OfflineStoreConfig.S3StorageConfig.ResolvedOutputS3Uri` field, which can be found from in the `DescribeFeatureGroup` API call. This is the S3 path under which the files for the specific feature group are written.

The following additional fields are added by Feature Store to each record when they persist in the offline store:

- **api_invocation_time** – The timestamp when the service receives the `PutRecord` or `DeleteRecord` call. If using managed ingestion (e.g. Data Wrangler), this is the timestamp when data was written into the offline store.
- **write_time** – The timestamp when data was written into the offline store. Can be used for constructing time-travel related queries.
- **is_deleted** – False by default. If `DeleteRecord` is called, a new `Record` is inserted into `RecordIdentifierValue` and set to `True` in the offline store.

### Amazon SageMaker Feature Store offline store URI structures

In the following examples `DOC-EXAMPLE-BUCKET` is the Amazon S3 bucket within your account, `example-prefix` is your example prefix, `111122223333` is your account ID, `AWS Region` is your region, `feature-group-name` is the name of your feature group.

**AWS Glue table format**

Records in the offline store stored using the AWS Glue table format are partitioned by event time into hourly partitions. You can’t configure the partitioning scheme. The following URI structure shows the organization of a Parquet file using the AWS Glue format:

```
s3://DOC-EXAMPLE-BUCKET/example-prefix/111122223333/sagemaker/AWS Region/offline-store/feature-group-name-feature-group-creation-time/data/year=year/month=month/day=day/hour=hour/timestamp_of_latest_event_time_in_file_16-random-alphanumeric-digits.parquet
```

The following example is the output location of a Parquet file for a file with `feature-group-name` as `customer-purchase-history-patterns`:

```
s3://DOC-EXAMPLE-BUCKET/example-prefix/111122223333/sagemaker/AWS Region/offline-store/customer-purchase-history-patterns-1593511200/data/year=2020/month=06/day=31/hour=00/20200631T064401Z_108934320012Az11.parquet
```

**Iceberg table format**

Records in the offline store stored in the Iceberg table format are partitioned by event time into daily partitions. You can’t configure the partitioning scheme. The following URI structure shows the organization of the data files saved in the Iceberg table format:
The following example is the output location of a Parquet file for a file with `feature-group-name` as `customer-purchase-history-patterns`, and the `event-time-feature-name` is `EventTime`:

```
```

The following example is the location of a metadata file for data files saved in the Iceberg table format.

```
s3://DOC-EXAMPLE-BUCKET/example-prefix/111122223333/sagemaker/AWS Region/offline-store/feature-group-name-feature-group-creation-time/metadata/
```

## Amazon SageMaker Feature Store resources

The following lists the available resources for Amazon SageMaker Feature Store users. For the Feature Store main page, see Amazon SageMaker Feature Store.

### Feature Store example notebooks and workshops

To get started using Amazon SageMaker Feature Store, you can choose from a variety of example Jupyter notebooks from the following table. If this is your first time using Feature Store, try out the Introduction to Feature Store notebook. To run any these notebooks, you must attach this policy to your IAM execution role: AmazonSageMakerFeatureStoreAccess.

See IAM Roles to access your role and attach this policy. For a walkthrough on how to view the policies attached to a role and how to add a policy to your role, see Adding policies to your IAM role.

The following table lists a variety of resources to help you get started with Feature Store. This table contains examples, instructions, and example notebooks to guide you in how to use Feature Store for the first time to specific use cases. The code in these resources use the SageMaker SDK for Python (Boto3).

<table>

Train machine learning models

The training stage of the full machine learning (ML) lifecycle spans from accessing your training dataset to generating a final model and selecting the best performing model for deployment. The following sections provide an overview of available SageMaker training features and resources with in-depth technical information for each.

The simplest training workflow in SageMaker

If you're using SageMaker for the first time and want to find a quick ML solution to train a model on your dataset, consider using a no-code or low-code solution such as SageMaker Canvas, SageMaker JumpStart within SageMaker Studio, or SageMaker Autopilot.

For intermediate coding experiences, consider using a SageMaker Studio notebook or SageMaker Notebook Instances. To get started, follow the instructions at the section called “Step 4: Train a Model” (p. 305) of the SageMaker Getting Started guide. We recommend this for use cases in which you create your own model and training script using an ML framework.

The following architecture diagram shows how SageMaker manages ML training jobs and provisions Amazon EC2 instances on behalf of SageMaker users. You as a SageMaker user can bring your own training dataset, saving it to Amazon S3. You can choose an ML model training from available SageMaker built-in algorithms, or bring your own training script with a model built with popular machine learning frameworks.

Full view of the SageMaker Training workflow and features

The full journey of ML training involves tasks beyond data ingestion to ML models, training models on compute instances, and obtaining model artifacts and outputs. You need to evaluate every phase of
before, during, and after training to make sure your model is trained well to meet the target accuracy for your objectives.

The following flow chart shows a high-level overview of your actions (in blue boxes) and available SageMaker Training features (in light blue boxes) throughout the training phase of the ML lifecycle.

The following sections walk you through each phase of training depicted in the previous flow chart and useful features offered by SageMaker throughout the three sub-stages of the ML training.

**Topics**
- Before training (p. 1516)
- During training (p. 1518)
- After training (p. 1520)

**Before training**

There are a number of scenarios of setting up data resources and access you need to consider before training. Refer to the following diagram and details of each before-training stage to get a sense of what decisions you need to make.
• **Prepare data:** Before training, you must have finished data cleaning and feature engineering during the data preparation stage. SageMaker has several labeling and feature engineering tools to help you. See [Label Data](#), [Prepare and Analyze Datasets](#), [Process Data](#), and [Create, Store, and Share Features](#) for more information.

• **Choose an algorithm or framework:** Depending on how much customization you need, there are different options for algorithms and frameworks.
  - If you prefer a low-code implementation of a pre-built algorithm, use one of the built-in algorithms offered by SageMaker. For more information, see [Choose an Algorithm](#).
  - If you need more flexibility to customize your model, run your training script using your preferred frameworks and toolkits within SageMaker. For more information, see [ML Frameworks and Toolkits](#).
  - To extend pre-built SageMaker Docker images as the base image of your own container, see [Use Pre-built SageMaker Docker images](#).
  - To bring your custom Docker container to SageMaker, see [Adapting your own Docker container to work with SageMaker](#). You need to install the sagemaker-training-toolkit to your container.

• **Manage data storage:** Understand mapping between the data storage (such as Amazon S3, Amazon EFS, or Amazon FSx) and the training container that runs in the Amazon EC2 compute instance.
SageMaker helps map the storage paths and local paths in the training container. You can also manually specify them. After mapping is done, consider using one of the data transmission modes: File, Pipe, and FastFile mode. To learn how SageMaker maps storage paths, see Training Storage Folders.

- **Set up access to training data**: Use Amazon SageMaker Domain, a Domain user profile, IAM, Amazon VPC, and AWS KMS to meet the requirements of the most security-sensitive organizations.
  - For account administration, see Amazon SageMaker Domain.
  - For a complete reference about IAM policies and security, see Security in Amazon SageMaker.
- **Stream your input data**: SageMaker provides three data input modes, File, Pipe, and FastFile. The default input mode is File mode, which loads the entire dataset during initializing the training job. To learn about general best practices for streaming data from your data storage to the training container, see Access Training Data.
  
  In case of Pipe mode, you can also consider using an augmented manifest file to stream your data directly from Amazon Simple Storage Service (Amazon S3) and train your model. Using pipe mode reduces disk space because Amazon Elastic Block Store only needs to store your final model artifacts, rather than storing your full training dataset. For more information, see Provide Dataset Metadata to Training Jobs with an Augmented Manifest File.
- **Analyze your data for bias**: Before training, you can analyze your dataset and model for bias against a disfavored group so that you can check that your model learns an unbiased dataset using SageMaker Clarify.
- **Choose which SageMaker SDK to use**: There are two ways to launch a training job in SageMaker: using the high-level SageMaker Python SDK, or using the low-level SageMaker APIs for the SDK for Python (Boto3) or the AWS CLI. The SageMaker Python SDK abstracts the low-level SageMaker API to provide convenient tools. As aforementioned in the section called “The simplest training workflow in SageMaker” (p. 1515), you can also pursue no-code or minimal-code options using SageMaker Canvas, SageMaker JumpStart within SageMaker Studio, or SageMaker Autopilot.

**During training**

During training, you need to continuously improve training stability, training speed, training efficiency while scaling compute resources, cost optimization, and, most importantly, model performance. Read on for more information about during-training stages and relevant SageMaker Training features.
During training

• **Set up infrastructure:** Choose the right instance type and infrastructure management tools for your use case. You can start from a small instance and scale up depending on your workload. For training a model on a tabular dataset, start with the smallest CPU instance of the C4 or C5 instance families. For training a large model for computer vision or natural language processing, start with the smallest GPU instance of the P2, P3, G4dn or G5 instance families. You can also mix different instance types in a cluster, or keep instances in warm pools using the following instance management tools offered by SageMaker. You can also use persistent cache to reduce latency and billable time on iterative training jobs over the latency reduction from warm pools alone. To learn more, see the following topics.
  - Train Using a Heterogeneous Cluster (p. 2293)
  - Train Using SageMaker Managed Warm Pools (p. 2307)
  - Using persistent cache (p. 2309)

You must have sufficient quota to run a training job. If you run your training job on an instance where you have insufficient quota, you will receive a `ResourceLimitExceeded` error. To check the currently available quotas in your account, use your Service Quotas console. To learn how to request a quota increase, see Supported Regions and Quotas. Also, to find pricing information and available instance types depending on the AWS Regions, look up the tables in the Amazon SageMaker Pricing page.

• **Run a training job from a local code:** You can annotate your local code with a remote decorator to run your code as a SageMaker training job from inside Amazon SageMaker Studio, an Amazon SageMaker notebook or from your local integrated development environment. For more information, see Run your local code as a SageMaker training job (p. 1813).

• **Track training jobs:** Monitor and track your training jobs using SageMaker Experiments, SageMaker Debugger, or Amazon CloudWatch. You can watch the model performance in terms of accuracy and convergence, and run comparative analysis of metrics between multiple training jobs by using SageMaker Experiments. You can watch the compute resource utilization rate by using SageMaker Debugger's profiling tools or Amazon CloudWatch. To learn more, see the following topics.
  - Manage Machine Learning with Amazon SageMaker Experiments
  - Profile Training Jobs Using Amazon SageMaker Debugger
  - Monitor and Analyze Using CloudWatch Metrics

Additionally, for deep learning tasks, use the Amazon SageMaker Debugger model debugging tools and built-in rules to identify more complex issues in model convergence and weight update processes.
• **Distributed training:** If your training job is going into a stable stage without breaking due to misconfiguration of the training infrastructure or out-of-memory issues, you might want to find more options to scale your job and run over an extended period of time for days and even months. When you're ready to scale up, consider distributed training. SageMaker provides various options for distributed computation from light ML workloads to heavy deep learning workloads.

For deep learning tasks that involve training very large models on very large datasets, consider using one of the [SageMaker distributed training strategies](https://docs.aws.amazon.com/sagemaker/latest/dg/distributed-training.html) to scale up and achieve data parallelism, model parallelism, or a combination of the two. You can also use [SageMaker Training Compiler](https://docs.aws.amazon.com/sagemaker/latest/dg/compiling-models.html) for compiling and optimizing model graphs on GPU instances. These SageMaker features support deep learning frameworks such as PyTorch, TensorFlow, and Hugging Face Transformers.

• **Model hyperparameter tuning:** Tune your model hyperparameters using [Automatic Model Tuning with SageMaker](https://docs.aws.amazon.com/sagemaker/latest/dg/model-optimization.html). SageMaker provides hyperparameter tuning methods such as grid search and Bayesian search, launching parallel hyperparameter tuning jobs with early-stopping functionality for non-improving hyperparameter tuning jobs.

• **Checkpointing and cost saving with Spot instances:** If training time is not a big concern, you might consider optimizing model training costs with managed Spot instances. Note that you must activate checkpointing for Spot training to keep restoring from intermittent job pauses due to Spot instance replacements. You can also use the checkpointing functionality to back up your models in case of unexpected training job termination. To learn more, see the following topics.

  • [Managed Spot Training](https://docs.aws.amazon.com/sagemaker/latest/dg/spot-instance-training.html)
  • [Use Checkpoints](https://docs.aws.amazon.com/sagemaker/latest/dg/checkpoints.html)

### After training

After training, you obtain a final model artifact to use for model deployment and inference. There are additional actions involved in the after-training phase as shown in the following diagram.
• **Obtain baseline model:** After you have the model artifact, you can set it as a baseline model. Consider the following post-training actions and using SageMaker features before moving on to model deployment to production.

• **Examine model performance and check for bias:** Use Amazon CloudWatch Metrics and SageMaker Clarify for post-training bias to detect any bias in incoming data and model over time against the baseline. You need to evaluate your new data and model predictions against the new data regularly or in real time. Using these features, you can receive alerts about any acute changes or anomalies, as well as gradual changes or drifts in data and model.

• You can also use the **Incremental Training** functionality of SageMaker to load and update your model (or fine-tune) with an expanded dataset.

• You can register model training as a step in your SageMaker Pipeline or as part of other Workflow features offered by SageMaker in order to orchestrate the full ML lifecycle.

---

**Train a Model with Amazon SageMaker**

The following diagram shows how you train and deploy a model with Amazon SageMaker. Your training code accesses your training data and outputs model artifacts from an S3 bucket. Then you can make requests to a model endpoint to run inference. You can store both the training and inference container images in an Amazon Elastic Container Registry (ECR).
The following guide highlights two components of SageMaker: model training and model deployment.

To train a model in SageMaker, you create a training job. The training job includes the following information:

- The URL of the Amazon Simple Storage Service (Amazon S3) bucket where you’ve stored the training data.
- The compute resources that you want SageMaker to use for model training. Compute resources are machine learning (ML) compute instances that are managed by SageMaker.
- The URL of the S3 bucket where you want to store the output of the job.
- The Amazon Elastic Container Registry path where the training code is stored. For more information, see Docker Registry Paths and Example Code.

**Note**
Your input dataset must be in the same AWS Region as your training job.

You have the following options for a training algorithm:

- **Use an algorithm provided by SageMaker**—SageMaker provides dozens of built-in training algorithms and hundreds of pre-trained models. If one of these meets your needs, it’s a great out-of-the-box solution for quick model training. For a list of algorithms provided by SageMaker, see Use Amazon SageMaker Built-in Algorithms or Pre-trained Models (p. 1528). To try an exercise that uses an algorithm provided by SageMaker, see Get started (p. 8). You can also use SageMaker JumpStart (p. 161) to use algorithms and models through the Studio UI.

- **Use SageMaker Debugger**—to inspect training parameters and data throughout the training process when working with the TensorFlow, PyTorch, and Apache MXNet learning frameworks or the XGBoost algorithm. Debugger automatically detects and alerts users to commonly occurring errors such as parameter values getting too large or small. For more information about using Debugger, see Use Amazon SageMaker Debugger to debug and improve model performance (p. 1916). Debugger sample notebooks are available at Amazon SageMaker Debugger Samples.

- **Use Apache Spark with SageMaker**—SageMaker provides a library that you can use in Apache Spark to train models with SageMaker. Using the library provided by SageMaker is similar to using Apache Spark MLLib. For more information, see Use Apache Spark with Amazon SageMaker (p. 3611).

- **Submit custom code to train with deep learning frameworks**—You can submit custom Python code that uses TensorFlow, PyTorch, or Apache MXNet for model training. For more information, see Use TensorFlow with Amazon SageMaker (p. 3627), Use PyTorch with Amazon SageMaker (p. 3623), and Use Apache MXNet with Amazon SageMaker (p. 3610).

- **Use your own custom algorithms**—Put your code together as a Docker image and specify the registry path of the image in a SageMaker CreateTrainingJob API call. For more information, see Use Docker containers to build models (p. 3281).

- **Use an algorithm that you subscribe to from AWS Marketplace**—For information, see Find and Subscribe to Algorithms and Model Packages on AWS Marketplace (p. 3576).

After you create the training job, SageMaker launches the ML compute instances and uses the training code and the training dataset to train the model. It saves the resulting model artifacts and other output in the S3 bucket you specified for that purpose.

You can create a training job with the SageMaker console or the API. For information about creating a training job with the API, see the CreateTrainingJob API.

When you create a training job with the API, SageMaker replicates the entire dataset on ML compute instances by default. To make SageMaker replicate a subset of the data on each ML compute instance, you must set the S3DataDistributionType field to ShardedByS3Key. You can set this field using the low-level SDK. For more information, see S3DataDistributionType in S3DataSource.
Important
To prevent your algorithm container from contending for memory, we reserve memory for our SageMaker critical system processes on your ML compute instances and therefore you cannot expect to see all the memory for your instance type.

Choose an Algorithm

Machine learning can help you accomplish empirical tasks that require some sort of inductive inference. This task involves induction as it uses data to train algorithms to make generalizable inferences. This means that the algorithms can make statistically reliable predictions or decisions, or complete other tasks when applied to new data that was not used to train them.

To help you select the best algorithm for your task, we classify these tasks on various levels of abstraction. At the highest level of abstraction, machine learning attempts to find patterns or relationships between features or less structured items, such as text in a data set. Pattern recognition techniques can be classified into distinct machine learning paradigms, each of which address specific problem types. There are currently three basic paradigms for machine learning used to address various problem types:

- Supervised learning (p. 1527)
- Unsupervised learning (p. 1527)
- Reinforcement learning (p. 1528)

The types of problems that each learning paradigm can address are identified by considering the inferences (or predictions, decisions, or other tasks) you want to make from the type of data that you have or could collect. Machine learning paradigms use algorithmic methods to address their various problem types. The algorithms provide recipes for solving these problems.

However, many algorithms, such as neural networks, can be deployed with different learning paradigms and on different types of problems. Multiple algorithms can also address a specific problem type. Some algorithms are more generally applicable and others are quite specific for certain kinds of objectives and data. So the mapping between machine learning algorithms and problem types is many-to-many. Also, there are various implementation options available for algorithms.

The following sections provide guidance concerning implementation options, machine learning paradigms, and algorithms appropriate for different problem types.

Topics
- Choose an algorithm implementation (p. 1524)
- Problem types for the basic machine learning paradigms (p. 1526)
- Use Amazon SageMaker Built-in Algorithms or Pre-trained Models (p. 1528)
- Use Reinforcement Learning with Amazon SageMaker (p. 1807)

Choose an algorithm implementation

After choosing an algorithm, you must decide which implementation of it you want to use. Amazon SageMaker supports three implementation options that require increasing levels of effort.

- **Pre-trained models** require the least effort and are models ready to deploy or to fine-tune and deploy using SageMaker JumpStart.
- **Built-in algorithms** require more effort and scale if the data set is large and significant resources are needed to train and deploy the model.
If there is no built-in solution that works, try to develop one that uses pre-made images for machine and deep learning frameworks for supported frameworks such as Scikit-Learn, TensorFlow, PyTorch, MXNet, or Chainer.

If you need to run custom packages or use any code which isn’t a part of a supported framework or available via PyPi, then you need to build your own custom Docker image that is configured to install the necessary packages or software. The custom image must also be pushed to an online repository like the Amazon Elastic Container Registry.

Topics
- Use a built-in algorithm (p. 1525)
- Use script mode in a supported framework (p. 1526)
- Use a custom Docker image (p. 1526)

Use a built-in algorithm

When choosing an algorithm for your type of problem and data, the easiest option is to use one of Amazon SageMaker's built-in algorithms. These built-in algorithms come with two major benefits.

- The built-in algorithms require no coding to start running experiments. The only inputs you need to provide are the data, hyperparameters, and compute resources. This allows you to run experiments more quickly, with less overhead for tracking results and code changes.
- The built-in algorithms come with parallelization across multiple compute instances and GPU support right out of the box for all applicable algorithms (some algorithms may not be included due to inherent limitations). If you have a lot of data with which to train your model, most built-in algorithms can easily scale to meet the demand. Even if you already have a pre-trained model, it may still be easier to use its corollary in SageMaker and input the hyper-parameters you already know than to port it over, using script mode on a supported framework.
For more information on the built-in algorithms provided by SageMaker, see Use Amazon SageMaker Built-in Algorithms or Pre-trained Models (p. 1528).

For important information about docker registry paths, data formats, recommended EC2 instance types, and CloudWatch logs common to all of the built-in algorithms provided by SageMaker, see Common Information About Built-in Algorithms (p. 1534).

**Use script mode in a supported framework**

If the algorithm you want to use for your model is not supported by a built-in choice and you are comfortable coding your own solution, then you should consider using an Amazon SageMaker supported framework. This is referred to as "script mode" because you write your custom code (script) in a text file with a .py extension. As the table above indicates, SageMaker supports most of the popular machine learning frameworks. These frameworks come preloaded with the corresponding framework and some additional Python packages, such as Pandas and NumPy, so you can write your own code for training an algorithm. These frameworks also allow you to install any Python package hosted on PyPi by including a requirements.txt file with your training code or to include your own code directories. R is also supported natively in SageMaker notebook kernels. Some frameworks, like scikit-learn and Spark ML, have pre-coded algorithms you can use easily, while other frameworks like TensorFlow and PyTorch may require you to implement the algorithm yourself. The only limitation when using a supported framework image is that you cannot import any software packages that are not hosted on PyPi or that are not already included with the framework's image.

For more information on the frameworks supported by SageMaker, see Machine Learning Frameworks and Languages (p. 3610).

**Use a custom Docker image**

Amazon SageMaker's built-in algorithms and supported frameworks should cover most use cases, but there are times when you may need to use an algorithm from a package not included in any of the supported frameworks. You might also have a pre-trained model picked or persisted somewhere which you need to deploy. SageMaker uses Docker images to host the training and serving of all models, so you can supply your own custom Docker image if the package or software you need is not included in a supported framework. This may be your own Python package or an algorithm coded in a language like Stan or Julia. For these images you must also configure the training of the algorithm and serving of the model properly in your Dockerfile. This requires intermediate knowledge of Docker and is not recommended unless you are comfortable writing your own machine learning algorithm. Your Docker image must be uploaded to an online repository, such as the Amazon Elastic Container Registry (ECR) before you can train and serve your model properly.

For more information on custom Docker images in SageMaker, see Use Docker containers to build models (p. 3281).

**Problem types for the basic machine learning paradigms**

The following three sections describe the main problem types addressed by the three basic paradigms for machine learning. For a list of the built-in algorithms that SageMaker provides to address these problem types, see Use Amazon SageMaker Built-in Algorithms or Pre-trained Models (p. 1528).

**Topics**
- Supervised learning (p. 1527)
- Unsupervised learning (p. 1527)
- Reinforcement learning (p. 1528)
Supervised learning

If your data set consists of features or attributes (inputs) that contain target values (outputs), then you have a supervised learning problem. If your target values are categorical (mathematically discrete), then you have a **classification problem**. It is a standard practice to distinguish binary from multiclass classification.

- **Binary classification** is a type of supervised learning that assigns an individual to one of two predefined and mutually exclusive classes based on the individual’s attributes. It is supervised because the models are trained using examples in which the attributes are provided with correctly labeled objects. A medical diagnosis for whether an individual has a disease or not based on the results of diagnostic tests is an example of binary classification.

- **Multiclass classification** is a type of supervised learning that assigns an individual to one of several classes based on the individual's attributes. It is supervised because the models are trained using examples in which the attributes are provided with correctly labeled objects. An example is the prediction of the topic most relevant to a text document. A document may be classified as being about religion, politics, or finance, or as about one of several other predefined topic classes.

If the target values you are trying to predict are mathematically continuous, then you have a **regression** problem. Regression estimates the values of a dependent target variable based on one or more other variables or attributes that are correlated with it. An example is the prediction of house prices using features like the number of bathrooms and bedrooms and the square footage of the house and garden. Regression analysis can create a model that takes one or more of these features as an input and predicts the price of a house.

For more information on the built-in supervised learning algorithms provided by SageMaker, see [Supervised Learning](p. 1532).

Unsupervised learning

If your data set consists of features or attributes (inputs) that do not contain labels or target values (outputs), then you have an unsupervised learning problem. In this type of problem, the output must be predicted based on the pattern discovered in the input data. The goal in unsupervised learning problems is to discover patterns such as groupings within the data. There are a large variety of tasks or problem types to which unsupervised learning can be applied. Principal component and cluster analyses are two of the main methods commonly deployed for preprocessing data. Here is a short list of problem types that can be addressed by unsupervised learning:

- **Dimension reduction** is typically part of a data exploration step used to determine the most relevant features to use for model construction. The idea is to transform data from a high-dimensional, sparsely populated space into a low-dimensional space that retains most significant properties of the original data. This provides relief for the curse of dimensionality that can arise with sparsely populated, high-dimensional data on which statistical analysis becomes problematic. It can also be used to help understand data, reducing high-dimensional data to a lower dimensionality that can be visualized.

- **Cluster analysis** is a class of techniques that are used to classify objects or cases into groups called clusters. It attempts to find discrete groupings within data, where members of a group are as similar as possible to one another and as different as possible from members of other groups. You define the features or attributes that you want the algorithm to use to determine similarity, select a distance function to measure similarity, and specify the number of clusters to use in the analysis.

- **Anomaly detection** is the identification of rare items, events, or observations in a data set which raise suspicions because they differ significantly from the rest of the data. The identification of anomalous items can be used, for example, to detect bank fraud or medical errors. Anomalies are also referred to as outliers, novelties, noise, deviations, and exceptions.

- **Density estimation** is the construction of estimates of unobservable underlying probability density functions based on observed data. A natural use of density estimates is for data exploration. Density
estimates can discover features such as skewness and multimodality in the data. The most basic form of density estimation is a rescaled histogram.

SageMaker provides several built-in machine learning algorithms that you can use for these unsupervised learning tasks. For more information on the built-in unsupervised algorithms provided by SageMaker, see Unsupervised Learning (p. 1533).

Reinforcement learning

Reinforcement learning is a type of learning that is based on interaction with the environment. This type of learning is used by an agent that must learn behavior through trial-and-error interactions with a dynamic environment in which the goal is to maximize the long-term rewards that the agent receives as a result of its actions. Rewards are maximized by trading off exploring actions that have uncertain rewards with exploiting actions that have known rewards.

For more information on SageMaker’s frameworks, toolkits, and environments for reinforcement learning, see Use Reinforcement Learning with Amazon SageMaker (p. 1807).

Use Amazon SageMaker Built-in Algorithms or Pre-trained Models

Amazon SageMaker provides a suite of built-in algorithms, pre-trained models, and pre-built solution templates to help data scientists and machine learning practitioners get started on training and deploying machine learning models quickly. For someone who is new to SageMaker, choosing the right algorithm for your particular use case can be a challenging task. The following table provides a quick cheat sheet that shows how you can start with an example problem or use case and find an appropriate built-in algorithm offered by SageMaker that is valid for that problem type. Additional guidance organized by learning paradigms (supervised and unsupervised) and important data domains (text and images) is provided in the sections following the table.

For important information about Docker registry paths, data formats, recommended Amazon EC2 instance types, and CloudWatch logs common to all of the built-in algorithms provided by SageMaker, see Common Information About Built-in Algorithms (p. 1534).

The following sections provide additional guidance for the Amazon SageMaker built-in algorithms grouped by the supervised and unsupervised learning paradigms to which they belong. For descriptions of these learning paradigms and their associated problem types, see Choose an Algorithm (p. 1524). Sections are also provided for the SageMaker built-in algorithms available to address two important machine learning domains: textual analysis and image processing.

- Pre-trained Models and Solution Templates (p. 1532)
  - Supervised Learning (p. 1532)
  - Unsupervised Learning (p. 1533)
  - Textual Analysis (p. 1533)
  - Image Processing (p. 1534)

### Pre-trained Models and Solution Templates

SageMaker JumpStart provides a wide range of pre-trained models, pre-built solution templates, and examples for popular problem types that use the SageMaker SDK as well as Studio. For more information about these models, solutions, and the example notebooks provided by SageMaker JumpStart, see SageMaker JumpStart (p. 161).

### Supervised Learning

Amazon SageMaker provides several built-in general purpose algorithms that can be used for either classification or regression problems.

- AutoGluon-Tabular (p. 1548)—an open-source AutoML framework that succeeds by ensembling models and stacking them in multiple layers.
- CatBoost (p. 1556)—an implementation of the gradient-boosted trees algorithm that introduces ordered boosting and an innovative algorithm for processing categorical features.
- Factorization Machines Algorithm (p. 1565)—an extension of a linear model that is designed to economically capture interactions between features within high-dimensional sparse datasets.
- K-Nearest Neighbors (k-NN) Algorithm (p. 1575)—a non-parametric method that uses the k nearest labeled points to assign a label to a new data point for classification or a predicted target value from the average of the k nearest points for regression.
- LightGBM (p. 1583)—an implementation of the gradient-boosted trees algorithm that adds two novel techniques for improved efficiency and scalability: Gradient-based One-Side Sampling (GOSS) and Exclusive Feature Bundling (EFB).
• Linear Learner Algorithm (p. 1593)—learns a linear function for regression or a linear threshold function for classification.
• TabTransformer (p. 1610)—a novel deep tabular data modeling architecture built on self-attention-based Transformers.
• XGBoost Algorithm (p. 1617)—an implementation of the gradient-boosted trees algorithm that combines an ensemble of estimates from a set of simpler and weaker models.

Amazon SageMaker also provides several built-in supervised learning algorithms that are used for more specialized tasks during feature engineering and forecasting from time series data.
• Object2Vec Algorithm (p. 1669)—a new highly customizable multi-purpose algorithm used for feature engineering. It can learn low-dimensional dense embeddings of high-dimensional objects to produce features that improve training efficiencies for downstream models. While this is a supervised algorithm, as it requires labeled data for training, there are many scenarios in which the relationship labels can be obtained purely from natural clusterings in data, without any explicit human annotation.
• DeepAR Forecasting Algorithm (p. 1708)—a supervised learning algorithm for forecasting scalar (one-dimensional) time series using recurrent neural networks (RNN).

Unsupervised Learning

Amazon SageMaker provides several built-in algorithms that can be used for a variety of unsupervised learning tasks such as clustering, dimension reduction, pattern recognition, and anomaly detection.
• Principal Component Analysis (PCA) Algorithm (p. 1741)—reduces the dimensionality (number of features) within a dataset by projecting data points onto the first few principal components. The objective is to retain as much information or variation as possible. For mathematicians, principal components are eigenvectors of the data's covariance matrix.
• K-Means Algorithm (p. 1733)—finds discrete groupings within data, where members of a group are as similar as possible to one another and as different as possible from members of other groups.
• IP Insights (p. 1724)—learns the usage patterns for IPv4 addresses. It is designed to capture associations between IPv4 addresses and various entities, such as user IDs or account numbers.
• Random Cut Forest (RCF) Algorithm (p. 1745)—detects anomalous data points within a data set that diverge from otherwise well-structured or patterned data.

Textual Analysis

SageMaker provides algorithms that are tailored to the analysis of textual documents used in natural language processing, document classification or summarization, topic modeling or classification, and language transcription or translation.
• BlazingText algorithm (p. 1647)—a highly optimized implementation of the Word2vec and text classification algorithms that scale to large datasets easily. It is useful for many downstream natural language processing (NLP) tasks.
• Sequence-to-Sequence Algorithm (p. 1685)—a supervised algorithm commonly used for neural machine translation.
• Latent Dirichlet Allocation (LDA) Algorithm (p. 1657)—an algorithm suitable for determining topics in a set of documents. It is an unsupervised algorithm, which means that it doesn't use example data with answers during training.
• Neural Topic Model (NTM) Algorithm (p. 1663)—another unsupervised technique for determining topics in a set of documents, using a neural network approach.
• Text Classification - TensorFlow (p. 1698)—a supervised algorithm that supports transfer learning with available pretrained models for text classification.
Image Processing

SageMaker also provides image processing algorithms that are used for image classification, object detection, and computer vision.

- **Image Classification - MXNet (p. 1754)**—uses example data with answers (referred to as a supervised algorithm). Use this algorithm to classify images.
- **Image Classification - TensorFlow (p. 1765)**—uses pretrained TensorFlow Hub models to fine-tune for specific tasks (referred to as a supervised algorithm). Use this algorithm to classify images.
- **Semantic Segmentation Algorithm (p. 1797)**—provides a fine-grained, pixel-level approach to developing computer vision applications.
- **Object Detection - MXNet (p. 1778)**—detects and classifies objects in images using a single deep neural network. It is a supervised learning algorithm that takes images as input and identifies all instances of objects within the image scene.
- **Object Detection - TensorFlow (p. 1789)**—detects bounding boxes and object labels in an image. It is a supervised learning algorithm that supports transfer learning with available pretrained TensorFlow models.

### Common Data Formats for Built-in Algorithms

The following topics explain the data formats for the algorithms provided by Amazon SageMaker.

**Topics**

- Common Data Formats for Training (p. 1537)
- Common Data Formats for Inference (p. 1541)

### Common Data Formats for Training

To prepare for training, you can preprocess your data using a variety of AWS services, including AWS Glue, Amazon EMR, Amazon Redshift, Amazon Relational Database Service, and Amazon Athena. After preprocessing, publish the data to an Amazon S3 bucket. For training, the data need to go through a series of conversions and transformations, including:

- Training data serialization (handled by you)
- Training data deserialization (handled by the algorithm)
- Training model serialization (handled by the algorithm)
- Trained model deserialization (optional, handled by you)

When using Amazon SageMaker in the training portion of the algorithm, make sure to upload all data at once. If more data is added to that location, a new training call would need to be made to construct a brand new model.

**Topics**

- Content Types Supported by Built-In Algorithms (p. 1538)
- Using Pipe Mode (p. 1538)
- Using CSV Format (p. 1538)
Content Types Supported by Built-In Algorithms

The following table lists some of the commonly supported ContentType values and the algorithms that use them:

**ContentTypes for Built-in Algorithms**

<table>
<thead>
<tr>
<th>ContentType</th>
<th>Algorithm</th>
</tr>
</thead>
<tbody>
<tr>
<td>application/x-image</td>

<tr>
<td>text/libsvm</td>
<td>XGBoost</td>
</tr>
</tbody>
</table>

For a summary of the parameters used by each algorithm, see the documentation for the individual algorithms or this table.

**Using Pipe Mode**

In *Pipe mode*, your training job streams data directly from Amazon Simple Storage Service (Amazon S3). Streaming can provide faster start times for training jobs and better throughput. This is in contrast to *File mode*, in which your data from Amazon S3 is stored on the training instance volumes. File mode uses disk space to store both your final model artifacts and your full training dataset. By streaming in your data directly from Amazon S3 in Pipe mode, you reduce the size of Amazon Elastic Block Store volumes of your training instances. Pipe mode needs only enough disk space to store your final model artifacts. See the AlgorithmSpecification for additional details on the training input mode.

**Using CSV Format**

Many Amazon SageMaker algorithms support training with data in CSV format. To use data in CSV format for training, in the input data channel specification, specify text/csv as the ContentType. Amazon SageMaker requires that a CSV file does not have a header record and that the target variable is in the first column. To run unsupervised learning algorithms that don't have a target, specify the number of label columns in the content type. For example, in this case 'content_type=text/csv;label_size=0'. For a notebook example that uses CSV format, see *Breast Cancer Prediction*. For more information, see *Now use Pipe mode with CSV datasets for faster training on Amazon SageMaker built-in algorithms*.

**Using RecordIO Format**

In the protobuf recordIO format, SageMaker converts each observation in the dataset into a binary representation as a set of 4-byte floats, then loads it in the protobuf values field. If you are using Python for your data preparation, we strongly recommend that you use these existing transformations. However,
if you are using another language, the protobuf definition file below provides the schema that you use to convert your data into SageMaker protobuf format.

**Note**
For an example that shows how to convert the commonly used numPy array into the protobuf recordIO format, see [An Introduction to Factorization Machines with MNIST](#).

```proto
syntax = "proto2";

package aialgs.data;

option java_package = "com.amazonaws.aialgorithms.proto";
option java_outer_classname = "RecordProtos";

// A sparse or dense rank-R tensor that stores data as doubles (float64).
message Float32Tensor {
  // Each value in the vector. If keys is empty, this is treated as a
  // dense vector.
  repeated float values = 1 [packed = true];

  // If key is not empty, the vector is treated as sparse, with
  // each key specifying the location of the value in the sparse vector.
  repeated uint64 keys = 2 [packed = true];

  // An optional shape that allows the vector to represent a matrix.
  // For example, if shape = [ 10, 20 ], floor(keys[i] / 20) gives the row,
  // and keys[i] % 20 gives the column.
  // This also supports n-dimensional tensors.
  // Note: If the tensor is sparse, you must specify this value.
  repeated uint64 shape = 3 [packed = true];
}

// A sparse or dense rank-R tensor that stores data as doubles (float64).
message Float64Tensor {
  // Each value in the vector. If keys is empty, this is treated as a
  // dense vector.
  repeated double values = 1 [packed = true];

  // If this is not empty, the vector is treated as sparse, with
  // each key specifying the location of the value in the sparse vector.
  repeated uint64 keys = 2 [packed = true];

  // An optional shape that allows the vector to represent a matrix.
  // For example, if shape = [ 10, 20 ], floor(keys[i] / 10) gives the row,
  // and keys[i] % 20 gives the column.
  // This also supports n-dimensional tensors.
  // Note: If the tensor is sparse, you must specify this value.
  repeated uint64 shape = 3 [packed = true];
}

// A sparse or dense rank-R tensor that stores data as 32-bit ints (int32).
message Int32Tensor {
  // Each value in the vector. If keys is empty, this is treated as a
  // dense vector.
  repeated int32 values = 1 [packed = true];

  // If this is not empty, the vector is treated as sparse with
  // each key specifying the location of the value in the sparse vector.
  repeated uint64 keys = 2 [packed = true];

  // An optional shape that allows the vector to represent a matrix.
  // For example, if shape = [ 10, 20 ], floor(keys[i] / 10) gives the row,
  // and keys[i] % 20 gives the column.
  // This also supports n-dimensional tensors.
  // Note: If the tensor is sparse, you must specify this value.
  repeated uint64 shape = 3 [packed = true];
}
```

1539
repeated uint64 shape = 3 [packed = true];
}

// Support for storing binary data for parsing in other ways (such as JPEG/etc).
// This is an example of another type of value and may not immediately be supported.
message Bytes {
  repeated bytes value = 1;
  // If the content type of the data is known, stores it.
  // This allows for the possibility of using decoders for common formats
  // in the future.
  optional string content_type = 2;
}

message Value {
  oneof value {
    // The numbering assumes the possible use of:
    // - float16, float128
    // - int8, int16, int32
    Float32Tensor float32_tensor = 2;
    Float64Tensor float64_tensor = 3;
    Int32Tensor int32_tensor = 7;
    Bytes bytes = 9;
  }
}

message Record {
  // Map from the name of the feature to the value.
  // For vectors and libsvm-like datasets,
  // a single feature with the name 'values'
  // should be specified.
  map<string, Value> features = 1;
  // An optional set of labels for this record.
  // Similar to the features field above, the key used for
  // generic scalar / vector labels should be 'values'.
  map<string, Value> label = 2;
  // A unique identifier for this record in the dataset.
  // Whilst not necessary, this allows better
  // debugging where there are data issues.
  optional string uid = 3;
  // Textual metadata describing the record.
  // This may include JSON-serialized information
  // about the source of the record.
  // This is not used by the algorithm directly.
  optional string metadata = 4;
  // An optional serialized JSON object that allows per-record
  // hyper-parameters/configuration/other information to be set.
  // The meaning/interpretation of this field is defined by
  // the algorithm author and may not be supported.
  // This is used to pass additional inference configuration
  // when batch inference is used (e.g. types of scores to return).
  optional string configuration = 5;
}
After creating the protocol buffer, store it in an Amazon S3 location that Amazon SageMaker can access and that can be passed as part of InputDataConfig in create_training_job.

**Note**

For all Amazon SageMaker algorithms, the ChannelName in InputDataConfig must be set to train. Some algorithms also support a validation or test input channels. These are typically used to evaluate the model's performance by using a hold-out dataset. Hold-out datasets are not used in the initial training but can be used to further tune the model.

**Trained Model Deserialization**

Amazon SageMaker models are stored as model.tar.gz in the S3 bucket specified in OutputDataConfig S3OutputPath parameter of the create_training_job call. The S3 bucket must be in the same AWS Region as the notebook instance. You can specify most of these model artifacts when creating a hosting model. You can also open and review them in your notebook instance. When model.tar.gz is untarred, it contains model_algo-1, which is a serialized Apache MXNet object. For example, you use the following to load the k-means model into memory and view it:

```python
import mxnet as mx
print(mx.ndarray.load('model_algo-1'))
```

**Common Data Formats for Inference**

Amazon SageMaker algorithms accept and produce several different MIME types for the HTTP payloads used in retrieving online and mini-batch predictions. You can use various AWS services to transform or preprocess records prior to running inference. At a minimum, you need to convert the data for the following:

- Inference request serialization (handled by you)
- Inference request deserialization (handled by the algorithm)
- Inference response serialization (handled by the algorithm)
- Inference response deserialization (handled by you)

**Topics**

- [Convert Data for Inference Request Serialization](#)
- [Convert Data for Inference Response Deserialization](#)
- [Common Request Formats for All Algorithms](#)
- [Use Batch Transform with Built-in Algorithms](#)

**Convert Data for Inference Request Serialization**

Content type options for Amazon SageMaker algorithm inference requests include: text/csv, application/json, and application/x-recordio-protobuf. Algorithms that don't support all of these types can support other types. XGBoost, for example, only supports text/csv from this list, but also supports text/libsvm.

For text/csv, the value for the Body argument to invoke_endpoint should be a string with commas separating the values for each feature. For example, a record for a model with four features might look like 1.5,16.0,14,23.0. Any transformations performed on the training data should also be performed on the data before obtaining inference. The order of the features matters and must remain unchanged.

application/json is significantly more flexible and provides multiple possible formats for developers to use in their applications. At a high level, in JavaScript, the payload might look like the following:

```javascript
let request = {
    // Instances might contain multiple rows that predictions are sought for.
}
```
"instances": [
  {
    // Request and algorithm specific inference parameters.
    "configuration": {},
    // Data in the specific format required by the algorithm.
    "data": {
      "<field name>": dataElement
    }
  }
]

You have the following options for specifying the dataElement:

**Protocol buffers equivalent**

// Has the same format as the protocol buffers implementation described for training.
let dataElement = {
  "keys": [],
  "values": [],
  "shape": []
}

**Simple numeric vector**

// An array containing numeric values is treated as an instance containing a 
// single dense vector.
let dataElement = [1.5, 16.0, 14.0, 23.0]

// It will be converted to the following representation by the SDK.
let converted = {
  "features": {
    "values": dataElement
  }
}

**For multiple records**

let request = {
  "instances": [
    // First instance.
    {
      "features": [ 1.5, 16.0, 14.0, 23.0 ]
    },
    // Second instance.
    {
      "features": [ -2.0, 100.2, 15.2, 9.2 ]
    }
  ]
}

**Convert Data for Inference Response Deserialization**

Amazon SageMaker algorithms return JSON in several layouts. At a high level, the structure is:

let response = {
  "predictions": []
}
The fields that are included in predictions differ across algorithms. The following are examples of output for the k-means algorithm.

**Single-record inference**

```javascript
let response = {
  "predictions": [{
    "closest_cluster": 5,
    "distance_to_cluster": 36.5
  }]
}
```

**Multi-record inference**

```javascript
let response = {
  "predictions": [
    // First instance prediction.
    {
      "closest_cluster": 5,
      "distance_to_cluster": 36.5
    },
    // Second instance prediction.
    {
      "closest_cluster": 2,
      "distance_to_cluster": 90.3
    }
  ]
}
```

**Multi-record inference with protobuf input**

```javascript
{
  "features": [],
  "label": {
    "closest_cluster": {
      "values": [ 5.0 ] // e.g. the closest centroid/cluster was 1.0
    },
    "distance_to_cluster": {
      "values": [ 36.5 ]
    }
  },
  "uid": "abc123",
  "metadata": "{ "created_at": '2017-06-03' }"
}
```

SageMaker algorithms also support the JSONLINES format, where the per-record response content is same as that in JSON format. The multi-record structure is a concatenation of per-record response objects separated by newline characters. The response content for the built-in KMeans algorithm for 2 input data points is:

```
{"distance_to_cluster": 23.40593910217285, "closest_cluster": 0.0}
{"distance_to_cluster": 27.250282287597656, "closest_cluster": 0.0}
```

While running batch transform, we recommended using the jsonlines response type by setting the Accept field in the CreateTransformJobRequest to application/jsonlines.

