Developer Guide - AWS SDK for Java 2.x

The AWS SDK for Java provides a Java API for AWS services. Using the SDK, you can build Java applications that work with Amazon S3, Amazon EC2, DynamoDB, and more.

The AWS SDK for Java 2.x is a major rewrite of the version 1.x code base. It's built on top of Java 8+ and adds several frequently requested features. These include support for non-blocking I/O and the ability to plug in a different HTTP implementation at runtime.

We regularly add support for new services to the AWS SDK for Java. For a list of changes and features in a particular version, view the change log.

Get started with the SDK

If you're ready to get hands-on with the SDK, follow the Get started tutorial tutorial.

To set up your development environment, see Setup.

If you're currently using version 1.x of the SDK for Java, see Migrate to version 2 for specific guidance.

For information on making requests to Amazon S3, DynamoDB, Amazon EC2 and other AWS services, see Use the SDK for Java and Work with AWS services.

Develop mobile applications

If you're a mobile app developer, Amazon Web Services provides the AWS Amplify framework.

Maintenance and support for SDK major versions

For information about maintenance and support for SDK major versions and their underlying dependencies, see the following topics in the AWS SDKs and Tools Reference Guide:

- AWS SDKs and Tools Maintenance Policy
- AWS SDKs and Tools Version Support Matrix
Additional resources

In addition to this guide, the following are valuable online resources for AWS SDK for Java developers:

- [AWS SDK for Java 2.x API Reference](#)
- [Java developer blog](#)
- [Java development topic in AWS re:Post](#)
- [SDK source](#) on GitHub
- [AWS SDK Code Examples library](#)
- [@awsforjava (Twitter)](#)

Contribute to the SDK

Developers can also contribute feedback through the following channels:

- Submit issues on GitHub:
  - [Submit Developer Guide documentation issues](#)
  - [Submit SDK issues](#)
- Join an informal chat about the SDK on the AWS SDK for Java 2.x [gitter channel](#)
Get started with the AWS SDK for Java 2.x

The AWS SDK for Java 2.x provides Java APIs for Amazon Web Services (AWS). Using the SDK, you can build Java applications that work with Amazon S3, Amazon EC2, DynamoDB, and more.

This tutorial shows you how to use Apache Maven to define dependencies for the SDK for Java 2.x and then write code that connects to Amazon S3 to upload a file.

Follow these steps to complete this tutorial:

• **Step 1: Set up for this tutorial**
• **Step 2: Create the project**
• **Step 3: Write the code**
• **Step 4: Build and run the application**

**Step 1: Set up for this tutorial**

Before you begin this tutorial, you need the following:

• Permission to access Amazon S3
• A Java development environment that is configured to access AWS services using single sign-on to the AWS IAM Identity Center

Use the instructions in ??? to get set up for this tutorial. After you have configured your development environment with single sign-on access for the Java SDK and you have an active AWS access portal session, continue with Step 2 of this tutorial.

**Step 2: Create the project**

To create the project for this tutorial, you run a Maven command that prompts you for input on how to configure the project. After all input is entered and confirmed, Maven finishes building out the project by creating a pom.xml and creates stub Java files.

1. Open a terminal or command prompt window and navigate to a directory of your choice, for example, your Desktop or Home folder.
2. Enter the following command at the terminal and press Enter.

```bash
mvn archetype:generate \
   -DarchetypeGroupId=software.amazon.awssdk \
   -DarchetypeArtifactId=archetype-app-quickstart \
   -DarchetypeVersion=2.20.43
```

3. Enter the value listed in the second column for each prompt.

<table>
<thead>
<tr>
<th>Prompt</th>
<th>Value to enter</th>
</tr>
</thead>
<tbody>
<tr>
<td>Define value for property 'service':</td>
<td>s3</td>
</tr>
<tr>
<td>Define value for property 'httpClient':</td>
<td>apache-client</td>
</tr>
<tr>
<td>Define value for property 'nativeImage':</td>
<td>false</td>
</tr>
<tr>
<td>Define value for property 'credentialProvider':</td>
<td>identity-center</td>
</tr>
<tr>
<td>Define value for property 'groupId':</td>
<td>org.example</td>
</tr>
<tr>
<td>Define value for property 'artifactId':</td>
<td>getstarted</td>
</tr>
<tr>
<td>Define value for property 'version' 1.0-SNAPSHOT:</td>
<td>&lt;Enter&gt;</td>
</tr>
<tr>
<td>Define value for property 'package' org.example:</td>
<td>&lt;Enter&gt;</td>
</tr>
</tbody>
</table>

4. After the last value is entered, Maven lists the choices you made. Confirm by entering Y or re-enter values by entering N.
Maven creates the project folder named getstarted based on the artifactId value that you entered. Inside the getstarted folder, find a README.md file that you can review, a pom.xml file, and a src directory.

Maven builds the following directory tree.

```
getstarted
    ### README.md
    ### pom.xml
    ### src
        ### main
            #       ### java
            #       #       ### org
            #       #       ### example
            #       #       ### App.java
            #       #       ### DependencyFactory.java
            #       #       ### Handler.java
            #       ### resources
            #       #       ### simplelogger.properties
        ### test
            ### java
                ### org
                    ### example
                        ### HandlerTest.java
```

10 directories, 7 files

The following shows the contents of the pom.xml project file.

**pom.xml**

The dependencyManagement section contains a dependency to the AWS SDK for Java 2.x and the dependencies section has a dependency for Amazon S3. The project uses Java 1.8 because of the 1.8 value in the maven.compiler.source and maven.compiler.target properties.

```xml
<?xml version="1.0" encoding="UTF-8"?>
    <modelVersion>4.0.0</modelVersion>
    <groupId>org.example</groupId>
    <!-- other elements... -->
</project>
```
<artifactId>getstarted</artifactId>
<version>1.0-SNAPSHOT</version>
<packaging>jar</packaging>

<properties>
    <project.build.sourceEncoding>UTF-8</project.build.sourceEncoding>
    <maven.compiler.source>1.8</maven.compiler.source>
    <maven.compiler.target>1.8</maven.compiler.target>
    <maven.shade.plugin.version>3.2.1</maven.shade.plugin.version>
    <maven.compiler.plugin.version>3.6.1</maven.compiler.plugin.version>
    <exec-maven-plugin.version>1.6.0</exec-maven-plugin.version>
    <aws.java.sdk.version>2.20.43</aws.java.sdk.version> <--------- SDK version picked up from archetype version.
    <slf4j.version>1.7.28</slf4j.version>

        <exclusion>
            <groupId>software.amazon.awssdk</groupId>
            <artifactId>netty-nio-client</artifactId>
        </exclusion>
        <exclusion>
            <groupId>software.amazon.awssdk</groupId>
            <artifactId>apache-client</artifactId>
        </exclusion>
    </exclusions>
</dependencies>

---

**Step 2: Create the project**

1. Open your preferred code editor.
2. Create a new Java project.
3. Right-click on the project and select *Import* -> *Existing Projects into Workspace...*.
4. Navigate to the `aws-sdk-java-get-started` directory and import the project.

---

**SDK version picked up from archetype version**.

1. Ensure you have added the following dependencies to your project's `pom.xml`:
   - `software.amazon.awssdk:s3
   - `software.amazon.awssdk:netty-nio-client
   - `software.amazon.awssdk:apache-client

---

After adding these dependencies, you are ready to move forward with your project development.
<dependency>
   <groupId>software.amazon.awssdk</groupId>
   <artifactId>sso</artifactId>
   <dependency>
   <groupId>software.amazon.awssdk</groupId>
   <artifactId>ssooidc</artifactId>
   <dependency>
   <groupId>software.amazon.awssdk</groupId>
   <artifactId>apache-client</artifactId>
   <exclusions>
   <exclusion>
   <groupId>commons-logging</groupId>
   <artifactId>commons-logging</artifactId>
   </exclusion>
   </exclusions>
   </dependency>
   <dependency>
   <groupId>org.slf4j</groupId>
   <artifactId>slf4j-api</artifactId>
   </dependency>
   <dependency>
   <groupId>org.slf4j</groupId>
   <artifactId>slf4j-simple</artifactId>
   <version>${slf4j.version}</version>
   </dependency>
   <dependency>
   <groupId>org.slf4j</groupId>
   <artifactId>jcl-over-slf4j</artifactId>
   </dependency>
</dependency>

<!-- Needed to adapt Apache Commons Logging used by Apache HTTP Client to Slf4j to avoid
ClassNotfoundException: org.apache.commons.logging.impl.LogFactoryImpl during runtime -->
<dependency>
   <groupId>org.slf4j</groupId>
   <artifactId>jcl-over-slf4j</artifactId>
   <version>${slf4j.version}</version>
</dependency>

Step 2: Create the project
Step 3: Write the code

The following code shows the App class created by Maven. The main method is the entry point into the application, which creates an instance of the Handler class and then calls its sendRequest method.

App class

```java
package org.example;
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;

public class App {
    private static final Logger logger = LoggerFactory.getLogger(App.class);

    public static void main(String... args) {
        logger.info("Application starts");

        Handler handler = new Handler();
        handler.sendRequest();
    }
}
```
The DependencyFactory class created by Maven contains the s3Client factory method that build and returns an S3Client instance. The S3Client instance uses an instance of the Apache-based HTTP client. This is because you specified apache-client when Maven prompted you for which HTTP client to use.

The DependencyFactory is shown in the following code.

**DependencyFactory class**

```java
package org.example;

import software.amazon.awssdk.http.apache.ApacheHttpClient;
import software.amazon.awssdk.services.s3.S3Client;

/**
 * The module containing all dependencies required by the @link Handler.
 */
public class DependencyFactory {

    private DependencyFactory() {}

    /**
     * @return an instance of S3Client
     */
    public static S3Client s3Client() {
        return S3Client.builder()
            .httpClientBuilder(ApacheHttpClient.builder())
            .build();
    }
}
```

The Handler class contains the main logic of your program. When an instance of Handler is created in the App class, the DependencyFactory furnishes the S3Client service client. Your code uses the S3Client instance to call the Amazon S3 service.

Maven generates the following Handler class with a TODO comment. The next step in the tutorial replaces the TODO with code.
To fill in the logic, replace the entire contents of the Handler class with the following code. The sendRequest method is filled in and the necessary imports are added.

### Handler class, implemented

The code first creates a new S3 bucket with the last part of the name generated using System.currentTimeMillis() in order to make the bucket name unique.

After creating the bucket in the createBucket() method, the program uploads an object using the putObject method of S3Client. The contents of the object is a simple string created with the RequestBody.fromString method.

Finally, the program deletes the object followed by the bucket in the cleanUp method.
import software.amazon.awssdk.services.s3.model.S3Exception;

public class Handler {
    private final S3Client s3Client;

    public Handler() {
        s3Client = DependencyFactory.s3Client();
    }

    public void sendRequest() {
        String bucket = "bucket" + System.currentTimeMillis();
        String key = "key";

        createBucket(s3Client, bucket);

        System.out.println("Uploading object...");

        s3Client.putObject(PutObjectRequest.builder().bucket(bucket).key(key)
                .build(),
                RequestBody.fromString("Testing with the {sdk-java}"));

        System.out.println("Upload complete");
        System.out.println(" %n");

        cleanUp(s3Client, bucket, key);

        System.out.println("Closing the connection to {S3}");
        s3Client.close();
        System.out.println("Connection closed");
        System.out.println("Exiting...");
    }

    public static void createBucket(S3Client s3Client, String bucketName) {
        try {
            s3Client.createBucket(CreateBucketRequest
                    .builder()
                    .bucket(bucketName)
                    .build());
            System.out.println("Creating bucket: "+ bucketName);
            s3Client.waiter().waitUntilBucketExists(HeadBucketRequest.builder()
                    .bucket(bucketName)
                    .build());
            System.out.println(bucketName + " is ready.");
        }
    }
}
public static void cleanUp(S3Client s3Client, String bucketName, String keyName) {
    System.out.println("Cleaning up...");
    try {
        System.out.println("Deleting object: " + keyName);
        DeleteObjectRequest deleteObjectRequest = DeleteObjectRequest.builder().bucket(bucketName).key(keyName).build();
        s3Client.deleteObject(deleteObjectRequest);
        System.out.println(keyName + " has been deleted.");
        System.out.println("Deleting bucket: " + bucketName);
        DeleteBucketRequest deleteBucketRequest = DeleteBucketRequest.builder().bucket(bucketName).build();
        s3Client.deleteBucket(deleteBucketRequest);
        System.out.println(bucketName + " has been deleted.");
        System.out.printf("\n");
    } catch (S3Exception e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
    System.out.println("Cleanup complete");
    System.out.printf("\n");
}

Step 4: Build and run the application

After the project is created and contains the complete Handler class, build and run the application.

1. Make sure that you have an active IAM Identity Center session. To do so, run the AWS Command Line Interface command `aws sts get-caller-identity` and check the response. If you don't have an active session, see this section for instructions.

2. Open a terminal or command prompt window and navigate to your project directory `getstarted`.

3. Use the following command to build your project:
4. Use the following command to run the application.

```
mvn exec:java -Dexec.mainClass="org.example.App"
```

To view the new bucket and object that the program creates, perform the following steps.

1. In `Handler.java`, comment out the line `cleanUp(s3Client, bucket, key)` in the `sendRequest` method and save the file.
2. Rebuild the project by running `mvn clean package`.
3. Rerun `mvn exec:java -Dexec.mainClass="org.example.App"` to upload the text object once more.
4. Sign in to [the S3 console](https://aws.amazon.com/s3) to view the new object in the newly created bucket.

After you view the file, delete the object, and then delete the bucket.

**Success**

If your Maven project built and ran without error, then congratulations! You have successfully built your first Java application using the SDK for Java 2.x.

**Cleanup**

To clean up the resources you created during this tutorial, do the following:

- If you haven't done so already, in [the S3 console](https://aws.amazon.com/s3), delete any objects and any buckets created when you ran the application.
- Delete the project folder (`getstarted`).

**Next steps**

Now that you have the basics down, you can learn about the following:

- [Working with Amazon S3](https://aws.amazon.com/s3)
• Working with other Amazon Web Services, such as DynamoDB, Amazon EC2, and various database services
• Use the SDK
• Security for the AWS SDK for Java
Set up the AWS SDK for Java 2.x

This section provides information about how to set up your development environment and projects to use the AWS SDK for Java 2.x.

Setup overview

To successfully develop applications that access AWS services using the AWS SDK for Java, the following conditions are required:

- The Java SDK must have access to credentials to authenticate requests on your behalf.
- The permissions of the IAM role configured for the SDK must allow access to the AWS services that your application requires. The permissions associated with the PowerUserAccess AWS managed policy are sufficient for most development needs.
- A development environment with the following elements:
  - Shared configuration files that are set up in at least one of the following ways:
    - The config file contains IAM Identity Center single sign-on settings so that the SDK can get AWS credentials.
    - The credentials file contains temporary credentials.
  - An installation of Java 8 or later.
  - A build automation tool such as Maven or Gradle.
  - A text editor to work with code.
  - (Optional, but recommended) An IDE (integrated development environment) such as IntelliJ IDEA, Eclipse, or NetBeans.

    When you use an IDE, you can also integrate AWS Toolkits to more easily work with AWS services. The AWS Toolkit for IntelliJ and AWS Toolkit for Eclipse are two toolkits that you can use for Java development.

- An active AWS access portal session when you are ready to run your application. You use the AWS Command Line Interface to initiate the sign-in process to IAM Identity Center's AWS access portal.
Important

The instructions in this setup section assume that you or organization uses IAM Identity Center. If your organization uses an external identity provider that works independently of IAM Identity Center, find out how you can get temporary credentials for the SDK for Java to use. Follow these instructions to add temporary credentials to the `~/aws/credentials` file.

If your identity provider adds temporary credentials automatically to the `~/aws/credentials` file, make sure that the profile name is `[default]` so that you do not need to provide a profile name to the SDK or AWS CLI.

Set up authentication

The Authentication and access topic in the AWS SDKs and Tools Reference Guide describes the different options to authenticate. We recommend that you follow the instructions to set up access to the IAM Identity Center so the SDK can acquire credentials. After following the instructions, your system is set up to allow the SDK to authenticate requests.

Setup for single sign-on access for the SDK

After you complete Step 2 in the programmatic access section so that the SDK can use IAM Identity Center authentication, your system should contain the following elements.

- The AWS CLI, which you use to start an AWS access portal session before you run your application.
- An `~/aws/config` file that contains a default profile. The SDK for Java uses the profile's SSO token provider configuration to acquire credentials before sending requests to AWS. The `sso_role_name` value, which is an IAM role connected to an IAM Identity Center permission set, should allow access to the AWS services used in your application.

The following sample config file shows a default profile set up with SSO token provider configuration. The profile's `sso_session` setting refers to the named `sso-session` section. The `sso-session` section contains settings to initiate an AWS access portal session.

```plaintext
[default]
sso_session = my-sso
```
sso_account_id = 111122223333
sso_role_name = SampleRole
region = us-east-1
output = json

[sso-session my-sso]
sso_region = us-east-1
sso_start_url = https://provided-domain.awsapps.com/start
sso_registration_scopes = sso:account:access

For more details about the settings used in the SSO token provider configuration, see SSO token provider configuration in the AWS SDKs and Tools Reference Guide.

If your development environment is not set up for programmatic access as previously shown, follow Step 2 in the SDKs Reference Guide.

Sign in using the AWS CLI

Before running an application that accesses AWS services, you need an active AWS access portal session in order for the SDK to use IAM Identity Center authentication to resolve credentials. Run the following command in the AWS CLI to sign in to the AWS access portal.

```
aws sso login
```

Since you have a default profile setup, you do not need to call the command with a --profile option. If your SSO token provider configuration is using a named profile, the command is aws sso login --profile named-profile.

To test if you already have an active session, run the following AWS CLI command.

```
aws sts get-caller-identity
```

The response to this command should report the IAM Identity Center account and permission set configured in the shared config file.

⚠️ **Note**

If you already have an active AWS access portal session and run aws sso login, you will not be required to provide credentials.
However, you will see a dialog that requests permission for botocore to access your information. botocore is the foundation for the AWS CLI. Select **Allow** to authorize access to your information for the AWS CLI and SDK for Java.

## Install Java and a build tool

Your development environment needs the following:

- **Java 8 or later.** The AWS SDK for Java works with the [Oracle Java SE Development Kit](https://www.oracle.com/technetwork/java/javase/downloads/) and with distributions of Open Java Development Kit (OpenJDK) such as [Amazon Corretto](https://aws.amazon.com/corretto/), [Red Hat OpenJDK](https://openjdk.java.net), and [Adoptium](https://adoptium.net).
- A build tool or IDE that supports Maven Central such as Apache Maven, Gradle, or IntelliJ.
  - For information about how to install and use Maven, see [https://maven.apache.org/](https://maven.apache.org/).
  - For information about how to install and use Gradle, see [https://gradle.org/](https://gradle.org/).
  - For information about how to install and use IntelliJ IDEA, see [https://www.jetbrains.com/idea/](https://www.jetbrains.com/idea/).

## Additional authentication options

For more options on authentication for the SDK, such as the use of profiles and environment variables, see the [configuration](https://aws.amazon.com/sdk-for-java/) chapter in the AWS SDKs and Tools Reference Guide.

## Set up an Apache Maven project

You can use [Apache Maven](https://maven.apache.org/) to set up and build AWS SDK for Java projects, or to **build the SDK itself**.

## Prerequisites

To use the AWS SDK for Java with Maven, you need the following:

- **Java 8.0 or later.** You can download the latest Java SE Development Kit software from [http://www.oracle.com/technetwork/java/javase/downloads/](http://www.oracle.com/technetwork/java/javase/downloads/). The AWS SDK for Java also works with [OpenJDK](https://openjdk.java.net) and Amazon Corretto, a distribution of the Open Java Development Kit (OpenJDK). Download the latest OpenJDK version from [https://openjdk.java.net/install/index.html](https://openjdk.java.net/install/index.html). Download the latest Amazon Corretto 8 or Amazon Corretto 11 version from [the Corretto page](https://aws.amazon.com/corretto/).
Create a Maven project

To create a Maven project from the command line, run the following command from a terminal or command prompt window.

```
mvn -B archetype:generate \
    -DarchetypeGroupId=software.amazon.awssdk \ 
    -DarchetypeArtifactId=archetype-lambda -Dservice=s3 -Dregion=US_WEST_2 \ 
    -DarchetypeVersion=2.X.X \ 
    -DgroupId=com.example.myapp \ 
    -DartifactId=myapp
```

**Note**

Replace `com.example.myapp` with the full package namespace of your application. Also replace `myapp` with your project name. This becomes the name of the directory for your project.

To use the latest version of the archetype, replace `2.X.X` with the latest from Maven central.

This command creates a Maven project using the archetype templating toolkit. The archetype generates the scaffolding for an AWS Lambda function handler project. This project archetype is preconfigured to compile with Java SE 8 and includes a dependency to the version of the SDK for Java 2.x specified with `-DarchetypeVersion`.

For more information about creating and configuring Maven projects, see the Maven Getting Started Guide.

Configure the Java compiler for Maven

If you created your project using the AWS Lambda project archetype as described previously, the configuration of the Java compiler is already done for you.

To verify that this configuration is present, start by opening the `pom.xml` file from the project folder you created (for example, `myapp`) when you executed the previous command. Look on
lines 11 and 12 to see the Java compiler version setting for this Maven project, and the required inclusion of the Maven compiler plugin on lines 71-75.

```xml
<project>
  <properties>
    <maven.compiler.source>1.8</maven.compiler.source>
    <maven.compiler.target>1.8</maven.compiler.target>
  </properties>
  <build>
    <plugins>
      <plugin>
        <groupId>org.apache.maven.plugins</groupId>
        <artifactId>maven-compiler-plugin</artifactId>
        <version>${maven.compiler.plugin.version}</version>
      </plugin>
    </plugins>
  </build>
</project>

If you create your project with a different archetype or by using another method, you must ensure that the Maven compiler plugin is part of the build and that its source and target properties are both set to 1.8 in the pom.xml file.

See the previous snippet for one way to configure these required settings.

Alternatively, you can configure the compiler configuration inline with the plugin declaration, as follows.

```xml
<project>
  <build>
    <plugins>
      <plugin>
        <groupId>org.apache.maven.plugins</groupId>
        <artifactId>maven-compiler-plugin</artifactId>
        <configuration>
          <source>1.8</source>
          <target>1.8</target>
        </configuration>
      </plugin>
    </plugins>
  </build>
</project>

Configure the Java compiler for Maven
Declare the SDK as a dependency

To use the AWS SDK for Java in your project, you need to declare it as a dependency in your project’s `pom.xml` file.

If you created your project using the project archetype as described previously, the latest version of the SDK is already configured as a dependency in your project.

The archetype generates a BOM (bill of materials) artifact dependency for the `software.amazon.awssdk` group id. With a BOM, you do not have to specify the maven version for individual artifact dependencies that share the same group id.

If you created your Maven project in a different way, configure the latest version of the SDK for your project by ensuring that the `pom.xml` file contains the following.

```
<project>
  <properties>
    <aws.java.sdk.version>2.X.X</aws.java.sdk.version>
  </properties>
  <dependencyManagement>
    <dependencies>
      <dependency>
        <groupId>software.amazon.awssdk</groupId>
        <artifactId>bom</artifactId>
        <version>${aws.java.sdk.version}</version>
        <type>pom</type>
        <scope>import</scope>
      </dependency>
    </dependencies>
  </dependencyManagement>
</project>
```

Note

Replace `2.X.X` in the `pom.xml` file with the **latest version of the AWS SDK for Java 2.x**.

Set dependencies for SDK modules

Now that you have configured the SDK, you can add dependencies for one or more of the AWS SDK for Java modules to use in your project.
Although you can specify the version number for each component, you don’t need to because you already declared the SDK version in the dependencyManagement section using the bill of materials artifact. To load a different version of a given module, specify a version number for its dependency.

If you created your project using the project archetype as described previously, your project is already configured with multiple dependencies. These include dependences for AWS Lambda function handlers and Amazon S3, as follows.

```xml
<project>
  <dependencies>
    <dependency>
      <groupId>software.amazon.awssdk</groupId>
      <artifactId>s3</artifactId>
      <exclusions>
        <exclusion>
          <groupId>software.amazon.awssdk</groupId>
          <artifactId>netty-nio-client</artifactId>
        </exclusion>
        <exclusion>
          <groupId>software.amazon.awssdk</groupId>
          <artifactId>apache-client</artifactId>
        </exclusion>
      </exclusions>
    </dependency>
    <dependency>
      <groupId>software.amazon.awssdk</groupId>
      <artifactId>url-connection-client</artifactId>
    </dependency>
    <dependency>
      <groupId>com.amazonaws</groupId>
      <artifactId>aws-lambda-java-core</artifactId>
      <version>${aws.lambda.java.version}</version>
    </dependency>
  </dependencies>
</project>
```
Note

In the pom.xml example above, the dependencies are from different groupIds. The s3 dependency is from software.amazon.awssdk, whereas the aws-lambda-java-core dependency is from com.amazonaws. The BOM dependency management configuration affects artifacts for software.amazon.awssdk, so a version is needed for the aws-lambda-java-core artifact.

For the development of Lambda function handlers using the SDK for Java 2.x, aws-lambda-java-core is the correct dependency. However, if your application needs to manage Lambda resources, using operations such as listFunctions, deleteFunction, invokeFunction, and createFunction, your application requires the following dependency.

<groupId>software.amazon.awssdk</groupId>
<artifactId>lambda</artifactId>

Note

The s3 dependency excludes the the netty-nio-client and apache-client transitive dependencies. In place of either of those HTTP clients, the archetype includes the url-connection-client dependency, which helps reduce the startup latency for AWS Lambda functions.

Add the modules to your project for the AWS service and features you need for your project. The modules (dependencies) that are managed by the AWS SDK for Java BOM are listed on the Maven central repository.

Note

You can look at the pom.xml file from a code example to determine which dependencies you need for your project. For example, if you’re interested in the dependencies for the DynamoDB service, see this example from the AWS Code Examples Repository on GitHub. (Look for the pom.xml file under /javav2/example_code/dynamodb.)
Build the entire SDK into your project

To optimize your application, we strongly recommend that you pull in only the components you need instead of the entire SDK. However, to build the entire AWS SDK for Java into your project, declare it in your `pom.xml` file, as follows.

```xml
<project>
  <dependencies>
    <dependency>
      <groupId>software.amazon.awssdk</groupId>
      <artifactId>aws-sdk-java</artifactId>
      <version>2.X.X</version>
    </dependency>
  </dependencies>
</project>
```

Build your project

After you configure the `pom.xml` file, you can use Maven to build your project.

To build your Maven project from the command line, open a terminal or command prompt window, navigate to your project directory (for example, `myapp`), enter or paste the following command, then press Enter or Return.

```bash
mvn package
```

This creates a single `.jar` file (JAR) in the `target` directory (for example, `myapp/target`). This JAR contains all of the SDK modules you specified as dependencies in your `pom.xml` file.

Set up a Gradle project

You can use [Gradle](https://gradle.org) to set up and build AWS SDK for Java projects.

The initial steps in the following example come from [Gradle's Getting Started guide](https://docs.gradle.org/current/userguide/getting-started.html) for version 8.4. If you use a different version, your results may differ slightly.

To create a Java application with Gradle (command line)

1. Create a directory to hold your project. In this example, `demo` is the directory name.
2. Inside the demo directory, execute the `gradle init` command and supply the values highlighted in red as shown in the following command line output. For the walk through, we choose Kotlin as the build script DSL language, but a complete example for Groovy is also shown at the end of this topic.

```
> gradle init
Starting a Gradle Daemon (subsequent builds will be faster)

Select type of project to generate:
1: basic
2: application
3: library
4: Gradle plugin
Enter selection (default: basic) [1..4] 2

Select implementation language:
1: C++
2: Groovy
3: Java
4: Kotlin
5: Scala
6: Swift
Enter selection (default: Java) [1..6] 3

Generate multiple subprojects for application? (default: no) [yes, no] no
Select build script DSL:
1: Kotlin
2: Groovy
Enter selection (default: Kotlin) [1..2] <Enter>

Select test framework:
1: JUnit 4
2: TestNG
3: Spock
4: JUnit Jupiter
Enter selection (default: JUnit Jupiter) [1..4] 4

Project name (default: demo): <Enter>
Source package (default: demo): <Enter>
Enter target version of Java (min. 7) (default: 11): <Enter>
Generate build using new APIs and behavior (some features may change in the next minor release)? (default: no) [yes, no] <Enter>
```
3. After the `init` task completes, the demo directory contains the following tree structure. We take a closer look at the main build file, `build.gradle.kts` (highlighted in red), in the next section.

```kotlin
### app
    ### build.gradle.kts
    ### src
        ### main
            ### java
                ### demo
                    ### App.java
            ### resources
        ### test
            ### java
                ### demo
                    ### AppTest.java
            ### resources
### gradle
    ### wrapper
        ### gradle-wrapper.jar
        ### gradle-wrapper.properties
### gradlew
### gradlew.bat
### settings.gradle.kts
```

The `build.gradle.kts` file contains the following scaffolded content.

```kotlin
/*
 * This file was generated by the Gradle 'init' task.
 *
 * This generated file contains a sample Java application project to get you started.
 * For more details on building Java & JVM projects, please refer to https://docs.gradle.org/8.4/userguide/building_java_projects.html in the Gradle documentation.
 */
```
plugins {
    // Apply the application plugin to add support for building a CLI application in Java.
    application
}

repositories {
    // Use Maven Central for resolving dependencies.
    mavenCentral()
}

dependencies {
    // Use JUnit Jupiter for testing.
    testImplementation("org.junit.jupiter:junit-jupiter:5.9.3")
    testRuntimeOnly("org.junit.platform:junit-platform-launcher")
    // This dependency is used by the application.
    implementation("com.google.guava:guava:32.1.1-jre")
}

// Apply a specific Java toolchain to ease working on different environments.
java {
    toolchain {
        languageVersion.set(JavaLanguageVersion.of(11))
    }
}

application {
    // Define the main class for the application.
    mainClass.set("demo.App")
}

tasks.named<Test>("test") {
    // Use JUnit Platform for unit tests.
    useJUnitPlatform()
}

4. Use the scaffolded Gradle build file as the basis for your AWS project.
a. To manage SDK dependencies for your Gradle project, add the Maven bill of materials (BOM) for the AWS SDK for Java 2.x to the dependencies section of the build.gradle.kts file.

```gradle
dependencies {
    implementation(platform("software.amazon.awssdk:bom:2.21.1"))
    // With the bom declared, you specify individual SDK dependencies without a version.
    ...
}
```

**Note**

In this example build file, replace 2.21.1 with the latest version of the SDK for Java 2.x. Find the latest version available in Maven central repository.

b. Specify the SDK modules your application needs in the dependencies section. As an example, the following adds a dependency on Amazon Simple Storage Service.

```gradle
dependencies {
    implementation(platform("software.amazon.awssdk:bom:2.21.1"))
    implementation("software.amazon.awssdk:s3")
    ...
}
```

Gradle automatically resolves the correct version of declared dependencies by using the information from the BOM.

The following examples show complete Gradle build files in both the Kotlin and Groovy DSLs. The build file contains dependencies for Amazon S3, authentication, logging, and testing. The source and target version of Java is version 11.
Kotlin DSL (build.gradle.kts)

/*
 * This file was generated by the Gradle 'init' task.
 * This generated file contains a sample Java application project to get you started.
 * For more details on building Java & JVM projects, please refer to https://docs.gradle.org/8.4/userguide/building_java_projects.html in the Gradle documentation.
 */

plugins {
    // Apply the application plugin to add support for building a CLI application in Java.
    application
}

repositories {
    // Use Maven Central for resolving dependencies.
    mavenCentral()
}

dependencies {
    implementation(platform("software.amazon.awssdk:bom:2.20.56"))
    implementation("software.amazon.awssdk:s3")
    implementation("software.amazon.awssdk:sso")
    implementation("software.amazon.awssdk:ssoidc")
    implementation(platform("org.apache.logging.log4j:log4j-bom:2.20.0"))
    implementation("org.apache.logging.log4j:log4j-jcl")
    implementation("org.apache.logging.log4j:log4j-1.2-api")
    testImplementation(platform("org.junit:junit-bom:5.10.0"))
    testImplementation("org.junit.jupiter:junit-jupiter")
}

// Apply a specific Java toolchain to ease working on different environments.
java {
    toolchain {
        languageVersion.set(JavaLanguageVersion.of(11))
    }
}

application {
    // Define the main class for the application.
mainClass.set("demo.App")
}

tasks.named<Test>("test") {
    // Use JUnit Platform for unit tests.
    useJUnitPlatform()
}

Groovy DSL (build.gradle)

/*
 * This file was generated by the Gradle 'init' task.
 *
 * This generated file contains a sample Java application project to get you started.
 * For more details on building Java & JVM projects, please refer to https://
docs.gradle.org/8.4/userguide/building_java_projects.html in the Gradle documentation.
 */

plugins {
    // Apply the application plugin to add support for building a CLI application in Java.
    id 'application'
}

repositories {
    // Use Maven Central for resolving dependencies.
    mavenCentral()
}

dependencies {
    implementation platform('software.amazon.awssdk:bom:2.21.1')
    implementation 'software.amazon.awssdk:s3'
    implementation 'software.amazon.awssdk:sso'
    implementation 'software.amazon.awssdk:ssoidc'
    implementation platform('org.apache.logging.log4j:log4j-bom:2.20.0')

    testImplementation 'org.junit.jupiter:junit-jupiter'
}
// Apply a specific Java toolchain to ease working on different environments.
java {
    toolchain {
        languageVersion = JavaLanguageVersion.of(11)
    }
}

application {
    // Define the main class for the application.
    mainClass = 'demo_groovy.App'
}

tasks.named('test') {
    // Use JUnit Platform for unit tests.
    useJUnitPlatform()
}

For next steps, see the Getting Started guide on the Gradle website for instructions on how to build and run a Gradle application.

Set up a GraalVM Native Image project for the AWS SDK for Java

With versions 2.16.1 and later, the AWS SDK for Java provides out-of-the-box support for GraalVM Native Image applications. Use the archetype-app-quickstart Maven archetype to set up a project with built-in native image support.

Prerequisites

- Complete the steps in Setting up the AWS SDK for Java 2.x.
- Install GraalVM Native Image.

Create a project using the archetype

To create a Maven project with built-in native image support, in a terminal or command prompt window, use the following command.
Note

Replace com.example.mynativeimageapp with the full package namespace of your application. Also replace mynativeimageapp with your project name. This becomes the name of the directory for your project.

```
mvn archetype:generate \
   -DarchetypeGroupId=software.amazon.awssdk \
   -DarchetypeArtifactId=archetype-app-quickstart \
   -DarchetypeVersion=2.16.1 \
   -DnativeImage=true \
   -DhttpClient=apache-client \
   -Dservice=s3 \
   -DgroupId=com.example.mynativeimageapp \
   -DartifactId=mynativeimageapp \
   -DinteractiveMode=false
```

This command creates a Maven project configured with dependencies for the AWS SDK for Java, Amazon S3, and the ApacheHttpClient HTTP client. It also includes a dependency for the GraalVM Native Image Maven plugin, so that you can build native images using Maven.

To include dependencies for a different Amazon Web Services, set the value of the -Dservice parameter to the artifact ID of that service. Examples include dynamodb, comprehend, and pinpoint. For a complete list of artifact IDs, see the list of managed dependencies for software.amazon.awssdk on Maven Central.

To use an asynchronous HTTP client, set the -DhttpClient parameter to netty-nio-client. To use UrlConnectionHttpClient as the synchronous HTTP client instead of apache-client, set the -DhttpClient parameter to url-connection-client.

**Build a native image**

After you create the project, run the following command from your project directory, for example, mynativeimageapp:

```
mvn package -P native-image
```
This creates a native image application in the `target` directory, for example, `target/mynativeimageapp`.
Use the AWS SDK for Java 2.x

After completing the steps in Setting up the SDK, you are ready to make requests to AWS services such as Amazon S3, DynamoDB, IAM, Amazon EC2, and more.

Work with service clients

Create a service client

To make a request to an AWS service, you must first instantiate a service client for that service by using the static factory method, builder(). The builder() method returns a builder object that allows you to customize the service client. The fluent setter methods return the builder object, so that you can chain the method calls for convenience and for more readable code. After you configure the properties you want, call the build() method to create the client.

As an example, the following code snippet instantiates an Ec2Client object as a service client for Amazon EC2.

```java
Region region = Region.US_WEST_2;
Ec2Client ec2Client = Ec2Client.builder()
    .region(region)
    .build();
```

Note

Service clients in the SDK are thread-safe. For best performance, treat them as long-lived objects. Each client has its own connection pool resource that is released when the client is garbage collected.

A service client object is immutable, so you must create a new client for each service to which you make requests, or if you want to use a different configuration for making requests to the same service.

Specifying the Region in the service client builder is not required for all AWS services; however, it is a best practice to set the Region for the API calls you make in your applications. See AWS region selection for more information.
Default client configuration

The client builders have another factory method named `create()`. This method creates a service client with the default configuration. It uses the default provider chain to load credentials and the AWS Region. If credentials or the Region can't be determined from the environment that the application is running in, the call to `create` fails. See Using credentials and Region selection for more information about how the SDK determines the credentials and Region to use.

For example, the following code snippet instantiates a DynamoDbClient object as a service client for Amazon DynamoDB:

```java
DynamoDbClient dynamoDbClient = DynamoDbClient.create();
```

Configure service clients

To customize the configuration of a service client, use the setters on the `builder()` factory method. For convenience and to create more readable code, chain the methods to set multiple configuration options.

The following example shows an S3Client that is configured with several custom settings.

```java
ClientOverrideConfiguration clientOverrideConfiguration =
    ClientOverrideConfiguration.builder()
    .apiCallAttemptTimeout(Duration.ofSeconds(1))
    .retryPolicy(RetryPolicy.builder().numRetries(10).build())
    .addMetricPublisher(CloudWatchMetricPublisher.create())
    .build();

Region region = Region.US_WEST_2;
S3Client s3Client = S3Client.builder()
    .region(region)
    .credentialsProvider(EnvironmentVariableCredentialsProvider.create())
    .overrideConfiguration(clientOverrideConfiguration)
    .httpClientBuilder(ApacheHttpClient.builder()
        .proxyConfiguration(proxyConfig.build(ProxyConfiguration.builder())))
    .build();
```
Make requests

Use the service client to make requests to the corresponding AWS service.

For example, this code snippet shows how to create a RunInstancesRequest object to create a new Amazon EC2 instance:

```java
// Create the request by using the fluid setter methods of the request builder.
RunInstancesRequest runInstancesRequest = RunInstancesRequest.builder()
    .imageId(amiId)
    .instanceType(InstanceType.T1_MICRO)
    .maxCount(1)
    .minCount(1)
    .build();

// Use the configured request with the service client.
RunInstancesResponse response = ec2Client.runInstances(runInstancesRequest);
```

Rather than create a request and pass in the instance, the SDK provides builders that you can use to create a request. With a builder you can use a Java lambda expressions to create the request 'inline'.

The following example rewrites the previous example by using the version of the runInstances method that uses a builder to create the request.

```java
// Create the request by using a lambda expression.
RunInstancesResponse response = ec2.runInstances(r -> r
    .imageId(amiId)
    .instanceType(InstanceType.T1_MICRO)
    .maxCount(1)
    .minCount(1));
```

Handle responses

You use a response handler to process the response back from the AWS service.

For example, this code snippet shows how to create a RunInstancesResponse object to handle the response from Amazon EC2 by printing out the instanceId for the new instance from the request above:
RunInstancesResponse runInstancesResponse =
  ec2Client.runInstances(runInstancesRequest);
System.out.println(runInstancesResponse.instances().get(0).instanceId());

Close the service client

As a best practice, you should use a service clients for multiple API service calls during the life of an application. However, if you need a service client for a one-time use or no longer need the service client, close it.

Call the close() method when the service client is no longer needed to free up resources.

ec2Client.close();

If you need a service client for one-time use, you can instantiate the service client as a resource in a try-with-resources statement. Service clients implement the Autoclosable interface, so the JDK automatically calls the close() method at the end of the statement.

The following example demonstrates how to use a service client for a one-off call. The StsClient that calls the AWS Security Token Service is closed after it returns the account ID.

import software.amazon.awssdk.services.sts.StsClient;

String getAccountID() {
  try (StsClient stsClient = StsClient.create()) {
    return stsClient.getCallerIdentity().account();
  }
}

Handle exceptions

The SDK uses runtime (or unchecked) exceptions, providing you fine-grained control over error handling and ensuring that exception handling will scale with your application.

An SdkServiceException, or one of its sub-classes, is the most common form of exception the SDK will throw. These exceptions represent responses from the AWS service. You can also handle an SdkClientException, which occurs when there’s a problem on the client side (i.e., in your development or application environment), such a network connection failure.
This code snippet demonstrates one way to handle service exceptions when you upload a file to Amazon S3. The example code catches both client and server exceptions, logs the details, and exists the application.

```java
Region region = Region.US_WEST_2;
s3Client = S3Client.builder()
    .region(region)
    .build();

try {
    PutObjectRequest putObjectRequest = PutObjectRequest.builder()
        .bucket(bucketName)
        .key(key)
        .build();

    s3Client.putObject(putObjectRequest, RequestBody.fromString("SDK for Java test"));

} catch (S3Exception se) {
    System.err.println("Service exception thrown.");
    System.err.println(se.awsErrorDetails().errorMessage());
} catch (SdkClientExeption ce){
    System.err.println("Client exception thrown.");
    System.err.println(ce.getMessage());
} finally {
    System.exit(1);
}
```

See [Handling exceptions](#) for more information.

## Use waiters

Some requests take time to process, such as creating a new table in DynamoDB or creating a new Amazon S3 bucket. To ensure the resource is ready before your code continues to run, use a *Waiter*.

For example, this code snippet creates a new table ("myTable") in DynamoDB, waits for the table to be in an `ACTIVE` status, and then prints out the response:

```java
DynamoDbClient dynamoDbClient = DynamoDbClient.create();
DynamoDbWaiter dynamoDbWaiter = dynamoDbClient.waiter();
```
WaiterResponse<DescribeTableResponse> waiterResponse =
    dynamoDbWaiter.waitUntilTableExists(r -> r.tableName("myTable"));

waiterResponse.matched().response().ifPresent(System.out::println);

See [Using waiters](#) for more information.

**HTTP clients**

You can change the default configuration for HTTP clients in applications you build with the AWS SDK for Java. For information on how to configure HTTP clients and settings, see [HTTP configuration](#).

**Retries**

You can change the default settings for retries in your service clients, including the retry mode and back-off strategy. For more information, refer to the [RetryPolicy class](#) in the AWS SDK for Java API Reference.

For more information about retries in AWS services, see [Error retries and exponential backoff in AWS](#).

**Timeouts**

You can configure timeouts for each of your service clients using the `apiCallTimeout` and the `apiCallAttemptTimeout` setters. The `apiCallTimeout` setting is the amount of time to allow the client to complete the execution of an API call. The `apiCallAttemptTimeout` setting is the amount of time to wait for the HTTP request to complete before giving up.

For more information, see [apiCallTimeout](#) and [apiCallAttemptTimeout](#) in the AWS SDK for Java API Reference.

**Execution interceptors**

You can write code that intercepts the execution of your API requests and responses at different parts of the request/response lifecycle. This enables you to publish metrics, modify a request in-flight, debug request processing, view exceptions, and more. For more information, see the [ExecutionInterceptor interface](#) in the AWS SDK for Java API Reference.
Additional information

- For complete examples of the code snippets above, see Working with Amazon DynamoDB, Working with Amazon EC2, and Working with Amazon S3.

Provide temporary credentials to the SDK

Before making a request to Amazon Web Services using the AWS SDK for Java 2.x, the SDK cryptographically signs temporary credentials issued by AWS. To access temporary credentials, the SDK retrieves configuration values by checking several locations.

This topic discusses several ways that you enable the SDK to access temporary credentials.

Topics

- Configure access to temporary credentials
- Default credentials provider chain
- Use a specific credentials provider or provider chain
- Use profiles
- Load temporary credentials from an external process
- Supply temporary credentials in code
- Read IAM role credentials on Amazon EC2

Configure access to temporary credentials

For increased security, AWS recommends that you configure the SDK for Java to use temporary credentials instead of long-lived credentials. Temporary credentials consist of access keys (access key id and secret access key) and a session token. We recommend that you configure the SDK to automatically get temporary credentials, since the token refresh process is automatic. You can, however, provide the SDK with temporary credentials directly.

IAM Identity Center configuration

When you configure the SDK to use IAM Identity Center single sign-on access as described in ?? in this guide, the SDK automatically uses temporary credentials.
The SDK uses the IAM Identity Center access token to gain access to the IAM role that is configured with the sso_role_name setting in your config file. The SDK assumes this IAM role and retrieves temporary credentials to use for AWS service requests.

For more details about how the SDK gets temporary credentials from the configuration, see the Understanding IAM Identity Center authentication section of the AWS SDKs and Tools Reference Guide.

**Retrieve from AWS access portal**

As an alternative to IAM Identity Center single sign-on configuration, you can copy and use temporary credentials available in the AWS access portal. You can use the temporary credentials in a profile or use them as values for system properties and environment variables.

**Set up a local credentials file for temporary credentials**

1. Created a shared credentials file
2. In the credentials file, paste the following placeholder text until you paste in working temporary credentials.

   ```
   [default]
   aws_access_key_id=<value from AWS access portal>
   aws_secret_access_key=<value from AWS access portal>
   aws_session_token=<value from AWS access portal>
   ```
3. Save the file. The file ~/.aws/credentials should now exist on your local development system. This file contains the [default] profile that the SDK for Java uses if a specific named profile is not specified.
4. Sign in to the AWS access portal
5. Follow these instructions under the Manual credential refresh heading to copy IAM role credentials from the AWS access portal.
   a. For step 4 in the linked instructions, choose the IAM role name that grants access for your development needs. This role typically has a name like PowerUserAccess or Developer.
   b. For step 7, select the Manually add a profile to your AWS credentials file option and copy the contents.
6. Paste the copied credentials into your local credentials file and remove the generated profile name. Your file should resemble the following.
7. Save the credentials file.

When the SDK for Java creates a service client, it will access these temporary credentials and use them for each request. The settings for the IAM role chosen in step 5a determine how long the temporary credentials are valid. The maximum duration is twelve hours.

After the temporary credentials expire, repeat steps 4 through 7.

**Default credentials provider chain**

The default credentials provider chain is implemented by the [DefaultCredentialsProvider](https://aws.amazon.com/get-started/guides/java-sdk-2.x/credentials-provider-chain/) class. It sequentially checks each place where you can set the default configuration for supplying temporary credentials, and then selects the first one you set.

To use the default credentials provider chain to supply temporary credentials, create a service client builder but don't specify a credentials provider. The following code snippet creates a DynamoDbClient that uses the default credentials provider chain to locate and retrieve default configuration settings.

```java
Region region = Region.US_WEST_2;
DynamoDbClient ddb =
    DynamoDbClient.builder()
    .region(region)
    .build();
```

**Credential settings retrieval order**

The default credentials provider chain of the SDK for Java 2.x searches for configuration in your environment using a predefined sequence.

1. Java system properties
   - The SDK uses the [SystemPropertyCredentialsProvider](https://aws.amazon.com/get-started/guides/java-sdk-2.x/credentials-provider-chain/) class to load temporary credentials from the `aws.accessKeyId`, `aws.secretAccessKey`, and `aws.sessionToken` Java system properties.
Note
For information on how to set Java system properties, see the System Properties tutorial on the official Java Tutorials website.

2. Environment variables

- The SDK uses the EnvironmentVariableCredentialsProvider class to load temporary credentials from the AWS_ACCESS_KEY_ID, AWS_SECRET_ACCESS_KEY, and AWS_SESSION_TOKEN environment variables.

3. Web identity token from AWS Security Token Service

- The SDK uses the WebIdentityTokenFileCredentialsProvider class to load temporary credentials from Java system properties or environment variables.

4. The shared credentials and config files

- The SDK uses the ProfileCredentialsProvider to load IAM Identity Center single sign-on settings or temporary credentials from the [default] profile in the shared credentials and config files.

The AWS SDKs and Tools Reference Guide has detailed information about how the SDK for Java works with the IAM Identity Center single sign-on token to get temporary credentials that the SDK uses to call AWS services.

Note
The credentials and config files are shared by various AWS SDKs and Tools. For more information, see The .aws/credentials and .aws/config files in the AWS SDKs and Tools Reference Guide.

5. Amazon ECS container credentials

- The SDK uses the ContainerCredentialsProvider class to load temporary credentials from the AWS_CONTAINER_CREDENTIALS_RELATIVE_URI system environment variable.

6. Amazon EC2 instance IAM role-provided credentials

- The SDK uses the InstanceProfileCredentialsProvider class to load temporary credentials from the Amazon EC2 metadata service.
Use a specific credentials provider or provider chain

As an alternative to the default credentials provider chain, you can specify which credentials provider the SDK should use. When you supply a specific credentials provider, the SDK skips the process of checking various locations, which slightly reduces the time to create a service client.

For example, if you set your default configuration using environment variables, supply an `EnvironmentVariableCredentialsProvider` object to the `credentialsProvider` method on the service client builder, as in the following code snippet.

```java
Region region = Region.US_WEST_2;
DynamoDbClient ddb = DynamoDbClient.builder()
    .region(region)
    .credentialsProvider(EnvironmentVariableCredentialsProvider.create())
    .build();
```

For a complete list of credential providers and provider chains, see All Known Implementing Classes in `AwsCredentialsProvider`.

**Note**
You can use your own credentials provider or provider chains by implementing the `AwsCredentialsProvider` interface.

Use profiles

Using the shared config and credentials file, you can set up several profiles. This enables your application to use multiple sets of credentials configuration. The `[default]` profile was mentioned previously. The SDK uses the `ProfileCredentialsProvider` class to load settings from profiles defined in the shared credentials file.

The following code snippet demonstrates how to build a service client that uses the settings defined as part of the profile named `my_profile`.

```java
Region region = Region.US_WEST_2;
DynamoDbClient ddb = DynamoDbClient.builder()
    .region(region)
    .credentialsProvider(ProfileCredentialsProvider.create("my_profile"))
    .build();
```
Set a different profile as the default

To set a profile other than the [default] profile as the default for your application, set the AWS_PROFILE environment variable to the name of your custom profile.

To set this variable on Linux, macOS, or Unix, use `export`:

```bash
export AWS_PROFILE="other_profile"
```

To set these variables on Windows, use `set`:

```bash
set AWS_PROFILE="other_profile"
```

Alternatively, set the `aws.profile` Java system property to the name of the profile.

Reload profile credentials

You can configure any credentials provider that has a `profileFile()` method on its builder to reload profile credentials. These credentials profile classes are: `ProfileCredentialsProvider`, `DefaultCredentialsProvider`, `InstanceProfileCredentialsProvider`, and `ProfileTokenProvider`.

Note

Profile credential reloading works only with the following settings in the profile file: `aws_access_key_id`, `aws_secret_access_key`, and `aws_session_token`. Settings such as `region`, `sso_session`, `sso_account_id`, and `source_profile` are ignored.

To configure a supported credentials provider to reload profile settings, provide an instance of `ProfileFileSupplier` to the `profileFile()` builder method. The following code example demonstrates a `ProfileCredentialsProvider` that reloads credential settings from the [default] profile.

```java
ProfileCredentialsProvider provider = ProfileCredentialsProvider
.builder()
.profileFile(ProfileFileSupplier.defaultSupplier())
.build();
```
// Set up a service client with the provider instance.
DynamoDbClient dynamoDbClient = DynamoDbClient.builder()
  .region(Region.US_EAST_1)
  .credentialsProvider(provider)
  .build();

/**
   * Before dynamoDbClient makes a request, it reloads the credentials settings
   * by calling provider.resolveCredentials().
   */

When ProfileCredentialsProvider.resolveCredentials() is called, the SDK for Java reloads the settings. ProfileFileSupplier.defaultSupplier() is one of several convenience implementations of ProfileFileSupplier provided by the SDK. If your use case requires, you can provide your own implementation.

The following example shows the use of the ProfileFileSupplier.reloadWhenModified() convenience method. reloadWhenModified() takes a Path parameter, which gives you flexibility in designating the source file for the configuration rather than the standard ~/.aws/credentials (or config) location.

The settings will be reloaded when resolveCredentials() is called only if SDK determines the file's content has been modified.

Path credentialsFilePath = ...

ProfileCredentialsProvider provider = ProfileCredentialsProvider
  .builder()
  .profileFile(ProfileFileSupplier.reloadWhenModified(credentialsFilePath,
      ProfileFile.Type.CREDENTIALS))
  .profileName("my-profile")
  .build();

/**
   * A service client configured with the provider instance calls
   * provider.resolveCredential() before each request.
   */

The ProfileFileSupplier.aggregate() method merges the contents of multiple configuration files. You decide whether a file is reloaded per call to resolveCredentials() or a file's settings are fixed at the time it was first read.
The following example shows a DefaultCredentialsProvider that merges the settings of two files that contain profile settings. The SDK reloads the settings in the file pointed to by the credentialsFilePath variable each time resolveCredentials() is called and the settings have changed. The settings from the profileFile object remain the same.

```java
Path credentialsFilePath = ...;
ProfileFile profileFile = ...;

DefaultCredentialsProvider provider = DefaultCredentialsProvider
    .builder()
    .profileFile(ProfileFileSupplier.aggregate(
        ProfileFileSupplier.reloadWhenModified(credentialsFilePath,
            ProfileFile.Type.CREDENTIALS),
        ProfileFileSupplier.fixedProfileFile(profileFile)))
    .profileName("my-profile")
    .build();

/*
 * A service client configured with the provider instance calls
 * provider.resolveCredential()
 * before each request.
 */
```

**Load temporary credentials from an external process**

⚠️ **Warning**

The following describes a method of sourcing temporary credentials from an external process. This can potentially be dangerous, so proceed with caution. Other credential providers should be preferred if at all possible. If using this option, you should make sure that the config file is as locked down as possible using security best practices for your operating system.

Make sure that your custom credentials tool does not write any secret information to StdErr. SDKs and AWS CLI can capture and log such information, potentially exposing it to unauthorized users.

With the SDK for Java 2.x, you can acquire temporary credentials from an external process for custom use cases. There are two ways to configure this functionality.
Use the `credential_process` setting

If you have a method that provides temporary credentials, you can integrate it by adding the `credential_process` setting as part of a profile definition in the config file. The value you specify must use the full path to the command file. If the file path contains any spaces, you must surround it with quotation marks.

The SDK calls the command exactly as given and then reads JSON data from stdout.

The following examples show the use of this setting for file paths without spaces and file paths with spaces.

**Linux/macOS**

**No spaces in file path**

```
[profile process-credential-profile]
credential_process = /path/to/credential/file/credential_file.sh --custom-command custom_parameter
```

**Spaces in file path**

```
[profile process-credential-profile]
credential_process = "/path/with/space to/credential/file/credential_file.sh" --custom-command custom_parameter
```

**Windows**

**No spaces in file path**

```
[profile process-credential-profile]
credential_process = C:\Path\To\credentials.cmd --custom_command custom_parameter
```

**Spaces in file path**

```
[profile process-credential-profile]
credential_process = "C:\Path\With Space To\credentials.cmd" --custom_command custom_parameter
```
The following code snippet demonstrates how to build a service client that uses the temporary credentials defined as part of the profile named `process-credential-profile`.

```java
Region region = Region.US_WEST_2;
S3Client s3Client = S3Client.builder()
    .region(region)
    .credentialsProvider(ProfileCredentialsProvider.create("process-credential-profile"))
    .build();
```

For detailed information about using an external process as a source of temporary credentials, refer to the [process credentials section](#) in the AWS SDKs and Tools Reference Guide.

**Use the ProcessCredentialsProvider**

As an alternative to using settings in the `config` file, you can use the SDK's `ProcessCredentialsProvider` to load temporary credentials using Java.

The following examples show various versions of how to specify an external process using the `ProcessCredentialsProvider` and configuring a service client that uses the temporary credentials.

**Linux/macOS**

**No spaces in file path**

```java
ProcessCredentialsProvider credentials =
    ProcessCredentialsProvider
    .builder()
    .command("/path/to/credentials.sh optional_param1 optional_param2")
    .build();

S3Client s3 = S3Client.builder()
    .region(Region.US_WEST_2)
    .credentialsProvider(credentials)
    .build();
```

**Spaces in file path**

```java
ProcessCredentialsProvider credentials =
    ProcessCredentialsProvider
    .command("/path/to/credentials.sh optional_param1 optional_param2")
    .build();
```
S3Client s3 = S3Client.builder()
    .region(Region.US_WEST_2)
    .credentialsProvider(credentials)
    .build();

Windows

No spaces in file path

ProcessCredentialsProvider credentials =
    ProcessCredentialsProvider
        .builder()
        .command("C:\Path\To\credentials.exe optional_param1 optional_param2")
        .build();

S3Client s3 = S3Client.builder()
    .region(Region.US_WEST_2)
    .credentialsProvider(credentials)
    .build();

Spaces in file path

ProcessCredentialsProvider credentials =
    ProcessCredentialsProvider
        .builder()
        .command("C:\Path\With Spaces To\credentials.exe" optional_param1 optional_param2")
        .build();

S3Client s3 = S3Client.builder()
    .region(Region.US_WEST_2)
    .credentialsProvider(credentials)
    .build();
Supply temporary credentials in code

If the default credential chain or a specific or custom provider or provider chain doesn't work for your application, you can supply temporary credentials directly in code. These can be IAM role credentials as described above or temporary credentials retrieved from AWS Security Token Service (AWS STS). If you retrieved temporary credentials using AWS STS, provide them to an AWS service client as shown in the following code example.

1. Assume a role by calling StsClient.assumeRole().
2. Create a StaticCredentialsProvider object and supply it with the AwsSessionCredentials object.
3. Configure the service client builder with the StaticCredentialsProvider and build the client.

The following example creates an Amazon S3 service client using temporary credentials returned by AWS STS for an IAM assumed role.

```java
// The AWS IAM Identity Center identity (user) who executes this method does not have permission to list buckets.
// The identity is configured in the [default] profile.
public static void assumeRole(String roleArn, String roleSessionName) {
    // The IAM role represented by the 'roleArn' parameter can be assumed by identities in two different accounts
    // and the role permits the user to only list buckets.
    // The SDK's default credentials provider chain will find the single sign-on settings in the [default] profile.
    // The identity configured with the [default] profile needs permission to call AssumeRole on the STS service.
    try {
        Credentials tempRoleCredentials;
        try (StsClient stsClient = StsClient.create()) {
            AssumeRoleRequest roleRequest = AssumeRoleRequest.builder()
                .roleArn(roleArn)
                .roleSessionName(roleSessionName)
                .build();

            AssumeRoleResponse roleResponse = stsClient.assumeRole(roleRequest);
            tempRoleCredentials = roleResponse.credentials();
        }
    }
```
// Use the following temporary credential items for the S3 client.
String key = tempRoleCredentials.accessKeyId();
String secKey = tempRoleCredentials.secretAccessKey();
String secToken = tempRoleCredentials.sessionToken();

// List all buckets in the account associated with the assumed role
// by using the temporary credentials retrieved by invoking
stsClient.assumeRole().
StaticCredentialsProvider staticCredentialsProvider =
StaticCredentialsProvider.create(
    AwsSessionCredentials.create(key, secKey, secToken));
try (S3Client s3 = S3Client.builder()
    .credentialsProvider(staticCredentialsProvider)
    .build()) {
    List<Bucket> buckets = s3.listBuckets().buckets();
    for (Bucket bucket : buckets) {
        System.out.println("bucket name: " + bucket.name());
    }
} catch (StsException | S3Exception e) {
    logger.error(e.getMessage());
    System.exit(1);
}

Permission set

The following permission set defined in AWS IAM Identity Center allows the identity (user) to perform the following two operations

1. The GetObject operation of the Amazon Simple Storage Service.

Without assuming the role, the s3.listBuckets() method shown in the example would fail.

{  
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject",
            ]
        }
    ]
}
Assumed role

Assumed role permissions policy

The following permissions policy is attached to the role that is assume in the previous example. This permissions policy permits the ability to list all buckets in the same account as the role.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:ListAllMyBuckets"
            ],
            "Resource": ["*"]
        }
    ]
}
```

Assumed role trust policy

The following trust policy is attached to the role that is assume in the previous example. The policy allows the role to be assumed by identities (users) in two accounts.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "*"
            }
        }
    ]
}
```
Read IAM role credentials on Amazon EC2

You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see Using an IAM role to grant permissions to applications running on Amazon EC2 instances in the IAM User Guide.

This topic provides information on how to set up your Java application to run on an EC2 instance and enable the SDK for Java to acquire IAM role credentials.

Acquire IAM role credentials from the environment

If your application creates an AWS service client by using the create method (or builder().build() methods), the SDK for Java uses the default credentials provider chain. The default credentials provider chain searches the execution environment for configuration elements that the SDK can trade for temporary credentials. The the section called “Default credentials provider chain“ section describes the full search process.

The final step in the default provider chain is available only when your application runs on an Amazon EC2 instance. In this step, the SDK uses an InstanceProfileCredentialsProvider to read the IAM role defined in the EC2 instance profile. The SDK then acquires temporary credentials for that IAM role.

Although these credentials are temporary and would eventually expire, an InstanceProfileCredentialsProvider periodically refreshes them for you so that they continue to allow access to AWS.
Acquire IAM role credentials programmatically

As an alternative to the default credentials provider chain that eventually uses an InstanceProfileCredentialsProvider on EC2, you can configure a service client explicitly with an InstanceProfileCredentialsProvider. This approach is shown in the following snippet.

```java
S3Client s3 = S3Client.builder()
    .credentialsProvider(InstanceProfileCredentialsProvider.create())
    .build();
```

Securely acquire IAM role credentials

By default, EC2 instances run IMDS (Instance Metadata Service) that allows the SDK’s InstanceProfileCredentialsProvider to access information such as the IAM role that has been configured. EC2 instances run two versions of IMDS by default:

- Instance Metadata Service Version 1 (IMDSv1) – a request/response method
- Instance Metadata Service Version 2 (IMDSv2) – a session-oriented method

**IMDSv2 is a more secure approach** than IMDSv1.

By default, the Java SDK first tries IMDSv2 to get the IAM role, but if that fails, it tries IMDSv1. However, since IMDSv1 is less secure, AWS recommends the use of IMDSv2 only and to disable the SDK from trying IMDSv1.

To use the more secure approach, disable the SDK from using IMDSv1 by providing one of the following settings with a value of `true`.

- Environment variable: `AWS_EC2_METADATA_V1_DISABLED`
- JVM system property: `aws.disableEc2MetadataV1`
- Shared config file setting: `ec2_metadata_v1_disabled`

With one of these settings set to `true`, the SDK does not load IMDS role credentials by using IMDSv1 if the initial IMDSv2 call fails.
Use AWS Regions

AWS Regions enable service clients to access AWS services that physically resides in a specific geographic area.

Explicitly configure an AWS Region

To explicitly set a Region, we recommend that you use the constants defined in the `Region` class. This is an enumeration of all publicly available regions.

To create a client with an enumerated Region from the class, use the client builder's `region` method.

```java
Ec2Client ec2 = Ec2Client.builder()
    .region(Region.US_WEST_2)
    .build();
```

If the Region you want to use isn’t one of the enumerations in the `Region` class, you can create a new Region by using the static `of` method. This method allows you access to new Regions without upgrading the SDK.

```java
Region newRegion = Region.of("us-east-42");
Ec2Client ec2 = Ec2Client.builder()
    .region(newRegion)
    .build();
```

**Note**

After you build a client with the builder, it's immutable and the AWS Region cannot be changed. If you need to work with multiple AWS Regions for the same service, you should create multiple clients—one per Region.

Let the SDK automatically determine the Region from the environment

When your code runs on Amazon EC2 or AWS Lambda, you might want to configure clients to use the same AWS Region that your code is running on. This decouples your code from the environment it’s running in and makes it easier to deploy your application to multiple AWS Regions for lower latency or redundancy.
To use the default credential/region provider chain to determine the Region from the environment, use the client builder's `create` method.

```java
Ec2Client ec2 = Ec2Client.create();
```

If you don’t explicitly set an AWS Region by using the `region` method, the SDK consults the default region provider chain to determine the Region to use.

**Understand the default region provider chain**

**The SDK takes the following steps to look for an AWS Region:**

1. Any explicit Region set by using `region` on the builder itself takes precedence over anything else.
2. The `AWS_REGION` environment variable is checked. If it’s set, that Region is used to configure the client.

   **Note**
   The Lambda container sets this environment variable.

3. The SDK checks the AWS shared configuration file and shared credentials file (usually located at `~/.aws/config` and `~/.aws/credentials`). If the `region` property is present, the SDK uses it.
   - If the SDK finds the `region` property in both files for the same profile (including the default profile), the SDK uses the value in the shared credentials file.
   - The `AWS_CONFIG_FILE` environment variable can be used to customize the location of the shared config file.
   - The `AWS_PROFILE` environment variable or the `aws.profile` system property can be used to specify the profile that the SDK loads.

4. The SDK attempts to use the Amazon EC2 instance metadata service (IMDS) to determine the Region of the currently running Amazon EC2 instance.
   - For greater security, you should disable the SDK from attempting to use version 1 of IMDS. You use the same setting to disable version 1 that are described in the *Securely* section.

5. If the SDK still hasn’t found a Region by this point, client creation fails with an exception.
When developing AWS applications, a common approach is to use the *shared configuration file* (described in [Credential retrieval order](#)) to set the Region for local development, and rely on the default region provider chain to determine the Region when the application runs on AWS infrastructure. This greatly simplifies client creation and keeps your application portable.

### Check for service availability in a Region

To see if a particular AWS service is available in a Region, use the `serviceMetadata` and `region` method on the service client.

```java
DynamoDbClient.serviceMetadata().regions().forEach(System.out::println);
```

See the [Region](#) class documentation for the AWS Regions you can specify, and use the endpoint prefix of the service to query.

### Choose a specific endpoint

In certain situations—such as to test preview features of a service before the features graduate to general availability—you may need to specify a specific endpoint in a Region. In these situations, service clients can be configured by calling the `endpointOverride` method.

For example, to configure an Amazon EC2 client to use the Europe (Ireland) Region with a specific endpoint, use the following code.

```java
Ec2Client ec2 = Ec2Client.builder()
    .region(Region.EU_WEST_1)
    .endpointOverride(URI.create("https://ec2.eu-west-1.amazonaws.com"))
    .build();
```

See [Regions and Endpoints](#) for the current list of regions and their corresponding endpoints for all AWS services.

### Reduce SDK startup time for AWS Lambda

One of the goals of the AWS SDK for Java 2.x is to reduce the startup latency for AWS Lambda functions. The SDK contains changes that reduce startup time, which are discussed at the end of this topic.

First, this topic focuses on changes that you can make to reduce cold start times. These include making changes in your code structure and in the configuration of service clients.
Use the SDK's **UrlConnectionHttpClient**

For *synchronous* scenarios, the SDK for Java 2.x offers the `UrlConnectionHttpClient` class, which is based on the JDK's HTTP client classes. Because the `UrlConnectionHttpClient` is based on classes already on the classpath, there are no extra dependencies to load.

For information on adding the `UrlConnectionHttpClient` to your Lambda project and configuring its use, see [Configure the URLConnection-based HTTP client](#).

---

**Note**

There are some feature limitations with the `UrlConnectionHttpClient` in comparison to the SDK's `ApacheHttpClient`. The `ApacheHttpClient` is the default asynchronous HTTP client in the SDK. For example, the `UrlConnectionHttpClient` does not support the HTTP PATCH method.

A handful of AWS API operations require PATCH requests. Those operation names usually start with `Update*`. The following are several examples.

- Several `Update*` operations in the AWS Security Hub API and also the `BatchUpdateFindings` operation
- All Amazon API Gateway API `Update*` operations
- Several `Update*` operations in the Amazon WorkDocs API

If you might use the `UrlConnectionHttpClient`, first refer to the API Reference for the AWS service that you're using. Check to see if the operations you need use the PATCH operation.

---

Use the SDK's **AwsCrtAsyncHttpClient**

The `AwsCrtAsyncHttpClient` is the *asynchronous* counterpart for reducing Lambda startup time in the SDK.

The `AwsCrtAsyncHttpClient` is an asynchronous, non-blocking HTTP client. It's built on top of the Java bindings of the AWS Common Runtime, which is written in the C programming language. Among the goals in the development of the AWS Common Runtime is fast performance.
This guide's section on configuring HTTP clients has information about adding an AWS-CrtAsyncHttpClient to your Lambda project and configuring its use.

**Remove unused HTTP client dependencies**

Along with the explicit use of URLConnectionHttpClient or AwsCrtAsyncHttpClient, you can remove other HTTP clients that the SDK brings in by default. Lambda startup time is reduced when fewer libraries need to be loaded, so you should remove any unused artifacts that the JVM needs to load.

The following snippet of a Maven pom.xml file shows the exclusion of the Apache-based HTTP client and the Netty-based HTTP client. (These clients aren't needed when you use the URLConnectionHttpClient.) This example excludes the HTTP client artifacts from the S3 client dependency and adds the url-connection-client artifact, which brings in the URLConnectionHttpClient class.

```xml
<project>
    <properties>
        <aws.java.sdk.version>2.17.290</aws.java.sdk.version>
    </properties>
    <dependencyManagement>
        <dependencies>
            <dependency>
                <groupId>software.amazon.awssdk</groupId>
                <artifactId>bom</artifactId>
                <version>${aws.java.sdk.version}</version>
                <type>pom</type>
                <scope>import</scope>
            </dependency>
        </dependencies>
    </dependencyManagement>
    <dependencies>
        <dependency>
            <groupId>software.amazon.awssdk</groupId>
            <artifactId>url-connection-client</artifactId>
        </dependency>
        <dependency>
            <groupId>software.amazon.awssdk</groupId>
            <artifactId>s3</artifactId>
            <exclusions>
                <exclusion>
                    <groupId>software.amazon.awssdk</groupId>
                </exclusion>
            </exclusions>
        </dependency>
    </dependencies>
</project>
```
If you use the AwsCrtAsyncHttpClient, replace the dependency on the url-connection-client to a dependency on the aws-crt-client.

Note
Add the `<exclusions>` element to all service client dependencies in your pom.xml file.

Configure service clients to shortcut lookups

Specify a region

When you create a service client, call the region method on the service client builder. This shortcuts the SDK's default Region lookup process that checks several places for the AWS Region information.

To keep the Lambda code independent of the region, use the following code inside the region method. This code accesses the AWS_REGION environment variable set by the Lambda container.

```java
Region.of(System.getenv(SdkSystemSetting.AWS_REGION.environmentVariable()))
```

Use the EnvironmentVariableCredentialProvider

Much like the default lookup behavior for the Region information, the SDK looks in several places for credentials. By specifying the EnvironmentVariableCredentialProvider when you build a service client, you save time in the SDK's lookup process.
Note

Using this credentials provider enables the code to be used in Lambda functions, but might not work on Amazon EC2 or other systems.

The following code snippet shows an S3 service client appropriately configured for use in a Lambda environment.

```java
S3Client client = S3Client.builder()
    .region(Region.of(System.getenv(SdkSystemSetting.AWS_REGION.environmentVariable())))
    .credentialsProvider(EnvironmentVariableCredentialsProvider.create())
    .httpClient(UrlConnectionHttpClient.builder().build())
    .build();
```

Initialize the SDK client outside of the Lambda function handler

We recommend initializing an SDK client outside of the Lambda handler method. This way, if the execution context is reused, the initialization of the service client can be skipped. By reusing the client instance and its connections, subsequent invocations of the handler method occur more quickly.

In the following example, the `S3Client` instance is initialized in the constructor using a static factory method. If the container that is managed by the Lambda environment is reused, the initialized `S3Client` instance is reused.

```java
public class App implements RequestHandler<Object, Object> {
    private final S3Client s3Client;

    public App() {
        s3Client = DependencyFactory.s3Client();
    }

    @Override
    public Object handleRequest(final Object input, final Context context) {
        ListBucketResponse response = s3Client.listBuckets();
        // Process the response.
    }
}
```
Minimize dependency injection

Dependency injection (DI) frameworks might take additional time to complete the setup process. They might also require additional dependencies, which take time to load.

If a DI framework is needed, we recommend using lightweight DI frameworks such as Dagger.

Use a Maven Archetype targeting AWS Lambda

The AWS Java SDK team has developed a Maven Archetype template to bootstrap a Lambda project with minimal startup time. You can build out a Maven project from the archetype and know that the dependencies are configured suitably for the Lambda environment.

To learn more about the archetype and work through an example deployment, see this blog post.

Consider Lambda SnapStart for Java

If your runtime requirements are compatible, AWS offers Lambda SnapStart for Java. Lambda SnapStart is an infrastructure-based solution that improves startup performance for Java functions. When you publish a new version of a function, Lambda SnapStart initializes it and takes an immutable, encrypted snapshot of the memory and disk state. SnapStart then caches the snapshot for reuse.

Version 2.x changes that affect startup time

In addition to changes that you make to your code, version 2.x of the SDK for Java includes three primary changes that reduce startup time:

- Use of jackson-jr, which is a serialization library that improves initialization time
- Use of the java.time libraries for date and time objects, which is part of the JDK
- Use of Slf4j for a logging facade

Additional resources

The AWS Lambda Developer Guide contains a section on best practices for developing Lambda functions that is not Java specific.

For an example of building a cloud-native application in Java that uses AWS Lambda, see this workshop content. The workshop discussion performance optimization and other best practices.
You can consider using static images that are compiled ahead of time to reduce startup latency. For example, you can use the SDK for Java 2.x and Maven to build a GraalVM native image.

**HTTP clients**

You can change the HTTP client to use for your service client as well as change the default configuration for HTTP clients with the AWS SDK for Java 2.x. This section discusses HTTP clients and settings for the SDK.

**HTTP clients available in the SDK for Java**

**Synchronous clients**

Synchronous HTTP clients in the SDK for Java implement the `SdkHttpClient` interface. A synchronous service client, such as the `S3Client` or the `DynamoDbClient`, requires the use of a synchronous HTTP client. The AWS SDK for Java offers three synchronous HTTP clients.

**ApacheHttpClient (default)**

`ApacheHttpClient` is the default HTTP client for synchronous service clients. For information about configuring the `ApacheHttpClient`, see Configure the Apache-based HTTP client.

**AwsCrtHttpClient**

`AwsCrtHttpClient` provides high throughput and non-blocking IO. It is built on the AWS Common Runtime (CRT) Http Client. For information about configuring the `AwsCrtHttpClient` and using it with service clients, see the section called “Configure AWS CRT-based HTTP clients”.

**UrlConnectionHttpClient**

To minimize the number of jars and third-party libraries your application uses, you can use the `UrlConnectionHttpClient`. For information about configuring the `UrlConnectionHttpClient`, see Configure the URLConnection-based HTTP client.

**Asynchronous clients**

Asynchronous HTTP clients in the SDK for Java implement the `SdkAsyncHttpClient` interface. An asynchronous service client, such as the `S3AsyncClient` or the `DynamoDbAsyncClient`, requires
the use of an asynchronous HTTP client. The AWS SDK for Java offers two asynchronous HTTP clients.

**NettyNioAsyncHttpClient (default)**

[NettyNioAsyncHttpClient](http://example.com) is the default HTTP client used by asynchronous clients. For information about configuring the NettyNioAsyncHttpClient, see [the section called “Configure the Netty-based HTTP client”](http://example.com).

**AwsCrtAsyncHttpClient**

The [AwsCrtAsyncHttpClient](http://example.com) is based on the AWS Common Runtime (CRT) HTTP Client. For information about configuring the AwsCrtAsyncHttpClient, see [the section called “Configure AWS CRT-based HTTP clients”](http://example.com).

**HTTP client recommendations**

Several factors come into play when you choose an HTTP client implementation. Use the following information to help you decide.

**Recommendation flowchart**

The following flowchart provides general guidance to help you determine which HTTP client to use.
# HTTP client comparison

The following table provides detailed information for each HTTP client.

<table>
<thead>
<tr>
<th>HTTP client</th>
<th>Sync or async</th>
<th>When to use</th>
<th>Limitation/ drawback</th>
</tr>
</thead>
<tbody>
<tr>
<td>Apache-based HTTP client</td>
<td>Sync</td>
<td>Use it if you prefer low latency over high throughput</td>
<td>Slower startup time compared to other HTTP clients</td>
</tr>
<tr>
<td><em>(default sync HTTP client)</em></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>URLConnection-based HTTP client</td>
<td>Sync</td>
<td>Use it if you have a hard requirement for limiting third-party dependencies</td>
<td>Does not support the HTTP PATCH method, required by some APIs like Amazon API Gateway Update operations</td>
</tr>
<tr>
<td>AWS CRT-based sync HTTP client</td>
<td>Sync</td>
<td>• Use it if your application is running in AWS Lambda</td>
<td>N/A</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Use it if you prefer high throughput over low latency</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Use it if you prefer sync SDK clients</td>
<td></td>
</tr>
<tr>
<td>Netty-based HTTP client</td>
<td>Async</td>
<td>• Use it if your application invokes APIs that require HTTP/2 support such as Kinesis API Subscribe ToShard</td>
<td>Slower startup time compared to other HTTP clients</td>
</tr>
<tr>
<td><em>(default async HTTP client)</em></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>HTTP client</td>
<td>Sync or async</td>
<td>When to use</td>
<td>Limitation/drawback</td>
</tr>
<tr>
<td>-------------</td>
<td>--------------</td>
<td>-------------</td>
<td>---------------------</td>
</tr>
</tbody>
</table>
| AWS CRT-based async HTTP client¹ | Async | • Use it if your application is running in AWS Lambda  
• Use it if you prefer high throughput over low latency  
• Use it if you prefer async SDK clients | • Does not support service clients that require HTTP/2 support such as KinesisAsyncClient and TranscribeStreamingAsyncClient |

¹Because of their added benefits, we recommend that you use the AWS CRT-based HTTP clients if possible.

### Smart configuration defaults

The AWS SDK for Java 2.x (version 2.17.102 or later) offers a smart configuration defaults feature. This feature optimizes two HTTP client properties along with other properties that don't affect the HTTP client.

The smart configuration defaults set sensible values for the `connectTimeoutInMillis` and `tlsNegotiationTimeoutInMillis` properties based on a defaults mode value that you provide. You choose the defaults mode value based on your application's characteristics.

For more information about smart configuration defaults and how to choose the defaults mode value that is best suited for your applications, see the [AWS SDKs and Tools Reference Guide](#).

Following are four ways to set the defaults mode for your application.

**Service client**

Use the service client builder to configure the defaults mode directly on the service client. The following example sets the defaults mode to `auto` for the `DynamoDbClient`.

```java
DynamoDbClient ddbClient = DynamoDbClient.builder()
```
System property

You can use the `aws.defaultsMode` system property to specify the defaults mode. If you set the system property in Java, you need to set the property before initializing any service client.

The following example shows you how to set the defaults mode to `auto` using a system property set in Java.

```java
System.setProperty("aws.defaultsMode", "auto");
```

The following example demonstrates how you set the defaults mode to `auto` using a `-D` option of the `java` command.

```java
java -Daws.defaultsMode=auto
```

Environment variable

Set a value for environment variable `AWS_DEFAULTS_MODE` to select the defaults mode for your application.

The following information shows the command to run to set the value for the defaults mode to `auto` using an environment variable.

<table>
<thead>
<tr>
<th>Operating system</th>
<th>Command to set environment variables</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux, macOS, or Unix</td>
<td><code>export AWS_DEFAULTS_MODE=auto</code></td>
</tr>
<tr>
<td>Windows</td>
<td><code>set AWS_DEFAULTS_MODE=auto</code></td>
</tr>
</tbody>
</table>

AWS config file

You can add a `defaults_mode` configuration property to the shared AWS config file as the following example shows.

```ini
[default]
defaults_mode = auto
```
If you set the defaults mode globally with the system property, environment variable, or AWS config file, you can override the settings when you build an HTTP client.

When you build an HTTP client with the `httpClientBuilder()` method, settings apply only to the instance that you are building. An example of this is shown here. The Netty-based HTTP client in this example overrides any default mode values set globally for `connectTimeoutInMillis` and `tlsNegotiationTimeoutInMillis`.

**Proxy support**

You can configure HTTP proxies by using code, by setting Java system properties, or by combining both approaches. The SDK currently does not support environment variables to configure proxies.

You configure proxies in code with a client-specific `ProxyConfiguration` builder when you build the service client. The section for each HTTP client in this topic shows a proxy configuration example. This example is for the Apache HTTP client.

**HTTP client support of Java system properties for HTTP proxies**

<table>
<thead>
<tr>
<th>System property</th>
<th>Description</th>
<th>HTTP client support</th>
</tr>
</thead>
<tbody>
<tr>
<td>http.proxyHost</td>
<td>Host name of the HTTP proxy server</td>
<td>All</td>
</tr>
<tr>
<td>http.proxyPort</td>
<td>Port number of the HTTP proxy server</td>
<td>All</td>
</tr>
<tr>
<td>http.proxyUser</td>
<td>Username for HTTP proxy authentication</td>
<td>All</td>
</tr>
<tr>
<td>http.proxyPassword</td>
<td>Password for HTTP proxy authentication</td>
<td>All</td>
</tr>
<tr>
<td>http.nonProxyHosts</td>
<td>List of hosts that should be reached directly, bypassing the proxy. Also valid when HTTPS is used.</td>
<td>All</td>
</tr>
<tr>
<td>https.proxyHost</td>
<td>Host name of the HTTPS proxy server</td>
<td>Netty, CRT</td>
</tr>
<tr>
<td><strong>System property</strong></td>
<td><strong>Description</strong></td>
<td><strong>HTTP client support</strong></td>
</tr>
<tr>
<td>--------------------------------------</td>
<td>------------------------------------------------------</td>
<td>-------------------------</td>
</tr>
<tr>
<td>https.proxyPort</td>
<td>Port number of the HTTPS proxy server</td>
<td>Netty, CRT</td>
</tr>
<tr>
<td>https.proxyUser</td>
<td>Username for HTTPS proxy authentication</td>
<td>Netty, CRT</td>
</tr>
<tr>
<td>https.proxyPassword</td>
<td>Password for HTTPS proxy authentication</td>
<td>Netty, CRT</td>
</tr>
</tbody>
</table>

The terms used in the tables mean:

- **All**: All HTTP clients offered by the SDK–UrlConnectionHttpClient, ApacheHttpClient, NettyNioAsyncHttpClient, AwsCrtAsyncHttpClient
- **Netty**: the Netty-based HTTP client (NettyNioAsyncHttpClient)
- **CRT**: the AWS CRT-based HTTP clients, (AwsCrtHttpClient and AwsCrtAsyncHttpClient)

You can use a mix of HTTP client configuration and system properties. Each HTTP client’s ProxyConfiguration builder provides a useSystemPropertyValues setting. By default, the setting is true. When the setting is true, the SDK automatically uses system property values for options that are not provided by using the ProxyConfiguration builder.

The following example shows configuration provided by a system property and by code.

```java
// Command line with the proxy password set as a system property.
$ java -Dhttp.proxyPassword=password -cp ... App

// Since the 'useSystemPropertyValues' setting is 'true' (the default), the SDK will supplement
// the proxy configuration in code with the 'http.proxyPassword' value from the system property.
SdkHttpClient apacheHttpClient = ApacheHttpClient.builder()
    .proxyConfiguration(ProxyConfiguration.builder()
        .endpoint(URI.create("http://localhost:1234"))
        .username("username")
        .build())
    .build();
```
// Use the apache HTTP client with proxy configuration.
DynamoDbClient dynamoDbClient = DynamoDbClient.builder()
    .httpClient(apacheHttpClient)
    .build();

### Note

Instead of setting the endpoint property in code as shown in the previous code snippet, you can use the following system properties.

-Dhttp.proxyHost=localhost -Dhttp.proxyPort=1234

---

**Configure the Apache-based HTTP client**

Synchronous service clients in the AWS SDK for Java 2.x use an Apache-based HTTP client, `ApacheHttpClient` by default. The SDK's `ApacheHttpClient` is based on the Apache `HttpClient`.

The SDK also offers the `UrlConnectionHttpClient`, which loads more quickly, but has fewer features. For information about configuring the `UrlConnectionHttpClient`, see the section called “Configure the URLConnection-based HTTP client”.

To see the full set of configuration options available to you for the `ApacheHttpClient`, see `ApacheHttpClient.Builder` and `ProxyConfiguration.Builder`.

**Access the ApacheHttpClient**

In most situations, you use the `ApacheHttpClient` without any explicit configuration. You declare your service clients and the SDK will configure the `ApacheHttpClient` with standard values for you.

If you want to explicitly configure the `ApacheHttpClient` or use it with multiple service clients, you need to make it available for configuration.

**No configuration needed**

When you declare a dependency on a service client in Maven, the SDK adds a *runtime* dependency on the `apache-client` artifact. This makes the `ApacheHttpClient` class available to your code at runtime, but not at compile time. If you are not configuring the Apache-based HTTP client, you do not need to specify a dependency for it.
In the following XML snippet of a Maven pom.xml file, the dependency declared with 
<artifactId>s3</artifactId> automatically brings in the Apache-based HTTP client. You don't need to declare a dependency specifically for it.

```xml
<dependencyManagement>
  <dependencies>
    <dependency>
      <groupId>software.amazon.awssdk</groupId>
      <artifactId>bom</artifactId>
      <version>2.17.290</version>
      <type>pom</type>
      <scope>import</scope>
    </dependency>
  </dependencies>
</dependencyManagement>

<dependencies>
  <!-- The s3 dependency automatically adds a runtime dependency on the ApacheHttpClient-->
  <dependency>
    <groupId>software.amazon.awssdk</groupId>
    <artifactId>s3</artifactId>
  </dependency>
</dependencies>
```

With these dependencies, you cannot make any explicit HTTP configuration changes, because the ApacheHttpClient library is only on the runtime classpath.

**Configuration needed**

To configure the ApacheHttpClient, you need to add a dependency on the apache-client library at *compile* time.

Refer to the following example of a Maven pom.xml file to configure the ApacheHttpClient.

```xml
<dependencyManagement>
  <dependencies>
    <dependency>
      <groupId>software.amazon.awssdk</groupId>
      <artifactId>bom</artifactId>
      <version>2.17.290</version>
      <type>pom</type>
      <scope>import</scope>
    </dependency>
  </dependencies>
</dependencyManagement>
```
Use and configure the ApacheHttpClient

You can configure an instance of ApacheHttpClient along with building a service client, or you can configure a single instance to share across multiple service clients.

With either approach, you use the ApacheHttpClient.Builder to configure the properties for the Apache-based HTTP client.

Best practice: dedicate an ApacheHttpClient instance to a service client

If you need to configure an instance of the ApacheHttpClient, we recommend that you build the dedicated ApacheHttpClient instance. You can do so by using the httpClientBuilder method of the service client's builder. This way, the lifecycle of the HTTP client is managed by the SDK, which helps avoid potential memory leaks if the ApacheHttpClient instance is not closed down when it's no longer needed.

The following example creates an S3Client and configures the embedded instance of ApacheHttpClient with maxConnections and connectionTimeout values. The HTTP instance is created using the httpClientBuilder method of S3Client.Builder.

Imports

```java
import software.amazon.awssdk.http.apache.ApacheHttpClient;
import software.amazon.awssdk.services.s3.S3Client;
import java.time.Duration;
```
**Code**

S3Client s3Client = S3Client // Singleton: Use the s3Client for all requests.
    .builder()
    .httpClientBuilder(ApacheHttpClient.builder()
        .maxConnections(100)
        .connectionTimeout(Duration.ofSeconds(5))
    ).build();

// Perform work with the s3Client.

s3Client.close(); // Requests completed: Close all service clients.

**Alternative approach: share an ApacheHttpClient instance**

To help keep resource and memory usage lower for your application, you can configure an ApacheHttpClient and share it across multiple service clients. The HTTP connection pool will be shared, which lowers resource usage.

**Note**

When an ApacheHttpClient instance is shared, you must close it when it is ready to be disposed. The SDK will not close the instance when the service client is closed.

The following example configures an Apache-based HTTP client that is used by two service clients. The configured ApacheHttpClient instance is passed to the httpClient method of each builder. When the service clients and the HTTP client are no longer needed, the code explicitly closes them. The code closes the HTTP client last.

**Imports**

```java
import software.amazon.awssdk.http.SdkHttpClient;
import software.amazon.awssdk.http.apache.ApacheHttpClient;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.s3.S3Client;
```

**Code**

```java
SdkHttpClient apacheHttpClient = ApacheHttpClient.builder()
        .maxConnections(100).build();
```
// Singletons: Use the s3Client and dynamoDbClient for all requests.
S3Client s3Client =
    S3Client.builder()
    .httpClient(apacheHttpClient).build();

DynamoDbClient dynamoDbClient =
    DynamoDbClient.builder()
    .httpClient(apacheHttpClient).build();

// Perform work with the s3Client and dynamoDbClient.

// Requests completed: Close all service clients.
s3Client.close();
dynamoDbClient.close();
apacheHttpClient.close();  // Explicitly close apacheHttpClient.

Proxy configuration example

The following code snippet uses the proxy configuration builder for the Apache HTTP client.

SdkHttpClient apacheHttpClient = ApacheHttpClient.builder()
    .proxyConfiguration(ProxyConfiguration.builder()
        .endpoint(URI.create("http://example.com:1234"))
        .username("username")
        .password("password")
        .addNonProxyHost("localhost")
        .addNonProxyHost("host.example.com")
        .build())
    .build();

The equivalent Java system properties for the proxy configuration are shown in the following command line snippet.

$ java -Dhttp.proxyHost=example.com -Dhttp.proxyPort=1234 -Dhttp.proxyUser=username \
-Dhttp.proxyPassword=password -Dhttp.nonProxyHosts=localhost|host.example.com -cp ... App

⚠️ Note

The Apache HTTP client does not currently support HTTPS proxy system properties.
Configure the URLConnection-based HTTP client

The AWS SDK for Java 2.x offers a lighter-weight URLConnectionHttpClient HTTP client in comparison to the default ApacheHttpClient. The URLConnectionHttpClient is based on Java's URLConnection.

The URLConnectionHttpClient loads more quickly than the Apache-based HTTP client, but has fewer features. Because it loads more quickly, it is a good solution for Java AWS Lambda functions.

The URLConnectionHttpClient has several configurable options that you can access.

Note

The URLConnectionHttpClient does not support the HTTP PATCH method. A handful of AWS API operations require PATCH requests. Those operation names usually start with Update*. The following are several examples.

- Several Update* operations in the AWS Security Hub API and also the BatchUpdateFindings operation
- All Amazon API Gateway API Update* operations
- Several Update* operations in the Amazon WorkDocs API

If you might use the URLConnectionHttpClient, first refer to the API Reference for the AWS service that you're using. Check to see if the operations you need use the PATCH operation.

Access the URLConnectionHttpClient

To configure and use the URLConnectionHttpClient, you declare a dependency on the url-connection-client Maven artifact in your pom.xml file.

Unlike the ApacheHttpClient, the URLConnectionHttpClient is not automatically added to your project, so use must specifically declare it.

The following example of a pom.xml file shows the dependencies required to use and configure the HTTP client.

<dependencyManagement>
<dependencies>
    <dependency>
        <groupId>software.amazon.awssdk</groupId>
        <artifactId>bom</artifactId>
        <version>2.17.290</version>
        <type>pom</type>
        <scope>import</scope>
    </dependency>
</dependencies>

<!-- other dependencies such as s3 or dynamodb -->

<dependencies>
    <dependency>
        <groupId>software.amazon.awssdk</groupId>
        <artifactId>url-connection-client</artifactId>
    </dependency>
</dependencies>

Use and configure the UrlConnectionHttpClient

You can configure an instance of UrlConnectionHttpClient along with building a service client, or you can configure a single instance to share across multiple service clients.

With either approach, you use the UrlConnectionHttpClient.Builder to configure the properties for the URLConnection-based HTTP client.

Best practice: dedicate an UrlConnectionHttpClient instance to a service client

If you need to configure an instance of the UrlConnectionHttpClient, we recommend that you build the dedicated UrlConnectionHttpClient instance. You can do so by using the httpClientBuilder method of the service client's builder. This way, the lifecycle of the HTTP client is managed by the SDK, which helps avoid potential memory leaks if the UrlConnectionHttpClient instance is not closed down when it's no longer needed.

The following example creates an S3Client and configures the embedded instance of UrlConnectionHttpClient with socketTimeout and proxyConfiguration values. The proxyConfiguration method takes a Java lambda expression of type Consumer<ProxyConfiguration.Builder>.

Imports
import software.amazon.awssdk.http.SdkHttpClient;
import software.amazon.awssdk.http.urlconnection.UrlConnectionHttpClient;
import java.net.URI;
import java.time.Duration;

Code

// Singleton: Use the s3Client for all requests.
S3Client s3Client =
    S3Client.builder()
    .httpClientBuilder(UrlConnectionHttpClient.builder()
        .socketTimeout(Duration.ofMinutes(5))
        .proxyConfiguration(proxy -> proxy.endpoint(URI.create("http://proxy.mydomain.net:8888"))))
        .credentialsProvider(EnvironmentVariableCredentialsProvider.create())
    .build();

// Perform work with the s3Client.

s3Client.close(); // Requests completed: Close the s3client.

Alternative approach: share an UrlConnectionHttpClient instance

To help keep resource and memory usage lower for your application, you can configure an UrlConnectionHttpClient and share it across multiple service clients. The HTTP connection pool will be shared, which lowers resource usage.

Note

When an UrlConnectionHttpClient instance is shared, you must close it when it is ready to be disposed. The SDK will not close the instance when the service client is closed.

The following example configures an URLConnection-based HTTP client that is used by two service clients. The configured UrlConnectionHttpClient instance is passed to the httpClient method of each builder. When the service clients and the HTTP client are no longer needed, the code explicitly closes them. The code closes the HTTP client last.

Imports

import software.amazon.awssdk.auth.credentials.EnvironmentVariableCredentialsProvider;
import software.amazon.awssdk.awscore.defaultsmode.DefaultsMode;
import software.amazon.awssdk.http.SdkHttpClient;
import software.amazon.awssdk.http.urlconnection.ProxyConfiguration;
import software.amazon.awssdk.http.urlconnection.UrlConnectionHttpClient;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.s3.S3Client;
import java.net.URI;
import java.time.Duration;

Code

SdkHttpClient urlHttpClient = UrlConnectionHttpClient.create();

// Singletons: Use the s3Client and dynamoDbClient for all requests.
S3Client s3Client =
    S3Client.builder()
    .httpClient(urlHttpClient)
    .defaultsMode(DefaultsMode.IN_REGION)
    .credentialsProvider(EnvironmentVariableCredentialsProvider.create())
    .build();

DynamoDbClient dynamoDbClient =
    DynamoDbClient.builder()
    .httpClient(urlHttpClient)
    .defaultsMode(DefaultsMode.IN_REGION)
    .credentialsProvider(EnvironmentVariableCredentialsProvider.create())
    .build();

// Perform work with the s3Client and dynamoDbClient.

// Requests completed: Close all service clients.
s3Client.close();
dynamoDbClient.close();
urlHttpClient.close();

Use UrlConnectionHttpClient and ApacheHttpClient together

When you use the UrlConnectionHttpClient in your application, you must supply each service client with either a UrlConnectionHttpClient instance or a ApacheHttpClient instance using the service client builder's httpClientBuilderFactory method.

An exception occurs if your program uses multiple service clients and both of the following are true:
• One service client is configured to use a `URLConnectionHttpClient` instance
• Another service client uses the default `ApacheHttpClient` without explicitly building it with the `httpClient()` or `httpClientBuilder()` methods

The exception will state that multiple HTTP implementations were found on the classpath.

The following example code snippet leads to an exception.

```java
// The dynamoDbClient uses the `URLConnectionHttpClient`
DynamoDbClient dynamoDbClient = DynamoDbClient.builder()
    .httpClient(UrlConnectionHttpClient.create())
    .build();

// The s3Client below uses the `ApacheHttpClient` at runtime, without specifying it.
// An `SdkClientException` is thrown with the message that multiple HTTP implementations were found on the classpath.
S3Client s3Client = S3Client.create();

// Perform work with the s3Client and dynamoDbClient.
dynamoDbClient.close();
s3Client.close();

Avoid the exception by explicitly configuring the `S3Client` with an `ApacheHttpClient`.

```java
DynamoDbClient dynamoDbClient = DynamoDbClient.builder()
    .httpClient(UrlConnectionHttpClient.create())
    .build();

S3Client s3Client = S3Client.builder()
    .httpClient(ApacheHttpClient.create())  // Explicitly build the
    .build();

// Perform work with the s3Client and dynamoDbClient.
dynamoDbClient.close();
s3Client.close();
```
To explicitly create the ApacheHttpClient, you must add a dependency on the apache-client artifact in your Maven project file.

**Proxy configuration example**

The following code snippet uses the proxy configuration builder for the URL connection HTTP client.

```java
SdkHttpClient urlHttpClient = UrlConnectionHttpClient.builder()
  .proxyConfiguration(ProxyConfiguration.builder()
    .endpoint(URI.create("http://example.com:1234"))
    .username("username")
    .password("password")
    .addNonProxyHost("localhost")
    .addNonProxyHost("host.example.com")
    .build())
  .build();
```

The equivalent Java system properties for the proxy configuration are shown in the following command line snippet.

```bash
$ java -Dhttp.proxyHost=example.com -Dhttp.proxyPort=1234 -Dhttp.proxyUser=username -Dhttp.proxyPassword=password -Dhttp.nonProxyHosts=localhost|host.example.com -cp ...
```

**Note**

The URL connection HTTP client does not currently support HTTPS proxy system properties.

**Configure the Netty-based HTTP client**

The default HTTP client for asynchronous operations in the AWS SDK for Java 2.x is the Netty-based `NettyNioAsyncHttpClient`. The Netty-based client is based on the asynchronous event-driven network framework of the Netty project.
As an alternative HTTP client, you can use the new AWS CRT-based HTTP client. This topic shows you how to configure the NettyNioAsyncHttpClient.

**Access the NettyNioAsyncHttpClient**

In most situations, you use the NettyNioAsyncHttpClient without any explicit configuration in asynchronous programs. You declare your asynchronous service clients and the SDK will configure the NettyNioAsyncHttpClient with standard values for you.

If you want to explicitly configure the NettyNioAsyncHttpClient or use it with multiple service clients, you need to make it available for configuration.

**No configuration needed**

When you declare a dependency on a service client in Maven, the SDK adds a runtime dependency on the netty-nio-client artifact. This makes the NettyNioAsyncHttpClient class available to your code at runtime, but not at compile time. If you are not configuring the Netty-based HTTP client, you don't need to specify a dependency for it.

In the following XML snippet of a Maven pom.xml file, the dependency declared with <artifactId>dynamodb-enhanced</artifactId> transitively brings in the Netty-based HTTP client. You don't need to declare a dependency specifically for it.

```xml
<dependencyManagement>
  <dependencies>
    <dependency>
      <groupId>software.amazon.awssdk</groupId>
      <artifactId>bom</artifactId>
      <version>2.17.290</version>
      <type>pom</type>
      <scope>import</scope>
    </dependency>
  </dependencies>
</dependencyManagement>
<dependencies>
  <dependency>
    <groupId>software.amazon.awssdk</groupId>
    <artifactId>dynamodb-enhanced</artifactId>
  </dependency>
</dependencies>
```
With these dependencies, you cannot make any HTTP configuration changes, since the NettyNioAsyncHttpClient library is only on the runtime classpath.

**Configuration needed**

To configure the NettyNioAsyncHttpClient, you need to add a dependency on the netty-nio-client artifact at *compile* time.

Refer to the following example of a Maven pom.xml file to configure the NettyNioAsyncHttpClient.

```xml
<dependencyManagement>
  <dependencies>
    <dependency>
      <groupId>software.amazon.awssdk</groupId>
      <artifactId>bom</artifactId>
      <version>2.17.290</version>
      <type>pom</type>
      <scope>import</scope>
    </dependency>
  </dependencies>
</dependencyManagement>

<dependencies>
  <dependency>
    <groupId>software.amazon.awssdk</groupId>
    <artifactId>dynamodb-enhanced</artifactId>
  </dependency>
  <!-- By adding the netty-nio-client dependency, NettyNioAsyncHttpClient will be added to the compile classpath so you can configure it. -->
  <dependency>
    <groupId>software.amazon.awssdk</groupId>
    <artifactId>netty-nio-client</artifactId>
  </dependency>
</dependencies>
```

**Use and configure the NettyNioAsyncHttpClient**

You can configure an instance of NettyNioAsyncHttpClient along with building a service client, or you can configure a single instance to share across multiple service clients.

With either approach, you use the `NettyNioAsyncHttpClient.Builder` to configure the properties for the Netty-based HTTP client instance.
Best practice: dedicate a NettyNioAsyncHttpClient instance to a service client

If you need to configure an instance of the NettyNioAsyncHttpClient, we recommend that you build a dedicated NettyNioAsyncHttpClient instance. You can do so by using the httpClientBuilder method of the service client's builder. This way, the lifecycle of the HTTP client is managed by the SDK, which helps avoid potential memory leaks if the NettyNioAsyncHttpClient instance is not closed down when it's no longer needed.

The following example creates a DynamoDbAsyncClient instance that is used by a DynamoDbEnhancedAsyncClient instance. The DynamoDbAsyncClient instance contains the NettyNioAsyncHttpClient instance with connectionTimeout and maxConcurrency values. The HTTP instance is created using httpClientBuilder method of DynamoDbAsyncClient.Builder.

Imports

```java
import software.amazon.awssdk.auth.credentials.EnvironmentVariableCredentialsProvider;
import software.amazon.awssdk.awscore.defaultsmode.DefaultsMode;
import software.amazon.awssdk.enhanced.dynamodb.DynamoDbEnhancedAsyncClient;
import software.amazon.awssdk.enhanced.dynamodb.extensions.AutoGeneratedTimestampRecordExtension;
import software.amazon.awssdk.services.dynamodb.DynamoDbAsyncClient;
import java.time.Duration;
```

Code

```java
// DynamoDbAsyncClient is the lower-level client used by the enhanced client.
DynamoDbAsyncClient dynamoDbAsyncClient =
    DynamoDbAsyncClient
        .builder()
        .httpClientBuilder(NettyNioAsyncHttpClient.builder()
            .connectionTimeout(Duration.ofMillis(5_000))
            .maxConcurrency(100)
            .tlsNegotiationTimeout(Duration.ofMillis(3_500)))
        .defaultsMode(DefaultsMode.IN_REGION)
        .credentialsProvider(EnvironmentVariableCredentialsProvider.create())
        .build();

// Singleton: Use dynamoDbAsyncClient and enhancedClient for all requests.
DynamoDbEnhancedAsyncClient enhancedClient =
```
DynamoDbEnhancedAsyncClient
    .builder()
    .dynamoDbClient(dynamoDbAsyncClient)
    .extensions(AutoGeneratedTimestampRecordExtension.create())
    .build();

// Perform work with the dynamoDbAsyncClient and enhancedClient.

// Requests completed: Close dynamoDbAsyncClient.
dynamoDbAsyncClient.close();

**Alternative approach: share a NettyNioAsyncHttpClient instance**

To help keep resource and memory usage lower for your application, you can configure a NettyNioAsyncHttpClient and share it across multiple service clients. The HTTP connection pool will be shared, which lowers resource usage.

**Note**

When a NettyNioAsyncHttpClient instance is shared, you must close it when it is ready to be disposed. The SDK will not close the instance when the service client is closed.

The following example configures a Netty-based HTTP client that is used by two service clients. The configured NettyNioAsyncHttpClient instance is passed to the httpClient method of each builder. When the service clients and the HTTP client are no longer needed, the code explicitly closes them. The code closes the HTTP client last.

**Imports**

```java
import software.amazon.awssdk.http.SdkHttpClient;
import software.amazon.awssdk.http.apache.ApacheHttpClient;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.s3.S3Client;
```

**Code**

```java
// Create a NettyNioAsyncHttpClient shared instance.
SdkAsyncHttpClient nettyHttpClient =
    NettyNioAsyncHttpClient.builder().maxConcurrency(100).build();
```
// Singletons: Use the s3AsyncClient, dbAsyncClient, and enhancedAsyncClient for all requests.
S3AsyncClient s3AsyncClient =
    S3AsyncClient.builder()
    .httpClient(nettyHttpClient)
    .build();

DynamoDbAsyncClient dbAsyncClient =
    DynamoDbAsyncClient.builder()
    .httpClient(nettyHttpClient)
    .defaultsMode(DefaultsMode.IN_REGION)
    .credentialsProvider(EnvironmentVariableCredentialsProvider.create())
    .build();

DynamoDbEnhancedAsyncClient enhancedAsyncClient =
    DynamoDbEnhancedAsyncClient.builder()
    .dynamoDbClient(dbAsyncClient)
    .extensions(AutoGeneratedTimestampRecordExtension.create())
    .build();

// Perform work with s3AsyncClient, dbAsyncClient, and enhancedAsyncClient.

// Requests completed: Close all service clients.
s3AsyncClient.close();
dbAsyncClient.close();
nettyHttpClient.close(); // Explicitly close nettyHttpClient.

Proxy configuration example

The following code snippet uses the proxy configuration builder for the Netty HTTP client.

SdkAsyncHttpClient nettyHttpClient = NettyNioAsyncHttpClient.builder()
    .proxyConfiguration(ProxyConfiguration.builder()
    .scheme("https")
    .host("myproxy")
    .port(1234)
    .username("username")
    .password("password")
    .build())
    .build();
The equivalent Java system properties for the proxy configuration are shown in the following command line snippet.

```bash
$ java -Dhttps.proxyHost=myproxy -Dhttps.proxyPort=1234 -Dhttps.proxyUser=username \
-Dhttps.proxyPassword=password -cp ... App
```

⚠️ **Important**

To use any of the HTTPS proxy system properties, the scheme property must be set in code to `https`. If the scheme property is not set in code, the scheme defaults to HTTP and the SDK looks only for `http.*` system properties.

## Configure AWS CRT-based HTTP clients

The AWS CRT-based HTTP clients include the synchronous `AwsCrtHttpClient` and asynchronous `AwsCrtAsyncHttpClient`. The AWS CRT-based HTTP clients provide the following HTTP client benefits:

- Faster SDK startup time
- Smaller memory footprint
- Reduced latency time
- Connection health management
- DNS load balancing

### AWS CRT-based components in the SDK

The AWS CRT-based HTTP clients, described in this topic, and the AWS CRT-based S3 client are different components in the SDK.

The synchronous and asynchronous AWS CRT-based HTTP clients are implementations SDK HTTP client interfaces and are used for general HTTP communication. They are alternatives to the other synchronous or asynchronous HTTP clients in the SDK with additional benefits.

The AWS CRT-based S3 client is an implementation of the `S3AsyncClient` interface and is used for working with the Amazon S3 service. It is an alternative to the Java-based implementation of the S3AsyncClient interface and offers several advantages.
Although both components use libraries from the AWS Common Runtime, the AWS CRT-based HTTP clients do not use the aws-c-s3 library and do not support the S3 multipart upload API features. The AWS CRT-based S3 client, by contrast, was purpose-built to support the S3 multipart upload API features.

**Access the AWS CRT-based HTTP clients**

Before you can use the AWS CRT-based HTTP clients, add the aws-crt-client artifact with a minimum version of 2.22.0 to your project's dependencies.

The following Maven pom.xml shows the AWS CRT-based HTTP clients declared using the bill of materials (BOM) mechanism.

```xml
<project>
  <properties>
    <aws.sdk.version>2.22.0</aws.sdk.version>
  </properties>
  <dependencyManagement>
    <dependencies>
      <dependency>
        <groupId>software.amazon.awssdk</groupId>
        <artifactId>bom</artifactId>
        <version>${aws.sdk.version}</version>
        <type>pom</type>
        <scope>import</scope>
      </dependency>
    </dependencies>
  </dependencyManagement>
  <dependencies>
    <dependency>
      <groupId>software.amazon.awssdk</groupId>
      <artifactId>aws-crt-client</artifactId>
    </dependency>
  </dependencies>
</project>
```

Visit the Maven central repository for the latest version.

**Use and configure an AWS CRT-based HTTP client**

You can configure an AWS CRT-based HTTP client along with building a service client, or you can configure a single instance to share across multiple service clients.
With either approach, you use a builder to configure the properties for the AWS CRT-based HTTP client instance.

**Best practice: dedicate an instance to a service client**

If you need to configure an instance of an AWS CRT-based HTTP client, we recommend that you dedicate the instance by building it along with the service client. You can do so by using the httpClientBuilder method of the service client's builder. This way, the lifecycle of the HTTP client is managed by the SDK, which helps avoid potential memory leaks if the AWS CRT-based HTTP client instance is not closed down when it’s no longer needed.

The following example creates an S3 service client and configures an AWS CRT-based HTTP client with connectionTimeout and maxConcurrency values.

**Synchronous client**

**Imports**

```java
import software.amazon.awssdk.http.crt.AwsCrtHttpClient;
import software.amazon.awssdk.services.s3.S3Client;
import java.time.Duration;
```

**Code**

```java
// Singleton: Use s3Client for all requests.
S3Client s3Client = S3Client.builder()
    .httpClientBuilder(AwsCrtHttpClient.builder()
        .connectionTimeout(Duration.ofSeconds(3))
        .maxConcurrency(100))
    .build();

// Perform work with the s3Client.

// Requests completed: Close the s3Client.
s3Client.close();
```

**Asynchronous client**

**Imports**

```java
import software.amazon.awssdk.http.crt.AwsCrtAsyncHttpClient;
```
import software.amazon.awssdk.services.s3.S3AsyncClient;
import java.time.Duration;

Code

// Singleton: Use s3AsyncClient for all requests.
S3AsyncClient s3AsyncClient = S3AsyncClient.builder()
    .httpClientBuilder(AwsCrtAsyncHttpClient
        .builder()
        .connectionTimeout(Duration.ofSeconds(3))
        .maxConcurrency(100))
    .build();

// Perform work with the s3AsyncClient.

// Requests completed: Close the s3AsyncClient.
s3AsyncClient.close();

Alternative approach: share an instance

To help keep resource and memory usage lower for your application, you can configure an AWS
CRT-based HTTP client and share it across multiple service clients. The HTTP connection pool will
be shared, which lowers resource usage.

Note

When an AWS CRT-based HTTP client instance is shared, you must close it when it is ready
to be disposed. The SDK will not close the instance when the service client is closed.

The following example configures an AWS CRT-based HTTP client instance with
connectionTimeout and maxConcurrency values. The configured instance is passed to the
httpClient method of each service client's builder. When the service clients and the HTTP client
are no longer needed, they are explicitly closed. The HTTP client is closed last.

Synchronous client

Imports
import
  software.amazon.awssdk.auth.credentials.EnvironmentVariableCredentialsProvider;
import software.amazon.awssdk.awscore.defaultsmode.DefaultsMode;
import software.amazon.awssdk.http.SdkHttpClient;
import software.amazon.awssdk.http.crt.AwsCrtHttpClient;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.s3.S3Client;
import java.time.Duration;

Code

// Create an AwsCrtHttpClient shared instance.
SdkHttpClient crtHttpClient = AwsCrtHttpClient.builder()
  .connectionTimeout(Duration.ofSeconds(3))
  .maxConcurrency(100)
  .build();

// Singleton: Use the s3Client and dynamoDbClient for all requests.
S3Client s3Client = S3Client.builder()
  .httpClient(crtHttpClient)
  .credentialsProvider(EnvironmentVariableCredentialsProvider.create()
    .defaultsMode(DefaultsMode.IN_REGION)
    .region(Region.US_EAST_1)
  .build();

DynamoDbClient dynamoDbClient = DynamoDbClient.builder()
  .httpClient(crtHttpClient)
  .credentialsProvider(EnvironmentVariableCredentialsProvider.create()
    .defaultsMode(DefaultsMode.IN_REGION)
    .region(Region.US_EAST_1)
  .build();

// Requests completed: Close all service clients.
s3Client.close();
dynamoDbClient.close();
crtHttpClient.close();  // Explicitly close crtHttpClient.

Asynchronous client

Imports
import software.amazon.awssdk.auth.credentials.EnvironmentVariableCredentialsProvider;
import software.amazon.awssdk.awscore.defaultsmode.DefaultsMode;
import software.amazon.awssdk.http.async.SdkAsyncHttpClient;
import software.amazon.awssdk.http.crt.AwsCrtAsyncHttpClient;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.DynamoDbAsyncClient;
import software.amazon.awssdk.services.s3.S3AsyncClient;
import java.time.Duration;

Code

// Create an AwsCrtAsyncHttpClient shared instance.
SdkAsyncHttpClient crtAsyncHttpClient = AwsCrtAsyncHttpClient.builder()
    .connectionTimeout(Duration.ofSeconds(3))
    .maxConcurrency(100)
    .build();

// Singletons: Use the s3AsyncClient and dynamoDbAsyncClient for all requests.
S3AsyncClient s3AsyncClient = S3AsyncClient.builder()
    .httpClient(crtAsyncHttpClient)
    .credentialsProvider(EnvironmentVariableCredentialsProvider.create())
    .defaultsMode(DefaultsMode.IN_REGION)
    .region(Region.US_EAST_1)
    .build();

DynamoDbAsyncClient dynamoDbAsyncClient = DynamoDbAsyncClient.builder()
    .httpClient(crtAsyncHttpClient)
    .credentialsProvider(EnvironmentVariableCredentialsProvider.create())
    .defaultsMode(DefaultsMode.IN_REGION)
    .region(Region.US_EAST_1)
    .build();

// Requests completed: Close all service clients.
s3AsyncClient.close();
dynamoDbAsyncClient.close();
crtAsyncHttpClient.close();  // Explicitly close crtAsyncHttpClient.
Set an AWS CRT-based HTTP client as the default

You can setup your Maven build file to have the SDK use an AWS CRT-based HTTP client as the default HTTP client for service clients.

You do this by adding an exclusions element with the default HTTP client dependencies to each service client artifact.

In the following pom.xml example, the SDK uses an AWS CRT-based HTTP client for S3 services. If the service client in your code is an S3AsyncClient, the SDK uses AwsCrtAsyncHttpClient. If the service client is an S3Client, the SDK uses AwsCrtHttpClient. With this setup the default Netty-based asynchronous HTTP client and the default Apache-based synchronous HTTP are not available.