**Common Request Formats for All Algorithms**

Most algorithms use several of the following inference request formats.
JSON Request Format

**Content type:** application/JSON

**Dense format**

```json
let request = {
    "instances": [
        {
            "features": [1.5, 16.0, 14.0, 23.0]
        }
    ]
}
```

```json
let request = {
    "instances": [
        {
            "data": {
                "features": {
                    "values": [1.5, 16.0, 14.0, 23.0]
                }
            }
        }
    ]
}
```

**Sparse format**

```json
[
    {
        "instances": [
            {
                "data": {
                    "features": {
                        "keys": [26, 182, 232, 243, 431],
                        "shape": [2000],
                        "values": [1, 1, 1, 4, 1]
                    }
                }
            },
            {
                "data": {
                    "features": {
                        "keys": [0, 182, 232, 243, 431],
                        "shape": [2000],
                        "values": [13, 1, 1, 4, 1]
                    }
                }
            }
        ]
    }
]
```

**JSONLINES Request Format**

**Content type:** application/JSONLINES

**Dense format**

A single record in dense format can be represented as either:

```json
{
    "features": [1.5, 16.0, 14.0, 23.0]
}
```

or:

```json
{
    "data": {
        "features": {
            "values": [1.5, 16.0, 14.0, 23.0]
        }
    }
}
```
**Sparse Format**

A single record in sparse format is represented as:

```
{"data": {"features": { "keys": [26, 182, 232, 243, 431], "shape": [2000], "values": [1, 1, 1, 4, 1] } } }
```

Multiple records are represented as a concatenation of the above single-record representations, separated by newline characters:

```
{"data": {"features": { "keys": [0, 1, 3], "shape": [4], "values": [1, 4, 1] } } }
{ "data": { "features": { "values": [1.5, 16.0, 14.0, 23.0] } }
{ "features": [1.5, 16.0, 14.0, 23.0] }
```

**CSV Request Format**

**Content type:** text/CSV; label_size=0

**Note**

CSV support is not available for factorization machines.

**RECORDIO Request Format**

Content type: application/x-recordio-protobuf

**Use Batch Transform with Built-in Algorithms**

While running batch transform, we recommended using the JSONLINES response type instead of JSON, if supported by the algorithm. This is accomplished by setting the Accept field in the CreateTransformJobRequest to application/jsonlines.

When you create a transform job, the SplitType must be set according to the ContentType of the input data. Similarly, depending on the Accept field in the CreateTransformJobRequest, AssembleWith must be set accordingly. Please use the following table to help appropriately set these fields:

<table>
<thead>
<tr>
<th>ContentType</th>
<th>Recommended SplitType</th>
</tr>
</thead>
<tbody>
<tr>
<td>application/x-recordio-protobuf</td>
<td>RecordIO</td>
</tr>
<tr>
<td>text/csv</td>

• IP Insights Inference Data Formats (p. 1731)
• K-Means Response Formats (p. 1740)
• k-NN Request and Response Formats (p. 1580)
• Linear learner response formats (p. 1608)
• NTM Response Formats (p. 1668)
• Data Formats for Object2Vec Inference (p. 1683)
• Encoder Embeddings for Object2Vec (p. 1684)
• PCA Response Formats (p. 1744)
• RCF Response Formats (p. 1751)

Instance Types for Built-in Algorithms

For training and hosting Amazon SageMaker algorithms, we recommend using the following Amazon EC2 instance types:

- ml.m5.xlarge, ml.m5.4xlarge, and ml.m5.12xlarge
- ml.c5.xlarge, ml.c5.2xlarge, and ml.c5.8xlarge
- ml.p3.xlarge, ml.p3.8xlarge, and ml.p3.16xlarge

Most Amazon SageMaker algorithms have been engineered to take advantage of GPU computing for training. For most algorithm training, we support P2, P3, G4dn, and G5 GPU instances. Despite higher per-instance costs, GPUs train more quickly, making them more cost effective. Exceptions are noted in this guide.

The size and type of data can have a great effect on which hardware configuration is most effective. When the same model is trained on a recurring basis, initial testing across a spectrum of instance types can discover configurations that are more cost-effective in the long run. Additionally, algorithms that train most efficiently on GPUs might not require GPUs for efficient inference. Experiment to determine the most cost effectiveness solution. To get an automatic instance recommendation or conduct custom load tests, use Amazon SageMaker Inference Recommender.

For more information on SageMaker hardware specifications, see Amazon SageMaker ML Instance Types.

Logs for Built-in Algorithms

Amazon SageMaker algorithms produce Amazon CloudWatch logs, which provide detailed information on the training process. To see the logs, in the AWS management console, choose CloudWatch, choose Logs, and then choose the /aws/sagemaker/TrainingJobs log group. Each training job has one log stream per node on which it was trained. The log stream's name begins with the value specified in the TrainingJobName parameter when the job was created.

**Note**
If a job fails and logs do not appear in CloudWatch, it's likely that an error occurred before the start of training. Reasons include specifying the wrong training image or S3 location.

The contents of logs vary by algorithms. However, you can typically find the following information:

- Confirmation of arguments provided at the beginning of the log
- Errors that occurred during training
- Measurement of an algorithm's accuracy or numerical performance
- Timings for the algorithm and any major stages within the algorithm
Common Errors

If a training job fails, some details about the failure are provided by the FailureReason return value in the training job description, as follows:

```python
sage = boto3.client('sagemaker')
sage.describe_training_job(TrainingJobName=job_name)['FailureReason']
```

Others are reported only in the CloudWatch logs. Common errors include the following:

1. Misspecifying a hyperparameter or specifying a hyperparameter that is invalid for the algorithm.

   **From the CloudWatch Log**

   ```
   [10/16/2017 23:45:17 ERROR 13962380605824 train.py:48]
   Additional properties are not allowed (u'mini_batch_siz' was unexpected)
   ```

2. Specifying an invalid value for a hyperparameter.

   **FailureReason**

   ```
   AlgorithmError: u'abc' is not valid under any of the given schemas
   schema["properties"]:
   {"oneOf":
   [["pattern": "^(\d+)$", "type": "string"],
   {"minimum": 1, "type": "integer"}]
   ```

3. Inaccurate protobuf file format.

   **From the CloudWatch log**

   ```
   [10/17/2017 18:01:04 ERROR 140234860816192 train.py:48] cannot
   copy sequence with size 785 to array axis with dimension 784
   ```

**Built-in SageMaker Algorithms for Tabular Data**

Amazon SageMaker provides built-in algorithms that are tailored to the analysis of tabular data. Tabular data refers to any datasets that are organized in tables consisting of rows (observations) and columns (features). The built-in SageMaker algorithms for tabular data can be used for either classification or regression problems.

- **AutoGluon-Tabular (p. 1548)**—an open-source AutoML framework that succeeds by ensembling models and stacking them in multiple layers.
- **CatBoost (p. 1556)**—an implementation of the gradient-boosted trees algorithm that introduces ordered boosting and an innovative algorithm for processing categorical features.
- **Factorization Machines Algorithm (p. 1565)**—an extension of a linear model that is designed to economically capture interactions between features within high-dimensional sparse datasets.
- **K-Nearest Neighbors (k-NN) Algorithm (p. 1575)**—a non-parametric method that uses the k nearest labeled points to assign a label to a new data point for classification or a predicted target value from the average of the k nearest points for regression.
• **LightGBM (p. 1583)**—an implementation of the gradient-boosted trees algorithm that adds two novel techniques for improved efficiency and scalability: Gradient-based One-Side Sampling (GOSS) and Exclusive Feature Bundling (EFB).

• **Linear Learner Algorithm (p. 1593)**—learns a linear function for regression or a linear threshold function for classification.

• **TabTransformer (p. 1610)**—a novel deep tabular data modeling architecture built on self-attention-based Transformers.

• **XGBoost Algorithm (p. 1617)**—an implementation of the gradient-boosted trees algorithm that combines an ensemble of estimates from a set of simpler and weaker models.

**AutoGluon-Tabular**

*AutoGluon-Tabular* is a popular open-source AutoML framework that trains highly accurate machine learning models on an unprocessed tabular dataset. Unlike existing AutoML frameworks that primarily
focus on model and hyperparameter selection, AutoGluon-Tabular succeeds by ensembling multiple models and stacking them in multiple layers.

**How to use SageMaker AutoGluon-Tabular**

You can use AutoGluon-Tabular as an Amazon SageMaker built-in algorithm. The following section describes how to use AutoGluon-Tabular with the SageMaker Python SDK. For information on how to use AutoGluon-Tabular from the Amazon SageMaker Studio UI, see [SageMaker JumpStart](p. 161).

- **Use AutoGluon-Tabular as a built-in algorithm**

  Use the AutoGluon-Tabular built-in algorithm to build an AutoGluon-Tabular training container as shown in the following code example. You can automatically spot the AutoGluon-Tabular built-in algorithm image URI using the SageMaker `image_uris.retrieve` API (or the `get_image_uri` API if using Amazon SageMaker Python SDK version 2).

  After specifying the AutoGluon-Tabular image URI, you can use the AutoGluon-Tabular container to construct an estimator using the SageMaker Estimator API and initiate a training job. The AutoGluon-Tabular built-in algorithm runs in script mode, but the training script is provided for you and there is no need to replace it. If you have extensive experience using script mode to create a SageMaker training job, then you can incorporate your own AutoGluon-Tabular training scripts.

```python
from sagemaker import image_uris, model_uris, script_uris

train_model_id, train_model_version, train_scope = "autogluon-classification-ensemble", "*", "training"
training_instance_type = "ml.p3.2xlarge"

train_image_uri = image_uris.retrieve(
    region=None,
    framework=None,
    model_id=train_model_id,
    model_version=train_model_version,
    image_scope=train_scope,
    instance_type=training_instance_type
)

train_source_uri = script_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version, script_scope=train_scope
)

train_model_uri = model_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version, model_scope=train_scope
)

# Sample training data is available in this bucket
training_data_bucket = f"Jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/tabular_binary/"

training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}/train"
validation_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}/validation"

output_bucket = sess.default_bucket()
output_prefix = "Jumpstart-example-tabular-training"
s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"

from sagemaker import hyperparameters

# Retrieve the default hyperparameters for training the model
```
hyperparameters = hyperparameters.retrieve_default(
    model_id=train_model_id, model_version=train_model_version
)

# [Optional] Override default hyperparameters with custom values
hyperparameters[
    "auto_stack"
] = "True"
print(hyperparameters)

from sagemaker.estimator import Estimator
from sagemaker.utils import name_from_base

training_job_name = name_from_base(f"built-in-algo-{train_model_id}-training")

# Create SageMaker Estimator instance
tabular_estimator = Estimator(
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
    instance_count=1,
    instance_type=training_instance_type,
    max_run=360000,
    hyperparameters=hyperparameters,
    output_path=s3_output_location
)

# Launch a SageMaker Training job by passing the S3 path of the training data
tabular_estimator.fit(
    {
        "training": training_dataset_s3_path,
        "validation": validation_dataset_s3_path,
    }, logs=True, job_name=training_job_name
)

For more information about how to set up the AutoGluon-Tabular as a built-in algorithm, see the following notebook examples. Any S3 bucket used in these examples must be in the same AWS Region as the notebook instance used to run them.

- [Tabular classification with Amazon SageMaker AutoGluon-Tabular algorithm](#)
- [Tabular regression with Amazon SageMaker AutoGluon-Tabular algorithm](#)

**Input and Output interface for the AutoGluon-Tabular algorithm**

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of AutoGluon-Tabular supports CSV for training and inference:

- For **Training ContentType**, valid inputs must be **text/csv**.
- For **Inference ContentType**, valid inputs must be **text/csv**.

**Note**
For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record.
For CSV inference, the algorithm assumes that CSV input does not have the label column.

**Input format for training data, validation data, and categorical features**
Be mindful of how to format your training data for input to the AutoGluon-Tabular model. You must provide the path to an Amazon S3 bucket that contains your training and validation data. You can also include a list of categorical features. Use both the training and validation channels to provide your input data. Alternatively, you can use only the training channel.

**Use both the training and validation channels**

You can provide your input data by way of two S3 paths, one for the training channel and one for the validation channel. Each S3 path can either be an S3 prefix that points to one or more CSV files or a full S3 path pointing to one specific CSV file. The target variables should be in the first column of your CSV file. The predictor variables (features) should be in the remaining columns. If multiple CSV files are provided for the training or validation channels, the AutoGluon-Tabular algorithm concatenates the files. The validation data is used to compute a validation score at the end of each boosting iteration. Early stopping is applied when the validation score stops improving.

If your predictors include categorical features, you can provide a JSON file named categorical_index.json in the same location as your training data file or files. If you provide a JSON file for categorical features, your training channel must point to an S3 prefix and not a specific CSV file. This file should contain a Python dictionary where the key is the string "cat_index_list" and the value is a list of unique integers. Each integer in the value list should indicate the column index of the corresponding categorical features in your training data CSV file. Each value should be a positive integer (greater than zero because zero represents the target value), less than the Int32.MaxValue (2147483647), and less than the total number of columns. There should only be one categorical index JSON file.

**Use only the training channel:**

You can alternatively provide your input data by way of a single S3 path for the training channel. This S3 path should point to a directory with a subdirectory named training/ that contains one or more CSV files. You can optionally include another subdirectory in the same location called validation/ that also has one or more CSV files. If the validation data is not provided, then 20% of your training data is randomly sampled to serve as the validation data. If your predictors include categorical features, you can provide a JSON file named categorical_index.json in the same location as your data subdirectories.

**Note**

For CSV training input mode, the total memory available to the algorithm (instance count multiplied by the memory available in the InstanceType) must be able to hold the training dataset.

SageMaker AutoGluon-Tabular uses the autogluon.tabular.TabularPredictor module to serialize or deserialize the model, which can be used for saving or loading the model.

**To use a model trained with SageMaker AutoGluon-Tabular with the AutoGluon framework**

- Use the following Python code:

```python
import tarfile
from autogluon.tabular import TabularPredictor

t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()

model = TabularPredictor.load(model_file_path)

# prediction with test data
# dtest should be a pandas DataFrame with column names feature_0, feature_1, ..., feature_d
pred = model.predict(dtest)
```
Amazon EC2 instance recommendation for the AutoGluon-Tabular algorithm

SageMaker AutoGluon-Tabular supports single-instance CPU and single-instance GPU training. Despite higher per-instance costs, GPUs train more quickly, making them more cost effective. To take advantage of GPU training, specify the instance type as one of the GPU instances (for example, P3). SageMaker AutoGluon-Tabular currently does not support multi-GPU training.

AutoGluon-Tabular sample notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker AutoGluon-Tabular algorithm.

<table>
<thead>
<tr>
<th>Notebook Title</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tabular classification with Amazon SageMaker AutoGluon-Tabular algorithm</td>
<td>This notebook demonstrates the use of the Amazon SageMaker AutoGluon-Tabular algorithm to train and host a tabular classification model.</td>
</tr>
<tr>
<td>Tabular regression with Amazon SageMaker AutoGluon-Tabular algorithm</td>
<td>This notebook demonstrates the use of the Amazon SageMaker AutoGluon-Tabular algorithm to train and host a tabular regression model.</td>
</tr>
</tbody>
</table>

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances (p. 298). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all of the SageMaker samples. To open a notebook, choose its Use tab and choose Create copy.

How AutoGluon-Tabular works

AutoGluon-Tabular performs advanced data processing, deep learning, and multi-layer model ensemble methods. It automatically recognizes the data type in each column for robust data preprocessing, including special handling of text fields.

AutoGluon fits various models ranging from off-the-shelf boosted trees to customized neural networks. These models are ensembled in a novel way: models are stacked in multiple layers and trained in a layer-wise manner that guarantees raw data can be translated into high-quality predictions within a given time constraint. This process mitigates overfitting by splitting the data in various ways with careful tracking of out-of-fold examples.

The AutoGluon-Tabular algorithm performs well in machine learning competitions because of its robust handling of a variety of data types, relationships, and distributions. You can use AutoGluon-Tabular for regression, classification (binary and multiclass), and ranking problems.

Refer to the following diagram illustrating how the multi-layer stacking strategy works.
AutoGluon-Tabular hyperparameters

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker AutoGluon-Tabular algorithm. Users set these parameters to facilitate the estimation of model parameters from data. The SageMaker AutoGluon-Tabular algorithm is an implementation of the open-source AutoGluon-Tabular package.

**Note**

The default hyperparameters are based on example datasets in the AutoGluon-Tabular sample notebooks (p. 1552).

By default, the SageMaker AutoGluon-Tabular algorithm automatically chooses an evaluation metric based on the type of classification problem. The algorithm detects the type of classification problem based on the number of labels in your data. For regression problems, the evaluation metric is root mean squared error. For binary classification problems, the evaluation metric is area under the receiver operating characteristic curve (AUC). For multiclass classification problems, the evaluation metric is accuracy. You can use the eval_metric hyperparameter to change the default evaluation metric. Refer to the following table for more information on AutoGluon-Tabular hyperparameters, including descriptions, valid values, and default values.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>

</tbody>
</table>
| **presets** | List of preset configurations for various arguments in fit().
| | - "best_quality": high predictive accuracy, slower inference times and higher disk usage
| | - "high_quality": high predictive accuracy and fast inference
| | - "good_quality": good predictive accuracy and very fast inference
| | - "medium_quality": medium predictive accuracy, very fast inference and training time
| | - "optimize_for_deployment": delete unused models and remove training artifacts
| | - "interpretable": fits only interpretable rule-based models from the imodels package
| | For more details, see AutoGluon Predictors.
| | Valid values: string, any of the following: ("best_quality", "high_quality", "good_quality", "medium_quality", "optimize_for_deployment", or "interpretable").
| | Default value: "medium_quality".
| **auto_stack** | Whether AutoGluon should automatically utilize bagging and multi-layer stack ensembling to boost predictive accuracy. Set auto_stack to "True" if you are willing to tolerate longer training times in order to maximize predictive accuracy. This automatically sets the num_bag_folds and num_stack_levels arguments based on dataset properties.
| | Valid values: string, "True" or "False".
| | Default value: "False".
| **num_bag_folds** | Number of folds used for bagging of models. When num_bag_folds is equal to k, training time is roughly increased by a factor of k. Set num_bag_folds to 0 to deactivate bagging. This is disabled by default, but we recommend using values between 5 and 10 to maximize predictive performance. Increasing num_bag_folds results in models with lower bias, but that are more prone to overfitting. One is an invalid value for this parameter, and will raise a ValueError. Values greater than 10 may produce diminishing returns and can even harm overall results due to overfitting. To further improve predictions, avoid increasing num_bag_folds and instead increase num_bag_sets.
| | Valid values: string, any integer between (and including) "0" and "10".
<p>| | Default value: &quot;0&quot;. |</p>
<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_bag_sets</td>
<td>Number of repeats of kfold bagging to perform (values must be greater than or equal to 1). The total number of models trained during bagging is equal to num_bag_folds * num_bag_sets. This parameter defaults to one if time_limit is not specified. This parameters is disabled if num_bag_folds is not specified. Values greater than one result in superior predictive performance, especially on smaller problems and with stacking enabled. Valid values: integer, range: [1, 20]. Default value: 1.</td>
</tr>
<tr>
<td>num_stack_levels</td>
<td>Number of stacking levels to use in stack ensemble. Roughly increases model training time by factor of num_stack_levels + 1. Set this parameter to 0 to deactivate stack ensembling. This parameter is deactivated by default, but we recommend using values between 1 and 3 to maximize predictive performance. To prevent overfitting and a ValueError, num_bag_folds must be greater than or equal to 2. Valid values: float, range: [0, 3]. Default value: 0.</td>
</tr>
<tr>
<td>refit_full</td>
<td>Whether or not to retrain all models on all of the data (training and validation) after the normal training procedure. For more details, see AutoGluon Predictors. Valid values: string, &quot;True&quot; or &quot;False&quot;. Default value: &quot;False&quot;.</td>
</tr>
<tr>
<td>set_best_to_refit_full</td>
<td>Whether or not to change the default model that the predictor uses for prediction. If set_best_to_refit_full is set to &quot;True&quot;, the default model changes to the model that exhibited the highest validation score as a result of refitting (activated by refit_full). Only valid if refit_full is set. Valid values: string, &quot;True&quot; or &quot;False&quot;. Default value: &quot;False&quot;.</td>
</tr>
<tr>
<td>save_space</td>
<td>Whether or not to reduce the memory and disk size of predictor by deleting auxiliary model files that aren't needed for prediction on new data. This has no impact on inference accuracy. We recommend setting save_space to &quot;True&quot; if the only goal is to use the trained model for prediction. Certain advanced functionality may no longer be available if save_space is set to &quot;True&quot;. Refer to the predictor.save_space() documentation for more details. Valid values: string, &quot;True&quot; or &quot;False&quot;. Default value: &quot;False&quot;.</td>
</tr>
</tbody>
</table>
### Use Built-in Algorithms

<table>
<thead>
<tr>

<th>Description</th>
</tr>
</thead>
</table>
| verbosity | The verbosity of print messages. `verbosity` levels range from 0 to 4, with higher levels corresponding to more detailed print statements. A `verbosity` of 0 suppresses warnings.  
Valid values: integer, any of the following: (0, 1, 2, 3, or 4).  
Default value: 2. |

#### Tuning an AutoGluon-Tabular model

Although AutoGluon-Tabular can be used with model tuning, its design can deliver good performance using stacking and ensemble methods, meaning hyperparameter optimization is not necessary. Rather than focusing on model tuning, AutoGluon-Tabular succeeds by stacking models in multiple layers and training in a layer-wise manner.

For more information about AutoGluon-Tabular hyperparameters, see [AutoGluon-Tabular hyperparameters](p. 1553).

#### CatBoost

*CatBoost* is a popular and high-performance open-source implementation of the Gradient Boosting Decision Tree (GBDT) algorithm. GBDT is a supervised learning algorithm that attempts to accurately predict a target variable by combining an ensemble of estimates from a set of simpler and weaker models.

CatBoost introduces two critical algorithmic advances to GBDT:

1. The implementation of ordered boosting, a permutation-driven alternative to the classic algorithm
2. An innovative algorithm for processing categorical features

Both techniques were created to fight a prediction shift caused by a special kind of target leakage present in all currently existing implementations of gradient boosting algorithms.

#### How to use SageMaker CatBoost

You can use CatBoost as an Amazon SageMaker built-in algorithm. The following section describes how to use CatBoost with the SageMaker Python SDK. For information on how to use CatBoost from the Amazon SageMaker Studio UI, see [SageMaker JumpStart](p. 161).

- **Use CatBoost as a built-in algorithm**

Use the CatBoost built-in algorithm to build a CatBoost training container as shown in the following code example. You can automatically spot the CatBoost built-in algorithm image URI using the SageMaker `image_uris.retrieve` API (or the `get_image_uri` API if using Amazon SageMaker Python SDK version 2).

After specifying the CatBoost image URI, you can use the CatBoost container to construct an estimator using the SageMaker Estimator API and initiate a training job. The CatBoost built-in algorithm runs in script mode, but the training script is provided for you and there is no need to replace it. If you have extensive experience using script mode to create a SageMaker training job, then you can incorporate your own CatBoost training scripts.

```python
from sagemaker import image_uris, model_uris, script_uris
```
train_model_id, train_model_version, train_scope = "catboost-classification-model", "*", "training"
training_instance_type = "ml.m5.xlarge"

# Retrieve the docker image
train_image_uri = image_uris.retrieve(
    region=None,
    framework=None,
    model_id=train_model_id,
    model_version=train_model_version,
    image_scope=train_scope,
    instance_type=training_instance_type
)

# Retrieve the training script
train_source_uri = script_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version, script_scope=train_scope
)

train_model_uri = model_uris.retrieve(

For more information about how to set up CatBoost as a built-in algorithm, see the following notebook examples.

- Tabular classification with Amazon SageMaker LightGBM and CatBoost algorithm
- Tabular regression with Amazon SageMaker LightGBM and CatBoost algorithm

## Input and Output interface for the CatBoost algorithm

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of CatBoost supports CSV for training and inference:

- For **Training ContentType**, valid inputs must be `text/csv`.
- For **Inference ContentType**, valid inputs must be `text/csv`.

**Note**

For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record.

For CSV inference, the algorithm assumes that CSV input does not have the label column.

### Input format for training data, validation data, and categorical features

Be mindful of how to format your training data for input to the CatBoost model. You must provide the path to an Amazon S3 bucket that contains your training and validation data. You can also include a list of categorical features. Use both the training and validation channels to provide your input data. Alternatively, you can use only the training channel.

**Use both the training and validation channels**

You can provide your input data by way of two S3 paths, one for the training channel and one for the validation channel. Each S3 path can either be an S3 prefix that points to one or more CSV files or a full S3 path pointing to one specific CSV file. The target variables should be in the first column of your CSV file. The predictor variables (features) should be in the remaining columns. If multiple CSV files are provided for the training or validation channels, the CatBoost algorithm concatenates the files. The validation data is used to compute a validation score at the end of each boosting iteration. Early stopping is applied when the validation score stops improving.

If your predictors include categorical features, you can provide a JSON file named `categorical_index.json` in the same location as your training data file or files. If you provide a JSON file for categorical features, your training channel must point to an S3 prefix and not a specific CSV file. This file should contain a Python dictionary where the key is the string "cat_index_list" and the value is a list of unique integers. Each integer in the value list should indicate the column index of the corresponding categorical features in your training data CSV file. Each value should be a positive integer (greater than zero because zero represents the target value), less than the `Int32.MaxValue` (2147483647), and less than the total number of columns. There should only be one categorical index JSON file.
Use only the training channel:

You can alternatively provide your input data by way of a single S3 path for the training channel. This S3 path should point to a directory with a subdirectory named `training/` that contains one or more CSV files. You can optionally include another subdirectory in the same location called `validation/` that also has one or more CSV files. If the validation data is not provided, then 20% of your training data is randomly sampled to serve as the validation data. If your predictors include categorical features, you can provide a JSON file named `categorical_index.json` in the same location as your data subdirectories.

Note
For CSV training input mode, the total memory available to the algorithm (instance count multiplied by the memory available in the `InstanceType`) must be able to hold the training dataset.

SageMaker CatBoost uses the `catboost.CatBoostClassifier` and `catboost.CatBoostRegressor` modules to serialize or deserialize the model, which can be used for saving or loading the model.

To use a model trained with SageMaker CatBoost with `catboost`

- Use the following Python code:

```python
import tarfile
from catboost import CatBoostClassifier
t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()

file_path = os.path.join(model_file_path, "model")
model = CatBoostClassifier()
model.load_model(file_path)

# prediction with test data
# dtest should be a pandas DataFrame with column names feature_0, feature_1, ..., feature_d
pred = model.predict(dtest)
```

Amazon EC2 instance recommendation for the CatBoost algorithm

SageMaker CatBoost currently only trains using CPUs. CatBoost is a memory-bound (as opposed to compute-bound) algorithm. So, a general-purpose compute instance (for example, M5) is a better choice than a compute-optimized instance (for example, C5). Further, we recommend that you have enough total memory in selected instances to hold the training data.

CatBoost sample notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker CatBoost algorithm.

</tr>
</tbody>
</table>
For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances (p. 298). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all of the SageMaker samples. To open a notebook, choose its Use tab and choose Create copy.

How CatBoost Works

CatBoost implements a conventional Gradient Boosting Decision Tree (GBDT) algorithm with the addition of two critical algorithmic advances:

1. The implementation of ordered boosting, a permutation-driven alternative to the classic algorithm
2. An innovative algorithm for processing categorical features

Both techniques were created to fight a prediction shift caused by a special kind of target leakage present in all currently existing implementations of gradient boosting algorithms.

The CatBoost algorithm performs well in machine learning competitions because of its robust handling of a variety of data types, relationships, distributions, and the diversity of hyperparameters that you can fine-tune. You can use CatBoost for regression, classification (binary and multiclass), and ranking problems.

For more information on gradient boosting, see How XGBoost Works (p. 1624). For in-depth details about the additional GOSS and EFB techniques used in the CatBoost method, see CatBoost: unbiased boosting with categorical features.

CatBoost hyperparameters

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker CatBoost algorithm. Users set these parameters to facilitate the estimation of model parameters from data. The SageMaker CatBoost algorithm is an implementation of the open-source CatBoost package.

Note The default hyperparameters are based on example datasets in the CatBoost sample notebooks (p. 1559).

By default, the SageMaker CatBoost algorithm automatically chooses an evaluation metric and loss function based on the type of classification problem. The CatBoost algorithm detects the type of classification problem based on the number of labels in your data. For regression problems, the evaluation metric and loss functions are both root mean squared error. For binary classification problems, the evaluation metric is Area Under the Curve (AUC) and the loss function is log loss. For multiclass classification problems, the evaluation metric and loss functions are multiclass cross entropy.

You can use the eval_metric hyperparameter to change the default evaluation metric. Refer to the following table for more information on LightGBM hyperparameters, including descriptions, valid values, and default values.

| **grow_policy** | The tree growing policy. Defines how to perform greedy tree construction.  
Valid values: string, any of the following: ("SymmetricTree", "Depthwise", or "Lossguide").  
Default value: "SymmetricTree". |
| **random_seed** | The random seed used for training.  
Valid values: integer, range: Non-negative integer.  
Default value: 1.0. |
| **thread_count** | The number of threads to use during the training. If thread_count is -1, then the number of threads is equal to the number of processor cores. thread_count cannot be 0.  
Valid values: integer, either: (-1 or positive integer).  
Default value: -1. |
| **verbose** | The verbosity of print messages, with higher levels corresponding to more detailed print statements.  
Valid values: integer, range: Positive integer.  
Default value: 1. |

**Tune a CatBoost model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. Model tuning focuses on the following hyperparameters:

**Note**
The learning loss function is automatically assigned based on the type of classification task, which is determined by the number of unique integers in the label column. For more information, see [CatBoost hyperparameters](#).

- A learning loss function to optimize during model training  
- An evaluation metric that is used to evaluate model performance during validation  
- A set of hyperparameters and a range of values for each to use when tuning the model automatically

Automatic model tuning searches your chosen hyperparameters to find the combination of values that results in a model that optimizes the chosen evaluation metric.

**Note**
Automatic model tuning for CatBoost is only available from the Amazon SageMaker SDKs, not from the SageMaker console.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](#).
Evaluation metrics computed by the CatBoost algorithm

The SageMaker CatBoost algorithm computes the following metrics to use for model validation. The evaluation metric is automatically assigned based on the type of classification task, which is determined by the number of unique integers in the label column.

Factorization Machines Algorithm

The Factorization Machines algorithm is a general-purpose supervised learning algorithm that you can use for both classification and regression tasks. It is an extension of a linear model that is designed to capture interactions between features within high dimensional sparse datasets economically. For example, in a click prediction system, the Factorization Machines model can capture click rate patterns observed when ads from a certain ad-category are placed on pages from a certain page-category. Factorization machines are a good choice for tasks dealing with high dimensional sparse datasets, such as click prediction and item recommendation.

Note
The Amazon SageMaker implementation of the Factorization Machines algorithm considers only pair-wise (2nd order) interactions between features.

Topics
- Input/Output Interface for the Factorization Machines Algorithm (p. 1565)
- EC2 Instance Recommendation for the Factorization Machines Algorithm (p. 1566)
- Factorization Machines Sample Notebooks (p. 1566)
- How Factorization Machines Work (p. 1566)
- Factorization Machines Hyperparameters (p. 1567)
- Tune a Factorization Machines Model (p. 1572)
- Factorization Machines Response Formats (p. 1573)

Input/Output Interface for the Factorization Machines Algorithm

The Factorization Machines algorithm can be run in either in binary classification mode or regression mode. In each mode, a dataset can be provided to the test channel along with the train channel dataset. The scoring depends on the mode used. In regression mode, the testing dataset is scored using Root Mean Square Error (RMSE). In binary classification mode, the test dataset is scored using Binary Cross Entropy (Log Loss), Accuracy (at threshold=0.5) and F1 Score (at threshold =0.5).

For training, the Factorization Machines algorithm currently supports only the recordIO-protoBuf format with float32 tensors. Because their use case is predominantly on sparse data, CSV is not a good candidate. Both File and Pipe mode training are supported for recordIO-wrapped protobuf.

For inference, the Factorization Machines algorithm supports the application/json and x-recordio-protobuf formats.

- For the binary classification problem, the algorithm predicts a score and a label. The label is a number and can be either 0 or 1. The score is a number that indicates how strongly the algorithm believes that the label should be 1. The algorithm computes score first and then derives the label from the score value. If the score is greater than or equal to 0.5, the label is 1.
- For the regression problem, just a score is returned and it is the predicted value. For example, if Factorization Machines is used to predict a movie rating, score is the predicted rating value.

Please see Factorization Machines Sample Notebooks (p. 1566) for more details on training and inference file formats.

EC2 Instance Recommendation for the Factorization Machines Algorithm

The Amazon SageMaker Factorization Machines algorithm is highly scalable and can train across distributed instances. We recommend training and inference with CPU instances for both sparse and dense datasets. In some circumstances, training with one or more GPUs on dense data might provide some benefit. Training with GPUs is available only on dense data. Use CPU instances for sparse data. The Factorization Machines algorithm supports P2, P3, G4dn, and G5 instances for training and inference.

Factorization Machines Sample Notebooks

For a sample notebook that uses the SageMaker Factorization Machines algorithm to analyze the images of handwritten digits from zero to nine in the MNIST dataset, see An Introduction to Factorization Machines with MNIST. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances (p. 298). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. Example notebooks that use Factorization Machines algorithm are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

How Factorization Machines Work

The prediction task for a Factorization Machines model is to estimate a function \( \hat{y} \) from a feature set \( x_i \) to a target domain. This domain is real-valued for regression and binary for classification. The Factorization Machines model is supervised and so has a training dataset \((x_i, y_j)\) available. The advantages this model presents lie in the way it uses a factorized parametrization to capture the pairwise feature interactions. It can be represented mathematically as follows:

\[
\hat{y} = w_0 + \sum_i w_i x_i + \sum_i \sum_{j > i} <v_i, v_j > x_i x_j
\]

The three terms in this equation correspond respectively to the three components of the model:

- The \( w_0 \) term represents the global bias.
- The \( w_i \) linear terms model the strength of the \( i^{th} \) variable.
- The \( <v_i, v_j> \) factorization terms model the pairwise interaction between the \( i^{th} \) and \( j^{th} \) variable.

The global bias and linear terms are the same as in a linear model. The pairwise feature interactions are modeled in the third term as the inner product of the corresponding factors learned for each feature. Learned factors can also be considered as embedding vectors for each feature. For example, in a classification task, if a pair of features tends to co-occur more often in positive labeled samples, then the inner product of their factors would be large. In other words, their embedding vectors would be close to each other in cosine similarity. For more information about the Factorization Machines model, see Factorization Machines.

For regression tasks, the model is trained by minimizing the squared error between the model prediction \( \hat{y}_n \) and the target value \( y_n \). This is known as the square loss:

\[
L = \frac{1}{N} \sum_n (y_n - \hat{y}_n)^2
\]

For a classification task, the model is trained by minimizing the cross entropy loss, also known as the log loss:

\[
L = \frac{1}{N} \sum_n [y_n \log \hat{p}_n + (1 - y_n) \log (1 - \hat{p}_n)]
\]
where:
\[ \hat{p}_n = \frac{1}{1 + e^{-y_n}} \]

For more information about loss functions for classification, see Loss functions for classification.

Factorization Machines Hyperparameters

The following table contains the hyperparameters for the Factorization Machines algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order.

Tune a Factorization Machines Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1863).

Metrics Computed by the Factorization Machines Algorithm

The Factorization Machines algorithm has both binary classification and regression predictor types. The predictor type determines which metric you can use for automatic model tuning. The algorithm reports a test:rmse regressor metric, which is computed during training. When tuning the model for regression tasks, choose this metric as the objective.

Tunable Factorization Machines Hyperparameters

You can tune the following hyperparameters for the Factorization Machines algorithm. The initialization parameters that contain the terms bias, linear, and factorization depend on their initialization method. There are three initialization methods: uniform, normal, and constant. These initialization methods are not themselves tunable. The parameters that are tunable are dependent on this choice of the initialization method. For example, if the initialization method is uniform, then only the scale parameters are tunable. Specifically, if bias_init_method==uniform, then bias_init_scale, linear_init_scale, and factors_init_scale are tunable. Similarly, if the initialization method is normal, then only sigma parameters are tunable. If the initialization method is constant, then only value parameters are tunable. These dependencies are listed in the following table.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Parameter Type</th>
<th>Recommended Ranges</th>
<th>Dependency</th>
</tr>
</thead>
<tbody>
<tr>
<td>bias_init_scale</td>

### Factorization Machines Response Formats

#### JSON Response Format

**Binary classification**

```javascript
let response = {
  "predictions": [
    {
      "score": 0.4,
      "predicted_label": 0
    }
  ]
}  
```
Regression

```json
let response = {
  "predictions": [
    {
      "score": 0.4
    }
  ]
}
```

**JSONLINES Response Format**

Binary classification

```json
{"score": 0.4, "predicted_label": 0}
```

Regression

```json
{"score": 0.4}
```

**RECORDIO Response Format**

Binary classification

```json
[ Record = {
    features = {},
    label = {
      'score': {
        keys: [],
        values: [0.4]  # float32
      },
      'predicted_label': {
        keys: [],
        values: [0.0]  # float32
      }
    }
  }
]
```

Regression

```json
[ Record = {
    features = {},
    label = {
      'score': {
        keys: [],
        values: [0.4]  # float32
      }
    }
  }
]```
K-Nearest Neighbors (k-NN) Algorithm

Amazon SageMaker k-nearest neighbors (k-NN) algorithm is an index-based algorithm. It uses a non-parametric method for classification or regression. For classification problems, the algorithm queries the \( k \) points that are closest to the sample point and returns the most frequently used label of their class as the predicted label. For regression problems, the algorithm queries the \( k \) closest points to the sample point and returns the average of their feature values as the predicted value.

Training with the k-NN algorithm has three steps: sampling, dimension reduction, and index building. Sampling reduces the size of the initial dataset so that it fits into memory. For dimension reduction, the algorithm decreases the feature dimension of the data to reduce the footprint of the k-NN model in memory and inference latency. We provide two methods of dimension reduction methods: random projection and the fast Johnson-Lindenstrauss transform. Typically, you use dimension reduction for high-dimensional (d >1000) datasets to avoid the “curse of dimensionality” that troubles the statistical analysis of data that becomes sparse as dimensionality increases. The main objective of k-NN's training is to construct the index. The index enables efficient lookups of distances between points whose values or class labels have not yet been determined and the k nearest points to use for inference.

Input/Output Interface for the k-NN Algorithm

SageMaker k-NN supports train and test data channels.

- Use a train channel for data that you want to sample and construct into the k-NN index.
- Use a test channel to emit scores in log files. Scores are listed as one line per mini-batch: accuracy for classifier, mean-squared error (mse) for regressor for score.

For training inputs, k-NN supports text/csv and application/x-recordio-protobuf data formats. For input type text/csv, the first label_size columns are interpreted as the label vector for that row. You can use either File mode or Pipe mode to train models on data that is formatted as recordIO-wrapped-protobuf or as CSV.

For inference inputs, k-NN supports the application/json, application/x-recordio-protobuf, and text/csv data formats. The text/csv format accepts a label_size and encoding parameter. It assumes a label_size of 0 and a UTF-8 encoding.

For inference outputs, k-NN supports the application/json and application/x-recordio-protobuf data formats. These two data formats also support a verbose output mode. In verbose output mode, the API provides the search results with the distances vector sorted from smallest to largest, and corresponding elements in the labels vector.

For batch transform, k-NN supports the application/jsonlines data format for both input and output. An example input is as follows:

```
content-type: application/jsonlines
```
Use a Jupyter notebook instance to run the example in SageMaker. To learn how to create and open a Jupyter notebook instance in SageMaker, see Amazon SageMaker Notebook Instances (p. 298). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker example notebooks. Find K-Nearest Neighbor notebooks in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

How the k-NN Algorithm Works

Step 1: Sample

To specify the total number of data points to be sampled from the training dataset, use the sample_size parameter. For example, if the initial dataset has 1,000 data points and the sample_size is set to 100, where the total number of instances is 2, each worker would sample 50 points. A total set of 100 data points would be collected. Sampling runs in linear time with respect to the number of data points.

Step 2: Perform Dimension Reduction

The current implementation of the k-NN algorithm has two methods of dimension reduction. You specify the method in the dimension_reduction_type hyperparameter. The sign method specifies a random projection, which uses a linear projection using a matrix of random signs, and the fjlt method specifies a fast Johnson-Lindenstrauss transform, a method based on the Fourier transform. Both methods preserve the L2 and inner product distances. The fjlt method should be used when the target dimension is large and has better performance with CPU inference. The methods differ in their computational complexity. The sign method requires O(ndk) time to reduce the dimension of a batch of n points of dimension d into a target dimension k. The fjlt method requires O(nd log(d)) time, but the constants involved are larger. Using dimension reduction introduces noise into the data and this noise can reduce prediction accuracy.

Step 3: Build an Index

During inference, the algorithm queries the index for the k-nearest-neighbors of a sample point. Based on the references to the points, the algorithm makes the classification or regression prediction. It makes the prediction based on the class labels or values provided. k-NN provides three different types of indexes: a flat index, an inverted index, and an inverted index with product quantization. You specify the type with the index_type parameter.

Serialize the Model

When the k-NN algorithm finishes training, it serializes three files to prepare for inference.

- model_algo-1: Contains the serialized index for computing the nearest neighbors.
• `model_algo-1.labels`: Contains serialized labels (np.float32 binary format) for computing the predicted label based on the query result from the index.

• `model_algo-1.json`: Contains the JSON-formatted model metadata which stores the k and `predictor_type` hyper-parameters from training for inference along with other relevant state.

With the current implementation of k-NN, you can modify the metadata file to change the way predictions are computed. For example, you can change k to 10 or change `predictor_type` to `regressor`.

```json
{
  "k": 5,
  "predictor_type": "classifier",
  "dimension_reduction": {
    "type": "sign",
    "seed": 3,
    "target_dim": 10,
    "input_dim": 20
  },
  "normalize": False,
  "version": "1.0"
}
```

**EC2 Instance Recommendation for the k-NN Algorithm**

We recommend training on a CPU instance (such as ml.m5.2xlarge) or on a GPU instance. The k-NN algorithm supports P2, P3, G4dn, and G5 GPU instance families for training and inference.

Inference requests from CPUs generally have a lower average latency than requests from GPUs because there is a tax on CPU-to-GPU communication when you use GPU hardware. However, GPUs generally have higher throughput for larger batches.

Tune a k-NN Model

The Amazon SageMaker k-nearest neighbors algorithm is a supervised algorithm. The algorithm consumes a test data set and emits a metric about the accuracy for a classification task or about the mean squared error for a regression task. These accuracy metrics compare the model predictions for their respective task to the ground truth provided by the empirical test data. To find the best model that reports the highest accuracy or lowest error on the test dataset, run a hyperparameter tuning job for k-NN.

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric appropriate for the prediction task of the algorithm. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric. The hyperparameters are used only to help estimate model parameters and are not used by the trained model to make predictions.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 1863).

Metrics Computed by the k-NN Algorithm

The k-nearest neighbors algorithm computes one of two metrics in the following table during training depending on the type of task specified by the `predictor_type` hyper-parameter.

- `classifier` specifies a classification task and computes `test:accuracy`
- `regressor` specifies a regression task and computes `test:mse`.

Choose the `predictor_type` value appropriate for the type of task undertaken to calculate the relevant objective metric when tuning a model.

<table>
<thead>
<tr>

Data Formats for k-NN Training Input

All Amazon SageMaker built-in algorithms adhere to the common input training formats described in Common Data Formats - Training. This topic contains a list of the available input formats for the SageMaker k-nearest-neighbor algorithm.

CSV Data Format

content-type: text/csv; label_size=1

4,1.2,1.3,9.6,20.3

The first label_size columns are interpreted as the label vector for that row.

RECORDIO Data Format

content-type: application/x-recordio-protobuf

```json
[  
  Record = {
    features = {
      'values': {
        values: [1.2, 1.3, 9.6, 20.3] # float32
      }
    },
    label = {
      'values': {
        values: [4] # float32
      }
    }
  }
]
```

k-NN Request and Response Formats

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. This topic contains a list of the available output formats for the SageMaker k-nearest-neighbor algorithm.

INPUT: CSV Request Format

content-type: text/csv
This accepts a `label_size` or encoding parameter. It assumes a `label_size` of 0 and a utf-8 encoding.

**INPUT: JSON Request Format**
```
content-type: application/json

{
    "instances": [
        {
            "data": {
                "features": {
                    "values": [-3, -1, -4, 2]
                }
            },
            "features": [3.0, 0.1, 0.04, 0.002]
        }
    ]
}
```

**INPUT: JSONLINES Request Format**
```
content-type: application/jsonlines

{"features": [1.5, 16.0, 14.0, 23.0]}
{"data": {"features": {"values": [1.5, 16.0, 14.0, 23.0]}}}
```

**INPUT: RECORDIO Request Format**
```
content-type: application/x-recordio-protobuf

[
    Record = {

LightGBM

LightGBM is a popular and efficient open-source implementation of the Gradient Boosting Decision Tree (GBDT) algorithm. GBDT is a supervised learning algorithm that attempts to accurately predict a target variable by combining an ensemble of estimates from a set of simpler and weaker models. LightGBM uses additional techniques to significantly improve the efficiency and scalability of conventional GBDT.