```
<project>
  <properties>
    <aws.sdk.version>VERSION</aws.sdk.version>
  </properties>
  <dependencies>
    <dependency>
      <groupId>software.amazon.awssdk</groupId>
      <artifactId>s3</artifactId>
      <version>${aws.sdk.version}</version>
      <exclusions>
        <exclusion>
          <groupId>software.amazon.awssdk</groupId>
          <artifactId>netty-nio-client</artifactId>
        </exclusion>
        <exclusion>
          <groupId>software.amazon.awssdk</groupId>
          <artifactId>apache-client</artifactId>
        </exclusion>
      </exclusions>
    </dependency>
    <dependency>
      <groupId>software.amazon.awssdk</groupId>
      <artifactId>aws-crt-client</artifactId>
    </dependency>
  </dependencies>
</project>
```

Visit the Maven central repository for the latest VERSION value.
Use a Java system property

To use the AWS CRT-based HTTP clients as the default HTTP for your application, you can set the Java system property `software.amazon.awssdk.http.async.service.impl` to a value of `software.amazon.awssdk.http.crt.AwsCrtSdkHttpService`.

To set during application startup, run a command similar to the following.

```
java app.jar -Dsoftware.amazon.awssdk.http.async.service.impl=\ 
software.amazon.awssdk.http.crt.AwsCrtSdkHttpService
```

Use the following code snippet to set the system property in your application code.

```
```

Note

You need to add a dependency on the `aws-crt-client` artifact in your `pom.xml` file when you use a system property to configure the use of the AWS CRT-based HTTP clients.

Advanced configuration of AWS CRT-based HTTP clients

You can use various configuration settings of the AWS CRT-based HTTP clients, including connection health configuration and maximum idle time. You can review the configuration options available for the `AwsCrtAsyncHttpClient`. You can configure the same options for the `AwsCrtHttpClient`.

Connection health configuration

You can configure connection health configuration for the AWS CRT-based HTTP clients by using the `connectionHealthConfiguration` method on the HTTP client builder.
The following example creates an S3 service client that uses a AWS CRT-based HTTP client instance configured with connection health configuration and a maximum idle time for connections.

**Synchronous client**

**Imports**

```java
import software.amazon.awssdk.http.crt.AwsCrtHttpClient;
import software.amazon.awssdk.services.s3.S3Client;
import java.time.Duration;
```

**Code**

```java
// Singleton: Use the s3Client for all requests.
S3Client s3Client = S3Client.builder()
    .httpClientBuilder(AwsCrtHttpClient
        .builder()
        .connectionHealthConfiguration(builder -> builder
            .minimumThroughputInBps(32000L)
            .minimumThroughputTimeout(Duration.ofSeconds(3)))
        .connectionMaxIdleTime(Duration.ofSeconds(5)))
    .build();

// Perform work with s3Client.

// Requests complete: Close the service client.
s3Client.close();
```

**Asynchronous client**

**Imports**

```java
import software.amazon.awssdk.http.crt.AwsCrtAsyncHttpClient;
import software.amazon.awssdk.services.s3.S3AsyncClient;
import java.time.Duration;
```

**Code**

```java
// Singleton: Use the s3AsyncClient for all requests.
S3AsyncClient s3AsyncClient = S3AsyncClient.builder()
    .httpClientBuilder(AwsCrtAsyncHttpClient

```
HTTP/2 support

The HTTP/2 protocol is not yet supported in the AWS CRT-based HTTP clients, but is planned for a future release.

In the meantime, if you are using service clients that require HTTP/2 support such as the KinesisAsyncClient or the TranscribeStreamingAsyncClient, consider using the NettyNioAsyncHttpClient instead.

Proxy configuration example

The following code snippet shows the use of the ProxyConfiguration.Builder that you use to configure proxy setting in code.

Synchronous client

Imports

```java
import software.amazon.awssdk.http.SdkHttpClient;
import software.amazon.awssdk.http.crt.AwsCrtHttpClient;
import software.amazon.awssdk.http.crt.ProxyConfiguration;
```

Code

```java
SdkHttpClient crtHttpClient = AwsCrtHttpClient.builder()
    .proxyConfiguration(ProxyConfiguration.builder()  
    .scheme("https")  
    .host("myproxy")
    .build();
```
Asynchronous client

Imports

```java
import software.amazon.awssdk.http.async.SdkAsyncHttpClient;
import software.amazon.awssdk.http.crt.AwsCrtAsyncHttpClient;
import software.amazon.awssdk.http.crt.ProxyConfiguration;
```

Code

```java
SdkAsyncHttpClient crtAsyncHttpClient = AwsCrtAsyncHttpClient.builder()
   .proxyConfiguration(ProxyConfiguration.builder()
   .scheme("https")
   .host("myproxy")
   .port(1234)
   .username("username")
   .password("password")
   .build())
   .build();
```

The equivalent Java system properties for the proxy configuration are shown in the following command line snippet.

```
$ java -Dhttps.proxyHost=myproxy -Dhttps.proxyPort=1234 -Dhttps.proxyUser=username -Dhttps.proxyPassword=password -cp ... App
```

⚠️ Important

To use any of the HTTPS proxy system properties, the `scheme` property must be set in code to `https`. If the `scheme` property is not set in code, the scheme defaults to HTTP and the SDK looks only for `http.*` system properties.
Exception handling for the AWS SDK for Java 2.x

Understanding how and when the AWS SDK for Java 2.x throws exceptions is important to building high-quality applications using the SDK. The following sections describe the different cases of exceptions that are thrown by the SDK and how to handle them appropriately.

Why unchecked exceptions?

The AWS SDK for Java uses runtime (or unchecked) exceptions instead of checked exceptions for these reasons:

- To allow developers fine-grained control over the errors they want to handle without forcing them to handle exceptional cases they aren't concerned about (and making their code overly verbose)
- To prevent scalability issues inherent with checked exceptions in large applications

In general, checked exceptions work well on small scales, but can become troublesome as applications grow and become more complex.

AwsServiceException (and subclasses)

AwsServiceException is the most common exception that you'll experience when using the AWS SDK for Java. AwsServiceException is a subclass of the more general SdkServiceException. AwsServiceExceptions represent an error response from an AWS service. For example, if you try to terminate an Amazon EC2 instance that doesn't exist, Amazon EC2 will return an error response and all the details of that error response will be included in the AwsServiceException that's thrown.

When you encounter an AwsServiceException, you know that your request was successfully sent to the AWS service but couldn't be successfully processed. This can be because of errors in the request’s parameters or because of issues on the service side.

AwsServiceException provides you with information such as:

- Returned HTTP status code
- Returned AWS error code
- Detailed error message from the service in the AwsErrorDetails class
- AWS request ID for the failed request
In most cases, a service-specific subclass of AwsServiceException is thrown to allow developers fine-grained control over handling error cases through catch blocks. The Java SDK API reference for AwsServiceException displays the large number of AwsServiceException subclasses. Use the subclass links to drill down to see the granular exceptions thrown by a service.

For example, the following links to the SDK API reference show the exception hierarchies for a few common AWS services. The list of subclasses shown on each pages shows the specific exceptions that your code can catch.

- Amazon S3
- DynamoDB
- Amazon SQS

To learn more about an exception, inspect the errorCode on the AwsErrorDetails object. You can use the errorCode value to look up information in the service guide API. For example if an S3Exception is caught and the AwsErrorDetails#errorCode() value is InvalidRequest, use the list of error codes in the Amazon S3 API Reference to see more details.

SdkClientException

SdkClientException indicates that a problem occurred inside the Java client code, either while trying to send a request to AWS or while trying to parse a response from AWS. An SdkClientException is generally more severe than an SdkServiceException, and indicates a major problem that is preventing the client from making service calls to AWS services. For example, the AWS SDK for Java throws an SdkClientException if no network connection is available when you try to call an operation on one of the clients.

Exceptions and retry behavior

The SDK for Java retries requests for several client-side exceptions and for HTTP status codes that it receives from AWS service responses. These errors are handled as part of the legacy RetryMode that service clients use by default. The Java API reference for RetryMode describes the various ways that you can configure the mode.

To customize the exceptions and HTTP status codes that trigger automatic retries, configure your service client with a RetryPolicy that adds RetryOnExceptionsCondition and RetryOnStatusCondition instances.
Logging with the SDK for Java 2.x

The AWS SDK for Java 2.x uses SLF4J, which is an abstraction layer that enables the use of any one of several logging systems at runtime.

Supported logging systems include the Java Logging Framework and Apache Log4j 2, among others. This topic shows you how to use Log4j 2 as the logging system for working with the SDK.

Log4j 2 configuration file

You typically use a configuration file, named log4j2.xml with Log4j 2. Example configuration files are shown below. To learn more about the values used in the configuration file, see the manual for Log4j configuration.

The log4j2.xml file needs to be on the classpath when your application starts up. For a Maven project, put the file in the <project-dir>/src/main/resources directory.

The log4j2.xml configuration file specifies properties such as logging level, where logging output is sent (for example, to a file or to the console), and the format of the output. The logging level specifies the level of detail that Log4j 2 outputs. Log4j 2 supports the concept of multiple logging hierarchies. The logging level is set independently for each hierarchy. The main logging hierarchy that you use with the AWS SDK for Java 2.x is software.amazon.awssdk.

Add logging dependency

To configure the Log4j 2 binding for SLF4J in your build file, use the following.

Maven

Add the following elements to your pom.xml file.

```
...  
<dependency>
  <groupId>org.apache.logging.log4j</groupId>
  <artifactId>log4j-slf4j2-impl</artifactId>
  <version>VERSION</version>
</dependency>
...  
```

Gradle–Kotlin DSL

Add the following to your build.gradle.kts file.
Use 2.20.0 for the minimum version of the log4j-slf4j2-impl artifact. For the latest version, use the version published to Maven central. Replace VERSION with version you'll use.

**SDK-specific errors and warnings**

We recommend that you always leave the "software.amazon.awssdk" logger hierarchy set to "WARN" to catch any important messages from the SDK's client libraries. For example, if the Amazon S3 client detects that your application hasn't properly closed an InputStream and could be leaking resources, the S3 client reports it through a warning message to the logs. This also ensures that messages are logged if the client has any problems handling requests or responses.

The following log4j2.xml file sets the rootLogger to "WARN", which causes warning and error-level messages from all loggers in the application to be output, including those in the "software.amazon.awssdk" hierarchy. Alternatively, you can explicitly set the "software.amazon.awssdk" logger hierarchy to "WARN" if <Root level="ERROR"> is used.

**Example Log4j2.xml configuration file**

This configuration will log messages at the "ERROR" and "WARN" levels to the console for all logger hierarchies.

```xml
<Configuration status="WARN">
  <Appenders>
    <Console name="ConsoleAppender" target="SYSTEM_OUT">
      <PatternLayout pattern="%d{YYYY-MM-dd HH:mm:ss} [%t] %-5p %c:%L - %m%n" />
    </Console>
  </Appenders>

  <Loggers>
    <Root level="WARN">
      <AppenderRef ref="ConsoleAppender"/>
    </Root>
  </Loggers>
</Configuration>
```
Request/response summary logging

Every request to an AWS service generates a unique AWS request ID that is useful if you run into an issue with how an AWS service is handling a request. AWS request IDs are accessible programmatically through `SdkServiceException` objects in the SDK for any failed service call, and can also be reported through the "DEBUG" log level of the "software.amazon.awssdk.request" logger.

The following `log4j2.xml` file enables a summary of requests and responses.

```xml
<Configuration status="WARN">
  <Appenders>
    <Console name="ConsoleAppender" target="SYSTEM_OUT">
      <PatternLayout pattern="%d{YYYY-MM-dd HH:mm:ss} [%t] %-5p %c:%L - %m%n" />
    </Console>
  </Appenders>

  <Loggers>
    <Root level="ERROR">
      <AppenderRef ref="ConsoleAppender"/>
    </Root>
    <Logger name="software.amazon.awssdk" level="WARN"/>
    <Logger name="software.amazon.awssdk.request" level="DEBUG"/>
  </Loggers>
</Configuration>
```

Here is an example of the log output:

```
2022-09-23 16:02:08 [main] DEBUG software.amazon.awssdk.request:85 - Sending Request: DefaultSdkHttpFullRequest(httpMethod=POST, protocol=https, host=dynamodb.us-east-1.amazonaws.com, encodedPath=/, headers=[amz-sdk-invocation-id, Content-Length, Content-Type, User-Agent, X-Amz-Target], queryParameters=[])
2022-09-23 16:02:08 [main] DEBUG software.amazon.awssdk.request:85 - Received successful response: 200, Request ID: QS9DUMME2NHEDH8TGT9N5V530JVV4KQNS05AEMVJF66Q9ASUAAJG, Extended Request ID: not available
```
If you are interested in only the request ID use `<Logger name="software.amazon.awssdk.requestId" level="DEBUG" />`.

**Verbose wire logging**

It can be useful to see the exact requests and responses that the SDK for Java 2.x sends and receives. If you need access to this information, you can temporarily enable it by adding the necessary configuration depending on the HTTP client the service client uses.

By default, synchronous service clients, such as the `S3Client`, use an underlying Apache HttpClient, and asynchronous service clients, such as the `S3AsyncClient`, use a Netty non-blocking HTTP client.

Here is a breakdown of HTTP clients you can use for the two categories of service clients:

<table>
<thead>
<tr>
<th>Synchronous HTTP Clients</th>
<th>Asynchronous HTTP Clients</th>
</tr>
</thead>
<tbody>
<tr>
<td>ApacheHttpClient (default)</td>
<td>NettyNioAsyncHttpClient (default)</td>
</tr>
<tr>
<td>UrlConnectionHttpClient</td>
<td>AwsCrtAsyncHttpClient</td>
</tr>
</tbody>
</table>

Consult the appropriate tab below for configuration settings you need to add depending on the underlying HTTP client.

⚠️ **Warning**

We recommend you only use wire logging for debugging purposes. Disable it in your production environments because it can log sensitive data. It logs the full request or response without encryption, even for an HTTPS call. For large requests (e.g., to upload a file to Amazon S3) or responses, verbose wire logging can also significantly impact your application’s performance.

**ApacheHttpClient**

Add the "org.apache.http.wire" logger to the `log4j2.xml` configuration file and set the level to "DEBUG".

The following `log4j2.xml` file turns on full wire logging for the Apache HttpClient.
An additional Maven dependency on the log4j-1.2-api artifact is required for wire logging with Apache since it uses 1.2 under the hood.

The full set of Maven dependencies for log4j 2, including wire logging for the Apache HTTP client are shown in the following build file snippets.

**Maven**

```xml
<dependencyManagement>
  ...
  <dependencies>
    <dependency>
      <groupId>org.apache.logging.log4j</groupId>
      <artifactId>log4j-bom</artifactId>
      <version>VERSION</version>
      <type>pom</type>
      <scope>import</scope>
    </dependency>
  </dependencies>
</dependencyManagement>

<!-- The following is needed for Log4j2 with SLF4J -->
<dependency>
  <groupId>org.apache.logging.log4j</groupId>
  <artifactId>log4j-slf4j2-impl</artifactId>
```
Gradle–Kotlin DSL

... dependencies {
  ... implementation(platform("org.apache.logging.log4j:log4j-bom:VERSION"))
  implementation("org.apache.logging.log4j:log4j-slf4j2-impl")
  implementation("org.apache.logging.log4j:log4j-1.2-api")
}
...

Use 2.20.0 for the minimum version of the log4j-bom artifact. For the latest version, use the version published to Maven central. Replace VERSION with version you'll use.

UrlConnectionHttpClient

To log details for service clients that use the UrlConnectionHttpClient, first create a logging.properties file with the following contents:

handlers=java.util.logging.ConsoleHandler
java.util.logging.ConsoleHandler.level=FINEST

Set the following JVM system property with the full path of the logging.properties:

-Djava.util.logging.config.file=/full/path/to/logging.properties

This configuration will log the only the headers of the request and response, for example:

<Request> FINE: sun.net.www.MessageHeader@35a9782c11 pairs: {GET /fileuploadtest HTTP/1.1: null}{amz-sdk-invocation-id: 5f7e707e-4ac5-bef5-ba62-00d71034ffdc}{amz-sdk-request: attempt=1; max=4}{Authorization: AWS4-HMAC-SHA256 Credential=<deleted>/20220927/us-east-1/s3/aws4_request, SignedHeaders=amz-sdk-
To see the request/response bodies, add `-Djavax.net.debug=all` to the JVM properties. This additional property logs a great deal of information, including all SSL information.

Within the log console or log file, search for "GET" or "POST" to quickly go to the section of the log containing actual requests and responses. Search for "Plaintext before ENCRYPTION" for requests and "Plaintext after DECRYPTION" for responses to see the full text of the headers and bodies.

NettyNioAsyncHttpClient

If your asynchronous service client uses the default NettyNioAsyncHttpClient, add two additional loggers to your `log4j2.xml` file to log HTTP headers and request/response bodies.

Here is a complete `log4j2.xml` example:

```
<Configuration status="WARN">
  <Appenders>
    <Console name="ConsoleAppender" target="SYSTEM_OUT">
      <PatternLayout pattern="%d{YYYY-MM-dd HH:mm:ss} [%t] %-5p %c:%L - %m%n" />
    </Console>
  </Appenders>
  <Loggers>
    <Root level="WARN">
      <AppenderRef ref="ConsoleAppender" />
    </Root>
  </Loggers>
</Configuration>
```
These settings log all header details and request/response bodies.

**AwsCrtAsyncHttpClient**

If you have configured your service client to use an instance of AwsCrtAsyncHttpClient, you can log details by setting JVM system properties or programmatically.

### Log to a file at "Debug" level

<table>
<thead>
<tr>
<th>Using system properties</th>
<th>Programmatically</th>
</tr>
</thead>
</table>
| -Daws.crt.log.level=Trace  
-Daws.crt.log.destination=File  
-Daws.crt.log.filename=<path to file> | import software.amazon.awssdk.crt.Log;  
// Execute this statement before constructing the SDK service client.  
Log.initLoggingToFile(Log.LogLevel.Trace, "<path to file>"); |

### Log to the console at "Debug" level

<table>
<thead>
<tr>
<th>Using system properties</th>
<th>Programmatically</th>
</tr>
</thead>
</table>
| -Daws.crt.log.level=Trace  
-Daws.crt.log.destination=Stdout | import software.amazon.awssdk.crt.Log;  
// Execute this statement before constructing the SDK service client.  
Log.initLoggingToStdout(Log.LogLevel.Trace); |

For security reasons, at the "Trace" level the AwsCrtAsyncHttpClient logs only response headers. Request headers, request bodies, and response bodies are not logged.
Set the JVM TTL for DNS name lookups

The Java virtual machine (JVM) caches DNS name lookups. When the JVM resolves a hostname to an IP address, it caches the IP address for a specified period of time, known as the time-to-live (TTL).

Because AWS resources use DNS name entries that occasionally change, we recommend that you configure your JVM with a TTL value of no more than 60 seconds. This ensures that when a resource's IP address changes, your application will be able to receive and use the resource's new IP address by requerying the DNS.

On some Java configurations, the JVM default TTL is set so that it will never refresh DNS entries until the JVM is restarted. Thus, if the IP address for an AWS resource changes while your application is still running, it won’t be able to use that resource until you manually restart the JVM and the cached IP information is refreshed. In this case, it’s crucial to set the JVM’s TTL so that it will periodically refresh its cached IP information.

Note

The default TTL can vary according to the version of your JVM and whether a security manager is installed. Many JVMs provide a default TTL less than 60 seconds. If you’re using such a JVM and not using a security manager, you can ignore the remainder of this topic.

How to set the JVM TTL

To modify the JVM’s TTL, set the networkaddress.cache.ttl property value. Use one of the following methods, depending on your needs:

• globally, for all applications that use the JVM. Set networkaddress.cache.ttl in the $JAVA_HOME/jre/lib/security/java.security file:

```
networkaddress.cache.ttl=60
```

• for your application only, set networkaddress.cache.ttl in your application’s initialization code:

```
java.security.Security.setProperty("networkaddress.cache.ttl" , "60");
```
Best practices for AWS SDK for Java 2.x

This section lists best practices for using the SDK for Java 2.x.

Topics

- Reuse an SDK client, if possible
- Close input streams from client operations
- Tune HTTP configurations based on performance tests
- Use OpenSSL for the Netty-based HTTP client
- Configure API timeouts
- Use metrics

Reuse an SDK client, if possible

Each SDK client maintains its own HTTP connection pool. A connection that already exists in the pool can be reused by a new request to cut down the time to establish a new connection. We recommend sharing a single instance of the client to avoid the overhead of having too many connection pools that aren't used effectively. All SDK clients are thread safe.

If you don't want to share a client instance, call `close()` on the instance to release the resources when the client is not needed.

Close input streams from client operations

For streaming operations such as `S3Client#getObject`, if you are working with `ResponseInputStream` directly, we recommend that you do the following:

- Read all the data from the input stream as soon as possible.
- Close the input stream as soon as possible.

We make these recommendations because the input stream is a direct stream of data from the HTTP connection and the underlying HTTP connection can't be reused until all data from the stream has been read and the stream is closed. If these rules are not followed, the client can run out of resources by allocating too many open, but unused, HTTP connections.
Tune HTTP configurations based on performance tests

The SDK provides a set of default http configurations that apply to general use cases. We recommend that customers tune HTTP configurations for their applications based on their use cases.

As a good starting point, the SDK offers a smart configuration defaults feature. This feature is available starting with version 2.17.102. You choose a mode depending on your use case, which provides sensible configuration values.

Use OpenSSL for the Netty-based HTTP client

By default, the SDK's NettyNioAsyncHttpClient uses the JDK's default SSL implementation as the SslProvider. Our testing found that OpenSSL performs better than JDK's default implementation. The Netty community also recommends using OpenSSL.

To use OpenSSL, add netty-tcnative to your dependencies. For configuration details, see the Netty project documentation.

After you have netty-tcnative configured for your project, the NettyNioAsyncHttpClient instance will automatically select OpenSSL. Alternatively, you can set the SslProvider explicitly using the NettyNioAsyncHttpClient builder as shown in the following snippet.

```java
NettyNioAsyncHttpClient.builder()
    .sslProvider(SslProvider.OPENSSL)
    .build();
```

Configure API timeouts

The SDK provides default values for some timeout options, such as connection timeout and socket timeouts, but not for API call timeouts or individual API call attempt timeouts. It is a good practice to set timeouts for both the individual attempts and the entire request. This will ensure your application fails fast in an optimal way when there are transient issues that could cause request attempts to take longer to complete or fatal network issues.

You can configure timeouts for all requests made by a service clients using ClientOverrideConfiguration#apiCallAttemptTimeout and ClientOverrideConfiguration#apiCallTimeout.
The following example shows the configuration of an Amazon S3 client with custom timeout values.

```java
S3Client.builder()
    .overrideConfiguration(
        b -> b.apiCallTimeout(Duration.ofSeconds(<custom value>))
            .apiCallAttemptTimeout(Duration.ofMillis(<custom value>)))
    .build();
```

**apiCallAttemptTimeout**

This setting sets the amount of time for a single HTTP attempt, after which the API call can be retried.

**apiCallTimeout**

The value for this property configures the amount of time for the entire execution, including all retry attempts.

As an alternative to setting these timeout values on the service client, you can use `RequestOverrideConfiguration#apiCallTimeout()` and `RequestOverrideConfiguration#apiCallAttemptTimeout()` to configure a single request.

The following example configures a single `listBuckets` request with custom timeout values.

```java
s3Client.listBuckets(lbr -> lbr.overrideConfiguration(
    b -> b.apiCallTimeout(Duration.ofSeconds(<custom value>))
        .apiCallAttemptTimeout(Duration.ofMillis(<custom value>))));
```

When you use these properties together, you set a hard limit on the total time spent on all attempts across retries. You also set an individual HTTP request to fail fast on a slow request.

**Use metrics**

The SDK for Java can collect metrics for the service clients in your application. You can use these metrics to identify performance issues, review overall usage trends, review service client exceptions returned, or to dig in to understand a particular issue.

We recommend that you collect metrics, then analyze the Amazon CloudWatch Logs, in order to gain a deeper understanding of your application’s performance.
Use features of the AWS SDK for Java 2.x

General features

The SDK for Java 2.x contains several features that make programming against AWS services easier.

- The SDK hides the complex mechanisms behind retrieving paginated results and polling for resources.
- Asynchronous programming with non-blocking I/O helps you write concurrent code with better performance. The SDK provides the benefits of HTTP/2, such as reduced latency, where possible.
- The Java SDK can generate metrics to help you monitor the operational health of your applications.

Service-specific features

In addition to the general features mentioned previously, the Java SDK provides features for specific AWS services.

- Amazon S3 – To simplify your work with files and directories with Amazon S3, the SDK provides the S3 Transfer Manager. To improve performance and reliability while using the SDK’s standard asynchronous S3 API, the SDK offers the AWS CRT-based S3 client.
- DynamoDB – Object-oriented, mapping capability is provided by the DynamoDB Enhanced Client API. Work with JSON-style, document-oriented data by using the Enhanced Document API.
- IAM – The IAM Policy Builder API provides a type-safe, object-oriented way to create IAM policies.

Work with paginated results using the AWS SDK for Java 2.x

Many AWS operations return paginated results when the response object is too large to return in a single response. In the AWS SDK for Java 1.0, the response contains a token you use to retrieve the next page of results. In contrast, the AWS SDK for Java 2.x has autopagination methods that make multiple service calls to get the next page of results for you automatically. You only have to write code that processes the results. Autopagination is available for both synchronous and asynchronous clients.
**Synchronous pagination**

The following examples demonstrate synchronous pagination methods to list objects in an Amazon S3 bucket.

**Iterate over pages**

The first example demonstrates the use of a `listRes` paginator object, a `ListObjectsV2Iterable` instance, to iterate through all the response pages with the `stream` method. The code streams over the response pages, converts the response stream to a stream of `S3Object` content, and then processes the content of the Amazon S3 object.

The following imports apply to all examples in this synchronous pagination section.

**Imports**

```java
import java.io.IOException;
import java.nio.ByteBuffer;
import java.util.Random;
import software.amazon.awssdk.core.waiters.WaiterResponse;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.paginators.ListObjectsV2Iterable;
import software.amazon.awssdk.core.sync.RequestBody;
import software.amazon.awssdk.services.s3.model.S3Exception;
import software.amazon.awssdk.services.s3.model.PutObjectRequest;
import software.amazon.awssdk.services.s3.model.ListObjectsV2Request;
import software.amazon.awssdk.services.s3.model.ListObjectsV2Response;
import software.amazon.awssdk.services.s3.model.S3Object;
import software.amazon.awssdk.services.s3.model.GetObjectRequest;
import software.amazon.awssdk.services.s3.model.DeleteObjectRequest;
import software.amazon.awssdk.services.s3.model.DeleteBucketRequest;
import software.amazon.awssdk.services.s3.model.CreateMultipartUploadRequest;
import software.amazon.awssdk.services.s3.model.CreateMultipartUploadResponse;
import software.amazon.awssdk.services.s3.model.CompletedMultipartUpload;
```
import software.amazon.awssdk.services.s3.model.CreateBucketRequest;
import software.amazon.awssdk.services.s3.model.CompletedPart;
import software.amazon.awssdk.services.s3.model.CreateBucketConfiguration;
import software.amazon.awssdk.services.s3.model.UploadPartRequest;
import software.amazon.awssdk.services.s3.model.CompleteMultipartUploadRequest;
import software.amazon.awssdk.services.s3.waiters.S3Waiter;
import software.amazon.awssdk.services.s3.model.HeadBucketRequest;
import software.amazon.awssdk.services.s3.model.HeadBucketResponse;

ListObjectsV2Request listReq = ListObjectsV2Request.builder()
    .bucket(bucketName)
    .maxKeys(1)
    .build();

ListObjectsV2Iterable listRes = s3.listObjectsV2Paginator(listReq);
// Process response pages
listRes.stream()
    .flatMap(r -> r.contents().stream())
    .forEach(content -> System.out
        .println(" Key: " + content.key() + " size = " + content.size()));

See the [complete example](https://github.com/aws/aws-sdk-java) on GitHub.

## Iterate over objects

The following examples show ways to iterate over the objects returned in the response instead of the pages of the response. The `contents` method of `ListObjectsV2Iterable` class returns an `SdkIterable` that provides several methods to process the underlying content elements.

### Use a stream

The following snippet uses the `stream` method on the response content to iterate over the paginated item collection.

```java
// Helper method to work with paginated collection of items directly.
listRes.contents().stream()
    .forEach(content -> System.out
        .println(" Key: " + content.key() + " size = " + content.size()));
```

---

**Synchronous pagination**

115
See the [complete example](https://github.com) on GitHub.

### Use a for-each loop

Since `SdkIterable` extends the `Iterable` interface, you can process the contents like any `Iterable`. The following snippet uses standard `for-each` loop to iterate through the contents of the response.

```java
for (S3Object content : listRes.contents()) {
    System.out.println(" Key: " + content.key() + " size = " + content.size());
}
```

See the [complete example](https://github.com) on GitHub.

### Manual pagination

If your use case requires it, manual pagination is still available. Use the next token in the response object for the subsequent requests. The following example uses a while loop.

```java
ListObjectsV2Request listObjectsReqManual =
    ListObjectsV2Request.builder()
        .bucket(bucketName)
        .maxKeys(1)
        .build();

boolean done = false;
while (!done) {
    ListObjectsV2Response listObjResponse = s3.listObjectsV2(listObjectsReqManual);
    for (S3Object content : listObjResponse.contents()) {
        System.out.println(content.key());
    }
    if (listObjResponse.nextContinuationToken() == null) {
        done = true;
    }
    listObjectsReqManual = listObjectsReqManual.toBuilder()
        .continuationToken(listObjResponse.nextContinuationToken())
        .build();
}
```

Synchronous pagination
Asynchronous pagination

The following examples demonstrate asynchronous pagination methods to list DynamoDB tables.

Iterate over pages of table names

The following two examples use an asynchronous DynamoDB client that call the listTablesPaginator method with a request to get a ListTablesPublisher. ListTablesPublisher implements two interfaces, which provides many options to process responses. We'll look at methods of each interface.

Use a Subscriber

The following code example demonstrates how to process paginated results by using the org.reactivestreams.Publisher interface implemented by ListTablesPublisher. To learn more about the reactive streams model, see the Reactive Streams GitHub repo.

The following imports apply to all examples in this asynchronous pagination section.

Imports

```java
import io.reactivex.rxjava3.core.Flowable;
import org.reactivestreams.Subscriber;
import org.reactivestreams.Subscription;
import reactor.core.publisher.Flux;
import software.amazon.awssdk.core.async.SdkPublisher;
import software.amazon.awssdk.services.dynamodb.DynamoDbAsyncClient;
import software.amazon.awssdk.services.dynamodb.model.ListTablesRequest;
import software.amazon.awssdk.services.dynamodb.model.ListTablesResponse;
import software.amazon.awssdk.services.dynamodb.paginators.ListTablesPublisher;
import java.util.List;
import java.util.concurrent.CompletableFuture;
import java.util.concurrent.ExecutionException;
```

The following code acquires a ListTablesPublisher instance.

```java
// Creates a default client with credentials and region loaded from the
```
final DynamoDbAsyncClient asyncClient = DynamoDbAsyncClient.create();

ListTablesRequest listTablesRequest = ListTablesRequest.builder().limit(3).build();
ListTablesPublisher publisher = asyncClient.listTablesPaginator(listTablesRequest);

The following code uses an anonymous implementation of org.reactivestreams.Subscriber to process the results for each page.

The `onSubscribe` method calls the `Subscription.request` method to initiate requests for data from the publisher. This method must be called to start getting data from the publisher.

The subscriber's `onNext` method processes a response page by accessing all the table names and printing out each one. After the page is processed, another page is requested from the publisher. This method that is called repeatedly until all pages are retrieved.

The `onError` method is triggered if an error occurs while retrieving data. Finally, the `onComplete` method is called when all pages have been requested.

// A Subscription represents a one-to-one life-cycle of a Subscriber subscribing
// to a Publisher.
publisher.subscribe(new Subscriber<ListTablesResponse>() {
    // Maintain a reference to the subscription object, which is required to request
    // data from the publisher.
    private Subscription subscription;

    @Override
    public void onSubscribe(Subscription s) {
        subscription = s;
        // Request method should be called to demand data. Here we request a single
        // page.
        subscription.request(1);
    }

    @Override
    public void onNext(ListTablesResponse response) {
        response.tableNames().forEach(System.out::println);
    }
});
// After you process the current page, call the request method to
// signal that
// you are ready for next page.
subscription.request(1);
}

@Override
public void onError(Throwable t) {
    // Called when an error has occurred while processing the requests.
}

@Override
public void onComplete() {
    // This indicates all the results are delivered and there are no more
    // pages left.
}
});

See the complete example on GitHub.

Use a Consumer

The SdkPublisher interface that ListTablesPublisher implements has a subscribe method
that takes a Consumer and returns a CompletableFuture<Void>.

The subscribe method from this interface can be used for simple use cases when an
org.reactivestreams.Subscriber might be too much overhead. As the code below consumes
each page, it calls the tableNames method on each. The tableNames method returns a
java.util.List of DynamoDB table names that are processed with the forEach method.

    // Use a Consumer for simple use cases.
    CompletableFuture<Void> future = publisher.subscribe(
        response -> response.tableNames()
            .forEach(System.out::println));

See the complete example on GitHub.

Iterate over table names

The following examples show ways to iterate over the objects returned in the response instead of
the pages of the response. Similar to the synchronous Amazon S3 example previously shown with
its contents method, the DynamoDB asynchronous result class, ListTablesPublisher has the tableNames convenience method to interact with the underlying item collection. The return type of the tableNames method is an SdkPublisher that can be used to request items across all pages.

**Use a Subscriber**

The following code acquires an SdkPublisher of the underlying collection of table names.

```java
// Create a default client with credentials and region loaded from the
// environment.
final DynamoDbAsyncClient asyncClient = DynamoDbAsyncClient.create();

ListTablesRequest listTablesRequest =
ListTablesRequest.builder().limit(3).build();
ListTablesPublisher listTablesPublisher =
asyncClient.listTablesPaginator(listTablesRequest);
SdkPublisher<String> publisher = listTablesPublisher.tableNames();
```

The following code uses an anonymous implementation of org.reactivestreams.Subscriber to process the results for each page.

The subscriber's onNext method processes an individual element of the collection. In this case, it's a table name. After the table name is processed, another table name is requested from the publisher. This method that is called repeatedly until all table names are retrieved.

```java
// Use a Subscriber.
publisher.subscribe(new Subscriber<String>() {
    private Subscription subscription;

    @Override
    public void onSubscribe(Subscription s) {
        subscription = s;
        subscription.request(1);
    }

    @Override
    public void onNext(String tableName) {
        System.out.println(tableName);
        subscription.request(1);
    }
```
```java
@Override
public void onError(Throwable t) {
}

@Override
public void onComplete() {
}
```
DynamoDbAsyncClient asyncClient = DynamoDbAsyncClient.create();
ListTablesPublisher publisher =
asyncClient.listTablesPaginator(ListTablesRequest.builder()
  .build());

// The Flowable class has many helper methods that work with
// an implementation of an org.reactivestreams.Publisher.
List<String> tables = Flowable.fromPublisher(publisher)
  .flatMapIterable(ListTablesResponse::tableNames)
  .toList();
System.out.println(tables);

See the [complete example](https://github.com/aws/aws-sdk-java-v2) on GitHub.

## Poll for resource states in the AWS SDK for Java 2.x: Waiters

The waiters utility of the AWS SDK for Java 2.x enables you to validate that AWS resources are in a specified state before performing operations on those resources.

A **waiter** is an abstraction used to poll AWS resources, such as DynamoDB tables or Amazon S3 buckets, until a desired state is reached (or until a determination is made that the resource won’t ever reach the desired state). Instead of writing logic to continuously poll your AWS resources, which can be cumbersome and error-prone, you can use waiters to poll a resource and have your code continue to run after the resource is ready.

### Prerequisites

Before you can use waiters in a project with the AWS SDK for Java, you must complete the steps in [Setting up the AWS SDK for Java 2.x](https://docs.aws.amazon.com/sdk-for-java/v1/developer-guide/setup.html).

You must also configure your project dependencies (for example, in your `pom.xml` or `build.gradle` file) to use version 2.15.0 or later of the AWS SDK for Java.

For example:

```xml
<project>
  <dependencyManagement>
    <dependencies>
      <dependency>
        <groupId>com.amazonaws</groupId>
        <artifactId>aws-sdk-java-v2</artifactId>
        <version>2.15.0</version>
      </dependency>
    </dependencies>
  </dependencyManagement>
</project>
```
Using waiters

To instantiate a waiters object, first create a service client. Set the service client’s `waiter()` method as the value of the waiter object. Once the waiter instance exists, set its response options to execute the appropriate code.

**Synchronous programming**

The following code snippet shows how to wait for a DynamoDB table to exist and be in an **ACTIVE** state.

```java
DynamoDbClient dynamo = DynamoDbClient.create();
DynamoDbWaiter waiter = dynamo.waiter();

WaiterResponse<DescribeTableResponse> waiterResponse =
    waiter.waitUntilTableExists(r -> r.tableName("myTable"));

// print out the matched response with a tableStatus of ACTIVE
waiterResponse.matched().response().ifPresent(System.out::println);
```

**Asynchronous programming**

The following code snippet shows how to wait for a DynamoDB table to no longer exist.

```java
DynamoDbAsyncClient asyncDynamo = DynamoDbAsyncClient.create();
DynamoDbAsyncWaiter asyncWaiter = asyncDynamo.waiter();

CompletableFuture<WaiterResponse<DescribeTableResponse>> waiterResponse =
    asyncWaiter.waitUntilTableNotExists(r -> r.tableName("myTable"));
```
Configure waiters

You can customize the configuration for a waiter by using the `overrideConfiguration()` on its builder. For some operations, you can apply a custom configuration when you make the request.

Configure a waiter

The following code snippet shows how to override the configuration on a waiter.

```java
// sync
DynamoDbWaiter waiter =
    DynamoDbWaiter.builder()
    .overrideConfiguration(b -> b.maxAttempts(10))
    .client(dynamoDbClient)
    .build();

// async
DynamoDbAsyncWaiter asyncWaiter =
    DynamoDbAsyncWaiter.builder()
    .client(dynamoDbAsyncClient)
    .overrideConfiguration(o -> o.backoffStrategy(
        FixedDelayBackoffStrategy.create(Duration.ofSeconds(2))))
    .scheduledExecutorService(Executors.newScheduledThreadPool(3))
    .build();
```

Override configuration for a specific request

The following code snippet shows how to override the configuration for a waiter on a per-request basis. Note that only some operations have customizable configurations.

```java
waiter.waitUntilTableNotExists(b -> b.tableName("myTable"),
    o -> o.maxAttempts(10));

asyncWaiter.waitUntilTableExists(b -> b.tableName("myTable"),
    o -> o.waitTimeout(Duration.ofMinutes(1)));"
Code examples

For a complete example using waiters with DynamoDB, see CreateTable.java in the AWS Code Examples Repository.

For a complete example using waiters with Amazon S3, see S3BucketOps.java in the AWS Code Examples Repository.

Use asynchronous programming

The AWS SDK for Java 2.x features asynchronous clients with non-blocking I/O support that implement high concurrency across a few threads. However, total non-blocking I/O is not guaranteed. Asynchronous client may perform blocking calls in some cases such as credential retrieval, request signing using AWS Signature Version 4 (SigV4), or endpoint discovery.

Synchronous methods block your thread's execution until the client receives a response from the service. Asynchronous methods return immediately, giving control back to the calling thread without waiting for a response.

Because an asynchronous method returns before a response is available, you need a way to get the response when it's ready. The methods for asynchronous client in 2.x of the AWS SDK for Java return CompletableFuture objects that allow you to access the response when it's ready.

Non-streaming operations

For non-streaming operations, asynchronous method calls are similar to synchronous methods. However, the asynchronous methods in the AWS SDK for Java return a CompletableFuture object that contains the results of the asynchronous operation in the future.

Call the CompletableFuture whenComplete() method with an action to complete when the result is available. CompletableFuture implements the Future interface, so you can also get the response object by calling the get() method.

The following is an example of an asynchronous operation that calls a Amazon DynamoDB function to get a list of tables, receiving a CompletableFuture that can hold a ListTablesResponse object. The action defined in the call to whenComplete() is done only when the asynchronous call is complete.

Imports
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.DynamoDbAsyncClient;
import software.amazon.awssdk.services.dynamodb.model.ListTablesRequest;
import software.amazon.awssdk.services.dynamodb.model.ListTablesResponse;
import java.util.List;
import java.util.concurrent.CompletableFuture;

Code

class DynamoDBAsyncListTables {

    public static void main(String[] args) throws InterruptedException {

        // Create the DynamoDbAsyncClient object
        Region region = Region.US_EAST_1;
        DynamoDbAsyncClient client = DynamoDbAsyncClient.builder()
            .region(region)
            .build();

        listTables(client);
    }

    public static void listTables(DynamoDbAsyncClient client) {

        CompletableFuture<ListTablesResponse> response =
            client.listTables(ListTablesRequest.builder()
                .build());

        // Map the response to another CompletableFuture containing just the table names
        CompletableFuture<List<String>> tableNames =
            response.thenApply(ListTablesResponse::tableNames);

        // When future is complete (either successfully or in error) handle the response
        tableNames.whenComplete((tables, err) -> {
            try {
                if (tables != null) {
                    tables.forEach(System.out::println);
                } else {
                    // Handle error
                    err.printStackTrace();
                }
        } catch (Exception e) {
            e.printStackTrace();
        }
    }
}

Non-streaming operations
The following code example shows you how to retrieve an Item from a table by using the Asynchronous client. Invoke the getItem method of the DynamoDbAsyncClient and pass it a GetItemRequest object with the table name and primary key value of the item you want. This is typically how you pass data that the operation requires. In this example, notice that a String value is passed.

**Imports**

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.model.GetItemRequest;
import software.amazon.awssdk.services.dynamodb.model.AttributeValue;
import software.amazon.awssdk.services.dynamodb.DynamoDbAsyncClient;
import java.util.HashMap;
import java.util.Map;
import java.util.Set;
import java.util.stream.Collectors;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
```

**Code**

```java
public static void getItem(DynamoDbAsyncClient client, String tableName, String key, String keyVal) {

    HashMap<String, AttributeValue> keyToGet =
        new HashMap<String, AttributeValue>();

    keyToGet.put(key, AttributeValue.builder()
        .s(keyVal).build());

    try {
        // Create a GetItemRequest instance
```
GetItemRequest request = GetItemRequest.builder()
    .key(keyToGet)
    .tableName(tableName)
    .build();

    // Invoke the DynamoDbAsyncClient object's getItem
    java.util.Collection<AttributeValue> returnedItem =
    client.getItem(request).join().item().values();

    // Convert Set to Map
    Map<String, AttributeValue> map =
    returnedItem.stream().collect(Collectors.toMap(AttributeValue::s, s->s));
    Set<String> keys = map.keySet();
    for (String sinKey : keys) {
        System.out.format("%s: %s\n", sinKey, map.get(sinKey).toString());
    }
} catch (DynamoDbException e) {
    System.err.println(e.getMessage());
    System.exit(1);
}

See the [complete example](https://github.com/aws/aws-sdk-java) on GitHub.

### Streaming operations

For streaming operations, you must provide an [AsyncRequestBody](https://docs.aws.amazon.com/AWSJavaSDK/latest/api/software/amazon/awssdk/core/async/AsyncRequestBody.html) to provide the content incrementally, or an [AsyncResponseTransformer](https://docs.aws.amazon.com/AWSJavaSDK/latest/api/software/amazon/awssdk/core/async/AsyncResponseTransformer.html) to receive and process the response.

The following example uploads a file to Amazon S3 asynchronously by using the PutObject operation.

#### Imports

```java
import software.amazon.awssdk.core.async.AsyncRequestBody;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.S3AsyncClient;
import software.amazon.awssdk.services.s3.model.PutObjectRequest;
import software.amazon.awssdk.services.s3.model.PutObjectResponse;
import java.nio.file.Paths;
import java.util.concurrent.CompletableFuture;
```

#### Code

```java
code
```
public class S3AsyncOps {

    public static void main(String[] args) {

        final String USAGE = "\n" +
            "Usage:\n" +
            "   S3AsyncOps <bucketName> <key> <path>\n" +
            "   Where:\n" +
            "     bucketName - the name of the Amazon S3 bucket (for example, 
bucket1). \n" +
            "     key - the name of the object (for example, book.pdf). \n" +
            "     path - the local path to the file (for example, C:/AWS/book.pdf). \n";

        if (args.length != 3) {
            System.out.println(USAGE);
            System.exit(1);
        }

        String bucketName = args[0];
        String key = args[1];
        String path = args[2];

        Region region = Region.US_WEST_2;
        S3AsyncClient client = S3AsyncClient.builder()
            .region(region)
            .build();

        PutObjectRequest objectRequest = PutObjectRequest.builder()
            .bucket(bucketName)
            .key(key)
            .build();

        // Put the object into the bucket
CompletableFuture<PutObjectResponse> future = client.putObject(objectRequest, AsyncRequestBody.fromFile(Paths.get(path)));
future.whenComplete((resp, err) -> {
  try {
    if (resp != null) {
      System.out.println("Object uploaded. Details: " + resp);
    } else {
      // Handle error
      err.printStackTrace();
    }
  } finally {
    // Only close the client when you are completely done with it
    client.close();
  }
});
future.join();
}

The following example gets a file from Amazon S3 asynchronously by using the GetObject operation.

Imports

```java
import software.amazon.awssdk.core.async.AsyncResponseTransformer;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.S3AsyncClient;
import software.amazon.awssdk.services.s3.model.GetObjectRequest;
import software.amazon.awssdk.services.s3.model.GetObjectResponse;
import java.nio.file.Paths;
import java.util.concurrent.CompletableFuture;
```

Code

```java
/**
 * To run this AWS code example, ensure that you have setup your development environment, including your AWS credentials.
 * 
 * For information, see this documentation topic:
 * 
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
```
public class S3AsyncStreamOps {

    public static void main(String[] args) {

        final String USAGE = "\n" +
            "Usage:\n" +
            " S3AsyncStreamOps <bucketName> <objectKey> <path>\n" +
            "Where:\n" +
            " bucketName - the name of the Amazon S3 bucket (for example, bucket1). \n" +
            " objectKey - the name of the object (for example, book.pdf). \n" +
            " path - the local path to the file (for example, C:/AWS/book.pdf). \n" ;

        if (args.length != 3) {
            System.out.println(USAGE);
            System.exit(1);
        }

        String bucketName = args[0];
        String objectKey = args[1];
        String path = args[2];

        Region region = Region.US_WEST_2;
        S3AsyncClient client = S3AsyncClient.builder()
            .region(region)
            .build();

        GetObjectRequest objectRequest = GetObjectRequest.builder()
            .bucket(bucketName)
            .key(objectKey)
            .build();

        CompletableFuture<GetObjectResponse> futureGet =
            client.getObject(objectRequest,
                AsyncResponseTransformer.toFile(Paths.get(path)));

        futureGet.whenComplete((resp, err) -> {
            try {
                if (resp != null) {
                    System.out.println("Object downloaded. Details: "+resp);
                } else {

                }

            } catch (Exception e) {
                e.printStackTrace();
            }
        });
    }
}
Advanced operations

The AWS SDK for Java 2.x uses Netty, an asynchronous event-driven network application framework, to handle I/O threads. The AWS SDK for Java 2.x creates an ExecutorService behind Netty, to complete the futures returned from the HTTP client request through to the Netty client. This abstraction reduces the risk of an application breaking the async process if developers choose to stop or sleep threads. By default, each asynchronous client creates a threadpool based on the number of processors and manages the tasks in a queue within the ExecutorService.

Advanced users can specify their thread pool size when creating an asynchronous client using the following option when building.

Code

```java
S3AsyncClient clientThread = S3AsyncClient.builder()
  .asyncConfiguration(
    b -> b.advancedOption(SdkAdvancedAsyncClientOption.FUTURE_COMPLETION_EXECUTOR,
      Executors.newFixedThreadPool(10)
    )
  )
  .build();
```

To optimize performance, you can manage your own thread pool executor, and include it when configuring your client.

```java
ThreadPoolExecutor executor = new ThreadPoolExecutor(50, 50,
  10, TimeUnit.SECONDS,
  new LinkedBlockingQueue<>(<custom_value>),
  new ThreadFactoryBuilder()
    .threadNamePrefix("sdk-async-response").build());
```
// Allow idle core threads to time out
executor.allowCoreThreadTimeOut(true);

S3AsyncClient clientThread = S3AsyncClient.builder()
    .asyncConfiguration(b -> b.advancedOption(SdkAdvancedAsyncClientOption
        .FUTURE_COMPLETION_EXECUTOR,
        executor)
    )
    .build();

Work with HTTP/2 in the AWS SDK for Java

HTTP/2 is a major revision of the HTTP protocol. This new version has several enhancements to improve performance:

- Binary data encoding provides more efficient data transfer.
- Header compression reduces the overhead bytes downloaded by the client, helping get the content to the client sooner. This is especially useful for mobile clients that are already constrained on bandwidth.
- Bidirectional asynchronous communication (multiplexing) allows multiple requests and response messages between the client and AWS to be in flight at the same time over a single connection, instead of over multiple connections, which improves performance.

Developers upgrading to the latest SDKs will automatically use HTTP/2 when it's supported by the service they're working with. New programming interfaces seamlessly take advantage of HTTP/2 features and provide new ways to build applications.

The AWS SDK for Java 2.x features new APIs for event streaming that implement the HTTP/2 protocol. For examples of how to use these new APIs, see Working with Kinesis.

Use SDK metrics from the AWS SDK for Java

With the AWS SDK for Java 2.x, you can collect metrics about the service clients in your application, analyze the output in Amazon CloudWatch, and then act on it.

By default, metrics collection is disabled in the SDK. This topic helps you to enable and configure it.
Prerequisites

Before you can enable and use metrics, you must complete the following steps:

- Complete the steps in Setup.

- Configure your project dependencies (for example, in your `pom.xml` or `build.gradle` file) to use version 2.14.0 or later of the AWS SDK for Java.

  To enabling publishing of metrics to CloudWatch, also include the artifactId `cloudwatch-metric-publisher` with the version number 2.14.0 or later in your project's dependencies.

  For example:

  ```xml
  <project>
  <dependencyManagement>
  <dependencies>
    <dependency>
      <groupId>software.amazon.awssdk</groupId>
      <artifactId>bom</artifactId>
      <version>2.14.0</version>
      <type>pom</type>
      <scope>import</scope>
    </dependency>
  </dependencies>
  </dependencyManagement>
  <dependencies>
    <dependency>
      <groupId>software.amazon.awssdk</groupId>
      <artifactId>cloudwatch-metric-publisher</artifactId>
      <version>2.14.0</version>
    </dependency>
  </dependencies>
  </project>
  ```

- Enable `cloudwatch:PutMetricData` permissions for the IAM identity to allow the SDK for Java to write metrics.

How to enable metrics collection

You can enable metrics in your application for a service client or on individual requests.
Enable metrics for a specific request

The following code snippet shows how to enable the CloudWatch metrics publisher for a request to Amazon DynamoDB. It uses the default metrics publisher configuration.

```java
MetricPublisher metricsPub = CloudWatchMetricPublisher.create();
DynamoDbClient ddb = DynamoDbClient.create();
ddb.listTables(ListTablesRequest.builder()
    .overrideConfiguration(c -> c.addMetricPublisher(metricsPub))
    .build());
```

Enable metrics for a specific service client

The following code snippet shows how to enable a CloudWatch metrics publisher with default settings for a service client.

```java
MetricPublisher metricsPub = CloudWatchMetricPublisher.create();

DynamoDbClient ddb = DynamoDbClient.builder()
    .overrideConfiguration(c -> c.addMetricPublisher(metricsPub))
    .build();
```

The following snippet demonstrates how to use a custom configuration for the metrics publisher for a specific service client. The customizations include loading a specific credentials profile, specifying a different region than the service client, and customizing how often the publisher sends metrics to CloudWatch.

```java
MetricPublisher metricsPub = CloudWatchMetricPublisher.builder()
    .cloudWatchClient(CloudWatchAsyncClient.builder()
        .region(Region.US_WEST_2)
    )
    .credentialsProvider(ProfileCredentialsProvider.create("cloudwatch"))
    .uploadFrequency(Duration.ofMinutes(5))
    .build();

DynamoDbClient ddb = DynamoDbClient.builder()
    .overrideConfiguration(c -> c.addMetricPublisher(metricsPub))
    .build();
```
When are metrics available?

Metrics are generally available within 5-10 minutes after the SDK for Java emits them. For accurate and up-to-date metrics, check Cloudwatch at least 10 minutes after emitting the metrics from your Java applications.

What information is collected?

Metrics collection includes the following:

- Number of API requests, including whether they succeed or fail
- Information about the AWS services you call in your API requests, including exceptions returned
- The duration for various operations such as Marshalling, Signing, and HTTP requests
- HTTP client metrics, such as the number of open connections, the number of pending requests, and the name of the HTTP client used

Note
The metrics available vary by HTTP client.

For a complete list, see Service client metrics.

How can I use this information?

You can use the metrics the SDK collects to monitor the service clients in your application. You can look at overall usage trends, identify anomalies, review service client exceptions returned, or to dig in to understand a particular issue. Using Amazon CloudWatch, you can also create alarms to notify you as soon as your application reaches a condition that you define.

For more information, see Using Amazon CloudWatch Metrics and Using Amazon CloudWatch Alarms in the Amazon CloudWatch User Guide.

Service client metrics

With the AWS SDK for Java 2.x, you can collect metrics from the service clients in your application and then publish (output) those metrics to Amazon CloudWatch.
These tables list the metrics that you can collect and any HTTP client usage requirement.

For more information about enabling and configuring metrics for the SDK, see [Enabling SDK metrics](#).

The terms used in the tables mean:

- **Apache**: the Apache-based HTTP client ([ApacheHttpClient](#))
- **Netty**: the Netty-based HTTP client ([NettyNioAsyncHttpClient](#))
- **CRT**: the AWS CRT-based HTTP client ([AwsCrtAsyncHttpClient](#))
- **Any**: the collection of metric data does not depend on the HTTP client; this includes use of the URLConnection-based HTTP client ([URLConnectionHttpClient](#))

## Metrics collected with each request

<table>
<thead>
<tr>
<th>Metric name</th>
<th>Description</th>
<th>Type</th>
<th>HTTP client required</th>
</tr>
</thead>
<tbody>
<tr>
<td>ApiCallDuration</td>
<td>The total time taken to finish a request (inclusive of all retries)</td>
<td>Duration</td>
<td>Any</td>
</tr>
<tr>
<td>ApiCallSuccessful</td>
<td>True if the API call was successful; false if not</td>
<td>Boolean</td>
<td>Any</td>
</tr>
<tr>
<td>CredentialsFetchDuration</td>
<td>The time taken to fetch AWS signing credentials for the request</td>
<td>Duration</td>
<td>Any</td>
</tr>
<tr>
<td>MarshallingDuration</td>
<td>The time taken to marshall the request</td>
<td>Duration</td>
<td>Any</td>
</tr>
<tr>
<td>OperationName</td>
<td>The name of the AWS API the request is made to</td>
<td>String</td>
<td>Any</td>
</tr>
<tr>
<td>Metric name</td>
<td>Description</td>
<td>Type</td>
<td>HTTP client required</td>
</tr>
<tr>
<td>-------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------</td>
<td>----------------------</td>
</tr>
<tr>
<td>RetryCount</td>
<td>Number of times the SDK retried the API call</td>
<td>Integer</td>
<td>Any</td>
</tr>
<tr>
<td>ServiceId</td>
<td>Service ID of the AWS service that the API request is made against</td>
<td>String</td>
<td>Any</td>
</tr>
<tr>
<td>TokenFetchDuration</td>
<td>The time taken to fetch token signing credentials for the request</td>
<td>Duration</td>
<td>Any</td>
</tr>
</tbody>
</table>

**Metrics collected for each request attempt**

Each API call might require multiple attempts before a response is received. These metrics are collected for each attempt.

<table>
<thead>
<tr>
<th>Metric name</th>
<th>Description</th>
<th>Type</th>
<th>HTTP client required</th>
</tr>
</thead>
<tbody>
<tr>
<td>AvailableConcurrency</td>
<td>The number of remaining concurrent requests that can be supported by the HTTP client without needing to establish another connection</td>
<td>Integer</td>
<td>Apache, Netty, CRT</td>
</tr>
<tr>
<td>AwsExtendedRequestId</td>
<td>The extended request ID of the service request</td>
<td>String</td>
<td>Any</td>
</tr>
<tr>
<td>AwsRequestId</td>
<td>The request ID of the service request</td>
<td>String</td>
<td>Any</td>
</tr>
<tr>
<td>Metric name</td>
<td>Description</td>
<td>Type</td>
<td>HTTP client required</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-------------------------------------------------------------------------------</td>
<td>-----------------</td>
<td>----------------------</td>
</tr>
<tr>
<td>BackoffDelayDuration</td>
<td>The duration of time the SDK waited before this API call attempt</td>
<td>Duration</td>
<td>Any</td>
</tr>
<tr>
<td>ConcurrencyAcquireDuration</td>
<td>The time taken to acquire a channel from the connection pool</td>
<td>Duration</td>
<td>Apache, Netty, CRT</td>
</tr>
<tr>
<td>HttpClientName</td>
<td>The name of the HTTP being used for the request</td>
<td>String</td>
<td>Apache, Netty, CRT</td>
</tr>
<tr>
<td>HttpStatusCode</td>
<td>The status code returned with the HTTP response</td>
<td>Integer</td>
<td>Any</td>
</tr>
<tr>
<td>LeasedConcurrency</td>
<td>The number of request currently being executed by the HTTP client</td>
<td>Integer</td>
<td>Apache, Netty, CRT</td>
</tr>
<tr>
<td>LocalStreamWindowSize</td>
<td>The local HTTP/2 window size in bytes for the stream that this request was executed on</td>
<td>Integer</td>
<td>Netty</td>
</tr>
<tr>
<td>MarshallingDuration</td>
<td>The time it takes to marshall an SDK request to an HTTP request</td>
<td>Duration</td>
<td>Any</td>
</tr>
<tr>
<td>Metric name</td>
<td>Description</td>
<td>Type</td>
<td>HTTP client required</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>------------</td>
<td>----------------------</td>
</tr>
<tr>
<td>MaxConcurrency</td>
<td>The max number of concurrent requests supported by the HTTP client</td>
<td>Integer</td>
<td>Apache, Netty, CRT</td>
</tr>
<tr>
<td>PendingConcurrency Acquires</td>
<td>The number of requests that are blocked, waiting for another TCP connection or a new stream to be available from the connection pool</td>
<td>Integer</td>
<td>Apache, Netty, CRT</td>
</tr>
<tr>
<td>RemoteStreamWindowSize</td>
<td>The remote HTTP/2 window size in bytes for the stream that this request was executed on</td>
<td>Integer</td>
<td>Netty</td>
</tr>
<tr>
<td>ServiceCallDuration</td>
<td>The time it takes to connect to the service, send the request, and receive the HTTP status code and header from the response</td>
<td>Duration</td>
<td>Any</td>
</tr>
<tr>
<td>SigningDuration</td>
<td>The time it takes to sign the HTTP request</td>
<td>Duration</td>
<td>Any</td>
</tr>
<tr>
<td>UnmarshallingDuration</td>
<td>The time it takes to unmarshall an HTTP response to an SDK response</td>
<td>Duration</td>
<td>Any</td>
</tr>
</tbody>
</table>
Work with AWS services using the AWS SDK for Java 2.x

This section provides short tutorials and guidance for how to work with select AWS services. For a complete set of examples, see the Code Examples section.

**Topics**

- Work with CloudWatch
- AWS database services and AWS SDK for Java 2.x
- Work with DynamoDB
- Work with Amazon EC2

- Work with Amazon Simple Queue Service
- Work with Amazon Transcribe

**Work with CloudWatch**

This section provides examples of programming Amazon CloudWatch by using the AWS SDK for Java 2.x.

Amazon CloudWatch monitors your Amazon Web Services (AWS) resources and the applications you run on AWS in real time. You can use CloudWatch to collect and track metrics, which are variables you can measure for your resources and applications. CloudWatch alarms send notifications or automatically make changes to the resources you are monitoring based on rules that you define.

The following examples include only the code needed to demonstrate each technique. The complete example code is available on GitHub. From there, you can download a single source file or clone the repository locally to get all the examples to build and run.

**Topics**
Get metrics from CloudWatch

Listing metrics

To list CloudWatch metrics, create a ListMetricsRequest and call the CloudWatchClient's listMetrics method. You can use the ListMetricsRequest to filter the returned metrics by namespace, metric name, or dimensions.

⚠️ Note

A list of metrics and dimensions that are posted by AWS services can be found within the Amazon CloudWatch Metrics and Dimensions Reference in the Amazon CloudWatch User Guide.

Imports

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.cloudwatch.CloudWatchClient;
import software.amazon.awssdk.services.cloudwatch.model.CloudWatchException;
import software.amazon.awssdk.services.cloudwatch.model.ListMetricsRequest;
import software.amazon.awssdk.services.cloudwatch.model.ListMetricsResponse;
import software.amazon.awssdk.services.cloudwatch.model.Metric;
```

Code

```java
public static void listMets( CloudWatchClient cw, String namespace) {
    boolean done = false;
    String nextToken = null;
    try {
        while(!done) {
```
ListMetricsResponse response;

if (nextToken == null) {
    ListMetricsRequest request = ListMetricsRequest.builder()
        .namespace(namespace)
        .build();

    response = cw.listMetrics(request);
} else {
    ListMetricsRequest request = ListMetricsRequest.builder()
        .namespace(namespace)
        .nextToken(nextToken)
        .build();

    response = cw.listMetrics(request);
}

for (Metric metric : response.metrics()) {
    System.out.printf(
        "Retrieved metric %s", metric.metricName());
    System.out.println();
}

if(response.nextToken() == null) {
    done = true;
} else {
    nextToken = response.nextToken();
}
}

} catch (CloudWatchException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

The metrics are returned in a ListMetricsResponse by calling its getMetrics method.

The results may be paged. To retrieve the next batch of results, call nextToken on the response object and use the token value to build a new request object. Then call the listMetrics method again with the new request.

See the complete example on GitHub.
More information

- [ListMetrics](#) in the Amazon CloudWatch API Reference

Publish custom metric data to CloudWatch

A number of AWS services publish their own metrics in namespaces beginning with "AWS". You can also publish custom metric data using your own namespace (as long as it doesn't begin with "AWS").

Publish custom metric data

To publish your own metric data, call the CloudWatchClient's `putMetricData` method with a `PutMetricDataRequest`. The `PutMetricDataRequest` must include the custom namespace to use for the data, and information about the data point itself in a `MetricDatum` object.

Note

You cannot specify a namespace that begins with "AWS". Namespaces that begin with "AWS" are reserved for use by Amazon Web Services products.

Imports

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.cloudwatch.CloudWatchClient;
import software.amazon.awssdk.services.cloudwatch.model.Dimension;
import software.amazon.awssdk.services.cloudwatch.model.MetricDatum;
import software.amazon.awssdk.services.cloudwatch.model.StandardUnit;
import software.amazon.awssdk.services.cloudwatch.model.PutMetricDataRequest;
import software.amazon.awssdk.services.cloudwatch.model.CloudWatchException;
import java.time.Instant;
import java.time.ZoneOffset;
import java.time.ZonedDateTime;
import java.time.format.DateTimeFormatter;
```

Code

```java
public static void putMetData(CloudWatchClient cw, Double dataPoint) {
```

Publish custom metric data to CloudWatch
try {
    Dimension dimension = Dimension.builder()
        .name("UNIQUE_PAGES")
        .value("URLS")
        .build();

    // Set an Instant object
    String time =
        ZonedDateTime.now(ZoneOffset.UTC).format(DateTimeFormatter.ISO_INSTANT);
    Instant instant = Instant.parse(time);

    MetricDatum datum = MetricDatum.builder()
        .metricName("PAGES_VISITED")
        .unit(StandardUnit.NONE)
        .value(dataPoint)
        .timestamp(instant)
        .dimensions(dimension).build();

    PutMetricDataRequest request = PutMetricDataRequest.builder()
        .namespace("SITE/TRAFFIC")
        .metricData(datum).build();

    cw.putMetricData(request);
} catch (CloudWatchException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
} 
System.out.printf("Successfully put data point %f", dataPoint);
}

See the [complete example](https://github.com/aws/aws-sdk-java) on GitHub.

Work with CloudWatch alarms

Create an alarm

To create an alarm based on a CloudWatch metric, call the CloudWatchClient's `putMetricAlarm` method with a `PutMetricAlarmRequest` filled with the alarm conditions.

Imports

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.cloudwatch.CloudWatchClient;
import software.amazon.awssdk.services.cloudwatch.model.Dimension;
import software.amazon.awssdk.services.cloudwatch.model.PutMetricAlarmRequest;
import software.amazon.awssdk.services.cloudwatch.model.ComparisonOperator;
import software.amazon.awssdk.services.cloudwatch.model.Statistic;
import software.amazon.awssdk.services.cloudwatch.model.StandardUnit;
import software.amazon.awssdk.services.cloudwatch.model.CloudWatchException;
```

Code

```java
public static void putMetricAlarm(CloudWatchClient cw, String alarmName, String instanceId) {
    try {
        Dimension dimension = Dimension.builder()
            .name("InstanceId")
            .value(instanceId).build();

        PutMetricAlarmRequest request = PutMetricAlarmRequest.builder()
            .alarmName(alarmName)
            .comparisonOperator(
                ComparisonOperator.GREATER_THAN_THRESHOLD)
            .evaluationPeriods(1)
            .metricName("CPUUtilization")
            .namespace("AWS/EC2")
            .period(60)
            .statistic(Statistic.AVERAGE)
            .threshold(70.0)
            .actionsEnabled(false)
            .alarmDescription("Alarm when server CPU utilization exceeds 70%")
            .unit(StandardUnit.SECONDS)
            .dimensions(dimension)
```
.build();

cw.putMetricAlarm(request);
System.out.printf(
    "Successfully created alarm with name %s", alarmName);

} catch (CloudWatchException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

See the [complete example](https://github.com/aws/aws-sdk-java) on GitHub.

### List alarms

To list the CloudWatch alarms that you have created, call the CloudWatchClient’s `describeAlarms` method with a `DescribeAlarmsRequest` that you can use to set options for the result.

### Imports

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.cloudwatch.CloudWatchClient;
import software.amazon.awssdk.services.cloudwatch.CloudWatchException;
import software.amazon.awssdk.services.cloudwatch.model.DescribeAlarmsRequest;
import software.amazon.awssdk.services.cloudwatch.model.DescribeAlarmsResponse;
import software.amazon.awssdk.services.cloudwatch.model.MetricAlarm;
```

### Code

```java
public static void describeAlarms(CloudWatchClient cw) {
    try {
        boolean done = false;
        String newToken = null;

        while (!done) {
            DescribeAlarmsResponse response;

            if (newToken != null) {
```
DescribeAlarmsRequest request =
DescribeAlarmsRequest.builder().build();
response = cw.describeAlarms(request);
} else {
DescribeAlarmsRequest request = DescribeAlarmsRequest.builder()
   .nextToken(newToken)
   .build();
response = cw.describeAlarms(request);
}

for(MetricAlarm alarm : response.metricAlarms()) {
    System.out.printf("Retrieved alarm %s", alarm.alarmName());
}

if(response.nextToken() == null) {
    done = true;
} else {
    newToken = response.nextToken();
}
}
}

try { catch (CloudWatchException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
System.out.printf("Done");
}

The list of alarms can be obtained by calling MetricAlarms on the DescribeAlarmsResponse that is returned by describeAlarms.

The results may be paged. To retrieve the next batch of results, call nextToken on the response object and use the token value to build a new request object. Then call the describeAlarms method again with the new request.

Note

You can also retrieve alarms for a specific metric by using the CloudWatchClient's describeAlarmsForMetric method. Its use is similar to describeAlarms.

See the complete example on GitHub.
Delete alarms

To delete CloudWatch alarms, call the CloudWatchClient's deleteAlarms method with a DeleteAlarmsRequest containing one or more names of alarms that you want to delete.

Imports

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.cloudwatch.CloudWatchClient;
import software.amazon.awssdk.services.cloudwatch.model.CloudWatchException;
import software.amazon.awssdk.services.cloudwatch.model.DeleteAlarmsRequest;
```

Code

```java
public static void deleteCWAlarm(CloudWatchClient cw, String alarmName) {
    try {
        DeleteAlarmsRequest request = DeleteAlarmsRequest.builder()
            .alarmNames(alarmName)
            .build();

        cw.deleteAlarms(request);
        System.out.printf("Successfully deleted alarm %s", alarmName);
    } catch (CloudWatchException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

See the complete example on GitHub.

More information

- [Using Amazon CloudWatch alarms](#) in the Amazon CloudWatch User Guide
- [PutMetricAlarm](#) in the Amazon CloudWatch API Reference
- [DescribeAlarms](#) in the Amazon CloudWatch API Reference
- [DeleteAlarms](#) in the Amazon CloudWatch API Reference
Use Amazon CloudWatch Events

CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources to Amazon EC2 instances, Lambda functions, Kinesis streams, Amazon ECS tasks, Step Functions state machines, Amazon SNS topics, Amazon SQS queues, or built-in targets. You can match events and route them to one or more target functions or streams by using simple rules.

Amazon EventBridge is the evolution of CloudWatch Events. Both services use the same API, so you can continue using the CloudWatch Events client provided by the SDK or migrate to the SDK for Java's EventBridge client for CloudWatch Events functionality. CloudWatch Events User Guide documentation and API reference are now available through the EventBridge documentation sites.

Add events

To add custom CloudWatch events, call the CloudWatchEventsClient’s putEvents method with a PutEventsRequest object that contains one or more PutEventsRequestEntry objects that provide details about each event. You can specify several parameters for the entry such as the source and type of the event, resources associated with the event, and so on.

Note

You can specify a maximum of 10 events per call to putEvents.

Imports

```
import software.amazon.awssdk.services.cloudwatch.model.CloudWatchException;
import software.amazon.awssdk.services.cloudwatchevents.CloudWatchEventsClient;
import software.amazon.awssdk.services.cloudwatchevents.model.PutEventsRequest;
import software.amazon.awssdk.services.cloudwatchevents.model.PutEventsRequestEntry;
```

Code

```
public static void putCWEvents(CloudWatchEventsClient cwe, String resourceArn ) {
    try {
        final String EVENTDETAILS =
            "{ "key1": "value1", "key2": "value2" }";

        PutEventsRequestEntry requestEntry = PutEventsRequestEntry.builder()
```
.detail(EVENT_DETAILS)
  .detailType("sampleSubmitted")
  .resources(resourceArn)
  .source("aws-sdk-java-cloudwatch-example")
  .build();

PutEventsRequest request = PutEventsRequest.builder()
  .entries(requestEntry)
  .build();

cwe.putEvents(request);
System.out.println("Successfully put CloudWatch event");

} catch (CloudWatchException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

See the complete example on GitHub.

Add rules

To create or update a rule, call the CloudWatchEventsClient’s putRule method with a PutRuleRequest with the name of the rule and optional parameters such as the event pattern, IAM role to associate with the rule, and a scheduling expression that describes how often the rule is run.

Imports

import software.amazon.awssdk.services.cloudwatch.model.CloudWatchException;
import software.amazon.awssdk.services.cloudwatchevents.CloudWatchEventsClient;
import software.amazon.awssdk.services.cloudwatchevents.model.PutRuleRequest;
import software.amazon.awssdk.services.cloudwatchevents.model.PutRuleResponse;
import software.amazon.awssdk.services.cloudwatchevents.model.RuleState;

Code

public static void putCWRule(CloudWatchEventsClient cwe, String ruleName, String roleArn) {
  try {
    PutRuleRequest request = PutRuleRequest.builder()
Add targets

Targets are the resources that are invoked when a rule is triggered. Example targets include Amazon EC2 instances, Lambda functions, Kinesis streams, Amazon ECS tasks, Step Functions state machines, and built-in targets.

To add a target to a rule, call the CloudWatchEventsClient’s putTargets method with a PutTargetsRequest containing the rule to update and a list of targets to add to the rule.

Imports

```java
import software.amazon.awssdk.services.cloudwatch.model.CloudWatchException;
import software.amazon.awssdk.services.cloudwatchevents.CloudWatchEventsClient;
import software.amazon.awssdk.services.cloudwatchevents.model.PutTargetsRequest;
import software.amazon.awssdk.services.cloudwatchevents.model.PutTargetsResponse;
import software.amazon.awssdk.services.cloudwatchevents.model.Target;
```

Code

```java
public static void putCWTargets(CloudWatchEventsClient cwe, String ruleName, String functionArn, String targetId) {
    try {
        Target target = Target.builder()
            .name(ruleName)
            .roleArn(functionArn)
            .scheduleExpression("rate(5 minutes)")
            .state(RuleState.ENABLED)
            .build();

        PutRuleResponse response = cwe.putRule(request);
        System.out.printf("Successfully created CloudWatch events rule %s with arn %s", roleArn, response.ruleArn());
    } catch (CloudWatchException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

See the [complete example](https://github.com/aws-ehub/aws-sdk-java) on GitHub.
```java
.functionArn
.id(targetId)
.build();

PutTargetsRequest request = PutTargetsRequest.builder()
    .targets(target)
    .rule(ruleName)
    .build();

PutTargetsResponse response = cwe.putTargets(request);
System.out.printf(
    "Successfully created CloudWatch events target for rule %s",
    ruleName);
} catch (CloudWatchException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
```

See the complete example on GitHub.

AWS database services and AWS SDK for Java 2.x

AWS offers several database types: relational, key-value, in-memory, document, and several others. The SDK for Java 2.x support varies depending on the nature of the database service in AWS.

Some database services, for example Amazon DynamoDB service, have web service APIs to manage the AWS resource (database) as well as web service APIs to interact with the data. In the SDK for Java 2.x these types of services have dedicated service clients, for example DynamoDBClient.
Other database services have web service APIs that interact with the resource, such the Amazon DocumentDB API (for cluster, instance and resource management), but do not have a web service API for working with the data. The SDK for Java 2.x has a corresponding DocDbClient interface for working with the resource. However, you need another Java API, such as MongoDB for Java to work with the data.

Use the examples below to learn how you use the SDK for Java 2.x service clients with the different types of databases.

### Amazon DynamoDB examples

Work with DynamoDB

This section provides examples that show you how to work with DynamoDB. The examples in this section use the standard, low-level DynamoDB client (DynamoDbClient) offered with the AWS SDK for Java 2.x.

The SDK also offers the DynamoDB Enhanced Client that provides a high-level, object-oriented approach for working with DynamoDB.

Topics
- Work with tables in DynamoDB
- Work with items in DynamoDB
- Map Java objects to DynamoDB items with the AWS SDK for Java 2.x

Work with tables in DynamoDB

Tables are the containers for all items in a DynamoDB database. Before you can add or remove data from DynamoDB, you must create a table.

For each table, you must define:

- A table name that is unique for your account and Region.
- A primary key for which every value must be unique; no two items in your table can have the same primary key value.

A primary key can be simple, consisting of a single partition (HASH) key, or composite, consisting of a partition and a sort (RANGE) key.

Each key value has an associated data type, enumerated by the ScalarAttributeType class. The key value can be binary (B), numeric (N), or a string (S). For more information, see Naming Rules and Data Types in the Amazon DynamoDB Developer Guide.
• **Provisioned throughput** are values that define the number of reserved read/write capacity units for the table.

[Note]

Amazon DynamoDB pricing is based on the provisioned throughput values that you set on your tables, so reserve only as much capacity as you think you’ll need for your table.

Provisioned throughput for a table can be modified at any time, so you can adjust capacity as your needs change.

**Create a table**

Use the DynamoDbClient’s `createTable` method to create a new DynamoDB table. You need to construct table attributes and a table schema, both of which are used to identify the primary key of your table. You must also supply initial provisioned throughput values and a table name.

[Note]

If a table with the name you chose already exists, an `DynamoDbException` is thrown.

**Create a table with a simple primary key**

This code creates a table with one attribute that is the table’s simple primary key. The example uses `AttributeDefinition` and `KeySchemaElement` objects for the `CreateTableRequest`.

**Imports**

```java
import software.amazon.awssdk.core.waiters.WaiterResponse;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.model.CreateTableRequest;
import software.amazon.awssdk.services.dynamodb.model.AttributeDefinition;
import software.amazon.awssdk.services.dynamodb.model.ScalarAttributeType;
import software.amazon.awssdk.services.dynamodb.model.ScalarAttributeType;
import software.amazon.awssdk.services.dynamodb.model.KeySchemaElement;
import software.amazon.awssdk.services.dynamodb.model.ProvisionedThroughput;
import software.amazon.awssdk.services.dynamodb.model.KeyType;
import software.amazon.awssdk.services.dynamodb.model.CreateTableResponse;
```
import software.amazon.awssdk.services.dynamodb.model.DescribeTableRequest;
import software.amazon.awssdk.services.dynamodb.model.DescribeTableResponse;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.waiters.DynamoDbWaiter;

public static String createTable(DynamoDbClient ddb, String tableName, String key) {
    DynamoDbWaiter dbWaiter = ddb.waiter();
    CreateTableRequest request = CreateTableRequest.builder()
        .attributeDefinitions(AttributeDefinition.builder()
            .attributeName(key)
            .attributeType(ScalarAttributeType.S)
            .build())
        .keySchema(KeySchemaElement.builder()
            .attributeName(key)
            .keyType(KeyType.HASH)
            .build())
        .provisionedThroughput(ProvisionedThroughput.builder()
            .readCapacityUnits(new Long(10))
            .writeCapacityUnits(new Long(10))
            .build())
        .tableName(tableName)
        .build();

    String newTable = "";
    try {
        CreateTableResponse response = ddb.createTable(request);
        DescribeTableRequest tableRequest = DescribeTableRequest.builder()
            .tableName(tableName)
            .build();

        // Wait until the Amazon DynamoDB table is created
        WaiterResponse<DescribeTableResponse> waiterResponse =
            dbWaiter.waitUntilTableExists(tableRequest);
        waiterResponse.matched().response().ifPresent(System.out::println);

        newTable = response.tableDescription().tableName();
        return newTable;
    } catch (DynamoDbException e) {
        e.printStackTrace();
    }
}

Work with tables in DynamoDB
} catch (DynamoDbException e) {
    System.err.println(e.getMessage());
    System.exit(1);
}
return "";
}

See the complete example on GitHub.

Create a table with a composite primary key

The following example creates a table with two attributes. Both attributes are used for the composite primary key.

Imports

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.model.AttributeDefinition;
import software.amazon.awssdk.services.dynamodb.model.CreateTableRequest;
import software.amazon.awssdk.services.dynamodb.model.CreateTableResponse;
import software.amazon.awssdk.services.dynamodb.model.KeySchemaElement;
import software.amazon.awssdk.services.dynamodb.model.KeyType;
import software.amazon.awssdk.services.dynamodb.model.ProvisionedThroughput;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
```

Code

```java
public static String createTableComKey(DynamoDbClient ddb, String tableName) {
    CreateTableRequest request = CreateTableRequest.builder()
        .attributeDefinitions(
            AttributeDefinition.builder()
                .attributeName("Language")
                .attributeType(ScalarAttributeType.S)
                .build(),
            AttributeDefinition.builder()
                .attributeName("Greeting")
                .attributeType(ScalarAttributeType.S)
                .build())
        .keySchema(
            KeySchemaElement.builder()
                .attributeName("Language")
```
KeySchemaElement.builder()
    .attributeName("Greeting")
    .keyType(KeyType.RANGE)
    .build())
  .provisionedThroughput(
    ProvisionedThroughput.builder()
    .readCapacityUnits(new Long(10))
    .writeCapacityUnits(new Long(10)).build())
  .tableName(tableName)
  .build();

String tableId = "";

try {
    CreateTableResponse result = ddb.createTable(request);
    tableId = result.tableDescription().tableId();
    return tableId;
} catch (DynamoDbException e) {
    System.err.println(e.getMessage());
    System.exit(1);
}
return "";

See the [complete example](https://github.com) on GitHub.

**List tables**

You can list the tables in a particular Region by calling the DynamoDbClient’s `listTables` method.

![Note]

If the named table doesn’t exist for your account and Region, a `ResourceNotFoundException` is thrown.

**Imports**

```java
import software.amazon.awssdk.regions.Region;
```
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.model.ListTablesResponse;
import software.amazon.awssdk.services.dynamodb.model.ListTablesRequest;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import java.util.List;

Code

```java
public static void listAllTables(DynamoDbClient ddb){
    boolean moreTables = true;
    String lastName = null;

    while(moreTables) {
        try {
            ListTablesResponse response = null;
            if (lastName == null) {
                ListTablesRequest request = ListTablesRequest.builder().build();
                response = ddb.listTables(request);
            } else {
                ListTablesRequest request = ListTablesRequest.builder()
                        .exclusiveStartTableName(lastName).build();
                response = ddb.listTables(request);
            }

            List<String> tableNames = response.tableNames();

            if (tableNames.size() > 0) {
                for (String curName : tableNames) {
                    System.out.format("* %s\n", curName);
                }
            } else {
                System.out.println("No tables found!");
                System.exit(0);
            }

            lastName = response.lastEvaluatedTableName();
            if (lastName == null) {
                moreTables = false;
            }
        } catch (DynamoDbException e) {
            System.err.println(e.getMessage());
            System.exit(1);
        }
    }
}
```

Work with tables in DynamoDB
System.out.println("\nDone!"瘙1
}

By default, up to 100 tables are returned per call—use `lastEvaluatedTableName` on the returned `ListTablesResponse` object to get the last table that was evaluated. You can use this value to start the listing after the last returned value of the previous listing.

See the complete example on GitHub.

### Describe (get information about) a table

Use the `DynamoDbClient`'s `describeTable` method to get information about a table.

**Note**

If the named table doesn’t exist for your account and Region, a `ResourceNotFoundException` is thrown.

**Imports**

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.AttributeDefinition;
import software.amazon.awssdk.services.dynamodb.model.DescribeTableRequest;
import software.amazon.awssdk.services.dynamodb.model.ProvisionedThroughputDescription;
import software.amazon.awssdk.services.dynamodb.model.TableDescription;
import java.util.List;
```

**Code**

```java
public static void describeDynamoDBTable(DynamoDbClient ddb, String tableName) {

    DescribeTableRequest request = DescribeTableRequest.builder()
            .tableName(tableName)
            .build();
```

Work with tables in DynamoDB
try {
    TableDescription tableInfo =
        ddb.describeTable(request).table();

    if (tableInfo != null) {
        System.out.format("Table name : %s\n",
                           tableInfo.tableName());
        System.out.format("Table ARN  : %s\n",
                           tableInfo.tableArn());
        System.out.format("Status     : %s\n",
                           tableInfo.tableStatus());
        System.out.format("Item count : %d\n",
                           tableInfo.itemCount().longValue());
        System.out.format("Size (bytes): %d\n",
                           tableInfo.tableSizeBytes().longValue());

        ProvisionedThroughputDescription throughputInfo =
            tableInfo.provisionedThroughput();
        System.out.println("Throughput");
        System.out.format("  Read Capacity : %d\n",
                           throughputInfo.readCapacityUnits().longValue());
        System.out.format("  Write Capacity: %d\n",
                           throughputInfo.writeCapacityUnits().longValue());

        List<AttributeDefinition> attributes =
            tableInfo.attributeDefinitions();
        System.out.println("Attributes");

        for (AttributeDefinition a : attributes) {
            System.out.format("%s (%s)\n",
                              a.attributeName(), a.attributeType());
        }
    }
} catch (DynamoDbException e) {
    System.err.println(e.getMessage());
    System.exit(1);
}
System.out.println("\nDone!");

See the [complete example](https://github.com/aws/aws-sdk-java) on GitHub.
Modify (update) a table

You can modify your table’s provisioned throughput values at any time by calling the DynamoDbClient’s `updateTable` method.

⚠️ **Note**

If the named table doesn’t exist for your account and Region, a `ResourceNotFoundException` is thrown.

**Imports**

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.model.ProvisionedThroughput;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.UpdateTableRequest;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
```

**Code**

```java
public static void updateDynamoDBTable(DynamoDbClient ddb,
        String tableName,
        Long readCapacity,
        Long writeCapacity) {
    System.out.format("Updating %s with new provisioned throughput values\n", tableName);
    System.out.format("Read capacity : %d\n", readCapacity);
    System.out.format("Write capacity : %d\n", writeCapacity);
    ProvisionedThroughput tableThroughput = ProvisionedThroughput.builder()
            .readCapacityUnits(readCapacity)
            .writeCapacityUnits(writeCapacity)
            .build();

    UpdateTableRequest request = UpdateTableRequest.builder()
            .provisionedThroughput(tableThroughput)
            .tableName(tableName)
            .build();
}
```
try {
    ddb.updateTable(request);
} catch (DynamoDbException e) {
    System.err.println(e.getMessage());
    System.exit(1);
}

System.out.println("Done!");

See the [complete example](https://github.com) on GitHub.

**Delete a table**

To delete a table, call `DynamoDbClient`’s `deleteTable` method and provide the table’s name.

**Note**

If the named table doesn’t exist for your account and Region, a `ResourceNotFoundException` is thrown.

**Imports**

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.DeleteTableRequest;
```

**Code**

```java
public static void deleteDynamoDBTable(DynamoDbClient ddb, String tableName) {
    DeleteTableRequest request = DeleteTableRequest.builder()
    .tableName(tableName)
    .build();

    try {
        ddb.deleteTable(request);
```
} catch (DynamoDbException e) {
    System.err.println(e.getMessage());
    System.exit(1);
}
System.out.println(tableName +" was successfully deleted!");

See the complete example on GitHub.

More information

- Guidelines for Working with Tables in the Amazon DynamoDB Developer Guide
- Working with Tables in DynamoDB in the Amazon DynamoDB Developer Guide

Work with items in DynamoDB

In DynamoDB, an item is a collection of attributes, each of which has a name and a value. An attribute value can be a scalar, set, or document type. For more information, see Naming Rules and Data Types in the Amazon DynamoDB Developer Guide.

Retrieve (get) an item from a table

Call the DynamoDbClient's getItem method and pass it a GetItemRequest object with the table name and primary key value of the item you want. It returns a GetItemResponse object with all of the attributes for that item. You can specify one or more projection expressions in the GetItemRequest to retrieve specific attributes.

You can use the returned GetItemResponse object's item() method to retrieve a Map of key (String) and value (AttributeValue) pairs that are associated with the item.

Imports

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.AttributeValue;
import software.amazon.awssdk.services.dynamodb.model.GetItemRequest;
import java.util.HashMap;
import java.util.Map;
```
import java.util.Set;

Code

```java
public static void getDynamoDBItem(DynamoDbClient ddb, String tableName, String key, String keyVal) {
    HashMap<String, AttributeValue> keyToGet = new HashMap<String, AttributeValue>();
    keyToGet.put(key, AttributeValue.builder().s(keyVal).build());

    GetItemRequest request = GetItemRequest.builder()
        .key(keyToGet)
        .tableName(tableName)
        .build();

    try {
        Map<String, AttributeValue> returnedItem = ddb.getItem(request).item();

        if (returnedItem != null) {
            Set<String> keys = returnedItem.keySet();
            System.out.println("Amazon DynamoDB table attributes: 
");
            for (String key1 : keys) {
                System.out.format("%s: %s
", key1, returnedItem.get(key1).toString());
            }
        } else {
            System.out.format("No item found with the key %s!
", key);
        }
    } catch (DynamoDbException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}
```

See the [complete example](https://github.com/) on GitHub.

Retrieve (get) an item from a table using the asynchronous client

Invoke the `getItem` method of the `DynamoDbAsyncClient` and pass it a `GetItemRequest` object with the table name and primary key value of the item you want.
You can return a `Collection` instance with all of the attributes for that item (refer to the following example).

**Imports**

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.model.GetItemRequest;
import software.amazon.awssdk.services.dynamodb.model.AttributeValue;
import software.amazon.awssdk.services.dynamodb.DynamoDbAsyncClient;
import java.util.HashMap;
import java.util.Map;
import java.util.Set;
import java.util.stream.Collectors;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
```

**Code**

```java
public static void getItem(DynamoDbAsyncClient client, String tableName, String key, String keyVal) {
    HashMap<String, AttributeValue> keyToGet =
    new HashMap<String, AttributeValue>();

    keyToGet.put(key, AttributeValue.builder().s(keyVal).build());

    try {

        // Create a GetItemRequest instance
        GetItemRequest request = GetItemRequest.builder()
            .key(keyToGet)
            .tableName(tableName)
            .build();

        // Invoke the DynamoDbAsyncClient object's getItem
        java.util.Collection<AttributeValue> returnedItem =
        client.getItem(request).join().item().values();

        // Convert Set to Map
        Map<String, AttributeValue> map =
        returnedItem.stream().collect(Collectors.toMap(AttributeValue::s, s->s));

        Set<String> keys = map.keySet();
        for (String sinKey : keys) {
```
See the complete example on GitHub.

Add a new item to a table

Create a Map of key-value pairs that represent the item's attributes. These must include values for the table's primary key fields. If the item identified by the primary key already exists, its fields are updated by the request.

Note
If the named table doesn’t exist for your account and region, a ResourceNotFoundException is thrown.

Imports

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.AttributeValue;
import software.amazon.awssdk.services.dynamodb.model.PutItemRequest;
import software.amazon.awssdk.services.dynamodb.model.ResourceNotFoundException;
import java.util.HashMap;
```

Code

```
public static void putItemInTable(DynamoDbClient ddb,
        String tableName,
        String key,
        String keyVal,
        String albumTitle,
        String albumTitleValue,
```
String awards,
String awardVal,
String songTitle,
String songTitleVal){

HashMap<String,AttributeValue> itemValues = new
HashMap<String,AttributeValue>();

// Add all content to the table
itemValues.put(key, AttributeValue.builder().s(keyVal).build());
itemValues.put(songTitle, AttributeValue.builder().s(songTitleVal).build());
itemValues.put(albumTitle, AttributeValue.builder().s(albumTitleValue).build());
itemValues.put(awards, AttributeValue.builder().s(awardVal).build());

PutItemRequest request = PutItemRequest.builder()
    .tableName(tableName)
    .item(itemValues)
    .build();

try {
    ddb.putItem(request);
    System.out.println(tableName +" was successfully updated");
}

} catch (ResourceNotFoundException e) {
    System.err.format("Error: The Amazon DynamoDB table "%s" can't be found.
\n", tableName);
    System.err.println("Be sure that it exists and that you've typed its name
correctly!");
    System.exit(1);
} catch (DynamoDbException e) {
    System.err.println(e.getMessage());
    System.exit(1);
}
}

See the complete example on GitHub.

**Update an existing item in a table**

You can update an attribute for an item that already exists in a table by using the
DynamoDbClient’s updateItem method, providing a table name, primary key value, and a map of
fields to update.
Note

If the named table doesn’t exist for your account and region, or if the item identified by the primary key you passed in doesn’t exist, a ResourceNotFoundException is thrown.

Imports

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.model.AttributeAction;
import software.amazon.awssdk.services.dynamodb.model.AttributeValue;
import software.amazon.awssdk.services.dynamodb.model.AttributeValueUpdate;
import software.amazon.awssdk.services.dynamodb.model.ResourceNotFoundException;
import software.amazon.awssdk.services.dynamodb.model.UpdateItemRequest;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import java.util.HashMap;
```

Code

```java
public static void updateTableItem(DynamoDbClient ddb,
        String tableName,
        String key,
        String keyVal,
        String name,
        String updateVal){

    HashMap<String,AttributeValue> itemKey = new HashMap<String,AttributeValue>();
    itemKey.put(key, AttributeValue.builder().s(keyVal).build());

    HashMap<String,AttributeValueUpdate> updatedValues =
            new HashMap<String,AttributeValueUpdate>();

    // Update the column specified by name with updatedVal
    updatedValues.put(name, AttributeValueUpdate.builder()
            .value(AttributeValue.builder().s(updateVal).build())
            .action(AttributeAction.PUT)
            .build());

    UpdateItemRequest request = UpdateItemRequest.builder()
            .tableName(tableName)
```
.key(itemKey)
 .attributeUpdates(updatedValues)
 .build();

 try {
     ddb.updateItem(request);
 } catch (ResourceNotFoundException e) {
     System.err.println(e.getMessage());
     System.exit(1);
 } catch (DynamoDbException e) {
     System.err.println(e.getMessage());
     System.exit(1);
 }

 System.out.println("Done!");

See the [complete example](#) on GitHub.

### Delete an existing item in a table

You can delete an item that exists in a table by using the DynamoDbClient's deleteItem method and providing a table name as well as the primary key value.

⚠️ **Note**

If the named table doesn't exist for your account and region, or if the item identified by the primary key you passed in doesn't exist, a `ResourceNotFoundException` is thrown.

### Imports

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.AttributeValue;
import software.amazon.awssdk.services.dynamodb.model.DeleteItemRequest;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import java.util.HashMap;
```

### Code

Work with items in DynamoDB
```java
public static void deleteDynamoDBItem(DynamoDbClient ddb, String tableName, String key, String keyVal) {
    HashMap<String, AttributeValue> keyToGet =
            new HashMap<String, AttributeValue>();

    keyToGet.put(key, AttributeValue.builder()
            .s(keyVal)
            .build());

    DeleteItemRequest deleteReq = DeleteItemRequest.builder()
            .tableName(tableName)
            .key(keyToGet)
            .build();

    try {
        ddb.deleteItem(deleteReq);
    } catch (DynamoDbException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}
```

See the [complete example](https://github.com/aws/aws-sdk-java) on GitHub.

**More information**

- [Guidelines for Working with Items](http://docs.aws.amazon.com/amazondynamodb/latest/developerguide/guidelines.html) in the Amazon DynamoDB Developer Guide
- [Working with Items in DynamoDB](http://docs.aws.amazon.com/amazondynamodb/latest/developerguide/guidelines.html) in the Amazon DynamoDB Developer Guide

**Map Java objects to DynamoDB items with the AWS SDK for Java 2.x**

The [DynamoDB Enhanced Client API](http://docs.aws.amazon.com/amazondynamodb/latest/developerguide/enhanced-client-api.html) is a high-level library that is the successor to the DynamoDBMapper class of in the SDK for Java v1.x. It offers a straightforward way to map client-side classes to DynamoDB tables. You define the relationships between tables and their corresponding model classes in your code. After you define those relationships, you can intuitively perform various create, read, update, or delete (CRUD) operations on tables or items in DynamoDB.

The DynamoDB Enhanced Client API also includes the [Enhanced Document API](http://docs.aws.amazon.com/amazondynamodb/latest/developerguide/enhanced-document-api.html) that enables you to work with document-type items that do not follow a defined schema.
The DynamoDB Enhanced Client API is discussed in the following topics.

- Get Started using the DynamoDB Enhanced Client API
- Learn the basics of the DynamoDB Enhanced Client API
- Use advanced mapping features
- Work with JSON documents with the Enhanced Document API for DynamoDB
- Use extensions
- Use the DynamoDB Enhanced Client API asynchronously
- Data class annotations

**Get Started using the DynamoDB Enhanced Client API**

The following tutorial introduces you to fundamentals that you need to work with the DynamoDB Enhanced Client API.

**Add dependencies**

To begin working with the DynamoDB Enhanced Client API in your project, add a dependency on the dynamodb-enhanced Maven artifact. This is shown in the following examples.

**Maven**

```xml
<project>
  <dependencyManagement>
    <dependencies>
      <dependency>
        <groupId>software.amazon.awssdk</groupId>
        <artifactId>bom</artifactId>
        <version>VERSION</version>
        <type>pom</type>
        <scope>import</scope>
      </dependency>
    </dependencies>
  </dependencyManagement>
  <dependencies>
    <dependency>
      <groupId>software.amazon.awssdk</groupId>
      <artifactId>dynamodb-enhanced</artifactId>
    </dependency>
  </dependencies>
</project>
```
Perform a search of the Maven central repository for the latest version and replace `<VERSION>` with this value.

Gradle

```groovy
repositories {
    mavenCentral()
}
dependencies {
    implementation(platform("software.amazon.awssdk:bom:<VERSION>"))
    implementation("software.amazon.awssdk:dynamodb-enhanced")
    ...
}
```

Perform a search of the Maven central repository for the latest version and replace `<VERSION>` with this value.

**Generate a TableSchema from a data class**

A TableSchema enables the enhanced client to map DynamoDB attribute values to and from your client-side classes. In this tutorial, you learn about TableSchemas derived from a static data class and generated from code by using a builder.

**Use an annotated data class**

The SDK for Java 2.x includes a set of annotations that you can use with a data class to quickly generate a TableSchema for mapping your classes to tables.

Start by creating a data class that conforms to the JavaBean specification. The specification requires that a class has a no-argument public constructor and has getters and setters for each attribute in the class. Include a class-level annotation to indicate that the data class is a DynamoDbBean. Also, at a minimum, include a DynamoDbPartitionKey annotation on the getter or setter for the primary key attribute.

You can apply attribute-level annotations to getters or setters, but not both.
Note

The term property is normally used for a value encapsulated in a JavaBean. However, this guide uses the term attribute instead, to be consistent with the terminology used by DynamoDB.

The following Customer class shows the annotations that link the class definition to the DynamoDB table.

Customer class

```java
package org.example.tests.model;

import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbBean;
import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbPartitionKey;
import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbSortKey;
import java.time.Instant;

@DynamoDbBean
public class Customer {

    private String id;
    private String name;
    private String email;
    private Instant regDate;

    @DynamoDbPartitionKey
    public String getId() { return this.id; }
    public void setId(String id) { this.id = id; }

    public String getCustName() { return this.name; }
    public void setCustName(String name) { this.name = name; }

    @DynamoDbSortKey
    public String getEmail() { return this.email; }
    public void setEmail(String email) { this.email = email; }
}
```

Map objects to DynamoDB items
public Instant getRegistrationDate() { return this.regDate; }

public void setRegistrationDate(Instant registrationDate) { this.regDate = registrationDate; }

@Override
public String toString() {
    return "Customer [id=" + id + ", name=" + name + ", email=" + email
    + ", regDate=" + regDate + "]";
}
}

After you have created an annotated data class, use it to create the TableSchema, as shown in the following snippet.

static final TableSchema<Customer> customerTableSchema =
    TableSchema.fromBean(Customer.class);

A TableSchema is designed to be static and immutable. You can usually instantiate it at class-load time.

The static TableSchema.fromBean() factory method introspects the bean to generate the mapping of data class attributes to and from DynamoDB attributes.

For an example of working with a data model made up of several data classes, see the Person class in the ???.

Use a builder

You can skip the cost of bean introspection if you define the table schema in code. If you code the schema, your class does not need to follow JavaBean naming standards nor does it need to be annotated. The following example uses a builder and is equivalent to the Customer class example that uses annotations.

static final TableSchema<Customer> customerTableSchema =
    TableSchema.builder(Customer.class)
        .newItemSupplier(Customer::new)
        .addAttribute(String.class, a -> a.name("id")
                        .getter(Customer::getId)
                        .setter(Customer::setId)
Create an enhanced client and DynamoDBTable

Create an enhanced client

The DynamoDBEnhancedClient class or its asynchronous counterpart, DynamoDBEnhancedAsyncClient, is the entry point to working with the DynamoDB Enhanced Client API.

The enhanced client requires a standard DynamoDBClient to perform work. The API offers two ways to create a DynamoDBEnhancedClient instance. The first option, shown in the following snippet, creates a standard DynamoDBClient with default settings picked up from configuration settings.

DynamoDBEnhancedClient enhancedClient = DynamoDBEnhancedClient.create();

If you want to configure the underlying standard client, you can supply it to the enhanced client's builder method as shown in the following snippet.

DynamoDBEnhancedClient enhancedClient = DynamoDBEnhancedClient.builder()
    .dynamoDbClient(
        // Configure an instance of the standard client.
        DynamoDbClient.builder()
            .region(Region.US_EAST_1)
            .credentialsProvider(ProfileCredentialsProvider.create())
    )
    .build();

Map objects to DynamoDB items
Create a `DynamoDbTable` instance

Think of a `DynamoDbTable` as the client-side representation of a DynamoDB table that uses the mapping functionality provided by a `TableSchema`. The `DynamoDbTable` class provides methods for CRUD operations that let you interact with a single DynamoDB table.

`DynamoDbTable<T>` is a generic class that takes a single type argument, whether it is a custom class or an `EnhancedDocument` when working with document-type items. This argument type establishes the relationship between the class that you use and the single DynamoDB table.

Use the `table()` factory method of the `DynamoDbEnhancedClient` to create a `DynamoDbTable` instance as shown in the following snippet.

```java
static final DynamoDbTable<Customer> customerTable =
    enhancedClient.table("Customer", TableSchema.fromBean(Customer.class));
```

`DynamoDbTable` instances are candidates for singletons because they are immutable and can be used throughout your application.

Your code now has an in-memory representation of a DynamoDB table that can store `Customer` instances. The actual DynamoDB table might or might not exist. If the table named `Customer` already exists, you can begin performing CRUD operations against it. If it doesn't exist, use the `DynamoDbTable` instance to create the table as discussed in the next section.

Create a DynamoDB table if needed

After you have created a `DynamoDbTable` instance, use it to perform a one-time creation of a table in DynamoDB.

Create table example code

The following example creates a DynamoDB table based on the `Customer` data class.

This example creates a DynamoDB table with the name `Customer`—identical to the class name—but the table name can be something else. Whatever you name the table, you must use this name in additional applications to work with the table. Supply this name to the `table()` method anytime you create another `DynamoDbTable` object in order to work with the underlying DynamoDB table.
The Java lambda parameter, builder, passed to the `createTable` method lets you customize the table. In this example, provisioned throughput is configured. If you want to use default settings when you create a table, skip the builder as shown in the following snippet.

```java
customerTable.createTable();
```

When default settings are used, values for provisioned throughput are not set. Instead, the billing mode for the table is set to on-demand.

The example also uses a `DynamoDbWaiter` before attempting to print out the table name received in the response. The creation of a table takes some time. Therefore, using a waiter means you don’t have to write logic that polls the DynamoDB service to see if the table exists before using the table.

### Imports

```java
import com.example.dynamodb.Customer;
import software.amazon.awssdk.core.internal.waiters.ResponseOrException;
import software.amazon.awssdk.enhanced.dynamodb.DynamoDbEnhancedClient;
import software.amazon.awssdk.enhanced.dynamodb.DynamoDbTable;
import software.amazon.awssdk.enhanced.dynamodb.TableSchema;
import software.amazon.awssdk.services.dynamodb.model.DescribeTableResponse;
import software.amazon.awssdk.services.dynamodb.waiters.DynamoDbWaiter;
```

### Code

```java
public static void createCustomerTable(DynamoDbTable<Customer> customerTable,
        DynamoDbClient dynamoDbClient) {
    // Create the DynamoDB table using the 'customerTable' DynamoDbTable instance.
    customerTable.createTable(builder -> builder
        .provisionedThroughput(b -> b
            .readCapacityUnits(10L)
            .writeCapacityUnits(10L)
        .build()));

    // The 'dynamoDbClient' instance passed to the builder for the DynamoDbWaiter is the same instance
    // that was passed to the builder of the DynamoDbEnhancedClient instance used to create the 'customerTable'.
    // This ensures that the same Region that was configured on the standard 'dynamoDbClient' instance is used for all service clients.
```

Map objects to DynamoDB items
```java
try (DynamoDbWaiter waiter = DynamoDbWaiter.builder().client(dynamoDbClient).build()) { // DynamoDbWaiter is Autocloseable
    ResponseOrException<DescribeTableResponse> response = waiter
        .waitUntilTableExists(builder -> builder.tableName("Customer").build())
        .matched();
    DescribeTableResponse tableDescription = response.response().orElseThrow(
        () -> new RuntimeException("Customer table was not created.");)
    // The actual error can be inspected in response.exception()
    logger.info("Customer table was created.");
}
```

### Note

A DynamoDB table's attribute names begin with a lowercase letter when the table is generated from a data class. If you want the table's attribute name to begin with an uppercase letter, use the `@DynamoDbAttribute(NAME) annotation` and provide the name you want as a parameter.

### Perform operations

After the table is created, use the DynamoDbTable instance to perform operations against the DynamoDB table.

In the following example, a singleton `DynamoDbTable<Customer>` is passed as a parameter along with a `Customer data class` instance to add a new item to the table.

```java
public static void putItemExample(DynamoDbTable<Customer> customerTable, Customer customer){
    logger.info(customer.toString());
    customerTable.putItem(customer);
}
```

### Customer object

```java
Customer customer = new Customer();
customer.setId("1");
customer.setCustName("Customer Name");
```
customer.setEmail("customer@example.com");
customer.setRegistrationDate(Instant.parse("2023-07-03T10:15:30.00Z"));

Before sending the customer object to the DynamoDB service, log the output of the object's
toString() method to compare it to what the enhanced client sends.

Customer [id=1, name=Customer Name, email=customer@example.com,
regDate=2023-07-03T10:15:30Z]

Wire-level logging shows the payload of the generated request. The enhanced client generated the
low-level representation from the data class. The regDate attribute, which is an Instant type in
Java, is represented as a DynamoDB string.

{
   "TableName": "Customer",
   "Item": {
      "registrationDate": {
         "S": "2023-07-03T10:15:30Z"
      },
      "id": {
         "S": "1"
      },
      "custName": {
         "S": "Customer Name"
      },
      "email": {
         "S": "customer@example.com"
      }
   }
}

Work with an existing table

The previous section showed how to create a DynamoDB table starting with a Java data class. If
you already have an existing table and want to use the features of the enhanced client, you can
create a Java data class to work with the table. You need to examine the DynamoDB table and add
the necessary annotations to the data class.

Before you work with an existing table, call the DynamoDbEnhanced.table() method. This was
done in the previous example with the following statement.
DynamoDbTable<Customer> customerTable = enhancedClient.table("Customer", TableSchema.fromBean(Customer.class));

After the DynamoDbTable instance is returned, you can begin working right away with the underlying table. You do not need to recreate the table by calling the DynamoDbTable.createTable() method.

The following example demonstrates this by immediately retrieving a Customer instance from the DynamoDB table.

DynamoDbTable<Customer> customerTable = enhancedClient.table("Customer", TableSchema.fromBean(Customer.class));
// The Customer table exists already and has an item with a primary key value of "1" and a sort key value of "customer@example.com".
customerTable.getItem(
    Key.builder().
    partitionValue("1").
    sortValue("customer@example.com").build());

⚠️ Important

The table name used in the table() method must match the existing DynamoDB table name.

Learn the basics of the DynamoDB Enhanced Client API

This topic discusses the basic features of the DynamoDB Enhanced Client API and compares it to the standard DynamoDB client API.

If you are new to the DynamoDB Enhanced Client API, we recommend that you go through the introductory tutorial to familiarize yourself with fundamental classes.

DynamoDB items in Java

DynamoDB tables store items. Depending on your use case, items on the Java side can take the form of statically structured data or structures created dynamically.

If your use case calls for items with a consistent set of attributes, use annotated classes or use a builder to generate the appropriate statically-typed TableSchema.
Alternatively, if you need to store items that consist of varying structures, create a DocumentTableSchema. DocumentTableSchema is part of the Enhanced Document API and requires only a statically-typed primary key and works with EnhancedDocument instances to hold the data elements. The Enhanced Document API is covered in another topic.

**Attribute types**

Although DynamoDB supports a small number of attribute types compared to the rich type system of Java, the DynamoDB Enhanced Client API provides mechanisms to convert members of a Java class to and from DynamoDB attribute types.

By default, the DynamoDB Enhanced Client API supports attribute converters for a large number of types, such as `Integer`, `String`, `BigDecimal`, and `Instant`. The list appears in the known implementing classes of the AttributeConverter interface. The list includes many types and collections such as maps, lists, and sets.

To store the data for an attribute type that isn't supported by default or doesn't conform to the JavaBean convention, you can write a custom AttributeConverter implementation to do the conversion. See the attribute conversion section for an example.

To store the data for an attribute type whose class conforms to the Java beans specification (or an immutable data class), you can take two approaches.

- If you have access to the source file, you can annotate the class with `@DynamoDbBean` (or `@DynamoDbImmutable`). The section that discusses nested attributes shows examples of using annotated classes.

- If you do not have access to the source file of the JavaBean data class for the attribute (or you don’t want to annotate the source file of a class that you do have access to), then you can use the builder approach. This creates a table schema without defining the keys. Then, you can nest this table schema inside another table schema to perform the mapping. The nested attribute section has an example showing use of nested schemas.

**Java primitive type values**

Although the enhanced client can work with attributes of primitive types, we encourage the use of object types because you cannot represent null values with primitive types.
Null values

When you use the putItem API, the enhanced client does not include null-valued attributes of a mapped data object in the request to DynamoDB.

For updateItem requests, null-valued attributes are removed from the item on the database. If you intend to update some attribute values and keep the other unchanged, either copy the values of other attributes that should not be changed or use the `ignoreNull()` method on the update builder.

The following example demonstrates `ignoreNulls()` for the `updateItem()` method.