How to use SageMaker LightGBM

You can use LightGBM as an Amazon SageMaker built-in algorithm. The following section describes how to use LightGBM with the SageMaker Python SDK. For information on how to use LightGBM from the Amazon SageMaker Studio UI, see SageMaker JumpStart (p. 161).

- **Use LightGBM as a built-in algorithm**

  Use the LightGBM built-in algorithm to build a LightGBM training container as shown in the following code example. You can automatically spot the LightGBM built-in algorithm image URI using the SageMaker image_uris.retrieve API (or the get_image_uri API if using Amazon SageMaker Python SDK version 2).

  After specifying the LightGBM image URI, you can use the LightGBM container to construct an estimator using the SageMaker Estimator API and initiate a training job. The LightGBM built-in algorithm runs in script mode, but the training script is provided for you and there is no need to replace it. If you have extensive experience using script mode to create a SageMaker training job, then you can incorporate your own LightGBM training scripts.
from sagemaker import image_uris, model_uris, script_uris

train_model_id, train_model_version, train_scope = "lightgbm-classification-model", "*", "training"
training_instance_type = "ml.m5.xlarge"

# Retrieve the docker image
train_image_uri = image_uris.retrieve(
    region=None,
    framework=None,
    model_id=train_model_id,
    model_version=train_model_version,
    image_scope=train_scope,
    instance_type=training_instance_type
)

# Retrieve the training script
train_source_uri = script_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version, script_scope=train_scope
)

train_model_uri = model_uris.retrieve(
    model_id=train_model_id, model_version=train_model_version, model_scope=train_scope
)

# Sample training data is available in this bucket
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/tabular_multiclass/"

training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}/train"
validation_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}/validation"

output_bucket = sess.default_bucket()
output_prefix = "jumpstart-example-tabular-training"
s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"

from sagemaker import hyperparameters

# Retrieve the default hyperparameters for training the model
hyperparameters = hyperparameters.retrieve_default(
    model_id=train_model_id, model_version=train_model_version
)

# [Optional] Override default hyperparameters with custom values
hyperparameters["num_boost_round"] = "500"
print(hyperparameters)

from sagemaker.estimator import Estimator
from sagemaker import utils

training_job_name = name_from_base(f"built-in-algo-{train_model_id}-training")

# Create SageMaker Estimator instance
tabular_estimator = Estimator(
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
instance_count=1, # for distributed training, specify an instance_count greater than
1
instance_type=training_instance_type,
max_run=360000,
hyperparameters=hyperparameters,
output_path=s3_output_location
}

# Launch a SageMaker Training job by passing the S3 path of the training data
tabular_estimator.fit(
{
    "train": training_dataset_s3_path,
    "validation": validation_dataset_s3_path,
}, logs=True, job_name=training_job_name
)

For more information about how to set up the LightGBM as a built-in algorithm, see the following notebook examples.

- Tabular classification with Amazon SageMaker LightGBM and CatBoost algorithm
- Tabular regression with Amazon SageMaker LightGBM and CatBoost algorithm

Input and Output interface for the LightGBM algorithm

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of LightGBM supports CSV for training and inference:

- For **Training ContentType**, valid inputs must be `text/csv`.
- For **Inference ContentType**, valid inputs must be `text/csv`.

**Note**
For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record.
For CSV inference, the algorithm assumes that CSV input does not have the label column.

Input format for training data, validation data, and categorical features

Be mindful of how to format your training data for input to the LightGBM model. You must provide the path to an Amazon S3 bucket that contains your training and validation data. You can also include a list of categorical features. Use both the **train** and validation channels to provide your input data. Alternatively, you can use only the **train** channel.

**Note**
Both **train** and training are valid channel names for LightGBM training.

Use both the train and validation channels

You can provide your input data by way of two S3 paths, one for the **train** channel and one for the validation channel. Each S3 path can either be an S3 prefix that points to one or more CSV files or a full S3 path pointing to one specific CSV file. The target variables should be in the first column of your CSV file. The predictor variables (features) should be in the remaining columns. If multiple CSV files are provided for the **train** or validation channels, the LightGBM algorithm concatenates the files. The validation data is used to compute a validation score at the end of each boosting iteration. Early stopping is applied when the validation score stops improving.

If your predictors include categorical features, you can provide a JSON file named `categorical_index.json` in the same location as your training data file or files. If you provide a
JSON file for categorical features, your train channel must point to an S3 prefix and not a specific CSV file. This file should contain a Python dictionary where the key is the string "cat_index_list" and the value is a list of unique integers. Each integer in the value list should indicate the column index of the corresponding categorical features in your training data CSV file. Each value should be a positive integer (greater than zero because zero represents the target value), less than the "Int32.MaxValue" (2147483647), and less than the total number of columns. There should only be one categorical index JSON file.

Use only the train channel:

You can alternatively provide your input data by way of a single S3 path for the train channel. This S3 path should point to a directory with a subdirectory named train/ that contains one or more CSV files. You can optionally include another subdirectory in the same location called validation/ that also has one or more CSV files. If the validation data is not provided, then 20% of your training data is randomly sampled to serve as the validation data. If your predictors include categorical features, you can provide a JSON file named categorical_index.json in the same location as your data subdirectories.

Note
For CSV training input mode, the total memory available to the algorithm (instance count multiplied by the memory available in the InstanceType) must be able to hold the training dataset.

SageMaker LightGBM uses the Python Joblib module to serialize or deserialize the model, which can be used for saving or loading the model.

To use a model trained with SageMaker LightGBM with the JobLib module

- Use the following Python code:

```python
import joblib
import tarfile
t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()
model = joblib.load(model_file_path)

# prediction with test data
# dtest should be a pandas DataFrame with column names feature_0, feature_1, ..., feature_d
pred = model.predict(dtest)
```

Amazon EC2 instance recommendation for the LightGBM algorithm

SageMaker LightGBM currently supports single-instance and multi-instance CPU training. For multi-instance CPU training (distributed training), specify an instance_count greater than 1 when you define your Estimator. For more information on distributed training with LightGBM, see Amazon SageMaker LightGBM Distributed training using Dask.

LightGBM is a memory-bound (as opposed to compute-bound) algorithm. So, a general-purpose compute instance (for example, M5) is a better choice than a compute-optimized instance (for example, C5). Further, we recommend that you have enough total memory in selected instances to hold the training data.

LightGBM sample notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker LightGBM algorithm.
### Tabular classification with Amazon SageMaker LightGBM and CatBoost algorithm

This notebook demonstrates the use of the Amazon SageMaker LightGBM algorithm to train and host a tabular classification model.

### Tabular regression with Amazon SageMaker LightGBM and CatBoost algorithm

This notebook demonstrates the use of the Amazon SageMaker LightGBM algorithm to train and host a tabular regression model.

### Amazon SageMaker LightGBM Distributed training using Dask

This notebook demonstrates distributed training with the Amazon SageMaker LightGBM algorithm using the Dask framework.

---

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see [Amazon SageMaker Notebook Instances](p. 298). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all of the SageMaker samples. To open a notebook, choose its Use tab and choose Create copy.

### How LightGBM works

LightGBM implements a conventional Gradient Boosting Decision Tree (GBDT) algorithm with the addition of two novel techniques: Gradient-based One-Side Sampling (GOSS) and Exclusive Feature Bundling (EFB). These techniques are designed to significantly improve the efficiency and scalability of GBDT.

The LightGBM algorithm performs well in machine learning competitions because of its robust handling of a variety of data types, relationships, distributions, and the diversity of hyperparameters that you can fine-tune. You can use LightGBM for regression, classification (binary and multiclass), and ranking problems.

For more information on gradient boosting, see [How XGBoost Works](p. 1624). For in-depth details about the additional GOSS and EFB techniques used in the LightGBM method, see *LightGBM: A Highly Efficient Gradient Boosting Decision Tree*.

### LightGBM hyperparameters

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker LightGBM algorithm. Users set these parameters to facilitate the estimation of model parameters from data. The SageMaker LightGBM algorithm is an implementation of the open-source LightGBM package.

#### Note

The default hyperparameters are based on example datasets in the LightGBM sample notebooks (p. 1586).

By default, the SageMaker LightGBM algorithm automatically chooses an evaluation metric and objective function based on the type of classification problem. The LightGBM algorithm detects the type of classification problem based on the number of labels in your data. For regression problems, the evaluation metric is root mean squared error and the objective function is L2 loss. For binary classification problems, the evaluation metric and objective function are both binary cross entropy. For multiclass classification problems, the evaluation metric is multiclass cross entropy and the objective function is softmax. You can use the `metric` hyperparameter to change the default evaluation metric. Refer to the following table for more information on LightGBM hyperparameters, including descriptions, valid values, and default values.
<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| num_boost_round            | The maximum number of boosting iterations. **Note:** Internally, LightGBM constructs `num_class * num_boost_round` trees for multi-class classification problems.  
  Valid values: integer, range: Positive integer.  
  Default value: 100.                        |
| early_stopping_rounds      | The training will stop if one metric of one validation data point does not improve in the last `early_stopping_rounds` round. If `early_stopping_rounds` is less than or equal to zero, this hyperparameter is ignored.  
  Valid values: integer.  
  Default value: 10.                          |
| metric                     | The evaluation metric for validation data. If `metric` is set to the default "auto" value, then the algorithm automatically chooses an evaluation metric based on the type of classification problem:  
  • rmse for regression  
  • binary_logloss for binary classification  
  • multi_logloss for multi-class classification  
  Valid values: string, any of the following: ("auto", "rmse", "l1", "l2", "huber", "fair", "binary_logloss", "binary_error", "auc", "average_precision", "multi_logloss", "multi_error", "auc_mu", or "cross_entropy").  
  Default value: "auto".                     |
| learning_rate              | The rate at which the model weights are updated after working through each batch of training examples.  
  Valid values: float, range: (0.0, 1.0).  
  Default value: 0.1.                         |
| num_leaves                 | The maximum number of leaves in one tree.  
  Valid values: integer, range: (1, 131072).  
  Default value: 64.                           |
| feature_fraction           | A subset of features to be selected on each iteration (tree). Must be less than 1.0.  
  Valid values: float, range: (0.0, 1.0).  
  Default value: 0.9.                          |
<p>| bagging_fraction           | A subset of features similar to <code>feature_fraction</code>, but <code>bagging_fraction</code> randomly selects part of the data without resampling.                                                                                                                                                  |</p>
<table>

</tbody>
</table>
| min_gain_to_split         | The minimum gain to perform a split. Can be used to speed up training.  
  Valid values: integer, float: Non-negative float.  
  Default value: 0.0. |
| scale_pos_weight          | The weight of the labels with positive class. Used only for binary classification tasks. scale_pos_weight cannot be used if is_unbalance is set to "True".  
  Valid values: float, range: Positive float.  
  Default value: 1.0. |
| tree_learner              | Tree learner type.  
  Valid values: string, any of the following: ("serial", "feature", "data", or "voting").  
  Default value: "serial". |
| feature_fraction_bynode   | Selects a subset of random features on each tree node. For example, if feature_fraction_bynode is 0.8, then 80% of features are selected. Can be used to deal with overfitting.  
  Valid values: integer, range: (0.0, 1.0].  
  Default value: 1.0. |
| is_unbalance              | Set to "True" if training data is unbalanced. Used only for binary classification tasks. is_unbalance cannot be used with scale_pos_weight.  
  Valid values: string, either: ("True" or "False").  
  Default value: "False". |
| max_bin                   | The maximum number of bins used to bucket feature values. A small number of bins may reduce training accuracy, but may increase general performance. Can be used to deal with overfitting.  
  Valid values: integer, range: (1, \(\infty\)).  
  Default value: 255. |
| tweedie_variance_power    | Controls the variance of the Tweedie distribution. Set this closer to 2.0 to shift toward a gamma distribution. Set this closer to 1.0 to shift toward a Poisson distribution. Used only for regression tasks.  
  Valid values: float, range: [1.0, 2.0].  
  Default value: 1.5. |
Parameter Name | Description
--- | ---
num_threads | Number of parallel threads used to run LightGBM. Value 0 means default number of threads in OpenMP.
| Valid values: integer, range: Non-negative integer.
| Default value: 0.

verbosity | The verbosity of print messages. If the verbosity is less than 0, then print messages only show fatal errors. If verbosity is set to 0, then print messages include errors and warnings. If verbosity is 1, then print messages show more information. A verbosity greater than 1 shows the most information in print messages and can be used for debugging.
| Valid values: integer.
| Default value: 1.

**Tune a LightGBM model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. Model tuning focuses on the following hyperparameters:

**Note**
The learning objective function is automatically assigned based on the type of classification task, which is determined by the number of unique integers in the label column. For more information, see [LightGBM hyperparameters](p. 1587).

- A learning objective function to optimize during model training
- An evaluation metric that is used to evaluate model performance during validation
- A set of hyperparameters and a range of values for each to use when tuning the model automatically

Automatic model tuning searches your specified hyperparameters to find the combination of values that results in a model that optimizes the chosen evaluation metric.

**Note**
Automatic model tuning for LightGBM is only available from the Amazon SageMaker SDKs, not from the SageMaker console.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 1863).

**Evaluation metrics computed by the LightGBM algorithm**

The SageMaker LightGBM algorithm computes the following metrics to use for model validation. The evaluation metric is automatically assigned based on the type of classification task, which is determined by the number of unique integers in the label column.

<table>

auc_mu | AUC-mu | maximize | "auc_mu: ([0-9\.]+)"
cross_entropy | cross entropy | minimize | "cross_entropy: ([0-9\.]+)"

### Tunable LightGBM hyperparameters
Tune the LightGBM model with the following hyperparameters. The hyperparameters that have the greatest effect on optimizing the LightGBM evaluation metrics are: learning_rate, num_leaves, feature_fraction, bagging_fraction, bagging_freq, max_depth and min_data_in_leaf. For a list of all the LightGBM hyperparameters, see [LightGBM hyperparameters](p. 1587).

Use Built-in Algorithms

### Linear Learner Algorithm

*Linear models* are supervised learning algorithms used for solving either classification or regression problems. For input, you give the model labeled examples \((x, y)\). \(x\) is a high-dimensional vector and \(y\) is a numeric label. For binary classification problems, the label must be either 0 or 1. For multiclass classification problems, the labels must be from 0 to \(\text{num_classes} - 1\). For regression problems, \(y\) is a real number. The algorithm learns a linear function, or, for classification problems, a linear threshold function, and maps a vector \(x\) to an approximation of the label \(y\).

The Amazon SageMaker linear learner algorithm provides a solution for both classification and regression problems. With the SageMaker algorithm, you can simultaneously explore different training objectives and choose the best solution from a validation set. You can also explore a large number of models and choose the best. The best model optimizes either of the following:

- Continuous objectives, such as mean square error, cross entropy loss, absolute error.
- Discrete objectives suited for classification, such as F1 measure, precision, recall, or accuracy.

Compared with methods that provide a solution for only continuous objectives, the SageMaker linear learner algorithm provides a significant increase in speed over naive hyperparameter optimization techniques. It is also more convenient.

The linear learner algorithm requires a data matrix, with rows representing the observations, and columns representing the dimensions of the features. It also requires an additional column that contains the labels that match the data points. At a minimum, Amazon SageMaker linear learner requires you to specify input and output data locations, and objective type (classification or regression) as arguments. The feature dimension is also required. For more information, see `CreateTrainingJob`. You can specify additional parameters in the `HyperParameters` string map of the request body. These parameters control the optimization procedure, or specifics of the objective function that you train on. For example, the number of epochs, regularization, and loss type.

If you’re using Managed Spot Training, the linear learner algorithm supports using checkpoints to take a snapshot of the state of the model.

Input/Output interface for the linear learner algorithm

The Amazon SageMaker linear learner algorithm supports three data channels: train, validation (optional), and test (optional). If you provide validation data, the S3DataDistributionType should be FullyReplicated. The algorithm logs validation loss at every epoch, and uses a sample of the validation data to calibrate and select the best model. If you don't provide validation data, the algorithm uses a sample of the training data to calibrate and select the model. If you provide test data, the algorithm logs include the test score for the final model.

For training, the linear learner algorithm supports both recordIO-wrapped protobuf and CSV formats. For the application/x-recordio-protobuf input type, only Float32 tensors are supported. For the text/csv input type, the first column is assumed to be the label, which is the target variable for prediction. You can use either File mode or Pipe mode to train linear learner models on data that is formatted as recordIO-wrapped-protobuf or as CSV.

For inference, the linear learner algorithm supports the application/json, application/x-recordio-protobuf, and text/csv formats. When you make predictions on new data, the format of the response depends on the type of model. For regression (predictor_type='regressor'), the score is the prediction produced by the model. For classification (predictor_type='binary_classifier' or predictor_type='multiclass_classifier'), the model returns a score and also a predicted_label. The predicted_label is the class predicted by the model and the score measures the strength of that prediction.

- For binary classification, predicted_label is 0 or 1, and score is a single floating point number that indicates how strongly the algorithm believes that the label should be 1.
- For multiclass classification, the predicted_class will be an integer from 0 to num_classes-1, and score will be a list of one floating point number per class.

To interpret the score in classification problems, you have to consider the loss function used. If the loss hyperparameter value is logistic for binary classification or softmax_loss for multiclass classification, then the score can be interpreted as the probability of the corresponding class. These are the loss values used by the linear learner when the loss value is auto default value. But if the loss is set to hinge_loss, then the score cannot be interpreted as a probability. This is because hinge loss corresponds to a Support Vector Classifier, which does not produce probability estimates.

For more information on input and output file formats, see Linear learner response formats (p. 1608). For more information on inference formats, and the Linear learner sample notebooks (p. 1594).

EC2 instance recommendation for the linear learner algorithm

The linear learner algorithm supports both CPU and GPU instances for training and inference. For GPU, the linear learner algorithm supports P2, P3, G4dn, and G5 GPU families.

During testing, we have not found substantial evidence that multi-GPU instances are faster than single-GPU instances. Results can vary, depending on your specific use case.

Linear learner sample notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker linear learner algorithm.

# Use Built-in Algorithms

## How to Build a Multiclass Classifier?

Using UCI's Covertype dataset, we demonstrate how to train a multiclass classifier.

## How to Build a Machine Learning (ML) Pipeline for Inference?

Using a Scikit-learn container, we demonstrate how to build an end-to-end ML pipeline.

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see [Amazon SageMaker Notebook Instances](p. 298). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all of the SageMaker samples. The topic modeling example notebooks using the linear learning algorithm are located in the Introduction to Amazon algorithms section. To open a notebook, choose its Use tab and choose Create copy.

### How linear learner works

There are three steps involved in the implementation of the linear learner algorithm: preprocess, train, and validate.

#### Step 1: Preprocess

Normalization, or feature scaling, is an important preprocessing step for certain loss functions that ensures the model being trained on a dataset does not become dominated by the weight of a single feature. The Amazon SageMaker Linear Learner algorithm has a normalization option to assist with this preprocessing step. If normalization is turned on, the algorithm first goes over a small sample of the data to learn the mean value and standard deviation for each feature and for the label. Each of the features in the full dataset is then shifted to have mean of zero and scaled to have a unit standard deviation.

**Note**

For best results, ensure your data is shuffled before training. Training with unshuffled data may cause training to fail.

You can configure whether the linear learner algorithm normalizes the feature data and the labels using the normalize_data and normalize_label hyperparameters, respectively. Normalization is enabled by default for both features and labels for regression. Only the features can be normalized for binary classification and this is the default behavior.

#### Step 2: Train

With the linear learner algorithm, you train with a distributed implementation of stochastic gradient descent (SGD). You can control the optimization process by choosing the optimization algorithm. For example, you can choose to use Adam, AdaGrad, stochastic gradient descent, or other optimization algorithms. You also specify their hyperparameters, such as momentum, learning rate, and the learning rate schedule. If you aren't sure which algorithm or hyperparameter value to use, choose a default that works for the majority of datasets.

During training, you simultaneously optimize multiple models, each with slightly different objectives. For example, you vary L1 or L2 regularization and try out different optimizer settings.

#### Step 3: Validate and set the threshold

When training multiple models in parallel, the models are evaluated against a validation set to select the most optimal model once training is complete. For regression, the most optimal model is the one that achieves the best loss on the validation set. For classification, a sample of the validation set is used to calibrate the classification threshold. The most optimal model selected is the one that achieves the best binary classification selection criteria on the validation set. Examples of such criteria include the F1 measure, accuracy, and cross-entropy loss.
Note
If the algorithm is not provided a validation set, then evaluating and selecting the most optimal model is not possible. To take advantage of parallel training and model selection ensure you provide a validation set to the algorithm.

Linear learner hyperparameters

The following table contains the hyperparameters for the linear learner algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order. When a hyperparameter is set to auto, Amazon SageMaker will automatically calculate and set the value of that hyperparameter.

</table>
| early_stopping_patience| If no improvement is made in the relevant metric, the number of epochs to wait before ending training. If you have provided a value for binary_classifier_model_selection_criteria, the metric is that value. Otherwise, the metric is the same as the value specified for the loss hyperparameter. The metric is evaluated on the validation data. If you haven't provided validation data, the metric is always the same as the value specified for the loss hyperparameter and is evaluated on the training data. To disable early stopping, set early_stopping_patience to a value greater than the value specified for epochs. **Optional**  
Valid values: Positive integer  
Default value: 3 |
| early_stopping_tolerance| The relative tolerance to measure an improvement in loss. If the ratio of the improvement in loss divided by the previous best loss is smaller than this value, early stopping considers the improvement to be zero. **Optional**  
Valid values: Positive floating-point integer  
Default value: 0.001 |
| epochs                 | The maximum number of passes over the training data. **Optional**  
Valid values: Positive integer  
Default value: 15 |
| f_beta                 | The value of beta to use when calculating F score metrics for binary or multiclass classification. Also used if the value specified for binary_classifier_model_selection_criteria is f_beta. **Optional**  
Valid values: Positive floating-point integers  
Default value: 1.0 |
| feature_dim            | The number of features in the input data. **Optional**  
Valid values: auto or positive integer  
Default values: auto |

</table>
| positive_example_weight_mult | The weight assigned to positive examples when training a binary classifier. The weight of negative examples is fixed at 1. If you want the algorithm to choose a weight so that errors in classifying negative vs. positive examples have equal impact on training loss, specify balanced. If you want the algorithm to choose the weight that optimizes performance, specify auto.  
  **Optional**  
  Valid values: balanced, auto, or a positive floating-point integer  
  Default value: 1.0                                                                                                                                                                                                                       |
| quantile         | The quantile for quantile loss. For quantile q, the model attempts to produce predictions so that the value of true_label is greater than the prediction with probability q.  
  **Optional**  
  Valid values: Floating-point integer between 0 and 1  
  Default value: 0.5                                                                                                                                                                                                                       |
| target_precision | The target precision. If binary_classifier_model_selection_criteria is recall_at_target_precision, then precision is held at this value while recall is maximized.  
  **Optional**  
  Valid values: Floating-point integer between 0 and 1.0  
  Default value: 0.8                                                                                                                                                                                                                       |
| target_recall    | The target recall. If binary_classifier_model_selection_criteria is precision_at_target_recall, then recall is held at this value while precision is maximized.  
  **Optional**  
  Valid values: Floating-point integer between 0 and 1.0  
  Default value: 0.8                                                                                                                                                                                                                       |
| unbias_data       | Unbiases the features before training so that the mean is 0. By default data is unbiased as the use_bias hyperparameter is set to true.  
  **Optional**  
  Valid values: auto, true, or false  
  Default value: auto                                                                                                                                                                                                                       |

  Default value: **auto** |

**Tune a linear learner model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

The linear learner algorithm also has an internal mechanism for tuning hyperparameters separate from the automatic model tuning feature described here. By default, the linear learner algorithm tunes hyperparameters by training multiple models in parallel. When you use automatic model tuning, the linear learner internal tuning mechanism is turned off automatically. This sets the number of parallel models, **num_models**, to 1. The algorithm ignores any value that you set for **num_models**.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 1863).

**Metrics computed by the linear learner algorithm**

The linear learner algorithm reports the metrics in the following table, which are computed during training. Choose one of them as the objective metric. To avoid overfitting, we recommend tuning the model against a validation metric instead of a training metric.
<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>test:absolute_loss</td>
<td>The absolute loss of the final model on the test dataset. This objective metric is only valid for regression.</td>
<td>Minimize</td>
</tr>
<tr>
<td>test:binary_classification</td>
<td>The accuracy of the final model on the test dataset. This objective metric is only valid for binary classification.</td>
<td>Maximize</td>
</tr>
<tr>
<td>test:binary_f_beta</td>
<td>The F-beta score of the final model on the test dataset. By default, it is the F1 score, which is the harmonic mean of precision and recall. This objective metric is only valid for binary classification.</td>
<td>Maximize</td>
</tr>

### Linear learner response formats

#### JSON response formats

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in [Common Data Formats - Inference](#). The following are the available output formats for the SageMaker linear learner algorithm.

#### Binary Classification

```json
let response = {
  "predictions": [
    {
      "score": 0.4,
      "predicted_label": 0
    }
  ]
}
```

#### Multiclass Classification

```json
let response = {
  "predictions": [
    {
      "score": [0.1, 0.2, 0.4, 0.3],
      "predicted_label": 2
    }
  ]
}
```

#### Regression

```json
let response = {
  "predictions": [
    {
      "score": 0.4
    }
  ]
}
```

### JSONLINES response formats

#### Binary Classification
Use Built-in Algorithms

Multiclass Classification

```
{"score": [0.1, 0.2, 0.4, 0.3], "predicted_label": 2}
```

Regression

```
{"score": 0.4}
```

**RECORDIO response formats**

**Binary Classification**

```
[  
  Record = {
    "features": [],
    "label": {
      "score": {
        "keys": [],
        "values": [0.4]  # float32
      },
      "predicted_label": {
        "keys": [],
        "values": [0.0]  # float32
      }
    }
  }
]
```

**Multiclass Classification**

```
[  
  Record = {
    "features": [],
    "label": {
      "score": {
        "values": [0.1, 0.2, 0.3, 0.4]
      },
      "predicted_label": {
        "values": [3]
      },
      "uid": "abc123",
      "metadata": "{created_at: '2017-06-03'}"
    }
  }
]
```

**Regression**

```
[  
  Record = {
    "features": [],
    "label": {
      "score": {
        "keys": [],
        "values": [0.4]  # float32
      }
    }
  }
]
```
TabTransformer

TabTransformer is a novel deep tabular data modeling architecture for supervised learning. The TabTransformer architecture is built on self-attention-based Transformers. The Transformer layers transform the embeddings of categorical features into robust contextual embeddings to achieve higher prediction accuracy. Furthermore, the contextual embeddings learned from TabTransformer are highly robust against both missing and noisy data features, and provide better interpretability.

How to use SageMaker TabTransformer

You can use TabTransformer as an Amazon SageMaker built-in algorithm. The following section describes how to use TabTransformer with the SageMaker Python SDK. For information on how to use TabTransformer from the Amazon SageMaker Studio UI, see SageMaker JumpStart (p. 161).

- Use TabTransformer as a built-in algorithm

Use the TabTransformer built-in algorithm to build a TabTransformer training container as shown in the following code example. You can automatically spot the TabTransformer built-in algorithm image URI using the SageMaker image_uris.retrieve API (or the get_image_uri API if using Amazon SageMaker Python SDK version 2).

After specifying the TabTransformer image URI, you can use the TabTransformer container to construct an estimator using the SageMaker Estimator API and initiate a training job. The TabTransformer built-in algorithm runs in script mode, but the training script is provided for you and there is no need to replace it. If you have extensive experience using script mode to create a SageMaker training job, then you can incorporate your own TabTransformer training scripts.

```python
from sagemaker import image_uris, model_uris, script_uris

train_model_id, train_model_version, train_scope = "pytorch-tabtransformerclassification-model", "*", "training"
training_instance_type = "ml.p3.2xlarge"

# Retrieve the docker image
train_image_uri = image_uris.retrieve(
    region=None,
    framework=None,
    model_id=train_model_id,
    model_version=train_model_version,
    image_scope=train_scope,
    instance_type=training_instance_type
)

# Retrieve the training script
train_source_uri = script_uris.retrieve(
    model_id=train_model_id,
    model_version=train_model_version,
    script_scope=train_scope
)

train_model_uri = model_uris.retrieve(
    model_id=train_model_id,
    model_version=train_model_version,
    model_scope=train_scope
)

# Sample training data is available in this bucket
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/tabular_binary/"
training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}/train"
```
validation_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}/validation"

output_bucket = sess.default_bucket()
output_prefix = "jumpstart-example-tabular-training"
s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"

from sagemaker import hyperparameters

# Retrieve the default hyperparameters for training the model
hyperparameters = hyperparameters.retrieve_default(
    model_id=train_model_id, model_version=train_model_version
)

# [Optional] Override default hyperparameters with custom values
hyperparameters['n_epochs'] = "50"

print(hyperparameters)

from sagemaker.estimator import Estimator
from sagemaker.utils import name_from_base

training_job_name = name_from_base(f"built-in-algo-{train_model_id}-training")

# Create SageMaker Estimator instance
tabular_estimator = Estimator(
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
    instance_count=1,
    instance_type=training_instance_type,
    max_run=360000,
    hyperparameters=hyperparameters,
    output_path=s3_output_location
)

# Launch a SageMaker Training job by passing the S3 path of the training data
tabular_estimator.fit(
    {
        "training": training_dataset_s3_path,
        "validation": validation_dataset_s3_path,
    }, logs=True, job_name=training_job_name
)

For more information about how to set up the TabTransformer as a built-in algorithm, see the following notebook examples.

- Tabular classification with Amazon SageMaker TabTransformer algorithm
- Tabular regression with Amazon SageMaker TabTransformer algorithm

**Input and Output interface for the TabTransformer algorithm**

TabTransformer operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of TabTransformer supports CSV for training and inference:

- For **Training ContentType**, valid inputs must be **text/csv**.
- For **Inference ContentType**, valid inputs must be **text/csv**.
Note
For CSV training, the algorithm assumes that the target variable is in the first column and that
the CSV does not have a header record.
For CSV inference, the algorithm assumes that CSV input does not have the label column.

Input format for training data, validation data, and categorical features

Be mindful of how to format your training data for input to the TabTransformer model. You must
provide the path to an Amazon S3 bucket that contains your training and validation data. You can also
include a list of categorical features. Use both the training and validation channels to provide your
input data. Alternatively, you can use only the training channel.

Use both the training and validation channels

You can provide your input data by way of two S3 paths, one for the training channel and one for the
validation channel. Each S3 path can either be an S3 prefix that points to one or more CSV files or a
full S3 path pointing to one specific CSV file. The target variables should be in the first column of your
CSV file. The predictor variables (features) should be in the remaining columns. If multiple CSV files are
provided for the training or validation channels, the TabTransformer algorithm concatenates the
files. The validation data is used to compute a validation score at the end of each boosting iteration.
Early stopping is applied when the validation score stops improving.

If your predictors include categorical features, you can provide a JSON file named
categorical_index.json in the same location as your training data file or files. If you provide a JSON
file for categorical features, your training channel must point to an S3 prefix and not a specific CSV
file. This file should contain a Python dictionary where the key is the string "cat_index_list" and
the value is a list of unique integers. Each integer in the value list should indicate the column index of
the corresponding categorical features in your training data CSV file. Each value should be a positive
integer (greater than zero because zero represents the target value), less than the Int32.MaxValue
(2147483647), and less than the total number of columns. There should only be one categorical index
JSON file.

Use only the training channel:

You can alternatively provide your input data by way of a single S3 path for the training channel. This
S3 path should point to a directory with a subdirectory named training/ that contains one or more
CSV files. You can optionally include another subdirectory in the same location called validation/ that
also has one or more CSV files. If the validation data is not provided, then 20% of your training data is
randomly sampled to serve as the validation data. If your predictors include categorical features, you can
provide a JSON file named categorical_index.json in the same location as your data subdirectories.

Note
For CSV training input mode, the total memory available to the algorithm (instance count
multiplied by the memory available in the InstanceType) must be able to hold the training
dataset.

Amazon EC2 instance recommendation for the TabTransformer algorithm

SageMaker TabTransformer supports single-instance CPU and single-instance GPU training. Despite
higher per-instance costs, GPUs train more quickly, making them more cost effective. To take advantage
of GPU training, specify the instance type as one of the GPU instances (for example, P3). SageMaker
TabTransformer currently does not support multi-GPU training.

TabTransformer sample notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon
SageMaker TabTransformer algorithm.
<table>
<thead>
<tr>
<th>Notebook Title</th>
<th>Description</th>

</tbody>
</table>

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances (p. 298). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all of the SageMaker samples. To open a notebook, choose its Use tab and choose Create copy.

**How TabTransformer works**

TabTransformer is a novel deep tabular data modeling architecture for supervised learning. The TabTransformer is built upon self-attention based Transformers. The Transformer layers transform the embeddings of categorical features into robust contextual embeddings to achieve higher prediction accuracy. Furthermore, the contextual embeddings learned from TabTransformer are highly robust against both missing and noisy data features, and provide better interpretability.

TabTransformer performs well in machine learning competitions because of its robust handling of a variety of data types, relationships, distributions, and the diversity of hyperparameters that you can fine-tune. You can use TabTransformer for regression, classification (binary and multiclass), and ranking problems.

The following diagram illustrates the TabTransformer architecture.
For more information, see TabTransformer: Tabular Data Modeling Using Contextual Embeddings.
TabTransformer hyperparameters

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker TabTransformer algorithm. Users set these parameters to facilitate the estimation of model parameters from data. The SageMaker TabTransformer algorithm is an implementation of the open-source TabTransformer package.

**Note**
The default hyperparameters are based on example datasets in the TabTransformer sample notebooks (p. 1612).

The SageMaker TabTransformer algorithm automatically chooses an evaluation metric and objective function based on the type of classification problem. The TabTransformer algorithm detects the type of classification problem based on the number of labels in your data. For regression problems, the evaluation metric is $r^2$ and the objective function is mean square error. For binary classification problems, the evaluation metric and objective function are both binary cross entropy. For multiclass classification problems, the evaluation metric and objective function are both multiclass cross entropy.

**Note**
The TabTransformer evaluation metric and objective functions are not currently available as hyperparameters. Instead, the SageMaker TabTransformer built-in algorithm automatically detects the type of classification task (regression, binary, or multiclass) based on the number of unique integers in the label column and assigns an evaluation metric and objective function.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>

Tune a TabTransformer model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. Model tuning focuses on the following hyperparameters:

- A learning objective function to optimize during model training
- An evaluation metric that is used to evaluate model performance during validation
- A set of hyperparameters and a range of values for each to use when tuning the model automatically

Automatic model tuning searches your chosen hyperparameters to find the combination of values that results in a model that optimizes the chosen evaluation metric.

**Note**

Automatic model tuning for TabTransformer is only available from the Amazon SageMaker SDKs, not from the SageMaker console.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1863).

Evaluation metrics computed by the TabTransformer algorithm

The SageMaker TabTransformer algorithm computes the following metrics to use for model validation. The evaluation metric is automatically assigned based on the type of classification task, which is determined by the number of unique integers in the label column.

<table>

$accuracy\_score$ | multiclass cross entropy | maximize | "metrics='accuracy': (\S+)"

**Tunable TabTransformer hyperparameters**

Tune the TabTransformer model with the following hyperparameters. The hyperparameters that have the greatest effect on optimizing the TabTransformer evaluation metrics are: `learning_rate`, `input_dim`, `n_blocks`, `attn_dropout`, `mlp_dropout`, and `frac_shared_embed`. For a list of all the TabTransformer hyperparameters, see [TabTransformer hyperparameters](p. 1615).

**XGBoost Algorithm**

The **XGBoost** (eXtreme Gradient Boosting) is a popular and efficient open-source implementation of the gradient boosted trees algorithm. Gradient boosting is a supervised learning algorithm that attempts to accurately predict a target variable by combining an ensemble of estimates from a set of simpler and weaker models. The XGBoost algorithm performs well in machine learning competitions because of its robust handling of a variety of data types, relationships, distributions, and the variety of hyperparameters that you can fine-tune. You can use XGBoost for regression, classification (binary and multiclass), and ranking problems.

You can use the new release of the XGBoost algorithm either as a Amazon SageMaker built-in algorithm or as a framework to run training scripts in your local environments. This implementation has a smaller memory footprint, better logging, improved hyperparameter validation, and an expanded set of metrics than the original versions. It provides an XGBoost estimator that executes a training script in a managed XGBoost environment. The current release of SageMaker XGBoost is based on the original XGBoost versions 1.0, 1.2, 1.3, 1.5, and 1.7.
Use Built-in Algorithms

Supported versions

- Framework (open source) mode: 1.0-1, 1.2-1, 1.2-2, 1.3-1, 1.5-1, 1.7-1
- Algorithm mode: 1.0-1, 1.2-1, 1.2-2, 1.3-1, 1.5-1, 1.7-1

Warning
Due to required compute capacity, version 1.7-1 of SageMaker XGBoost is not compatible with GPU instances from the P2 instance family for training or inference.

Important
When you retrieve the SageMaker XGBoost image URI, do not use :latest or :1 for the image URI tag. You must specify one of the Supported versions (p. 1618) to choose the SageMaker-managed XGBoost container with the native XGBoost package version that you want to use. To find the package version migrated into the SageMaker XGBoost containers, see Docker Registry Paths and Example Code, choose your AWS Region, and navigate to the XGBoost (algorithm) section.

Warning
The XGBoost 0.90 versions are deprecated. Supports for security updates or bug fixes for XGBoost 0.90 is discontinued. It is highly recommended to upgrade the XGBoost version to one of the newer versions.

Note
XGBoost v1.1 is not supported on SageMaker because XGBoost 1.1 has a broken capability to run prediction when the test input has fewer features than the training data in LIBSVM inputs. This capability has been restored in XGBoost v1.2. Consider using SageMaker XGBoost 1.2-2 or later.

How to Use SageMaker XGBoost

With SageMaker, you can use XGBoost as a built-in algorithm or framework. By using XGBoost as a framework, you have more flexibility and access to more advanced scenarios, such as k-fold cross-validation, because you can customize your own training scripts. The following sections describe how to use XGBoost with the SageMaker Python SDK. For information on how to use XGBoost from the Amazon SageMaker Studio UI, see SageMaker JumpStart (p. 161).

Use XGBoost as a framework

Use XGBoost as a framework to run your customized training scripts that can incorporate additional data processing into your training jobs. In the following code example, you can find how SageMaker Python SDK provides the XGBoost API as a framework in the same way it provides other framework APIs, such as TensorFlow, MXNet, and PyTorch.

```python
import boto3
import sagemaker
from sagemaker.xgboost.estimator import XGBoost
from sagemaker.session import Session
from sagemaker.inputs import TrainingInput

# initialize hyperparameters
hyperparameters = {
    "max_depth":5,
    "eta":0.2,
    "gamma":4,
    "min_child_weight":6,
    "subsample":0.7,
    "verbosity":1,
    "objective":"reg:squarederror",
    "num_round":50"
}
```
# set an output path where the trained model will be saved
bucket = sagemaker.Session().default_bucket()
prefix = 'DEMO-xgboost-as-a-framework'
output_path = 's3://{}/{}'.format(bucket, prefix, 'output')

# construct a SageMaker XGBoost estimator
# specify the entry_point to your xgboost training script
estimator = XGBoost(entry_point = "your_xgboost_abalone_script.py",
framework_version='1.7-1',
hyperparameters=hyperparameters,
role=sagemaker.get_execution_role(),
instance_count=1,
instance_type='ml.m5.2xlarge',
output_path=output_path)

# define the data type and paths to the training and validation datasets
content_type = "libsvm"
train_input = TrainingInput("s3://{}/{}/*".format(bucket, prefix, 'train'),
content_type=content_type)
validation_input = TrainingInput("s3://{}/{}/*".format(bucket, prefix, 'validation'),
content_type=content_type)

# execute the XGBoost training job
estimator.fit({'train': train_input, 'validation': validation_input})

For an end-to-end example of using SageMaker XGBoost as a framework, see Regression with Amazon SageMaker XGBoost

• Use XGBoost as a built-in algorithm

Use the XGBoost built-in algorithm to build an XGBoost training container as shown in the following code example. You can automatically spot the XGBoost built-in algorithm image URI using the SageMaker image_uris.retrieve API (or the get_image_uri API if using Amazon SageMaker Python SDK version 1). If you want to ensure if the image_uri.retrieve API finds the correct URI, see Common parameters for built-in algorithms and look up xgboost from the full list of built-in algorithm image URIs and available regions.

After specifying the XGBoost image URI, you can use the XGBoost container to construct an estimator using the SageMaker Estimator API and initiate a training job. This XGBoost built-in algorithm mode does not incorporate your own XGBoost training script and runs directly on the input datasets.

Important
When you retrieve the SageMaker XGBoost image URI, do not use :latest or :1 for the image URI tag. You must specify one of the Supported versions (p. 1618) to choose the SageMaker-managed XGBoost container with the native XGBoost package version that you want to use. To find the package version migrated into the SageMaker XGBoost containers, see Docker Registry Paths and Example Code, choose your AWS Region, and navigate to the XGBoost (algorithm) section.

import sagemaker
import boto3
from sagemaker import image_uris
from sagemaker.session import Session
from sagemaker.inputs import TrainingInput

# initialize hyperparameters
hyperparameters = {
    "max_depth":"5",
    "eta":"0.2",
    "gamma":"4",
    "min_child_weight":"6",
    "subsample":"0.7",
    "objective":"reg:squarederror",
}
"num_round":50}

# set an output path where the trained model will be saved
bucket = sagemaker.Session().default_bucket()
prefix = 'DEMO-xgboost-as-a-built-in-algo'
output_path = 's3://{}/{}/{}/output'.format(bucket, prefix, 'abalone-xgb-built-in-algo')

# this line automatically looks for the XGBoost image URI and builds an XGBoost container.
# specify the repo_version depending on your preference.
xgboost_container = sagemaker.image_uris.retrieve("xgboost", region, "1.7-1")

# construct a SageMaker estimator that calls the xgboost-container
estimator = sagemaker.estimator.Estimator(image_uri=xgboost_container,
                                           hyperparameters=hyperparameters,
                                           role=sagemaker.get_execution_role(),
                                           instance_count=1,
                                           instance_type='ml.m5.2xlarge',
                                           volume_size=5, # 5 GB
                                           output_path=output_path)

# define the data type and paths to the training and validation datasets
content_type = "libsvm"
train_input = TrainingInput("s3://{}/{}/{}".format(bucket, prefix, 'train'),
                           content_type=content_type)
validation_input = TrainingInput("s3://{}/{}/{}".format(bucket, prefix, 'validation'),
                                 content_type=content_type)

# execute the XGBoost training job
estimator.fit({'train': train_input, 'validation': validation_input})

For more information about how to set up the XGBoost as a built-in algorithm, see the following notebook examples.
- Managed Spot Training for XGBoost
- Regression with Amazon SageMaker XGBoost (Parquet input)

Input/Output Interface for the XGBoost Algorithm

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of XGBoost supports the following data formats for training and inference:

- text/libsvm (default)
- text/csv
- application/x-parquet
- application/x-recordio-protobuf

**Note**

There are a few considerations to be aware of regarding training and inference input:

- For training with columnar input, the algorithm assumes that the target variable (label) is the first column. For inference, the algorithm assumes that the input has no label column.
- For CSV data, the input should not have a header record.
- For LIBSVM training, the algorithm assumes that subsequent columns after the label column contain the zero-based index value pairs for features. So each row has the format: :<label> <index0>:<value0> <index1>:<value1>.
For information on instance types and distributed training, see EC2 Instance Recommendation for the XGBoost Algorithm (p. 1621).

For CSV training input mode, the total memory available to the algorithm (Instance Count * the memory available in the InstanceType) must be able to hold the training dataset. For libsvm training input mode, it's not required, but we recommend it.

For v1.3-1 and later, SageMaker XGBoost saves the model in the XGBoost internal binary format, using Booster.save_model. Previous versions use the Python pickle module to serialize/deserialize the model.

**Note**
Be mindful of versions when using an SageMaker XGBoost model in open source XGBoost. Versions 1.3-1 and later use the XGBoost internal binary format while previous versions use the Python pickle module.

To use a model trained with SageMaker XGBoost v1.3-1 or later in open source XGBoost

- Use the following Python code:

```python
import xgboost as xgb
xgb_model = xgb.Booster()
xgb_model.load_model(model_file_path)
xgb_model.predict(dtest)
```

To use a model trained with previous versions of SageMaker XGBoost in open source XGBoost

- Use the following Python code:

```python
import pickle as pkl
import tarfile
t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()
model = pkl.load(open(model_file_path, 'rb'))
# prediction with test data
pred = model.predict(dtest)
```

To differentiate the importance of labelled data points use Instance Weight Supports

- SageMaker XGBoost allows customers to differentiate the importance of labelled data points by assigning each instance a weight value. For text/libsvm input, customers can assign weight values to data instances by attaching them after the labels. For example, label:weight idx_0:val_0 idx_1:val_1.... For text/csv input, customers need to turn on the csv_weights flag in the parameters and attach weight values in the column after labels. For example: label,weight,val_0,val_1,...).

EC2 Instance Recommendation for the XGBoost Algorithm

SageMaker XGBoost supports CPU and GPU training and inference. Instance recommendations depend on training and inference needs, as well as the version of the XGBoost algorithm. Choose one of the following options for more information:
Training

The SageMaker XGBoost algorithm supports CPU and GPU training.

CPU training

SageMaker XGBoost 1.0-1 or earlier only trains using CPUs. It is a memory-bound (as opposed to compute-bound) algorithm. So, a general-purpose compute instance (for example, M5) is a better choice than a compute-optimized instance (for example, C4). Further, we recommend that you have enough total memory in selected instances to hold the training data. Although it supports the use of disk space to handle data that does not fit into main memory (the out-of-core feature available with the libsvm input mode), writing cache files onto disk slows the algorithm processing time.

GPU training

SageMaker XGBoost version 1.2-2 or later supports GPU training. Despite higher per-instance costs, GPUs train more quickly, making them more cost effective.

SageMaker XGBoost version 1.2-2 or later supports P2, P3, G4dn, and G5 GPU instance families.

SageMaker XGBoost version 1.7-1 or later supports P3, G4dn, and G5 GPU instance families. Note that due to compute capacity requirements, version 1.7-1 or later does not support the P2 instance family.

To take advantage of GPU training, specify the instance type as one of the GPU instances (for example, P3) and set the `tree_method` hyperparameter to `gpu_hist` in your existing XGBoost script.

Distributed training

SageMaker XGBoost supports CPU and GPU instances for distributed training.

Distributed CPU training

To run CPU training on multiple instances, set the `instance_count` parameter for the estimator to a value greater than one. The input data must be divided between the total number of instances.

Divide input data across instances

Divide the input data using the following steps:

1. Break the input data down into smaller files. The number of files should be at least equal to the number of instances used for distributed training. Using multiple smaller files as opposed to one large file also decreases the data download time for the training job.

2. When creating your `TrainingInput`, set the distribution parameter to `ShardedByS3Key`. This parameter ensures that each instance gets approximately $1/n$ of the number of files in S3 if there are $n$ instances specified in the training job.

Distributed GPU training

You can use distributed training with either single-GPU or multi-GPU instances.
Distributed training with single-GPU instances

SageMaker XGBoost versions 1.2-2 through 1.3-1 only support single-GPU instance training. This means that even if you select a multi-GPU instance, only one GPU is used per instance.

If you use XGBoost versions 1.2-2 through 1.3-1, or if you do not need to use multi-GPU instances, then you must divide your input data between the total number of instances. For more information, see Divide input data across instances (p. 1622).

**Note**
Versions 1.2-2 through 1.3-1 of SageMaker XGBoost only use one GPU per instance even if you choose a multi-GPU instance.

Distributed training with multi-GPU instances

Starting with version 1.5-1, SageMaker XGBoost offers distributed GPU training with Dask. With Dask you can utilize all GPUs when using one or more multi-GPU instances. Dask also works when using single-GPU instances.

Train with Dask using the following steps:

1. Either omit the distribution parameter in your `TrainingInput` or set it to `FullyReplicated`.
2. When defining your hyperparameters, set `use_dask_gpu_training` to "true".

**Important**
Distributed training with Dask only supports CSV and Parquet input formats. If you use other data formats such as LIBSVM or PROTOBUF, the training job fails.
For Parquet data, ensure that the column names are saved as strings. Columns that have names of other data types will fail to load.

**Important**
Distributed training with Dask does not support pipe mode. If pipe mode is specified, the training job fails.

There are a few considerations to be aware of when training SageMaker XGBoost with Dask. Be sure to split your data into smaller files. Dask reads each Parquet file as a partition. There is a Dask worker for every GPU, so the number of files should be greater than the total number of GPUs (instance count * number of GPUs per instance). Having a very large number of files can also degrade performance. For more information, see Dask Best Practices.

Variations in output

The specified `tree_method` hyperparameter determines the algorithm that is used for XGBoost training. The tree methods `approx`, `hist` and `gpu_hist` are all approximate methods and use sketching for quantile calculation. For more information, see Tree Methods in the XGBoost documentation. Sketching is an approximate algorithm. Therefore, you can expect variations in the model depending on factors such as the number of workers chosen for distributed training. The significance of the variation is data-dependent.

Inference

SageMaker XGBoost supports CPU and GPU instances for inference. For information about the instance types for inference, see Amazon SageMaker ML Instance Types.

XGBoost Sample Notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker XGBoost algorithm.
### Notebook Title | Description
--- | ---
**How to Create a Custom XGBoost container?** | This notebook shows you how to build a custom XGBoost Container with Amazon SageMaker Batch Transform.

**Regression with XGBoost using Parquet** | This notebook shows you how to use the Abalone dataset in Parquet to train a XGBoost model.

**How to Train and Host a Multiclass Classification Model?** | This notebook shows how to use the MNIST dataset to train and host a multiclass classification model.

**How to train a Model for Customer Churn Prediction?** | This notebook shows you how to train a model to Predict Mobile Customer Departure in an effort to identify unhappy customers.

**An Introduction to Amazon SageMaker Managed Spot infrastructure for XGBoost Training** | This notebook shows you how to use Spot Instances for training with a XGBoost Container.

**How to use Amazon SageMaker Debugger to debug XGBoost Training Jobs?** | This notebook shows you how to use Amazon SageMaker Debugger to monitor training jobs to detect inconsistencies using built-in debugging rules.

**How to use Amazon SageMaker Debugger to debug XGBoost Training Jobs in Real-Time?** | This notebook shows you how to use the MNIST dataset and Amazon SageMaker Debugger to perform real-time analysis of XGBoost training jobs while training jobs are running.

---

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances (p. 298). After you have created a notebook instance and opened it, choose the **SageMaker Examples** tab to see a list of all of the SageMaker samples. The topic modeling example notebooks using the linear learning algorithm are located in the **Introduction to Amazon algorithms** section. To open a notebook, choose its **Use** tab and choose **Create copy**.

### How XGBoost Works

**XGBoost** is a popular and efficient open-source implementation of the gradient boosted trees algorithm. Gradient boosting is a supervised learning algorithm, which attempts to accurately predict a target variable by combining the estimates of a set of simpler, weaker models.

When using **gradient boosting** for regression, the weak learners are regression trees, and each regression tree maps an input data point to one of its leaves that contains a continuous score. XGBoost minimizes a regularized (L1 and L2) objective function that combines a convex loss function (based on the difference between the predicted and target outputs) and a penalty term for model complexity (in other words, the regression tree functions). The training proceeds iteratively, adding new trees that predict the residuals or errors of prior trees that are then combined with previous trees to make the final prediction. It's called gradient boosting because it uses a gradient descent algorithm to minimize the loss when adding new models.

Below is a brief illustration on how gradient tree boosting works.
For more detail on XGBoost, see:
- XGBoost: A Scalable Tree Boosting System
- Gradient Tree Boosting
- Introduction to Boosted Trees

**XGBoost Hyperparameters**

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker XGBoost algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order. The SageMaker XGBoost algorithm is an implementation of the open-source DMLC XGBoost package. For details about full set of hyperparameter that can be configured for this version of XGBoost, see [XGBoost Parameters](#).

verbosity | Verbosity of printing messages. Valid values: 0 (silent), 1 (warning), 2 (info), 3 (debug). Optional Default value: 1

### Tune an XGBoost Model

**Automatic model tuning**, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. You choose three types of hyperparameters:

- a learning objective function to optimize during model training
- an eval_metric to use to evaluate model performance during validation
- a set of hyperparameters and a range of values for each to use when tuning the model automatically

You choose the evaluation metric from set of evaluation metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the evaluation metric.

**Note**

Automatic model tuning for XGBoost 0.90 is only available from the Amazon SageMaker SDKs, not from the SageMaker console.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 1863).

### Evaluation Metrics Computed by the XGBoost Algorithm

The XGBoost algorithm computes the following metrics to use for model validation. When tuning the model, choose one of these metrics to evaluate the model. For full list of valid eval_metric values, refer to [XGBoost Learning Task Parameters](p. 1863).

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>

Deprecated Versions of XGBoost and their Upgrades

This topic contains documentation for previous versions of Amazon SageMaker XGBoost that are still available but deprecated. It also provides instructions on how to upgrade deprecated versions of XGBoost, when possible, to more current versions.
Upgrade XGBoost Version 0.90 to Version 1.5

If you are using the SageMaker Python SDK, to upgrade existing XGBoost 0.90 jobs to version 1.5, you must have version 2.x of the SDK installed and change the XGBoost version and framework_version parameters to 1.5-1. If you are using Boto3, you need to update the Docker image, and a few hyperparameters and learning objectives.

Topics
- **Upgrade SageMaker Python SDK Version 1.x to Version 2.x (p. 1635)**
- **Change the image tag to 1.5-1 (p. 1635)**
- **Change Docker Image for Boto3 (p. 1636)**
- **Update Hyperparameters and Learning Objectives (p. 1636)**

Upgrade SageMaker Python SDK Version 1.x to Version 2.x

If you are still using Version 1.x of the SageMaker Python SDK, you must to upgrade version 2.x of the SageMaker Python SDK. For information on the latest version of the SageMaker Python SDK, see Use Version 2.x of the SageMaker Python SDK. To install the latest version, run:

```
python -m pip install --upgrade sagemaker
```

Change the image tag to 1.5-1

If you are using the SageMaker Python SDK and using the XGBoost build-in algorithm, change the version parameter in `image_uris.retrieve`.

```
from sagemaker import image_uris
image_uris.retrieve(framework="xgboost", region="us-west-2", version="1.5-1")

estimator = sagemaker.estimator.Estimator(image_uri=xgboost_container,
                                           hyperparameters=hyperparameters,
                                           role=sagemaker.get_execution_role(),
                                           instance_count=1,
                                           instance_type='ml.m5.2xlarge',
                                           volume_size=5, # 5 GB
                                           output_path=output_path)
```

If you are using the SageMaker Python SDK and using XGBoost as a framework to run your customized training scripts, change the `framework_version` parameter in the XGBoost API.

```
estimator = XGBoost(entry_point = "your_xgboost_abalone_script.py",
                     framework_version='1.5-1',
                     hyperparameters=hyperparameters,
                     role=sagemaker.get_execution_role(),
                     instance_count=1,
                     instance_type='ml.m5.2xlarge',
                     output_path=output_path)
```

`sagemaker.session.s3_input` in SageMaker Python SDK version 1.x has been renamed to `sagemaker.inputs.TrainingInput`. You must use `sagemaker.inputs.TrainingInput` as in the following example.
content_type = "libsvm"
train_input = TrainingInput("s3://{}/{}/{}".format(bucket, prefix, 'train'),
    content_type=content_type)
validation_input = TrainingInput("s3://{}/{}/{}".format(bucket, prefix, 'validation'),
    content_type=content_type)

For the full list of SageMaker Python SDK version 2.x changes, see Use Version 2.x of the SageMaker Python SDK.

Change Docker Image for Boto3

If you are using Boto3 to train or deploy your model, change the docker image tag (1, 0.72, 0.90-1 or 0.90-2) to 1.5-1.

```
{
    "AlgorithmSpecification": {
        "TrainingImage": "746614075791.dkr.ecr.us-west-1.amazonaws.com/sagemaker-xgboost:1.5-1"
    }
}
```

If you using the SageMaker Python SDK to retrieve registry path, change the version parameter in `image_uris.retrieve`.

```
from sagemaker import image_uris
image_uris.retrieve(framework="xgboost", region="us-west-2", version="1.5-1")
```

Update Hyperparameters and Learning Objectives

The silent parameter has been deprecated and is no longer available in XGBoost 1.5 and later versions. Use verbosity instead. If you were using the `reg:linear` learning objective, it has been deprecated as well in favor of `reg:squarederror`. Use `reg:squarederror` instead.

```
hyperparameters = {
    "verbosity": "2",
    "objective": "reg:squarederror",
    "num_round": "50",
    ...
}
estimator = sagemaker.estimator.Estimator(image_uri=xgboost_container,
                                           hyperparameters=hyperparameters,
                                           ...
```

XGBoost Version 0.72

**Important**
The XGBoost 0.72 is deprecated by Amazon SageMaker. You can still use this old version of XGBoost (as a built-in algorithm) by pulling its image URI as shown in the following code sample. For XGBoost, the image URI ending with :1 is for the old version.

SageMaker Python SDK v1

```
import boto3
from sagemaker.amazon.amazon_estimator import get_image_uri
```
xgb_image_uri = get_image_uri(boto3.Session().region_name, "xgboost", repo_version="1")

SageMaker Python SDK v2

```python
import boto3
from sagemaker import image_uris

xgb_image_uri = image_uris.retrieve("xgboost", boto3.Session().region_name, "1")
```

If you want to use newer versions, you have to explicitly specify the image URI tags (see Supported versions (p. 1618)).

This previous release of the Amazon SageMaker XGBoost algorithm is based on the 0.72 release. XGBoost (eXtreme Gradient Boosting) is a popular and efficient open-source implementation of the gradient boosted trees algorithm. Gradient boosting is a supervised learning algorithm that attempts to accurately predict a target variable by combining the estimates of a set of simpler, weaker models. XGBoost has done remarkably well in machine learning competitions because it robustly handles a variety of data types, relationships, and distributions, and because of the large number of hyperparameters that can be tweaked and tuned for improved fits. This flexibility makes XGBoost a solid choice for problems in regression, classification (binary and multiclass), and ranking.

Customers should consider using the new release of XGBoost Algorithm (p. 1617). They can use it as a SageMaker built-in algorithm or as a framework to run scripts in their local environments as they would typically, for example, do with a Tensorflow deep learning framework. The new implementation has a smaller memory footprint, better logging, improved hyperparameter validation, and an expanded set of metrics. The earlier implementation of XGBoost remains available to customers if they need to postpone migrating to the new version. But this previous implementation will remain tied to the 0.72 release of XGBoost.

Input/Output Interface for the XGBoost Release 0.72

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of XGBoost supports CSV and libsvm formats for training and inference:

- For Training ContentType, valid inputs are `text/libsvm` (default) or `text/csv`.
- For Inference ContentType, valid inputs are `text/libsvm` or (the default) `text/csv`.

Note

For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record. For CSV inference, the algorithm assumes that CSV input does not have the label column.

For libsvm training, the algorithm assumes that the label is in the first column. Subsequent columns contain the zero-based index value pairs for features. So each row has the format:

```plaintext
<label> <index0>:<value0> <index1>:<value1> ... Inference requests for libsvm may or may not have labels in the libsvm format.
```

This differs from other SageMaker algorithms, which use the protobuf training input format to maintain greater consistency with standard XGBoost data formats.

For CSV training input mode, the total memory available to the algorithm (Instance Count * the memory available in the InstanceType) must be able to hold the training dataset. For libsvm training input mode, it's not required, but we recommend it.
SageMaker XGBoost uses the Python pickle module to serialize/deserialize the model, which can be used for saving/loading the model.

**To use a model trained with SageMaker XGBoost in open source XGBoost**

- Use the following Python code:

```python
import pickle as pkl
import tarfile
import xgboost

t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()

model = pkl.load(open(model_file_path, 'rb'))

# prediction with test data
pred = model.predict(dtest)
```

**To differentiate the importance of labelled data points use Instance Weight Supports**

- SageMaker XGBoost allows customers to differentiate the importance of labelled data points by assigning each instance a weight value. For text/libsvm input, customers can assign weight values to data instances by attaching them after the labels. For example, label:weight id0:val_0 id1:val_1.... For text/csv input, customers need to turn on the csv_weights flag in the parameters and attach weight values in the column after labels. For example: label,weight,val_0,val_1,...).

**EC2 Instance Recommendation for the XGBoost Release 0.72**

SageMaker XGBoost currently only trains using CPUs. It is a memory-bound (as opposed to compute-bound) algorithm. So, a general-purpose compute instance (for example, M4) is a better choice than a compute-optimized instance (for example, C4). Further, we recommend that you have enough total memory in selected instances to hold the training data. Although it supports the use of disk space to handle data that does not fit into main memory (the out-of-core feature available with the libsvm input mode), writing cache files onto disk slows the algorithm processing time.

**XGBoost Release 0.72 Sample Notebooks**

For a sample notebook that shows how to use the latest version of SageMaker XGBoost as a built-in algorithm to train and host a regression model, see [Regression with Amazon SageMaker XGBoost algorithm](#). To use the 0.72 version of XGBoost, you need to change the version in the sample code to 0.72. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see [Amazon SageMaker Notebook Instances](#). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the XGBoost algorithms are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

**XGBoost Release 0.72 Hyperparameters**

The following table contains the hyperparameters for the XGBoost algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order. The SageMaker XGBoost algorithm is an implementation of the open-source XGBoost package. Currently SageMaker supports version 0.72. For more detail about hyperparameter configuration for this version of XGBoost, see [XGBoost Parameters](#).
<table>
<thead>
<tr>
<th>Parameter Name</th>

**Parameter Name** | **Description**
---|---
updater | A comma-separated string that defines the sequence of tree updaters to run. This provides a modular way to construct and to modify the trees.

For a full list of valid inputs, please refer to XGBoost Parameters.

Optional

Valid values: comma-separated string.
Default value: grow_colmaker, prune

---

**Tune an XGBoost Release 0.72 Model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. You choose three types of hyperparameters:

- a learning objective function to optimize during model training
- an eval_metric to use to evaluate model performance during validation
- a set of hyperparameters and a range of values for each to use when tuning the model automatically

You choose the evaluation metric from set of evaluation metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the evaluation metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1863).

**Metrics Computed by the XGBoost Release 0.72 Algorithm**

The XGBoost algorithm based on version 0.72 computes the following nine metrics to use for model validation. When tuning the model, choose one of these metrics to evaluate the model. For full list of valid eval_metric values, refer to XGBoost Learning Task Parameters

<table>
<thead>

### Built-in SageMaker Algorithms for Text Data

SageMaker provides algorithms that are tailored to the analysis of textual documents used in natural language processing, document classification or summarization, topic modeling or classification, and language transcription or translation.

- **BlazingText algorithm (p. 1647)**—a highly optimized implementation of the Word2vec and text classification algorithms that scale to large datasets easily. It is useful for many downstream natural language processing (NLP) tasks.
- **Latent Dirichlet Allocation (LDA) Algorithm (p. 1657)**—an algorithm suitable for determining topics in a set of documents. It is an unsupervised algorithm, which means that it doesn't use example data with answers during training.
- **Neural Topic Model (NTM) Algorithm (p. 1663)**—another unsupervised technique for determining topics in a set of documents, using a neural network approach.
- **Object2Vec Algorithm** *(p. 1669)*—a general-purpose neural embedding algorithm that can be used for recommendation systems, document classification, and sentence embeddings.
- **Sequence-to-Sequence Algorithm** *(p. 1685)*—a supervised algorithm commonly used for neural machine translation.
- **Text Classification - TensorFlow** *(p. 1698)*—a supervised algorithm that supports transfer learning with available pretrained models for text classification.

**BlazingText algorithm**

The Amazon SageMaker BlazingText algorithm provides highly optimized implementations of the Word2vec and text classification algorithms. The Word2vec algorithm is useful for many downstream natural language processing (NLP) tasks, such as sentiment analysis, named entity recognition, machine translation, etc. Text classification is an important task for applications that perform web searches, information retrieval, ranking, and document classification.

The Word2vec algorithm maps words to high-quality distributed vectors. The resulting vector representation of a word is called a *word embedding*. Words that are semantically similar correspond to vectors that are close together. That way, word embeddings capture the semantic relationships between words.
Many natural language processing (NLP) applications learn word embeddings by training on large collections of documents. These pretrained vector representations provide information about semantics and word distributions that typically improves the generalizability of other models that are later trained on a more limited amount of data. Most implementations of the Word2vec algorithm are not optimized for multi-core CPU architectures. This makes it difficult to scale to large datasets.

With the BlazingText algorithm, you can scale to large datasets easily. Similar to Word2vec, it provides the Skip-gram and continuous bag-of-words (CBOW) training architectures. BlazingText's implementation of the supervised multi-class, multi-label text classification algorithm extends the fastText text classifier to use GPU acceleration with custom CUDA kernels. You can train a model on more than a billion words in a couple of minutes using a multi-core CPU or a GPU. And, you achieve performance on par with the state-of-the-art deep learning text classification algorithms.

The BlazingText algorithm is not parallelizable. For more information on parameters related to training, see Docker Registry Paths for SageMaker Built-in Algorithms.

The SageMaker BlazingText algorithms provides the following features:

- Accelerated training of the fastText text classifier on multi-core CPUs or a GPU and Word2Vec on GPUs using highly optimized CUDA kernels. For more information, see BlazingText: Scaling and Accelerating Word2Vec using Multiple GPUs.
- Enriched Word Vectors with Subword Information by learning vector representations for character n-grams. This approach enables BlazingText to generate meaningful vectors for out-of-vocabulary (OOV) words by representing their vectors as the sum of the character n-gram (subword) vectors.
- A batch_skipgram mode for the Word2Vec algorithm that allows faster training and distributed computation across multiple CPU nodes. The batch_skipgram mode does mini-batching using the Negative Sample Sharing strategy to convert level-1 BLAS operations into level-3 BLAS operations. This efficiently leverages the multiply-add instructions of modern architectures. For more information, see Parallelizing Word2Vec in Shared and Distributed Memory.

To summarize, the following modes are supported by BlazingText on different types instances:

<table>
<thead>
<tr>
<th>Modes</th>

- EC2 Instance Recommendation for the BlazingText Algorithm (p. 1651)
- BlazingText Sample Notebooks (p. 1652)
Input/Output Interface for the BlazingText Algorithm

The BlazingText algorithm expects a single preprocessed text file with space-separated tokens. Each line in the file should contain a single sentence. If you need to train on multiple text files, concatenate them into one file and upload the file in the respective channel.

Training and Validation Data Format

Training and Validation Data Format for the Word2Vec Algorithm

For Word2Vec training, upload the file under the `train` channel. No other channels are supported. The file should contain a training sentence per line.

Training and Validation Data Format for the Text Classification Algorithm

For supervised mode, you can train with file mode or with the augmented manifest text format.

Train with File Mode

For supervised mode, the training/validation file should contain a training sentence per line along with the labels. Labels are words that are prefixed by the string `__label__`. Here is an example of a training/validation file:

```
__label__4  linux ready for prime time, intel says, despite all the linux hype, the open-source movement has yet to make a huge splash in the desktop market. that may be about to change, thanks to chipmaking giant intel corp.
__label__2  bowled by the slower one again, kolkata, november 14 the past caught up with sourav ganguly as the indian skippers return to international cricket was short lived.
```

**Note**
The order of labels within the sentence doesn't matter.

Upload the training file under the train channel, and optionally upload the validation file under the validation channel.

Train with Augmented Manifest Text Format

Supervised mode for CPU instances also supports the augmented manifest format, which enables you to do training in pipe mode without needing to create RecordIO files. While using the format, an S3 manifest file needs to be generated that contains the list of sentences and their corresponding labels. The manifest file format should be in JSON Lines format in which each line represents one sample. The sentences are specified using the `source` tag and the label can be specified using the `label` tag. Both `source` and `label` tags should be provided under the `AttributeNames` parameter value as specified in the request.

```
{"source":"linux ready for prime time, intel says, despite all the linux hype","label":1}
{"source":"bowled by the slower one again, kolkata, november 14 the past caught up with sourav ganguly","label":2}
```

Multi-label training is also supported by specifying a JSON array of labels.

```
{"source":"linux ready for prime time, intel says, despite all the linux hype","label": [1, 3]}
```
For more information on augmented manifest files, see Provide Dataset Metadata to Training Jobs with an Augmented Manifest File (p. 2327).

Model Artifacts and Inference

Model Artifacts for the Word2Vec Algorithm

For Word2Vec training, the model artifacts consist of vectors.txt, which contains words-to-vectors mapping, and vectors.bin, a binary used by BlazingText for hosting, inference, or both. vectors.txt stores the vectors in a format that is compatible with other tools like Gensim and Spacy. For example, a Gensim user can run the following commands to load the vectors.txt file:

```python
from gensim.models import KeyedVectors
word_vectors = KeyedVectors.load_word2vec_format('vectors.txt', binary=False)
word_vectors.most_similar(positive=['woman', 'king'], negative=['man'])
word_vectors.doesnt_match("breakfast cereal dinner lunch".split())
```

If the evaluation parameter is set to True, an additional file, eval.json, is created. This file contains the similarity evaluation results (using Spearman's rank correlation coefficients) on WS-353 dataset. The number of words from the WS-353 dataset that aren't there in the training corpus are reported.

For inference requests, the model accepts a JSON file containing a list of strings and returns a list of vectors. If the word is not found in vocabulary, inference returns a vector of zeros. If subwords is set to True during training, the model is able to generate vectors for out-of-vocabulary (OOV) words.

**Sample JSON Request**

Mime-type: application/json

```json
{
  "instances": ["word1", "word2", "word3"]
}
```

Model Artifacts for the Text Classification Algorithm

Training with supervised outputs creates a model.bin file that can be consumed by BlazingText hosting. For inference, the BlazingText model accepts a JSON file containing a list of sentences and returns a list of corresponding predicted labels and probability scores. Each sentence is expected to be a string with space-separated tokens, words, or both.

**Sample JSON Request**

Mime-type: application/json

```json
{
  "instances": ["the movie was excellent", "i did not like the plot ."]
}
```

By default, the server returns only one prediction, the one with the highest probability. For retrieving the top k predictions, you can set k in the configuration, as follows:

```json
{
  "instances": ["the movie was excellent", "i did not like the plot ."],
  "configuration": {"k": 2}
}
```
For BlazingText, the content-type and accept parameters must be equal. For batch transform, they both need to be application/jsonlines. If they differ, the Accept field is ignored. The format for input follows:

```
content-type: application/jsonlines

{"source": "source_0"}
{"source": "source_1"}
```

If you need to pass the value of k for top-k, then you can do it in the following way:

```
{"source": "source_0", "k": 2}
{"source": "source_1", "k": 3}
```

The format for output follows:

```
accept: application/jsonlines

["prob": [prob_1], "label": ["__label__1"]]
["prob": [prob_1], "label": ["__label__1"]]
```

If you have passed the value of k to be more than 1, then response will be in this format:

```
["prob": [prob_1, prob_2], "label": ["__label__1", "__label__2"]]
["prob": [prob_1, prob_2], "label": ["__label__1", "__label__2"]]
```

For both supervised (text classification) and unsupervised (Word2Vec) modes, the binaries (*.bin) produced by BlazingText can be cross-consumed by fastText and vice versa. You can use binaries produced by BlazingText by fastText. Likewise, you can host the model binaries created with fastText using BlazingText.

Here is an example of how to use a model generated with BlazingText with fastText:

```
#Download the model artifact from S3
aws s3 cp s3://<YOUR_S3_BUCKET>/<PREFIX>/model.tar.gz model.tar.gz

#Unzip the model archive
tar -xzf model.tar.gz

#Use the model archive with fastText
fasttext predict ./model.bin test.txt
```

However, the binaries are only supported when training on CPU and single GPU; training on multi-GPU will not produce binaries.

**EC2 Instance Recommendation for the BlazingText Algorithm**

For cbow and skipgram modes, BlazingText supports single CPU and single GPU instances. Both of these modes support learning of subwords embeddings. To achieve the highest speed without compromising accuracy, we recommend that you use an ml.p3.2xlarge instance.

For batch_skipgram mode, BlazingText supports single or multiple CPU instances. When training on multiple instances, set the value of the S3DataDistributionType field of the S3DataSource object that you pass to CreateTrainingJob to FullyReplicated. BlazingText takes care of distributing data across machines.

For the supervised text classification mode, a C5 instance is recommended if the training dataset is less than 2 GB. For larger datasets, use an instance with a single GPU. BlazingText supports P2, P3, G4dn, and G5 instances for training and inference.
BlazingText Sample Notebooks

For a sample notebook that trains and deploys the SageMaker BlazingText algorithm to generate word vectors, see Learning Word2Vec Word Representations using BlazingText. For instructions for creating and accessing Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances (p. 298). After creating and opening a notebook instance, choose the SageMaker Examples tab to see a list of all the SageMaker examples. The topic modeling example notebooks that use the Blazing Text are located in the Introduction to Amazon algorithms section. To open a notebook, choose its Use tab, then choose Create copy.

BlazingText Hyperparameters

When you start a training job with a CreateTrainingJob request, you specify a training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The hyperparameters for the BlazingText algorithm depend on which mode you use: Word2Vec (unsupervised) and Text Classification (supervised).

Word2Vec Hyperparameters

The following table lists the hyperparameters for the BlazingText Word2Vec training algorithm provided by Amazon SageMaker.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>

### Use Built-in Algorithms

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| subwords       | Whether to learn subword embeddings on not.  
                   **Optional**  
                   Valid values: (Boolean) True or False  
                   Default value: False |
| vector_dim     | The dimension of the word vectors that the algorithm learns.  
                   **Optional**  
                   Valid values: Positive integer  
                   Default value: 100 |
| window_size    | The size of the context window. The context window is the number of words surrounding the target word used for training.  
                   **Optional**  
                   Valid values: Positive integer  
                   Default value: 5 |

### Text Classification Hyperparameters

The following table lists the hyperparameters for the Text Classification training algorithm provided by Amazon SageMaker.

**Note**
Although some of the parameters are common between the Text Classification and Word2Vec modes, they might have different meanings depending on the context.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| mode           | The training mode.  
                   **Required**  
                   Valid values: supervised |
| buckets        | The number of hash buckets to use for word n-grams.  
                   **Optional**  
                   Valid values: Positive integer  
                   Default value: 2000000 |
| early_stopping | Whether to stop training if validation accuracy doesn't improve after a patience number of epochs. Note that a validation channel is required if early stopping is used.  
                   **Optional**  
                   Valid values: (Boolean) True or False |
<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>

### Tune a BlazingText Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 1863).

### Metrics Computed by the BlazingText Algorithm

The BlazingText Word2Vec algorithm (skipgram, cbow, and batch_skipgram modes) reports on a single metric during training: `train:mean_rho`. This metric is computed on [WS-353 word similarity datasets](https://arabesque.github.io/word2vec-resources). When tuning the hyperparameter values for the Word2Vec algorithm, use this metric as the objective.

The BlazingText Text Classification algorithm (supervised mode), also reports on a single metric during training: `validation:accuracy`. When tuning the hyperparameter values for the text classification algorithm, use these metrics as the objective.

### Latent Dirichlet Allocation (LDA) Algorithm

The Amazon SageMaker Latent Dirichlet Allocation (LDA) algorithm is an unsupervised learning algorithm that attempts to describe a set of observations as a mixture of distinct categories. LDA is most commonly used to discover a user-specified number of topics shared by documents within a text corpus. Here each observation is a document, the features are the presence (or occurrence count) of each word, and the categories are the topics. Since the method is unsupervised, the topics are not specified up front, and are not guaranteed to align with how a human may naturally categorize documents. The topics are learned as a probability distribution over the words that occur in each document. Each document, in turn, is described as a mixture of topics.

The exact content of two documents with similar topic mixtures will not be the same. But overall, you would expect these documents to more frequently use a shared subset of words, than when compared with a document from a different topic mixture. This allows LDA to discover these word groups and use them to form topics. As an extremely simple example, given a set of documents where the only words that occur within them are: *eat, sleep, play, meow, and bark*, LDA might produce topics like the following:

<table>
<thead>
<tr>
<th>Topic</th>
<th>eat</th>
<th>sleep</th>
<th>play</th>
<th>meow</th>
<th>bark</th>
</tr>
</thead>
<tbody>
<tr>
<td>Topic 1</td>
<td>0.1</td>
<td>0.3</td>
<td>0.2</td>
<td>0.4</td>
<td>0.0</td>
</tr>
</tbody>
</table>
You can infer that documents that are more likely to fall into Topic 1 are about cats (who are more likely to **meow** and **sleep**), and documents that fall into Topic 2 are about dogs (who prefer to **play** and **bark**). These topics can be found even though the words dog and cat never appear in any of the texts.

### Topics

### Choosing between Latent Dirichlet Allocation (LDA) and Neural Topic Model (NTM)

Topic models are commonly used to produce topics from corpuses that (1) coherently encapsulate semantic meaning and (2) describe documents well. As such, topic models aim to minimize perplexity and maximize topic coherence.

Perplexity is an intrinsic language modeling evaluation metric that measures the inverse of the geometric mean per-word likelihood in your test data. A lower perplexity score indicates better generalization performance. Research has shown that the likelihood computed per word often does not align to human judgement, and can be entirely non-correlated, thus topic coherence has been introduced. Each inferred topic from your model consists of words, and topic coherence is computed to the top N words for that particular topic from your model. It is often defined as the average or median of the pairwise word-similarity scores of the words in that topic e.g., Pointwise Mutual Information (PMI). A promising model generates coherent topics or topics with high topic coherence scores.

While the objective is to train a topic model that minimizes perplexity and maximizes topic coherence, there is often a tradeoff with both LDA and NTM. Recent research by Amazon, Ding et al., 2018 has shown that NTM is promising for achieving high topic coherence but LDA trained with collapsed Gibbs sampling achieves better perplexity. There is a tradeoff between perplexity and topic coherence. From a practicality standpoint regarding hardware and compute power, SageMaker NTM hardware is more flexible than LDA and can scale better because NTM can run on CPU and GPU and can be parallelized across multiple GPU instances, whereas LDA only supports single-instance CPU training.

### Input/Output Interface for the LDA Algorithm

LDA expects data to be provided on the train channel, and optionally supports a test channel, which is scored by the final model. LDA supports both recordIO-wrapped-protobuf (dense and sparse)
Use Built-in Algorithms

CSV file formats. For CSV, the data must be dense and have dimension equal to \( \text{number of records} \times \text{vocabulary size} \). LDA can be trained in File or Pipe mode when using recordIO-wrapped protobuf, but only in File mode for the CSV format.

For inference, text/csv, application/json, and application/x-recordio-protobuf content types are supported. Sparse data can also be passed for application/json and application/x-recordio-protobuf. LDA inference returns application/json or application/x-recordio-protobuf \textit{predictions}, which include the topic_mixture vector for each observation.

Please see the \textbf{LDA Sample Notebooks (p. 1659)} for more detail on training and inference formats.

EC2 Instance Recommendation for the LDA Algorithm

LDA currently only supports single-instance CPU training. CPU instances are recommended for hosting/inference.

\textbf{LDA Sample Notebooks}

For a sample notebook that shows how to train the SageMaker Latent Dirichlet Allocation algorithm on a dataset and then how to deploy the trained model to perform inferences about the topic mixtures in input documents, see the \textit{An Introduction to SageMaker LDA}. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see \textit{Amazon SageMaker Notebook Instances (p. 298)}. Once you have created a notebook instance and opened it, select the \textbf{SageMaker Examples} tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the NTM algorithms are located in the \textit{Introduction to Amazon algorithms} section. To open a notebook, click on its \textbf{Use} tab and select \textbf{Create copy}.

\textbf{How LDA Works}

Amazon SageMaker LDA is an unsupervised learning algorithm that attempts to describe a set of observations as a mixture of different categories. These categories are themselves a probability distribution over the features. LDA is a generative probability model, which means it attempts to provide a model for the distribution of outputs and inputs based on latent variables. This is opposed to discriminative models, which attempt to learn how inputs map to outputs.

You can use LDA for a variety of tasks, from clustering customers based on product purchases to automatic harmonic analysis in music. However, it is most commonly associated with topic modeling in text corpuses. Observations are referred to as documents. The feature set is referred to as vocabulary. A feature is referred to as a word. And the resulting categories are referred to as topics.

\textbf{Note}

Lemmatization significantly increases algorithm performance and accuracy. Consider pre-processing any input text data. For more information, see \textit{Stemming and lemmatization}.

An LDA model is defined by two parameters:

- \( \alpha \)—A prior estimate on topic probability (in other words, the average frequency that each topic within a given document occurs).
- \( \beta \)—a collection of \( k \) topics where each topic is given a probability distribution over the vocabulary used in a document corpus, also called a "topic-word distribution."

LDA is a "bag-of-words" model, which means that the order of words does not matter. LDA is a generative model where each document is generated word-by-word by choosing a topic mixture \( \theta \sim \text{Dirichlet}(\alpha) \).

For each word in the document:

- Choose a topic \( z \sim \text{Multinomial}(\theta) \)
• Choose the corresponding topic-word distribution \( \beta_z \).
• Draw a word \( w \sim \text{Multinomial}(\beta_z) \).

When training the model, the goal is to find parameters \( \alpha \) and \( \beta \), which maximize the probability that the text corpus is generated by the model.

The most popular methods for estimating the LDA model use Gibbs sampling or Expectation Maximization (EM) techniques. The Amazon SageMaker LDA uses tensor spectral decomposition. This provides several advantages:

• **Theoretical guarantees on results.** The standard EM-method is guaranteed to converge only to local optima, which are often of poor quality.
• **Embarrassingly parallelizable.** The work can be trivially divided over input documents in both training and inference. The EM-method and Gibbs Sampling approaches can be parallelized, but not as easily.
• **Fast.** Although the EM-method has low iteration cost it is prone to slow convergence rates. Gibbs Sampling is also subject to slow convergence rates and also requires a large number of samples.

At a high-level, the tensor decomposition algorithm follows this process:

1. The goal is to calculate the spectral decomposition of a \( V \times V \times V \) tensor, which summarizes the moments of the documents in our corpus. \( V \) is vocabulary size (in other words, the number of distinct words in all of the documents). The spectral components of this tensor are the LDA parameters \( \alpha \) and \( \beta \), which maximize the overall likelihood of the document corpus. However, because vocabulary size tends to be large, this \( V \times V \times V \) tensor is prohibitively large to store in memory.
2. Instead, it uses a \( V \times V \) moment matrix, which is the two-dimensional analog of the tensor from step 1, to find a whitening matrix of dimension \( V \times k \). This matrix can be used to convert the \( V \times V \) moment matrix into a \( k \times k \) identity matrix. \( k \) is the number of topics in the model.
3. This same whitening matrix can then be used to find a smaller \( k \times k \times k \) tensor. When spectrally decomposed, this tensor has components that have a simple relationship with the components of the \( V \times V \times V \) tensor.
4. **Alternating Least Squares** is used to decompose the smaller \( k \times k \times k \) tensor. This provides a substantial improvement in memory consumption and speed. The parameters \( \alpha \) and \( \beta \) can be found by "unwhitening" these outputs in the spectral decomposition.

After the LDA model's parameters have been found, you can find the topic mixtures for each document. You use stochastic gradient descent to maximize the likelihood function of observing a given topic mixture corresponding to these data.

Topic quality can be improved by increasing the number of topics to look for in training and then filtering out poor quality ones. This is in fact done automatically in SageMaker LDA: 25% more topics are computed and only the ones with largest associated Dirichlet priors are returned. To perform further topic filtering and analysis, you can increase the topic count and modify the resulting LDA model as follows:

```python
> import mxnet as mx
> alpha, beta = mx.ndarray.load('model.tar.gz')
> # modify alpha and beta
> mx.nd.save('new_model.tar.gz', [new_alpha, new_beta])
> # upload to S3 and create new SageMaker model using the console
```

For more information about algorithms for LDA and the SageMaker implementation, see the following:

**LDA Hyperparameters**

In the `CreateTrainingJob` request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the LDA training algorithm provided by Amazon SageMaker. For more information, see How LDA Works (p. 1659).

**Tune an LDA Model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

LDA is an unsupervised topic modeling algorithm that attempts to describe a set of observations (documents) as a mixture of different categories (topics). The “per-word log-likelihood” (PWLL) metric measures the likelihood that a learned set of topics (an LDA model) accurately describes a test document dataset. Larger values of PWLL indicate that the test data is more likely to be described by the LDA model.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 1863).

**Metrics Computed by the LDA Algorithm**

The LDA algorithm reports on a single metric during training: `test:pwll`. When tuning a model, choose this metric as the objective metric.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>test:pwll</code></td>
<td>Per-word log-likelihood on the test dataset. The likelihood that the test dataset is accurately described by the learned LDA model.</td>
<td>Maximize</td>
</tr>
</tbody>
</table>

**Tunable LDA Hyperparameters**

You can tune the following hyperparameters for the LDA algorithm. Both hyperparameters, `alpha0` and `num_topics`, can affect the LDA objective metric (`test:pwll`). If you don't already know the optimal values for these hyperparameters, which maximize per-word log-likelihood and produce an accurate LDA model, automatic model tuning can help find them.

</tr>
</tbody>
</table>

**Neural Topic Model (NTM) Algorithm**

Amazon SageMaker NTM is an unsupervised learning algorithm that is used to organize a corpus of documents into *topics* that contain word groupings based on their statistical distribution. Documents that contain frequent occurrences of words such as "bike", "car", "train", "mileage", and "speed" are likely to share a topic on "transportation" for example. Topic modeling can be used to classify or summarize documents based on the topics detected or to retrieve information or recommend content based on topic similarities. The topics from documents that NTM learns are characterized as a *latent representation* because the topics are inferred from the observed word distributions in the corpus. The semantics of topics are usually inferred by examining the top ranking words they contain. Because the method is unsupervised, only the number of topics, not the topics themselves, are prespecified. In addition, the topics are not guaranteed to align with how a human might naturally categorize documents.

Topic modeling provides a way to visualize the contents of a large document corpus in terms of the learned topics. Documents relevant to each topic might be indexed or searched for based on their soft topic labels. The latent representations of documents might also be used to find similar documents in the topic space. You can also use the latent representations of documents that the topic model learns for input to another supervised algorithm such as a document classifier. Because the latent representations of documents are expected to capture the semantics of the underlying documents, algorithms based in part on these representations are expected to perform better than those based on lexical features alone.

Although you can use both the Amazon SageMaker NTM and LDA algorithms for topic modeling, they are distinct algorithms and can be expected to produce different results on the same input data.

For more information on the mathematics behind NTM, see [Neural Variational Inference for Text Processing](#).

**Topics**

- [Input/Output Interface for the NTM Algorithm (p. 1663)](#)
- [EC2 Instance Recommendation for the NTM Algorithm (p. 1664)](#)
- [NTM Sample Notebooks (p. 1664)](#)
- [NTM Hyperparameters (p. 1664)](#)
- [Tune an NTM Model (p. 1667)](#)
- [NTM Response Formats (p. 1668)](#)

**Input/Output Interface for the NTM Algorithm**

Amazon SageMaker Neural Topic Model supports four data channels: train, validation, test, and auxiliary. The validation, test, and auxiliary data channels are optional. If you specify any of these optional channels, set the value of the S3DataDistributionType parameter for them to `FullyReplicated`. If you provide validation data, the loss on this data is logged at every epoch, and the model stops training as soon as it detects that the validation loss is not improving. If you don't provide validation data, the algorithm stops early based on the training data, but this can be less efficient. If you provide test data, the algorithm reports the test loss from the final model.

The train, validation, and test data channels for NTM support both recordIO-wrapped-protobuf (dense and sparse) and CSV file formats. For CSV format, each row must be represented densely with...
zero counts for words not present in the corresponding document, and have dimension equal to:
(number of records) * (vocabulary size). You can use either File mode or Pipe mode to train models on
data that is formatted as recordIO-wrapped-protobuf or as CSV. The auxiliary channel is used to
supply a text file that contains vocabulary. By supplying the vocabulary file, users are able to see the top
words for each of the topics printed in the log instead of their integer IDs. Having the vocabulary file also
allows NTM to compute the Word Embedding Topic Coherence (WETC) scores, a new metric displayed in
the log that captures similarity among the top words in each topic effectively. The ContentType for the
auxiliary channel is text/plain, with each line containing a single word, in the order corresponding to
the integer IDs provided in the data. The vocabulary file must be named vocab.txt and currently only
UTF-8 encoding is supported.

For inference, text/csv, application/json, application/jsonlines, and application/x-recordio-protobuf content types are supported. Sparse data can also be passed for application/json and application/x-recordio-protobuf. NTM inference returns application/json or application/x-recordio-protobuf predictions, which include the topic_weights vector for each observation.