```java
public void updateItemNullsExample(){
    Customer customer = new Customer();
    customer.setCustName("CustName");
    customer.setEmail("email");
    customer.setId("1");
    customer.setRegistrationDate(Instant.now());
    
    // Put item with values for all attributes.
    customerDynamoDbTable.putItem(customer);
    
    // Create a Customer instance with the same id value, but a different name
    // value.
    // Do not set the 'registrationDate' attribute.
    Customer custForUpdate = new Customer();
    custForUpdate.setCustName("NewName");
    custForUpdate.setEmail("email");
    custForUpdate.setId("1");
    
    // Update item without setting the registrationDate attribute.
    customerDynamoDbTable.updateItem(b -> b
        .item(custForUpdate)
        .ignoreNulls(Boolean.TRUE));
    
    Customer updatedWithNullsIgnored = customerDynamoDbTable.getItem(customer);
    // registrationDate value is unchanged.
    logger.info(updatedWithNullsIgnored.toString());
    
    customerDynamoDbTable.updateItem(custForUpdate);
    Customer updatedWithNulls = customerDynamoDbTable.getItem(customer);
    // registrationDate value is null because ignoreNulls() was not used.
    logger.info(updatedWithNulls.toString());
}
```
DynamoDB Enhanced Client basic methods

Basic methods of the enhanced client map to the DynamoDB service operations that they're named after. The following examples show the simplest variation of each method. You can customize each method by passing in an enhanced request object. Enhanced request objects offer most of the features available in the standard DynamoDB client. They are fully documented in the AWS SDK for Java 2.x API Reference.

The example uses the the section called “Customer class” shown previously.

```java
// CreateTable
customerTable.createTable();

// GetItem
Customer customer =
customerTable.getItem(Key.builder().partitionValue("a123").build());

// UpdateItem
Customer updatedCustomer = customerTable.updateItem(customer);

// PutItem
customerTable.putItem(customer);

// DeleteItem
Customer deletedCustomer =
customerTable.deleteItem(Key.builder().partitionValue("a123").sortValue(456).build());

// Query
PageIterable<Customer> customers = customerTable.query(keyEqualTo(k ->
    k.partitionValue("a123")));

// Scan
PageIterable<Customer> customers = customerTable.scan();

// BatchGetItem
```
BatchGetResultPageIterable batchResults =
    enhancedClient.batchGetItem(r -> r.addReadBatch(ReadBatch.builder(Customer.class)
        .mappedTableResource(customerTable)
        .addItem(key1)
        .addItem(key2)
        .addItem(key3)
        .build()));

// BatchWriteItem
batchResults = enhancedClient.batchWriteItem(r ->
    r.addWriteBatch(WriteBatch.builder(Customer.class)
        .mappedTableResource(customerTable)
        .addItem(customer)
        .addDeleteItem(key1)
        .addDeleteItem(key1)
        .build()));

// TransactGetItems
transactResults = enhancedClient.transactGetItems(r -> r.addItem(customerTable,
    key1)
    .addItem(customerTable,
    key2));

// TransactWriteItems
enhancedClient.transactWriteItems(r -> r.addConditionCheck(customerTable,
    i -> i.key(orderKey)
    .conditionExpression(conditionExpression))
    .addItem(customerTable, customer)
    .addDeleteItem(customerTable, key));

**Compare DynamoDB Enhanced Client to standard DynamoDB client**

Both DynamoDB client APIs—**standard** and **enhanced**—let you work with DynamoDB tables to perform CRUD (create, read, update and delete) data-level operations. The difference between the client APIs is how that is accomplished. Using the standard client, you work directly with low-level data attributes. The enhanced client API uses familiar Java classes and maps to the low-level API behind the scenes.

While both client APIs support data-level operations, the standard DynamoDB client also supports resource-level operations. Resource-level operations manage the database, such as creating
backups, listing tables, and updating tables. The enhanced client API supports a select number of resource-level operations such as creating, describing, and deleting tables.

To illustrate the different approaches used by the two client APIs, the following code examples show the creation of the same ProductCatalog table using the standard client and the enhanced client.

**Compare: Create a table using the standard DynamoDB client**

```java
DependencyFactory.dynamoDbClient().createTable(builder -> builder
    .tableName(TABLE_NAME)
    .attributeDefinitions(
        b -> b.attributeName("id").attributeType(ScalarAttributeType.N),
        b -> b.attributeName("title").attributeType(ScalarAttributeType.S),
        b -> b.attributeName("isbn").attributeType(ScalarAttributeType.S)
    )
    .keySchema(
        builder1 -> builder1.attributeName("id").keyType(KeyType.HASH),
        builder2 -> builder2.attributeName("title").keyType(KeyType.RANGE)
    )
    .globalSecondaryIndexes(builder3 -> builder3
        .indexName("products_by_isbn")
        .keySchema(builder2 -> builder2
            .attributeName("isbn").keyType(KeyType.HASH))
        .projection(builder2 -> builder2
            .projectionType(ProjectionType.INCLUDE)
            .nonKeyAttributes("price", "authors"))
        .provisionedThroughput(builder4 -> builder4
            .writeCapacityUnits(5L).readCapacityUnits(5L))
    )
    .provisionedThroughput(builder1 -> builder1
        .readCapacityUnits(5L).writeCapacityUnits(5L))
);
```

**Compare: Create a table using the DynamoDB Enhanced Client**

```java
DynamoDbEnhancedClient enhancedClient = DependencyFactory.enhancedClient();
productCatalog = enhancedClient.table(TABLE_NAME,
    TableSchema.fromImmutableClass(ProductCatalog.class));
productCatalog.createTable(b -> b
    .provisionedThroughput(b1 -> b1.readCapacityUnits(5L).writeCapacityUnits(5L))
    .globalSecondaryIndices(b2 -> b2.indexName("products_by_isbn")
        .projection(b4 -> b4
            .writeCapacityUnits(5L).readCapacityUnits(5L))
    );
```
The enhanced client uses the following annotated data class. The DynamoDB Enhanced Client maps Java data types to DynamoDB data types for less verbose code that is easier to follow. ProductCatalog is an example of using an immutable class with the DynamoDB Enhanced Client. The use of Immutable classes for mapped data classes is discussed later in this topic.

**ProductCatalog class**

```java
package org.example.tests.model;

import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbIgnore;
import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbImmutable;
import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbPartitionKey;
import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbSecondaryPartitionKey;
import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbSortKey;
import java.math.BigDecimal;
import java.util.Objects;
import java.util.Set;

@DynamoDbImmutable(builder = ProductCatalog.Builder.class)
public class ProductCatalog implements Comparable<ProductCatalog> {
    private Integer id;
    private String title;
    private String isbn;
    private Set<String> authors;
    private BigDecimal price;

    private ProductCatalog(Builder builder){
        this.authors = builder.authors;
        this.id = builder.id;
        this.isbn = builder.isbn;
        this.price = builder.price;
        this.title = builder.title;
    }

    // Constructor
    // Getters and Setters
    // Other methods
}
```
public static Builder builder() { return new Builder(); }

@DynamoDbPartitionKey
public Integer id() { return id; }

@DynamoDbSortKey
public String title() { return title; }

@DynamoDbSecondaryPartitionKey(indexNames = "products_by_isbn")
public String isbn() { return isbn; }
public Set<String> authors() { return authors; }
public BigDecimal price() { return price; }

public static final class Builder {
    private Integer id;
    private String title;
    private String isbn;
    private Set<String> authors;
    private BigDecimal price;
    private Builder(){}

    public Builder id(Integer id) { this.id = id; return this; }
    public Builder title(String title) { this.title = title; return this; }
    public Builder isbn(String ISBN) { this.isbn = ISBN; return this; }
    public Builder authors(Set<String> authors) { this.authors = authors; return this; }
    public Builder price(BigDecimal price) { this.price = price; return this; }

    public ProductCatalog build() { return new ProductCatalog(this); }
}

@Override
public String toString() {
    final StringBuffer sb = new StringBuffer("ProductCatalog{"
        sb.append("id=").append(id);
        sb.append(" title='").append(title).append(''");
        sb.append(" isbn='").append(isbn).append(''");
        sb.append(" authors='").append(authors);
        sb.append(" price='").append(price);
        return sb.toString();
    }

    Map objects to DynamoDB items

```java
@Override
public boolean equals(Object o) {
    if (this == o) return true;
    if (o == null || getClass() != o.getClass()) return false;
    ProductCatalog that = (ProductCatalog) o;
    return id.equals(that.id) && title.equals(that.title) && Objects.equals(isbn,
            that.isbn) && Objects.equals(authors, that.authors) && Objects.equals(price,
            that.price);
}

@Override
public int hashCode() {
    return Objects.hash(id, title, isbn, authors, price);
}

@Override
@DynamoDbIgnore
public int compareTo(ProductCatalog other) {
    if (this.id.compareTo(other.id) != 0){
        return this.id.compareTo(other.id);
    } else {
        return this.title.compareTo(other.title);
    }
}
```

The following two code examples of a batch write illustrate the verboseness and lack of type safety when using the standard client as opposed to the enhanced client.

**Compare: Batch write using the standard DynamoDB client**

```java
public static void batchWriteStandard(DynamoDbClient dynamoDbClient, String
        tableName) {

    Map<String, AttributeValue> catalogItem = Map.of(
            "authors", AttributeValue.builder().ss("a", "b").build(),
            "id", AttributeValue.builder().n("1").build(),
            "isbn", AttributeValue.builder().s("1-565-85698").build(),
            "title", AttributeValue.builder().s("Title 1").build(),
            "price", AttributeValue.builder().n("52.13").build());

    Map<String, AttributeValue> catalogItem2 = Map.of(
```
Map<String, AttributeValue> catalogItem3 = Map.of(
    "authors", AttributeValue.builder().ss("g", "k", "c").build(),
    "id", AttributeValue.builder().n("3").build(),
    "isbn", AttributeValue.builder().s("7-236-98618").build(),
    "title", AttributeValue.builder().s("Title 3").build(),
    "price", AttributeValue.builder().n("42.00").build());

Set<WriteRequest> writeRequests = Set.of(
    WriteRequest.builder().putRequest(b -> b.item(catalogItem)).build(),
    WriteRequest.builder().putRequest(b -> b.item(catalogItem2)).build(),
    WriteRequest.builder().putRequest(b -> b.item(catalogItem3)).build());

Map<String, Set<WriteRequest>> productCatalogItems = Map.of(
    "ProductCatalog", writeRequests);

BatchWriteItemResponse response = dynamoDbClient.batchWriteItem(b ->
    b.requestItems(productCatalogItems));

logger.info("Unprocessed items: " + response.unprocessedItems().size());
}

Compare: Batch write using the DynamoDB Enhanced Client

public static void batchWriteEnhanced(DynamoDbTable<ProductCatalog> productCatalog) {
    ProductCatalog prod = ProductCatalog.builder()
        .id(1)
        .isbn("1-565-85698")
        .authors(new HashSet<>(Arrays.asList("a", "b")))
        .price(BigDecimal.valueOf(52.13))
        .title("Title 1")
        .build();

    ProductCatalog prod2 = ProductCatalog.builder()
        .id(2)
        .isbn("1-208-98073")
        .authors(new HashSet<>(Arrays.asList("a", "b", "c")))
        .price(BigDecimal.valueOf(21.99))
        .build();
Work with immutable data classes

The mapping feature of the DynamoDB Enhanced Client API works with immutable data classes. An immutable class has only getters and requires a builder class that the SDK uses to create instances of the class. Instead of using the @DynamoDbBean annotation as shown in the Customer class, immutable classes use the @DynamoDbImmutable annotation, which takes a parameter that indicates the builder class to use.

The following class is an immutable version of Customer.

```java
package org.example.tests.model.immutable;

import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbImmutable;
import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbPartitionKey;
import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbSecondaryPartitionKey;
import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbSecondarySortKey;
import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbSortKey;
import java.time.Instant;
```
@DynamoDbImmutable(builder = CustomerImmutable.Builder.class)
public class CustomerImmutable {
    private final String id;
    private final String name;
    private final String email;
    private final Instant regDate;

    private CustomerImmutable(Builder b) {
        this.id = b.id;
        this.email = b.email;
        this.name = b.name;
        this.regDate = b.regDate;
    }

    // This method will be automatically discovered and used by the TableSchema.
    public static Builder builder() { return new Builder(); }

    @DynamoDbPartitionKey
    public String id() { return this.id; }

    @DynamoDbSortKey
    public String email() { return this.email; }

    @DynamoDbSecondaryPartitionKey(indexNames = "customers_by_name")
    public String name() { return this.name; }

    @DynamoDbSecondarySortKey(indexNames = {"customers_by_date", "customers_by_name"})
    public Instant regDate() { return this.regDate; }

    public static final class Builder {
        private String id;
        private String email;
        private String name;
        private Instant regDate;

        // The private Builder constructor is visible to the enclosing Customer class.
        private Builder() {}

        public Builder id(String accountId) { this.id = id; return this; }
        public Builder email(String email) { this.email = email; return this; }
        public Builder name(String name) { this.name = name; return this; }
        public Builder regDate(Instant regDate) { this.regDate = regDate; return this; }
    }
}
public CustomerImmutable build() { return new CustomerImmutable(this); }
}

You must meet the following requirements when you annotate a data class with @DynamoDbImmutable.

1. Every method that is both not an override of Object.class and has not been annotated with @DynamoDbIgnore must be a getter for an attribute of the DynamoDB table.
2. Every getter must have a corresponding case-sensitive setter on the builder class.
3. Only one of the following construction conditions must be met.
   - The builder class must have a public default constructor.
   - The data class must have a public static method named builder() that takes no parameters and returns an instance of the builder class. This option is shown in the immutable Customer class.
4. The builder class must have a public method named build() that takes no parameters and returns an instance of the immutable class.

To create a TableSchema for your immutable class, use the fromImmutableClass() method on TableSchema as shown in the following snippet.

```java
static final TableSchema<CustomerImmutable> customerImmutableTableSchema =
    TableSchema.fromImmutableClass(CustomerImmutable.class);
```

Just as you can create a DynamoDB table from a mutable class, you can create one from an immutable class with a one-time call to createTable() of DynamoDbTable as shown in the following snippet example.

```java
static void createTableFromImmutable(DynamoDbEnhancedClient enhancedClient, String
    tableName, DynamoDbWaiter waiter){
    // First, create an in-memory representation of the table using the 'table()' method of the DynamoDb Enhanced Client.
    // 'table()' accepts a name for the table and a TableSchema instance that you created previously.
    DynamoDbTable<CustomerImmutable> customerDynamoDbTable = enhancedClient
        .table(tableName, TableSchema.fromImmutableClass(CustomerImmutable.class));
```
// Second, call the 'createTable()' method on the DynamoDbTable instance.
customerDynamoDbTable.createTable();
waiter.waitUntilTableExists(b -> b.tableName(tableName));
}

**Use third-party libraries, such as Lombok**

Third-party libraries, such as [Project Lombok](https://projectlombok.org), help generate boilerplate code associated with immutable objects. The DynamoDB Enhanced Client API works with these libraries as long as the data classes follow the conventions detailed in this section.

The following example shows the immutable `CustomerImmutable` class with Lombok annotations. Note how Lombok's `onMethod` feature copies attribute-based DynamoDB annotations, such as `@DynamoDbPartitionKey`, onto the generated code.

```java
@Value
@Builder
@DynamoDbImmutable(builder = Customer.CustomerBuilder.class)
public class Customer {
    @Getter(onMethod_=@DynamoDbPartitionKey)
    private String id;

    @Getter(onMethod_=@DynamoDbSortKey)
    private String email;

    @Getter(onMethod_=@DynamoDbSecondaryPartitionKey(indexNames = "customers_by_name"))
    private String name;

    @Getter(onMethod_=@DynamoDbSecondarySortKey(indexNames = {"customers_by_date", "customers_by_name"}))
    private Instant createdDate;
}
```

**Use expressions and conditions**

Expressions in the DynamoDB Enhanced Client API are Java representations of [DynamoDB expressions](https://docs.aws.amazon.com/AWSJavaSDK/latest/api/software/amazon/aws/aws/dynamodb/fastjson/ExpressionBuilder.html).

The DynamoDB Enhanced Client API uses three types of expressions:
Expression

The Expression class is used when you define conditions and filters.

QueryConditional

This type of expression represents key conditions for query operations.

UpdateExpression

This class helps you write DynamoDB update expressions and is currently used in the extension framework when you update an item.

Expression anatomy

An expression is made up of the following:

- A string expression (required). The string contains a DynamoDB logic expression with placeholder names for attribute names and attribute values.
- A map of expression values (usually required).
- A map of expression names (optional).

Use a builder to generate an Expression object that takes the following general form.

```java
Expression expression = Expression.builder()
    .expression(<String>)
    .expressionNames(<Map>)
    .expressionValues(<Map>)
    .build()
```

Expressions usually require a map of expression values. The map provides the values for the placeholders in the string expression. The map key consists of the placeholder name preceded with a colon (:) and the map value is an instance of AttributeValue. The AttributeValues class has convenience methods to generate an AttributeValue instance from a literal. Alternatively, you can use the AttributeValue.Builder to generate an AttributeValue instance.

The following snippet shows a map with two entries after comment line 2. The string passed to the expression() method, shown after comment line 1, contains the placeholders that DynamoDB resolves before performing the operation. This snippet doesn't contain a map of expression names, because price is a permissible attribute name.
public static void scanAsync(DynamoDbAsyncTable productCatalog) {
    ScanEnhancedRequest request = ScanEnhancedRequest.builder()
        .consistentRead(true)
        .attributesToProject("id", "title", "authors", "price")
        .filterExpression(Expression.builder()
            .expression("price >= :min_value AND price <= :max_value")
            .expressionValues(
                Map.of("min_value", numberValue(8.00),
                    "max_value", numberValue(400_000.00)))
            .build())
        .build();
}

If an attribute name in the DynamoDB table is a reserved word, begins with a number, or contains a space, a map of expression names is required for the `Expression`.

For example, if the attribute name was `1price` instead of `price` in the previous code example, the example would need to be modified as shown in the following example.

```java
ScanEnhancedRequest request = ScanEnhancedRequest.builder()
    .filterExpression(Expression.builder()
        .expression("#price >= :min_value AND #price <= :max_value")
        .expressionNames( Map.of("#price", "1price") )
        .expressionValues(
            Map.of("min_value", numberValue(8.00),
                "max_value", numberValue(400_000.00)))
        .build())
    .build();
```

A placeholder for an expression name begins with the pound sign (`#`). An entry for the map of expression names uses the placeholder as the key and the attribute name as the value. The map is added to the expression builder with the `expressionNames()` method. DynamoDB resolves the attribute name before it performs the operation.

Expression values are not required if a function is used in the string expression. An example of an expression function is `attribute_exists(<attribute_name>)`.
The following example builds an Expression that uses a **DynamoDB function**. The expression string in this example uses no placeholders. This expression could be used on a putItem operation to check if an item already exists in the database with a `movie` attribute's value equal to the data object's `movie` attribute.

```java
Expression exp = Expression.builder().expression("attribute_not_exists (movie)").build();
```

The DynamoDB Developer Guide contains complete information on the **low-level expressions** that are used with DynamoDB.

**Condition expressions and conditionals**

When you use the `putItem()`, `updateItem()`, and `deleteItem()` methods, and also when you use transaction and batch operations, you use `Expression` objects to specify conditions that DynamoDB must meet to proceed with the operation. These expressions are named condition expressions. For an example, see the condition expression used in the `addDeleteItem()` method (after comment line 1) of **transaction example** shown in this guide.

When you work with the `query()` methods, a condition is expressed as a `QueryConditional`. The `QueryConditional` class has several static convenience methods that help you write the criteria that determine which items to read from DynamoDB.

For examples of `QueryConditionals`, see the first code example of the **the section called “Query method examples”** section of this guide.

**Filter expressions**

Filter expressions are used in scan and query operations to filter the items that are returned.

A filter expression is applied after all the data is read from the database, so the read cost is the same as if there were no filter. The *Amazon DynamoDB Developer Guide* has more information about using filter expressions for both `query` and `scan` operations.

The following example shows a filter expression added to a scan request. The criteria restricts the items returned to items with a price between 8.00 and 80.00 inclusive.

```java
Map<String, AttributeValue> expressionValues = Map.of(  " :min_value", numberValue(8.00),
```

*Map objects to DynamoDB items*
"max_value", numberValue(80.00));

ScanEnhancedRequest request = ScanEnhancedRequest.builder()
  .consistentRead(true)
  // 1. the 'attributesToProject()' method allows you to specify which
  .attributesToProject("id", "title", "authors", "price")
  // 2. Filter expression limits the items returned that match the
  provided criteria.
  .filterExpression(Expression.builder()
    .expression("price >= :min_value AND price <= :max_value")
    .expressionValues(expressionValues)
    .build())
  .build();

Update expressions

The DynamoDB Enhanced Client's updateItem() method provides a standard way to update
items in DynamoDB. However, when you require more functionality, UpdateExpressions provide
a type-safe representation of DynamoDB update expression syntax. For example, you can use
UpdateExpressions to increase values without first reading items from DynamoDB, or add
individual members to a list. Update expressions are currently available in custom extensions for
the updateItem() method.

For an example that uses update expressions, see the custom extension example in this guide.

More information about update expressions is available in the Amazon DynamoDB Developer
Guide.

Work with paginated results: scans and queries

The scan, query and batch methods of the DynamoDB Enhanced Client API return responses
with one or more pages. A page contains one or more items. Your code can process the response on
per-page basis or it can process individual items.

A paginated response returned by the synchronous DynamoDbEnhancedClient
client returns a PageIterator object, whereas a response returned by the asynchronous
DynamoDbEnhancedAsyncClient returns a PagePublisher object.

This section looks at processing paginated results and provides examples that use the scan and
query APIs.
Scan a table

The SDK’s scan method corresponds to the DynamoDB operation of the same name. The DynamoDB Enhanced Client API offers the same options but it uses a familiar object model and handles the pagination for you.

First, we explore the PageIterable interface by looking at the scan method of the synchronous mapping class, DynamoDbTable.

Use the synchronous API

The following example shows the scan method that uses an expression to filter the items that are returned. The ProductCatalog is the model object that was shown earlier.

The filtering expression shown after comment line 1 limits the ProductCatalog items that are returned to those with a price value between 8.00 and 80.00 inclusively.

This example also excludes the isbn values by using the attributesToProject method shown after comment line 2.

On comment line 3, the PageIterable object, pagedResult, is returned by the scan method. The stream method of PageIterable returns a java.util.Stream object, which you can use to process the pages. In this example, the number of pages is counted and logged.

Starting with comment line 4, the example shows two variations of accessing the ProductCatalog items. The version after comment line 2a streams through each page and sorts and logs the items on each page. The version after comment line 2b skips the page iteration and accesses the items directly.

The PageIterable interface offers multiple ways to process results because of its two parent interfaces—java.lang.Iterable and SdkIterable. Iterable brings the forEach, iterator and spliterator methods, and SdkIterable brings the stream method.

```java
public static void scanSync(DynamoDbTable<ProductCatalog> productCatalog) {
    Map<String, AttributeValue> expressionValues = Map.of(
        "min_value", numberValue(8.00),
        "max_value", numberValue(80.00));

    ScanEnhancedRequest request = ScanEnhancedRequest.builder()
        .consistentRead(true)
```
// 1. the 'attributesToProject()' method allows you to specify which
values you want returned.
   .attributesToProject("id", "title", "authors", "price")
// 2. Filter expression limits the items returned that match the
provided criteria.
   .filterExpression(Expression.builder()
      .expression("price >= :min_value AND price <= :max_value")
      .expressionValues(expressionValues)
      .build())
   .build();

// 3. A PageIterable object is returned by the scan method.
PageIterable<ProductCatalog> pagedResults = productCatalog.scan(request);
logger.info("page count: ", pagedResults.stream().count());

// 4. Log the returned ProductCatalog items using two variations.
// 4a. This version sorts and logs the items of each page.
pagedResults.stream().forEach(p -> p.items().stream()
   .sorted(Comparator.comparing(ProductCatalog::price))
   .forEach(
        item -> logger.info(item.toString())
   ));
// 4b. This version sorts and logs all items for all pages.
pagedResults.items().stream()
   .sorted(Comparator.comparing(ProductCatalog::price))
   .forEach(
        item -> logger.info(item.toString())
   );
}

Use the asynchronous API

The asynchronous scan method returns results as a PagePublisher object. The PagePublisher interface has two subscribe methods that you can use to process response pages. One subscribe method comes from the org.reactivestreams.Publisher parent interface. To process pages using this first option, pass a Subscriber instance to the subscribe method. The first example that follows shows the use of subscribe method.

The second subscribe method comes from the SdkPublisher interface. This version of subscribe accepts a Consumer rather than a Subscriber. This subscribe method variation is shown in the second example that follows.
The following example shows the asynchronous version of the `scan` method that uses the same filter expression shown in the previous example.

After comment line 3, `DynamoDbAsyncTable.scan` returns a `PagePublisher` object. On the next line, the code creates an instance of the `org.reactivestreams.Subscriber` interface, `ProductCatalogSubscriber`, which subscribes to the `PagePublisher` after comment line 4.

The `Subscriber` object collects the `ProductCatalog` items from each page in the `onNext` method after comment line 8 in the `ProductCatalogSubscriber` class example. The items are stored in the private `List` variable and are accessed in the calling code with the `ProductCatalogSubscriber.getSubscribedItems()` method. This is called after comment line 5.

After the list is retrieved, the code sorts all `ProductCatalog` items by price and logs each item.

The `CountDownLatch` in the `ProductCatalogSubscriber` class blocks the calling thread until all items have been added to the list before continuing after comment line 5.

```java
public static void scanAsync(DynamoDbAsyncTable productCatalog) {
    ScanEnhancedRequest request = ScanEnhancedRequest.builder()
        .consistentRead(true)
        .attributesToProject("id", "title", "authors", "price")
        .filterExpression(Expression.builder()
            .expression("price >= :min_value AND price <= :max_value")
            .expressionValues(
                Map.of(":min_value", numberValue(8.00),
                      ":max_value", numberValue(400_000.00)))
            .build())
        .build();

    // 1. :min_value and :max_value are placeholders for the values
    // provided by the map
    // 2. Two values are needed for the expression and each is
    // supplied as a map entry.
    .expressionValues(
        Map.of(":min_value", numberValue(8.00),
                ":max_value", numberValue(400_000.00)))
        .build();

    // 3. A PagePublisher object is returned by the scan method.
    PagePublisher<ProductCatalog> pagePublisher = productCatalog.scan(request);
    ProductCatalogSubscriber subscriber = new ProductCatalogSubscriber();
    // 4. Subscribe the ProductCatalogSubscriber to the PagePublisher.
    pagePublisher.subscribe(subscriber);
    // 5. Retrieve all collected ProductCatalog items accumulated by the
    // subscriber.
    subscriber.getSubscribedItems().stream()
```
.sorted(Comparator.comparing(ProductCatalog::price))
    .forEach(item ->
        logger.info(item.toString()));
    // 6. Use a Consumer to work through each page.
    pagePublisher.subscribe(page -> page
        .items().stream()
        .sorted(Comparator.comparing(ProductCatalog::price))
        .forEach(item ->
            logger.info(item.toString())))
    .join(); // If needed, blocks the subscribe() method thread until it is
    finished processing.
    // 7. Use a Consumer to work through each ProductCatalog item.
    pagePublisher.items()
        .subscribe(product -> logger.info(product.toString()))
        .exceptionally(failure -> {
            logger.error("ERROR - ", failure);
            return null;
        })
        .join(); // If needed, blocks the subscribe() method thread until it is
    finished processing.
}

private static class ProductCatalogSubscriber implements
    Subscriber<Page<ProductCatalog>> {
    private CountDownLatch latch = new CountDownLatch(1);
    private Subscription subscription;
    private List<ProductCatalog> itemsFromAllPages = new ArrayList<>();

    @Override
    public void onSubscribe(Subscription sub) {
        subscription = sub;
        subscription.request(1L);
        try {
            latch.await(); // Called by main thread blocking it until latch is
            released.
        } catch (InterruptedException e) { 
            throw new RuntimeException(e);
        }
    }

    @Override
    public void onNext(Page<ProductCatalog> productCatalogPage) {

        Map objects to DynamoDB items
    }
The following snippet example uses the version of the PagePublisher.subscribe method that accepts a Consumer after comment line 6. The Java lambda parameter consumes pages, which further process each item. In this example, each page is processed and the items on each page are sorted and then logged.

```java
// 6. Use a Consumer to work through each page.
pagePublisher.subscribe(page -> page
    .items().stream()
    .sorted(Comparator.comparing(ProductCatalog::price))
    .forEach(item ->
        logger.info(item.toString()))
    .join()); // If needed, blocks the subscribe() method thread until it is finished processing.
```

The items method of PagePublisher unwraps the model instances so that your code can process the items directly. This approach is shown in the following snippet.

```java
// 7. Use a Consumer to work through each ProductCatalog item.
pagePublisher.items()
    .subscribe(product -> logger.info(product.toString()))
    .exceptionally(failure -> {
      logger.error("ERROR - ", failure);
```

Map objects to DynamoDB items
Query a table

The `query()` method of the DynamoDbTable class finds items based on primary key values. The `@DynamoDbPartitionKey` annotation and the optional `@DynamoDbSortKey` annotation are used to define the primary key on your data class.

The `query()` method requires a partition key value that finds items that match the supplied value. If your table also defines a sort key, you can add a value for it to your query as an additional comparison condition to fine tune the results.

Except for processing the results, the synchronous and asynchronous versions of `query()` work the same. As with the scan API, the query API returns a `PageIterable` for a synchronous call and a `PagePublisher` for asynchronous call. We discussed the use of `PageIterable` and `PagePublisher` previously in the scan section.

Query method examples

The `query()` method code example that follows uses the MovieActor class. The data class defines a composite primary key that is made up of the `movie` attribute for the partition key and the `actor` attribute for the sort key.

The class also signals that it uses a global secondary index named `acting_award_year`. The index's composite primary key is composed of the `actingaward` attribute for the partition key and the `actingyear` for the sort key. Later in this topic, when we show how to create and use indexes, we'll refer to the `acting_award_year` index.

MovieActor class

```java
package org.example.tests.model;

import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbAttribute;
import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbBean;

</table>

Map objects to DynamoDB items
The following code defines two `QueryConditional` instances. QueryConditionals work with key values—either the partition key alone or in combination with the sort key—and correspond to the key conditional expressions of the DynamoDB service API. After comment line 1, the example defines the `keyEqual` instance that matches items with a partition value of `movie01`.

This example also defines a filter expression that filters off any item that has no `actingschoolname` on after comment line 2.

After comment line 3, the example shows the `QueryEnhancedRequest` instance that the code passes to the `DynamoDbTable.query()` method. This object combines the key condition and filter that the SDK uses to generate the request to the DynamoDB service.

```
public static void query(DynamoDbTable movieActorTable) {
    // 1. Define a QueryConditional instance to return items matching a partition value.
    QueryConditional keyEqual = QueryConditional.keyEqualTo(b -> b.partitionValue("movie01"));
    // 1a. Define a QueryConditional that adds a sort key criteria to the partition value criteria.
    QueryConditional sortGreaterThanOrEqualTo = QueryConditional.sortGreaterThanOrEqualTo(b -> b.partitionValue("movie01").sortValue("actor2"));
    // 2. Define a filter expression that filters out items whose attribute value is null.
    final Expression filterOutNoActingschoolname = Expression.builder().expression("attribute_exists(actingschoolname)").build();
    // 3. Build the query request.
    QueryEnhancedRequest tableQuery = QueryEnhancedRequest.builder()
        .queryConditional(keyEqual)
        .filterExpression(filterOutNoActingschoolname)
        .build();
    // 4. Perform the query.
    PageIterable<MovieActor> pagedResults = movieActorTable.query(tableQuery);
}
```
logger.info("page count: ", pagedResults.stream().count()); // Log number of pages.

pagedResults.items().stream()
  .sorted()
  .forEach(
    item -> logger.info(item.toString()) // Log the sorted list of items.
  );

The following is the output from running the method. The output displays items with a movieName value of **movie01** and displays no items with actingSchoolName equal to **null**.

2023-03-05 13:11:05 [main] INFO  org.example.tests.QueryDemo:46 - page count: 1
2023-03-05 13:11:05 [main] INFO  org.example.tests.QueryDemo:51 - MovieActor{movieName='movie01', actorName='actor1', actingAward='actingaward1', actingYear=2001, actingSchoolName='actingschool1'}
2023-03-05 13:11:05 [main] INFO  org.example.tests.QueryDemo:51 - MovieActor{movieName='movie01', actorName='actor2', actingAward='actingaward2', actingYear=2001, actingSchoolName='actingschool2'}
2023-03-05 13:11:05 [main] INFO  org.example.tests.QueryDemo:51 - MovieActor{movieName='movie01', actorName='actor4', actingAward='actingaward4', actingYear=2001, actingSchoolName='actingschool4'}

In the following query request variation shown previously after comment line 3, the code replaces the keyEqual QueryConditional with the sortGreaterThanOrEqualTo QueryConditional that was defined after comment line 1a. The following code also removes the filter expression.

```java
QueryEnhancedRequest tableQuery = QueryEnhancedRequest.builder()
  .queryConditional(sortGreaterThanOrEqualTo)
```

Because this table has a composite primary key, all QueryConditional instances require a partition key value. QueryConditional methods that begin with sort... indicate that a sort key is required. The results are not sorted.

The following output displays the results from the query. The query returns items that have a movieName value equal to **movie01** and only items that have an actorName value that is greater than or equal to **actor2**. Because the filter was removed, the query returns items that have no value for the actingSchoolName attribute.

2023-03-05 13:15:00 [main] INFO  org.example.tests.QueryDemo:46 - page count: 1
Perform batch operations

The DynamoDB Enhanced Client API offers two batch methods, `batchGetItem()` and `batchWriteItem()`.

**batchGetItem() example**

With the `DynamoDbTable.batchGetItem()` method, you can retrieve up to 100 individual items across multiple tables in one overall request. The following example uses the `Customer` and `MovieActor` data classes shown previously.

In the example after lines 1 and 2, you build `ReadBatch` objects that you later add as parameters to the `batchGetItem()` method after comment line 3. The code after comment line 1 builds the batch to read from the `Customer` table. The code after comment line 1a shows the use of a `GetItemEnhancedRequest` builder that takes primary key values to specify the item to read.

In contrast to specifying key values to request an item, you can use a data class to request an item as shown after comment line 1b. The SDK extracts the key values behind the scenes before submitting the request.

When you specify the item using the key-based approach as shown in the two statements after 2a, you can also specify that DynamoDB should perform a strongly consistent read. When the `consistentRead()` method is used, it must be used on all requested items for the same table.

To retrieve the items that DynamoDB found, use the `resultsForTable()` method that is shown after comment line 4. Call the method for each table that was read in the request. `resultsForTable()` returns a list of found items that you can process using any `java.util.List` method. This example logs each item.

To discover items that DynamoDB did not process, use the approach after comment line 5. The `BatchGetResultPage` class has the `unprocessedKeysForTable()` method that gives you...
access to each key that was unprocessed. The [BatchGetItem API reference](https://docs.aws.amazon.com/AWSJavaSDK/latest/api/com/amazonaws/dynamodb/model/Request.html) has more information about situations that result in unprocessed items.

```java
public static void batchGetItemExample(DynamoDbEnhancedClient enhancedClient,
   DynamoDbTable<Customer> customerTable,
   DynamoDbTable<MovieActor> movieActorTable) {

    Customer customer2 = new Customer();
    customer2.setId("2");
    customer2.setEmail("cust2@example.org");

    // 1. Build a batch to read from the Customer table.
    ReadBatch customerBatch = ReadBatch.builder(Customer.class)
        .mappedTableResource(customerTable)
        // 1a. Specify the primary key values for the item.
        .addGetItem(b -> b.key(k ->
            k.partitionValue("1").sortValue("cust1@orgname.org")))
        // 1b. Alternatively, supply a data class instances to provide the
        primary key values.
        .addGetItem(customer2)
        .build();

    // 2. Build a batch to read from the MovieActor table.
    ReadBatch movieActorBatch = ReadBatch.builder(MovieActor.class)
        .mappedTableResource(movieActorTable)
        // 2a. Call consistentRead(Boolean.TRUE) for each item for the same
        table.
        .addGetItem(b -> b.key(k ->
            k.partitionValue("movie01").sortValue("actor1")).consistentRead(Boolean.TRUE))
        .addGetItem(b -> b.key(k ->
            k.partitionValue("movie01").sortValue("actor4")).consistentRead(Boolean.TRUE))
        .build();

    // 3. Add ReadBatch objects to the request.
    BatchGetResultPageIterable resultPages = enhancedClient.batchGetItem(b ->
        b.readBatches(customerBatch, moveActorBatch));

    // 4. Retrieve the successfully requested items from each table.
    resultPages.resultsForTable(customerTable).forEach(item ->
        logger.info(item.toString()));
    resultPages.resultsForTable(movieActorTable).forEach(item ->
        logger.info(item.toString()));
```

Map objects to DynamoDB items
AWS SDK for Java 2.x

Developer Guide for version 2.x

// 5. Retrieve the keys of the items requested but not processed by the service.
resultPages.forEach((BatchGetResultPage pageResult) -> {
    pageResult.unprocessedKeysForTable(customerTable).forEach(key ->
        logger.info("Unprocessed item key: " + key.toString()));
    pageResult.unprocessedKeysForTable(customerTable).forEach(key ->
        logger.info("Unprocessed item key: " + key.toString()));
});

Assume that the following items are in the two tables before running the example code.

Items in tables

Customer [id=1, name=CustName1, email=cust1@example.org,
    regDate=2023-03-31T15:46:27.688Z]
Customer [id=2, name=CustName2, email=cust2@example.org,
    regDate=2023-03-31T15:46:28.688Z]
Customer [id=3, name=CustName3, email=cust3@example.org,
    regDate=2023-03-31T15:46:29.688Z]
Customer [id=4, name=CustName4, email=cust4@example.org,
    regDate=2023-03-31T15:46:30.688Z]
Customer [id=5, name=CustName5, email=cust5@example.org,
    regDate=2023-03-31T15:46:31.689Z]
MovieActor{movieName='movie01', actorName='actor0', actingAward='actingaward0',
    actingYear=2001, actingSchoolName='null'}
MovieActor{movieName='movie01', actorName='actor1', actingAward='actingaward1',
    actingYear=2001, actingSchoolName='actingschool1'}
MovieActor{movieName='movie01', actorName='actor2', actingAward='actingaward2',
    actingYear=2001, actingSchoolName='actingschool2'}
MovieActor{movieName='movie01', actorName='actor3', actingAward='actingaward3',
    actingYear=2001, actingSchoolName='null'}
MovieActor{movieName='movie01', actorName='actor4', actingAward='actingaward4',
    actingYear=2001, actingSchoolName='actingschool4'}

The following output shows the items returned and logged after comment line 4.

Customer [id=1, name=CustName1, email=cust1@example.org,
    regDate=2023-03-31T15:46:27.688Z]
Customer [id=2, name=CustName2, email=cust2@example.org,
    regDate=2023-03-31T15:46:28.688Z]
MovieActor{movieName='movie01', actorName='actor4', actingAward='actingaward4',
    actingYear=2001, actingSchoolName='actingschool4'}
batchWriteItem() example

The batchWriteItem() method puts or deletes multiple items in one or more tables. You can specify up to 25 individual put or delete operations in the request. The following example uses the ProductCatalog and MovieActor model classes shown previously.

WriteBatch objects are built after comment lines 1 and 2. For the ProductCatalog table, the code puts one item and deletes one item. For the MovieActor table after comment line 2, the code puts two items and deletes one.

The batchWriteItem method is called after comment line 3. The builder parameter provides the batch requests for each table.

The returned BatchWriteResult object provides separate methods for each operation to view unprocessed requests. The code after comment line 4a provides the keys for unprocessed delete requests and the code after comment line 4b provides the unprocessed put items.

```java
public static void batchWriteItemExample(DynamoDbEnhancedClient enhancedClient,
                                         DynamoDbTable<ProductCatalog> catalogTable,
                                         DynamoDbTable<MovieActor> movieActorTable)
{
    // 1. Build a batch to write to the ProductCatalog table.
    WriteBatch products = WriteBatch.builder(ProductCatalog.class)
        .mappedTableResource(catalogTable)
        .addPutItem(b -> b.item(getProductCatItem1()))
        .addDeleteItem(b -> b.key(k -> k
            .partitionValue(getProductCatItem2().id())
            .sortValue(getProductCatItem2().title())))
        .build();

    // 2. Build a batch to write to the MovieActor table.
    WriteBatch movies = WriteBatch.builder(MovieActor.class)
        .mappedTableResource(movieActorTable)
        .addPutItem(getMovieActorYeoh())
        .addPutItem(getMovieActorBlanchettPartial())
        .addDeleteItem(b -> b.key(k -> k
            .partitionValue(getMovieActorStreep().getMovieName())))
        .build();
```
// 3. Add WriteBatch objects to the request.
BatchWriteResult batchWriteResult = enhancedClient.batchWriteItem(b -
  b.writeBatches(products, movies));
// 4. Retrieve keys for items the service did not process.
// 4a. 'unprocessedDeleteItemsForTable()' returns keys for delete requests that
did not process.
  if (batchWriteResult.unprocessedDeleteItemsForTable(movieActorTable).size() >
    0) {
    batchWriteResult.unprocessedDeleteItemsForTable(movieActorTable).forEach(key ->
      logger.info(key.toString()));
  }
// 4b. 'unprocessedPutItemsForTable()' returns keys for put requests that did
not process.
  if (batchWriteResult.unprocessedPutItemsForTable(catalogTable).size() > 0) {
    batchWriteResult.unprocessedPutItemsForTable(catalogTable).forEach(key ->
      logger.info(key.toString()));
  }
}

The following helper methods provide the model objects for the put and delete operations.

### Helper methods

```java
public static ProductCatalog getProductCatItem1() {
  return ProductCatalog.builder()
    .id(2)
    .isbn("1-565-85698")
    .authors(new HashSet<>(Arrays.asList("a", "b")))
    .price(BigDecimal.valueOf(30.22))
    .title("Title 55")
    .build();
}

public static ProductCatalog getProductCatItem2() {
  return ProductCatalog.builder()
    .id(4)
    .price(BigDecimal.valueOf(40.00))
    .title("Title 1")
    .build();
}
```
public static MovieActor getMovieActorBlanchettPartial() {
    MovieActor movieActor = new MovieActor();
    movieActor.setActorName("Cate Blanchett");
    movieActor.setMovieName("Blue Jasmine");
    movieActor.setActingYear(2023);
    movieActor.setActingAward("Best Actress");
    return movieActor;
}

public static MovieActor getMovieActorStreep() {
    MovieActor movieActor = new MovieActor();
    movieActor.setActorName("Meryl Streep");
    movieActor.setMovieName("Sophie's Choice");
    movieActor.setActingYear(1982);
    movieActor.setActingAward("Best Actress");
    movieActor.setActingSchoolName("Yale School of Drama");
    return movieActor;
}

public static MovieActor getMovieActorYeoh() {
    MovieActor movieActor = new MovieActor();
    movieActor.setActorName("Michelle Yeoh");
    movieActor.setMovieName("Everything Everywhere All at Once");
    movieActor.setActingYear(2023);
    movieActor.setActingAward("Best Actress");
    movieActor.setActingSchoolName("Royal Academy of Dance");
    return movieActor;
}

Assume that the tables contain the following items before you run the example code.

MovieActor{movieName='Blue Jasmine', actorName='Cate Blanchett', actingAward='Best Actress', actingYear=2013, actingSchoolName='National Institute of Dramatic Art'}
MovieActor{movieName='Sophie's Choice', actorName='Meryl Streep', actingAward='Best Actress', actingYear=1982, actingSchoolName='Yale School of Drama'}
ProductCatalog{id=4, title='Title 1', isbn='orig_isbn', authors=[b, g], price=10}

After the example code finishes, the tables contain the following items.

MovieActor{movieName='Blue Jasmine', actorName='Cate Blanchett', actingAward='Best Actress', actingYear=2013, actingSchoolName='null'}
Notice in the MovieActor table that the Blue Jasmine movie item has been replaced with the item used in the put request acquired through the getMovieActorBlanchettPartial() helper method. If a data bean attribute value was not provided, the value in the database is removed. This is why the resulting actingSchoolName is null for the Blue Jasmine movie item.

**Note**

Although the API documentation suggests that condition expressions can be used and that consumed capacity and collection metrics can be returned with individual put and delete requests, this is not the case in a batch write scenario. To improve performance for batch operations, these individual options are ignored.

**Perform transaction operations**

The DynamoDB Enhanced Client API provides the transactGetItems() and the transactWriteItems() methods. The transaction methods of the SDK for Java provide atomicity, consistency, isolation, and durability (ACID) in DynamoDB tables, helping you to maintain data correctness in your applications.

**transactGetItems() example**

The transactGetItems() method accepts up to 100 individual requests for items. All items are read in a single atomic transaction. The Amazon DynamoDB Developer Guide has information about the conditions that cause a transactGetItems() method to fail, and also about the isolation level used when you call transactGetItem().

After comment line 1 in the following example, the code calls the transactGetItems() method with a builder parameter. The builder's addGetItem() is invoked three times with a data object that contains the key values that the SDK will use to generate the final request.

The request returns a list of Document objects after comment line 2. The list of documents that is returned contains non-null Document instances of item data in the same order as requested. The Document.getItem(MappedTableResource<T> mappedTableResource) method converts
an untyped Document object into a typed Java object if item data was returned, otherwise the method returns null.

```java
public static void transactGetItemsExample(DynamoDbEnhancedClient enhancedClient,
                                          DynamoDbTable<ProductCatalog> catalogTable,
                                          DynamoDbTable<MovieActor> movieActorTable) {

    // 1. Request three items from two tables using a builder.
    final List<Document> documents = enhancedClient.transactGetItems(b -> b
            .addGetItem(catalogTable, Key.builder().partitionValue(2).sortValue("Title 55").build())
            .addGetItem(movieActorTable, Key.builder().partitionValue("Sophie's Choice").sortValue("Meryl Streep").build())
            .addGetItem(movieActorTable, Key.builder().partitionValue("Blue Jasmine").sortValue("Cate Blanchett").build()))
            .build();

    // 2. A list of Document objects is returned in the same order as requested.
    ProductCatalog title55 = documents.get(0).getItem(catalogTable);
    if (title55 != null) {
        logger.info(title55.toString());
    }

    MovieActor sophiesChoice = documents.get(1).getItem(movieActorTable);
    if (sophiesChoice != null) {
        logger.info(sophiesChoice.toString());
    }

    // 3. The getItem() method returns null if the Document object contains no item from DynamoDB.
    MovieActor blueJasmine = documents.get(2).getItem(movieActorTable);
    if (blueJasmine != null) {
        logger.info(blueJasmine.toString());
    }
}
```

The DynamoDB tables contain the following items before the code example runs.

```plaintext
ProductCatalog{id=2, title='Title 55', isbn='orig_isbn', authors=[b, g], price=10}
```
The following output is logged. If an item is requested but not found, it not returned as is the case for the request for the movie named Blue Jasmine.

transactWriteItems() examples

The `transactWriteItems()` accepts up to 100 put, update, or delete actions in a single atomic transaction across multiple tables. The Amazon DynamoDB Developer Guide contains details about restrictions and failure conditions of the underlying DynamoDB service operation.

Basic example

In the following example, four operations are requested for two tables. The corresponding model classes `ProductCatalog` and `MovieActor` were shown previously.

Each of the three possible operations—put, update, and delete—uses a dedicated request parameter to specify the details.

The code after comment line 1 shows the simple variation of the `addPutItem()` method. The method accepts a `MappedTableResource` object and the data object instance to put. The statement after comment line 2 shows the variation that accepts a `TransactPutItemEnhancedRequest` instance. This variation lets you add more options in the request, such as a condition expression. A subsequent example shows a condition expression for an individual operation.

An update operation is requested after comment line 3. `TransactUpdateItemEnhancedRequest` has an `ignoreNulls()` method that lets you configure what the SDK does with null values on the model object. If the `ignoreNulls()` method returns true, the SDK does not remove the table's attribute values for data object attributes that are null. If the `ignoreNulls()` method returns false, the SDK requests the DynamoDB service to remove the attributes from the item in the table. The default value for `ignoreNulls` is false.

The statement after comment line 4 shows the variation of a delete request that takes a data object. The enhanced client extracts the key values before dispatching the final request.
public static void transactWriteItems(DynamoDbEnhancedClient enhancedClient, DynamoDbTable<ProductCatalog> catalogTable, DynamoDbTable<MovieActor> movieActorTable) {

    enhancedClient.transactWriteItems(b -> b
        // 1. Simplest variation of put item request.
        .addPutItem(catalogTable, getProductCatId2())
        // 2. Put item request variation that accommodates condition
        expressions.
            .addPutItem(movieActorTable,
                TransactPutItemEnhancedRequest.builder(MovieActor.class)
                    .item(getMovieActorStreep())
                    .conditionExpression(Expression.builder().expression("attribute_not_exists (movie)").build())
                    .build())
        // 3. Update request that does not remove attribute values on the table
        if the data object's value is null.
            .addUpdateItem(catalogTable,
                TransactUpdateItemEnhancedRequest.builder(ProductCatalog.class)
                    .item(getProductCatId4ForUpdate())
                    .ignoreNulls(Boolean.TRUE)
                    .build())
        // 4. Variation of delete request that accepts a data object. The key
        values are extracted for the request.
            .addDeleteItem(movieActorTable, getMovieActorBlanchett()));
    }
}

The following helper methods provide the data objects for the add*Item parameters.

**Helper methods**

```java
public static ProductCatalog getProductCatId2() {
    return ProductCatalog.builder()
        .id(2)
        .isbn("1-565-85698")
        .authors(new HashSet<>(Arrays.asList("a", "b")))
        .price(BigDecimal.valueOf(30.22))
        .title("Title 55")
        .build();
}
```
public static ProductCatalog getProductCatId4ForUpdate() {
    return ProductCatalog.builder()
        .id(4)
        .price(BigDecimal.valueOf(40.00))
        .title("Title 1")
        .build();
}

public static MovieActor getMovieActorBlanchett() {
    MovieActor movieActor = new MovieActor();
    movieActor.setActorName("Cate Blanchett");
    movieActor.setMovieName("Tar");
    movieActor.setActingYear(2022);
    movieActor.setActingAward("Best Actress");
    movieActor.setActingSchoolName("National Institute of Dramatic Art");
    return movieActor;
}

public static MovieActor getMovieActorStreep() {
    MovieActor movieActor = new MovieActor();
    movieActor.setActorName("Meryl Streep");
    movieActor.setMovieName("Sophie's Choice");
    movieActor.setActingYear(1982);
    movieActor.setActingAward("Best Actress");
    movieActor.setActingSchoolName("Yale School of Drama");
    return movieActor;
}

The DynamoDB tables contain the following items before the code example runs.

1 | ProductCatalog{id=4, title='Title 1', isbn='orig_isbn', authors=[b, g], price=10}
2 | MovieActor{movieName='Tar', actorName='Cate Blanchett', actingAward='Best Actress',
            actingYear=2022, actingSchoolName='National Institute of Dramatic Art'}

The following items are in the tables after the code finishes running.

3 | ProductCatalog{id=2, title='Title 55', isbn='1-565-85698', authors=[a, b],
                price=30.22}
4 | ProductCatalog{id=4, title='Title 1', isbn='orig_isbn', authors=[b, g], price=40.0}
5 | MovieActor{movieName='Sophie's Choice', actorName='Meryl Streep', actingAward='Best Actress',
            actingYear=1982, actingSchoolName='Yale School of Drama'}
The item on line 2 has been deleted and lines 3 and 5 show the items that were put. Line 4 shows the update of line 1. The price value is the only value that changed on the item. If ignoreNulls() had returned false, line 4 would look like the following line.

```
ProductCatalog{id=4, title='Title 1', isbn='null', authors=null, price=40.0}
```

**Condition check example**

The following example shows the use of a condition check. A condition check is used to check that an item exists or to check the condition of specific attributes of an item in the database. The item checked in the condition check cannot be used in another operation in the transaction.

ℹ️ **Note**

You can't target the same item with multiple operations within the same transaction. For example, you can't perform a condition check and also attempt to update the same item in the same transaction.

The example shows one of each type of operation in a transactional write items request. After comment line 2, the addConditionCheck() method supplies the condition that fails the transaction if the conditionExpression parameter evaluates to false. The condition expression that is returned from the method shown in the Helper methods block checks if the award year for the movie Sophie's Choice is not equal to 1982. If it is, the expression evaluates to false and the transaction fails.

This guide discusses expressions in depth in another topic.

```java
public static void conditionCheckFailExample(DynamoDbEnhancedClient enhancedClient,
                                          DynamoDbTable<ProductCatalog> catalogTable,
                                          DynamoDbTable<MovieActor> movieActorTable) {

  try {
    enhancedClient.transactWriteItems(b -> b
      // 1. Perform one of each type of operation with the next three methods.
      .addPutItem(catalogTable,
                  TransactPutItemEnhancedRequest.builder(ProductCatalog.class)
```
TransactUpdateItemEnhancedRequest.builder(ProductCatalog.class)
    .item(getProductCatId2()).build()
    .addUpdateItem(catalogTable,
      TransactUpdateItemEnhancedRequest.builder(ProductCatalog.class)
        .item(getProductCatId4ForUpdate())
        .ignoreNulls(Boolean.TRUE).build())
    .addDeleteItem(movieActorTable,
      TransactDeleteItemEnhancedRequest.builder()
        .key(b1 -> b1
    .partitionValue(getMovieActorBlanchett().getMovieName())
    .sortValue(getMovieActorBlanchett().getActorName())).build())
  // 2. Add a condition check on a table item that is not involved in another operation in this request.
  .addConditionCheck(movieActorTable, ConditionCheck.builder()
    .conditionExpression(buildConditionCheckExpression())
    .key(k -> k
      .partitionValue("Sophie's Choice")
      .sortValue("Meryl Streep"))
    // 3. Specify the request to return existing values from the item if the condition evaluates to true.
    .returnValuesOnConditionCheckFailure(ReturnValuesOnConditionCheckFailure.ALL_OLD)
    .build();
  // 4. Catch the exception if the transaction fails and log the information.
} catch (TransactionCanceledException ex) {
  ex.cancellationReasons().stream().forEach(cancellationReason -> {
    logger.info(cancellationReason.toString());
  });
}

The following helper methods are used in the previous code example.

**Helper methods**

```java
private static Expression buildConditionCheckExpression() {
  Map<String, AttributeValue> expressionValue = Map.of(
    ":year", numberValue(1982));

  return Expression.builder()
    .expression("actingyear <> :year")
    .expressionValues(expressionValue)
```
The DynamoDB tables contain the following items before the code example runs.

1 | ProductCatalog{id=4, title='Title 1', isbn='orig_isbn', authors=[b, g], price=10}
2 | MovieActor{movieName='Sophie's Choice', actorName='Meryl Streep', actingAward='Best Actress', actingYear=1982, actingSchoolName='Yale School of Drama'}
3 | MovieActor{movieName='Tar', actorName='Cate Blanchett', actingAward='Best Actress', actingYear=2022, actingSchoolName='National Institute of Dramatic Art'}

The following items are in the tables after the code finishes running.

ProductCatalog{id=4, title='Title 1', isbn='orig_isbn', authors=[b, g], price=10}
Items remain unchanged in the tables because the transaction failed. The actingYear value for the movie Sophie's Choice is 1982, as shown on line 2 of the items in the table before the transactWriteItem() method is called.

To capture the cancellation information for the transaction, enclose the transactWriteItems() method call in a try block and catch the TransactionCanceledException. After comment line 4 of the example, the code logs each CancellationReason object. Because the code following comment line 3 of the example specifies that values should be returned for the item that caused the transaction to fail, the log displays the raw database values for the Sophie's Choice movie item.

```java
CancellationReason(Code=None)
CancellationReason(Code=None)
CancellationReason(Code=None)
CancellationReason(Item={actor=AttributeValue(S=Meryl Streep),
    movie=AttributeValue(S=Sophie's Choice), actingaward=AttributeValue(S=Best Actress),
    actingyear=AttributeValue(N=1982), actingschoolname=AttributeValue(S=Yale School of Drama)}, ¬
    Code=ConditionalCheckFailed, Message=The conditional request failed.)
```

**Single operation condition example**

The following example shows the use of a condition on a single operation in a transaction request. The delete operation after comment line 1 contains a condition that checks the value of the target item of the operation against the database. In this example, the condition expression created with the helper method after comment line 2 specifies that the item should be deleted from the database if the acting year of the movie is not equal to 2013.

Expressions are discussed later in this guide.

```java
public static void singleOperationConditionFailExample(DynamoDbEnhancedClient enhancedClient,
    DynamoDbTable<ProductCatalog> catalogTable,
    DynamoDbTable<MovieActor> movieActorTable) {
```
The following helper methods are used in the previous code example.

```java
Map objects to DynamoDB items
```
Helper methods

```
public static ProductCatalog getProductCatId2() {
    return ProductCatalog.builder()
        .id(2)
        .isbn("1-565-85698")
        .authors(new HashSet<>(Arrays.asList("a", "b")))
        .price(BigDecimal.valueOf(30.22))
        .title("Title 55")
        .build();
}

public static ProductCatalog getProductCatId4ForUpdate() {
    return ProductCatalog.builder()
        .id(4)
        .price(BigDecimal.valueOf(40.00))
        .title("Title 1")
        .build();
}

public static MovieActor getMovieActorBlanchett() {
    MovieActor movieActor = new MovieActor();
    movieActor.setActorName("Cate Blanchett");
    movieActor.setMovieName("Blue Jasmine");
    movieActor.setActingYear(2013);
    movieActor.setActingAward("Best Actress");
    movieActor.setActingSchoolName("National Institute of Dramatic Art");
    return movieActor;
}
```

The DynamoDB tables contain the following items before the code example runs.

```
1 | ProductCatalog{id=4, title='Title 1', isbn='orig_isbn', authors=[b, g], price=10}
2 | MovieActor{movieName='Blue Jasmine', actorName='Cate Blanchett', actingAward='Best Actress', actingYear=2013, actingSchoolName='National Institute of Dramatic Art'}
```

The following items are in the tables after the code finishes running.

```
ProductCatalog{id=4, title='Title 1', isbn='orig_isbn', authors=[b, g], price=10}
2023-03-15 11:29:07 [main] INFO org.example.tests.TransactDemoTest:168 - 
   MovieActor{movieName='Blue Jasmine', actorName='Cate Blanchett', actingAward='Best Actress', actingYear=2013, actingSchoolName='National Institute of Dramatic Art'}
```
Items remain unchanged in the tables because the transaction failed. The `actingYear` value for the movie `Blue Jasmine` is 2013 as shown on line 2 in the list of items before the code example runs.

The following lines are logged to the console.

```java
CancellationReason(Code=None)
CancellationReason(Code=None)
CancellationReason(Item={actor=AttributeValue(S=Cate Blanchett),
movie=AttributeValue(S=Blue Jasmine), actingaward=AttributeValue(S=Best Actress),
actingyear=AttributeValue(N=2013), actingschoolname=AttributeValue(S=National Institute of Dramatic Art)},
    Code=ConditionalCheckFailed, Message=The conditional request failed)
```

Use secondary indices

Secondary indices improve data access by defining alternative keys that you use in query and scan operations. Global secondary indices (GSI) have a partition key and a sort key that can be different from those on the base table. In contrast, local secondary indices (LSI) use the partition key of the primary index.

Annotate data class with secondary index annotations

Attributes that participate in secondary indices require either the `@DynamoDbSecondaryPartitionKey` or `@DynamoDbSecondarySortKey` annotation.

The following class shows annotations for two indices. The GSI named `SubjectLastPostedDateIndex` uses the `Subject` attribute for the partition key and the `LastPostedDateTime` for the sort key. The LSI named `ForumLastPostedDateIndex` uses the `ForumName` as its partition key and `LastPostedDateTime` as its sort key.

Note that the `Subject` attribute serves a dual role. It is the primary key's sort key and the partition key of the GSI named `SubjectLastPostedDateIndex`.

**MessageThread class**

The `MessageThread` class is suitable to use as a data class for the [example Thread table](#) in the *Amazon DynamoDB Developer Guide*.

**Imports**

```java
import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbBean;
```
import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbPartitionKey;
import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbSecondaryPartitionKey;
import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbSecondarySortKey;
import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.DynamoDbSortKey;
import java.util.List;

@DynamoDbBean
public class MessageThread {
    private String ForumName;
    private String Subject;
    private String Message;
    private String LastPostedBy;
    private String LastPostedDateTime;

}

public void setAnswered(Integer answered) {
    Answered = answered;
}

public List<String> getTags() {
    return Tags;
}

public void setTags(List<String> tags) {
    Tags = tags;
}

public MessageThread() {
    this.Answered = 0;
    this.LastPostedBy = "";
    this.ForumName = "";
    this.Message = "";
    this.LastPostedDateTime = "";
    this.Replies = 0;
    this.Views = 0;
    this.Subject = "";
}

@Override
public String toString() {
    return "MessageThread{"
        + "ForumName='" + ForumName + "' + "",
        + Subject='" + Subject + "' + "",
        + Message='" + Message + "' + "",
        + LastPostedBy='" + LastPostedBy + "' + "",
        + LastPostedDateTime='" + LastPostedDateTime + "' + "",
        + Views=" + Views + "",
        + Replies=" + Replies + "",
        + Answered=" + Answered + "",
        + Tags=" + Tags + "}");
}
}
Create the index

Beginning with version 2.20.86 of the SDK for Java, the `createTable()` method automatically generates secondary indexes from data class annotations. By default, all attributes from the base table are copied to an index and the provisioned throughput values are 20 read capacity units and 20 write capacity units.

However, if you use an SDK version prior to 2.20.86, you need to build the index along with the table as shown in the following example. This example builds the two indexes for the `Thread` table. The `builder` parameter has methods to configure both types of indexes as shown after comment lines 1 and 2. You use the index builder's `indexName()` method to associate the index names specified in the data class annotations with the intended type of index.

This code configures all of the table attributes to end up in both indexes after comment lines 3 and 4. More information about attribute projections is available in the Amazon DynamoDB Developer Guide.

```java
public static void createMessageThreadTable(DynamoDbTable<MessageThread> messageThreadDynamoDbTable, DynamoDbClient dynamoDbClient) {
    messageThreadDynamoDbTable.createTable(b -> b
        // 1. Generate the GSI.
        .globalSecondaryIndices(gsi ->
            gsi.indexName("SubjectLastPostedDateIndex")
                // 3. Populate the GSI with all attributes.
                .projection(p -> p
                    .projectionType(ProjectionType.ALL))
        )
        // 2. Generate the LSI.
        .localSecondaryIndices(lsi -> lsi.indexName("ForumLastPostedDateIndex")
            // 4. Populate the LSI with all attributes.
            .projection(p -> p
                .projectionType(ProjectionType.ALL))
        )
    );
}
```

Query by using an index

The following example queries the local secondary index `ForumLastPostedDateIndex`.

Following comment line 2, you create a `QueryConditional` object that is required when calling the `DynamoDbIndex.query()` method.
You get a reference to the index you want to query after comment line 3 by passing in the name of the index. Following comment line 4, you call the `query()` method on the index passing in the `QueryConditional` object.

You also configure the query to return three attribute values as shown after comment line 5. If `attributesToProject()` is not called, the query returns all attribute values. Notice that the specified attribute names begin with lowercase letters. These attribute names match those used in the table, not necessarily the attribute names of the data class.

Following comment line 6, iterate through the results and log each item returned by the query and also store it in the list to return to the caller.

```java
public static List<MessageThread> queryUsingSecondaryIndices(DynamoDbEnhancedClient enhancedClient,
                                                             String lastPostedDate,
                                                             DynamoDbTable<MessageThread> threadTable) {
    // 1. Log the parameter value.
    logger.info("lastPostedDate value: ", lastPostedDate);

    // 2. Create a QueryConditional whose sort key value must be greater than or equal to the parameter value.
    QueryConditional queryConditional =
        QueryConditional.sortGreaterThanOrEqualTo(qc ->
            qc.partitionValue("Forum02").sortValue(lastPostedDate));

    // 3. Specify the index name to query the DynamoDbIndex instance.
    final DynamoDbIndex<MessageThread> forumLastPostedDateIndex =
        threadTable.index("ForumLastPostedDateIndex");

    // 4. Perform the query by using the QueryConditional object.
    final SdkIterable<Page<MessageThread>> pagedResult =
        forumLastPostedDateIndex.query(q -> q
            .queryConditional(queryConditional)
            // 5. Request three attribute in the results.
            .attributesToProject("forumName", "subject", "lastPostedDateTime");

    List<MessageThread> collectedItems = new ArrayList<>();
    // 6. Iterate through the pages response and sort the items.
    pagedResult.stream().forEach(page -> page.items().stream()
        .sorted(Comparator.comparing(MessageThread::getLastPostedDateTime))
        .forEach(mt -> {

    
```

// 7. Log the returned items and add the collection to return to the caller.
logger.info(mt.toString());
collectedItems.add(mt);
});
return collectedItems;
}

The following items exist in the database before the query is run.

```java
MessageThread{ForumName='Forum01', Subject='Subject01', Message='Message01',
LastPostedBy='', LastPostedDateTime='2023.03.28', Views=0, Replies=0, Answered=0,
Tags=null}
MessageThread{ForumName='Forum02', Subject='Subject02', Message='Message02',
LastPostedBy='', LastPostedDateTime='2023.03.29', Views=0, Replies=0, Answered=0,
Tags=null}
MessageThread{ForumName='Forum02', Subject='Subject04', Message='Message04',
LastPostedBy='', LastPostedDateTime='2023.03.31', Views=0, Replies=0, Answered=0,
Tags=null}
MessageThread{ForumName='Forum02', Subject='Subject08', Message='Message08',
LastPostedBy='', LastPostedDateTime='2023.04.04', Views=0, Replies=0, Answered=0,
Tags=null}
MessageThread{ForumName='Forum02', Subject='Subject10', Message='Message10',
LastPostedBy='', LastPostedDateTime='2023.04.06', Views=0, Replies=0, Answered=0,
Tags=null}
MessageThread{ForumName='Forum03', Subject='Subject03', Message='Message03',
LastPostedBy='', LastPostedDateTime='2023.03.30', Views=0, Replies=0, Answered=0,
Tags=null}
MessageThread{ForumName='Forum03', Subject='Subject06', Message='Message06',
LastPostedBy='', LastPostedDateTime='2023.04.02', Views=0, Replies=0, Answered=0,
Tags=null}
MessageThread{ForumName='Forum03', Subject='Subject09', Message='Message09',
LastPostedBy='', LastPostedDateTime='2023.04.05', Views=0, Replies=0, Answered=0,
Tags=null}
MessageThread{ForumName='Forum05', Subject='Subject05', Message='Message05',
LastPostedBy='', LastPostedDateTime='2023.04.01', Views=0, Replies=0, Answered=0,
Tags=null}
MessageThread{ForumName='Forum07', Subject='Subject07', Message='Message07',
LastPostedBy='', LastPostedDateTime='2023.04.03', Views=0, Replies=0, Answered=0,
Tags=null}
```

The logging statements at lines 1 and 6 result in the following console output.
The query returned items with a `forumName` value of `Forum02` and a `lastPostedDateTime` value greater than or equal to `2023.03.31`. The results show `message` values with an empty string although the `message` attributes have values in the index. This is because the `message` attribute was not projected after comment line 5.

**Use advanced mapping features**

Learn about advanced table schema features in the DynamoDB Enhanced Client API.

**Understand table schema types**

`TableSchema` is the interface to the mapping functionality of the DynamoDB Enhanced Client API. It can map a data object to and from a map of `AttributeValue`. A `TableSchema` object needs to know about the structure of the table it is mapping. This structure information is stored in a `TableMetadata` object.

The enhanced client API has several implementations of `TableSchema`, which follow.

**Table schema generated from annotated classes**

It is a moderately expensive operation to build a `TableSchema` from annotated classes, so we recommend doing this once, at application startup.

`BeanTableSchema`

This implementation is built based on attributes and annotations of a bean class. An example of this approach is demonstrated in the [Get started section](#).

**Note**

If a `BeanTableSchema` is not behaving as you expect, enable debug logging for `software.amazon.awssdk.enhanced.dynamodb.beans`.

---

Map objects to DynamoDB items

236
ImmutableTableSchema

This implementation is built from an immutable data class. This approach is described in the ??? section.

Table schema generated with a builder

The following TableSchemas are built from code by using a builder. This approach is less costly than the approach that uses annotated data classes. The builder approach avoids the use of annotations and doesn't require JavaBean naming standards.

StaticTableSchema

This implementation is built for mutable data classes. The getting started section of this guide demonstrated how to generate a StaticTableSchema using a builder.

StaticImmutableTableSchema

Similarly to how you build a StaticTableSchema, you generate an implementation of this type of TableSchema using a builder for use with immutable data classes.

Table schema for data without a fixed schema

DocumentTableSchema

Unlike other implementations of TableSchema, you don't define attributes for a DocumentTableSchema instance. Usually, you specify only primary keys and attribute converter providers. An EnhancedDocument instance provides the attributes that you build from individual elements or from a JSON string.

Explicitly include or exclude attributes

The DynamoDB Enhanced Client API offers annotations to exclude data class attributes from becoming attributes on a table. With the API, you can also use an attribute name that's different from the data class attribute name.

Exclude attributes

To ignore attributes that should not be mapped to a DynamoDB table, mark the attribute with the @DynamoDbIgnore annotation.
private String internalKey;

@DynamoDbIgnore
public String getInternalKey() { return this.internalKey; }
public void setInternalKey(String internalKey) { return this.internalKey =
internalKey;}

Include attributes
To change the name of an attribute used in the DynamoDB table, mark it with the
@DynamoDbAttribute annotation and supply a different name.

private String internalKey;

@DynamoDbAttribute("renamedInternalKey")
public String getInternalKey() { return this.internalKey; }
public void setInternalKey(String internalKey) { return this.internalKey =
internalKey;}

Control attribute conversion
By default, a table schema provides converters for all primitive types and many common Java
types through a default implementation of the AttributeConverterProvider interface.
You can change the overall default behavior with a custom AttributeConverterProvider implementation. You can also change the converter for a single attribute.

For a list of available converters, see the AttributeConverter interface Java doc.

Provide custom attribute converter providers
You can provide a single AttributeConverterProvider or a chain of ordered
AttributeConverterProviders through the @DynamoDbBean (converterProviders
= {...}) annotation. Any custom AttributeConverterProvider must extend the
AttributeConverterProvider interface.

Note that if you supply your own chain of attribute converter providers, you will override the
default converter provider, DefaultAttributeConverterProvider. If you want to use the
functionality of the DefaultAttributeConverterProvider, you must include it in the chain.
It's also possible to annotate the bean with an empty array `{}`. This disables the use of any attribute converter providers, including the default. In this case all attributes that are to be mapped must have their own attribute converter.

The following snippet shows a single converter provider.

```java
@DynamoDbBean(converterProviders = ConverterProvider1.class)
public class Customer {
}
```

The following snippet shows the use of a chain of converter providers. Since the SDK default is provided last, it has the lowest priority.

```java
@DynamoDbBean(converterProviders = {
    ConverterProvider1.class,
    ConverterProvider2.class,
    DefaultAttributeConverterProvider.class
})
public class Customer {
}
```

The static table schema builders have an `attributeConverterProviders()` method that works the same way. This is shown in the following snippet.

```java
private static final StaticTableSchema<Customer> CUSTOMER_TABLE_SCHEMA =
    StaticTableSchema.builder(Customer.class)
        .newItemSupplier(Customer::new)
        .addAttribute(String.class, a -> a.name("name")
            a.getter(Customer::getName)
            a.setter(Customer::setName))
        .attributeConverterProviders(converterProvider1, converterProvider2)
        .build();
```

### Override the mapping of a single attribute

To override the way a single attribute is mapped, supply an `AttributeConverter` for the attribute. This addition overrides any converters provided by `AttributeConverterProviders` in the table schema. This adds a custom converter for only that attribute. Other attributes, even those of the same type, won't use that converter unless it is explicitly specified for those other attributes.
The @DynamoDbConvertedBy annotation is used to specify the custom AttributeConverter class as shown in the following snippet.

```java
@DynamoDbConvertedBy(CustomAttributeConverter.class)
public String getName() { return this.name; }
public void setName(String name) { this.name = name; }
```

The builders for static schemas have an equivalent attribute builder attributeConverter() method. This method takes an instance of an AttributeConverter as the following shows.

```java
private static final StaticTableSchema<Customer> CUSTOMER_TABLE_SCHEMA =
    StaticTableSchema.builder(Customer.class)
        .newItemSupplier(Customer::new)
        .addAttribute(String.class, a -> a.name("name")
                    a.getter(Customer::getName)
                    a.setter(Customer::setName)
                    a.attributeConverter(customAttributeConverter))
        .build();
```

Example

This example shows an AttributeConverterProvider implementation that provides an attribute converter for `java.net.HttpCookie` objects.

The following SimpleUser class contains an attribute named lastUsedCookie that is an instance of HttpCookie.

The parameter to the @DynamoDbBean annotations lists the two AttributeConverterProvider classes that provide converters.

Class with annotations

```java
@DynamoDbBean(converterProviders = {CookieConverterProvider.class,
            DefaultAttributeConverterProvider.class})
public static final class SimpleUser {
    private String name;
```
private HttpCookie lastUsedCookie;

@DynamoDbPartitionKey
public String getName() {
    return name;
}

public void setName(String name) {
    this.name = name;
}

public HttpCookie getLastUsedCookie() {
    return lastUsedCookie;
}

public void setLastUsedCookie(HttpCookie lastUsedCookie) {
    this.lastUsedCookie = lastUsedCookie;
}

Static table schema

private static final TableSchema<SimpleUser> SIMPLE_USER_TABLE_SCHEMA =
    TableSchema.builder(SimpleUser.class)
        .newItemSupplier(SimpleUser::new)
        .attributeConverterProviders(CookieConverterProvider.create(),
                                   AttributeConverterProvider.defaultProvider())
        .addAttribute(String.class, a -> a.name("name")
                        .setter(SimpleUser::setName)
                        .getter(SimpleUser::getName)
                        .tags(StaticAttributeTags.primaryPartitionKey()))
        .addAttribute(HttpCookie.class, a -> a.name("lastUsedCookie")
                        .setter(SimpleUser::setLastUsedCookie)
                        .getter(SimpleUser::getLastUsedCookie))
        .build();

The CookieConverterProvider in the following example provides an instance of an HttpCookieConverter.

public static final class CookieConverterProvider implements AttributeConverterProvider {
    private final Map<EnhancedType<?>, AttributeConverter<?>> converterCache =
        ImmutableMap.of("
// 1. Add HttpCookieConverter to the internal cache.
   EnhancedType.of(HttpCookie.class), new HttpCookieConverter());

   public static CookieConverterProvider create() {
       return new CookieConverterProvider();
   }

   // The SDK calls this method to find out if the provider contains a
   // AttributeConverter instance
   // for the EnhancedType<T> argument.
   @SuppressWarnings("unchecked")
   @Override
   public <T> AttributeConverter<T> converterFor(EnhancedType<T> enhancedType) {
       return (AttributeConverter<T>) converterCache.get(enhancedType);
   }

Conversion code

In the transformFrom() method of the following HttpCookieConverter class, the code receives an HttpCookie instance and transforms it into a DynamoDB map that is stored as an attribute.

The transformTo() method receives a DynamoDB map parameter, then invokes the HttpCookie constructor that requires a name and a value.

   public static final class HttpCookieConverter implements
      AttributeConverter<HttpCookie> {

       @Override
       public AttributeValue transformFrom(HttpCookie httpCookie) {

           return AttributeValue.fromM(
               Map.of("cookieName", AttributeValue.fromS(httpCookie.getName()),
                   "cookieValue", AttributeValue.fromS(httpCookie.getValue()))
           );
       }

       @Override
       public HttpCookie transformTo(AttributeValue attributeValue) {
           Map<String, AttributeValue> map = attributeValue.m();
           return new HttpCookie(
               map.get("cookieName").s(),
Change update behavior of attributes

You can customize the update behavior of individual attributes when you perform an `update` operation. Some examples of update operations in the DynamoDB Enhanced Client API are `updateItem()` and `transactWriteItems()`.

For example, imagine that you want to store a `created on` timestamp on your record. However, you want its value to be written only if there's no existing value for the attribute already in the database. In this case, you use the `WRITE_IF_NOT_EXISTS` update behavior.

The following example shows the annotation that adds the behavior to the `createdOn` attribute.

```java
@DynamoDbBean
public class Customer extends GenericRecord {
    private String id;
    private Instant createdOn;

    @DynamoDbPartitionKey
    public String getId() { return this.id; }
    public void setId(String id) { this.name = id; }

    @DynamoDbUpdateBehavior(UpdateBehavior.WRITE_IF_NOT_EXISTS)
    public Instant getCreatedOn() { return this.createdOn; }
    public void setCreatedOn(Instant createdOn) { this.createdOn = createdOn; }
}
```

You can declare the same update behavior when you build a static table schema as shown in the following example after comment line 1.
static final TableSchema<Customer> CUSTOMER_TABLE_SCHEMA =
    TableSchema.builder(Customer.class)
    .newItemSupplier(Customer::new)
    .addAttribute(String.class, a -> a.name("id")
        .getter(Customer::getId)
        .setter(Customer::setId)
    .tags(StaticAttributeTags.primaryPartitionKey()))
    .addAttribute(Instant.class, a -> a.name("createdOn")
        .getter(Customer::getCreatedOn)
        .setter(Customer::setCreatedOn)
    // 1. Add an UpdateBehavior.
    .tags(StaticAttributeTags.updateBehavior(UpdateBehavior.WRITE_IF_NOT_EXISTS)))
    .build();

Flatten attributes from other classes

If the attributes for your table are spread across several different Java classes, either through inheritance or composition, the DynamoDB Enhanced Client API provides support to flatten the attributes into one class.

Use inheritance

If your classes use inheritance, use the following approaches to flatten the hierarchy.

Use annotated beans

For the annotation approach, both classes must carry the @DynamoDbBean annotation and a class must carry one or more primary key annotations.

The following shows examples of data classes that have an inheritance relationship.

Standard data class

```java
@DynamoDbBean
public class Customer extends GenericRecord {
    private String name;

    public String getName() { return name; }
    public void setName(String name) { this.name = name; }
}
```
@DynamoDbBean
public abstract class GenericRecord {
    private String id;
    private String createdDate;

    @DynamoDbPartitionKey
    public String getId() { return id; }
    public void setId(String id) { this.id = id; }

    public String getCreatedDate() { return createdDate; }
    public void setCreatedDate(String createdDate) { this.createdDate = createdDate; }
}

Lombok

Lombok’s onMethod option copies attribute-based DynamoDB annotations, such as @DynamoDbPartitionKey, onto the generated code.

@DynamoDbBean
@Data
@ToString(callSuper = true)
public class Customer extends GenericRecord {
    private String name;
}

@Data
@DynamoDbBean
public abstract class GenericRecord {
    @Getter(onMethod_=@DynamoDbPartitionKey)
    private String id;
    private String createdDate;
}

Use static schemas

For the static schema approach, use the extend() method of the builder to collapse the attributes of the parent class onto the child class. This is shown after comment line 1 in the following example.

    StaticTableSchema<org.example.tests.model.inheritance.stat.GenericRecord>
    GENERIC_RECORD_SCHEMA =
StaticTableSchema.builder(org.example.tests.model.inheritance.stat.GenericRecord.class)
   // The partition key will be inherited by the top level mapper.
   .addAttribute(String.class, a -> a.name("id")
   .getter(org.example.tests.model.inheritance.stat.GenericRecord::getId)
   .setter(org.example.tests.model.inheritance.stat.GenericRecord::setId)
   .tags(primaryPartitionKey()))
   .addAttribute(String.class, a -> a.name("created_date")
   .getter(org.example.tests.model.inheritance.stat.GenericRecord::getCreatedDate)
   .setter(org.example.tests.model.inheritance.stat.GenericRecord::setCreatedDate))
   .build();

StaticTableSchema<org.example.tests.model.inheritance.stat.Customer>
CUSTOMER_SCHEMA =
StaticTableSchema.builder(org.example.tests.model.inheritance.stat.Customer.class)
   .newItemSupplier(org.example.tests.model.inheritance.stat.Customer::new)
   .addAttribute(String.class, a -> a.name("name")
   .getter(org.example.tests.model.inheritance.stat.Customer::getName)
   .setter(org.example.tests.model.inheritance.stat.Customer::setName))
   // 1. Use the extend() method to collapse the parent attributes
onto the child class.
   .extend(GENERIC_RECORD_SCHEMA) // All the attributes of the
GenericRecord schema are added to Customer.
   .build();

The previous static schema example uses the following data classes. Because the mapping is
defined when you build the static table schema, the data classes don't require annotations.

Data classes

Standard data class

public class Customer extends GenericRecord {
   private String name;
public String getName() { return name; }
public void setName(String name) { this.name = name; }
}

public abstract class GenericRecord {
    private String id;
    private String createdDate;

    public String getId() { return id; }
    public void setId(String id) { this.id = id; }

    public String getCreatedDate() { return createdDate; }
    public void setCreatedDate(String createdDate) { this.createdDate = createdDate; }
}

Lombok

@Data
@ToString(callSuper = true)
public class Customer extends GenericRecord{
    private String name;
}

@Data
public abstract class GenericRecord {
    private String id;
    private String createdDate;
}

Use composition

If your classes use composition, use the following approaches to flatten the hierarchy.

Use annotated beans

The @DynamoDbFlatten annotation flattens the contained class.

The following data class examples use the @DynamoDbFlatten annotation to effectively add all attributes of the contained GenericRecord class to the Customer class.
**Standard data class**

```java
@DynamoDbBean
public class Customer {
    private String name;
    private GenericRecord record;

    public String getName() { return this.name; }
    public void setName(String name) { this.name = name; }

    @DynamoDbFlatten
    public GenericRecord getRecord() { return this.record; }
    public void setRecord(GenericRecord record) { this.record = record; }

    @DynamoDbBean
    public class GenericRecord {
        private String id;
        private String createdDate;

        @DynamoDbPartitionKey
        public String getId() { return this.id; }
        public void setId(String id) { this.id = id; }

        public String getCreatedDate() { return this.createdDate; }
        public void setCreatedDate(String createdDate) { this.createdDate = createdDate; }
    }
}
```

**Lombok**

```java
@Data
@DynamoDbBean
public class Customer {
    private String name;
    @Getter(onMethod_=@DynamoDbFlatten)
    private GenericRecord record;
}

@Data
@DynamoDbBean
public class GenericRecord {
    @Getter(onMethod_=@DynamoDbPartitionKey)
    private String id;
}
```

private String createdDate;
}

You can use the `flatten` annotation to flatten as many different eligible classes as you need to. The following constraints apply:

- All attribute names must be unique after they are flattened.
- There must never be more than one partition key, sort key, or table name.

**Use static schemas**

When you build a static table schema, use the `flatten()` method of the builder. You also supply the getter and setter methods that identify the contained class.

```java
StaticTableSchema<GenericRecord> GENERIC_RECORD_SCHEMA =
    StaticTableSchema.builder(GenericRecord.class)
    .newItemSupplier(GenericRecord::new)
    .addAttribute(String.class, a -> a.name("id")
        .getter(GenericRecord::getId)
        .setter(GenericRecord::setId)
        .tags(primaryPartitionKey()))
    .addAttribute(String.class, a -> a.name("created_date")
        .getter(GenericRecord::getCreatedDate)
        .setter(GenericRecord::setCreatedDate))
    .build();

StaticTableSchema<Customer> CUSTOMER_SCHEMA =
    StaticTableSchema.builder(Customer.class)
    .newItemSupplier(Customer::new)
    .addAttribute(String.class, a -> a.name("name")
        .getter(Customer::getName)
        .setter(Customer::setName))
    // Because we are flattening a component object, we supply a getter and setter so the
    // mapper knows how to access it.
    .flatten(GENERIC_RECORD_SCHEMA, Customer::getRecord,
             Customer::setRecord)
    .build();
```

The previous static schema example uses the following data classes.
Data classes

Standard data class

```java
public class Customer {
    private String name;
    private GenericRecord record;

    public String getName() { return this.name; }
    public void setName(String name) { this.name = name; }

    public GenericRecord getRecord() { return this.record; }
    public void setRecord(GenericRecord record) { this.record = record; }

public class GenericRecord {
    private String id;
    private String createdDate;

    public String getId() { return this.id; }
    public void setId(String id) { this.id = id; }

    public String getCreatedDate() { return this.createdDate; }
    public void setCreatedDate(String createdDate) { this.createdDate = createdDate; }
}
```

Lombok

```java
@Data
public class Customer {
    private String name;
    private GenericRecord record;
}

@Data
public class GenericRecord {
    private String id;
    private String createdDate;
}
```

You can use the builder pattern to flatten as many different eligible classes as you need to.
Implications for other code

When you use the `@DynamoDbFlatten` attribute (or `flatten()` builder method), the item in DynamoDB contains an attribute for each attribute of the composed object. It also includes the attributes of the composing object.

In contrast, if you annotate a data class with a composed class and don't use `@DynamoDbFlatten`, the item is saved with the composed object as a single attribute.

For example, compare the `Customer` class shown in the flattening with composition example with and without flattening of the `record` attribute. You can visualize the difference with JSON as shown in the following table.

<table>
<thead>
<tr>
<th>With flattening</th>
<th>Without flattening</th>
</tr>
</thead>
<tbody>
<tr>
<td>3 attributes</td>
<td>2 attributes</td>
</tr>
</tbody>
</table>

```json
{  
  "id": "1",  
  "createdDate": "today",  
  "name": "my name"
}
```

```json
{  
  "id": "1",  
  "record": {  
    "createdDate": "today",  
    "name": "my name"
  }
}
```

The difference becomes important if you have other code accessing the DynamoDB table that expects to find certain attributes.

Work with nested attributes

A nested attribute in DynamoDB is embedded in another attribute. Examples are list elements and map entries.

In Java, a DynamoDB nested attribute corresponds to a member of a class that is a `List` or `Map`. It also corresponds to an instance of a complex type, such as `Address` or `PhoneNumber`, as used in the following `Person` class.

**Person class**

```java
@DynamoDbBean
```
public class Person {
    Integer id;
    String firstName;
    String lastName;
    Integer age;
    Map<String, Address> addresses;
    List<PhoneNumber> phoneNumbers;
    List<String> hobbies;

    @DynamoDbPartitionKey
    public Integer getId() {
        return id;
    }

    public void setId(Integer id) {
        this.id = id;
    }

    public String getFirstName() {
        return firstName;
    }

    public void setFirstName(String firstName) {
        this.firstName = firstName;
    }

    public String getLastName() {
        return lastName;
    }

    public void setLastName(String lastName) {
        this.lastName = lastName;
    }

    public Integer getAge() {
        return age;
    }

    public void setAge(Integer age) {
        this.age = age;
    }

    public Map<String, Address> getAddresses() {
        Map<String, Address> addresses = new HashMap<>();
        // Add addresses to the map
        return addresses;
    }
}
return addresses;
}

public void setAddresses(Map<String, Address> addresses) {
    this.addresses = addresses;
}

public List<PhoneNumber> getPhoneNumbers() {
    return phoneNumbers;
}

public void setPhoneNumbers(List<PhoneNumber> phoneNumbers) {
    this.phoneNumbers = phoneNumbers;
}

public List<String> getHobbies() {
    return hobbies;
}

public void setHobbies(List<String> hobbies) {
    this.hobbies = hobbies;
}

@Override
public String toString() {
    return "Person{" +
    "id=" + id +
    ", firstName='" + firstName + '\"' +
    ", lastName='" + lastName + '\"' +
    ", age=" + age +
    ", addresses=" + addresses +
    ", phoneNumbers=" + phoneNumbers +
    ", hobbies=" + hobbies +
    '}";
}
}

Address class

@dynamodbBean
public class Address {
    private String street;
    private String city;
private String state;
private String zipCode;

public Address() {
}

custom String getStreet() {
    return this.street;
}

custom String getCity() {
    return this.city;
}

custom String getState() {
    return this.state;
}

custom String getZipCode() {
    return this.zipCode;
}

custom void setStreet(String street) {
    this.street = street;
}

custom void setCity(String city) {
    this.city = city;
}

custom void setState(String state) {
    this.state = state;
}

custom void setZipCode(String zipCode) {
    this.zipCode = zipCode;
}

@Override
custom boolean equals(Object o) {
    if (this == o) return true;
    if (o == null || getClass() != o.getClass()) return false;
    Address address = (Address) o;
    if (Objects.equals(address.street, street) &&
    Objects.equals(address.city, city) &&
    Objects.equals(address.state, state) &&
    Objects.equals(address.zipCode, zipCode))
    return true;
    return false;
}
return Objects.equals(street, address.street) && Objects.equals(city, address.city) && Objects.equals(state, address.state) && Objects.equals(zipCode, address.zipCode);
}

@Override
public int hashCode() {
    return Objects.hash(street, city, state, zipCode);
}

@Override
public String toString() {
    return "Address{" +
        "street='" + street + '"' +
        ', city='" + city + '"' +
        ', state='" + state + '"' +
        ', zipCode='" + zipCode + '"' +
    '}";
}

PhoneNumber class

@DynamoDbBean
public class PhoneNumber {
    String type;
    String number;

    public String getType() {
        return type;
    }

    public void setType(String type) {
        this.type = type;
    }

    public String getNumber() {
        return number;
    }

    public void setNumber(String number) {
        this.number = number;
    }

    Map objects to DynamoDB items
@Override
public String toString() {
    return "PhoneNumber{" +
            "type='" + type + '}' +
            ", number='" + number + '}' +
    "};
}

Map nested attributes

Use annotated classes

You can save nested attributes for custom classes by annotating them. The Address class and PhoneNumber class shown previously are annotated with only the @DynamoDbBean annotation. When the DynamoDB Enhanced Client API builds the table schema for the Person class with the following snippet, the API discovers the use of the Address and PhoneNumber classes and builds the corresponding mappings to work with DynamoDB.

```java
TableSchema<Person> personTableSchema = TableSchema.fromBean(Person.class);
```

Use nested schemas

The alternative approach is to use static table schema builders for each of the classes as shown in the following code.

The table schemas for the Address and PhoneNumber classes are abstract in the sense that they cannot be used with a DynamoDB table. This is because they lack definitions for the primary key. They are used, however, as nested schemas in the table schema for the Person class.

After comment lines 1 and 2 in the definition of PERSON_TABLE_SCHEMA, you see the code that uses the abstract table schemas. The use of documentOf in the EnhanceType.documentOf(...) method does not indicate that the method returns an EnhancedDocument type of the Enhanced Document API. The documentOf(...) method in this context returns an object that knows how to map its class argument to and from DynamoDB table attributes by using the table schema argument.

Static schema code

```java
// Abstract table schema that cannot be used to work with a DynamoDB table,
```
// but can be used as a nested schema.
public static final TableSchema<Address> TABLE_SCHEMA_ADDRESS =
    TableSchema.builder(Address.class)
        .newItemSupplier(Address::new)
        .addAttribute(String.class, a -> a.name("street")
            .getter(Address::getStreet)
            .setter(Address::setStreet))
        .addAttribute(String.class, a -> a.name("city")
            .getter(Address::getCity)
            .setter(Address::setCity))
        .addAttribute(String.class, a -> a.name("zipcode")
            .getter(Address::getZipCode)
            .setter(Address::setZipCode))
        .addAttribute(String.class, a -> a.name("state")
            .getter(Address::getState)
            .setter(Address::setState))
        .build();

// Abstract table schema that cannot be used to work with a DynamoDB table,
// but can be used as a nested schema.
public static final TableSchema<PhoneNumber> TABLE_SCHEMA_PHONENUMBER =
    TableSchema.builder(PhoneNumber.class)
        .newItemSupplier(PhoneNumber::new)
        .addAttribute(String.class, a -> a.name("type")
            .getter(PhoneNumber::getType)
            .setter(PhoneNumber::setType))
        .addAttribute(String.class, a -> a.name("number")
            .getter(PhoneNumber::getNumber)
            .setter(PhoneNumber::setNumber))
        .build();

// A static table schema that can be used with a DynamoDB table.
// The table schema contains two nested schemas that are used to perform mapping
to/from DynamoDB.
public static final TableSchema<Person> PERSON_TABLE_SCHEMA =
    TableSchema.builder(Person.class)
        .newItemSupplier(Person::new)
        .addAttribute(Integer.class, a -> a.name("id")
            .getter(Person::getId)
            .setter(Person::setId)
            .addTag(StaticAttributeTags.primaryPartitionKey()))
        .addAttribute(String.class, a -> a.name("firstName")
            .getter(Person::getFirstName)
            .setter(Person::setFirstName))
        .build();
```java
    .addAttribute(String.class, a -> a.name("lastName")
      .getter(Person::getLastName)
      .setter(Person::setLastName))
    .addAttribute(Integer.class, a -> a.name("age")
      .getter(Person::getAge)
      .setter(Person::setAge))
    .addAttribute(EnhancedType.listOf(String.class), a -> a.name("hobbies")
      .getter(Person::getHobbies)
      .setter(Person::setHobbies))
    .addAttribute(EnhancedType.mapOf(
      EnhancedType.of(String.class),
      // 1. Use mapping functionality of the Address table
      EnhancedType.documentOf(Address.class, TABLE_SCHEMA_ADDRESS)), a -> a.name("addresses")
      .getter(Person::getAddresses)
      .setter(Person::setAddresses))
    .addAttribute(EnhancedType.listOf(
      // 2. Use mapping functionality of the PhoneNumber table
      EnhancedType.documentOf(PhoneNumber.class, TABLE_SCHEMA_PHONENUMBER)), a -> a.name("phoneNumbers")
      .getter(Person::getPhoneNumbers)
      .setter(Person::setPhoneNumbers))
    .build();
```

### Project nested attributes

For `query()` and `scan()` methods, you can specify which attributes you want to be returned in the results by using method calls such as `addNestedAttributeToProject()` and `attributesToProject()`. The DynamoDB Enhanced Client API converts the Java method call parameters into **projection expressions** before the request is sent.

The following example populates the `Person` table with two items, then performs three scan operations.

The first scan accesses all items in the table in order to compare the results to the other scan operations.

The second scan uses the `addNestedAttributeToProject()` builder method to return only the street attribute value.
The third scan operation uses the `attributesToProject()` builder method to return the data for the first-level attribute, hobbies. The attribute type of hobbies is a list. To access individual list items, perform a `get()` operation on the list.

```java
personDynamoDbTable = getDynamoDbEnhancedClient().table("Person",
    PERSON_TABLE_SCHEMA);
    PersonUtils.createPersonTable(personDynamoDbTable, getDynamoDbClient());
    // Use a utility class to add items to the Person table.
    List<Person> personList = PersonUtils.getItemsForCount(2);
    // This utility method performs a put against DynamoDB to save the instances in
    the list argument.
    PersonUtils.putCollection(getDynamoDbEnhancedClient(), personList,
        personDynamoDbTable);
    // The first scan logs all items in the table to compare to the results of the
    subsequent scans.
    final PageIterable<Person> allItems = personDynamoDbTable.scan();
    allItems.items().forEach(p ->
        // 1. Log what is in the table.
        logger.info(p.toString()));

    // Scan for nested attributes.
    PageIterable<Person> streetScanResult = personDynamoDbTable.scan(b -> b
        // Use the 'addNestedAttributeToProject()' or
        'addNestedAttributesToProject()' to access data nested in maps in DynamoDB.
        .addNestedAttributeToProject(
            NestedAttributeName.create("addresses", "work", "street")
        ));
    streetScanResult.items().forEach(p ->
        // 2. Log the results of requesting nested attributes.
        logger.info(p.toString()));

    // Scan for a top-level list attribute.
    PageIterable<Person> phoneNumbersScanResult = personDynamoDbTable.scan(b -> b
        // Use the 'attributesToProject()' method to access first-level
        attributes.
        .attributesToProject("hobbies"));
    phoneNumbersScanResult.items().forEach((p) -> {
        // 3. Log the results of the request for the 'hobbies' attribute.
        logger.info(p.toString());
    })
```
To access an item in a list, first get the parent attribute, 'hobbies', then access items in the list.

```java
String hobby = p.getHobbies().get(1);
// 4. Log an item in the list.
logger.info(hobby);
```
ScanEnhancedRequest lastOverwrites = ScanEnhancedRequest.builder()
    .addNestedAttributeToProject(
        NestedAttributeName.create("addresses", "work", "street"))
    .addAttributeToProject("firstName")
    // If the 'attributesToProject()' method follows other builder methods
    // that add attributes for projection,
    // its list of attributes replace all previous attributes.
    .attributesToProject("hobbies")
    .build();
PageIterable<Person> hobbiesOnlyResult =
    personDynamoDbTable.scan(lastOverwrites);
hobbiesOnlyResult.items().forEach(p ->
    logger.info(p.toString()));

// Logged results.
Person{id=null, firstName='null', lastName='null', age=null, addresses=null,
    phoneNumbers=null, hobbies=[hobby 2, hobby 21]}
Person{id=null, firstName='null', lastName='null', age=null, addresses=null,
    phoneNumbers=null, hobbies=[hobby 1, hobby 11]}

The following code snippet uses the attributesToProject() method first. This ordering preserves all other requested attributes.

ScanEnhancedRequest attributesPreserved = ScanEnhancedRequest.builder()
    // Use 'attributesToProject()' first so that the method call does not
    // replace all other attributes
    // that you want to project.
    .attributesToProject("firstName")
    .addNestedAttributeToProject(
        NestedAttributeName.create("addresses", "work", "street"))
    .addAttributeToProject("hobbies")
    .build();
PageIterable<Person> allAttributesResult =
    personDynamoDbTable.scan(attributesPreserved);
allAttributesResult.items().forEach(p ->
    logger.info(p.toString()));

// Logged results.
Person{id=null, firstName='first name 2', lastName='null', age=null,
    addresses={work=Address{street='street 21', city='null', state='null',
        zipCode='null'}}, phoneNumbers=null, hobbies=[hobby 2, hobby 21]}
Preserve empty objects with @DynamoDbPreserveEmptyObject

If you save a bean to Amazon DynamoDB with empty objects and you want the SDK to recreate the empty objects upon retrieval, annotate the getter of the inner bean with @DynamoDbPreserveEmptyObject.

To illustrate how the annotation works, the code example uses the following two beans.

Example beans

The following data class contains two InnerBean fields. The getter method, getInnerBeanWithoutAnno(), is not annotated with @DynamoDbPreserveEmptyObject. The getInnerBeanWithAnno() method is annotated.

```
@DynamoDbBean
public class MyBean {

    private String id;
    private String name;
    private InnerBean innerBeanWithoutAnno;
    private InnerBean innerBeanWithAnno;

    @DynamoDbPartitionKey
    public String getId() { return id; }
    public void setId(String id) { this.id = id; }

    public String getName() { return name; }
    public void setName(String name) { this.name = name; }

    public InnerBean getInnerBeanWithoutAnno() { return innerBeanWithoutAnno; }
    public void setInnerBeanWithoutAnno(InnerBean innerBeanWithoutAnno) {
        this.innerBeanWithoutAnno = innerBeanWithoutAnno;
    }

    @DynamoDbPreserveEmptyObject
    public InnerBean getInnerBeanWithAnno() { return innerBeanWithAnno; }
    public void setInnerBeanWithAnno(InnerBean innerBeanWithAnno) {
        this.innerBeanWithAnno = innerBeanWithAnno;
    }
```
Instances of the following `InnerBean` class are fields of `MyBean` and are initialized as empty objects in the example code.

```java
@DynamoDbBean
class InnerBean {

    private String innerBeanField;

    public String getInnerBeanField() {
        return innerBeanField;
    }

    public void setInnerBeanField(String innerBeanField) {
        this.innerBeanField = innerBeanField;
    }

    @Override
    public String toString() {
        return "InnerBean{"
            + "innerBeanField='" + innerBeanField + "'
            + '}';
    }
}
```

The following code example saves a `MyBean` object with initialized inner beans to DynamoDB and then retrieves the item. The logged output shows that the `innerBeanWithoutAnno` is not initialized, but `innerBeanWithAnno` has been created.

```java
public MyBean preserveEmptyObjectAnnoUsingGetItemExample(DynamoDbTable<MyBean> myBeanTable) {
```
// Save an item to DynamoDB.
MyBean bean = new MyBean();
bean.setId("1");
bean.setInnerBeanWithoutAnno(new InnerBean()); // Instantiate the inner bean.
bean.setInnerBeanWithAnno(new InnerBean()); // Instantiate the inner bean.
myBeanTable.putItem(bean);

GetItemEnhancedRequest request = GetItemEnhancedRequest.builder()
    .key(Key.builder().partitionValue("1").build())
    .build();
MyBean myBean = myBeanTable.getItem(request);

logger.info(myBean.toString());
// Output 'MyBean[innerBeanWithoutAnno=null, innerBeanWithAnno=InnerBean{innerBeanField='null'}, id='1', name='null']'.

return myBean;

Alternative static schema

You can use the following StaticTableSchema version of the table schemas in place of the annotations on the beans.

```java
public static TableSchema<MyBean> buildStaticSchemas() {

    StaticTableSchema<InnerBean> innerBeanStaticTableSchema =
        StaticTableSchema.builder(InnerBean.class)
            .newItemSupplier(InnerBean::new)
            .addAttribute(String.class, a -> a.name("innerBeanField")
                .getter(InnerBean::getInnerBeanField)
                .setter(InnerBean::setInnerBeanField))
            .build();

    return StaticTableSchema.builder(MyBean.class)
        .newItemSupplier(MyBean::new)
        .addAttribute(String.class, a -> a.name("id")
            .getter(MyBean::getId)
            .setter(MyBean::setId)
            .addTag(primaryPartitionKey()))
        .addAttribute(String.class, a -> a.name("name")
            .getter(MyBean::getName)
            .setter(MyBean::setName))
```

Map objects to DynamoDB items
Add Attribute

```java
.addAttribute(EnhancedType.documentOf(InnerBean.class,
        innerBeanStaticTableSchema),
    a -> a.name("innerBean1")
        .getter(MyBean::getInnerBeanWithoutAnno)
        .setter(MyBean::setInnerBeanWithoutAnno))

.addAttribute(EnhancedType.documentOf(InnerBean.class,
        innerBeanStaticTableSchema,
    b -> b.preserveEmptyObject(true)),
    a -> a.name("innerBean2")
        .getter(MyBean::getInnerBeanWithAnno)
        .setter(MyBean::setInnerBeanWithAnno))

.build();
```

Avoid saving null attributes of nested objects

You can skip null attributes of nested objects when saving a data class object to DynamoDB by applying the `@DynamoDbIgnoreNulls` annotation. By contrast, top-level attributes with null values are never saved to the database.

To illustrate how the annotation works, the code example uses the following two beans.

**Example beans**

The following data class contains two `InnerBean` fields. The getter method, `getInnerBeanWithoutAnno()`, is not annotated. The `getInnerBeanWithIgnoreNullsAnno()` method is annotated with `@DynamoDbIgnoreNulls`.

```java
@DynamoDbBean
public class MyBean {

    private String id;
    private String name;
    private InnerBean innerBeanWithoutAnno;
    private InnerBean innerBeanWithIgnoreNullsAnno;

    @DynamoDbPartitionKey
    public String getId() { return id; }
    public void setId(String id) { this.id = id; }

    public String getName() { return name; }
    public void setName(String name) { this.name = name; }
```

Map objects to DynamoDB items
AWS SDK for Java 2.x

Developer Guide for version 2.x

public InnerBean getInnerBeanWithoutAnno() { return innerBeanWithoutAnno; }
public void setInnerBeanWithoutAnno(InnerBean innerBeanWithoutAnno)
{ this.innerBeanWithoutAnno = innerBeanWithoutAnno; }
@DynamoDbIgnoreNulls
public InnerBean getInnerBeanWithIgnoreNullsAnno() { return
innerBeanWithIgnoreNullsAnno; }
public void setInnerBeanWithIgnoreNullsAnno(InnerBean innerBeanWithAnno)
{ this.innerBeanWithIgnoreNullsAnno = innerBeanWithAnno; }
@Override
public String toString() {
return new StringJoiner(", ", MyBean.class.getSimpleName() + "[", "]")
.add("innerBeanWithoutAnno=" + innerBeanWithoutAnno)
.add("innerBeanWithIgnoreNullsAnno=" + innerBeanWithIgnoreNullsAnno)
.add("id='" + id + "'")
.add("name='" + name + "'")
.toString();
}
}

Instances of the following InnerBean class are ﬁelds of MyBean and are used in the following
example code.
@DynamoDbBean
public class InnerBean {
private String innerBeanFieldString;
private Integer innerBeanFieldInteger;
public String getInnerBeanFieldString() { return innerBeanFieldString; }
public void setInnerBeanFieldString(String innerBeanFieldString)
{ this.innerBeanFieldString = innerBeanFieldString; }
public Integer getInnerBeanFieldInteger() { return innerBeanFieldInteger; }
public void setInnerBeanFieldInteger(Integer innerBeanFieldInteger)
{ this.innerBeanFieldInteger = innerBeanFieldInteger; }
@Override
public String toString() {
return new StringJoiner(", ", InnerBean.class.getSimpleName() + "[", "]")
.add("innerBeanFieldString='" + innerBeanFieldString + "'")
.add("innerBeanFieldInteger=" + innerBeanFieldInteger)
Map objects to DynamoDB items

266


The following code example creates an InnerBean object and sets only one of its two attributes with a value.

```java
public void ignoreNullsAnnoUsingPutItemExample(DynamoDbTable<MyBean> myBeanTable) {
    // Create an InnerBean object and give only one attribute a value.
    InnerBean innerBeanOneAttributeSet = new InnerBean();
    innerBeanOneAttributeSet.setInnerBeanFieldInteger(200);

    // Create a MyBean instance and use the same InnerBean instance both for attributes.
    MyBean bean = new MyBean();
    bean.setId("1");
    bean.setInnerBeanWithoutAnno(innerBeanOneAttributeSet);
    bean.setInnerBeanWithIgnoreNullsAnno(innerBeanOneAttributeSet);

    Map<String, AttributeValue> itemMap = myBeanTable.tableSchema().itemToMap(bean,
    true);
    logger.info(itemMap.toString());
    // Log the map that is sent to the database.
    //
    {innerBeanWithIgnoreNullsAnno=AttributeValue(M={innerBeanFieldInteger=AttributeValue(N=200)}),
    id=AttributeValue(S=1),
    innerBeanWithoutAnno=AttributeValue(M={innerBeanFieldInteger=AttributeValue(N=200),
    innerBeanFieldString=AttributeValue(NUL=true)})

    // Save the MyBean object to the table.
    myBeanTable.putItem(bean);
}
```

To visualize the low-level data that is sent to DynamoDB, the code logs the attribute map before saving the MyBean object.

The logged output shows that the `innerBeanWithIgnoreNullsAnno` outputs one attribute,

```java
innerBeanWithIgnoreNullsAnno=AttributeValue(M={innerBeanFieldInteger=AttributeValue(N=200)})
```

The `innerBeanWithoutAnno` instance outputs two attributes. One attribute has a value of 200 and the other is a null-valued attribute.
innerBeanWithoutAnno=AttributeValue(M={innerBeanFieldInteger=AttributeValue(N=200),
 innerBeanFieldString=AttributeValue(NUL=true)})

JSON representation of the attribute map

The following JSON representation makes it easier to see the data that is saved to DynamoDB.

```
{
   "id": {
      "S": "1"
   },
   "innerBeanWithIgnoreNullsAnno": {
      "M": {
         "innerBeanFieldInteger": {
            "N": "200"
         }
      }
   },
   "innerBeanWithoutAnno": {
      "M": {
         "innerBeanFieldInteger": {
            "N": "200"
         },
         "innerBeanFieldString": {
            "NULL": true
         }
      }
   }
}
```

Alternative static schema

You can use the following StaticTableSchema version of the table schemas in place data class annotations.

```java
public static TableSchema<MyBean> buildStaticSchemas() {
    StaticTableSchema<InnerBean> innerBeanStaticTableSchema =
        StaticTableSchema.builder(InnerBean.class)
            .newItemSupplier(InnerBean::new)
            .addAttribute(String.class, a -> a.name("innerBeanFieldString"))
            .getter(InnerBean::getInnerBeanFieldString)
    return ...
}
```
Work with JSON documents with the Enhanced Document API for DynamoDB

The Enhanced Document API for AWS SDK for Java 2.x is designed to work with document-oriented data that has no fixed schema. However, it also lets you use custom classes to map individual attributes.

The Enhanced Document API is the successor to the Document API of the AWS SDK for Java v1.x.

Contents

- Get started using the Enhanced Document API
  - Create a DocumentTableSchema and a DynamoDbTable
- Build enhanced documents
• Build from a JSON string
• Build from individual elements
• Perform CRUD operations
• Access enhanced document attributes as custom objects
• Use an EnhancedDocument without DynamoDB

Get started using the Enhanced Document API

The Enhanced Document API requires the same dependencies that are needed for the DynamoDB Enhanced Client API. It also requires a DynamoDbEnhancedClient instance as shown at the start of this topic.

Because the Enhanced Document API was released with version 2.20.3 of the AWS SDK for Java 2.x, you need that version or greater.

Create a DocumentTableSchema and a DynamoDbTable

To invoke commands against a DynamoDB table using the Enhanced Document API, associate the table with a client-side DynamoDbTable<EnhancedDocument> resource object.

The enhanced client's table() method creates a DynamoDbTable<EnhancedDocument> instance and requires parameters for the DynamoDB table name and a DocumentTableSchema.

The builder for a DocumentTableSchema requires a primary index key and one or more attribute converter providers. The AttributeConverterProvider.defaultProvider() method provides converters for default types. It should be specified even if you provide a custom attribute converter provider. You can add an optional secondary index key to the builder.

The following code snippet shows the code that generates the client-side representation of a DynamoDB person table that stores schemaless EnhancedDocument objects.

```java
dynamoDbTable<EnhancedDocument> documentDynamoDbTable =
enhancedClient.table("person",
    TableSchema.documentSchemaBuilder()
        .addIndexPartitionKey(TableMetadata.primaryIndexName(), "id", AttributeValueType.S)
        .addIndexSortKey(TableMetadata.primaryIndexName(), "lastName", AttributeValueType.S)
        // Specify the primary key attributes.
    )
```

Map objects to DynamoDB items
// Specify attribute converter providers. Minimally add the
default one.

.attributeConverterProviders(AttributeConverterProvider.defaultProvider())
    .build());

// Call documentTable.createTable() if "person" does not exist in DynamoDB.
// createTable() should be called only one time.

The following shows the JSON representation of a person object that is used throughout this section.

**JSON person object**

```json
{
    "id": 1,
    "firstName": "Richard",
    "lastName": "Roe",
    "age": 25,
    "addresses": {
        "home": {
            "zipCode": "00000",
            "city": "Any Town",
            "state": "FL",
            "street": "123 Any Street"
        },
        "work": {
            "zipCode": "00001",
            "city": "Anywhere",
            "state": "FL",
            "street": "100 Main Street"
        }
    },
    "hobbies": [
        "Hobby 1",
        "Hobby 2"
    ],
    "phoneNumbers": [
        {
            "type": "Home",
            "number": "555-0100"
        }
    ]
}
```
Build enhanced documents

An `EnhancedDocument` represents a document-type object that has complex structure with nested attributes. An EnhancedDocument requires top-level attributes that match the primary key attributes specified for the DocumentTableSchema. The remaining content is arbitrary and can consist of top-level attributes and also deeply nested attributes.

You create an EnhancedDocument instance by using a builder that provides several ways to add elements.

Build from a JSON string

With a JSON string, you can build an EnhancedDocument in one method call. The following snippet creates an EnhancedDocument from a JSON string returned by the `jsonPerson()` helper method. The `jsonPerson()` method returns the JSON string version of the person object shown previously.

```java
EnhancedDocument document =
    EnhancedDocument.builder()
    .json( jsonPerson() )
    .build();
```

Build from individual elements

Alternatively, you can build an EnhancedDocument instance from individual components using type-safe methods of the builder.