See the blog post and the companion notebook for more details on using the auxiliary channel and the
WETC scores. For more information on how to compute the WETC score, see Coherence-Aware Neural
Topic Modeling. We used the pairwise WETC described in this paper for the Amazon SageMaker Neural
Topic Model.

For more information on input and output file formats, see NTM Response Formats (p. 1668) for
inference and the NTM Sample Notebooks (p. 1664).

**EC2 Instance Recommendation for the NTM Algorithm**

NTM training supports both GPU and CPU instance types. We recommend GPU instances, but for certain
workloads, CPU instances may result in lower training costs. CPU instances should be sufficient for
inference. NTM training supports P2, P3, G4dn, and G5 GPU instance families for training and inference.

**NTM Sample Notebooks**

For a sample notebook that uses the SageMaker NTM algorithm to uncover topics in documents from a
synthetic data source where the topic distributions are known, see the Introduction to Basic Functionality
of NTM. For instructions how to create and access Jupyter notebook instances that you can use to
run the example in SageMaker, see Amazon SageMaker Notebook Instances (p. 298). Once you have
created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the
SageMaker samples. The topic modeling example notebooks using the NTM algorithms are located in the
Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create
copy.

Tune an NTM Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

Amazon SageMaker NTM is an unsupervised learning algorithm that learns latent representations of large collections of discrete data, such as a corpus of documents. Latent representations use inferred variables that are not directly measured to model the observations in a dataset. Automatic model tuning on NTM helps you find the model that minimizes loss over the training or validation data. Training loss measures how well the model fits the training data. Validation loss measures how well the model can generalize to data that it is not trained on. Low training loss indicates that a model is a good fit to the training data. Low validation loss indicates that a model has not overfit the training data and so should be able to model documents successfully on which it has not been trained. Usually, it's preferable to have both losses be small. However, minimizing training loss too much might result in overfitting and increase validation loss, which would reduce the generality of the model.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1863).

Metrics Computed by the NTM Algorithm

The NTM algorithm reports a single metric that is computed during training: validation:total_loss. The total loss is the sum of the reconstruction loss and Kullback-Leibler divergence. When tuning hyperparameter values, choose this metric as the objective.

<table>
<thead>
<tr>

<td>Total Loss on validation set</td>
<td>Minimize</td>
</tr>
</tbody>
</table>

Tunable NTM Hyperparameters

You can tune the following hyperparameters for the NTM algorithm. Usually setting low mini_batch_size and small learning_rate values results in lower validation losses, although it
might take longer to train. Low validation losses don't necessarily produce more coherent topics as interpreted by humans. The effect of other hyperparameters on training and validation loss can vary from dataset to dataset. To see which values are compatible, see NTM Hyperparameters (p. 1664).

**NTM Response Formats**

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. This topic contains a list of the available output formats for the SageMaker NTM algorithm.

**JSON Response Format**

```json
{
    "predictions": [
        {
            "topic_weights": [0.02, 0.1, 0,...],
            "topic_weights": [0.25, 0.067, 0,...]
        }
    ]
}
```

**JSONLINES Response Format**

```json
{"topic_weights": [0.02, 0.1, 0,...]}
{"topic_weights": [0.25, 0.067, 0,...]}
```

**RECORDIO Response Format**

```json
[
    Record = {
        features = {},
        label = {
            'topic_weights': {
                keys: [],
                values: [0.25, 0.067, 0, ...] # float32
            }
        }
    },
    Record = {
        features = {},
        label = {
```
Object2Vec Algorithm

The Amazon SageMaker Object2Vec algorithm is a general-purpose neural embedding algorithm that is highly customizable. It can learn low-dimensional dense embeddings of high-dimensional objects. The embeddings are learned in a way that preserves the semantics of the relationship between pairs of objects in the original space in the embedding space. You can use the learned embeddings to efficiently compute nearest neighbors of objects and to visualize natural clusters of related objects in low-dimensional space, for example. You can also use the embeddings as features of the corresponding objects in downstream supervised tasks, such as classification or regression.

Object2Vec generalizes the well-known Word2Vec embedding technique for words that is optimized in the SageMaker BlazingText algorithm (p. 1647). For a blog post that discusses how to apply Object2Vec to some practical use cases, see Introduction to Amazon SageMaker Object2Vec.

I/O Interface for the Object2Vec Algorithm

You can use Object2Vec on many input data types, including the following examples.

<table>
<thead>
<tr>
<th>Input Data Type</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sentence-sentence pairs</td>
<td>&quot;A soccer game with multiple males playing.&quot; and &quot;Some men are playing a sport.&quot;</td>
</tr>
<tr>
<td>Labels-sequence pairs</td>
<td>The genre tags of the movie &quot;Titanic&quot;, such as &quot;Romance&quot; and &quot;Drama&quot;, and its short description: &quot;James Cameron's Titanic is an epic, action-packed romance set against the ill-fated maiden voyage of the R.M.S. Titanic. She was the most luxurious liner of her era, a ship of dreams, which ultimately carried over 1,500 people to their death in the ice cold waters of the North Atlantic in the early hours of April 15, 1912.&quot;</td>
</tr>
<tr>
<td>Customer-customer pairs</td>
<td>The customer ID of Jane and customer ID of Jackie.</td>
</tr>
<tr>
<td>Product-product pairs</td>
<td>The product ID of football and product ID of basketball.</td>
</tr>
</tbody>
</table>
### Input Data Type

<table>
<thead>
<tr>
<th>Input Data Type</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Item review user-item pairs</td>
<td>A user's ID and the items she has bought, such as apple, pear, and orange.</td>
</tr>
</tbody>
</table>

To transform the input data into the supported formats, you must preprocess it. Currently, Object2Vec natively supports two types of input:

- A discrete token, which is represented as a list of a single integer-id. For example, [10].
- A sequence of discrete tokens, which is represented as a list of integer-ids. For example, [0,12,10,13].

The object in each pair can be asymmetric. For example, the pairs can be (token, sequence) or (token, token) or (sequence, sequence). For token inputs, the algorithm supports simple embeddings as compatible encoders. For sequences of token vectors, the algorithm supports the following as encoders:

- Average-pooled embeddings
- Hierarchical convolutional neural networks (CNNs),
- Multi-layered bidirectional long short-term memory (BiLSTMs)

The input label for each pair can be one of the following:

- A categorical label that expresses the relationship between the objects in the pair
- A score that expresses the strength of the similarity between the two objects

For categorical labels used in classification, the algorithm supports the cross-entropy loss function. For ratings/score-based labels used in regression, the algorithm supports the mean squared error (MSE) loss function. Specify these loss functions with the `output_layer` hyperparameter when you create the model training job.

### EC2 Instance Recommendation for the Object2Vec Algorithm

The type of Amazon Elastic Compute Cloud (Amazon EC2) instance that you use depends on whether you are training or running inference.

When training a model using the Object2Vec algorithm on a CPU, start with an ml.m5.2xlarge instance. For training on a GPU, start with an ml.p2.xlarge instance. If the training takes too long on this instance, you can use a larger instance. Currently, the Object2Vec algorithm can train only on a single machine. However, it does offer support for multiple GPUs. Object2Vec supports P2, P3, G4dn, and G5 GPU instance families for training and inference.

For inference with a trained Object2Vec model that has a deep neural network, we recommend using ml.p3.2xlarge GPU instance. Due to GPU memory scarcity, the `INFERERCE_PREFERRED_MODE` environment variable can be specified to optimize on whether the section called “GPU optimization: Classification or Regression” (p. 1683) or the section called “GPU optimization: Encoder Embeddings” (p. 1684) inference network is loaded into GPU.

### Object2Vec Sample Notebooks

- **Using Object2Vec to Encode Sentences into Fixed Length Embeddings**

### Note

To run the notebooks on a notebook instance, see Example Notebooks (p. 330). To run the notebooks on Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 225).
How Object2Vec Works

When using the Amazon SageMaker Object2Vec algorithm, you follow the standard workflow: process the data, train the model, and produce inferences.

Topics

• **Step 1: Process Data** (p. 1671)
• **Step 2: Train a Model** (p. 1671)
• **Step 3: Produce Inferences** (p. 1672)

Step 1: Process Data

During preprocessing, convert the data to the JSON Lines text file format specified in Data Formats for Object2Vec Training (p. 1683). To get the highest accuracy during training, also randomly shuffle the data before feeding it into the model. How you generate random permutations depends on the language. For python, you could use `np.random.shuffle`; for Unix, `shuf`.

Step 2: Train a Model

The SageMaker Object2Vec algorithm has the following main components:

• **Two input channels** – The input channels take a pair of objects of the same or different types as inputs, and pass them to independent and customizable encoders.

• **Two encoders** – The two encoders, enc0 and enc1, convert each object into a fixed-length embedding vector. The encoded embeddings of the objects in the pair are then passed into a comparator.

• **A comparator** – The comparator compares the embeddings in different ways and outputs scores that indicate the strength of the relationship between the paired objects. In the output score for a sentence pair. For example, 1 indicates a strong relationship between a sentence pair, and 0 represents a weak relationship.

During training, the algorithm accepts pairs of objects and their relationship labels or scores as inputs. The objects in each pair can be of different types, as described earlier. If the inputs to both encoders are composed of the same token-level units, you can use a shared token embedding layer by setting the `tied_token_embedding_weight` hyperparameter to `True` when you create the training job. This is possible, for example, when comparing sentences that both have word token-level units. To generate negative samples at a specified rate, set the `negative_sampling_rate` hyperparameter to the desired ratio of negative to positive samples. This hyperparameter expedites learning how to discriminate between the positive samples observed in the training data and the negative samples that are not likely to be observed.

Pairs of objects are passed through independent, customizable encoders that are compatible with the input types of corresponding objects. The encoders convert each object in a pair into a fixed-length embedding vector of equal length. The pair of vectors are passed to a comparator operator, which assembles the vectors into a single vector using the value specified in the `he comparator_list` hyperparameter. The assembled vector then passes through a multilayer perceptron (MLP) layer, which produces an output that the loss function compares with the labels that you provided. This comparison evaluates the strength of the relationship between the objects in the pair as predicted by the model. The following figure shows this workflow.
Step 3: Produce Inferences

After the model is trained, you can use the trained encoder to preprocess input objects or to perform two types of inference:

- To convert singleton input objects into fixed-length embeddings using the corresponding encoder
- To predict the relationship label or score between a pair of input objects

The inference server automatically figures out which of the types is requested based on the input data. To get the embeddings as output, provide only one input. To predict the relationship label or score, provide both inputs in the pair.

Object2Vec Hyperparameters

In the `CreateTrainingJob` request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the Object2Vec training algorithm.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>enc0_max_seq_len</code></td>
<td>The maximum sequence length for the <code>enc0</code> encoder.</td>
</tr>
<tr>
<td><strong>Required</strong></td>
<td>Valid values: $1 \leq \text{integer} \leq 5000$</td>
</tr>
<tr>
<td><code>enc0_vocab_size</code></td>
<td>The vocabulary size of <code>enc0</code> tokens.</td>
</tr>
<tr>
<td><strong>Required</strong></td>
<td>Valid values: $2 \leq \text{integer} \leq 3000000$</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-------------</td>
</tr>
<tr>
<td>bucket_width</td>
<td>The allowed difference between data sequence length when bucketing is enabled. To enable bucketing, specify a non-zero value for this parameter.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: $0 \leq \text{integer} \leq 100$</td>
</tr>
<tr>
<td></td>
<td>Default value: 0 (no bucketing)</td>
</tr>
<tr>
<td>comparator_list</td>
<td>A list used to customize the way in which two embeddings are compared. The Object2Vec comparator operator layer takes the encodings from both encoders as inputs and outputs a single vector. This vector is a concatenation of subvectors. The string values passed to the comparator_list and the order in which they are passed determine how these subvectors are assembled. For example, if comparator_list=&quot;hadamard, concat&quot;, then the comparator operator constructs the vector by concatenating the Hadamard product of two encodings and the concatenation of two encodings. If, on the other hand, comparator_list=&quot;hadamard&quot;, then the comparator operator constructs the vector as the hadamard product of only two encodings.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: A string that contains any combination of the names of the three binary operators: hadamard, concat, or abs_diff. The Object2Vec algorithm currently requires that the two vector encodings have the same dimension. These operators produce the subvectors as follows:</td>
</tr>
<tr>
<td></td>
<td>• hadamard: Constructs a vector as the Hadamard (element-wise) product of two encodings.</td>
</tr>
<tr>
<td></td>
<td>• concat: Constructs a vector as the concatenation of two encodings.</td>
</tr>
<tr>
<td></td>
<td>• abs_diff: Constructs a vector as the absolute difference between two encodings.</td>
</tr>
<tr>
<td>dropout</td>
<td>The dropout probability for network layers. Dropout is a form of regularization used in neural networks that reduces overfitting by trimming codependent neurons.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: $0.0 \leq \text{float} \leq 1.0$</td>
</tr>
<tr>
<td></td>
<td>Default value: 0.0</td>
</tr>
</tbody>
</table>
## Use Built-in Algorithms

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>

### Tune an Object2Vec Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. For the objective metric, you use one of the metrics that the algorithm computes. Automatic model tuning searches the chosen hyperparameters to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker (p. 1863)](https://docs.aws.amazon.com/sagemaker/latest/dg/perform-auto-model-tuning.html).

### Metrics Computed by the Object2Vec Algorithm

The Object2Vec algorithm has both classification and regression metrics. The `output_layer` type determines which metric you can use for automatic model tuning.

#### Regressor Metrics Computed by the Object2Vec Algorithm

The algorithm reports a mean squared error regressor metric, which is computed during testing and validation. When tuning the model for regression tasks, choose this metric as the objective.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>

<td><code>test:mean_squared_error</code></td>
<td>Mean Square Error</td>
<td>Minimize</td>
</tr>
<tr>
<td><code>validation:mean_squared_error</code></td>
<td>Mean Square Error</td>
<td>Minimize</td>
</tr>
</tbody>
</table>

#### Classification Metrics Computed by the Object2Vec Algorithm

The Object2Vec algorithm reports accuracy and cross-entropy classification metrics, which are computed during test and validation. When tuning the model for classification tasks, choose one of these as the objective.

Data Formats for Object2Vec Training

Input: JSON Lines Request Format

Content-type: application/jsonlines

```json
[{
  "label": 0,
  "in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821, 4],
  "in1": [16, 21, 13, 45, 14, 9, 80, 59, 164, 4]
},
{
  "label": 1,
  "in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4],
  "in1": [22, 32, 13, 25, 1016, 573, 3252, 4]
},
{
  "label": 1,
  "in0": [774, 14, 21, 206],
  "in1": [21, 366, 125]
}]
```

The "in0" and "in1" are the inputs for encoder0 and encoder1, respectively. The same format is valid for both classification and regression problems. For regression, the field "label" can accept real valued inputs.

Data Formats for Object2Vec Inference

GPU optimization: Classification or Regression

Due to GPU memory scarcity, the INFORCE_PREFERRED_MODE environment variable can be specified to optimize on whether the classification/regression or the section called "Output: Encoder Embeddings" (p. 1685) inference network is loaded into GPU. If the majority of your inference is for classification or regression, specify \texttt{INFORCE\_PREFERRED\_MODE=classification}. The following is a Batch Transform example of using 4 instances of \texttt{ml.p2.xlarge} that optimizes for classification/regression inference:

```python
transformer = o2v.transformer(instance_count=4,
instance_type="ml.p2.xlarge",
max_concurrent_transforms=2,
max_payload=1, # 1MB
strategy='MultiRecord',
env={'INFERENCE_PREFERRED_MODE': 'classification'}, # only useful with GPU
output_path=output_s3_path)
```

Input: Classification or Regression Request Format

Content-type: application/json

```json
{
  "instances": [
    {
      "in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821, 4],
      "in1": [16, 21, 13, 45, 14, 9, 80, 59, 164, 4]
    },
    {
      "in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4],
      "in1": [22, 32, 13, 25, 1016, 573, 3252, 4]
    },
    {
      "in0": [774, 14, 21, 206],
      "in1": [21, 366, 125]
    }
  ]
}
```

Content-type: application/jsonlines

```json
[{
  "in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821, 4],
  "in1": [16, 21, 13, 45, 14, 9, 80, 59, 164, 4]
}]
```

For classification problems, the length of the scores vector corresponds to num_classes. For regression problems, the length is 1.
Output: Classification or Regression Response Format

Accept: application/json

```json
{
  "predictions": [
    {
      "scores": [
        0.6533935070037842,
        0.07582679390907288,
        0.2707797586917877
      ]
    },
    {
      "scores": [
        0.026291321963071823,
        0.6577019095420837,
        0.31600672006607056
      ]
    }
  ]
}
```

Accept: application/jsonlines

```json
{"scores":[0.195667684078216,0.395351558923721,0.4089807271957399]}
{"scores":[0.251988261938095,0.258233487606048,0.489778339862823]}
{"scores":[0.280087798833847,0.368331134319305,0.351581096649169]}
```

In both the classification and regression formats, the scores apply to individual labels.

**Encoder Embeddings for Object2Vec**

**GPU optimization: Encoder Embeddings**

An embedding is a mapping from discrete objects, such as words, to vectors of real numbers.

Due to GPU memory scarcity, the INCLUSION_PREFERRED_MODE environment variable can be specified to optimize on whether the the section called "Inference Formats: Scoring" (p. 1683) or the encoder embedding inference network is loaded into GPU. If the majority of your inference is for encoder embeddings, specify INCLUSION_PREFERRED_MODE=embedding. The following is a Batch Transform example of using 4 instances of p3.2xlarge that optimizes for encoder embedding inference:

```python
transformer = o2v.transformer(instance_count=4,
  instance_type="ml.p2.xlarge",
  max_concurrent_transforms=2,
  max_payload=1,  # 1MB
  strategy='MultiRecord',
  env={'INCLUSION_PREFERRED_MODE': 'embedding'},  # only useful
  output_path=output_s3_path)
```

**Input: Encoder Embeddings**

Content-type: application/json; infer_max_seqlens=<FWD-LENGTH>,<BCK-LENGTH>

Where <FWD-LENGTH> and <BCK-LENGTH> are integers in the range [1,5000] and define the maximum sequence lengths for the forward and backward encoder.
Content-type: application/jsonlines; infer_max_seqlen=<FWD-LENGTH>,<BCK-LENGTH>

Where <FWD-LENGTH> and <BCK-LENGTH> are integers in the range [1,5000] and define the maximum sequence lengths for the forward and backward encoder.

In both of these formats, you specify only one input type: “in0” or “in1.” The inference service then invokes the corresponding encoder and outputs the embeddings for each of the instances.

**Output: Encoder Embeddings**

Content-type: application/json

```json
{
  "predictions": [
    {
      "embeddings": [0.057368703186511, 0.030703511089086, 0.099890425801277, 0.063688032329082, 0.026327300816774, 0.003637571120634, 0.021305780857801, 0.004316598642617, 0.0, 0.003397724591195, 0.0, 0.000378780066967, 0.0, 0.0, 0.0, 0.007419463712722]
    },
    {
      "embeddings": [0.150190666317939, 0.05145975202322, 0.098204270005226, 0.064249359071254, 0.056249320507049, 0.01513972133398, 0.047553978860378, 0.0, 0.0, 0.011533712036907, 0.011472506448626, 0.010696629062294, 0.0, 0.0, 0.0, 0.008508535102009]
    }
  ]
}
```

The vector length of the embeddings output by the inference service is equal to the value of one of the following hyperparameters that you specify at training time: enc0_token_embedding_dim, enc1_token_embedding_dim, or enc_dim.

**Sequence-to-Sequence Algorithm**

Amazon SageMaker Sequence to Sequence is a supervised learning algorithm where the input is a sequence of tokens (for example, text, audio) and the output generated is another sequence of tokens. Example applications include: machine translation (input a sentence from one language and predict what that sentence would be in another language), text summarization (input a longer string of words and predict a shorter string of words that is a summary), speech-to-text (audio clips converted into output sentences in tokens). Recently, problems in this domain have been successfully modeled with deep neural networks that show a significant performance boost over previous methodologies. Amazon SageMaker seq2seq uses Recurrent Neural Networks (RNNs) and Convolutional Neural Network (CNN) models with attention as encoder-decoder architectures.

**Topics**

- Input/Output Interface for the Sequence-to-Sequence Algorithm (p. 1686)
- EC2 Instance Recommendation for the Sequence-to-Sequence Algorithm (p. 1687)
- Sequence-to-Sequence Sample Notebooks (p. 1687)
Input/Output Interface for the Sequence-to-Sequence Algorithm

Training

SageMaker seq2seq expects data in RecordIO-Protobuf format. However, the tokens are expected as integers, not as floating points, as is usually the case.

A script to convert data from tokenized text files to the protobuf format is included in the seq2seq example notebook. In general, it packs the data into 32-bit integer tensors and generates the necessary vocabulary files, which are needed for metric calculation and inference.

After preprocessing is done, the algorithm can be invoked for training. The algorithm expects three channels:

- **train**: It should contain the training data (for example, the train.rec file generated by the preprocessing script).
- **validation**: It should contain the validation data (for example, the val.rec file generated by the preprocessing script).
- **vocab**: It should contain two vocabulary files (vocab.src.json and vocab.trg.json)

If the algorithm doesn't find data in any of these three channels, training results in an error.

Inference

For hosted endpoints, inference supports two data formats. To perform inference using space separated text tokens, use the application/json format. Otherwise, use the recordio-protobuf format to work with the integer encoded data. Both modes support batching of input data.

- **application/json**: Expects the input in JSON format and returns the output in JSON format. Both content and accept types should be application/json. Each sequence is expected to be a string with whitespace separated tokens. This format is recommended when the number of source sequences in the batch is small. It also supports the following additional configuration options:

  configuration: {attention_matrix: true}: Returns the attention matrix for the particular input sequence.

  configuration: {application/x-recordio-protobuf}: Expects the input in recordio-protobuf format and returns the output in recordio-protobuf format. Both content and accept types should be application/x-recordio-protobuf. For this format, the source sequences must be converted into a list of integers for subsequent protobuf encoding. This format is recommended for bulk inference.

For batch transform, inference supports JSON Lines format. Batch transform expects the input in JSON Lines format and returns the output in JSON Lines format. Both content and accept types should be application/jsonlines. The format for input is as follows:

```json
content-type: application/jsonlines

{"source": "source_sequence_0"}
{"source": "source_sequence_1"}
```

The format for response is as follows:

```json
content-type: application/jsonlines

{"source": "sequence_0"}
{"source": "sequence_1"}
```
For additional details on how to serialize and deserialize the inputs and outputs to specific formats for inference, see the Sequence-to-Sequence Sample Notebooks (p. 1687).

**EC2 Instance Recommendation for the Sequence-to-Sequence Algorithm**

The Amazon SageMaker seq2seq algorithm only supports on GPU instance types and can only train on a single machine. However, you can use instances with multiple GPUs. The seq2seq algorithm supports P2, P3, G4dn, and G5 GPU instance families.

**Sequence-to-Sequence Sample Notebooks**

For a sample notebook that shows how to use the SageMaker Sequence to Sequence algorithm to train an English-German translation model, see Machine Translation English-German Example Using SageMaker Seq2Seq. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances (p. 298). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the NTM algorithms are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

**How Sequence-to-Sequence Works**

Typically, a neural network for sequence-to-sequence modeling consists of a few layers, including:

- **An embedding layer.** In this layer, the input matrix, which is input tokens encoded in a sparse way (for example, one-hot encoded) are mapped to a dense feature layer. This is required because a high-dimensional feature vector is more capable of encoding information regarding a particular token (word for text corpora) than a simple one-hot-encoded vector. It is also a standard practice to initialize this embedding layer with a pre-trained word vector like FastText or Glove or to initialize it randomly and learn the parameters during training.

- **An encoder layer.** After the input tokens are mapped into a high-dimensional feature space, the sequence is passed through an encoder layer to compress all the information from the input embedding layer (of the entire sequence) into a fixed-length feature vector. Typically, an encoder is made of RNN-type networks like long short-term memory (LSTM) or gated recurrent units (GRU). (Colah's blog explains LSTM in a great detail.)

- **A decoder layer.** The decoder layer takes this encoded feature vector and produces the output sequence of tokens. This layer is also usually built with RNN architectures (LSTM and GRU).

The whole model is trained jointly to maximize the probability of the target sequence given the source sequence. This model was first introduced by Sutskever et al. in 2014.

**Attention mechanism.** The disadvantage of an encoder-decoder framework is that model performance decreases as and when the length of the source sequence increases because of the limit of how much information the fixed-length encoded feature vector can contain. To tackle this problem, in 2015, Bahdanau et al. proposed the attention mechanism. In an attention mechanism, the decoder tries to find the location in the encoder sequence where the most important information could be located and uses that information and previously decoded words to predict the next token in the sequence.

For more in details, see the whitepaper Effective Approaches to Attention-based Neural Machine Translation by Luong, et al. that explains and simplifies calculations for various attention mechanisms. Additionally, the whitepaper Google's Neural Machine Translation System: Bridging the Gap between Human and Machine Translation by Wu, et al. describes Google's architecture for machine translation, which uses skip connections between encoder and decoder layers.

**Tune a Sequence-to-Sequence Model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 1863).

**Metrics Computed by the Sequence-to-Sequence Algorithm**

The sequence to sequence algorithm reports three metrics that are computed during training. Choose one of them as an objective to optimize when tuning the hyperparameter values.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>validation:accuracy</td>
<td>Accuracy computed on the validation dataset.</td>
<td>Maximize</td>
</tr>
<tr>
<td>validation:bleu</td>
<td>Bleu score computed on the validation dataset. Because BLEU computation is expensive, you can choose to compute BLEU on a random subsample of the validation dataset to speed up the overall training process. Use the bleu_sample_size parameter to specify the subsample.</td>
<td>Maximize</td>
</tr>
<tr>
<td>validation:perplexity</td>
<td>Perplexity, is a loss function computed on the validation dataset. Perplexity measures the cross-entropy between an empirical sample and the distribution predicted by a model and so provides a measure of how well a model predicts the sample values, Models that are good at predicting a sample have a low perplexity.</td>
<td>Minimize</td>
</tr>
</tbody>
</table>

**Tunable Sequence-to-Sequence Hyperparameters**

You can tune the following hyperparameters for the SageMaker Sequence to Sequence algorithm. The hyperparameters that have the greatest impact on sequence to sequence objective...
metrics are: batch_size, optimizer_type, learning_rate, num_layers_encoder, and num_layers_decoder.

<table>

Text Classification - TensorFlow

The Amazon SageMaker Text Classification - TensorFlow algorithm is a supervised learning algorithm that supports transfer learning with many pretrained models from the TensorFlow Hub. Use transfer learning to fine-tune one of the available pretrained models on your own dataset, even if a large amount of text data is not available. The text classification algorithm takes a text string as input and outputs a probability for each of the class labels. Training datasets must be in CSV format.

Topics

- How to use the SageMaker Text Classification - TensorFlow algorithm (p. 1698)
- Input and output interface for the Text Classification - TensorFlow algorithm (p. 1699)

How to use the SageMaker Text Classification - TensorFlow algorithm

You can use Text Classification - TensorFlow as an Amazon SageMaker built-in algorithm. The following section describes how to use Text Classification - TensorFlow with the SageMaker Python SDK. For information on how to use Text Classification - TensorFlow from the Amazon SageMaker Studio UI, see SageMaker JumpStart (p. 161).

The Text Classification - TensorFlow algorithm supports transfer learning using any of the compatible pretrained TensorFlow models. For a list of all available pretrained models, see TensorFlow Hub Models (p. 1701). Every pretrained model has a unique model_id. The following example uses BERT Base Uncased (model_id: tensorflow-tc-bert-en-uncased-L-12-H-768-A-12-2) to fine-tune on a custom dataset. The pretrained models are all pre-downloaded from the TensorFlow Hub and stored in Amazon S3 buckets so that training jobs can run in network isolation. Use these pre-generated model training artifacts to construct a SageMaker Estimator.

First, retrieve the Docker image URI, training script URI, and pretrained model URI. Then, change the hyperparameters as you see fit. You can see a Python dictionary of all available hyperparameters and their default values with hyperparameters.retrieve_default. For more information, see Text Classification - TensorFlow Hyperparameters (p. 1704). Use these values to construct a SageMaker Estimator.

Note

Default hyperparameter values are different for different models. For example, for larger models, the default batch size is smaller.
This example uses the SST2 dataset, which contains positive and negative movie reviews. We pre-downloaded the dataset and made it available with Amazon S3. To fine-tune your model, call .fit using the Amazon S3 location of your training dataset. Any S3 bucket used in a notebook must be in the same AWS Region as the notebook instance that accesses it.

```
from sagemaker import image_uris, model_uris, script_uris, hyperparameters
from sagemaker.estimator import Estimator

model_id, model_version = "tensorflow-tc-bert-en-uncased-L-12-H-768-A-12-2", "*
training_instance_type = "ml.p3.2xlarge"

# Retrieve the Docker image
train_image_uri =
    image_uris.retrieve(model_id=model_id,model_version=model_version,image_scope="training",instance_type=training_instance_type)

# Retrieve the training script
train_source_uri = script_uris.retrieve(model_id=model_id, model_version=model_version,
    script_scope="training")

# Retrieve the pretrained model tarball for transfer learning
train_model_uri = model_uris.retrieve(model_id=model_id, model_version=model_version,
    model_scope="training")

# Retrieve the default hyperparameters for fine-tuning the model
hyperparameters = hyperparameters.retrieve_default(model_id=model_id,
    model_version=model_version)

# [Optional] Override default hyperparameters with custom values
hyperparameters["epochs"] = "5"

# Sample training data is available in this bucket
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/SST2/"
training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}"

output_bucket = sess.default_bucket()
output_prefix = "jumpstart-example-tc-training"
s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"

# Create an Estimator instance
tf_tc_estimator = Estimator(  
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
    instance_count=1,
    instance_type=training_instance_type,
    max_run=360000,
    hyperparameters=hyperparameters,
    output_path=s3_output_location,
)

# Launch a training job
tf_tc_estimator.fit({"training": training_dataset_s3_path}, logs=True)
```

For more information about how to use the SageMaker Text Classification - TensorFlow algorithm for transfer learning on a custom dataset, see the Introduction to JumpStart - Text Classification notebook.

**Input and output interface for the Text Classification - TensorFlow algorithm**

Each of the pretrained models listed in TensorFlow Hub Models can be fine-tuned to any dataset made up of text sentences with any number of classes. The pretrained model attaches a classification layer to
the Text Embedding model and initializes the layer parameters to random values. The output dimension of the classification layer is determined based on the number of classes detected in the input data.

Be mindful of how to format your training data for input to the Text Classification - TensorFlow model.

- **Training data input format:** A directory containing a data.csv file. Each row of the first column should have integer class labels between 0 and the number of classes. Each row of the second column should have the corresponding text data.

The following is an example of an input CSV file. Note that the file should not have any header. The file should be hosted in an Amazon S3 bucket with a path similar to the following:

```
s3://bucket_name/input_directory/. Note that the trailing / is required.
```

<p>| | |</p>

</tr>
<tr>
<td>1</td>
<td>that loves its characters and communicates something rather beautiful about human nature</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
</tbody>
</table>

**Incremental training**

You can seed the training of a new model with artifacts from a model that you trained previously with SageMaker. Incremental training saves training time when you want to train a new model with the same or similar data.

**Note**

You can only seed a SageMaker Text Classification - TensorFlow model with another Text Classification - TensorFlow model trained in SageMaker.

You can use any dataset for incremental training, as long as the set of classes remains the same. The incremental training step is similar to the fine-tuning step, but instead of starting with a pretrained model, you start with an existing fine-tuned model.

For more information on using incremental training with the SageMaker Text Classification - TensorFlow algorithm, see the [Introduction to JumpStart - Text Classification](#) sample notebook.

**Inference with the Text Classification - TensorFlow algorithm**

You can host the fine-tuned model that results from your TensorFlow Text Classification training for inference. Any raw text formats for inference must be content type application/x-text.

Running inference results in probability values, class labels for all classes, and the predicted label corresponding to the class index with the highest probability encoded in JSON format. The Text Classification - TensorFlow model processes a single string per request and outputs only one line. The following is an example of a JSON format response:

```
accept: application/json;verbose

{"probabilities": [prob_0, prob_1, prob_2, ...],
"labels": [label_0, label_1, label_2, ...],
"predicted_label": predicted_label}
```

If accept is set to application/json, then the model only outputs probabilities.

**Amazon EC2 instance recommendation for the Text Classification - TensorFlow algorithm**

The Text Classification - TensorFlow algorithm supports all CPU and GPU instances for training, including:
• `ml.p2.xlarge`
• `ml.p2.16xlarge`
• `ml.p3.2xlarge`
• `ml.p3.16xlarge`
• `ml.g4dn.xlarge`
• `ml.g4dn.16.xlarge`
• `ml.g5.xlarge`
• `ml.g5.48xlarge`

We recommend GPU instances with more memory for training with large batch sizes. Both CPU (such as M5) and GPU (P2, P3, G4dn, or G5) instances can be used for inference. For a comprehensive list of SageMaker training and inference instances across AWS Regions, see Amazon SageMaker Pricing.

Text Classification - TensorFlow sample notebooks

For more information about how to use the SageMaker Text Classification - TensorFlow algorithm for transfer learning on a custom dataset, see the Introduction to JumpStart - Text Classification notebook.

For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances. After you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. To open a notebook, choose its Use tab and choose Create copy.

How Text Classification - TensorFlow Works

The Text Classification - TensorFlow algorithm takes text as classifies it into one of the output class labels. Deep learning networks such as BERT are highly accurate for text classification. There are also deep learning networks that are trained on large text datasets, such as TextNet, which has more than 11 million texts with about 11,000 categories. After a network is trained with TextNet data, you can then fine-tune the network on a dataset with a particular focus to perform more specific text classification tasks. The Amazon SageMaker Text Classification - TensorFlow algorithm supports transfer learning on many pretrained models that are available in the TensorFlow Hub.

According to the number of class labels in your training data, a text classification layer is attached to the pretrained TensorFlow model of your choice. The classification layer consists of a dropout layer, a dense layer, and a fully connected layer with 2-norm regularization, and is initialized with random weights. You can change the hyperparameter values for the dropout rate of the dropout layer and the L2 regularization factor for the dense layer.

You can fine-tune either the entire network (including the pretrained model) or only the top classification layer on new training data. With this method of transfer learning, training with smaller datasets is possible.

TensorFlow Hub Models

The following pretrained models are available to use for transfer learning with the Text Classification - TensorFlow algorithm.

The following models vary significantly in size, number of model parameters, training time, and inference latency for any given dataset. The best model for your use case depends on the complexity of your fine-tuning dataset and any requirements that you have on training time, inference latency, or model accuracy.

</tr>
<tr>
<td>warmup_steps_fraction</td>
<td>The fraction of the total number of gradient update steps, where the learning rate increases from 0 to the initial learning rate as a warm up. Only used with the adamw optimizer. Valid values: float, range: [0.0, 1.0]. Default value: 0.1.</td>
</tr>
</tbody>
</table>

**Tune a Text Classification - TensorFlow model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 1863).

**Metrics computed by the Text Classification - TensorFlow algorithm**

Refer to the following chart to find which metrics are computed by the Text Classification - TensorFlow algorithm.

<table>

**Tunable Text Classification - TensorFlow hyperparameters**

Tune a text classification model with the following hyperparameters. The hyperparameters that have the greatest impact on text classification objective metrics are: batch_size, learning_rate, and optimizer. Tune the optimizer-related hyperparameters, such as momentum, regularizers_12, beta_1, beta_2, and eps based on the selected optimizer. For example, use beta_1 and beta_2 only when adamw or adam is the optimizer.
For more information about which hyperparameters are used for each optimizer, see Text Classification - TensorFlow Hyperparameters (p. 1704).

**DeepAR Forecasting Algorithm**

The Amazon SageMaker DeepAR forecasting algorithm is a supervised learning algorithm for forecasting scalar (one-dimensional) time series using recurrent neural networks (RNN). Classical forecasting methods, such as autoregressive integrated moving average (ARIMA) or exponential smoothing (ETS), fit a single model to each individual time series. They then use that model to extrapolate the time series into the future.
In many applications, however, you have many similar time series across a set of cross-sectional units. For example, you might have time series groupings for demand for different products, server loads, and requests for webpages. For this type of application, you can benefit from training a single model jointly over all of the time series. DeepAR takes this approach. When your dataset contains hundreds of related time series, DeepAR outperforms the standard ARIMA and ETS methods. You can also use the trained model to generate forecasts for new time series that are similar to the ones it has been trained on.

The training input for the DeepAR algorithm is one or, preferably, more target time series that have been generated by the same process or similar processes. Based on this input dataset, the algorithm trains a model that learns an approximation of this process/processes and uses it to predict how the target time series evolves. Each target time series can be optionally associated with a vector of static (time-independent) categorical features provided by the cat field and a vector of dynamic (time-dependent) time series provided by the dynamic_feat field. SageMaker trains the DeepAR model by randomly sampling training examples from each target time series in the training dataset. Each training example consists of a pair of adjacent context and prediction windows with fixed predefined lengths. To control how far in the past the network can see, use the context_length hyperparameter. To control how far in the future predictions can be made, use the prediction_length hyperparameter. For more information, see How the DeepAR Algorithm Works (p. 1713).

Input/Output Interface for the DeepAR Algorithm

DeepAR supports two data channels. The required train channel describes the training dataset. The optional test channel describes a dataset that the algorithm uses to evaluate model accuracy after training. You can provide training and test datasets in JSON Lines format. Files can be in gzip or Parquet file format.

When specifying the paths for the training and test data, you can specify a single file or a directory that contains multiple files, which can be stored in subdirectories. If you specify a directory, DeepAR uses all files in the directory as inputs for the corresponding channel, except those that start with a period (.) and those named _SUCCESS. This ensures that you can directly use output folders produced by Spark jobs as input channels for your DeepAR training jobs.

By default, the DeepAR model determines the input format from the file extension (.json, .json.gz, or .parquet) in the specified input path. If the path does not end in one of these extensions, you must explicitly specify the format in the SDK for Python. Use the content_type parameter of the s3_input class.

The records in your input files should contain the following fields:

- start—A string with the format YYYY-MM-DD HH:MM:SS. The start timestamp can't contain time zone information.
- target—An array of floating-point values or integers that represent the time series. You can encode missing values as null literals, or as "NaN" strings in JSON, or as nan floating-point values in Parquet.
- dynamic_feat (optional)—An array of arrays of floating-point values or integers that represents the vector of custom feature time series (dynamic features). If you set this field, all records must have the
same number of inner arrays (the same number of feature time series). In addition, each inner array must be the same length as the associated target value plus prediction_length. Missing values are not supported in the features. For example, if target time series represents the demand of different products, an associated dynamic_feat might be a boolean time-series which indicates whether a promotion was applied (1) to the particular product or not (0):

```
{"start": ..., "target": [1, 5, 10, 2], "dynamic_feat": [[0, 1, 1, 0]]}
```

- **cat** (optional)—An array of categorical features that can be used to encode the groups that the record belongs to. Categorical features must be encoded as a 0-based sequence of positive integers. For example, the categorical domain {R, G, B} can be encoded as {0, 1, 2}. All values from each categorical domain must be represented in the training dataset. That's because the DeepAR algorithm can forecast only for categories that have been observed during training. And, each categorical feature is embedded in a low-dimensional space whose dimensionality is controlled by the embedding_dimension hyperparameter. For more information, see DeepAR Hyperparameters (p. 1715).

If you use a JSON file, it must be in JSON Lines format. For example:

```
{"start": "2009-11-01 00:00:00", "target": [4.3, "NaN", 5.1, ...], "cat": [0, 1], "dynamic_feat": [[1.1, 1.2, 0.5, ...]]}
{"start": "2012-01-30 00:00:00", "target": [1.0, -5.0, ...], "cat": [2, 3], "dynamic_feat": [[1.1, 2.05, ...]]}
{"start": "1999-01-30 00:00:00", "target": [2.0, 1.0], "cat": [1, 4], "dynamic_feat": [[1.3, 0.4]]}
```

In this example, each time series has two associated categorical features and one time series features.

For Parquet, you use the same three fields as columns. In addition, "start" can be the datatime type. You can compress Parquet files using gzip (gzip) or the Snappy compression library (snappy).

If the algorithm is trained without cat and dynamic_feat fields, it learns a "global" model, that is a model that is agnostic to the specific identity of the target time series at inference time and is conditioned only on its shape.

If the model is conditioned on the cat and dynamic_feat feature data provided for each time series, the prediction will probably be influenced by the character of time series with the corresponding cat features. For example, if the target time series represents the demand of clothing items, you can associate a two-dimensional cat vector that encodes the type of item (e.g. 0 = shoes, 1 = dress) in the first component and the color of an item (e.g. 0 = red, 1 = blue) in the second component. A sample input would look as follows:

```
{ "start": ..., "target": ..., "cat": [0, 0], ... } # red shoes
{ "start": ..., "target": ..., "cat": [1, 1], ... } # blue dress
```

At inference time, you can request predictions for targets with cat values that are combinations of the cat values observed in the training data, for example:

```
{ "start": ..., "target": ..., "cat": [0, 1], ... } # blue shoes
{ "start": ..., "target": ..., "cat": [1, 0], ... } # red dress
```

The following guidelines apply to training data:

- The start time and length of the time series can differ. For example, in marketing, products often enter a retail catalog at different dates, so their start dates naturally differ. But all series must have the same frequency, number of categorical features, and number of dynamic features.
Use Built-in Algorithms

- Shuffle the training file with respect to the position of the time series in the file. In other words, the time series should occur in random order in the file.
- Make sure to set the `start` field correctly. The algorithm uses the `start` timestamp to derive the internal features.
- If you use categorical features (`cat`), all time series must have the same number of categorical features. If the dataset contains the `cat` field, the algorithm uses it and extracts the cardinality of the groups from the dataset. By default, `cardinality` is "auto". If the dataset contains the `cat` field, but you don’t want to use it, you can disable it by setting `cardinality` to "". If a model was trained using a `cat` feature, you must include it for inference.
- If your dataset contains the `dynamic_feat` field, the algorithm uses it automatically. All time series have to have the same number of feature time series. The time points in each of the feature time series correspond one-to-one to the time points in the target. In addition, the entry in the `dynamic_feat` field should have the same length as the target. If the dataset contains the `dynamic_feat` field, but you don’t want to use it, disable it by setting `num_dynamic_feat` to "". If the model was trained with the `dynamic_feat` field, you must provide this field for inference. In addition, each of the features has to have the length of the provided target plus the `prediction_length`. In other words, you must provide the feature value in the future.

If you specify optional test channel data, the DeepAR algorithm evaluates the trained model with different accuracy metrics. The algorithm calculates the root mean square error (RMSE) over the test data as follows:

\[
RMSE = \sqrt{\frac{1}{nT} \sum_{i,t} (\hat{y}_{i,t} - y_{i,t})^2}
\]

\(y_{i,t}\) is the true value of time series \(i\) at the time \(t\). \(\hat{y}_{i,t}\) is the mean prediction. The sum is over all \(n\) time series in the test set and over the last \(T\) time points for each time series, where \(T\) corresponds to the forecast horizon. You specify the length of the forecast horizon by setting the `prediction_length` hyperparameter. For more information, see DeepAR Hyperparameters (p. 1715).

In addition, the algorithm evaluates the accuracy of the forecast distribution using weighted quantile loss. For a quantile in the range \([0, 1]\), the weighted quantile loss is defined as follows:

\[
w\text{QuantileLoss}[\tau] = 2 \frac{\sum_{i,t} Q^{(\tau)}_{i,t}}{\sum_{i,t} |y_{i,t}|}, \quad \text{with} \quad Q^{(\tau)}_{i,t} = \begin{cases} (1 - \tau)|q^{(\tau)}_{i,t} - y_{i,t}| & \text{if } q^{(\tau)}_{i,t} > y_{i,t} \\ \tau|q^{(\tau)}_{i,t} - y_{i,t}| & \text{otherwise} \end{cases}
\]

\(q_{i,t}^{(\tau)}\) is the \(\tau\)-quantile of the distribution that the model predicts. To specify which quantiles to calculate loss for, set the `test_quantiles` hyperparameter. In addition to these, the average of the prescribed quantile losses is reported as part of the training logs. For information, see DeepAR Hyperparameters (p. 1715).

For inference, DeepAR accepts JSON format and the following fields:

- "instances", which includes one or more time series in JSON Lines format
- A name of "configuration", which includes parameters for generating the forecast

For more information, see DeepAR Inference Formats (p. 1720).

**Best Practices for Using the DeepAR Algorithm**

When preparing your time series data, follow these best practices to achieve the best results:
• Except for when splitting your dataset for training and testing, always provide the entire time series for training, testing, and when calling the model for inference. Regardless of how you set context_length, don't break up the time series or provide only a part of it. The model uses data points further back than the value set in context_length for the lagged values feature.

• When tuning a DeepAR model, you can split the dataset to create a training dataset and a test dataset. In a typical evaluation, you would test the model on the same time series used for training, but on the future prediction_length time points that follow immediately after the last time point visible during training. You can create training and test datasets that satisfy this criteria by using the entire dataset (the full length of all time series that are available) as a test set and removing the last prediction_length time points from each time series for training. During training, the model doesn't see the target values for time points on which it is evaluated during testing. During testing, the algorithm withholding the last prediction_length points of each time series in the test set and generates a prediction. Then it compares the forecast with the withheld values. You can create more complex evaluations by repeating time series multiple times in the test set, but cutting them at different endpoints. With this approach, accuracy metrics are averaged over multiple forecasts from different time points. For more information, see Tune a DeepAR Model (p. 1719).

• Avoid using very large values (>400) for the prediction_length because it makes the model slow and less accurate. If you want to forecast further into the future, consider aggregating your data at a lower frequency. For example, use 5min instead of 1min.

• Because lags are used, a model can look further back in the time series than the value specified for context_length. Therefore, you don't need to set this parameter to a large value. We recommend starting with the value that you used for prediction_length.

• We recommend training a DeepAR model on as many time series as are available. Although a DeepAR model trained on a single time series might work well, standard forecasting algorithms, such as ARIMA or ETS, might provide more accurate results. The DeepAR algorithm starts to outperform the standard methods when your dataset contains hundreds of related time series. Currently, DeepAR requires that the total number of observations available across all training time series is at least 300.

EC2 Instance Recommendations for the DeepAR Algorithm

You can train DeepAR on both GPU and CPU instances and in both single and multi-machine settings. We recommend starting with a single CPU instance (for example, ml.c4.2xlarge or ml.c4.4xlarge), and switching to GPU instances and multiple machines only when necessary. Using GPUs and multiple machines improves throughput only for larger models (with many cells per layer and many layers) and for large mini-batch sizes (for example, greater than 512).

For inference, DeepAR supports only CPU instances.

Specifying large values for context_length, prediction_length, num_cells, num_layers, or mini_batch_size can create models that are too large for small instances. In this case, use a larger instance type or reduce the values for these parameters. This problem also frequently occurs when running hyperparameter tuning jobs. In that case, use an instance type large enough for the model tuning job and consider limiting the upper values of the critical parameters to avoid job failures.

DeepAR Sample Notebooks

For a sample notebook that shows how to prepare a time series dataset for training the SageMaker DeepAR algorithm and how to deploy the trained model for performing inferences, see DeepAR demo on electricity dataset, which illustrates the advanced features of DeepAR on a real world dataset. For instructions on creating and accessing Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances (p. 298). After creating and opening a notebook instance, choose the SageMaker Examples tab to see a list of all of the SageMaker examples. To open a notebook, choose its Use tab, and choose Create copy.
How the DeepAR Algorithm Works

During training, DeepAR accepts a training dataset and an optional test dataset. It uses the test dataset to evaluate the trained model. In general, the datasets don't have to contain the same set of time series. You can use a model trained on a given training set to generate forecasts for the future of the time series in the training set, and for other time series. Both the training and the test datasets consist of one or, preferably, more target time series. Each target time series can optionally be associated with a vector of feature time series and a vector of categorical features. For more information, see Input/Output Interface for the DeepAR Algorithm (p. 1709).

For example, the following is an element of a training set indexed by $i$ which consists of a target time series, $Z_{i,t}$, and two associated feature time series, $X_{i,1,t}$ and $X_{i,2,t}$:

The target time series might contain missing values, which are represented by line breaks in the time series. DeepAR supports only feature time series that are known in the future. This allows you to run "what if?" scenarios. What happens, for example, if I change the price of a product in some way?

Each target time series can also be associated with a number of categorical features. You can use these features to encode which groupings a time series belongs to. Categorical features allow the model to learn typical behavior for groups, which it can use to increase model accuracy. DeepAR implements this by learning an embedding vector for each group that captures the common properties of all time series in the group.

How Feature Time Series Work in the DeepAR Algorithm

To facilitate learning time-dependent patterns, such as spikes during weekends, DeepAR automatically creates feature time series based on the frequency of the target time series. It uses these derived feature time series with the custom feature time series that you provide during training and inference. The following figure shows two of these derived time series features: $u_{i,1,t}$ represents the hour of the day and $u_{i,2,t}$ the day of the week.
The DeepAR algorithm automatically generates these feature time series. The following table lists the derived features for the supported basic time frequencies.

<table>
<thead>
<tr>
<th>Frequency of the Time Series</th>

</tbody>
</table>

DeepAR trains a model by randomly sampling several training examples from each of the time series in the training dataset. Each training example consists of a pair of adjacent context and prediction windows with fixed predefined lengths. The context_length hyperparameter controls how far in the past the network can see, and the prediction_length hyperparameter controls how far in the future predictions can be made. During training, the algorithm ignores training set elements containing time series that are shorter than a specified prediction length. The following figure represents five samples with context lengths of 12 hours and prediction lengths of 6 hours drawn from element i. For brevity, we've omitted the feature time series $x_{i,1,t}$ and $u_{i,2,t}$.
To capture seasonality patterns, DeepAR also automatically feeds lagged values from the target time series. In the example with hourly frequency, for each time index, \( t = T \), the model exposes the \( z_{i,t} \) values, which occurred approximately one, two, and three days in the past.

For inference, the trained model takes as input target time series, which might or might not have been used during training, and forecasts a probability distribution for the next `prediction_length` values. Because DeepAR is trained on the entire dataset, the forecast takes into account patterns learned from similar time series.

For information on the mathematics behind DeepAR, see [DeepAR: Probabilistic Forecasting with Autoregressive Recurrent Networks](#).

### DeepAR Hyperparameters

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>context_length</code></td>
<td>The number of time-points that the model gets to see before making the prediction. The value for this parameter should be about the same as the <code>prediction_length</code>. The model also receives lagged inputs from the target, so <code>context_length</code> can be much smaller than typical seasonalities. For example, a daily time series can have yearly seasonality. The model automatically includes a lag of one year, so the context length can be shorter than a year. The lag values that the model picks depend on the frequency of the time series. For example, lag values for daily frequency are previous week, 2 weeks, 3 weeks, 4 weeks, and year. <strong>Required</strong> Valid values: Positive integer</td>
</tr>
<tr>
<td><code>epochs</code></td>
<td>The maximum number of passes over the training data. The optimal value depends on your data size and learning rate. See also <code>early_stopping_patience</code>. Typical values range from 10 to 1000. <strong>Required</strong> Valid values: Positive integer</td>
</tr>
<tr>
<td><code>prediction_length</code></td>
<td>The number of time-steps that the model is trained to predict, also called the forecast horizon. The trained model always generates forecasts with this length. It can't generate longer forecasts. <strong>Required</strong> Valid values: Positive integer</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-------------</td>
</tr>
<tr>
<td>prediction_length</td>
<td>prediction_length is fixed when a model is trained and it cannot be changed later. Required Valid values: Positive integer</td>
</tr>
</tbody>
</table>
| time_freq | The granularity of the time series in the dataset. Use time_freq to select appropriate date features and lags. The model supports the following basic frequencies. It also supports multiples of these basic frequencies. For example, 5min specifies a frequency of 5 minutes.  
- M: monthly  
- W: weekly  
- D: daily  
- H: hourly  
- min: every minute Required Valid values: An integer followed by M, W, D, H, or min. For example, 5min. |
<p>| cardinality | When using the categorical features (cat), cardinality is an array specifying the number of categories (groups) per categorical feature. Set this to auto to infer the cardinality from the data. The auto mode also works when no categorical features are used in the dataset. This is the recommended setting for the parameter. Set cardinality to ignore to force DeepAR to not use categorical features, even if they are present in the data. To perform additional data validation, it is possible to explicitly set this parameter to the actual value. For example, if two categorical features are provided where the first has 2 and the other has 3 possible values, set this to [2, 3]. For more information on how to use categorical feature, see the data-section on the main documentation page of DeepAR. Optional Valid values: auto, ignore, array of positive integers, empty string, or Default value: auto |
| dropout_rate | The dropout rate to use during training. The model uses zoneout regularization. For each iteration, a random subset of hidden neurons are not updated. Typical values are less than 0.2. Optional Valid values: float Default value: 0.1 |</p>
<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>early_stopping_patience</td>
<td>If this parameter is set, training stops when no progress is made within the specified number of epochs. The model that has the lowest loss is returned as the final model. <em>Optional</em></td>
</tr>
<tr>
<td></td>
<td>Valid values: integer</td>
</tr>
<tr>
<td>embedding_dimension</td>
<td>Size of embedding vector learned per categorical feature (same value is used for all categorical features). The DeepAR model can learn group-level time series patterns when a categorical grouping feature is provided. To do this, the model learns an embedding vector of size embedding_dimension for each group, capturing the common properties of all time series in the group. A larger embedding_dimension allows the model to capture more complex patterns. However, because increasing the embedding_dimension increases the number of parameters in the model, more training data is required to accurately learn these parameters. Typical values for this parameter are between 10-100. <em>Optional</em></td>
</tr>
<tr>
<td></td>
<td>Valid values: positive integer</td>
</tr>
<tr>
<td></td>
<td>Default value: 10</td>
</tr>
<tr>
<td>learning_rate</td>
<td>The learning rate used in training. Typical values range from 1e-4 to 1e-1. <em>Optional</em></td>

<tr>
<td></td>
<td>Default value: 1e-3</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| likelihood        | The model generates a probabilistic forecast, and can provide quantiles of the distribution and return samples. Depending on your data, select an appropriate likelihood (noise model) that is used for uncertainty estimates. The following likelihoods can be selected:  
  - *gaussian*: Use for real-valued data.  
  - *beta*: Use for real-valued targets between 0 and 1 inclusive.  
  - *negative-binomial*: Use for count data (non-negative integers).  
  - *student-T*: An alternative for real-valued data that works well for bursty data.  
  - *deterministic-L1*: A loss function that does not estimate uncertainty and only learns a point forecast.  
  
  Optional  
  Valid values: One of *gaussian*, *beta*, *negative-binomial*, *student-T*, or *deterministic-L1*.  
  Default value: *student-T* |
| mini_batch_size   | The size of mini-batches used during training. Typical values range from 32 to 512.  
  
  Optional  
  Valid values: positive integer  
  Default value: 128 |
| num_cells         | The number of cells to use in each hidden layer of the RNN. Typical values range from 30 to 100.  
  
  Optional  
  Valid values: positive integer  
  Default value: 40 |
| num_dynamic_feat  | The number of dynamic feat provided in the data. Set this to auto to infer the number of dynamic features from the data. The auto mode also works when no dynamic features are used in the dataset. This is the recommended setting for the parameter.  
  
  To force DeepAR to not use dynamic features, even if they are present in the data, set *num_dynamic_feat* to *ignore*.  
  
  To perform additional data validation, it is possible to explicitly set this parameter to the actual integer value. For example, if two dynamic features are provided, set this to 2.  
  
  Optional  
  Valid values: auto, *ignore*, positive integer, or empty string  
  Default value: auto |
Use Built-in Algorithms

<table>

</tbody>
</table>

**Tune a DeepAR Model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 1863).

**Metrics Computed by the DeepAR Algorithm**

The DeepAR algorithm reports three metrics, which are computed during training. When tuning a model, choose one of these as the objective. For the objective, use either the forecast accuracy on a provided test channel (recommended) or the training loss. For recommendations for the training/test split for the DeepAR algorithm, see [Best Practices for Using the DeepAR Algorithm](p. 1711).

<table>
<thead>
<tr>

**DeepAR Inference Formats**

**DeepAR JSON Request Formats**

Query a trained model by using the model's endpoint. The endpoint takes the following JSON request format.

In the request, the instances field corresponds to the time series that should be forecast by the model.

If the model was trained with categories, you must provide a cat for each instance. If the model was trained without the cat field, it should be omitted.

If the model was trained with a custom feature time series (dynamic_feat), you have to provide the same number of dynamic_feat values for each instance. Each of them should have a length given by length(target) + prediction_length, where the last prediction_length values correspond to 1720.
the time points in the future that will be predicted. If the model was trained without custom feature time series, the field should not be included in the request.

```
{
    "instances": [
        {
            "start": "2009-11-01 00:00:00",
            "target": [4.0, 10.0, "NaN", 100.0, 113.0],
            "cat": [0, 1],
            "dynamic_feat": [[1.0, 1.1, 2.1, 0.5, 3.1, 4.1, 1.2, 5.0, ...]]
        },
        {
            "start": "2012-01-30",
            "target": [1.0],
            "cat": [2, 1],
            "dynamic_feat": [[2.0, 3.1, 4.5, 1.5, 1.8, 3.2, 0.1, 3.0, ...]]
        },
        {
            "start": "1999-01-30",
            "target": [2.0, 1.0],
            "cat": [1, 3],
            "dynamic_feat": [[1.0, 0.1, -2.5, 0.3, 2.0, -1.2, -0.1, -3.0, ...]]
        }
    ],
    "configuration": {
        "num_samples": 50,
        "output_types": ["mean", "quantiles", "samples"],
        "quantiles": ["0.5", "0.9"]
    }
}
```

The configuration field is optional. `configuration.num_samples` sets the number of sample paths that the model generates to estimate the mean and quantiles. `configuration.output_types` describes the information that will be returned in the request. Valid values are "mean", "quantiles" and "samples". If you specify "quantiles", each of the quantile values in `configuration.quantiles` is returned as a time series. If you specify "samples", the model also returns the raw samples used to calculate the other outputs.

**DeepAR JSON Response Formats**

The following is the format of a response, where [... ] are arrays of numbers:

```
{
    "predictions": [
        {
            "quantiles": {
                "0.9": [...],
                "0.5": [...]
            },
            "samples": [...],
            "mean": [...]
        },
        {
            "quantiles": {
                "0.9": [...],
                "0.5": [...]
            },
            "samples": [...],
            "mean": [...]
        },
        {
            "quantiles": {
                "0.9": [...],
                "0.5": [...]
            },
            "samples": [...],
            "mean": [...]
        }
    ]
}
```
DeepAR has a response timeout of 60 seconds. When passing multiple time series in a single request, the forecasts are generated sequentially. Because the forecast for each time series typically takes about 300 to 1000 milliseconds or longer, depending on the model size, passing too many time series in a single request can cause time outs. It's better to send fewer time series per request and send more requests. Because the DeepAR algorithm uses multiple workers per instance, you can achieve much higher throughput by sending multiple requests in parallel.

By default, DeepAR uses one worker per CPU for inference, if there is sufficient memory per CPU. If the model is large and there isn't enough memory to run a model on each CPU, the number of workers is reduced. The number of workers used for inference can be overwritten using the environment variable MODEL_SERVER_WORKERS For example, by setting MODEL_SERVER_WORKERS=1 when calling the SageMaker CreateModel API.

Batch Transform with the DeepAR Algorithm

DeepAR forecasting supports getting inferences by using batch transform from data using the JSON Lines format. In this format, each record is represented on a single line as a JSON object, and lines are separated by newline characters. The format is identical to the JSON Lines format used for model training. For information, see Input/Output Interface for the DeepAR Algorithm (p. 1709). For example:

```json
[{
  "start": "2009-11-01 00:00:00",
  "target": [4.3, NaN, 5.1, ...],
  "cat": [0, 1],
  "dynamic_feat": [[1.1, 1.2, 0.5, ..]]
},
{
  "start": "2012-01-30 00:00:00",
  "target": [1.0, -5.0, ...],
  "cat": [2, 3],
  "dynamic_feat": [[1.1, 2.05, ...]]
},
{
  "start": "1999-01-30 00:00:00",
  "target": [2.0, 1.0],
  "cat": [1, 4],
  "dynamic_feat": [[1.3, 0.4]]
}
]
```

**Note**

When creating the transformation job with CreateTransformJob, set the BatchStrategy value to SingleRecord and set the SplitType value in the TransformInput configuration to Line, as the default values currently cause runtime failures.

Similar to the hosted endpoint inference request format, the cat and the dynamic_feat fields for each instance are required if both of the following are true:

- The model is trained on a dataset that contained both the cat and the dynamic_feat fields.
- The corresponding cardinality and num_dynamic_feat values used in the training job are not set to "".

Unlike hosted endpoint inference, the configuration field is set once for the entire batch inference job using an environment variable named DEEPAR_INFEERENCE_CONFIG. The value of DEEPAR_INFEERENCE_CONFIG can be passed when the model is created by calling CreateTransformJob API. If DEEPAR_INFEERENCE_CONFIG is missing in the container environment, the inference container uses the following default:

```json
{
  "num_samples": 100,
  "output_types": ["mean", "quantiles"],
  "quantiles": ["0.1", "0.2", "0.3", "0.4", "0.5", "0.6", "0.7", "0.8", "0.9"]
}
```
The output is also in JSON Lines format, with one line per prediction, in an order identical to the instance order in the corresponding input file. Predictions are encoded as objects identical to the ones returned by responses in online inference mode. For example:

```json
{ "quantiles": { "0.1": [...], "0.2": [...] }, "samples": [...], "mean": [...] }
```

Note that in the `TransformInput` configuration of the SageMaker `CreateTransformJob` request clients must explicitly set the `AssembleWith` value to `Line`, as the default value `None` concatenates all JSON objects on the same line.

For example, here is a SageMaker `CreateTransformJob` request for a DeepAR job with a custom DEEPAR_INFERENCE_CONFIG:

```json
{
   "BatchStrategy": "SingleRecord",
   "Environment": {
      "DEEPAR_INFERENCE_CONFIG": "{ "num_samples": 200, "output_types": ["mean"] }",
      ...
   },
   "TransformInput": {
      "SplitType": "Line",
      ...
   },
   "TransformOutput": {
      "AssembleWith": "Line",
      ...
   }
}
```

## Unsupervised Built-in SageMaker Algorithms

Amazon SageMaker provides several built-in algorithms that can be used for a variety of unsupervised learning tasks such as clustering, dimension reduction, pattern recognition, and anomaly detection.

- **IP Insights (p. 1724)**—learns the usage patterns for IPv4 addresses. It is designed to capture associations between IPv4 addresses and various entities, such as user IDs or account numbers.
- **K-Means Algorithm (p. 1733)**—finds discrete groupings within data, where members of a group are as similar as possible to one another and as different as possible from members of other groups.
- **Principal Component Analysis (PCA) Algorithm (p. 1741)**—reduces the dimensionality (number of features) within a dataset by projecting data points onto the first few principal components. The objective is to retain as much information or variation as possible. For mathematicians, principal components are eigenvectors of the data's covariance matrix.
- **Random Cut Forest (RCF) Algorithm (p. 1745)**—detects anomalous data points within a data set that diverge from otherwise well-structured or patterned data.

IP Insights

Amazon SageMaker IP Insights is an unsupervised learning algorithm that learns the usage patterns for IPv4 addresses. It is designed to capture associations between IPv4 addresses and various entities, such as user IDs or account numbers. You can use it to identify a user attempting to log into a web service from an anomalous IP address, for example. Or you can use it to identify an account that is attempting to create computing resources from an unusual IP address. Trained IP Insight models can be hosted at an endpoint for making real-time predictions or used for processing batch transforms.

SageMaker IP insights ingests historical data as (entity, IPv4 Address) pairs and learns the IP usage patterns of each entity. When queried with an (entity, IPv4 Address) event, a SageMaker IP Insights model returns a score that infers how anomalous the pattern of the event is. For example, when a user attempts to log in from an IP address, if the IP Insights score is high enough, a web login server might decide to trigger a multi-factor authentication system. In more advanced solutions, you can feed the IP Insights score into another machine learning model. For example, you can combine the IP Insight score with other features to rank the findings of another security system, such as those from Amazon GuardDuty.

The SageMaker IP Insights algorithm can also learn vector representations of IP addresses, known as embeddings. You can use vector-encoded embeddings as features in downstream machine learning tasks that use the information observed in the IP addresses. For example, you can use them in tasks such as measuring similarities between IP addresses in clustering and visualization tasks.

Input/Output Interface for the IP Insights Algorithm

Training and Validation

The SageMaker IP Insights algorithm supports training and validation data channels. It uses the optional validation channel to compute an area-under-curve (AUC) score on a predefined negative sampling strategy. The AUC metric validates how well the model discriminates between positive and negative samples. Training and validation data content types need to be in text/csv format. The first column of the CSV data is an opaque string that provides a unique identifier for the entity. The second column
is an IPv4 address in decimal-dot notation. IP Insights currently supports only File mode. For more information and some examples, see [IP Insights Training Data Formats (p. 1731)](#).

**Inference**

For inference, IP Insights supports text/csv, application/json, and application/jsonlines data content types. For more information about the common data formats for inference provided by SageMaker, see [Common Data Formats for Inference (p. 1541)](#). IP Insights inference returns output formatted as either application/json or application/jsonlines. Each record in the output data contains the corresponding dot_product (or compatibility score) for each input data point. For more information and some examples, see [IP Insights Inference Data Formats (p. 1731)](#).

**EC2 Instance Recommendation for the IP Insights Algorithm**

The SageMaker IP Insights algorithm can run on both GPU and CPU instances. For training jobs, we recommend using GPU instances. However, for certain workloads with large training datasets, distributed CPU instances might reduce training costs. For inference, we recommend using CPU instances. IP Insights supports P2, P3, G4dn, and G5 GPU families.

**GPU Instances for the IP Insights Algorithm**

IP Insights supports all available GPUs. If you need to speed up training, we recommend starting with a single GPU instance, such as ml.p3.2xlarge, and then moving to a multi-GPU environment, such as ml.p3.8xlarge and ml.p3.16xlarge. Multi-GPUs automatically divide the mini batches of training data across themselves. If you switch from a single GPU to multiple GPUs, the mini_batch_size is divided equally into the number of GPUs used. You may want to increase the value of the mini_batch_size to compensate for this.

**CPU Instances for the IP Insights Algorithm**

The type of CPU instance that we recommend depends largely on the instance’s available memory and the model size. The model size is determined by two hyperparameters: `vector_dim` and `num_entity_vectors`. The maximum supported model size is 8 GB. The following table lists typical EC2 instance types that you would deploy based on these input parameters for various model sizes. In Table 1, the value for `vector_dim` in the first column range from 32 to 2048 and the values for `num_entity_vectors` in the first row range from 10,000 to 50,000,000.

<table>

The values for the mini_batch_size, num_ip_encoder_layers, random_negative_sampling_rate, and shuffled_negative_sampling_rate hyperparameters also affect the amount of memory required. If these values are large, you might need to use a larger instance type than normal.
IP Insights Sample Notebooks

For a sample notebook that shows how to train the SageMaker IP Insights algorithm and perform inferences with it, see An Introduction to the SageMakerIP Insights Algorithm. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances (p. 298). After creating a notebook instance, choose the SageMaker Examples tab to see a list of all the SageMaker examples. To open a notebook, choose its Use tab and choose Create copy.

How IP Insights Works

Amazon SageMaker IP Insights is an unsupervised algorithm that consumes observed data in the form of (entity, IPv4 address) pairs that associates entities with IP addresses. IP Insights determines how likely it is that an entity would use a particular IP address by learning latent vector representations for both entities and IP addresses. The distance between these two representations can then serve as the proxy for how likely this association is.

The IP Insights algorithm uses a neural network to learn the latent vector representations for entities and IP addresses. Entities are first hashed to a large but fixed hash space and then encoded by a simple embedding layer. Character strings such as user names or account IDs can be fed directly into IP Insights as they appear in log files. You don't need to preprocess the data for entity identifiers. You can provide entities as an arbitrary string value during both training and inference. The hash size should be configured with a value that is high enough to ensure that the number of collisions, which occur when distinct entities are mapped to the same latent vector, remain insignificant. For more information about how to select appropriate hash sizes, see Feature Hashing for Large Scale Multitask Learning. For representing IP addresses, on the other hand, IP Insights uses a specially designed encoder network to uniquely represent each possible IPv4 address by exploiting the prefix structure of IP addresses.

During training, IP Insights automatically generates negative samples by randomly pairing entities and IP addresses. These negative samples represent data that is less likely to occur in reality. The model is trained to discriminate between positive samples that are observed in the training data and these generated negative samples. More specifically, the model is trained to minimize the cross entropy, also known as the log loss, defined as follows:

$$L = \frac{1}{N} \sum_n \left[y_n \log p_n + (1 - y_n) \log (1 - p_n)\right]$$

$y_n$ is the label that indicates whether the sample is from the real distribution governing observed data ($y_n=1$) or from the distribution generating negative samples ($y_n=0$). $p_n$ is the probability that the sample is from the real distribution, as predicted by the model.

Generating negative samples is an important process that is used to achieve an accurate model of the observed data. If negative samples are extremely unlikely, for example, if all of the IP addresses in negative samples are 10.0.0.0, then the model trivially learns to distinguish negative samples and fails to accurately characterize the actual observed dataset. To keep negative samples more realistic, IP Insights generates negative samples both by randomly generating IP addresses and randomly picking IP addresses from training data. You can configure the type of negative sampling and the rates at which negative samples are generated with the random_negative_sampling_rate and shuffled_negative_sampling_rate hyperparameters.

Given an nth (entity, IP address pair), the IP Insights model outputs a score, $S_n$, that indicates how compatible the entity is with the IP address. This score corresponds to the log odds ratio for a given (entity, IP address) of the pair coming from a real distribution as compared to coming from a negative distribution. It is defined as follows:

$$S_n = \log \left(\frac{P_{\text{real}}(n)}{P_{\text{neg}}(n)}\right)$$

The score is essentially a measure of the similarity between the vector representations of the nth entity and IP address. It can be interpreted as how much more likely it would be to observe this event in reality.
than in a randomly generated dataset. During training, the algorithm uses this score to calculate an estimate of the probability of a sample coming from the real distribution, $p_n$, to use in the cross entropy minimization, where:

$$ p_n = \frac{1}{1 + e^{-s_n}} $$

### IP Insights Hyperparameters

In the `CreateTransformJob` request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the Amazon SageMaker IP Insights algorithm.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_entity_vectors</td>
<td>The number of entity vector representations (entity embedding vectors) to train. Each entity in the training set is randomly assigned to one of these vectors using a hash function. Because of hash collisions, it might be possible to have multiple entities assigned to the same vector. This would cause the same vector to represent multiple entities. This generally has a negligible effect on model performance, as long as the collision rate is not too severe. To keep the collision rate low, set this value as high as possible. However, the model size, and, therefore, the memory requirement, for both training and inference, scales linearly with this hyperparameter. We recommend that you set this value to twice the number of unique entity identifiers. <strong>Required</strong>&lt;br&gt;Valid values: $1 \leq$ positive integer $\leq 250,000,000$</td>
</tr>
<tr>
<td>vector_dim</td>
<td>The size of embedding vectors to represent entities and IP addresses. The larger the value, the more information that can be encoded using these representations. In practice, model size scales linearly with this parameter and limits how large the dimension can be. In addition, using vector representations that are too large can cause the model to overfit, especially for small training datasets. Overfitting occurs when a model doesn't learn any pattern in the data but effectively memorizes the training data and, therefore, cannot generalize well and performs poorly during inference. The recommended value is 128. <strong>Required</strong>&lt;br&gt;Valid values: $4 \leq$ positive integer $\leq 4096$</td>
</tr>
<tr>
<td>batch_metrics_publish_interval</td>
<td>The interval (every X batches) at which the Apache MXNet Speedometer function prints the training speed of the network (samples/second). <strong>Optional</strong>&lt;br&gt;Valid values: positive integer $\geq 1$ Default value: 1,000</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>epochs</td>
<td>The number of passes over the training data. The optimal value depends on your data size and learning rate. Typical values range from 5 to 100.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: positive integer ≥ 1</td>
</tr>
<tr>
<td></td>
<td>Default value: 10</td>
</tr>
<tr>
<td>learning_rate</td>
<td>The learning rate for the optimizer. IP Insights use a gradient-descent-based Adam optimizer. The learning rate effectively controls the step size to update model parameters at each iteration. Too large a learning rate can cause the model to diverge because the training is likely to overshoot a minima. On the other hand, too small a learning rate slows down convergence. Typical values range from 1e-4 to 1e-1.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: 1e-6 ≤ float ≤ 10.0</td>
</tr>
<tr>
<td></td>
<td>Default value: 0.001</td>
</tr>
<tr>
<td>mini_batch_size</td>
<td>The number of examples in each mini batch. The training procedure processes data in mini batches. The optimal value depends on the number of unique account identifiers in the dataset. In general, the larger the mini_batch_size, the faster the training and the greater the number of possible shuffled-negative-sample combinations. However, with a large mini_batch_size, the training is more likely to converge to a poor local minimum and perform relatively worse for inference.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: 1 ≤ positive integer ≤ 500000</td>
</tr>
<tr>
<td></td>
<td>Default value: 10,000</td>
</tr>
<tr>
<td>num_ip_encoder_layers</td>
<td>The number of fully connected layers used to encode the IP address embedding. The larger the number of layers, the greater the model's capacity to capture patterns among IP addresses. However, using a large number of layers increases the chance of overfitting.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: 0 ≤ positive integer ≤ 100</td>
</tr>
<tr>
<td></td>
<td>Default value: 1</td>
</tr>
</tbody>
</table>
### Parameter Name | Description
---|---
**random_negative_sampling_rate** | The number of random negative samples, R, to generate per input example. The training procedure relies on negative samples to prevent the vector representations of the model collapsing to a single point. Random negative sampling generates R random IP addresses for each input account in the mini batch. The sum of the `random_negative_sampling_rate` (R) and `shuffled_negative_sampling_rate` (S) must be in the interval: 1 ≤ R + S ≤ 500.  
Optional  
Valid values: 0 ≤ positive integer ≤ 500  
Default value: 1

**shuffled_negative_sampling_rate** | The number of shuffled negative samples, S, to generate per input example. In some cases, it helps to use more realistic negative samples that are randomly picked from the training data itself. This kind of negative sampling is achieved by shuffling the data within a mini batch. Shuffled negative sampling generates S negative IP addresses by shuffling the IP address and account pairings within a mini batch. The sum of the `random_negative_sampling_rate` (R) and `shuffled_negative_sampling_rate` (S) must be in the interval: 1 ≤ R + S ≤ 500.  
Optional  
Valid values: 0 ≤ positive integer ≤ 500  
Default value: 1

**weight_decay** | The weight decay coefficient. This parameter adds an L2 regularization factor that is required to prevent the model from overfitting the training data.  
Optional  
Valid values: 0.0 ≤ float ≤ 10.0  
Default value: 0.00001

---

**Tune an IP Insights Model**

*Automatic model tuning*, also called hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 1863).
Metrics Computed by the IP Insights Algorithm

The Amazon SageMaker IP Insights algorithm is an unsupervised learning algorithm that learns associations between IP addresses and entities. The algorithm trains a discriminator model, which learns to separate observed data points (positive samples) from randomly generated data points (negative samples). Automatic model tuning on IP Insights helps you find the model that can most accurately distinguish between unlabeled validation data and automatically generated negative samples. The model accuracy on the validation dataset is measured by the area under the receiver operating characteristic curve. This validation:discriminator_auc metric can take values between 0.0 and 1.0, where 1.0 indicates perfect accuracy.

The IP Insights algorithm computes a validation:discriminator_auc metric during validation, the value of which is used as the objective function to optimize for hyperparameter tuning.

<table>

IP Insights Data Formats

This section provides examples of the available input and output data formats used by the IP Insights algorithm during training and inference.

Topics
- IP Insights Training Data Formats (p. 1731)
- IP Insights Inference Data Formats (p. 1731)

IP Insights Training Data Formats

The following are the available data input formats for the IP Insights algorithm. Amazon SageMaker built-in algorithms adhere to the common input training format described in Common Data Formats for Training (p. 1537). However, the SageMaker IP Insights algorithm currently supports only the CSV data input format.

IP Insights Training Data Input Formats

**INPUT: CSV**

The CSV file must have two columns. The first column is an opaque string that corresponds to an entity's unique identifier. The second column is the IPv4 address of the entity's access event in decimal-dot notation.

```
content-type: text/csv

entity_id_1, 192.168.1.2
entity_id_2, 10.10.1.2
```

IP Insights Inference Data Formats

The following are the available input and output formats for the IP Insights algorithm. Amazon SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats for Inference (p. 1541). However, the SageMaker IP Insights algorithm does not currently support RecordIO format.

IP Insights Input Request Formats

**INPUT: CSV Format**

The CSV file must have two columns. The first column is an opaque string that corresponds to an entity's unique identifier. The second column is the IPv4 address of the entity's access event in decimal-dot notation.

```
content-type: text/csv

entity_id_1, 192.168.1.2
entity_id_2, 10.10.1.2
```

**INPUT: JSON Format**

JSON data can be provided in different formats. IP Insights follows the common SageMaker formats. For more information about inference formats, see Common Data Formats for Inference (p. 1541).

```
content-type: application/json
```

1731
Use Built-in Algorithms

INPUT: JSONLINES Format

The JSON Lines content type is useful for running batch transform jobs. For more information on SageMaker inference formats, see Common Data Formats for Inference (p. 1541). For more information on running batch transform jobs, see Use Batch Transform (p. 2545).

close-up:application/jsonlines

```
{"data": {"features": {"values": ["entity_id_1", "192.168.1.2"]},
"features": ["entity_id_2", "10.10.1.2"]}}
```

IP Insights Output Response Formats

OUTPUT: JSON Response Format

The default output of the SageMaker IP Insights algorithm is the dot_product between the input entity and IP address. The dot_product signifies how compatible the model considers the entity and IP address. The dot_product is unbounded. To make predictions about whether an event is anomalous, you need to set a threshold based on your defined distribution. For information about how to use the dot_product for anomaly detection, see the An Introduction to the SageMakerIP Insights Algorithm.

close-up:application/json

```
{  "predictions": [
   {"dot_product": 0.0},
   {"dot_product": 2.0}
  ]
}
```

Advanced users can access the model's learned entity and IP embeddings by providing the additional content-type parameter verbose=True to the Accept header. You can use the entity_embedding and ip_embedding for debugging, visualizing, and understanding the model. Additionally, you can use these embeddings in other machine learning techniques, such as classification or clustering.

close-up:application/json;verbose=True

```
{  "predictions": [
   {"dot_product": 0.0,
    "entity_embedding": [1.0, 0.0, 0.0],
    "ip_embedding": [0.0, 1.0, 0.0]}
   ,
   {"dot_product": 2.0,
    "entity_embedding": [1.0, 0.0, 1.0],
    "ip_embedding": [1.0, 0.0, 1.0]}
  ]
}
```
K-Means Algorithm

K-means is an unsupervised learning algorithm. It attempts to find discrete groupings within data, where members of a group are as similar as possible to one another and as different as possible from members of other groups. You define the attributes that you want the algorithm to use to determine similarity.

Amazon SageMaker uses a modified version of the web-scale k-means clustering algorithm. Compared with the original version of the algorithm, the version used by Amazon SageMaker is more accurate. Like the original algorithm, it scales to massive datasets and delivers improvements in training time. To do this, the version used by Amazon SageMaker streams mini-batches (small, random subsets) of the training data. For more information about mini-batch k-means, see [Web-scale k-means Clustering](#).

The k-means algorithm expects tabular data, where rows represent the observations that you want to cluster, and the columns represent attributes of the observations. The n attributes in each row represent a point in n-dimensional space. The Euclidean distance between these points represents the similarity of the corresponding observations. The algorithm groups observations with similar attribute values (the points corresponding to these observations are closer together). For more information about how k-means works in Amazon SageMaker, see [How K-Means Clustering Works](#) (p. 1734).

Topics
- **Input/Output Interface for the K-Means Algorithm** (p. 1733)
- **EC2 Instance Recommendation for the K-Means Algorithm** (p. 1734)
- **K-Means Sample Notebooks** (p. 1734)
- **How K-Means Clustering Works** (p. 1734)
- **K-Means Hyperparameters** (p. 1737)
- **Tune a K-Means Model** (p. 1739)
- **K-Means Response Formats** (p. 1740)

Input/Output Interface for the K-Means Algorithm

For training, the k-means algorithm expects data to be provided in the `train` channel (recommended `S3DataDistributionType=ShardedByS3Key`), with an optional test channel (recommended `S3DataDistributionType=FullyReplicated`) to score the data on. Both recordIO-wrapped-protobuf and CSV formats are supported for training. You can use either File mode or Pipe mode to train models on data that is formatted as recordIO-wrapped-protobuf or as CSV.

For inference, `text/csv`, `application/json`, and `application/x-recordio-protobuf` are supported. k-means returns a `closest_cluster` label and the `distance_to_cluster` for each observation.

For more information on input and output file formats, see [K-Means Response Formats](#) (p. 1740) for inference and the [K-Means Sample Notebooks](#) (p. 1734). The k-means algorithm does not support
multiple instance learning, in which the training set consists of labeled “bags”, each of which is a collection of unlabeled instances.

**EC2 Instance Recommendation for the K-Means Algorithm**

We recommend training k-means on CPU instances. You can train on GPU instances, but should limit GPU training to single-GPU instances (such as ml.g4dn.xlarge) because only one GPU is used per instance. The k-means algorithm supports P2, P3, G4dn, and G5 instances for training and inference.

**K-Means Sample Notebooks**

For a sample notebook that uses the SageMaker K-means algorithm to segment the population of counties in the United States by attributes identified using principle component analysis, see [Analyze US census data for population segmentation using Amazon SageMaker](#). For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see [Amazon SageMaker Notebook Instances](#). Once you have created a notebook instance and opened it, select the **SageMaker Examples** tab to see a list of all the SageMaker samples. To open a notebook, click on its **Use** tab and select **Create copy**.

**How K-Means Clustering Works**

K-means is an algorithm that trains a model that groups similar objects together. The k-means algorithm accomplishes this by mapping each observation in the input dataset to a point in the n-dimensional space (where n is the number of attributes of the observation). For example, your dataset might contain observations of temperature and humidity in a particular location, which are mapped to points $(t, h)$ in 2-dimensional space.

**Note**

Clustering algorithms are unsupervised. In unsupervised learning, labels that might be associated with the objects in the training dataset aren't used. For more information, see [Unsupervised learning](#).

In k-means clustering, each cluster has a center. During model training, the k-means algorithm uses the distance of the point that corresponds to each observation in the dataset to the cluster centers as the basis for clustering. You choose the number of clusters ($k$) to create.

For example, suppose that you want to create a model to recognize handwritten digits and you choose the MNIST dataset for training. The dataset provides thousands of images of handwritten digits (0 through 9). In this example, you might choose to create 10 clusters, one for each digit (0, 1, ..., 9). As part of model training, the k-means algorithm groups the input images into 10 clusters.

Each image in the MNIST dataset is a 28x28-pixel image, with a total of 784 pixels. Each image corresponds to a point in a 784-dimensional space, similar to a point in a 2-dimensional space $(x, y)$. To find a cluster to which a point belongs, the k-means algorithm finds the distance of that point from all of the cluster centers. It then chooses the cluster with the closest center as the cluster to which the image belongs.

**Note**

Amazon SageMaker uses a customized version of the algorithm where, instead of specifying that the algorithm create $k$ clusters, you might choose to improve model accuracy by specifying extra cluster centers ($K = k \times x$). However, the algorithm ultimately reduces these to $k$ clusters.

In SageMaker, you specify the number of clusters when creating a training job. For more information, see [CreateTrainingJob](#). In the request body, you add the HyperParameters string map to specify the $k$ and `extra_center_factor` strings.

The following is a summary of how k-means works for model training in SageMaker:

1. It determines the initial $K$ cluster centers.
Note
In the following topics, K clusters refer to $k \times x$, where you specify $k$ and $x$ when creating a model training job.

2. It iterates over input training data and recalculates cluster centers.
3. It reduces resulting clusters to $k$ (if the data scientist specified the creation of $k \times x$ clusters in the request).

The following sections also explain some of the parameters that a data scientist might specify to configure a model training job as part of the HyperParameters string map.

Topics
- Step 1: Determine the Initial Cluster Centers (p. 1735)
- Step 2: Iterate over the Training Dataset and Calculate Cluster Centers (p. 1736)
- Step 3: Reduce the Clusters from K to k (p. 1736)

Step 1: Determine the Initial Cluster Centers

When using k-means in SageMaker, the initial cluster centers are chosen from the observations in a small, randomly sampled batch. Choose one of the following strategies to determine how these initial cluster centers are selected:

- The random approach—Randomly choose $K$ observations in your input dataset as cluster centers. For example, you might choose a cluster center that points to the 784-dimensional space that corresponds to any 10 images in the MNIST training dataset.

- The k-means++ approach, which works as follows:
  1. Start with one cluster and determine its center. You randomly select an observation from your training dataset and use the point corresponding to the observation as the cluster center. For example, in the MNIST dataset, randomly choose a handwritten digit image. Then choose the point in the 784-dimensional space that corresponds to the image as your cluster center. This is cluster center 1.
  2. Determine the center for cluster 2. From the remaining observations in the training dataset, pick an observation at random. Choose one that is different than the one you previously selected. This observation corresponds to a point that is far away from cluster center 1. Using the MNIST dataset as an example, you do the following:
    - For each of the remaining images, find the distance of the corresponding point from cluster center 1. Square the distance and assign a probability that is proportional to the square of the distance. That way, an image that is different from the one that you previously selected has a higher probability of getting selected as cluster center 2.
    - Choose one of the images randomly, based on probabilities assigned in the previous step. The point that corresponds to the image is cluster center 2.
  3. Repeat Step 2 to find cluster center 3. This time, find the distances of the remaining images from cluster center 2.
  4. Repeat the process until you have the $K$ cluster centers.

To train a model in SageMaker, you create a training job. In the request, you provide configuration information by specifying the following HyperParameters string maps:

- To specify the number of clusters to create, add the $k$ string.
- For greater accuracy, add the optional extra_center_factor string.
- To specify the strategy that you want to use to determine the initial cluster centers, add the init_method string and set its value to random or k-means++.  

1735
For more information about the SageMaker k-means estimator, see K-means in the Amazon SageMaker Python SDK documentation.

You now have an initial set of cluster centers.

Step 2: Iterate over the Training Dataset and Calculate Cluster Centers

The cluster centers that you created in the preceding step are mostly random, with some consideration for the training dataset. In this step, you use the training dataset to move these centers toward the true cluster centers. The algorithm iterates over the training dataset, and recalculates the $K$ cluster centers.

1. Read a mini-batch of observations (a small, randomly chosen subset of all records) from the training dataset and do the following.

   Note
   When creating a model training job, you specify the batch size in the mini_batch_size string in the HyperParameters string map.

   a. Assign all of the observations in the mini-batch to one of the clusters with the closest cluster center.

   b. Calculate the number of observations assigned to each cluster. Then, calculate the proportion of new points assigned per cluster.

   For example, consider the following clusters:

   Cluster c1 = 100 previously assigned points. You added 25 points from the mini-batch in this step.

   Cluster c2 = 150 previously assigned points. You added 40 points from the mini-batch in this step.

   Cluster c3 = 450 previously assigned points. You added 5 points from the mini-batch in this step.

   Calculate the proportion of new points assigned to each of clusters as follows:

   $p_1 = \frac{25}{100+25}$
   $p_2 = \frac{40}{150+40}$
   $p_3 = \frac{5}{450+5}$

   c. Compute the center of the new points added to each cluster:

   $d_1 = \text{center of the new points added to cluster 1}$
   $d_2 = \text{center of the new points added to cluster 2}$
   $d_3 = \text{center of the new points added to cluster 3}$

   d. Compute the weighted average to find the updated cluster centers as follows:

   Center of cluster 1 = $((1 - p_1) \times \text{center of cluster 1}) + (p_1 \times d_1)$
   Center of cluster 2 = $((1 - p_2) \times \text{center of cluster 2}) + (p_2 \times d_2)$
   Center of cluster 3 = $((1 - p_3) \times \text{center of cluster 3}) + (p_3 \times d_3)$

2. Read the next mini-batch, and repeat Step 1 to recalculate the cluster centers.

3. For more information about mini-batch k-means, see Web-scale k-means Clustering.

Step 3: Reduce the Clusters from $K$ to $k$

If the algorithm created $K$ clusters—($K = k \times x$) where $x$ is greater than 1—then it reduces the $K$ clusters to $k$ clusters. (For more information, see extra_center_factor in the preceding discussion.) It does this
by applying Lloyd's method with kmeans++ initialization to the $K$ cluster centers. For more information about Lloyd's method, see *k-means clustering*.

### K-Means Hyperparameters

In the *CreateTrainingJob* request, you specify the training algorithm that you want to use. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the k-means training algorithm provided by Amazon SageMaker. For more information about how k-means clustering works, see *How K-Means Clustering Works* (p. 1734).

<table>

### Tune a K-Means Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

The Amazon SageMaker k-means algorithm is an unsupervised algorithm that groups data into clusters whose members are as similar as possible. Because it is unsupervised, it doesn't use a validation dataset that hyperparameters can optimize against. But it does take a test dataset and emits metrics that depend on the squared distance between the data points and the final cluster centroids at the end of each training run. To find the model that reports the tightest clusters on the test dataset, you can use a hyperparameter tuning job. The clusters optimize the similarity of their members.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 1863).