The following example builds a person enhanced document similar to the enhanced document that is built from the JSON string in the previous example.

```java
/* Define the shape of an address map whose JSON representation looks like the following.
Use 'addressMapEnhancedType' in the following EnhancedDocument.builder() to simplify the code.
```
EnhancedType<Map<String, String>> addressMapEnhancedType =
    EnhancedType.mapOf(EnhancedType.of(String.class),
    EnhancedType.of(String.class));

    // Use the builder's typesafe methods to add elements to the enhanced document.
        .putNumber("id", 50)
        .putString("firstName", "Shirley")
        .putString("lastName", "Rodriguez")
        .putNumber("age", 53)
        .putNull("nullAttribute")
        .putJson("phoneNumbers", phoneNumbersJSONString())
        /* Add the map of addresses whose JSON representation looks like the following.
           {
              "home": {
                "zipCode": "00000",
                "city": "Any Town",
                "state": "FL",
                "street": "123 Any Street"
              }
            } */
        .putMap("addresses", getAddresses(), EnhancedType.of(String.class),
            addressMapEnhancedType)
        .putList("hobbies", List.of("Theater", "Golf"),
            EnhancedType.of(String.class))
        .build();

Helper methods

private static String phoneNumbersJSONString() {
    return "  [" +
        "   {" +
        "      "type": "Home"," +
        "      "number": "555-0140" +
    "]" +
}
private static Map<String, Map<String, String>> getAddresses() {
    return Map.of(
        "home", Map.of(
            "zipCode", "00002",
            "city", "Any Town",
            "state", "ME",
            "street", "123 Any Street"));
}

Perform CRUD operations

After you define an EnhancedDocument instance, you can save it to a DynamoDB table. The following code snippet uses the personDocument that was created from individual elements.

documentDynamoDbTable.putItem(personDocument);

After you read an enhanced document instance from DynamoDB, you can extract the individual attribute values using getters as shown in the following code snippet that access the data saved from the personDocument. Alternatively, you can extract the complete content to a JSON string as shown in the last part of the example code.

    // Read the item.
    EnhancedDocument personDocFromDb =
        documentDynamoDbTable.getItem(Key.builder().partitionValue(50).build());

    // Access top-level attributes.
    logger.info("Name: {} ", personDocFromDb.getString("firstName"),
            personDocFromDb.getString("lastName"));
    // Name: Shirley Rodriguez

    // Typesafe access of a deeply nested attribute. The addressMapEnhancedType shown previously defines the shape of an addresses map.
Map<String, Map<String, String>> addresses = 
    personDocFromDb.getMap("addresses", EnhancedType.of(String.class),
    addressMapEnhancedType);
    addresses.keySet().forEach(k -> logger.info(addresses.get(k).toString()));
    // {zipCode=00002, city=Any Town, street=123 Any Street, state=ME}

    // Alternatively, work with AttributeValue types checking along the way for
deply nested attributes.
    Map<String, AttributeValue> addressesMap = 
    personDocFromDb.getMapOfUnknownType("addresses");
    addressesMap.keySet().forEach((String k) -> {
        logger.info("Looking at data for [{}] address", k);
        // Looking at data for [home] address
        AttributeValue value = addressesMap.get(k);
        AttributeValue cityValue = value.m().get("city");
        if (cityValue != null) {
            logger.info(cityValue.s());
            // Any Town
        }
    });

    List<AttributeValue> phoneNumbers = 
    personDocFromDb.getListOfUnknownType("phoneNumbers");
    phoneNumbers.forEach((AttributeValue av) -> {
        if (av.hasM()) {
            AttributeValue type = av.m().get("type");
            if (type.s() != null) {
                logger.info("Type of phone: {}", type.s());
                // Type of phone: Home
                // Type of phone: Work
            }
        }
    });

    String jsonPerson = personDocFromDb.toJson();
    logger.info(jsonPerson);
    // {"firstName":"Shirley","lastName":"Rodriguez","addresses":
    // {"home":{"zipCode":"00002","city":"Any Town","street":"123 Any
Street","state":"ME"},"hobbies":["Theater","Golf"],
    //   "id":50,"nullAttribute":null,"age":53,"phoneNumbers":
    // ["number":"555-0140","type":"Home"],"number":"555-0155","type":"Work"}]}
EnhancedDocument instances can be used with any method of DynamoDbTable or DynamoDbEnhancedClient in place of mapped data classes.

**Access enhanced document attributes as custom objects**

In addition to providing an API to read and write attributes with schemaless structures, the Enhanced Document API lets you convert attributes to and from instances of custom classes.

The Enhanced Document API uses AttributeConverterProviders and AttributeConverters that were shown in the control attribute conversion section as part of the DynamoDB Enhanced Client API.

In the following example, we use a CustomAttributeConverterProvider with its nested AddressConverter class to convert Address objects.

This example shows that you can mix data from classes and also data from structures that are built as needed. This example also shows that custom classes can be used at any level of a nested structure. The Address objects in this example are values used in a map.

```java
public static void attributeToAddressClassMappingExample(DynamoDbEnhancedClient enhancedClient, DynamoDbClient standardClient) {
    String tableName = "customer";

    // Define the DynamoDbTable for an enhanced document.
    // The schema builder provides methods for attribute converter providers and keys.
    DynamoDbTable<EnhancedDocument> documentDynamoDbTable =
        enhancedClient.table(tableName,
            DocumentTableSchema.builder()
                // Add the CustomAttributeConverterProvider along with the default when you build the table schema.
                .attributeConverterProviders(
                    List.of(
                        new CustomAttributeConverterProvider(),
                        AttributeConverterProvider.defaultProvider()))
                .addIndexPartitionKey(TableMetadata.primaryIndexName(), "id",
                    AttributeValueType.N)
                .addIndexSortKey(TableMetadata.primaryIndexName(), "lastName",
                    AttributeValueType.S)
                .build());

    // Create the DynamoDB table if needed.
    documentDynamoDbTable.createTable();
    waitForTableCreation(tableName, standardClient);
}
```
// The getAddressesForCustomMappingExample() helper method that provides 'addresses' shows the use of a custom Address class
// rather than using a Map<String, Map<String, String>> to hold the address data.
Map<String, Address> addresses = getAddressesForCustomMappingExample();

// Build an EnhancedDocument instance to save an item with a mix of structures defined as needed and static classes.
    .putNumber("id", 50)
    .putString("firstName", "Shirley")
    .putString("lastName", "Rodriguez")
    .putNumber("age", 53)
    .putNull("nullAttribute")
    .putJson("phoneNumbers", phoneNumbersJSONString())
    // Note the use of 'EnhancedType.of(Address.class)' instead of the more generic
    // 'EnhancedType.mapOf(EnhancedType.of(String.class), EnhancedType.of(String.class))' that was used in a previous example.
    .putMap("addresses", addresses, EnhancedType.of(String.class), EnhancedType.of(Address.class))
    .putList("hobbies", List.of("Hobby 1", "Hobby 2"), EnhancedType.of(String.class))
    .build();

// Save the item to DynamoDB.
documentDynamoDbTable.putItem(personDocument);

// Retrieve the item just saved.
EnhancedDocument srPerson =
documentDynamoDbTable.getItem(Key.builder().partitionValue(50).sortValue("Rodriguez").build());

// Access the addresses attribute.
Map<String, Address> srAddresses = srPerson.get("addresses",
    EnhancedType.mapOf(EnhancedType.of(String.class),
    EnhancedType.of(Address.class)));

srAddresses.keySet().forEach(k -> logger.info(addresses.get(k).toString()));

documentDynamoDbTable.deleteTable();

// The content logged to the console shows that the saved maps were converted to Address instances.
CustomAttributeConverterProvider code

```java
public class CustomAttributeConverterProvider implements AttributeConverterProvider {

    private final Map<EnhancedType<?>, AttributeConverter<?>> converterCache =
        ImmutableMap.of(
            // 1. Add AddressConverter to the internal cache.
            EnhancedType.of(Address.class), new AddressConverter());

    public static CustomAttributeConverterProvider create() {
        return new CustomAttributeConverterProvider();
    }

    // 2. The enhanced client queries the provider for attribute converters if it
    //    encounters a type that it does not know how to convert.
    @SuppressWarnings("unchecked")
    @Override
    public <T> AttributeConverter<T> converterFor(EnhancedType<T> enhancedType) {
        return (AttributeConverter<T>) converterCache.get(enhancedType);
    }

    // 3. Custom attribute converter
    private class AddressConverter implements AttributeConverter<Address> {
        // 4. Transform an Address object into a DynamoDB map.
        @Override
        public AttributeValue transformFrom(Address address) {
            Map<String, AttributeValue> attributeValueMap = Map.of(
                "street", AttributeValue.fromS(address.getStreet()),
                "city", AttributeValue.fromS(address.getCity()),
                "state", AttributeValue.fromS(address.getState()),
                "zipCode", AttributeValue.fromS(address.getZipCode()));

            return AttributeValue.fromM(attributeValueMap);
        }

        // 5. Transform the DynamoDB map attribute to an Address object.
        @Override
        public Address transformTo(AttributeValue attributeValue) {
            Map<String, AttributeValue> m = attributeValue.m();
```
Address address = new Address();
adress.setStreet(m.get("street").s());
adress.setCity(m.get("city").s());
adress.setState(m.get("state").s());
adress.setZipCode(m.get("zipCode").s());

return address;
}

@Override
public EnhancedType<Address> type() {
    return EnhancedType.of(Address.class);
}

@override
public AttributeValue<address> attributeValue() {
    return AttributeValue.of(address);
}

public class Address {
    private String street;
    private String city;
    private String state;
    private String zipCode;

    public Address() {
    }

    public String getStreet() {
        return this.street;
    }

    public String getCity() {
        return this.city;
    }

    public String getState() {
        return this.state;
    }

    public String getZipCode() {
        return this.zipCode;
    }
}
public String getZipCode() {
    return this.zipCode;
}

public void setStreet(String street) {
    this.street = street;
}

public void setCity(String city) {
    this.city = city;
}

public void setState(String state) {
    this.state = state;
}

public void setZipCode(String zipCode) {
    this.zipCode = zipCode;
}

Helper method that provides addresses

The following helper method provides the map that use custom Address instances for values rather than generic Map<String, String> instances for values.

private static Map<String, Address> getAddressesForCustomMappingExample() {
    Address homeAddress = new Address();
    homeAddress.setStreet("100 Any Street");
    homeAddress.setCity("Any Town");
    homeAddress.setState("NC");
    homeAddress.setZipCode("00000");

    Address workAddress = new Address();
    workAddress.setStreet("123 Main Street");
    workAddress.setCity("Any Town");
    workAddress.setState("NC");
    workAddress.setZipCode("00000");

    return Map.of("home", homeAddress,
                   "work", workAddress);
}
Use an EnhancedDocument without DynamoDB

Although you usually use an instance of an EnhancedDocument to read and write document-type DynamoDB items, it can also be used independently of DynamoDB.

You can use EnhancedDocuments for their ability to convert between JSON strings or custom objects to low-level maps of AttributeValues as shown in the following example.

```java
public static void conversionWithoutDynamoDbExample() {
    Address address = new Address();
    address.setCity("my city");
    address.setState("my state");
    address.setStreet("my street");
    address.setZipCode("00000");

    // Build an EnhancedDocument instance for its conversion functionality alone.
    EnhancedDocument addressEnhancedDoc = EnhancedDocument.builder()
        .attributeConverterProviders(new CustomAttributeConverterProvider(),
        DefaultAttributeConverterProvider.create())
        .put("addressDoc", address, Address.class)
        .build();

    // Convert address to a low-level item representation.
    final Map<String, AttributeValue> addressAsAttributeMap = addressEnhancedDoc.getMapOfUnknownType("addressDoc");
    logger.info("addressAsAttributeMap: ", addressAsAttributeMap.toString());

    // Convert address to a JSON string.
    String addressAsJsonString = addressEnhancedDoc.getJson("addressDoc");
    logger.info("addressAsJsonString: ", addressAsJsonString);

    // Convert addressEnhancedDoc back to an Address instance.
    Address addressConverted = addressEnhancedDoc.get("addressDoc", Address.class);
    logger.info("addressConverted: ", addressConverted.toString());
}

/* Console output:
addressAsAttributeMap: {zipCode=AttributeValue(S=00000),
state=AttributeValue(S=my state), street=AttributeValue(S=my street),
city=AttributeValue(S=my city})
*/
addressAsString: {"zipCode":"00000","state":"my state","street":"my street","city":"my city"}
addressConverted: Address{street='my street', city='my city', state='my state', zipCode='00000'}
*/

**Note**
When you use an enhanced document independent of a DynamoDB table, make sure you explicitly set attribute converter providers on the builder. In contrast, the document table schema supplies the converter providers when an enhanced document is used with a DynamoDB table.

### Use extensions

The DynamoDB Enhanced Client API supports plugin extensions that provide functionality beyond mapping operations. Extensions have two hook methods, `beforeWrite()` and `afterRead()`. `beforeWrite()` modifies a write operation before it happens, and the `afterRead()` method modifies the results of a read operation after it happens. Because some operations (such as item updates) perform both a write and then a read, both hook methods are called.

Extensions are loaded in the order that they are specified in the enhanced client builder. The load order can be important because one extension can act on values that have been transformed by a previous extension.

The enhanced client API comes with a set of plugin extensions that are located in the `extensions` package. By default, the enhanced client loads the `VersionedRecordExtension` and the `AtomicCounterExtension`. You can override the default behavior with the enhance client builder and load any extension. You can also specify none if you don't want the default extensions.

If you load your own extensions, the enhanced client doesn't load any default extensions. If you want the behavior provided by either default extension, you need to explicitly add it to the list of extensions.

In the following example, a custom extension named `verifyChecksumExtension` is loaded after the `VersionedRecordExtension`, which is usually loaded by default by itself. The `AtomicCounterExtension` is not loaded in this example.
DynamoDbEnhancedClientExtension versionedRecordExtension = VersionedRecordExtension.builder().build();

DynamoDbEnhancedClient enhancedClient =
    DynamoDbEnhancedClient.builder()
    .dynamoDbClient(dynamoDbClient)
    .extensions(versionedRecordExtension,
               verifyChecksumExtension)
    .build();

**VersionedRecordExtension**

The `VersionedRecordExtension` is loaded by default and will increment and track an item version number as items are written to the database. A condition will be added to every write that causes the write to fail if the version number of the actual persisted item doesn't match the value that the application last read. This behavior effectively provides optimistic locking for item updates. If another process updates an item between the time the first process has read the item and is writing an update to it, the write will fail.

To specify which attribute to use to track the item version number, tag a numeric attribute in the table schema.

The following snippet specifies that the `version` attribute should hold the item version number.

```java
@DynamoDbVersionAttribute
public Integer getVersion() {...};
public void setVersion(Integer version) {...};
```

The equivalent static table schema approach is shown in the following snippet.

```java
        .addAttribute(Integer.class, a -> a.name("version")
            .getter(Customer::getVersion)
            .setter(Customer::setVersion)
            // Apply the 'version' tag to the attribute.
            .tags(VersionedRecordExtension.AttributeTags.versionAttribute())
```
AtomicCounterExtension

The AtomicCounterExtension is loaded by default and increments a tagged numerical attribute each time a record is written to the database. Start and increment values can be specified. If no values are specified, the start value is set to 0 and the attribute's value increments by 1.

To specify which attribute is a counter, tag an attribute of type Long in the table schema.

The following snippet shows the use of the default start and increment values for the counter attribute.

```java
@DynamoDbAtomicCounter
public Long getCounter() {...};
public void setCounter(Long counter) {...};
```

The static table schema approach is shown in the following snippet. The atomic counter extension uses a start value of 10 and increments the value by 5 each time the record is written.

```java
.addAttribute(Integer.class, a -> a.name("counter")
    .getter(Customer::getCounter)
    .setter(Customer::setCounter)
    // Apply the 'atomicCounter' tag to the attribute with start and increment values.
    .tags(StaticAttributeTags.atomicCounter(10L, 5L))
```

AutoGeneratedTimestampRecordExtension

The AutoGeneratedTimestampRecordExtension automatically updates tagged attributes of type Instant with a current timestamp every time the item is successfully written to the database.

This extension is not loaded by default. Therefore, you need to specify it as a custom extension when you build the enhanced client as shown in the first example in this topic.

To specify which attribute to update with the current timestamp, tag the Instant attribute in the table schema.

The lastUpdate attribute is the target of the extensions behavior in the following snippet. Note the requirement that the attribute must be an Instant type.
The equivalent static table schema approach is shown in the following snippet.

```java
.addAttribute(Instant.class, a -> a.name("lastUpdate")
    .getter(Customer::getLastUpdate)
    .setter(Customer::setLastUpdate)
    // Applying the 'autoGeneratedTimestamp' tag to
    .tags(AutoGeneratedTimestampRecordExtension.AttributeTags.autoGeneratedTimestampAttribute())
```

### Custom extensions

The following custom extension class shows a `beforeWrite()` method that uses an update expression. After comment line 2, we create a `SetAction` to set the `registrationDate` attribute if the item in the database doesn't already have a `registrationDate` attribute. Whenever a `Customer` object is updated, the extension makes sure that a `registrationDate` is set.

```java
public final class CustomExtension implements DynamoDbEnhancedClientExtension {

    // 1. In a custom extension, use an UpdateExpression to define what action to take
    //     before an item is updated.
    @Override
    public WriteModification beforeWrite(DynamoDbExtensionContext.BeforeWrite context) {
        if ( context.operationContext().tableName().equals("Customer")
            && context.operationName().equals(OperationName.UPDATE_ITEM)) {
            return WriteModification.builder()
                .updateExpression(createUpdateExpression())
                .build();
        }
        return WriteModification.builder().build();  // Return an "empty"
        WriteModification instance if the extension should not be applied.
    }

    private static UpdateExpression createUpdateExpression() {

```
// 2. Use a SetAction, a subclass of UpdateAction, to provide the values in the update.
SetAction setAction =
    SetAction.builder()
    .path("registrationDate")
    .value("if_not_exists(registrationDate, :regValue)")
    .putExpressionValue(":regValue",
        AttributeValue.fromS(Instant.now().toString()))
    .build();
// 3. Build the UpdateExpression with one or more UpdateAction.
return UpdateExpression.builder()
    .addAction(setAction)
    .build();
}

Use the DynamoDB Enhanced Client API asynchronously

If your application requires non-blocking, asynchronous calls to DynamoDB, you can use the DynamoDbEnhancedAsyncClient. It's similar to the synchronous implementation but with the following key differences:

1. When you build the DynamoDbEnhancedAsyncClient, you must provide the asynchronous version of the standard client, DynamoDbAsyncClient, as shown in the following snippet.

    DynamoDbEnhancedAsyncClient enhancedClient =
        DynamoDbEnhancedAsyncClient.builder()
        .dynamoDbClient(dynamoDbAsyncClient)
        .build();

2. Methods that return a single data object return a CompletableFuture of the result instead of only the result. Your application can then do other work without having to block on the result. The following snippet shows the asynchronous getItem() method.

    CompletableFuture<Customer> result = customerDynamoDbTable.getItem(customer);
    // Perform other work here.
    return result.join(); // Now block and wait for the result.

3. Methods that return paginated lists of results return an SdkPublisher instead of an SdkIterable that the synchronous DynamoDbEnhanceClient returns for the same methods.
Your application can then subscribe a handler to that publisher to deal with the results asynchronously without having to block.

```java
PagePublisher<Customer> results = customerDynamoDbTable.query(r ->
    r.queryConditional(keyEqualTo(k -> k.partitionValue("Smith"))));
results.subscribe(myCustomerResultsProcessor);
// Perform other work and let the processor handle the results asynchronously.
```

For a more complete example of working with the SdkPublisher API, see the example in the section that discusses the asynchronous `scan()` method of this guide.

### Data class annotations

The following table lists the annotations that can be used on data classes and provides links to information and examples in this guide. The table is sorted in ascending alphabetical order by annotation name.

#### Data class annotations used in this guide

<table>
<thead>
<tr>
<th>Annotation name</th>
<th>Annotation applies to</th>
<th>What it does</th>
<th>Where it is shown in this guide</th>
</tr>
</thead>
<tbody>
<tr>
<td>DynamoDbAtomicCounter</td>
<td>attribute</td>
<td>Increments a tagged numerical attribute each time a record is written to the database.</td>
<td>Introduction and discussion.</td>
</tr>
</tbody>
</table>
| DynamoDbAttribute                      | attribute              | Defines or renames a bean property that is mapped to a DynamoDB table attribute. | • Initial discussion.  
• Get started section —see Note.  
• In MovieActor class  
In Query method examples. |
<p>| DynamoDbAutoGeneratedTimestampAttribute | attribute              | Updates a tagged attribute with a current timestamp                         | Introduction and discussion.                                      |</p>

</table>

\(^1\)You can apply an attribute-level annotations to the getter or setter, but not both. This guide shows annotations on getters.
The term property is normally used for a value encapsulated in a JavaBean data class. However, this guide uses the term attribute instead, to be consistent with the terminology used by DynamoDB.

## Work with Amazon EC2

This section provides examples of programming Amazon EC2 that use the AWS SDK for Java 2.x.

### Topics

- Manage Amazon EC2 instances
- Use AWS Regions and Availability Zones
- Work with security groups in Amazon EC2
- Work with Amazon EC2 instance metadata

### Manage Amazon EC2 instances

#### Create an instance

Create a new Amazon EC2 instance by calling the `Ec2Client`'s `runInstances` method, providing it with a `RunInstancesRequest` containing the Amazon Machine Image (AMI) to use and an instance type.

#### Imports

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.ec2.Ec2Client;
import software.amazon.awssdk.services.ec2.model.InstanceType;
import software.amazon.awssdk.services.ec2.model.RunInstancesRequest;
import software.amazon.awssdk.services.ec2.model.RunInstancesResponse;
import software.amazon.awssdk.services.ec2.model.Tag;
import software.amazon.awssdk.services.ec2.model.CreateTagsRequest;
import software.amazon.awssdk.services.ec2.model.Ec2Exception;
```

#### Code

```java
public static String createEC2Instance(Ec2Client ec2,String name, String amiId ) {
    RunInstancesRequest runRequest = RunInstancesRequest.builder()
```
```java
.imageId(amiId)
.instanceType(InstanceType.T1_MICRO)
.maxCount(1)
.minCount(1)
.build();

RunInstancesResponse response = ec2.runInstances(runRequest);
String instanceId = response.instances().get(0).instanceId();

Tag tag = Tag.builder()
    .key("Name")
    .value(name)
    .build();

CreateTagsRequest tagRequest = CreateTagsRequest.builder()
    .resources(instanceId)
    .tags(tag)
    .build();

try {
    ec2.createTags(tagRequest);
    System.out.printf(
        "Successfully started EC2 Instance %s based on AMI %s",
        instanceId, amiId);

    return instanceId;
} catch (Ec2Exception e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

return "";
```

See the [complete example](https://github.com/aws/aws-sdk-java) on GitHub.

### Start an instance

To start an Amazon EC2 instance, call the Ec2Client's `startInstances` method, providing it with a `StartInstancesRequest` containing the ID of the instance to start.

### Imports

See the [complete example](https://github.com/aws/aws-sdk-java) on GitHub.
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.ec2.Ec2Client;
import software.amazon.awssdk.services.ec2.model.StartInstancesRequest;
import software.amazon.awssdk.services.ec2.model.StopInstancesRequest;

Code

```java
public static void startInstance(Ec2Client ec2, String instanceId) {

    StartInstancesRequest request = StartInstancesRequest.builder()
        .instanceIds(instanceId)
        .build();

    ec2.startInstances(request);
    System.out.printf("Successfully started instance %s", instanceId);
}
```

See the [complete example](#) on GitHub.

**Stop an instance**

To stop an Amazon EC2 instance, call the Ec2Client's `stopInstances` method, providing it with a `StopInstancesRequest` containing the ID of the instance to stop.

Imports

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.ec2.Ec2Client;
import software.amazon.awssdk.services.ec2.model.StartInstancesRequest;
import software.amazon.awssdk.services.ec2.model.StopInstancesRequest;
```

Code

```java
public static void stopInstance(Ec2Client ec2, String instanceId) {

    StopInstancesRequest request = StopInstancesRequest.builder()
        .instanceIds(instanceId)
        .build();

    ec2.stopInstances(request);
    System.out.printf("Successfully stopped instance %s", instanceId);
}
```
Reboot an instance

To reboot an Amazon EC2 instance, call the Ec2Client's `rebootInstances` method, providing it with a `RebootInstancesRequest` containing the ID of the instance to reboot.

Imports

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.ec2.Ec2Client;
import software.amazon.awssdk.services.ec2.model.Ec2Exception;
import software.amazon.awssdk.services.ec2.model.RebootInstancesRequest;
```

Code

```java
public static void rebootEC2Instance(Ec2Client ec2, String instanceId) {
    try {
        RebootInstancesRequest request = RebootInstancesRequest.builder()
            .instanceIds(instanceId)
            .build();

        ec2.rebootInstances(request);
        System.out.printf("Successfully rebooted instance %s", instanceId);
    } catch (Ec2Exception e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

Describe instances

To list your instances, create a `DescribeInstancesRequest` and call the Ec2Client's `describeInstances` method. It will return a `DescribeInstancesResponse` object that you can use to list the Amazon EC2 instances for your account and region.
Instances are grouped by *reservation*. Each reservation corresponds to the call to `startInstances` that launched the instance. To list your instances, you must first call the `DescribeInstancesResponse` class' `reservations` method, and then call `instances` on each returned `Reservation` object.

**Imports**

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.ec2.Ec2Client;
import software.amazon.awssdk.services.ec2.model.DescribeInstancesRequest;
import software.amazon.awssdk.services.ec2.model.DescribeInstancesResponse;
import software.amazon.awssdk.services.ec2.model.Instance;
import software.amazon.awssdk.services.ec2.model.Reservation;
import software.amazon.awssdk.services.ec2.model.Ec2Exception;
```

**Code**

```java
public static void describeEC2Instances( Ec2Client ec2){
    String nextToken = null;

    try {
        do {
            DescribeInstancesRequest request =
            DescribeInstancesRequest.builder().maxResults(6).nextToken(nextToken).build();
            DescribeInstancesResponse response = ec2.describeInstances(request);

            for (Reservation reservation : response.reservations()) {
                for (Instance instance : reservation.instances()) {
                    System.out.println("Instance Id is " + instance.instanceId());
                    System.out.println("Image id is " + instance.imageId());
                    System.out.println("Instance type is " +
                    instance.instanceType());
                    System.out.println("Instance state name is " +
                    instance.state().name());
                    System.out.println("monitoring information is " +
                    instance.monitoring().state());
                }
            }
            nextToken = response.nextToken();
        }
    }
```
Results are paged; you can get further results by passing the value returned from the result object's `nextToken` method to a new request object's `nextToken` method, then using the new request object in your next call to `describeInstances`.

See the [complete example](https://github.com) on GitHub.

### Monitor an instance

You can monitor various aspects of your Amazon EC2 instances, such as CPU and network utilization, available memory, and disk space remaining. To learn more about instance monitoring, see [Monitoring Amazon EC2](https://docs.aws.amazon.com) in the Amazon EC2 User Guide for Linux Instances.

To start monitoring an instance, you must create a `MonitorInstancesRequest` with the ID of the instance to monitor, and pass it to the Ec2Client's `monitorInstances` method.

#### Imports

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.ec2.Ec2Client;
import software.amazon.awssdk.services.ec2.model.MonitorInstancesRequest;
import software.amazon.awssdk.services.ec2.model.UnmonitorInstancesRequest;
```

#### Code

```java
public static void monitorInstance( Ec2Client ec2, String instanceId) {
    MonitorInstancesRequest request = MonitorInstancesRequest.builder()
        .instanceIds(instanceId).build();

    ec2.monitorInstances(request);
    System.out.printf(
        "Successfully enabled monitoring for instance %s",
        instanceId);
}
```
Stop instance monitoring

To stop monitoring an instance, create an `UnmonitorInstancesRequest` with the ID of the instance to stop monitoring, and pass it to the `Ec2Client`'s `unmonitorInstances` method.

**Imports**

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.ec2.Ec2Client;
import software.amazon.awssdk.services.ec2.model.MonitorInstancesRequest;
import software.amazon.awssdk.services.ec2.model.UnmonitorInstancesRequest;
```

**Code**

```java
public static void unmonitorInstance(Ec2Client ec2, String instanceId) {
    UnmonitorInstancesRequest request = UnmonitorInstancesRequest.builder()
        .instanceIds(instanceId).build();

    ec2.unmonitorInstances(request);

    System.out.printf(
        "Successfully disabled monitoring for instance %s",
        instanceId);
}
```

See the [complete example](#) on GitHub.

Use AWS Regions and Availability Zones

Describe Regions

To list the Regions available to your account, call the Ec2Client's describeRegions method. It returns a `DescribeRegionsResponse`. Call the returned object's `regions` method to get a list of `Region` objects that represent each Region.

Imports

```java
import software.amazon.awssdk.services.ec2.Ec2Client;
import software.amazon.awssdk.services.ec2.model.DescribeRegionsResponse;
import software.amazon.awssdk.services.ec2.model.DescribeAvailabilityZonesResponse;
import software.amazon.awssdk.services.ec2.model.Ec2Exception;
```

Code

```java
try {
    DescribeRegionsResponse regionsResponse = ec2.describeRegions();
    regionsResponse.regions().forEach(region -> {
        System.out.printf(
            "Found Region %s with endpoint %s%n",
            region.regionName(),
            region.endpoint());
    System.out.println();
    });
}
```

See the [complete example](https://github.com) on GitHub.

Describe availability zones

To list each Availability Zone available to your account, call the Ec2Client's `describeAvailabilityZones` method. It returns a `DescribeAvailabilityZonesResponse`. Call its `availabilityZones` method to get a list of `AvailabilityZone` objects that represent each Availability Zone.
Imports

```java
import software.amazon.awssdk.services.ec2.Ec2Client;
import software.amazon.awssdk.services.ec2.model.DescribeRegionsResponse;
import software.amazon.awssdk.services.ec2.model.DescribeAvailabilityZonesResponse;
import software.amazon.awssdk.services.ec2.model.Ec2Exception;
```

Code

Create the Ec2Client.

```java
software.amazon.awssdk.regions.Region region =
software.amazon.awssdk.regions.Region.US_EAST_1;
Ec2Client ec2 = Ec2Client.builder()
    .region(region)
    .build();
```

Then call describeAvailabilityZones() and retrieve results.

```java
DescribeAvailabilityZonesResponse zonesResponse =
    ec2.describeAvailabilityZones();
zonesResponse.availabilityZones().forEach(zone -> {
    System.out.printf(
        "Found Availability Zone %s with status %s in region %s\n",
        zone.zoneName(),
        zone.state(),
        zone.regionName() )
    ;
    System.out.println();
});
```

See the complete example on GitHub.

Describe accounts

To list EC2-related information about your account, call the Ec2Client’s describeAccountAttributes method. This method returns a DescribeAccountAttributesResponse object. Invoke this objects accountAttributes method
to get a list of AccountAttribute objects. You can iterate through the list to retrieve an AccountAttribute object.

You can get your account's attribute values by invoking the AccountAttribute object's attributeValues method. This method returns a list of AccountAttributeValue objects. You can iterate through this second list to display the value of attributes (see the following code example).

**Imports**

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.ec2.Ec2Client;
import software.amazon.awssdk.services.ec2.model.DescribeAccountAttributesResponse;
import software.amazon.awssdk.services.ec2.model.Ec2Exception;
```

**Code**

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.ec2.Ec2Client;
import software.amazon.awssdk.services.ec2.model.DescribeAccountAttributesResponse;
import software.amazon.awssdk.services.ec2.model.Ec2Exception;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 * For more information, see the following documentation topic:
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class DescribeAccount {
    public static void main(String[] args) {
        Region region = Region.US_EAST_1;
        Ec2Client ec2 = Ec2Client.builder()
            .region(region)
            .build();

        describeEC2Account(ec2);
        System.out.print("Done");
        ec2.close();
    }

    public static void describeEC2Account(Ec2Client ec2) {
        try {
```
DescribeAccountAttributesResponse accountResults =
ec2.describeAccountAttributes();
accountResults.accountAttributes().forEach(attribute -> {
    System.out.println("The name of the attribute is " +
    attribute.attributeName());
    attribute.attributeValues().forEach(
        myValue -> System.out.println("The value of the attribute is " +
        myValue.attributeValue()));
});
}
} catch (Ec2Exception e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
}

See the [complete example](#) on GitHub.

Work with security groups in Amazon EC2

Create a security group

To create a security group, call the Ec2Client's `createSecurityGroup` method with a `CreateSecurityGroupRequest` that contains the key's name.

Imports

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.ec2.Ec2Client;
import software.amazon.awssdk.services.ec2.model.CreateSecurityGroupRequest;
import software.amazon.awssdk.services.ec2.model.AuthorizeSecurityGroupIngressRequest;
import software.amazon.awssdk.services.ec2.model.AuthorizeSecurityGroupIngressResponse;
import software.amazon.awssdk.services.ec2.model.Ec2Exception;
import software.amazon.awssdk.services.ec2.model.IpPermission;
```
import software.amazon.awssdk.services.ec2.model.CreateSecurityGroupResponse;
import software.amazon.awssdk.services.ec2.model.IpRange;

Code

CreateSecurityGroupRequest createRequest =
CreateSecurityGroupRequest.builder()
    .groupName(groupName)
    .description(groupDesc)
    .vpcId(vpcId)
    .build();

CreateSecurityGroupResponse resp= ec2.createSecurityGroup(createRequest);

See the complete example on GitHub.

Configure a security group

A security group can control both inbound (ingress) and outbound (egress) traffic to your Amazon EC2 instances.

To add ingress rules to your security group, use the Ec2Client's authorizeSecurityGroupIngress method, providing the name of the security group and the access rules (IpPermission) you want to assign to it within an AuthorizeSecurityGroupIngressRequest object. The following example shows how to add IP permissions to a security group.

Imports

import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.ec2.Ec2Client;
import software.amazon.awssdk.services.ec2.model.CreateSecurityGroupRequest;
import software.amazon.awssdk.services.ec2.model.AuthorizeSecurityGroupIngressRequest;
import software.amazon.awssdk.services.ec2.model.AuthorizeSecurityGroupIngressResponse;
import software.amazon.awssdk.services.ec2.model.Ec2Exception;
import software.amazon.awssdk.services.ec2.model.IpPermission;
import software.amazon.awssdk.services.ec2.model.CreateSecurityGroupResponse;
import software.amazon.awssdk.services.ec2.model.IpRange;

Code

First, create an Ec2Client
Region region = Region.US_WEST_2;
Ec2Client ec2 = Ec2Client.builder()
    .region(region)
    .build();

Then use the Ec2Client's authorizeSecurityGroupIngress method,

IpRange ipRange = IpRange.builder()
    .cidrIp("0.0.0.0/0").build();

IpPermission ipPerm = IpPermission.builder()
    .ipProtocol("tcp")
    .toPort(80)
    .fromPort(80)
    .ipRanges(ipRange)
    .build();

IpPermission ipPerm2 = IpPermission.builder()
    .ipProtocol("tcp")
    .toPort(22)
    .fromPort(22)
    .ipRanges(ipRange)
    .build();

AuthorizeSecurityGroupIngressRequest authRequest =
    AuthorizeSecurityGroupIngressRequest.builder()
    .groupName(groupName)
    .ipPermissions(ipPerm, ipPerm2)
    .build();

AuthorizeSecurityGroupIngressResponse authResponse =
    ec2.authorizeSecurityGroupIngress(authRequest);

System.out.printf(
    "Successfully added ingress policy to Security Group %s",
    groupName);

    return resp.groupId();

} catch (Ec2Exception e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
To add an egress rule to the security group, provide similar data in an
AuthorizeSecurityGroupEgressRequest to the Ec2Client's authorizeSecurityGroupEgress
method.

See the complete example on GitHub.

Describe security groups

To describe your security groups or get information about them, call the Ec2Client's
describeSecurityGroups method. It returns a DescribeSecurityGroupsResponse that you can
use to access the list of security groups by calling its securityGroups method, which returns a
list of SecurityGroup objects.

Imports

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.ec2.Ec2Client;
import software.amazon.awssdk.services.ec2.model.DescribeSecurityGroupsRequest;
import software.amazon.awssdk.services.ec2.model.DescribeSecurityGroupsResponse;
import software.amazon.awssdk.services.ec2.model.SecurityGroup;
import software.amazon.awssdk.services.ec2.model.Ec2Exception;
```

Code

```java
public static void describeEC2SecurityGroups(Ec2Client ec2, String groupId) {
    try {
        DescribeSecurityGroupsRequest request =
            DescribeSecurityGroupsRequest.builder()
                .groupIds(groupId).build();

        DescribeSecurityGroupsResponse response =
            ec2.describeSecurityGroups(request);

        for(SecurityGroup group : response.securityGroups()) {
            System.out.printf("Found Security Group with id %s, " +
                          "vpc id %s " +}
See the [complete example](#) on GitHub.

### Delete a security group

To delete a security group, call the Ec2Client's `deleteSecurityGroup` method, passing it a `DeleteSecurityGroupRequest` that contains the ID of the security group to delete.

#### Imports

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.ec2.Ec2Client;
import software.amazon.awssdk.services.ec2.model.DeleteSecurityGroupRequest;
import software.amazon.awssdk.services.ec2.model.Ec2Exception;
```

#### Code

```java
public static void deleteEC2SecGroup(Ec2Client ec2, String groupId) {

    try {
        DeleteSecurityGroupRequest request = DeleteSecurityGroupRequest.builder()
            .groupId(groupId)
            .build();

        ec2.deleteSecurityGroup(request);
        System.out.printf("Successfully deleted Security Group with id %s", groupId);

    } catch (Ec2Exception e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
See the complete example on GitHub.

Work with Amazon EC2 instance metadata

A Java SDK client for the Amazon EC2 Instance Metadata Service (metadata client) allows your applications to access metadata on their local EC2 instance. The metadata client works with the local instance of IMDSv2 (Instance Metadata Service v2) and uses session-oriented requests.

Two client classes are available in the SDK. The synchronous Ec2MetadataClient is for blocking operations, and the Ec2MetadataAsyncClient is for asynchronous, non-blocking use cases.

Get started

To use the metadata client, add the imds Maven artifact to your project. You also need classes for an SdkHttpClient (or an SdkAsyncHttpClient for the asynchronous variant) on the classpath.

The following Maven XML shows dependency snippets for using the synchronous UrlConnectionHttpClient along with the dependency for metadata clients.
Search the [Maven central repository](https://search.maven.org/) for the latest version of the bom artifact.

To use an asynchronous HTTP client, replace the dependency snippet for the `url-connection-client` artifact. For example, the following snippet brings in the [NettyNioAsyncHttpClient](https://docs.aws.amazon.com/AmazonS3/latest/userguide/s3-cf-netty.html) implementation.

```xml
<dependency>
  <groupId>software.amazon.awssdk</groupId>
  <artifactId>netty-nio-client</artifactId>
</dependency>
```

### Use the metadata client

#### Instantiate a metadata client

You can instantiate an instance of a synchronous `Ec2MetadataClient` when only one implementation of the `SdkHttpClient` interface is present on the classpath. To do so, call the static `Ec2MetadataClient#create()` method as shown in the following snippet.

```java
Ec2MetadataClient client = Ec2MetadataClient.create(); // 'Ec2MetadataAsyncClient#create' is the asynchronous version.
```

If your application has multiple implementations of the `SdkHttpClient` or `SdkHttpAsyncClient` interface, you must specify an implementation for the metadata client to use as shown in the [the section called “Configurable HTTP client”](https://docs.aws.amazon.com/AmazonS3/latest/userguide/s3-cf-netty.html).
Note
For most service clients, such as Amazon S3, the SDK for Java automatically adds implementations of the SdkHttpClient or SdkHttpAsyncClient interface. If your metadata client uses the same implementation, then Ec2MetadataClient#create() will work. If you require a different implementation, you must specify it when you create the metadata client.

Send requests
To retrieve instance metadata, instantiate the EC2MetadataClient class and call the get method with a path parameter that specifies the instance metadata category.

The following example prints the value associated with the ami-id key to the console.

```java
Ec2MetadataClient client = Ec2MetadataClient.create();
Ec2MetadataResponse response = client.get("/latest/meta-data/ami-id");
System.out.println(response.asString());
client.close(); // Closes the internal resources used by the Ec2MetadataClient class.
```

If the path isn't valid, the get method throws an exception.

Reuse the same client instance for multiple requests, but call close on the client when it is no longer needed to release resources. After the close method is called, the client instance can't be used anymore.

Parse responses
EC2 instance metadata can be output in different formats. Plain text and JSON are the most commonly used formats. The metadata clients offer ways to work with those formats.

As the following example shows, use the asString method to get the data as a Java string. You can also use the asList method to separate a plain text response that returns multiple lines.

```java
Ec2MetadataClient client = Ec2MetadataClient.create();
Ec2MetadataResponse response = client.get("/latest/meta-data/");
String fullResponse = response.asString();
List<String> splits = response.asList();
```
If the response is in JSON, use the `Ec2MetadataResponse.asDocument` method to parse the JSON response into a `Document` instance as shown in the following code snippet.

```java
Document fullResponse = response.asDocument();
```

An exception will be thrown if the format of the metadata is not in JSON. If the response is successfully parsed, you can use the `document API` to inspect the response in more detail. Consult the instance `metadata category chart` to learn which metadata categories deliver JSON-formatted responses.

### Configure a metadata client

#### Retries

You can configure a metadata client with a retry mechanism. If you do, then the client can automatically retry requests that fail for unexpected reasons. By default, the client retries three times on a failed request with an exponential backoff time between attempts.

If your use case requires a different retry mechanism, you can customize the client using the `retryPolicy` method on its builder. For example, the following example shows a synchronous client configured with a fixed delay of two seconds between attempts and five retry attempts.

```java
BackoffStrategy fixedBackoffStrategy =
    FixedDelayBackoffStrategy.create(Duration.ofSeconds(2));
Ec2MetadataClient client =
    Ec2MetadataClient.builder()
        .retryPolicy(retryPolicyBuilder ->
            retryPolicyBuilder.numRetries(5)
                .backoffStrategy(fixedBackoffStrategy))
    .build();
```

There are several `BackoffStrategies` that you can use with a metadata client.

You can also disable the retry mechanism entirely, as the following snippet shows.

```java
Ec2MetadataClient client =
    Ec2MetadataClient.builder()
        .retryPolicy(Ec2MetadataRetryPolicy.none())
    .build();
```
Using `Ec2MetadataRetryPolicy#none()` disables the default retry policy so that the metadata client attempts no retries.

**IP version**

By default, a metadata client uses the IPV4 endpoint at http://169.254.169.254. To change the client to use the IPV6 version, use either the `endpointMode` or the `endpoint` method of the builder. An exception results if both methods are called on the builder.

The following examples show both IPV6 options.

```java
Ec2MetadataClient client =
    Ec2MetadataClient.builder()
        .endpointMode(EndpointMode.IPV6)
        .build();

Ec2MetadataClient client =
    Ec2MetadataClient.builder()
        .endpoint(URI.create("http://[fd00:ec2::254]"))
        .build();
```

**Key features**

**Asynchronous client**

To use the non-blocking version of the client, instantiate an instance of the `Ec2MetadataAsyncClient` class. The code in the following example creates an asynchronous client with default settings and uses the `get` method to retrieve the value for the `ami-id` key.

```java
Ec2MetadataAsyncClient asyncClient = Ec2MetadataAsyncClient.create();
CompletableFuture<Ec2MetadataResponse> response = asyncClient.get("/latest/meta-data/ami-id");
```

The `java.util.concurrent.CompletableFuture` returned by the `get` method completes when the response returns. The following example prints the `ami-id` metadata to the console.

```java
response.thenAccept(metadata -> System.out.println(metadata.asString()));
```
Configurable HTTP client

The builder for each metadata client has a `httpClient` method that you can use to supply a customized HTTP client.

The following example shows code for a custom `UrlConnectionHttpClient` instance.

```java
SdkHttpClient httpClient =
    UrlConnectionHttpClient.builder()
    .socketTimeout(Duration.ofMinutes(5))
    .proxyConfiguration(proxy ->
       proxy.endpoint(URI.create("http://proxy.example.net:8888")))
    .build();
Ec2MetadataClient metaDataClient =
    Ec2MetadataClient.builder()
    .httpClient(httpClient)
    .build();
// Use the metaDataClient instance.
metaDataClient.close(); // Close the instance when no longer needed.
```

The following example shows code for a custom `NettyNioAsyncHttpClient` instance with an asynchronous metadata client.

```java
SdkAsyncHttpClient httpAsyncClient =
    NettyNioAsyncHttpClient.builder()
    .connectionTimeout(Duration.ofMinutes(5))
    .maxConcurrency(100)
    .build();
Ec2MetadataAsyncClient asyncMetaDataClient =
    Ec2MetadataAsyncClient.builder()
    .httpClient(httpAsyncClient)
    .build();
// Use the asyncMetaDataClient instance.
asyncMetaDataClient.close(); // Close the instance when no longer needed.
```

The section called “HTTP clients” topic in this guide provides details on how to configure the HTTP clients that are available in the SDK for Java.
Token caching

Because the metadata clients use IMDSv2, all requests are associated with a session. A session is defined by a token that has an expiration, which the metadata client manages for you. Every metadata request automatically reuses the token until it expires.

By default, a token lasts for six hours (21,600 seconds). We recommend that you keep the default time-to-live value, unless your specific use case requires advanced configuration.

If needed, configure the duration by using the `tokenTtl` builder method. For example, the code in the following snippet creates a client with a session duration of five minutes.

```java
Ec2MetadataClient client =
    Ec2MetadataClient.builder()
    .tokenTtl(Duration.ofMinutes(5))
    .build();
```

If you omit calling the `tokenTtl` method on the builder, the default duration of 21,600 is used instead.

Work with IAM

This section provides examples of programming AWS Identity and Access Management (IAM) by using the AWS SDK for Java 2.x.

AWS Identity and Access Management (IAM) enables you to securely control access to AWS services and resources for your users. Using IAM, you can create and manage AWS users and groups, and use permissions to allow and deny their access to AWS resources. For a complete guide to IAM, visit the IAM User Guide.

The following examples include only the code needed to demonstrate each technique. The complete example code is available on GitHub. From there, you can download a single source file or clone the repository locally to get all the examples to build and run.

Topics

- Manage IAM access keys
- Manage IAM Users
- Create IAM policies with the AWS SDK for Java 2.x
- Work with IAM policies
• **Work with IAM server certificates**

## Manage IAM access keys

### Create an access key

To create an IAM access key, call the IamClient’s `createAccessKey` method with a `CreateAccessKeyRequest` object.

**Note**

You must set the region to `AWS_GLOBAL` for IamClient calls to work because IAM is a global service.

### Imports

```java
import software.amazon.awssdk.services.iam.model.CreateAccessKeyRequest;
import software.amazon.awssdk.services.iam.model.CreateAccessKeyResponse;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
import software.amazon.awssdk.services.iam.model.IamException;
```

### Code

```java
public static String createIAMAccessKey(IamClient iam, String user) {
    try {
        CreateAccessKeyRequest request = CreateAccessKeyRequest.builder()
            .userName(user).build();

        CreateAccessKeyResponse response = iam.createAccessKey(request);
        String keyId = response.accessKey().accessKeyId();
        return keyId;
    } catch (IamException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
    return "";
}
```
List access keys

To list the access keys for a given user, create a `ListAccessKeysRequest` object that contains the user name to list keys for, and pass it to the `IamClient`’s `listAccessKeys` method.

⚠️ Note

If you do not supply a user name to `listAccessKeys`, it will attempt to list access keys associated with the AWS account that signed the request.

Imports

```java
import software.amazon.awssdk.services.iam.model.AccessKeyMetadata;
import software.amazon.awssdk.services.iam.model.IamException;
import software.amazon.awssdk.services.iam.model.ListAccessKeysRequest;
import software.amazon.awssdk.services.iam.model.ListAccessKeysResponse;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
```

Code

```java
public static void listKeys( IamClient iam, String userName ){
    try {
        boolean done = false;
        String newMarker = null;

        while (!done) {
            ListAccessKeysResponse response;

            if(newMarker == null) {
                ListAccessKeysRequest request = ListAccessKeysRequest.builder()
                    .userName(userName).build();
                response = iam.listAccessKeys(request);
            } else {
                ListAccessKeysRequest request = ListAccessKeysRequest.builder()
```
.userName(userName)
    .marker(newMarker).build();
response = iam.listAccessKeys(request);
}

for (AccessKeyMetadata metadata :
    response.accessKeyMetadata()) {
    System.out.format("Retrieved access key %s",
        metadata.accessKeyId());
}

if (!response.isTruncated()) {
    done = true;
} else {
    newMarker = response.marker();
}
}

} catch (IamException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
}

The results of listAccessKeys are paged (with a default maximum of 100 records per call). You can call isTruncated on the returned ListAccessKeysResponse object to see if the query returned fewer results then are available. If so, then call marker on the ListAccessKeysResponse and use it when creating a new request. Use that new request in the next invocation of listAccessKeys.

See the complete example on GitHub.

**Retrieve an access key’s last used time**

To get the time an access key was last used, call the IamClient’s getAccessKeyLastUsed method with the access key's ID (which can be passed in using a GetAccessKeyLastUsedRequest object.

You can then use the returned GetAccessKeyLastUsedResponse object to retrieve the key's last used time.

**Imports**
See the [complete example](https://github.com/aws/aws-sdk-java) on GitHub.

### Activate or deactivate access keys

You can activate or deactivate an access key by creating an `UpdateAccessKeyRequest` object, providing the access key ID, optionally the user name, and the desired status, then passing the request object to the IamClient’s updateAccessKey method.

#### Imports

```java
import software.amazon.awssdk.services.iam.model.IamException;
import software.amazon.awssdk.services.iam.model.StatusType;
import software.amazon.awssdk.services.iam.model.UpdateAccessKeyRequest;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
```
public static void updateKey(IamClient iam, String username, String accessId, String status) {

    try {
        if (status.toLowerCase().equalsIgnoreCase("active")) {
            statusType = StatusType.ACTIVE;
        } else if (status.toLowerCase().equalsIgnoreCase("inactive")) {
            statusType = StatusType.INACTIVE;
        } else {
            statusType = StatusType.UNKNOWN_TO_SDK_VERSION;
        }

        UpdateAccessKeyRequest request = UpdateAccessKeyRequest.builder()
            .accessKeyId(accessId)
            .userName(username)
            .status(statusType)
            .build();

        iam.updateAccessKey(request);

        System.out.printf("Successfully updated the status of access key %s to" +
                "status %s for user %s", accessId, status, username);
    } catch (IamException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}

See the [complete example](https://github.com/aws/aws-sdk-java) on GitHub.

### Delete an access key

To permanently delete an access key, call the IamClient’s `deleteKey` method, providing it with a `DeleteAccessKeyRequest` containing the access key's ID and username.

⚠️ **Note**

Once deleted, a key can no longer be retrieved or used. To temporarily deactivate a key so that it can be activated again later, use `updateAccessKey` method instead.
Imports

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
import software.amazon.awssdk.services.iam.model.DeleteAccessKeyRequest;
import software.amazon.awssdk.services.iam.model.IamException;
```

Code

```java
public static void deleteKey(IamClient iam, String username, String accessKey) {
    try {
        DeleteAccessKeyRequest request = DeleteAccessKeyRequest.builder()
            .accessKeyId(accessKey)
            .userName(username)
            .build();

        iam.deleteAccessKey(request);
        System.out.println("Successfully deleted access key " + accessKey + " from user " + username);
    }
    catch (IamException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

See the [complete example](https://github.com) on GitHub.

Manage IAM Users

Create a User

Create a new IAM user by providing the user name to the `IamClient`'s `createUser` method using a `CreateUserRequest` object containing the user name.

Imports

```java
import software.amazon.awssdk.core.waiters.WaiterResponse;
import software.amazon.awssdk.services.iam.model.CreateUserRequest;
import software.amazon.awssdk.services.iam.model.CreateUserResponse;
import software.amazon.awssdk.services.iam.model.IamException;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
import software.amazon.awssdk.services.iam.waiters.IamWaiter;
import software.amazon.awssdk.services.iam.model.GetUserRequest;
import software.amazon.awssdk.services.iam.model.GetUserResponse;
```

Code

```java
public static String createIAMUser(IamClient iam, String username) {
    try {
        // Create an IamWaiter object
        IamWaiter iamWaiter = iam.waiter();

        CreateUserRequest request = CreateUserRequest.builder()
            .userName(username)
            .build();

        CreateUserResponse response = iam.createUser(request);

        // Wait until the user is created
        GetUserRequest userRequest = GetUserRequest.builder()
            .userName(response.user().userName())
            .build();

        WaiterResponse<GetUserResponse> waitUntilUserExists =
            iamWaiter.waitUntilUserExists(userRequest);

        waitUntilUserExists.matched().response().ifPresent(System.out::println);
        return response.user().userName();
    }
}
```
} catch (IamException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
} } return "";
}

See the complete example on GitHub.

List Users

To list the IAM users for your account, create a new ListUsersRequest and pass it to the IamClient's listUsers method. You can retrieve the list of users by calling users on the returned ListUsersResponse object.

The list of users returned by listUsers is paged. You can check to see there are more results to retrieve by calling the response object's isTruncated method. If it returns true, then call the response object's marker() method. Use the marker value to create a new request object. Then call the listUsers method again with the new request.

Imports

```java
import software.amazon.awssdk.services.iam.model.IamException;
import software.amazon.awssdk.services.iam.model.ListUsersRequest;
import software.amazon.awssdk.services.iam.model.ListUsersResponse;
import software.amazon.awssdk.services.iam.model.User;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
```

Code

```java
public static void listAllUsers(IamClient iam ) {
    try {
        boolean done = false;
        String newMarker = null;

        while(!done) {
            ListUsersResponse response;
            if (newMarker == null) {
```
ListUsersRequest request = ListUsersRequest.builder().build();
response = iam.listUsers(request);
}
else {
ListUsersRequest request = ListUsersRequest.builder()
.marker(newMarker).build();
response = iam.listUsers(request);
}

for(User user : response.users()) {
    System.out.format("\n Retrieved user %s", user.userName());
}

if(!response.isTruncated()) {
    done = true;
} else {
    newMarker = response.marker();
}
} catch (IamException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

See the [complete example](https://github.com) on GitHub.

**Update a User**

To update a user, call the IamClient object's updateUser method, which takes a
**UpdateUserRequest** object that you can use to change the user's name or path.

**Imports**

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
import software.amazon.awssdk.services.iam.model.IamException;
import software.amazon.awssdk.services.iam.model.UpdateUserRequest;
```

**Code**

```java
public static void updateIAMUser(IamClient iam, String curName,String newName) {
    try {
```
UpdateUserRequest request = UpdateUserRequest.builder()
  .userName(curName)
  .newUserName(newName)
  .build();

iam.updateUser(request);
System.out.printf("Successfully updated user to username %s",
  newName);
} catch (IamException e) {
  System.err.println(e.awsErrorDetails().errorMessage());
  System.exit(1);
}

See the [complete example](#) on GitHub.

### Delete a User

To delete a user, call the IamClient's `deleteUser` request with a `UpdateUserRequest` object set with the user name to delete.

#### Imports

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
import software.amazon.awssdk.services.iam.model.DeleteUserRequest;
import software.amazon.awssdk.services.iam.model.IamException;
```

#### Code

```java
public static void deleteIAMUser(IamClient iam, String userName) {
  try {
    DeleteUserRequest request = DeleteUserRequest.builder()
      .userName(userName)
      .build();

    iam.deleteUser(request);
    System.out.println("Successfully deleted IAM user " + userName);
  } catch (IamException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
  }
}
```
Create IAM policies with the AWS SDK for Java 2.x

The IAM Policy Builder API is a library that you can use to build IAM policies in Java and upload them to AWS Identity and Access Management (IAM).

Instead of building an IAM policy by manually assembling a JSON string or by reading a file, the API provides a client-side, object-oriented approach to generate the JSON string. When you read an existing IAM policy in JSON format, the API converts it to an IamPolicy instance for handling.

The IAM Policy Builder API became available with version 2.20.105 of the SDK, so use that version or a later one in your Maven build file. The latest version number of the SDK is listed on Maven central.

The following snippet shows an example dependency block for a Maven pom.xml file. This allows you to use the IAM Policy Builder API in your project.