### Metrics Computed by the K-Means Algorithm

The k-means algorithm computes the following metrics during training. When tuning a model, choose one of these metrics as the objective metric.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>test:msd</td>
<td>Mean squared distances between each record in the test set and the closest center of the model.</td>
<td>Minimize</td>
</tr>
<tr>
<td>test:ssd</td>
<td>Sum of the squared distances between each record in the test set and the closest center of the model.</td>
<td>Minimize</td>
</tr>
</tbody>
</table>

### Tunable K-Means Hyperparameters

Tune the Amazon SageMaker k-means model with the following hyperparameters. The hyperparameters that have the greatest impact on k-means objective metrics are: mini_batch_size,
extra_center_factor, and init_method. Tuning the hyperparameter epochs generally results in minor improvements.

<table>

**K-Means Response Formats**

All SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. This topic contains a list of the available output formats for the SageMaker k-means algorithm.

**JSON Response Format**

```json
{
  "predictions": [
    {
      "closest_cluster": 1.0,
      "distance_to_cluster": 3.0,
    },
    {
      "closest_cluster": 2.0,
      "distance_to_cluster": 5.0,
    },
    ....
  ]
}
```

**JSONLINES Response Format**

```json
{"closest_cluster": 1.0, "distance_to_cluster": 3.0}
{"closest_cluster": 2.0, "distance_to_cluster": 5.0}
```

**RECORDIO Response Format**

```json
[  
  Record = {
    features = {},
    label = {
      'closest_cluster': {
        keys: [],
        values: [1.0, 2.0]  # float32
      },
      'distance_to_cluster': {
        keys: [],
        values: [3.0, 5.0]  # float32
      }
    }
  }
]
```
CSV Response Format

The first value in each line corresponds to closest_cluster.

The second value in each line corresponds to distance_to_cluster.

1.0, 3.0
2.0, 5.0

Principal Component Analysis (PCA) Algorithm

PCA is an unsupervised machine learning algorithm that attempts to reduce the dimensionality (number of features) within a dataset while still retaining as much information as possible. This is done by finding a new set of features called components, which are composites of the original features that are uncorrelated with one another. They are also constrained so that the first component accounts for the largest possible variability in the data, the second component the second most variability, and so on.

In Amazon SageMaker, PCA operates in two modes, depending on the scenario:

- **regular**: For datasets with sparse data and a moderate number of observations and features.
- **randomized**: For datasets with both a large number of observations and features. This mode uses an approximation algorithm.

PCA uses tabular data. The rows represent observations you want to embed in a lower dimensional space. The columns represent features that you want to find a reduced approximation for. The algorithm calculates the covariance matrix (or an approximation thereof in a distributed manner), and then performs the singular value decomposition on this summary to produce the principal components.

- How PCA Works (p. 1742)
- PCA Hyperparameters (p. 1743)
- PCA Response Formats (p. 1744)

Input/Output Interface for the PCA Algorithm

For training, PCA expects data provided in the train channel, and optionally supports a dataset passed to the test dataset, which is scored by the final algorithm. Both recordIO-wrapped-protobuf and CSV formats are supported for training. You can use either File mode or Pipe mode to train models on data that is formatted as recordIO-wrapped-protobuf or as CSV.

For inference, PCA supports text/csv, application/json, and application/x-recordio-protobuf. Results are returned in either application/json or application/x-recordio-protobuf format with a vector of “projections.”
EC2 Instance Recommendation for the PCA Algorithm

PCA supports CPU and GPU instances for training and inference. Which instance type is most performant depends heavily on the specifics of the input data. For GPU instances, PCA supports P2, P3, G4dn, and G5.

PCA Sample Notebooks

For a sample notebook that shows how to use the SageMaker Principal Component Analysis algorithm to analyze the images of handwritten digits from zero to nine in the MNIST dataset, see An Introduction to PCA with MNIST. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances (p. 298). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the NTM algorithms are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

How PCA Works

Principal Component Analysis (PCA) is a learning algorithm that reduces the dimensionality (number of features) within a dataset while still retaining as much information as possible.

PCA reduces dimensionality by finding a new set of features called components, which are composites of the original features, but are uncorrelated with one another. The first component accounts for the largest possible variability in the data, the second component the second most variability, and so on.

It is an unsupervised dimensionality reduction algorithm. In unsupervised learning, labels that might be associated with the objects in the training dataset aren't used.

Given the input of a matrix with rows $x_1, \ldots, x_n$ each of dimension $1 \times d$, the data is partitioned into mini-batches of rows and distributed among the training nodes (workers). Each worker then computes a summary of its data. The summaries of the different workers are then unified into a single solution at the end of the computation.

**Modes**

The Amazon SageMaker PCA algorithm uses either of two modes to calculate these summaries, depending on the situation:

- **regular**: for datasets with sparse data and a moderate number of observations and features.
- **randomized**: for datasets with both a large number of observations and features. This mode uses an approximation algorithm.

As the algorithm’s last step, it performs the singular value decomposition on the unified solution, from which the principal components are then derived.

**Mode 1: Regular**

The workers jointly compute both $\sum x_i^T x_i$ and $\sum x_i$.

**Note**

Because $x_i$ are $1 \times d$ row vectors, $x_i^T x_i$ is a matrix (not a scalar). Using row vectors within the code allows us to obtain efficient caching.
The covariance matrix is computed as \( \sum x_i^T x_i - (1/n)(\sum x_i)(\sum x_i)^T \), and its top \( \text{num\_components} \) singular vectors form the model.

**Note**

If \( \text{subtract\_mean} \) is False, we avoid computing and subtracting \( \sum x_i \).

Use this algorithm when the dimension \( d \) of the vectors is small enough so that \( d^2 \) can fit in memory.

**Mode 2: Randomized**

When the number of features in the input dataset is large, we use a method to approximate the covariance metric. For every mini-batch \( X_i \) of dimension \( b \times d \), we randomly initialize a \((\text{num\_components} + \text{extra\_components}) \times b\) matrix that we multiply by each mini-batch, to create a \((\text{num\_components} + \text{extra\_components}) \times d\) matrix. The sum of these matrices is computed by the workers, and the servers perform SVD on the final \((\text{num\_components} + \text{extra\_components}) \times d\) matrix. The top right \( \text{num\_components} \) singular vectors of it are the approximation of the top singular vectors of the input matrix.

Let \( \ell = \text{num\_components} + \text{extra\_components} \). Given a mini-batch \( X_i \) of dimension \( b \times d \), the worker draws a random matrix \( H_i \) of dimension \( \ell \times b \). Depending on whether the environment uses a GPU or CPU and the dimension size, the matrix is either a random sign matrix where each entry is \(+1\) or \(-1\) or a \( \text{FJLT} \) (fast Johnson Lindenstrauss transform; for information, see \text{FJLT Transforms} and the follow-up papers). The worker then computes \( H_i X_i \) and maintains \( B = \sum H_i X_i \). The worker also maintains \( h^T \), the sum of columns of \( H_1, \ldots, H_T \) (\( T \) being the total number of mini-batches), and \( s \), the sum of all input rows. After processing the entire shard of data, the worker sends the server \( B, h, s, \) and \( n \) (the number of input rows).

Denote the different inputs to the server as \( B^i, h^i, s^i, n^i \). The server computes \( B, h, s, n \) the sums of the respective inputs. It then computes \( C = B - (1/n)h^T s \), and finds its singular value decomposition. The top-right singular vectors and singular values of \( C \) are used as the approximate solution to the problem.

**PCA Hyperparameters**

In the \text{CreateTrainingJob} request, you specify the training algorithm. You can also specify algorithm-specific HyperParameters as string-to-string maps. The following table lists the hyperparameters for the PCA training algorithm provided by Amazon SageMaker. For more information about how PCA works, see \text{How PCA Works (p. 1742)}.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\text{feature_dim}</td>
<td>Input dimension.</td>
</tr>
<tr>
<td></td>
<td><strong>Required</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: positive integer</td>
</tr>
<tr>
<td>\text{mini_batch_size}</td>
<td>Number of rows in a mini-batch.</td>
</tr>
<tr>
<td></td>
<td><strong>Required</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: positive integer</td>
</tr>
<tr>
<td>\text{num_components}</td>
<td>The number of principal components to compute.</td>

</tbody>
</table>
### Parameter Name | Description
--- | ---
algorithm_mode | Mode for computing the principal components.  
Optional  
Valid values: regular or randomized  
Default value: regular
extra_components | As the value increases, the solution becomes more accurate but the runtime and memory consumption increase linearly. The default, -1, means the maximum of 10 and num_components. Valid for randomized mode only.  
Optional  
Valid values: Non-negative integer or -1  
Default value: -1
subtract_mean | Indicates whether the data should be unbiased both during training and at inference.  
Optional  
Valid values: One of true or false  
Default value: true

### PCA Response Formats
All Amazon SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. This topic contains a list of the available output formats for the SageMaker PCA algorithm.

**JSON Response Format**
Accept—application/json

```json

   "projection": [1.0, 2.0, 3.0, 4.0, 5.0]
}
{
   "projection": [6.0, 7.0, 8.0, 9.0, 0.0]
}
```
RECORDIO Response Format

Accept—application/x-recordio-protobuf

```
[  
  Record = {
    features = {},
    label = {
      'projection': {
        keys: [],
        values: [1.0, 2.0, 3.0, 4.0, 5.0]
      }
    }
  },
  Record = {
    features = {},
    label = {
      'projection': {
        keys: [],
        values: [1.0, 2.0, 3.0, 4.0, 5.0]
      }
    }
  }
]
```

Random Cut Forest (RCF) Algorithm

Amazon SageMaker Random Cut Forest (RCF) is an unsupervised algorithm for detecting anomalous data points within a data set. These are observations which diverge from otherwise well-structured or patterned data. Anomalies can manifest as unexpected spikes in time series data, breaks in periodicity, or unclassifiable data points. They are easy to describe in that, when viewed in a plot, they are often easily distinguishable from the "regular" data. Including these anomalies in a data set can drastically increase the complexity of a machine learning task since the "regular" data can often be described with a simple model.

With each data point, RCF associates an anomaly score. Low score values indicate that the data point is considered "normal." High values indicate the presence of an anomaly in the data. The definitions of "low" and "high" depend on the application but common practice suggests that scores beyond three standard deviations from the mean score are considered anomalous.

While there are many applications of anomaly detection algorithms to one-dimensional time series data such as traffic volume analysis or sound volume spike detection, RCF is designed to work with arbitrary-dimensional input. Amazon SageMaker RCF scales well with respect to number of features, data set size, and number of instances.

Topics
- Input/Output Interface for the RCF Algorithm (p. 1745)
- Instance Recommendations for the RCF Algorithm (p. 1746)
- RCF Sample Notebooks (p. 1746)
- How RCF Works (p. 1747)
- RCF Hyperparameters (p. 1749)
- Tune an RCF Model (p. 1750)
- RCF Response Formats (p. 1751)

Input/Output Interface for the RCF Algorithm

Amazon SageMaker Random Cut Forest supports the train and test data channels. The optional test channel is used to compute accuracy, precision, recall, and F1-score metrics on labeled data. Train and
test data content types can be either `application/x-recordio-protobuf` or `text/csv` formats. For the test data, when using `text/csv` format, the content must be specified as `text/csv;label_size=1` where the first column of each row represents the anomaly label: "1" for an anomalous data point and "0" for a normal data point. You can use either File mode or Pipe mode to train RCF models on data that is formatted as recordIO-wrapped-protobuf or as CSV.

The train channel only supports `S3DataDistributionType=ShardedByS3Key` and the test channel only supports `S3DataDistributionType=FullyReplicated`. The following example specifies the S3 distribution type for the train channel using the Amazon SageMaker Python SDK.

**Note**
The `sagemaker.inputs.s3_input` method was renamed to `sagemaker.inputs.TrainingInput` in SageMaker Python SDK v2.

```python
import sagemaker

# specify Random Cut Forest training job information and hyperparameters
rcf = sagemaker.estimator.Estimator(...)

# explicitly specify "ShardedByS3Key" distribution type
train_data = sagemaker.inputs.TrainingInput(
    s3_data=s3_training_data_location,
    content_type='text/csv;label_size=0',
    distribution='ShardedByS3Key')

# run the training job on input data stored in S3
rcf.fit({'train': train_data})
```

To avoid common errors around execution roles, ensure that you have the execution roles required, AmazonSageMakerFullAccess and AmazonEC2ContainerRegistryFullAccess. To avoid common errors around your image not existing or its permissions being incorrect, ensure that your ECR image is not larger then the allocated disk space on the training instance. To avoid this, run your training job on an instance that has sufficient disk space. In addition, if your ECR image is from a different AWS account's Elastic Container Service (ECS) repository, and you do not set repository permissions to grant access, this will result in an error. See the ECR repository permissions for more information on setting a repository policy statement.

See the S3DataSource for more information on customizing the S3 data source attributes. Finally, in order to take advantage of multi-instance training the training data must be partitioned into at least as many files as instances.

For inference, RCF supports `application/x-recordio-protobuf`, `text/csv` and `application/json` input data content types. See the Common Data Formats for Built-in Algorithms (p. 1537) documentation for more information. RCF inference returns application/x-recordio-protobuf or application/json formatted output. Each record in these output data contains the corresponding anomaly scores for each input data point. See Common Data Formats--Inference for more information.

For more information on input and output file formats, see RCF Response Formats (p. 1751) for inference and the RCF Sample Notebooks (p. 1746).

**Instance Recommendations for the RCF Algorithm**

For training, we recommend the ml.m4, ml.c4, and ml.c5 instance families. For inference we recommend using a ml.c5.xl instance type in particular, for maximum performance as well as minimized cost per hour of usage. Although the algorithm could technically run on GPU instance types it does not take advantage of GPU hardware.

**RCF Sample Notebooks**

For an example of how to train an RCF model and perform inferences with it, see the An Introduction to SageMaker Random Cut Forests notebook. For instructions how to create and access Jupyter notebook
instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances (p. 298). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. To open a notebook, click on its Use tab and select Create copy.

How RCF Works

Amazon SageMaker Random Cut Forest (RCF) is an unsupervised algorithm for detecting anomalous data points within a dataset. These are observations which diverge from otherwise well-structured or patterned data. Anomalies can manifest as unexpected spikes in time series data, breaks in periodicity, or unclassifiable data points. They are easy to describe in that, when viewed in a plot, they are often easily distinguishable from the "regular" data. Including these anomalies in a dataset can drastically increase the complexity of a machine learning task since the "regular" data can often be described with a simple model.

The main idea behind the RCF algorithm is to create a forest of trees where each tree is obtained using a partition of a sample of the training data. For example, a random sample of the input data is first determined. The random sample is then partitioned according to the number of trees in the forest. Each tree is given such a partition and organizes that subset of points into a k-d tree. The anomaly score assigned to a data point by the tree is defined as the expected change in complexity of the tree as a result adding that point to the tree; which, in approximation, is inversely proportional to the resulting depth of the point in the tree. The random cut forest assigns an anomaly score by computing the average score from each constituent tree and scaling the result with respect to the sample size. The RCF algorithm is based on the one described in reference [1].

Sample Data Randomly

The first step in the RCF algorithm is to obtain a random sample of the training data. In particular, suppose we want a sample of size $K$ from $N$ total data points. If the training data is small enough, the entire dataset can be used, and we could randomly draw elements from this set. However, frequently the training data is too large to fit all at once, and this approach isn't feasible. Instead, we use a technique called reservoir sampling.

Reservoir sampling is an algorithm for efficiently drawing random samples from a dataset $S = \{S_1,\ldots,S_N\}$ where the elements in the dataset can only be observed one at a time or in batches. In fact, reservoir sampling works even when $N$ is not known a priori. If only one sample is requested, such as when $K = 1$, the algorithm is like this:

**Algorithm: Reservoir Sampling**

- Input: dataset or data stream $S = \{S_1,\ldots,S_N\}$
- Initialize the random sample $X = S_1$
- For each observed sample $S_n, n = 2,\ldots,N$:
  - Pick a uniform random number $\xi \in [0,1]$
  - If $\xi < 1/n$
    - Set $X = S_n$
  - Return $X$

This algorithm selects a random sample such that $P(X = S_n) = 1/N$ for all $n = 1,\ldots,N$. When $K > 1$ the algorithm is more complicated. Additionally, a distinction must be made between random sampling that is with and without replacement. RCF performs an augmented reservoir sampling without replacement on the training data based on the algorithms described in [2].

Train a RCF Model and Produce Inferences

The next step in RCF is to construct a random cut forest using the random sample of data. First, the sample is partitioned into a number of equal-sized partitions equal to the number of trees in the forest.
Then, each partition is sent to an individual tree. The tree recursively organizes its partition into a binary tree by partitioning the data domain into bounding boxes.

This procedure is best illustrated with an example. Suppose a tree is given the following two-dimensional dataset. The corresponding tree is initialized to the root node:

A two-dimensional dataset where the majority of data lies in a cluster (blue) except for one anomalous data point (orange). The tree is initialized with a root node.

The RCF algorithm organizes these data in a tree by first computing a bounding box of the data, selecting a random dimension (giving more weight to dimensions with higher "variance"), and then randomly determining the position of a hyperplane "cut" through that dimension. The two resulting subspaces define their own sub tree. In this example, the cut happens to separate a lone point from the remainder of the sample. The first level of the resulting binary tree consists of two nodes, one which will consist of the subtree of points to the left of the initial cut and the other representing the single point on the right.
A random cut partitioning the two-dimensional dataset. An anomalous data point is more likely to lie isolated in a bounding box at a smaller tree depth than other points.

Bounding boxes are then computed for the left and right halves of the data and the process is repeated until every leaf of the tree represents a single data point from the sample. Note that if the lone point is sufficiently far away then it is more likely that a random cut would result in point isolation. This observation provides the intuition that tree depth is, loosely speaking, inversely proportional to the anomaly score.

When performing inference using a trained RCF model the final anomaly score is reported as the average across scores reported by each tree. Note that it is often the case that the new data point does not already reside in the tree. To determine the score associated with the new point the data point is inserted into the given tree and the tree is efficiently (and temporarily) reassembled in a manner equivalent to the training process described above. That is, the resulting tree is as if the input data point were a member of the sample used to construct the tree in the first place. The reported score is inversely proportional to the depth of the input point within the tree.

Choose Hyperparameters

The primary hyperparameters used to tune the RCF model are num_trees and num_samples_per_tree. Increasing num_trees has the effect of reducing the noise observed in anomaly scores since the final score is the average of the scores reported by each tree. While the optimal value is application-dependent we recommend using 100 trees to begin with as a balance between score noise and model complexity. Note that inference time is proportional to the number of trees. Although training time is also affected it is dominated by the reservoir sampling algorithm described above.

The parameter num_samples_per_tree is related to the expected density of anomalies in the dataset. In particular, num_samples_per_tree should be chosen such that 1/num_samples_per_tree approximates the ratio of anomalous data to normal data. For example, if 256 samples are used in each tree then we expect our data to contain anomalies 1/256 or approximately 0.4% of the time. Again, an optimal value for this hyperparameter is dependent on the application.

| eval_metrics           | A list of metrics used to score a labeled test data set. The following metrics can be selected for output:  
|                        | • accuracy - returns fraction of correct predictions.                        |
|                        | • precision_recall_fscore - returns the positive and negative precision, recall, and F1-scores.             |
|                        | **Optional**  
|                        | Valid values: a list with possible values taken from accuracy or precision_recall_fscore.             |
|                        | Default value: Both accuracy, precision_recall_fscore are calculated.         |
| num_samples_per_tree   | Number of random samples given to each tree from the training data set.      |
|                        | **Optional**  
|                        | Valid values: Positive integer (min: 1, max: 2048)                          |
|                        | Default value: 256                                                          |
| num_trees              | Number of trees in the forest.                                              |
|                        | **Optional**  
|                        | Valid values: Positive integer (min: 50, max: 1000)                         |
|                        | Default value: 100                                                          |

**Tune an RCF Model**

*Automatic model tuning*, also known as hyperparameter tuning or hyperparameter optimization, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

The Amazon SageMaker RCF algorithm is an unsupervised anomaly-detection algorithm that requires a labeled test dataset for hyperparameter optimization. RCF calculates anomaly scores for test data points and then labels the data points as anomalous if their scores are beyond three standard deviations from the mean score. This is known as the three-sigma limit heuristic. The F1-score is based on the difference between calculated labels and actual labels. The hyperparameter tuning job finds the model that maximizes that score. The success of hyperparameter optimization depends on the applicability of the three-sigma limit heuristic to the test dataset.

**Metrics Computed by the RCF Algorithm**

The RCF algorithm computes the following metric during training. When tuning the model, choose this metric as the objective metric.
<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>test:f1</td>
<td>F1-score on the test dataset, based on the difference between calculated labels and actual labels.</td>
<td>Maximize</td>
</tr>
</tbody>
</table>

### Tunable RCF Hyperparameters

You can tune a RCF model with the following hyperparameters.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Parameter Type</th>
<th>Recommended Ranges</th>

</tbody>
</table>

### RCF Response Formats

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in [Common Data Formats - Inference](#). Note that SageMaker Random Cut Forest supports both dense and sparse JSON and RecordIO formats. This topic contains a list of the available output formats for the SageMaker RCF algorithm.

#### JSON Response Format

ACCEPT: application/json.

```json
{
    "scores": [
        {
            "score": 0.02,
        },
        {
            "score": 0.25
        }
    ]
}
```

#### JSONLINES Response Format

ACCEPT: application/jsonlines.

```json
{"score": 0.02},
```

1751
RECORDIO Response Format

ACCEPT: application/x-recordio-protobuf.

```python
[
    Record = {
        features = {},
        label = {
            'score': {
                keys: [],
                values: [0.25]  # float32
            }
        }
    },
    Record = {
        features = {},
        label = {
            'score': {
                keys: [],
                values: [0.25]  # float32
            }
        }
    }
]
```
Built-in SageMaker Algorithms for Computer Vision

SageMaker provides image processing algorithms that are used for image classification, object detection, and computer vision.

- **Image Classification - MXNet (p. 1754)**—uses example data with answers (referred to as a *supervised algorithm*). Use this algorithm to classify images.

- **Image Classification - TensorFlow (p. 1765)**—uses pretrained TensorFlow Hub models to fine-tune for specific tasks (referred to as a *supervised algorithm*). Use this algorithm to classify images.

- **Object Detection - MXNet (p. 1778)**—detects and classifies objects in images using a single deep neural network. It is a supervised learning algorithm that takes images as input and identifies all instances of objects within the image scene.

- **Object Detection - TensorFlow (p. 1789)**—detects bounding boxes and object labels in an image. It is a supervised learning algorithm that supports transfer learning with available pretrained TensorFlow models.

- **Semantic Segmentation Algorithm (p. 1797)**—provides a fine-grained, pixel-level approach to developing computer vision applications.

**Image Classification - MXNet**

The Amazon SageMaker image classification algorithm is a supervised learning algorithm that supports multi-label classification. It takes an image as input and outputs one or more labels assigned to that image. It uses a convolutional neural network that can be trained from scratch or trained using transfer learning when a large number of training images are not available.

The recommended input format for the Amazon SageMaker image classification algorithms is Apache MXNet RecordIO. However, you can also use raw images in .jpg or .png format. Refer to this discussion for a broad overview of efficient data preparation and loading for machine learning systems.

**Note**
To maintain better interoperability with existing deep learning frameworks, this differs from the protobuf data formats commonly used by other Amazon SageMaker algorithms.

For more information on convolutional networks, see:

- Deep residual learning for image recognition Kaiming He, et al., 2016 IEEE Conference on Computer Vision and Pattern Recognition

• **Tune an Image Classification Model (p. 1764)**

### Input/Output Interface for the Image Classification Algorithm

The SageMaker Image Classification algorithm supports both RecordIO (application/x-recordio) and image (image/png, image/jpeg, and application/x-image) content types for training in file mode, and supports the RecordIO (application/x-recordio) content type for training in pipe mode. However, you can also train in pipe mode using the image files (image/png, image/jpeg, and application/x-image), without creating RecordIO files, by using the augmented manifest format.

Distributed training is supported for file mode and pipe mode. When using the RecordIO content type in pipe mode, you must set the S3DataDistributionType of the S3DataSource to FullyReplicated. The algorithm supports a fully replicated model where your data is copied onto each machine.

The algorithm supports image/png, image/jpeg, and application/x-image for inference.

#### Train with RecordIO Format

If you use the RecordIO format for training, specify both `train` and `validation` channels as values for the `InputDataConfig` parameter of the `CreateTrainingJob` request. Specify one RecordIO (.rec) file in the `train` channel and one RecordIO file in the `validation` channel. Set the content type for both channels to `application/x-recordio`.

#### Train with Image Format

If you use the Image format for training, specify `train`, `validation`, `train_lst`, and `validation_lst` channels as values for the `InputDataConfig` parameter of the `CreateTrainingJob` request. Specify the individual image data (.jpg or .png files) for the `train` and `validation` channels. Specify one .lst file in each of the `train_lst` and `validation_lst` channels. Set the content type for all four channels to `application/x-image`.

**Note**

SageMaker reads the training and validation data separately from different channels, so you must store the training and validation data in different folders.

A .lst file is a tab-separated file with three columns that contains a list of image files. The first column specifies the image index, the second column specifies the class label index for the image, and the third column specifies the relative path of the image file. The image index in the first column must be unique across all of the images. The set of class label indices are numbered successively and the numbering should start with 0. For example, 0 for the cat class, 1 for the dog class, and so on for additional classes.

The following is an example of a .lst file:

<table>
<thead>
<tr>
<th>Image Index</th>
<th>Class Index</th>
<th>Relative Path</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>1</td>
<td><code>your_image_directory/train_img_dog1.jpg</code></td>
</tr>
<tr>
<td>1000</td>
<td>0</td>
<td><code>your_image_directory/train_img_cat1.jpg</code></td>
</tr>
<tr>
<td>22</td>
<td>1</td>
<td><code>your_image_directory/train_img_dog2.jpg</code></td>
</tr>
</tbody>
</table>

For example, if your training images are stored in s3://<your_bucket>/train/class_dog, s3://<your_bucket>/train/class_cat, and so on, specify the path for your `train` channel as s3://<your_bucket>/train, which is the top-level directory for your data. In the .lst file, specify the relative path for an individual file named `train_img_dog1.jpg` in the `class_dog` class directory as `class_dog/train_img_dog1.jpg`. You can also store all your image files under one subdirectory inside the `train` directory. In that case, use that subdirectory for the relative path. For example, s3://<your_bucket>/train/<your_image_directory>.

#### Train with Augmented Manifest Image Format

The augmented manifest format enables you to do training in Pipe mode using image files without needing to create RecordIO files. You need to specify both `train` and `validation` channels as values for
the InputDataConfig parameter of the CreateTrainingJob request. While using the format, an S3 manifest file needs to be generated that contains the list of images and their corresponding annotations. The manifest file format should be in JSON Lines format in which each line represents one sample. The images are specified using the 'source-ref' tag that points to the S3 location of the image. The annotations are provided under the "AttributeNames" parameter value as specified in the CreateTrainingJob request. It can also contain additional metadata under the metadata tag, but these are ignored by the algorithm. In the following example, the "AttributeNames" are contained in the list of image and annotation references ['"source-ref", "class"']. The corresponding label value is "0" for the first image and "1" for the second image:

```json
{"source-ref": "s3://image/filename1.jpg", "class": "0"}
{"source-ref": "s3://image/filename2.jpg", "class": "1", "class-metadata": {"class-name": "cat", "type": "groundtruth/image-classification"}}
```

The order of "AttributeNames" in the input files matters when training the ImageClassification algorithm. It accepts piped data in a specific order, with image first, followed by label. So the "AttributeNames" in this example are provided with "source-ref" first, followed by "class". When using the ImageClassification algorithm with Augmented Manifest, the value of the RecordWrapperType parameter must be "RecordIO".

Multi-label training is also supported by specifying a JSON array of values. The num_classes hyperparameter must be set to match the total number of classes. There are two valid label formats: multi-hot and class-id.

In the multi-hot format, each label is a multi-hot encoded vector of all classes, where each class takes the value of 0 or 1. In the following example, there are three classes. The first image is labeled with classes 0 and 2, while the second image is labeled with class 2 only:

```json
{"image-ref": "s3://mybucket/sample01/image1.jpg", "class": ":[1, 0, 1]"}
{"image-ref": "s3://mybucket/sample02/image2.jpg", "class": ":[0, 0, 1]"}
```

In the class-id format, each label is a list of the class ids, from [0, num_classes), which apply to the data point. The previous example would instead look like this:

```json
{"image-ref": "s3://mybucket/sample01/image1.jpg", "class": ":[0, 2]"}
{"image-ref": "s3://mybucket/sample02/image2.jpg", "class": ":[2]"}
```

The multi-hot format is the default, but can be explicitly set in the content type with the label-format parameter: "application/x-recordio; label-format=multi-hot". The class-id format, which is the format outputted by GroundTruth, must be set explicitly: "application/x-recordio; label-format=class-id".

For more information on augmented manifest files, see [Provide Dataset Metadata to Training Jobs with an Augmented Manifest File](p. 2327).

**Incremental Training**

You can also seed the training of a new model with the artifacts from a model that you trained previously with SageMaker. Incremental training saves training time when you want to train a new model with the same or similar data. SageMaker image classification models can be seeded only with another built-in image classification model trained in SageMaker.

To use a pretrained model, in the CreateTrainingJob request, specify the ChannelName as "model" in the InputDataConfig parameter. Set the ContentType for the model channel to application/x-sagemaker-model. The input hyperparameters of both the new model and the pretrained model that
you upload to the model channel must have the same settings for the `num_layers`, `image_shape` and `num_classes` input parameters. These parameters define the network architecture. For the pretrained model file, use the compressed model artifacts (in .tar.gz format) output by SageMaker. You can use either RecordIO or image formats for input data.

**Inference with the Image Classification Algorithm**

The generated models can be hosted for inference and support encoded .jpg and .png image formats as `image/png`, `image/jpeg`, and `application/x-image` content-type. The input image is resized automatically. The output is the probability values for all classes encoded in JSON format, or in JSON Lines text format for batch transform. The image classification model processes a single image per request and so outputs only one line in the JSON or JSON Lines format. The following is an example of a response in JSON Lines format:

```plaintext
accept: application/jsonlines

{"prediction": [prob_0, prob_1, prob_2, prob_3, ...]}
```

For more details on training and inference, see the image classification sample notebook instances referenced in the introduction.

**EC2 Instance Recommendation for the Image Classification Algorithm**

For image classification, we support P2, P3, G4dn, and G5 instances. We recommend using GPU instances with more memory for training with large batch sizes. You can also run the algorithm on multi-GPU and multi-machine settings for distributed training. Both CPU (such as C4) and GPU (P2, P3, G4dn, or G5) instances can be used for inference.

**Image Classification Sample Notebooks**

For a sample notebook that uses the SageMaker image classification algorithm, see [Build and Register an MXNet Image Classification Model via SageMaker Pipelines](#). For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see [Amazon SageMaker Notebook Instances](#). Once you have created a notebook instance and opened it, select the **SageMaker Examples** tab to see a list of all the SageMaker samples. The example image classification notebooks are located in the [Introduction to Amazon algorithms](#) section. To open a notebook, click on its **Use** tab and select **Create copy**.

**How Image Classification Works**

The image classification algorithm takes an image as input and classifies it into one of the output categories. Deep learning has revolutionized the image classification domain and has achieved great performance. Various deep learning networks such as ResNet, DenseNet, Inception, and so on, have been developed to be highly accurate for image classification. At the same time, there have been efforts to collect labeled image data that are essential for training these networks. ImageNet is one such large dataset that has more than 11 million images with about 11,000 categories. Once a network is trained with ImageNet data, it can then be used to generalize with other datasets as well, by simple re-adjustment or fine-tuning. In this transfer learning approach, a network is initialized with weights (in this example, trained on ImageNet), which can be later fine-tuned for an image classification task in a different dataset.

Image classification in Amazon SageMaker can be run in two modes: full training and transfer learning. In full training mode, the network is initialized with random weights and trained on user data from scratch. In transfer learning mode, the network is initialized with pre-trained weights and just the top fully connected layer is initialized with random weights. Then, the whole network is fine-tuned with new data. In this mode, training can be achieved even with a smaller dataset. This is because the network is already trained and therefore can be used in cases without sufficient training data.
Image Classification Hyperparameters

Hyperparameters are parameters that are set before a machine learning model begins learning. The following hyperparameters are supported by the Amazon SageMaker built-in Image Classification algorithm. See Tune an Image Classification Model (p. 1764) for information on image classification hyperparameter tuning.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_classes</td>
<td>Number of output classes. This parameter defines the dimensions of the network output and is typically set to the number of classes in the dataset.</td>
</tr>
</tbody>
</table>
|                        | Besides multi-class classification, multi-label classification is supported too. Please refer to Input/Output Interface for the Image Classification Algorithm (p. 1755) for details on how to work with multi-label classification with augmented manifest files. | Required
|                        | Valid values: positive integer                                                                                                                                                                           |
| num_training_samples   | Number of training examples in the input dataset.                                                                                                                                                        |
|                        | If there is a mismatch between this value and the number of samples in the training set, then the behavior of the lr_scheduler_step parameter is undefined and distributed training accuracy might be affected.                         | Required
|                        | Valid values: positive integer                                                                                                                                                                           |
| augmentation_type      | Data augmentation type. The input images can be augmented in multiple ways as specified below.                                                                                                            |
|                        | • crop: Randomly crop the image and flip the image horizontally                                                                                  |
|                        | • crop_color: In addition to ‘crop’, three random values in the range [−36, 36], [−50, 50], and [−50, 50] are added to the corresponding Hue-Saturation-Lightness channels respectively |
|                        | • crop_color_transform: In addition to crop_color, random transformations, including rotation, shear, and aspect ratio variations are applied to the image. The maximum angle of rotation is 10 degrees, the maximum shear ratio is 0.1, and the maximum aspect changing ratio is 0.25. | Optional
|                        | Valid values: crop, crop_color, or crop_color_transform.                                                                                                                                                 |
|                        | Default value: no default value                                                                                                                                                                         |
| beta_1                 | The beta1 for adam, that is the exponential decay rate for the first moment estimates.                                                                                                                      | Optional
<p>|                        | Valid values: float. Range in [0, 1].                                                                                                                                                                 |</p>

<tr>
<td>image_shape</td>
<td>The input image dimensions, which is the same size as the input layer of the network. The format is defined as 'num_channels, height, width'. The image dimension can take on any value as the network can handle varied dimensions of the input. However, there may be memory constraints if a larger image dimension is used. Pretrained models can use only a fixed 224 x 224 image size. Typical image dimensions for image classification are '3,224,224'. This is similar to the ImageNet dataset. For training, if any input image is smaller than this parameter in any dimension, training fails. If an image is larger, a portion of the image is cropped, with the cropped area specified by this parameter. If hyperparameter augmentation_type is set, random crop is taken; otherwise, central crop is taken. At inference, input images are resized to the image_shape that was used during training. Aspect ratio is not preserved, and images are not cropped. <strong>Optional</strong> Valid values: string Default value: ‘3,224,224’</td>
</tr>
<tr>
<td>kv_store</td>
<td>Weight update synchronization mode during distributed training. The weight updates can be updated either synchronously or asynchronously across machines. Synchronous updates typically provide better accuracy than asynchronous updates but can be slower. See distributed training in MXNet for more details. This parameter is not applicable to single machine training. • dist_sync: The gradients are synchronized after every batch with all the workers. With dist_sync, batch-size now means the batch size used on each machine. So if there are n machines and we use batch size b, then dist_sync behaves like local with batch size n*b • dist_async: Performs asynchronous updates. The weights are updated whenever gradients are received from any machine and the weight updates are atomic. However, the order is not guaranteed. <strong>Optional</strong> Valid values: dist_sync or dist_async Default value: no default value</td>

</table>
| lr_scheduler_factor | The ratio to reduce learning rate used in conjunction with the lr_scheduler_step parameter, defined as $lr_{new} = lr_{old} \times lr_{scheduler\_factor}$.  
  **Optional**  
  Valid values: float. Range in [0, 1].  
  Default value: 0.1 |
| lr_scheduler_step | The epochs at which to reduce the learning rate. As explained in the lr_scheduler_factor parameter, the learning rate is reduced by lr_scheduler_factor at these epochs. For example, if the value is set to "10, 20", then the learning rate is reduced by lr_scheduler_factor after 10th epoch and again by lr_scheduler_factor after 20th epoch. The epochs are delimited by ".".  
  **Optional**  
  Valid values: string  
  Default value: no default value |
| mini_batch_size | The batch size for training. In a single-machine multi-GPU setting, each GPU handles mini_batch_size/num_gpu training samples. For the multi-machine training in dist_sync mode, the actual batch size is mini_batch_size*number of machines. See MXNet docs for more details.  
  **Optional**  
  Valid values: positive integer  
  Default value: 32 |
| momentum | The momentum for sgd and nag, ignored for other optimizers.  
  **Optional**  
  Valid values: float. Range in [0, 1].  
  Default value: 0.9 |
| multi_label | Flag to use for multi-label classification where each sample can be assigned multiple labels. Average accuracy across all classes is logged.  
  **Optional**  
  Valid values: 0 or 1  
  Default value: 0 |

**Parameter Name** | **Description**
--- | ---
top_k | Reports the top-k accuracy during training. This parameter has to be greater than 1, since the top-1 training accuracy is the same as the regular training accuracy that has already been reported.

**Optional**
Valid values: positive integer larger than 1.
Default value: no default value

use_pretrained_model | Flag to use pre-trained model for training. If set to 1, then the pretrained model with the corresponding number of layers is loaded and used for training. Only the top FC layer are reinitialized with random weights. Otherwise, the network is trained from scratch.

**Optional**
Valid values: 0 or 1
Default value: 0

use_weighted_loss | Flag to use weighted cross-entropy loss for multi-label classification (used only when multi_label = 1), where the weights are calculated based on the distribution of classes.

**Optional**
Valid values: 0 or 1
Default value: 0

weight_decay | The coefficient weight decay for sgd and nag, ignored for other optimizers.

**Optional**
Valid values: float. Range in [0, 1].
Default value: 0.0001

### Tune an Image Classification Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker (p. 1863)](https://docs.aws.amazon.com/sagemaker/latest/dg/automated-model-tuning.html).

### Metrics Computed by the Image Classification Algorithm

The image classification algorithm is a supervised algorithm. It reports an accuracy metric that is computed during training. When tuning the model, choose this metric as the objective metric.
**Tunable Image Classification Hyperparameters**

Tune an image classification model with the following hyperparameters. The hyperparameters that have the greatest impact on image classification objective metrics are: mini_batch_size, learning_rate, and optimizer. Tune the optimizer-related hyperparameters, such as momentum, weight_decay, beta_1, beta_2, eps, and gamma, based on the selected optimizer. For example, use beta_1 and beta_2 only when adam is the optimizer.

For more information about which hyperparameters are used in each optimizer, see Image Classification Hyperparameters (p. 1758).

**Image Classification - TensorFlow**

The Amazon SageMaker Image Classification - TensorFlow algorithm is a supervised learning algorithm that supports transfer learning with many pretrained models from the TensorFlow Hub. Use transfer learning to fine-tune one of the available pretrained models on your own dataset, even if a large amount of image data is not available. The image classification algorithm takes an image as input and outputs a probability for each provided class label. Training datasets must consist of images in .jpg, .jpeg, or .png format.

**Topics**
- How to use the SageMaker Image Classification - TensorFlow algorithm (p. 1766)
How to use the SageMaker Image Classification - TensorFlow algorithm

You can use Image Classification - TensorFlow as an Amazon SageMaker built-in algorithm. The following section describes how to use Image Classification - TensorFlow with the SageMaker Python SDK. For information on how to use Image Classification - TensorFlow from the Amazon SageMaker Studio UI, see SageMaker JumpStart (p. 161).

The Image Classification - TensorFlow algorithm supports transfer learning using any of the compatible pretrained TensorFlow Hub models. For a list of all available pretrained models, see TensorFlow Hub Models (p. 1769). Every pretrained model has a unique model_id. The following example uses MobileNet V2 1.00 224 (model_id: tensorflow-ic-imagenet-mobilenet-v2-100-224-classification-4) to fine-tune on a custom dataset. The pretrained models are all pre-downloaded from the TensorFlow Hub and stored in Amazon S3 buckets so that training jobs can run in network isolation. Use these pre-generated model training artifacts to construct a SageMaker Estimator.

First, retrieve the Docker image URI, training script URI, and pretrained model URI. Then, change the hyperparameters as you see fit. You can see a Python dictionary of all available hyperparameters and their default values with hyperparameters.retrieve_default. For more information, see Image Classification - TensorFlow Hyperparameters (p. 1774). Use these values to construct a SageMaker Estimator.

Note

Default hyperparameter values are different for different models. For larger models, the default batch size is smaller and the train_only_top_layer hyperparameter is set to "True".

This example uses the tf_flowers dataset, which contains five classes of flower images. We pre-downloaded the dataset from TensorFlow under the Apache 2.0 license and made it available with Amazon S3. To fine-tune your model, call .fit using the Amazon S3 location of your training dataset.

```python
from sagemaker import image_uris, model_uris, script_uris, hyperparameters
from sagemaker.estimator import Estimator

model_id, model_version = "tensorflow-ic-imagenet-mobilenet-v2-100-224-classification-4",
"*
training_instance_type = "ml.p3.2xlarge"

# Retrieve the Docker image
train_image_uri =
image_uris.retrieve(model_id=model_id,model_version=model_version,image_scope="training",instance_type=training_instance_type)

# Retrieve the training script
train_source_uri = script_uris.retrieve(model_id=model_id, model_version=model_version,
script_scope="training")

# Retrieve the pretrained model tarball for transfer learning
train_model_uri = model_uris.retrieve(model_id=model_id, model_version=model_version,
model_scope="training")

# Retrieve the default hyper-parameters for fine-tuning the model
hyperparameters = hyperparameters.retrieve_default(model_id=model_id,
model_version=model_version)
```
# Optional] Override default hyperparameters with custom values
hyperparameters["epochs"] = "5"

The sample training data is available in the following S3 bucket:
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/tf_flowers/"

training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}"

output_bucket = sess.default_bucket()
output_prefix = "jumpstart-example-ic-training"
s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"

Create SageMaker Estimator instance:
tf_ic_estimator = Estimator(
    role=aws_role,
    image_uri=train_image_uri,
    source_dir=train_source_uri,
    model_uri=train_model_uri,
    entry_point="transfer_learning.py",
    instance_count=1,
    instance_type=training_instance_type,
    max_run=360000,
    hyperparameters=hyperparameters,
    output_path=s3_output_location,
)

Use S3 path of the training data to launch SageMaker TrainingJob:
tf_ic_estimator.fit({"training": training_dataset_s3_path}, logs=True)

Input and output interface for the Image Classification - TensorFlow algorithm

Each of the pretrained models listed in TensorFlow Hub Models can be fine-tuned to any dataset with any number of image classes. Be mindful of how to format your training data for input to the Image Classification - TensorFlow model.

- **Training data input format**: Your training data should be a directory with as many subdirectories as the number of classes. Each subdirectory should contain images belonging to that class in .jpg, .jpeg, or .png format.

The following is an example of an input directory structure. This example dataset has two classes: roses and dandelion. The image files in each class folder can have any name. The input directory should be hosted in an Amazon S3 bucket with a path similar to the following: s3://bucket_name/input_directory/. Note that the trailing / is required.

```
input_directory
 |-- roses
 |  |-- abc.jpg
 |  |-- def.jpg
 |-- dandelion
 |  |-- ghi.jpg
 |  |-- jkl.jpg
```

Trained models output label mapping files that map class folder names to the indices in the list of output class probabilities. This mapping is in alphabetical order. For example, in the preceding example, the dandelion class is index 0 and the roses class is index 1.

After training, you have a fine-tuned model that you can further train using incremental training or deploy for inference. The Image Classification - TensorFlow algorithm automatically adds a pre-processing and post-processing signature to the fine-tuned model so that it can take in images as input.
and return class probabilities. The file mapping class indices to class labels is saved along with the models.

**Incremental training**

You can seed the training of a new model with artifacts from a model that you trained previously with SageMaker. Incremental training saves training time when you want to train a new model with the same or similar data.

*Note*

You can only seed a SageMaker Image Classification - TensorFlow model with another Image Classification - TensorFlow model trained in SageMaker.

You can use any dataset for incremental training, as long as the set of classes remains the same. The incremental training step is similar to the fine-tuning step, but instead of starting with a pretrained model, you start with an existing fine-tuned model. For an example of incremental training with the SageMaker Image Classification - TensorFlow algorithm, see the [Introduction to SageMaker TensorFlow - Image Classification](#) sample notebook.

**Inference with the Image Classification - TensorFlow algorithm**

You can host the fine-tuned model that results from your TensorFlow Image Classification training for inference. Any input image for inference must be in .jpg, .jpeg, or .png format and be content type application/x-image. The Image Classification - TensorFlow algorithm resizes input images automatically.

Running inference results in probability values, class labels for all classes, and the predicted label corresponding to the class index with the highest probability encoded in JSON format. The Image Classification - TensorFlow model processes a single image per request and outputs only one line. The following is an example of a JSON format response:

```json
accept: application/json;verbose

{"probabilities": [prob_0, prob_1, prob_2, ...],
 "labels": [label_0, label_1, label_2, ...],
 "predicted_label": predicted_label}
```

If `accept` is set to `application/json`, then the model only outputs probabilities. For more information on training and inference with the Image Classification - TensorFlow algorithm, see the [Introduction to SageMaker TensorFlow - Image Classification](#) sample notebook.

**Amazon EC2 instance recommendation for the Image Classification - TensorFlow algorithm**

The Image Classification - TensorFlow algorithm supports all CPU and GPU instances for training, including:

- `ml.p2.xlarge`
- `ml.p2.16xlarge`
- `ml.p3.2xlarge`
- `ml.p3.16xlarge`
- `ml.g4dn.xlarge`
- `ml.g4dn.16.xlarge`
- `ml.g5.xlarge`
- `ml.g5.48xlarge`

We recommend GPU instances with more memory for training with large batch sizes. Both CPU (such as M5) and GPU (P2, P3, G4dn, or G5) instances can be used for inference.
Image Classification - TensorFlow sample notebooks

For more information about how to use the SageMaker Image Classification - TensorFlow algorithm for transfer learning on a custom dataset, see the Introduction to SageMaker TensorFlow - Image Classification notebook.

For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances (p. 298). After you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. To open a notebook, choose its Use tab and choose Create copy.

How Image Classification - TensorFlow Works

The Image Classification - TensorFlow algorithm takes an image as input and classifies it into one of the output class labels. Various deep learning networks such as MobileNet, ResNet, Inception, and EfficientNet are highly accurate for image classification. There are also deep learning networks that are trained on large image datasets, such as ImageNet, which has over 11 million images and almost 11,000 classes. After a network is trained with ImageNet data, you can then fine-tune the network on a dataset with a particular focus to perform more specific classification tasks. The Amazon SageMaker Image Classification - TensorFlow algorithm supports transfer learning on many pretrained models that are available in the TensorFlow Hub.

According to the number of class labels in your training data, a classification layer is attached to the pretrained TensorFlow Hub model of your choice. The classification layer consists of a dropout layer, a dense layer, and a fully-connected layer with 2-norm regularizer that is initialized with random weights. The model has hyperparameters for the dropout rate of the dropout layer and the L2 regularization factor for the dense layer. You can then fine-tune either the entire network (including the pretrained model) or only the top classification layer on new training data. With this method of transfer learning, training with smaller datasets is possible.

TensorFlow Hub Models

The following pretrained models are available to use for transfer learning with the Image Classification - TensorFlow algorithm.

The following models vary significantly in size, number of model parameters, training time, and inference latency for any given dataset. The best model for your use case depends on the complexity of your fine-tuning dataset and any requirements that you have on training time, inference latency, or model accuracy.

**Image Classification - TensorFlow Hyperparameters**

Hyperparameters are parameters that are set before a machine learning model begins learning. The following hyperparameters are supported by the Amazon SageMaker built-in Image Classification - TensorFlow algorithm. See [Tune an Image Classification - TensorFlow model](#) for information on hyperparameter tuning.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>augmentation</td>
<td>Set to &quot;True&quot; to apply augmentation_random_flip, augmentation_random_rotation, and augmentation_random_zoom to the training data. Valid values: string, either: (&quot;True&quot; or &quot;False&quot;). Default value: &quot;False&quot;.</td>
</tr>
<tr>
<td>augmentation_random_flip</td>
<td>Indicates which flip mode to use for data augmentation when augmentation is set to &quot;True&quot;. For more information, see RandomFlip in the TensorFlow documentation. Valid values: string, any of the following: (&quot;horizontal_and_vertical&quot;, &quot;vertical&quot;, or &quot;None&quot;). Default value: &quot;horizontal_and_vertical&quot;.</td>
</tr>
<tr>
<td>augmentation_random_rotation</td>
<td>Indicates how much rotation to use for data augmentation when augmentation is set to &quot;True&quot;. Values represent a fraction of $2\pi$. Positive values rotate counterclockwise while negative values rotate clockwise. 0 means no rotation. For more information, see RandomRotation in the TensorFlow documentation. Valid values: float, range: [-1.0, 1.0]. Default value: 0.2.</td>
</tr>
<tr>
<td>augmentation_random_zoom</td>
<td>Indicates how much vertical zoom to use for data augmentation when augmentation is set to &quot;True&quot;. Positive values zoom out while negative values zoom in. 0 means no zoom. For more information, see RandomZoom in the TensorFlow documentation. Valid values: float, range: [-1.0, 1.0]. Default value: 0.1.</td>
</tr>
<tr>
<td>batch_size</td>
<td>The batch size for training. For training on instances with multiple GPUs, this batch size is used across the GPUs. Valid values: positive integer. Default value: 32.</td>
</tr>
<tr>
<td>beta_1</td>
<td>The beta1 for the &quot;adam&quot; optimizer. Represents the exponential decay rate for the first moment estimates. Ignored for other optimizers. Valid values: float, range: [0.0, 1.0]. Default value: 0.9.</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>beta_2</td>
<td>The beta2 for the &quot;adam&quot; optimizer. Represents the exponential decay rate for the second moment estimates. Ignored for other optimizers. Valid values: float, range: [0.0, 1.0]. Default value: 0.999.</td>
</tr>
<tr>
<td>binary_mode</td>
<td>When binary_mode is set to &quot;True&quot;, the model returns a single probability number for the positive class and can use additional eval_metric options. Use only for binary classification problems. Valid values: string, either: (&quot;True&quot; or &quot;False&quot;). Default value: &quot;False&quot;.</td>
</tr>
<tr>
<td>dropout_rate</td>
<td>The dropout rate for the dropout layer in the top classification layer. Valid values: float, range: [0.0, 1.0]. Default value: 0.2</td>
</tr>
<tr>
<td>early_stopping</td>
<td>Set to &quot;True&quot; to use early stopping logic during training. If &quot;False&quot;, early stopping is not used. Valid values: string, either: (&quot;True&quot; or &quot;False&quot;). Default value: &quot;False&quot;.</td>
</tr>
<tr>
<td>early_stopping_min_delta</td>
<td>The minimum change needed to qualify as an improvement. An absolute change less than the value of early_stopping_min_delta does not qualify as improvement. Used only when early_stopping is set to &quot;True&quot;. Valid values: float, range: [0.0, 1.0]. Default value: 0.0.</td>
</tr>
<tr>
<td>early_stopping_patience</td>
<td>The number of epochs to continue training with no improvement. Used only when early_stopping is set to &quot;True&quot;. Valid values: positive integer. Default value: 5.</td>
</tr>
<tr>
<td>epochs</td>
<td>The number of training epochs. Valid values: positive integer. Default value: 3.</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>epsilon</td>
<td>The epsilon for &quot;adam&quot;, &quot;rmsprop&quot;, &quot;adadelta&quot;, and &quot;adagrad&quot; optimizers. Usually set to a small value to avoid division by 0. Ignored for other optimizers.</td>
</tr>
<tr>
<td>eval_metric</td>
<td>If binary_mode is set to &quot;False&quot;, eval_metric can only be &quot;accuracy&quot;. If binary_mode is &quot;True&quot;, select any of the valid values. For more information, see Metrics in the TensorFlow documentation.</td>
</tr>
<tr>
<td>image_resize_interpolation</td>
<td>Indicates interpolation method used when resizing images. For more information, see image.resize in the TensorFlow documentation.</td>
</tr>
<tr>
<td>initial_accumulator_value</td>
<td>The starting value for the accumulators, or the per-parameter momentum values, for the &quot;adagrad&quot; optimizer. Ignored for other optimizers.</td>
</tr>
<tr>
<td>label_smoothing</td>
<td>Indicates how much to relax the confidence on label values. For example, if label_smoothing is 0.1, then non-target labels are 0.1/num_classes and target labels are 0.9+0.1/num_classes.</td>
</tr>
<tr>
<td>learning_rate</td>
<td>The optimizer learning rate.</td>
</tr>
<tr>
<td>momentum</td>
<td>The momentum for &quot;sgd&quot;, &quot;nesterov&quot;, and &quot;rmsprop&quot; optimizers. Ignored for other optimizers.</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>optimizer</td>
<td>The optimizer type. For more information, see Optimizers in the TensorFlow documentation. Valid values: string, any of the following: (&quot;adam&quot;, &quot;sgd&quot;, &quot;nesterov&quot;, &quot;rmsprop&quot;, &quot;adagrad&quot;, &quot;adadelta&quot;). Default value: &quot;adam&quot;.</td>
</tr>
<tr>
<td>regularizers_l2</td>
<td>The L2 regularization factor for the dense layer in the classification layer. Valid values: float, range: [0.0, 1.0]. Default value: 0.0001.</td>
</tr>
<tr>
<td>reinitialize_top_layer</td>
<td>If set to &quot;Auto&quot;, the top classification layer parameters are re-initialized during fine-tuning. For incremental training, top classification layer parameters are not re-initialized unless set to &quot;True&quot;. Valid values: string, any of the following: (&quot;Auto&quot;, &quot;True&quot; or &quot;False&quot;). Default value: &quot;Auto&quot;.</td>
</tr>
<tr>
<td>rho</td>
<td>The discounting factor for the gradient of the &quot;adadelta&quot; and &quot;rmsprop&quot; optimizers. Ignored for other optimizers. Valid values: float, range: [0.0, 1.0]. Default value: 0.95.</td>
</tr>
<tr>
<td>train_only_top_layer</td>
<td>If &quot;True&quot;, only the top classification layer parameters are fine-tuned. If &quot;False&quot;, all model parameters are fine-tuned. Valid values: string, either: (&quot;True&quot; or &quot;False&quot;). Default value: &quot;False&quot;.</td>
</tr>
</tbody>
</table>

**Tune an Image Classification - TensorFlow model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 1863).

**Metrics computed by the Image Classification - TensorFlow algorithm**

The image classification algorithm is a supervised algorithm. It reports an accuracy metric that is computed during training. When tuning the model, choose this metric as the objective metric.
Use Built-in Algorithms

<table>

Tunable Image Classification - TensorFlow hyperparameters

Tune an image classification model with the following hyperparameters. The hyperparameters that have the greatest impact on image classification objective metrics are: batch_size, learning_rate, and optimizer. Tune the optimizer-related hyperparameters, such as momentum, regularizers_l2, beta_1, beta_2, and eps based on the selected optimizer. For example, use beta_1 and beta_2 only when adam is the optimizer.

For more information about which hyperparameters are used for each optimizer, see Image Classification - TensorFlow Hyperparameters (p. 1774).

Object Detection - MXNet

The Amazon SageMaker Object Detection - MXNet algorithm detects and classifies objects in images using a single deep neural network. It is a supervised learning algorithm that takes images as input and identifies all instances of objects within the image scene. The object is categorized into one of the classes in a specified collection with a confidence score that it belongs to the class. Its location and scale in the image are indicated by a rectangular bounding box. It uses the Single Shot multibox Detector (SSD) framework and supports two base networks: VGG and ResNet. The network can be trained from scratch, or trained with models that have been pre-trained on the ImageNet dataset.

Topics
Input/Output Interface for the Object Detection Algorithm

The SageMaker Object Detection algorithm supports both RecordIO (application/x-recordio) and image (image/png, image/jpeg, and application/x-image) content types for training in file mode and supports RecordIO (application/x-recordio) for training in pipe mode. However, you can also train in pipe mode using the image files (image/png, image/jpeg, and application/x-image), without creating RecordIO files, by using the augmented manifest format. The recommended input format for the Amazon SageMaker object detection algorithms is Apache MXNet RecordIO. However, you can also use raw images in .jpg or .png format. The algorithm supports only application/x-image for inference.

Note
To maintain better interoperability with existing deep learning frameworks, this differs from the protobuf data formats commonly used by other Amazon SageMaker algorithms.

See the Object Detection Sample Notebooks (p. 1781) for more details on data formats.

Train with the RecordIO Format

If you use the RecordIO format for training, specify both train and validation channels as values for the InputDataConfig parameter of the CreateTrainingJob request. Specify one RecordIO (.rec) file in the train channel and one RecordIO file in the validation channel. Set the content type for both channels to application/x-recordio. An example of how to generate RecordIO file can be found in the object detection sample notebook. You can also use tools from the MXNet's GluonCV to generate RecordIO files for popular datasets like the PASCAL Visual Object Classes and Common Objects in Context (COCO).

Train with the Image Format

If you use the image format for training, specify train, validation, train_annotation, and validation_annotation channels as values for the InputDataConfig parameter of CreateTrainingJob request. Specify the individual image data (.jpg or .png) files for the train and validation channels. For annotation data, you can use the JSON format. Specify the corresponding .json files in the train_annotation and validation_annotation channels. Set the content type for all four channels to image/png or image/jpeg based on the image type. You can also use the content type application/x-image when your dataset contains both .jpg and .png images. The following is an example of a .json file.

```json
{
    "file": "your_image_directory/sample_image1.jpg",
    "image_size": [
        {
            "width": 500,
            "height": 400,
            "depth": 3
        }
    ],
    "annotations": [
        {
            "class_id": 0,
            "left": 111,
            "top": 123,
            "width": 100,
            "height": 200
        }
    ]
}
```
Each image needs a .json file for annotation, and the .json file should have the same name as the corresponding image. The name of above .json file should be "sample_image1.json". There are four properties in the annotation .json file. The property "file" specifies the relative path of the image file. For example, if your training images and corresponding .json files are stored in s3://your_bucket/train/sample_image and s3://your_bucket/train_annotation, specify the path for your train and train_annotation channels as s3://your_bucket/train and s3://your_bucket/train_annotation, respectively.

In the .json file, the relative path for an image named sample_image1.jpg should be sample_image/sample_image1.jpg. The "image_size" property specifies the overall image dimensions. The SageMaker object detection algorithm currently only supports 3-channel images. The "annotations" property specifies the categories and bounding boxes for objects within the image. Each object is annotated by a "class_id" index and by four bounding box coordinates ("left", "top", "width", "height"). The "left" (x-coordinate) and "top" (y-coordinate) values represent the upper-left corner of the bounding box. The "width" (x-coordinate) and "height" (y-coordinate) values represent the dimensions of the bounding box. The origin (0, 0) is the upper-left corner of the entire image. If you have multiple objects within one image, all the annotations should be included in a single .json file. The "categories" property stores the mapping between the class index and class name. The class indices should be numbered successively and the numbering should start with 0. The "categories" property is optional for the annotation .json file.

**Train with Augmented Manifest Image Format**

The augmented manifest format enables you to do training in pipe mode using image files without needing to create RecordIO files. You need to specify both train and validation channels as values for the `InputDataConfig` parameter of the `CreateTrainingJob` request. While using the format, an S3 manifest file needs to be generated that contains the list of images and their corresponding annotations. The manifest file format should be in **JSON Lines** format in which each line represents one sample. The images are specified using the 'source-ref' tag that points to the S3 location of the image. The annotations are provided under the "AttributeNames" parameter value as specified in the
CreateTrainingJob request. It can also contain additional metadata under the metadata tag, but these are ignored by the algorithm. In the following example, the "AttributeNames are contained in the list ["source-ref", "bounding-box"]:

```
[
  {"source-ref": "s3://your_bucket/image1.jpg", "bounding-box": {"image_size": [{"width": 500, "height": 400, "depth": 3}], "annotations": [{"class_id": 0, "left": 111, "top": 134, "width": 61, "height": 128}, {"class_id": 5, "left": 161, "top": 250, "width": 80, "height": 50}]
    },
  }],
  "bounding-box-metadata": {
    "class-map": {
      "0": "dog",
      "5": "horse",
      "type": "groundtruth/object-detection"
    }
  }
```

The order of "AttributeNames" in the input files matters when training the Object Detection algorithm. It accepts piped data in a specific order, with image first, followed by annotations. So the "AttributeNames" in this example are provided with "source-ref" first, followed by "bounding-box". When using Object Detection with Augmented Manifest, the value of parameter RecordWrapperType must be set as "RecordIO".

For more information on augmented manifest files, see [Provide Dataset Metadata to Training Jobs with an Augmented Manifest File](p. 2327).

### Incremental Training

You can also seed the training of a new model with the artifacts from a model that you trained previously with SageMaker. Incremental training saves training time when you want to train a new model with the same or similar data. SageMaker object detection models can be seeded only with another built-in object detection model trained in SageMaker.

To use a pretrained model, in the CreateTrainingJob request, specify the ChannelName as "model" in the InputDataConfig parameter. Set the ContentType for the model channel to application/x-sagemaker-model. The input hyperparameters of both the new model and the pretrained model that you upload to the model channel must have the same settings for the base_network and num_classes input parameters. These parameters define the network architecture. For the pretrained model file, use the compressed model artifacts (in .tar.gz format) output by SageMaker. You can use either RecordIO or image formats for input data.

For more information on incremental training and for instructions on how to use it, see [Use Incremental Training in Amazon SageMaker](p. 2301).

### EC2 Instance Recommendation for the Object Detection Algorithm

The object detection algorithm supports P2, P3, G4dn, and G5 GPU instance families. We recommend using GPU instances with more memory for training with large batch sizes. You can run the object detection algorithm on multi-GPU and multi-machine settings for distributed training.

You can use both CPU (such as C5 and M5) and GPU (such as P3 and G4dn) instances for inference.

### Object Detection Sample Notebooks

For a sample notebook that shows how to use the SageMaker Object Detection algorithm to train and host a model on the

Caltech Birds (CUB 200 2011) dataset using the Single Shot multibox Detector algorithm, see [Amazon SageMaker Object Detection for Bird Species](#). For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see [Amazon SageMaker Notebook Instances](p. 298). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The object detection example notebook using
the Object Detection algorithm is located in the **Introduction to Amazon Algorithms** section. To open a notebook, click on its **Use** tab and select **Create copy**.

**How Object Detection Works**

The object detection algorithm identifies and locates all instances of objects in an image from a known collection of object categories. The algorithm takes an image as input and outputs the category that the object belongs to, along with a confidence score that it belongs to the category. The algorithm also predicts the object's location and scale with a rectangular bounding box. Amazon SageMaker Object Detection uses the **Single Shot multibox Detector (SSD)** algorithm that takes a convolutional neural network (CNN) pretrained for classification task as the base network. SSD uses the output of intermediate layers as features for detection.

Various CNNs such as **VGG** and **ResNet** have achieved great performance on the image classification task. Object detection in Amazon SageMaker supports both VGG-16 and ResNet-50 as a base network for SSD. The algorithm can be trained in full training mode or in transfer learning mode. In full training mode, the base network is initialized with random weights and then trained on user data. In transfer learning mode, the base network weights are loaded from pretrained models.

The object detection algorithm uses standard data augmentation operations, such as flip, rescale, and jitter, on the fly internally to help avoid overfitting.

**Object Detection Hyperparameters**

In the **CreateTrainingJob** request, you specify the training algorithm that you want to use. You can also specify algorithm-specific hyperparameters that are used to help estimate the parameters of the model from a training dataset. The following table lists the hyperparameters provided by Amazon SageMaker for training the object detection algorithm. For more information about how object training works, see **How Object Detection Works** (p. 1782).

<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>label_width</td>
<td>The force padding label width used to sync across training and validation data. For example, if one image in the data contains at most 10 objects, and each object's annotation is specified with 5 numbers, [class_id, left, top, width, height], then the label_width should be no smaller than $10 \times 5 + \text{header information length}$. The header information length is usually 2. We recommend using a slightly larger label_width for the training, such as 60 for this example. Optional Valid values: Positive integer large enough to accommodate the largest annotation information length in the data. Default: 350</td>
</tr>
<tr>
<td>learning_rate</td>
<td>The initial learning rate. Optional Valid values: float in $(0, 1]$ Default: 0.001</td>
</tr>
<tr>
<td>lr_scheduler_factor</td>
<td>The ratio to reduce learning rate. Used in conjunction with the lr_scheduler_step parameter defined as $\text{lr}<em>{\text{new}} = \text{lr}</em>{\text{old}} \times \text{lr}_{\text{scheduler_factor}}$. Optional Valid values: float in $(0, 1)$ Default: 0.1</td>
</tr>
<tr>
<td>lr_scheduler_step</td>
<td>The epochs at which to reduce the learning rate. The learning rate is reduced by lr_scheduler_factor at epochs listed in a comma-delimited string: &quot;epoch1, epoch2, ...&quot;. For example, if the value is set to &quot;10, 20&quot; and the lr_scheduler_factor is set to 1/2, then the learning rate is halved after 10th epoch and then halved again after 20th epoch. Optional Valid values: string Default: empty string</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>mini_batch_size</td>
<td>The batch size for training. In a single-machine multi-gpu setting, each GPU handles mini_batch_size/num_gpus training samples. For the multi-machine training in dist_sync mode, the actual batch size is mini_batch_size*number of machines. A large mini_batch_size usually leads to faster training, but it may cause out of memory problem. The memory usage is related to mini_batch_size, image_shape, and base_network architecture. For example, on a single p3.2xlarge instance, the largest mini_batch_size without an out of memory error is 32 with the base_network set to &quot;resnet-50&quot; and an image_shape of 300. With the same instance, you can use 64 as the mini_batch_size with the base network vgg-16 and an image_shape of 300.</td>
</tr>
<tr>
<td>momentum</td>
<td>The momentum for sgd. Ignored for other optimizers.</td>
</tr>
<tr>
<td>nms_threshold</td>
<td>The non-maximum suppression threshold.</td>
</tr>
<tr>
<td>optimizer</td>
<td>The optimizer types. For details on optimizer values, see <a href="https://mxnet.apache.org/api/">MXNet's API</a>.</td>
</tr>
<tr>
<td>overlap_threshold</td>
<td>The evaluation overlap threshold.</td>
</tr>
</tbody>
</table>

### Tune an Object Detection Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1863).

### Metrics Computed by the Object Detection Algorithm

The object detection algorithm reports on a single metric during training: \textit{validation:mAP}. When tuning a model, choose this metric as the objective metric.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>

**Object Detection Request and Response Formats**

**Request Format**

Query a trained model by using the model's endpoint. The endpoint takes .jpg and .png image formats with `image/jpeg` and `image/png` content-types.

**Response Formats**

The response is the class index with a confidence score and bounding box coordinates for all objects within the image encoded in JSON format. The following is an example of response .json file:

```
{"prediction":
[ [4.0, 0.8641945540904998, 0.3088374733924866, 0.07030484080314636, 0.7110607028007507, 0.954266819000244],
 [0.0, 0.73376623592150510, 0.5714187026023865, 0.40427327156066895, 0.827075183391571, 0.9712159633636475],
 [4.0, 0.3264398545026792, 0.3677481412887573, 0.03488352931573486, 0.6318609714508057, 0.5967587828636169],
 [8.0, 0.2255249679085925, 0.6152569651603699, 0.572782611846924, 0.882301390171051, 0.8985623121261597],
 [3.0, 0.4226029917597770, 0.01930551230907402, 0.08386176824569702, 0.9574796557426453]
]}
```

Each row in this .json file contains an array that represents a detected object. Each of these object arrays consists of a list of six numbers. The first number is the predicted class label. The second number is the associated confidence score for the detection. The last four numbers represent the bounding box coordinates [xmin, ymin, xmax, ymax]. These output bounding box corner indices are normalized by the overall image size. Note that this encoding is different than that use by the input .json format. For example, in the first entry of the detection result, 0.3088374733924866 is the left coordinate (x-coordinate of upper-left corner) of the bounding box as a ratio of the overall image width, 0.07030484080314636 is the top coordinate (y-coordinate of upper-left corner) of the bounding box as a ratio of the overall image height, 0.7110607028007507 is the right coordinate (x-coordinate of lower-right corner) of the bounding box as a ratio of the overall image width, and 0.954266819000244 is the bottom coordinate (y-coordinate of lower-right corner) of the bounding box as a ratio of the overall image height.

To avoid unreliable detection results, you might want to filter out the detection results with low confidence scores. In the object detection sample notebook, we provide examples of scripts that use a threshold to remove low confidence detections and to plot bounding boxes on the original images.

For batch transform, the response is in JSON format, where the format is identical to the JSON format described above. The detection results of each image is represented as a JSON file. For example:

```
{"prediction": [[label_id, confidence_score, xmin, ymin, xmax, ymax], [label_id, confidence_score, xmin, ymin, xmax, ymax]]}
```
For more details on training and inference, see the Object Detection Sample Notebooks (p. 1781).

OUTPUT: JSON Response Format

}
```

Object Detection - TensorFlow

The Amazon SageMaker Object Detection - TensorFlow algorithm is a supervised learning algorithm that supports transfer learning with many pretrained models from the TensorFlow Model Garden. Use transfer learning to fine-tune one of the available pretrained models on your own dataset, even if a large amount of image data is not available. The object detection algorithm takes an image as input and outputs a list of bounding boxes. Training datasets must consist of images in .jpg, .jpeg, or .png format.

How to use the SageMaker Object Detection - TensorFlow algorithm

You can use Object Detection - TensorFlow as an Amazon SageMaker built-in algorithm. The following section describes how to use Object Detection - TensorFlow with the SageMaker Python SDK. For information on how to use Object Detection - TensorFlow from the Amazon SageMaker Studio UI, see SageMaker JumpStart (p. 161).

The Object Detection - TensorFlow algorithm supports transfer learning using any of the compatible pretrained TensorFlow models. For a list of all available pretrained models, see TensorFlow Models (p. 1793). Every pretrained model has a unique model_id. The following example uses ResNet50 (model_id: tensorflow-od1-ssd-resnet50-v1-fpn-640x640-coco17-tpu-8) to fine-tune on a custom dataset. The pretrained models are all pre-downloaded from the TensorFlow Hub and stored in Amazon S3 buckets so that training jobs can run in network isolation. Use these pre-generated model training artifacts to construct a SageMaker Estimator.

First, retrieve the Docker image URI, training script URI, and pretrained model URI. Then, change the hyperparameters as you see fit. You can see a Python dictionary of all available hyperparameters and their default values with hyperparameters.retrieve_default. For more information, see Object Detection - TensorFlow Hyperparameters (p. 1794). Use these values to construct a SageMaker Estimator.

Note
Default hyperparameter values are different for different models. For example, for larger models, the default number of epochs is smaller.

This example uses the PennFudanPed dataset, which contains images of pedestrians in the street. We pre-downloaded the dataset and made it available with Amazon S3. To fine-tune your model, call .fit using the Amazon S3 location of your training dataset.

```python
from sagemaker import image_uris, model_uris, script_uris, hyperparameters
from sagemaker.estimator import Estimator

model_id, model_version = "tensorflow-od1-ssd-resnet50-v1-fpn-640x640-coco17-tpu-8", "*
training_instance_type = "ml.p3.2xlarge"

# Retrieve the Docker image
train_image_uri =
    image_uris.retrieve(model_id=model_id, model_version=model_version,image_scope="training",instance_type=training_instance_type,region=None,framework=None)

# Retrieve the training script
train_source_uri = script_uris.retrieve(model_id=model_id, model_version=model_version,script_scope="training")

# Retrieve the pretrained model tarball for transfer learning
train_model_uri = model_uris.retrieve(model_id=model_id, model_version=model_version,
    model_scope="training")

# Retrieve the default hyperparameters for fine-tuning the model
hyperparameters = hyperparameters.retrieve_default(model_id=model_id,
    model_version=model_version)

# [Optional] Override default hyperparameters with custom values
hyperparameters["epochs"] = "5"

# Sample training data is available in this bucket
training_data_bucket = f"jumpstart-cache-prod-{aws_region}"
training_data_prefix = "training-datasets/PennFudanPed_COCO_format/"

training_dataset_s3_path = f"s3://{training_data_bucket}/{training_data_prefix}"

output_bucket = sess.default_bucket()
output_prefix = "jumpstart-example-od-training"
s3_output_location = f"s3://{output_bucket}/{output_prefix}/output"
```
# Create an Estimator instance
    tf_od_estimator = Estimator(
        role=aws_role,
        image_uri=train_image_uri,
        source_dir=train_source_uri,
        model_uri=train_model_uri,
        entry_point="transfer_learning.py",
        instance_count=1,
        instance_type=training_instance_type,
        max_run=360000,
        hyperparameters=hyperparameters,
        output_path=s3_output_location,
    )

# Launch a training job
    tf_od_estimator.fit(\{"training": training_dataset_s3_path\}, logs=True)

For more information about how to use the SageMaker Object Detection - TensorFlow algorithm for transfer learning on a custom dataset, see the Introduction to SageMaker TensorFlow - Object Detection notebook.

Input and output interface for the Object Detection - TensorFlow algorithm

Each of the pretrained models listed in TensorFlow Models can be fine-tuned to any dataset with any number of image classes. Be mindful of how to format your training data for input to the Object Detection - TensorFlow model.

- **Training data input format:** Your training data should be a directory with an images subdirectory and an annotations.json file.

The following is an example of an input directory structure. The input directory should be hosted in an Amazon S3 bucket with a path similar to the following: s3://bucket_name/input_directory/. Note that the trailing / is required.

```
input_directory
    |--images
    |   |--abc.png
    |   |--def.png
    |   |--annotations.json
```

The annotations.json file should contain information for bounding boxes and their class labels in the form of a dictionary "images" and "annotations" keys. The value for the "images" key should be a list of dictionaries. There should be one dictionary for each image with the following information:

```
"file_name": image_name, "height": height, "width": width, "id": image_id
```

The value for the "annotations" key should also be a list of dictionaries. There should be one dictionary for each bounding box with the following information:

```
"image_id": image_id, "bbox": [xmin, ymin, xmax, ymax], "category_id": bbox_label
```

After training, a label mapping file and trained model are saved to your Amazon S3 bucket.

**Incremental training**

You can seed the training of a new model with artifacts from a model that you trained previously with SageMaker. Incremental training saves training time when you want to train a new model with the same or similar data.

**Note**

You can use any dataset for incremental training, as long as the set of classes remains the same. The incremental training step is similar to the fine-tuning step, but instead of starting with a pretrained model, you start with an existing fine-tuned model. For more information about how to use incremental training with the SageMaker Object Detection - TensorFlow, see the Introduction to SageMaker TensorFlow - Object Detection notebook.

Inference with the Object Detection - TensorFlow algorithm

You can host the fine-tuned model that results from your TensorFlow Object Detection training for inference. Any input image for inference must be in .jpg, .jpeg, or .png format and be content type application/x-image. The Object Detection - TensorFlow algorithm resizes input images automatically.

Running inference results in bounding boxes, predicted classes, and the scores of each prediction encoded in JSON format. The Object Detection - TensorFlow model processes a single image per request and outputs only one line. The following is an example of a JSON format response:

```json
accept: application/json;verbose

{"normalized_boxes":[[xmin1, xmax1, ymin1, ymax1],...],
 "classes":[classidx1, class_idx2,...],
 "scores":[score_1, score_2,...],
 "labels":[label1, label2,...],
 "tensorflow_model_output":<original output of the model>}
```

If accept is set to application/json, then the model only outputs normalized boxes, classes, and scores.

Amazon EC2 instance recommendation for the Object Detection - TensorFlow algorithm

The Object Detection - TensorFlow algorithm supports all GPU instances for training, including:

- ml.p2.xlarge
- ml.p2.16xlarge
- ml.p3.2xlarge
- ml.p3.16xlarge

We recommend GPU instances with more memory for training with large batch sizes. Both CPU (such as M5) and GPU (P2 or P3) instances can be used for inference. For a comprehensive list of SageMaker training and inference instances across AWS Regions, see Amazon SageMaker Pricing.

Object Detection - TensorFlow sample notebooks

For more information about how to use the SageMaker Object Detection - TensorFlow algorithm for transfer learning on a custom dataset, see the Introduction to SageMaker TensorFlow - Object Detection notebook.

For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances (p. 298). After you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. To open a notebook, choose its Use tab and choose Create copy.

How Object Detection - TensorFlow Works

The Object Detection - TensorFlow algorithm takes an image as input and predicts bounding boxes and object labels. Various deep learning networks such as MobileNet, ResNet, Inception, and EfficientNet are highly accurate for object detection. There are also deep learning networks that are trained on large
image datasets, such as Common Objects in Context (COCO), which has 328,000 images. After a network is trained with COCO data, you can then fine-tune the network on a dataset with a particular focus to perform more specific object detection tasks. The Amazon SageMaker Object Detection - TensorFlow algorithm supports transfer learning on many pretrained models that are available in the TensorFlow Model Garden.

According to the number of class labels in your training data, an object detection layer is attached to the pretrained TensorFlow model of your choice. You can then fine-tune either the entire network (including the pretrained model) or only the top classification layer on new training data. With this method of transfer learning, training with smaller datasets is possible.

TensorFlow Models

The following pretrained models are available to use for transfer learning with the Object Detection - TensorFlow algorithm.

The following models vary significantly in size, number of model parameters, training time, and inference latency for any given dataset. The best model for your use case depends on the complexity of your fine-tuning dataset and any requirements that you have on training time, inference latency, or model accuracy.

Object Detection - TensorFlow Hyperparameters

Hyperparameters are parameters that are set before a machine learning model begins learning. The following hyperparameters are supported by the Amazon SageMaker built-in Object Detection - TensorFlow algorithm. See [Tune an Object Detection - TensorFlow model](p. 1796) for information on hyperparameter tuning.

<table>
<thead>
<tr>

| rho                         | The discounting factor for the gradient of the "adadelta" and "rmsprop" optimizers. Ignored for other optimizers.  |
|                             | Valid values: float, range: [0.0, 1.0].                                                                          |
|                             | Default value: 0.95.                                                                                               |

| train_only_on_top_layer     | If "True", only the top classification layer parameters are fine-tuned. If "False", all model parameters are fine-tuned. |
|                             | Valid values: string, either: ("True" or "False").                                                               |
|                             | Default value: "False".

**Tune an Object Detection - TensorFlow model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 1863).

**Metrics computed by the Object Detection - TensorFlow algorithm**

Refer to the following chart to find which metrics are computed by the Object Detection - TensorFlow algorithm.

<table>
<thead>
<tr>
<th>Metric Name</th>

</table>
Tunable Object Detection - TensorFlow hyperparameters

Tune an object detection model with the following hyperparameters. The hyperparameters that have the greatest impact on object detection objective metrics are: batch_size, learning_rate, and optimizer. Tune the optimizer-related hyperparameters, such as momentum, regularizers_l2, beta_1, beta_2, and eps based on the selected optimizer. For example, use beta_1 and beta_2 only when adam is the optimizer.

For more information about which hyperparameters are used for each optimizer, see [Object Detection - TensorFlow Hyperparameters](p. 1794).

Semantic Segmentation Algorithm

The SageMaker semantic segmentation algorithm provides a fine-grained, pixel-level approach to developing computer vision applications. It tags every pixel in an image with a class label from a predefined set of classes. Tagging is fundamental for understanding scenes, which is critical to an increasing number of computer vision applications, such as self-driving vehicles, medical imaging diagnostics, and robot sensing.

For comparison, the SageMaker [Image Classification - MXNet](p. 1754) is a supervised learning algorithm that analyzes only whole images, classifying them into one of multiple output categories. The [Object Detection - MXNet](p. 1778) is a supervised learning algorithm that detects and classifies all instances of an object in an image. It indicates the location and scale of each object in the image with a rectangular bounding box.

Because the semantic segmentation algorithm classifies every pixel in an image, it also provides information about the shapes of the objects contained in the image. The segmentation output is
represented as a grayscale image, called a segmentation mask. A segmentation mask is a grayscale image with the same shape as the input image.

The SageMaker semantic segmentation algorithm is built using the MXNet Gluon framework and the Gluon CV toolkit. It provides you with a choice of three built-in algorithms to train a deep neural network. You can use the Fully-Convolutional Network (FCN) algorithm, Pyramid Scene Parsing (PSP) algorithm, or DeepLabV3.

Each of the three algorithms has two distinct components:

- The backbone (or encoder)—A network that produces reliable activation maps of features.
- The decoder—A network that constructs the segmentation mask from the encoded activation maps.

You also have a choice of backbones for the FCN, PSP, and DeepLabV3 algorithms: ResNet50 or ResNet101. These backbones include pretrained artifacts that were originally trained on the ImageNet classification task. You can fine-tune these backbones for segmentation using your own data. Or, you can initialize and train these networks from scratch using only your own data. The decoders are never pretrained.

To deploy the trained model for inference, use the SageMaker hosting service. During inference, you can request the segmentation mask either as a PNG image or as a set of probabilities for each class for each pixel. You can use these masks as part of a larger pipeline that includes additional downstream image processing or other applications.

**Topics**

- Semantic Segmentation Sample Notebooks (p. 1798)
- Input/Output Interface for the Semantic Segmentation Algorithm (p. 1798)
- EC2 Instance Recommendation for the Semantic Segmentation Algorithm (p. 1801)
- Semantic Segmentation Hyperparameters (p. 1801)
- Tuning a Semantic Segmentation Model (p. 1806)

**Semantic Segmentation Sample Notebooks**

For a sample Jupyter notebook that uses the SageMaker semantic segmentation algorithm to train a model and deploy it to perform inferences, see the Semantic Segmentation Example. For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Amazon SageMaker Notebook Instances (p. 298).

To see a list of all of the SageMaker samples, create and open a notebook instance, and choose the SageMaker Examples tab. The example semantic segmentation notebooks are located under Introduction to Amazon algorithms. To open a notebook, choose its Use tab, and choose Create copy.

**Input/Output Interface for the Semantic Segmentation Algorithm**

SageMaker semantic segmentation expects the customer's training dataset to be on Amazon Simple Storage Service (Amazon S3). Once trained, it produces the resulting model artifacts on Amazon S3. The input interface format for the SageMaker semantic segmentation is similar to that of most standardized semantic segmentation benchmarking datasets. The dataset in Amazon S3 is expected to be presented in two channels, one for train and one for validation using four directories, two for images and two for annotations. Annotations are expected to be uncompressed PNG images. The dataset might also have a label map that describes how the annotation mappings are established. If not, the algorithm uses a default. It also supports the augmented manifest image format (application/x-image) for training in Pipe input mode straight from Amazon S3. For inference, an endpoint accepts images with an image/jpeg content type.
How Training Works

The training data is split into four directories: train, train_annotation, validation, and validation_annotation. There is a channel for each of these directories. The dataset also expected to have one label_map.json file per channel for train_annotation and validation_annotation respectively. If you don't provide these JSON files, SageMaker provides the default set label map.

The dataset specifying these files should look similar to the following example:

```
s3://bucket_name
    |- train
    |    |- 0000.jpg
    |    |- coffee.jpg
    |- validation
    |    |- 00a0.jpg
    |    |- banana.jpg
    |- train_annotation
    |    |- 0000.png
    |    |- coffee.png
    |- validation_annotation
    |    |- 00a0.png
    |    |- banana.png
    |- label_map
    |    |- train_label_map.json
    |    |- validation_label_map.json
```

Every JPG image in the train and validation directories has a corresponding PNG label image with the same name in the train_annotation and validation_annotation directories. This naming convention helps the algorithm to associate a label with its corresponding image during training. The train, train_annotation, validation, and validation_annotation channels are mandatory. The annotations are single-channel PNG images. The format works as long as the metadata (modes) in the image helps the algorithm read the annotation images into a single-channel 8-bit unsigned integer. For more information on our support for modes, see the Python Image Library documentation. We recommend using the 8-bit pixel, true color P mode.

The image that is encoded is a simple 8-bit integer when using modes. To get from this mapping to a map of a label, the algorithm uses one mapping file per channel, called the label map. The label map is used to map the values in the image with actual label indices. In the default label map, which is provided by default if you don't provide one, the pixel value in an annotation matrix (image) directly index the label. These images can be grayscale PNG files or 8-bit indexed PNG files. The label map file for the unscaled default case is the following:

```
{
   "scale": "1"
}
```

To provide some contrast for viewing, some annotation software scales the label images by a constant amount. To support this, the SageMaker semantic segmentation algorithm provides a rescaling option to scale down the values to actual label values. When scaling down doesn't convert the value to an appropriate integer, the algorithm defaults to the greatest integer less than or equal to the scale value. The following code shows how to set the scale value to rescale the label values:

```
{
   "scale": "3"
}
```
The following example shows how this "scale" value is used to rescale the encoded_label values of the input annotation image when they are mapped to the mapped_label values to be used in training. The label values in the input annotation image are 0, 3, 6, with scale 3, so they are mapped to 0, 1, 2 for training:

```
encoded_label = [0, 3, 6]
mapped_label = [0, 1, 2]
```

In some cases, you might need to specify a particular color mapping for each class. Use the map option in the label mapping as shown in the following example of a label_map file:

```
{
  "map": {
    "0": 5,
    "1": 0,
    "2": 2
  }
}
```

This label mapping for this example is:

```
encoded_label = [0, 5, 2]
mapped_label = [1, 0, 2]
```

With label mappings, you can use different annotation systems and annotation software to obtain data without a lot of preprocessing. You can provide one label map per channel. The files for a label map in the label_map channel must follow the naming conventions for the four directory structure. If you don't provide a label map, the algorithm assumes a scale of 1 (the default).

### Training with the Augmented Manifest Format

The augmented manifest format enables you to do training in Pipe mode using image files without needing to create RecordIO files. The augmented manifest file contains data objects and should be in JSON Lines format, as described in the `CreateTrainingJob` request. Each line in the manifest is an entry containing the Amazon S3 URI for the image and the URI for the annotation image.

Each JSON object in the manifest file must contain a `source-ref` key. The `source-ref` key should contain the value of the Amazon S3 URI to the image. The labels are provided under the `AttributeNames` parameter value as specified in the `CreateTrainingJob` request. It can also contain additional metadata under the metadata tag, but these are ignored by the algorithm. In the example below, the `AttributeNames` are contained in the list of image and annotation references ["source-ref", "city-streets-ref"]. These names must have -ref appended to them. When using the Semantic Segmentation algorithm with Augmented Manifest, the value of the RecordWrapperType parameter must be "RecordIO" and value of the ContentType parameter must be application/x-recordio.

```
{"source-ref": "S3 bucket location", "city-streets-ref": "S3 bucket location", "city-streets-metadata": {"job-name": "label-city-streets", }}
```

For more information on augmented manifest files, see [Provide Dataset Metadata to Training Jobs with an Augmented Manifest File](p. 2327).

### Incremental Training

You can also seed the training of a new model with a model that you trained previously using SageMaker. This incremental training saves training time when you want to train a new model with the same or similar data. Currently, incremental training is supported only for models trained with the built-in SageMaker Semantic Segmentation.
To use your own pre-trained model, specify the ChannelName as "model" in the InputDataConfig for the CreateTrainingJob request. Set the ContentType for the model channel to application/x-sagemaker-model. The backbone, algorithm, crop_size, and num_classes input parameters that define the network architecture must be consistently specified in the input hyperparameters of the new model and the pre-trained model that you upload to the model channel. For the pretrained model file, you can use the compressed (.tar.gz) artifacts from SageMaker outputs. You can only use image formats for input data. For more information on incremental training and for instructions on how to use it, see Use Incremental Training in Amazon SageMaker (p. 2301).

Produce Inferences

To query a trained model that is deployed to an endpoint, you need to provide an image and an AcceptType that denotes the type of output required. The endpoint takes JPEG images with an image/jpeg content type. If you request an AcceptType of image/png, the algorithm outputs a PNG file with a segmentation mask in the same format as the labels themselves. If you request an accept type of application/x-recordio-protobuf, the algorithm returns class probabilities encoded in recordio-protobuf format. The latter format outputs a 3D tensor where the third dimension is the same size as the number of classes. This component denotes the probability of each class label for each pixel.

EC2 Instance Recommendation for the Semantic Segmentation Algorithm

The SageMaker semantic segmentation algorithm only supports GPU instances for training, and we recommend using GPU instances with more memory for training with large batch sizes. The algorithm can be trained using P2, P3, G4dn, or G5 instances in single machine configurations.

For inference, you can use either CPU instances (such as C5 and M5) and GPU instances (such as P3 and G4dn) or both. For information about the instance types that provide varying combinations of CPU, GPU, memory, and networking capacity for inference, see Amazon SageMaker ML Instance Types.

Semantic Segmentation Hyperparameters

The following tables list the hyperparameters supported by the Amazon SageMaker semantic segmentation algorithm for network architecture, data inputs, and training. You specify Semantic Segmentation for training in the AlgorithmName of the CreateTrainingJob request.