```
<dependency>
    <groupId>software.amazon.awssdk</groupId>
    <artifactId>iam-policy-builder</artifactId>
    <version>2.20.139</version>
</dependency>
```

Create an IamPolicy

This section shows several examples of how to build policies by using the IAM Policy Builder API.
In each of the following examples, start with the `IamPolicy.Builder` and add one or more statements by using the `addStatement` method. Following this pattern, the `IamStatement.Builder` has methods to add the effect, actions, resources, and conditions to the statement.

**Example: Create a time-based policy**

The following example creates an identity-based policy that permits the Amazon DynamoDB `GetItem` action between two points in time.

```java
public String timeBasedPolicyExample() {
    IamPolicy policy = IamPolicy.builder()
        .addStatement(b -> b
            .effect(IamEffect.ALLOW)
            .addAction("dynamodb:GetItem")
            .addResource(IamResource.ALL)
            .addCondition(b1 -> b1
                .operator(IamConditionOperator.DATE_GREATER_THAN)
                .key("aws:CurrentTime")
                .value("2020-04-01T00:00:00Z"))
            .addCondition(b1 -> b1
                .operator(IamConditionOperator.DATE_LESS_THAN)
                .key("aws:CurrentTime")
                .value("2020-06-30T23:59:59Z"))
        .build();

    // Use an IamPolicyWriter to write out the JSON string to a more readable format.
    return policy.toJson(IamPolicyWriter.builder()
        .prettyPrint(true)
        .build());
}
```

**JSON output**

The last statement in the previous example returns the following JSON string.

```json
{
    "Version" : "2012-10-17",
    "Statement" : {
        "Effect" : "Allow",
    }
}
```

Read more about this example in the *AWS Identity and Access Management User Guide*. 
"Action" : "dynamodb:GetItem",
"Resource" : "*",
"Condition" : {
   "DateGreaterThan" : {
      "aws:CurrentTime" : "2020-04-01T00:00:00Z"
   },
   "DateLessThan" : {
   }
}

Example: Specify multiple conditions

The following example shows how you can create an identity-based policy that allows access to specific DynamoDB attributes. The policy contains two conditions.

```java
public String multipleConditionsExample() {
   IamPolicy policy = IamPolicy.builder()
      .addStatement(b -> b
         .effect(IamEffect.ALLOW)
         .addAction("dynamodb:GetItem")
         .addAction("dynamodb:BatchGetItem")
         .addAction("dynamodb:Query")
         .addAction("dynamodb:PutItem")
         .addAction("dynamodb:UpdateItem")
         .addAction("dynamodb:DeleteItem")
         .addAction("dynamodb:BatchWriteItem")
         .addResource("arn:aws:dynamodb:*:*:table/table-name")
         .addConditions(IamConditionOperator.STRING_EQUALS.addPrefix("ForAllValues:"),
            "dynamodb:Attributes",
            List.of("column-name1", "column-name2", "column-name3"))
         .addCondition(b1 ->
            b1.operator(IamConditionOperator.STRING_EQUALS.addSuffix("IfExists"))
               .key("dynamodb:Select")
               .value("SPECIFIC_ATTRIBUTES")))
      .build();

   return policy.toJson(IamPolicyWriter.builder()
      .prettyPrint(true).build());
}
```
JSON output

The last statement in the previous example returns the following JSON string.

Read more about this example in the AWS Identity and Access Management User Guide.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
                "dynamodb:PutItem", "dynamodb:UpdateItem", "dynamodb:DeleteItem",
                "dynamodb:BatchWriteItem" ],
    "Resource": "arn:aws:dynamodb::*:*:table/table-name",
    "Condition": {
      "ForAllValues:StringEquals": {
        "dynamodb:Attributes": [ "column-name1", "column-name2", "column-name3" ]
      },
      "StringEqualsIfExists": {
        "dynamodb:Select": "SPECIFIC_ATTRIBUTES"
      }
    }
  }
}
```

Example: Specify principals

The following example shows how to create a resource-based policy that denies access to a bucket for all principals except for those specified in the condition.

```
public String specifyPrincipalsExample() {
  IamPolicy policy = IamPolicy.builder()
    .addStatement(b -> b
                  .effect(IamEffect.DENY)
                  .addAction("s3:*")
                  .addPrincipal(IamPrincipal.ALL)
                  .addResource("arn:aws:s3:::BUCKETNAME/*")
                  .addResource("arn:aws:s3:::BUCKETNAME")
                  .addCondition(b1 -> b1
                                 .operator(IamConditionOperator.ARN_NOT_EQUALS)
                                 .key("aws:PrincipalArn")
                                 .value("arn:aws:iam::444455566666:user/user-name"))
                  .build();
  return policy.toJson(IamPolicyWriter.builder()
```
The last statement in the previous example returns the following JSON string.

Read more about this example in the AWS Identity and Access Management User Guide.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Deny",
    "Principal": "*",
    "Action": "s3:*",
    "Resource": [ "arn:aws:s3:::BUCKETNAME/*", "arn:aws:s3:::BUCKETNAME" ],
    "Condition": {
      "ArnNotEquals": {
        "aws:PrincipalArn": "arn:aws:iam::444455556666:user/user-name"
      }
    }
  }
}
```

Example: Allow cross-account access

The following example shows how to allow another AWS account to upload objects to your bucket while retaining full owner control of the uploaded objects.

```
public String allowCrossAccountAccessExample() {
    IamPolicy policy = IamPolicy.builder()
        .addStatement(b -> b
            .effect(IamEffect.ALLOW)
            .addPrincipal(IamPrincipalType.AWS, "111122223333")
            .addAction("s3:PutObject")
            .addResource("arn:aws:s3:::DOC-EXAMPLE-BUCKET/*")
            .addCondition(b1 -> b1
                .operator(IamConditionOperator.STRING_EQUALS)
                .key("s3:x-amz-acl")
                .value("bucket-owner-full-control"))
            .build();
    return policy.toJson(IamPolicyWriter.builder()
JSON output

The last statement in the previous example returns the following JSON string.

Read more about this example in the Amazon Simple Storage Service User Guide.

```json
{
  "Version" : "2012-10-17",
  "Statement" : {
    "Effect" : "Allow",
    "Principal" : {
      "AWS" : "111122223333"
    },
    "Action" : "s3:PutObject",
    "Resource" : "arn:aws:s3:::DOC-EXAMPLE-BUCKET/**",
    "Condition" : {
      "StringEquals" : {
        "s3:x-amz-acl" : "bucket-owner-full-control"
      }
    }
  }
}
```

Use an IamPolicy with IAM

After you have created a IamPolicy instance, you use an IamClient to work with the IAM service.

The following example builds a policy that allows an IAM identity to write items to a DynamoDB table in the account that is specified with the accountID parameter. The policy is then uploaded to IAM as a JSON string.

```java
public String createAndUploadPolicyExample(IamClient iam, String accountID, String policyName) {
    // Build the policy.
    IamPolicy policy =
            IamPolicy.builder() // 'version' defaults to "2012-10-17".
                    .addStatement(IamStatement.builder()
                              .effect(IamEffect.ALLOW)
```

Create IAM policies
public String createNewBasedOnExistingPolicyExample(IamClient iam, String accountID, String policyName, String newPolicyName) {

    String policyArn = "arn:aws:iam::" + accountID + ":policy/" + policyName;
    GetPolicyResponse getPolicyResponse = iam.getPolicy(r -> r.policyArn(policyArn));

    String policyVersion = getPolicyResponse.policy().defaultVersionId();
    GetPolicyVersionResponse getPolicyVersionResponse =
        iam.getPolicyVersion(r -> r.policyArn(policyArn).versionId(policyVersion));

    // Create an IamPolicy instance from the JSON string returned from IAM.
    String decodedPolicy =
        URLDecoder.decode(getPolicyVersionResponse.policyVersion().document(), StandardCharsets.UTF_8);
    IamPolicy policy = IamPolicy.fromJson(decodedPolicy);

    /*
     * All IamPolicy components are immutable, so use the copy method that
     * creates a new instance that
     * can be altered in the same method call.
     *
     * Add the ability to get an item from DynamoDB as an additional action.
     */
    IamStatement newStatement = policy.statements().get(0).copy(s ->
        s.addAction("dynamodb:GetItem"));

    // Create a new statement that replaces the original statement.
IamPolicy newPolicy = policy.copy(p ->
    p.statements(Arrays.asList(newStatement)));

    // Upload the new policy. IAM now has both policies.
    iam.createPolicy(r -> r.policyName(newPolicyName)
        .policyDocument(newPolicy.toJson()));

    return newPolicy.toJson(IamPolicyWriter.builder().prettyPrint(true).build());
}

IamClient

The previous examples use an IamClient argument that is created as shown in the following snippet.

IamClient iam = IamClient.builder().region(Region.AWS_GLOBAL).build();

Policies in JSON

The examples return the following JSON strings.

First example
{
    "Version": "2012-10-17",
    "Statement": [{
        "Effect": "Allow",
        "Action": "dynamodb:PutItem",
        "Resource": "arn:aws:dynamodb:us-east-1:111122223333:table/exampleTableName"
    }]
}

Second example
{
    "Version": "2012-10-17",
    "Statement": [{
        "Effect": "Allow",
        "Action": ["dynamodb:PutItem", "dynamodb:GetItem"],
        "Resource": "arn:aws:dynamodb:us-east-1:111122223333:table/exampleTableName"
    }]
}
Work with IAM policies

Create a policy

To create a new policy, provide the policy's name and a JSON-formatted policy document in a `CreatePolicyRequest` to the `IamClient`'s `createPolicy` method.

Imports

```java
import software.amazon.awssdk.core.waiters.WaiterResponse;
import software.amazon.awssdk.services.iam.model.CreatePolicyRequest;
import software.amazon.awssdk.services.iam.model.CreatePolicyResponse;
import software.amazon.awssdk.services.iam.model.GetPolicyRequest;
import software.amazon.awssdk.services.iam.model.GetPolicyResponse;
import software.amazon.awssdk.services.iam.model.IamException;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
import software.amazon.awssdk.services.iam.waiters.IamWaiter;
```

Code

```java
public static String createIAMPolicy(IamClient iam, String policyName) {
    try {
        // Create an IamWaiter object
        IamWaiter iamWaiter = iam.waiter();

        CreatePolicyRequest request = CreatePolicyRequest.builder()
            .policyName(policyName)
            .policyDocument(PolicyDocument).build();

        CreatePolicyResponse response = iam.createPolicy(request);

        // Wait until the policy is created
        GetPolicyRequest polRequest = GetPolicyRequest.builder()
            .policyArn(response.policy().arn()).build();

        WaiterResponse<GetPolicyResponse> waitUntilPolicyExists =
            iamWaiter.waitUntilPolicyExists(polRequest);
        waitUntilPolicyExists.matched().response().ifPresent(System.out::println);
        return response.policy().arn();
    }
}
```
} catch (IamException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

return "";
}

See the complete example on GitHub.

Get a policy

To retrieve an existing policy, call the IamClient's getPolicy method, providing the policy's ARN within a GetPolicyRequest object.

Imports

```java
import software.amazon.awssdk.services.iam.model.GetPolicyRequest;
import software.amazon.awssdk.services.iam.model.GetPolicyResponse;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
import software.amazon.awssdk.services.iam.model.IamException;
```

Code

```java
public static void getIAMPolicy(IamClient iam, String policyArn) {
    try {
        GetPolicyRequest request = GetPolicyRequest.builder()
            .policyArn(policyArn).build();

        GetPolicyResponse response = iam.getPolicy(request);
        System.out.format("Successfully retrieved policy %s",
            response.policy().policyName());
    } catch (IamException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}

See the complete example on GitHub.
Attach a role policy

You can attach a policy to an IAM role by calling the IamClient's attachRolePolicy method, providing it with the role name and policy ARN in an AttachRolePolicyRequest.

Imports

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
import software.amazon.awssdk.services.iam.model.IamException;
import software.amazon.awssdk.services.iam.model.AttachRolePolicyRequest;
import software.amazon.awssdk.services.iam.model.AttachedPolicy;
import software.amazon.awssdk.services.iam.model.ListAttachedRolePoliciesRequest;
import software.amazon.awssdk.services.iam.model.ListAttachedRolePoliciesResponse;
import java.util.List;
```

Code

```java
public static void attachIAMRolePolicy(IamClient iam, String roleName, String policyArn ) {

    try {

        ListAttachedRolePoliciesRequest request = 
        ListAttachedRolePoliciesRequest.builder()
        .roleName(roleName)
        .build();

        ListAttachedRolePoliciesResponse  response = 
        iam.listAttachedRolePolicies(request);
        List<AttachedPolicy> attachedPolicies = response.attachedPolicies();

        // Ensure that the policy is not attached to this role
        String polArn = "";
        for (AttachedPolicy policy: attachedPolicies) {
            polArn = policy.policyArn();
            if (polArn.compareTo(policyArn)==0) {
                System.out.println(roleName +
                " policy is already attached to this role.");
                return;
            }
        }
    }
} 
```
AttachRolePolicyRequest attachRequest =
    AttachRolePolicyRequest.builder()
    .roleName(roleName)
    .policyArn(policyArn)
    .build();

    iam.attachRolePolicy(attachRequest);

    System.out.println("Successfully attached policy " + policyArn + " to role " + roleName);

} catch (IamException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

    System.out.println("Done");
}

See the [complete example](https://github.com) on GitHub.

**List attached role policies**

List attached policies on a role by calling the IamClient's `listAttachedRolePolicies` method. It takes a `ListAttachedRolePoliciesRequest` object that contains the role name to list the policies for.

Call `getAttachedPolicies` on the returned `ListAttachedRolePoliciesResponse` object to get the list of attached policies. Results may be truncated; if the `ListAttachedRolePoliciesResponse` object's `isTruncated` method returns `true`, call the `ListAttachedRolePoliciesResponse` object's `marker` method. Use the marker returned to create a new request and use it to call `listAttachedRolePolicies` again to get the next batch of results.

**Imports**

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
import software.amazon.awssdk.services.iam.IamException;
import software.amazon.awssdk.services.iam.model.AttachRolePolicyRequest;
import software.amazon.awssdk.services.iam.model.AttachedPolicy;
import software.amazon.awssdk.services.iam.model.ListAttachedRolePoliciesRequest;
import software.amazon.awssdk.services.iam.model.ListAttachedRolePoliciesResponse;
import java.util.List;
```
public static void attachIAMRolePolicy(IamClient iam, String roleName, String policyArn) {
    try {
        ListAttachedRolePoliciesRequest request = 
            ListAttachedRolePoliciesRequest.builder()
                .roleName(roleName)
                .build();

        ListAttachedRolePoliciesResponse response = 
            iam.listAttachedRolePolicies(request);
        List<AttachedPolicy> attachedPolicies = response.attachedPolicies();

        // Ensure that the policy is not attached to this role
        String polArn = "";
        for (AttachedPolicy policy: attachedPolicies) {
            polArn = policy.policyArn();
            if (polArn.compareTo(policyArn) == 0) {
                System.out.println(roleName + " policy is already attached to this role.");
                return;
            }
        }

        AttachRolePolicyRequest attachRequest = 
            AttachRolePolicyRequest.builder()
                .roleName(roleName)
                .policyArn(policyArn)
                .build();

        iam.attachRolePolicy(attachRequest);

        System.out.println("Successfully attached policy " + policyArn + " to role " + roleName);
    } catch (IamException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }

    System.out.println("Done");
}
See the complete example on GitHub.

**Detach a role policy**

To detach a policy from a role, call the IamClient's detachRolePolicy method, providing it with the role name and policy ARN in a `DetachRolePolicyRequest`.

**Imports**

```java
import software.amazon.awssdk.services.iam.model.DetachRolePolicyRequest;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
import software.amazon.awssdk.services.iam.model.IamException;
```

**Code**

```java
public static void detachPolicy(IamClient iam, String roleName, String policyArn )
{
    try {
        DetachRolePolicyRequest request = DetachRolePolicyRequest.builder()
            .roleName(roleName)
            .policyArn(policyArn)
            .build();

        iam.detachRolePolicy(request);
        System.out.println("Successfully detached policy " + policyArn + " from role " + roleName);
    }
    catch (IamException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

See the complete example on GitHub.

**More information**

- Overview of IAM Policies in the IAM User Guide.
Work with IAM server certificates

To enable HTTPS connections to your website or application on AWS, you need an SSL/TLS server certificate. You can use a server certificate provided by AWS Certificate Manager or one that you obtained from an external provider.

We recommend that you use ACM to provision, manage, and deploy your server certificates. With ACM you can request a certificate, deploy it to your AWS resources, and let ACM handle certificate renewals for you. Certificates provided by ACM are free. For more information about ACM, see the AWS Certificate Manager User Guide.

Get a server certificate

You can retrieve a server certificate by calling the IamClient’s `GetServerCertificate` method, passing it a `GetServerCertificateRequest` with the certificate’s name.

Imports

```java
import software.amazon.awssdk.services.iam.model.GetServerCertificateRequest;
import software.amazon.awssdk.services.iam.model.GetServerCertificateResponse;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
import software.amazon.awssdk.services.iam.model.IamException;
```

Code

```java
public static void getCertificate(IamClient iam, String certName) {
    try {
        GetServerCertificateRequest request = GetServerCertificateRequest.builder()
            .serverCertificateName(certName)
```
import software.amazon.awssdk.services.iam.model.IamException;
import software.amazon.awssdk.services.iam.model.ListServerCertificatesRequest;
import software.amazon.awssdk.services.iam.model.ListServerCertificatesResponse;
import software.amazon.awssdk.services.iam.model.ServerCertificateMetadata;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;

public static void listCertificates(IamClient iam) {
    try {
        .build();

        GetServerCertificateResponse response = iam.getServerCertificate(request);
        System.out.format("Successfully retrieved certificate with body %s",
                          response.serverCertificate().certificateBody());

        } catch (IamException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }

See the complete example on GitHub.

List server certificates

To list your server certificates, call the IamClient's listServerCertificates method with a ListServerCertificatesRequest. It returns a ListServerCertificatesResponse.

Call the returned ListServerCertificateResponse object's serverCertificateMetadataList method to get a list of ServerCertificateMetadata objects that you can use to get information about each certificate.

Results may be truncated; if the ListServerCertificateResponse object's isTruncated method returns true, call the ListServerCertificatesResponse object's marker method and use the marker to create a new request. Use the new request to call listServerCertificates again to get the next batch of results.

Imports

Code
boolean done = false;
String newMarker = null;

while(!done) {
    ListServerCertificatesResponse response;

    if (newMarker == null) {
        ListServerCertificatesRequest request =
            ListServerCertificatesRequest.builder().build();
        response = iam.listServerCertificates(request);
    } else {
        ListServerCertificatesRequest request =
            ListServerCertificatesRequest.builder()
                .marker(newMarker).build();
        response = iam.listServerCertificates(request);
    }

    for(ServerCertificateMetadata metadata :
        response.serverCertificateMetadataList()) {
        System.out.printf("Retrieved server certificate %s",
            metadata.serverCertificateName());
    }

    if(!response.isTruncated()) {
        done = true;
    } else {
        newMarker = response.marker();
    }
}

} catch (IamException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

See the [complete example](https://github.com/aws/aws-sdk-java) on GitHub.

**Update a server certificate**

You can update a server certificate's name or path by calling the IamClient's `updateServerCertificate` method. It takes a `UpdateServerCertificateRequest` object set with the server certificate's current name and either a new name or new path to use.
### Imports

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
import software.amazon.awssdk.services.iam.model.IamException;
import software.amazon.awssdk.services.iam.model.UpdateServerCertificateRequest;
import software.amazon.awssdk.services.iam.model.UpdateServerCertificateResponse;
```

### Code

```java
public static void updateCertificate(IamClient iam, String curName, String newName)
{
    try {
        UpdateServerCertificateRequest request =
            UpdateServerCertificateRequest.builder()
            .serverCertificateName(curName)
            .newServerCertificateName(newName)
            .build();

        UpdateServerCertificateResponse response =
            iam.updateServerCertificate(request);

        System.out.printf("Successfully updated server certificate to name %s", newName);
    }
    catch (IamException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

See the [complete example](#) on GitHub.

### Delete a server certificate

To delete a server certificate, call the IamClient's `deleteServerCertificate` method with a `DeleteServerCertificateRequest` containing the certificate's name.

### Imports

```java
import software.amazon.awssdk.services.iam.model.DeleteServerCertificateRequest;
```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
import software.amazon.awssdk.services.iam.model.IamException;

Code

```java
public static void deleteCert(IamClient iam, String certName) {
    try {
        DeleteServerCertificateRequest request =
            DeleteServerCertificateRequest.builder()
                .serverCertificateName(certName)
                .build();

        iam.deleteServerCertificate(request);
        System.out.println("Successfully deleted server certificate " +
            certName);
    } catch (IamException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

See the complete example on GitHub.

Work with Kinesis

This section provides examples of programming [Amazon Kinesis](#) using the AWS SDK for Java 2.x.

For more information about Kinesis, see the [Amazon Kinesis Developer Guide](#).
The following examples include only the code needed to demonstrate each technique. The complete example code is available on GitHub. From there, you can download a single source file or clone the repository locally to get all the examples to build and run.

Topics

- Subscribe to Amazon Kinesis Data Streams

Subscribe to Amazon Kinesis Data Streams

The following examples show you how to retrieve and process data from Amazon Kinesis Data Streams using the `subscribeToShard` method. Kinesis Data Streams now employs the enhanced fanout feature and a low-latency HTTP/2 data retrieval API, making it easier for developers to run multiple low-latency, high-performance applications on the same Kinesis Data Stream.

Set up

First, create an asynchronous Kinesis client and a `SubscribeToShardRequest` object. These objects are used in each of the following examples to subscribe to Kinesis events.

Imports

```java
import java.util.concurrent.CompletableFuture;
import java.util.concurrent.atomic.AtomicInteger;
import org.reactivestreams.Subscriber;
import org.reactivestreams.Subscription;
import software.amazon.awssdk.core.async.SdkPublisher;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.kinesis.KinesisAsyncClient;
import software.amazon.awssdk.services.kinesis.model.ShardIteratorType;
import software.amazon.awssdk.services.kinesis.model.SubscribeToShardEvent;
import software.amazon.awssdk.services.kinesis.model.SubscribeToShardEventStream;
import software.amazon.awssdk.services.kinesis.model.SubscribeToShardRequest;
import software.amazon.awssdk.services.kinesis.model.SubscribeToShardResponse;
import software.amazon.awssdk.services.kinesis.model.SubscribeToShardResponseHandler;
```

Code

```java
Region region = Region.US_EAST_1;
KinesisAsyncClient client = KinesisAsyncClient.builder()
    .region(region)
```
Use the builder interface

You can use the `builder` method to simplify the creation of the `SubscribeToShardResponseHandler`. Using the builder, you can set each lifecycle callback with a method call instead of implementing the full interface.

Code

```java
private static CompletableFuture<Void> responseHandlerBuilder(KinesisAsyncClient client, SubscribeToShardRequest request) {
        builder()
        .onError(t -> System.err.println("Error during stream - " + t.getMessage()))
        .onComplete(() -> System.out.println("All records stream successfully"))
        .subscriber(e -> System.out.println("Received event - " + e))
    .build();
    return client.subscribeToShard(request, responseHandler);
}
```

For more control of the publisher, you can use the `publisherTransformer` method to customize the publisher.

Code

```java
private static CompletableFuture<Void> responseHandlerBuilderPublisherTransformer(KinesisAsyncClient client, SubscribeToShardRequest request) {
        builder()
        .onError(t -> System.err.println("Error during stream - " + t.getMessage()))
        .onComplete(() -> System.out.println("All records stream successfully"))
    .subscriber(e -> System.out.println("Received event - " + e))
    .build();
    return client.subscribeToShard(request, responseHandler);
}
```
See the [complete example](#) on GitHub.

**Use a custom response handler**

For full control of the subscriber and publisher, implement the `SubscribeToShardResponseHandler` interface.

In this example, you implement the `onEventStream` method, which allows you full access to the publisher. This demonstrates how to transform the publisher to event records for printing by the subscriber.

**Code**

```java
private static CompletableFuture<Void> responseHandlerBuilderClassic(KinesisAsyncClient client, SubscribeToShardRequest request) {
    SubscribeToShardResponseHandler responseHandler = new SubscribeToShardResponseHandler() {
        @Override
        public void responseReceived(SubscribeToShardResponse response) {
            System.out.println("Received initial response");
        }

        @Override
        public void onEventStream(SdkPublisher<SubscribeToShardEventStream> publisher) {
            publisher
                // Filter to only SubscribeToShardEvents
                .filter(SubscribeToShardEvent.class)
                // Flat map into a publisher of just records
                .flatMapIterable(SubscribeToShardEvent::records)
                // Limit to 1000 total records
        }
    };
    return client.subscribeToShard(request, responseHandler);
}
```
.limit(1000)
  // Batch records into lists of 25
.buffer(25)
  // Print out each record batch
.subscribe(batch -> System.out.println("Record Batch - " + batch));
}

@Override
public void complete() {
    System.out.println("All records stream successfully");
}

@Override
public void exceptionOccurred(Throwable throwable) {
    System.err.println("Error during stream - " + throwable.getMessage());
}

return client.subscribeToShard(request, responseHandler);

See the [complete example](https://github.com/aws/aws-sdk-java) on GitHub.

**Use the visitor interface**

You can use a [Visitor](https://docs.aws.amazon.com/sdk-for-java/v1/developer-guide/java-sdk-reference-com-stream.html) object to subscribe to specific events you're interested in watching.

**Code**

```java
private static CompletableFuture<Void>
    responseHandlerBuilderVisitorBuilder(KinesisAsyncClient client,
                  SubscribeToShardRequest request) {
    SubscribeToShardResponseHandler.Visitor visitor =
        SubscribeToShardResponseHandler.Visitor
            .builder()
            .onSubscribeToShardEvent(e -> System.out.println("Received subscribe to shard event " + e))
            .build();
    SubscribeToShardResponseHandler responseHandler =
        SubscribeToShardResponseHandler
            .builder()
            .onError(t -> System.err.println("Error during stream - " +
t.getMessage()))
```
See the complete example on GitHub.

Use a custom subscriber

You can also implement your own custom subscriber to subscribe to the stream.

This code snippet shows an example subscriber.

Code

```java
private static class MySubscriber implements Subscriber<SubscribeToShardEventStream> {
    private Subscription subscription;
    private AtomicInteger eventCount = new AtomicInteger(0);

    @Override
    public void onSubscribe(Subscription subscription) {
        this.subscription = subscription;
        this.subscription.request(1);
    }

    @Override
    public void onNext(SubscribeToShardEventStream shardSubscriptionEventStream) {
        System.out.println("Received event " + shardSubscriptionEventStream);
        if (eventCount.incrementAndGet() >= 100) {
            // You can cancel the subscription at any time if you wish to stop receiving events.
            subscription.cancel();
        }
        subscription.request(1);
    }

    @Override
    public void onError(Throwable throwable) {
        System.err.println("Error occurred while stream - " + throwable.getMessage());
    }
}
```
@Override
public void onComplete() {
    System.out.println("Finished streaming all events");
}

You can pass the custom subscriber to the subscribe method as shown in the following code snippet.

**Code**

```java
private static CompletableFuture<Void>
responseHandlerBuilderSubscriber(KinesisAsyncClient client, SubscribeToShardRequest request) {
    SubscribeToShardResponseHandler responseHandler =
    SubscribeToShardResponseHandler
        .builder()
        .onError(t -> System.err.println("Error during stream - " +
        t.getMessage()))
        .subscriber(MySubscriber::new)
        .build();
    return client.subscribeToShard(request, responseHandler);
}
```

See the [complete example](https://github.com) on GitHub.

**Write data records into a Kinesis data stream**

You can use the [KinesisClient](https://kinesis) object to write data records into a Kinesis data stream by using the putRecords method. To successfully invoke this method, create a [PutRecordsRequest](https://putrecords) object. You pass the name of the data stream to the streamName method. Also you must pass the data by using the putRecords method (as shown in the following code example).

**Imports**

```java
import software.amazon.awssdk.core.SdkBytes;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.kinesis.KinesisClient;
import software.amazon.awssdk.services.kinesis.model.PutRecordRequest;
import software.amazon.awssdk.services.kinesis.model.KinesisException;
import software.amazon.awssdk.services.kinesis.model.DescribeStreamRequest;
```
In the following Java code example, notice that **StockTrade** object is used as the data to write to the Kinesis data stream. Before running this example, ensure that you have created the data stream.

**Code**

```java
import software.amazon.awssdk.core.SdkBytes;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.kinesis.KinesisClient;
import software.amazon.awssdk.services.kinesis.model.PutRecordRequest;
import software.amazon.awssdk.services.kinesis.model.KinesisException;
import software.amazon.awssdk.services.kinesis.model.DescribeStreamRequest;
import software.amazon.awssdk.services.kinesis.model.DescribeStreamResponse;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 * 
 * For more information, see the following documentation topic:
 * 
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class StockTradesWriter {
    public static void main(String[] args) {
        final String usage = """;

        Usage:
        <streamName>

        Where:
        streamName - The Amazon Kinesis data stream to which records are written (for example, StockTradeStream)
        """,

        if (args.length != 1) {
            System.out.println(usage);
            System.exit(1);
        }

        String streamName = args[0];
        Region region = Region.US_EAST_1;
```
KinesisClient kinesisClient = KinesisClient.builder()
    .region(region)
    .build();

    // Ensure that the Kinesis Stream is valid.
    validateStream(kinesisClient, streamName);
    setStockData(kinesisClient, streamName);
    kinesisClient.close();
}

public static void setStockData(KinesisClient kinesisClient, String streamName) {
    try {
        // Repeatedly send stock trades with a 100 milliseconds wait in between.
        StockTradeGenerator stockTradeGenerator = new StockTradeGenerator();

        // Put in 50 Records for this example.
        int index = 50;
        for (int x = 0; x < index; x++) {
            StockTrade trade = stockTradeGenerator.getRandomTrade();
            sendStockTrade(trade, kinesisClient, streamName);
            Thread.sleep(100);
        }
    } catch (KinesisException | InterruptedException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
    System.out.println("Done");
}

private static void sendStockTrade(StockTrade trade, KinesisClient kinesisClient,
    String streamName) {
    byte[] bytes = trade.toJsonAsBytes();

    // The bytes could be null if there is an issue with the JSON serialization by
    // the Jackson JSON library.
    if (bytes == null) {
        System.out.println("Could not get JSON bytes for stock trade");
        return;
    }

    System.out.println("Putting trade: " + trade);
    PutRecordRequest request = PutRecordRequest.builder()
.partitionKey(trade.getTickerSymbol()) // We use the ticker symbol as the partition key, explained in // the Supplemental Information
.streamName(streamName)
.data(SdkBytes.fromByteArray(bytes))
.build();

try {
    kinesisClient.putRecord(request);
} catch (KinesisException e) {
    System.err.println(e.getMessage());
}

private static void validateStream(KinesisClient kinesisClient, String streamName) {
    try {
        DescribeStreamRequest describeStreamRequest = DescribeStreamRequest.builder()
            .streamName(streamName)
            .build();

        DescribeStreamResponse describeStreamResponse = kinesisClient.describeStream(describeStreamRequest);

        if (!describeStreamResponse.streamDescription().streamStatus().toString().equals("ACTIVE")) {
            System.err.println("Stream " + streamName + " is not active. Please wait a few moments and try again.");
            System.exit(1);
        }
    } catch (KinesisException e) {
        System.err.println("Error found while describing the stream " + streamName);
        System.err.println(e);
        System.exit(1);
    }
}
See the [complete example](https://github.com/aws/aws-sdk-java) on GitHub.

**Use a third-party library**

You can use other third-party libraries instead of implementing a custom subscriber. This example demonstrates using the RxJava implementation, but you can use any library that implements the Reactive Streams interfaces. See the [RxJava wiki page on Github](https://github.com/reactive-streams/rxjava) for more information on that library.

To use the library, add it as a dependency. If you’re using Maven, the example shows the POM snippet to use.

**POM Entry**

```xml
<dependency>
  <groupId>io.reactivex.rxjava2</groupId>
  <artifactId>rxjava</artifactId>
  <version>2.1.14</version>
</dependency>
```

**Imports**

```java
import java.net.URI;
import java.util.concurrent.CompletableFuture;

import io.reactivex.Flowable;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.core.async.SdkPublisher;
import software.amazon.awssdk.http.SdkHttpConfigurationOption;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.kinesis.KinesisAsyncClient;
import software.amazon.awssdk.services.kinesis.model.ShardIteratorType;
import software.amazon.awssdk.services.kinesis.model.StartingPosition;
import software.amazon.awssdk.services.kinesis.model.SubscribeToShardEvent;
import software.amazon.awssdk.services.kinesis.model.SubscribeToShardRequest;
import software.amazon.awssdk.utils.AttributeMap;
```

This example uses RxJava in the `onEventStream` lifecycle method. This gives you full access to the publisher, which can be used to create an Rx Flowable.
You can also use the `publisherTransformer` method with the `Flowable` publisher. You must adapt the `Flowable` publisher to an `SdkPublisher`, as shown in the following example.

```java
SubscribeToShardResponseHandler responseHandler =
SubscribeToShardResponseHandler
   .builder()
   .onError(t -> System.err.println("Error during stream - " +
   t.getMessage()))
   .onEventStream(p -> Flowable.fromPublisher(p)
               .ofType(SubscribeToShardEvent.class)
               .flatMapIterable(SubscribeToShardEvent::records)
               .limit(1000)
               .buffer(25)
               .subscribe(e -> System.out.println("Record\nbatch = " + e)))
   .build();
```

See the [complete example](https://github.com) on GitHub.

More information

- [SubscribeToShardEvent](https://github.com) in the Amazon Kinesis API Reference
- [SubscribeToShard](https://github.com) in the Amazon Kinesis API Reference
Invoke, list, and delete AWS Lambda functions

This section provides examples of programming with the Lambda service client by using the AWS SDK for Java 2.x.

Topics

- **Invoke a Lambda function**
- **List Lambda functions**
- **Delete a Lambda function**

Invoke a Lambda function

You can invoke a Lambda function by creating a `LambdaClient` object and invoking its `invoke` method. Create an `InvokeRequest` object to specify additional information such as the function name and the payload to pass to the Lambda function. Function names appear as `arn:aws:lambda:us-east-1:123456789012:function:HelloFunction`. You can retrieve the value by looking at the function in the AWS Management Console.

To pass payload data to a function, create a `SdkBytes` object that contains information. For example, in the following code example, notice the JSON data passed to the Lambda function.

Imports

```java
import software.amazon.awssdk.services.lambda.LambdaClient;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.lambda.model.InvokeRequest;
import software.amazon.awssdk.core.SdkBytes;
import software.amazon.awssdk.services.lambda.model.InvokeResponse;
import software.amazon.awssdk.services.lambda.model.LambdaException;
```

Code

The following code example demonstrates how to invoke a Lambda function.

```java
public static void invokeFunction(LambdaClient awsLambda, String functionName) {
    InvokeResponse res = null ;
    try {
        // Your code here
    } catch (LambdaException e) {
        // Handle exception
    }
}
```
// Need a SdkBytes instance for the payload
String json = "{"Hello ":"Paris"}";
SdkBytes payload = SdkBytes.fromUtf8String(json);

// Setup an InvokeRequest
InvokeRequest request = InvokeRequest.builder()
    .functionName(functionName)
    .payload(payload)
    .build();

res = awsLambda.invoke(request);
String value = res.payload().asUtf8String();
System.out.println(value);
}

} catch(LambdaException e) {
    System.err.println(e.getMessage());
    System.exit(1);
}

See the complete example on GitHub.

List Lambda functions

Build a LambdaClient object and invoke its listFunctions method. This method returns a ListFunctionsResponse object. You can invoke this object's functions method to return a list of FunctionConfiguration objects. You can iterate through the list to retrieve information about the functions. For example, the following Java code example shows how to get each function name.

Imports

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.lambda.LambdaClient;
import software.amazon.awssdk.services.lambda.model.LambdaException;
import software.amazon.awssdk.services.lambda.model.ListFunctionsResponse;
import software.amazon.awssdk.services.lambda.model.FunctionConfiguration;
import java.util.List;
```

Code

The following Java code example demonstrates how to retrieve a list of function names.
public static void listFunctions(LambdaClient awsLambda) {
    try {
        ListFunctionsResponse functionResult = awsLambda.listFunctions();
        List<FunctionConfiguration> list = functionResult.functions();

        for (FunctionConfiguration config: list) {
            System.out.println("The function name is "+config.functionName());
        }
    } catch(LambdaException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}

See the complete example on GitHub.

Delete a Lambda function

Build a LambdaClient object and invoke its deleteFunction method. Create a DeleteFunctionRequest object and pass it to the deleteFunction method. This object contains information such as the name of the function to delete. Function names appear as arn:aws:lambda:us-east-1:123456789012:function:HelloFunction. You can retrieve the value by looking at the function in the AWS Management Console.

Imports

import software.amazon.awssdk.services.lambda.LambdaClient;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.lambda.model.DeleteFunctionRequest;
import software.amazon.awssdk.services.lambda.model.LambdaException;

Code

The following Java code demonstrates how to delete a Lambda function.

    public static void deleteLambdaFunction(LambdaClient awsLambda, String functionName ) {
            try {
                DeleteFunctionRequest request = DeleteFunctionRequest.builder()
awsLambda.deleteFunction(request);
System.out.println("The " + functionName + " function was deleted");
}
}

See the complete example on GitHub.

Work with Amazon S3

This section provides examples of programming with Amazon Simple Storage Service (S3) using the AWS SDK for Java 2.x.

The following examples include only the code needed to demonstrate each technique. The complete example code is available on GitHub. From there, you can download a single source file or clone the repository locally to get all the examples to build and run.

Note

From version 2.18.x and onward, the AWS SDK for Java 2.x uses virtual host-style addressing when including an endpoint override. This applies as long as the bucket name is a valid DNS label.

Call the forcePathStyle method with true in your client builder to force the client to use path-style addressing for buckets.

The following example shows a service client configured with an endpoint override and using path-style addressing.

```java
S3Client client = S3Client.builder()
  .region(Region.US_WEST_2)
  .endpointOverride(URI.create("https://s3.us-west-2.amazonaws.com"))
  .forcePathStyle(true)
  .build();
```
Use access points or Multi-Region Access Points

After Amazon S3 access points or Multi-Region Access Points are set up, you can call object methods, such as putObject and getObject and provide the access point identifier instead of a bucket name.

For example, if an access point ARN identifier is `arn:aws:s3:us-west-2:123456789012:accesspoint/test`, you can use the following snippet to call the putObject method.

```java
Path path = Paths.get(URI.create("file:///temp/file.txt"));

s3Client.putObject(builder -> builder
    .key("myKey")
    .bucket("arn:aws:s3:us-west-2:123456789012:accesspoint/test")
    , path);
```

In place of the ARN string, you can also use the bucket-style alias of the access point for the bucket parameter.

To use Multi-Region Access Point, replace the bucket parameter with the Multi-Region Access Point ARN that has the following format.

```java
arn:aws:s3::account-id:accesspoint/MultiRegionAccessPoint_alias
```

Add the following Maven dependency to work with Multi-Region Access Points using the SDK for Java. Search maven central for the latest version.

```xml
<dependency>
  <groupId>software.amazon.awssdk</groupId>
  <artifactId>auth-crt</artifactId>
  <version>VERSION</version>
</dependency>
```

Topics

- Create, list, and delete Amazon S3 buckets
- Work with Amazon S3 objects
- Work with Amazon S3 pre-signed URLs
Create, list, and delete Amazon S3 buckets

Every object (file) in Amazon S3 must reside within a bucket. A bucket represents a collection (container) of objects. Each bucket must have a unique key (name). For detailed information about buckets and their configuration, see Working with Amazon S3 Buckets in the Amazon Simple Storage Service User Guide.

Note

Best Practice
We recommend that you enable the AbortIncompleteMultipartUpload lifecycle rule on your Amazon S3 buckets.

This rule directs Amazon S3 to abort multipart uploads that don't complete within a specified number of days after being initiated. When the set time limit is exceeded, Amazon S3 aborts the upload and then deletes the incomplete upload data.

For more information, see Lifecycle Configuration for a Bucket with Versioning in the Amazon Simple Storage Service User Guide.

Note

These code snippets assume that you understand the material in basics, and have configured default AWS credentials using the information in the section called “Setup for single sign-on access for the SDK”.

Create a bucket

Build a CreateBucketRequest and provide a bucket name. Pass it to the S3Client's createBucket method. Use the S3Client to do additional operations such as listing or deleting buckets as shown in later examples.
Imports

```java
import software.amazon.awssdk.core.waiters.WaiterResponse;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.model.CreateBucketRequest;
import software.amazon.awssdk.services.s3.model.S3Exception;
import software.amazon.awssdk.services.s3.model.HeadBucketRequest;
import software.amazon.awssdk.services.s3.model.HeadBucketResponse;
import software.amazon.awssdk.services.s3.model.ListBucketsRequest;
import software.amazon.awssdk.services.s3.model.ListBucketsResponse;
import software.amazon.awssdk.services.s3.model.DeleteBucketRequest;
import software.amazon.awssdk.services.s3.waiters.S3Waiter;
```

Code

First create an S3Client.

```java
Region region = Region.US_EAST_1;
S3Client s3 = S3Client.builder()
    .region(region)
    .build();
```

Make a Create Bucket Request.

```java
/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 */
```
public class S3BucketOps {
    public static void main(String[] args) {
        Region region = Region.US_EAST_1;
        S3Client s3 = S3Client.builder()
                .region(region)
                .build();

        String bucket = "bucket" + System.currentTimeMillis();
        System.out.println(bucket);
        createBucket(s3, bucket);
        performOperations(s3, bucket);
    }

    // Create a bucket by using a S3Waiter object
    public static void createBucket(S3Client s3Client, String bucketName) {
        try {
            S3Waiter s3Waiter = s3Client.waiter();
            CreateBucketRequest bucketRequest = CreateBucketRequest.builder()
                    .bucket(bucketName)
                    .build();

            s3Client.createBucket(bucketRequest);
            HeadBucketRequest bucketRequestWait = HeadBucketRequest.builder()
                    .bucket(bucketName)
                    .build();

            // Wait until the bucket is created and print out the response.
            WaiterResponse<HeadBucketResponse> waiterResponse =
                    s3Waiter.waitUntilBucketExists(bucketRequestWait);
            waiterResponse.matched().response().ifPresent(System.out::println);
            System.out.println(bucketName + " is ready");
        } catch (S3Exception e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }

    public static void performOperations(S3Client s3, String bucket) {
        // Add operations here...
    }
}

See the complete example on GitHub.
List buckets

Build a `ListBucketsRequest`. Use the S3Client's `listBuckets` method to retrieve the list of buckets. If the request succeeds a `ListBucketsResponse` is returned. Use this response object to retrieve the list of buckets.

Imports

```java
import software.amazon.awssdk.core.waiters.WaiterResponse;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.model.CreateBucketRequest;
import software.amazon.awssdk.services.s3.model.S3Exception;
import software.amazon.awssdk.services.s3.model.HeadBucketRequest;
import software.amazon.awssdk.services.s3.model.HeadBucketResponse;
import software.amazon.awssdk.services.s3.model.ListBucketsRequest;
import software.amazon.awssdk.services.s3.model.ListBucketsResponse;
import software.amazon.awssdk.services.s3.model.DeleteBucketRequest;
import software.amazon.awssdk.services.s3.waiters.S3Waiter;
```

Code

First create an S3Client.

```java
Region region = Region.US_EAST_1;
S3Client s3 = S3Client.builder()
    .region(region)
    .build();
```

Make a List Buckets Request.

```java
// List buckets
ListBucketsRequest listBucketsRequest = ListBucketsRequest.builder().build();
ListBucketsResponse listBucketsResponse = s3.listBuckets(listBucketsRequest);
listBucketsResponse.buckets().stream().forEach(x ->
    System.out.println(x.name()));
```

See the [complete example](https://github.com/aws/aws-sdk-java) on GitHub.
Delete a bucket

Before you can delete an Amazon S3 bucket, you must ensure that the bucket is empty or the service will return an error. If you have a versioned bucket, you must also delete any versioned objects that are in the bucket.

Topics

- Delete objects in a bucket
- Delete an empty bucket

Delete objects in a bucket

Build a ListObjectsV2Request and use the S3Client's listObjects method to retrieve the list of objects in the bucket. Then use the deleteObject method on each object to delete it.

Imports

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.model.DeleteBucketRequest;
import software.amazon.awssdk.services.s3.model.DeleteObjectRequest;
import software.amazon.awssdk.services.s3.model.ListObjectsV2Request;
import software.amazon.awssdk.services.s3.model.ListObjectsV2Response;
import software.amazon.awssdk.services.s3.model.S3Exception;
import software.amazon.awssdk.services.s3.model.S3Object;
```

Code

First create an S3Client.

```java
ProfileCredentialsProvider credentialsProvider = ProfileCredentialsProvider.create();
Region region = Region.US_EAST_1;
S3Client s3 = S3Client.builder()
    .region(region)
    .credentialsProvider(credentialsProvider)
    .build();
```

Delete all objects in the bucket.

```java
import software.amazon.awssdk.regions.Region;
```
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.model.DeleteBucketRequest;
import software.amazon.awssdk.services.s3.model.DeleteObjectRequest;
import software.amazon.awssdk.services.s3.model.ListObjectsV2Request;
import software.amazon.awssdk.services.s3.model.ListObjectsV2Response;
import software.amazon.awssdk.services.s3.model.S3Exception;
import software.amazon.awssdk.services.s3.model.S3Object;

/**

 */
public class S3BucketDeletion {
    public static void main(String[] args) throws Exception {
        final String usage = ""
            Usage:
                <bucket>

                Where:
                    bucket - The bucket to delete (for example, bucket1).\n
        
            if (args.length != 1) {
                System.out.println(usage);
                System.exit(1);
            }

            String bucket = args[0];
            Region region = Region.US_EAST_1;
            S3Client s3 = S3Client.builder()
                .region(region)
                .build();

            deleteObjectsInBucket(s3, bucket);
            s3.close();
    }

    public static void deleteObjectsInBucket(S3Client s3, String bucket) {
        try {

// To delete a bucket, all the objects in the bucket must be deleted first.
ListObjectsV2Request listObjectsV2Request = ListObjectsV2Request.builder()
    .bucket(bucket)
    .build();
ListObjectsV2Response listObjectsV2Response;

do {
    listObjectsV2Response = s3.listObjectsV2(listObjectsV2Request);
    for (S3Object s3Object : listObjectsV2Response.contents()) {
        DeleteObjectRequest request = DeleteObjectRequest.builder()
            .bucket(bucket)
            .key(s3Object.key())
            .build();
        s3.deleteObject(request);
    }
} while (listObjectsV2Response.isTruncated());
DeleteBucketRequest deleteBucketRequest = DeleteBucketRequest.builder().bucket(bucket).build();
s3.deleteBucket(deleteBucketRequest);

} catch (S3Exception e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

See the complete example on GitHub.

Delete an empty bucket

Build a DeleteBucketRequest with a bucket name and pass it to the S3Client's deleteBucket method.

Imports

```java
import software.amazon.awssdk.core.waiters.WaiterResponse;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.model.CreateBucketRequest;
import software.amazon.awssdk.services.s3.model.S3Exception;
import software.amazon.awssdk.services.s3.model.HeadBucketRequest;
import software.amazon.awssdk.services.s3.model.HeadBucketResponse;
```
Code

First create an S3Client.

```java
Region region = Region.US_EAST_1;
S3Client s3 = S3Client.builder()
    .region(region)
    .build();
```

Delete the bucket.

```java
DeleteBucketRequest deleteBucketRequest = DeleteBucketRequest.builder()
    .bucket(bucket)
    .build();

s3.deleteBucket(deleteBucketRequest);
s3.close();
```

See the [complete example](https://github.com) on GitHub.

Work with Amazon S3 objects

An Amazon S3 object represents a file or collection of data. Every object must be contained in a bucket.

⚠️ Note

Best Practice

We recommend that you enable the [AbortIncompleteMultipartUpload](https://aws.amazon.com) lifecycle rule on your Amazon S3 buckets.

This rule directs Amazon S3 to abort multipart uploads that don't complete within a specified number of days after being initiated. When the set time limit is exceeded, Amazon S3 aborts the upload and then deletes the incomplete upload data.
For more information, see Lifecycle Configuration for a Bucket with Versioning in the Amazon Simple Storage Service User Guide.

Note

These code snippets assume that you understand the material in basics, and have configured default AWS credentials using the information in the section called “Setup for single sign-on access for the SDK”.

Topics

- **Upload an object**
- **Upload objects in multiple parts**
- **Delete an object**
- **List objects**
- **More examples**

Upload an object

Build a `PutObjectRequest` and supply a bucket name and key name. Then use the S3Client's `putObject` method with a `RequestBody` that contains the object content and the `PutObjectRequest` object. *The bucket must exist, or the service will return an error.*

Imports

```java
import java.io.IOException;
import java.nio.ByteBuffer;
import java.util.Random;
import software.amazon.awssdk.core.waiters.WaiterResponse;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.paginators.ListObjectsV2Iterable;
import software.amazon.awssdk.core.sync.RequestBody;
import software.amazon.awssdk.services.s3.model.S3Exception;
import software.amazon.awssdk.services.s3.model.PutObjectRequest;
import software.amazon.awssdk.services.s3.model.ListObjectsV2Request;
import software.amazon.awssdk.services.s3.model.ListObjectsV2Response;
```
import software.amazon.awssdk.services.s3.model.S3Object;
import software.amazon.awssdk.services.s3.model.GetObjectRequest;
import software.amazon.awssdk.services.s3.model.DeleteObjectRequest;
import software.amazon.awssdk.services.s3.model.DeleteBucketRequest;
import software.amazon.awssdk.services.s3.model.CreateMultipartUploadRequest;
import software.amazon.awssdk.services.s3.model.CreateMultipartUploadResponse;
import software.amazon.awssdk.services.s3.model.DeleteBucketRequest;
import software.amazon.awssdk.services.s3.model.CreateMultipartUploadRequest;
import software.amazon.awssdk.services.s3.model.CreateMultipartUploadResponse;
import software.amazon.awssdk.services.s3.model.CompletedMultipartUpload;
import software.amazon.awssdk.services.s3.model.CreateBucketRequest;
import software.amazon.awssdk.services.s3.model.CompletedPart;
import software.amazon.awssdk.services.s3.model.CreateBucketConfiguration;
import software.amazon.awssdk.services.s3.model.UploadPartRequest;
import software.amazon.awssdk.services.s3.model.CompleteMultipartUploadRequest;
import software.amazon.awssdk.services.s3.waiters.S3Waiter;
import software.amazon.awssdk.services.s3.model.HeadBucketRequest;
import software.amazon.awssdk.services.s3.model.HeadBucketResponse;

Code

Region region = Region.US_WEST_2;
s3 = S3Client.builder()
    .region(region)
    .build();

createBucket(s3, bucketName, region);

PutObjectRequest objectRequest = PutObjectRequest.builder()
    .bucket(bucketName)
    .key(key)
    .build();

s3.putObject(objectRequest,
RequestBody.fromByteBuffer(getRandomByteBuffer(10_000)));

See the [complete example](https://github.com) on GitHub.

**Upload objects in multiple parts**

Use the S3Client's `createMultipartUpload` method to get an upload ID. Then use the `uploadPart` method to upload each part. Finally, use the S3Client's `completeMultipartUpload` method to tell Amazon S3 to merge all the uploaded parts and finish the upload operation.

**Imports**
import java.io.IOException;
import java.nio.ByteBuffer;
import java.util.Random;
import software.amazon.awssdk.core.waiters.WaiterResponse;
import software.amazon.awssdk.regions.Region;

import software.amazon.awssdk.services.s3.model.HeadBucketRequest;
import software.amazon.awssdk.services.s3.model.HeadBucketResponse;

Code

// First create a multipart upload and get the upload id
CreateMultipartUploadRequest createMultipartUploadRequest =
CreateMultipartUploadRequest.builder()
    .bucket(bucketName)
    .key(key)
    .build();

CreateMultipartUploadResponse response =
s3.createMultipartUpload(createMultipartUploadRequest);
String uploadId = response.uploadId();
System.out.println(uploadId);

// Upload all the different parts of the object
UploadPartRequest uploadPartRequest1 = UploadPartRequest.builder()
    .bucket(bucketName)
    .key(key)
    .uploadId(uploadId)
    .partNumber(1).build();

String etag1 = s3
    .uploadPart(uploadPartRequest1,
    RequestBody.fromByteBuffer(getRandomByteBuffer(5 * mB)))
    .eTag();

CompletedPart part1 =
    CompletedPart.builder().partNumber(1).eTag(etag1).build();

UploadPartRequest uploadPartRequest2 =
    UploadPartRequest.builder().bucket(bucketName).key(key)
    .uploadId(uploadId)
    .partNumber(2).build();

String etag2 = s3
    .uploadPart(uploadPartRequest2,
    RequestBody.fromByteBuffer(getRandomByteBuffer(3 * mB)))
    .eTag();

CompletedPart part2 =
    CompletedPart.builder().partNumber(2).eTag(etag2).build();

// Finally call completeMultipartUpload operation to tell S3 to merge all
// uploaded
// parts and finish the multipart operation.
CompletedMultipartUpload completedMultipartUpload =
    CompletedMultipartUpload.builder()
    .parts(part1, part2)
    .build();

CompleteMultipartUploadRequest completeMultipartUploadRequest =
    CompleteMultipartUploadRequest.builder()
    .bucket(bucketName)
    .key(key)
    .uploadId(uploadId)
    .multipartUpload(completedMultipartUpload)
    .build();

s3.completeMultipartUpload(completeMultipartUploadRequest);
See the [complete example](https://github.com/aws/aws-sdk-java) on GitHub.

## Delete an object

Build a [DeleteObjectRequest](https://github.com/aws/aws-sdk-java) and supply a bucket name and key name. Use the S3Client's `deleteObject` method, and pass it the name of a bucket and object to delete. *The specified bucket and object key must exist, or the service will return an error.*

### Imports

```java
import java.io.IOException;
import java.nio.ByteBuffer;
import java.util.Random;
import software.amazon.awssdk.core.waiters.WaiterResponse;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.paginators.ListObjectsV2Iterable;
import software.amazon.awssdk.core.sync.RequestBody;
import software.amazon.awssdk.services.s3.model.S3Exception;
import software.amazon.awssdk.services.s3.model.PutObjectRequest;
import software.amazon.awssdk.services.s3.model.ListObjectsV2Request;
import software.amazon.awssdk.services.s3.model.ListObjectsV2Response;
import software.amazon.awssdk.services.s3.model.S3Object;
import software.amazon.awssdk.services.s3.model.GetObjectRequest;
import software.amazon.awssdk.services.s3.model.DeleteObjectRequest;
import software.amazon.awssdk.services.s3.model.DeleteBucketRequest;
import software.amazon.awssdk.services.s3.model.CreateMultipartUploadRequest;
import software.amazon.awssdk.services.s3.model.CreateMultipartUploadResponse;
import software.amazon.awssdk.services.s3.model.CompletedMultipartUpload;
import software.amazon.awssdk.services.s3.model.CreateBucketRequest;
import software.amazon.awssdk.services.s3.model.CompletedPart;
import software.amazon.awssdk.services.s3.model.CreateBucketConfiguration;
import software.amazon.awssdk.services.s3.model.UploadPartRequest;
import software.amazon.awssdk.services.s3.waiters.S3Waiter;
import software.amazon.awssdk.services.s3.model.HeadBucketRequest;
import software.amazon.awssdk.services.s3.model.HeadBucketResponse;
```

### Code

```java
DeleteObjectRequest deleteObjectRequest = DeleteObjectRequest.builder()
    .bucket(bucketName)
    .key(key)
```
Copy an object

Build a CopyObjectRequest and supply a bucket name that the object is copied into, a URL encoded string value (see the URLEncoder.encode method), and the key name of the object. Use the S3Client's copyObject method, and pass the CopyObjectRequest object. **The specified bucket and object key must exist, or the service will return an error.**

Imports

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.model.CopyObjectRequest;
import software.amazon.awssdk.services.s3.model.CopyObjectResponse;
import software.amazon.awssdk.services.s3.model.S3Exception;
```

Code

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.model.CopyObjectRequest;
import software.amazon.awssdk.services.s3.model.CopyObjectResponse;
import software.amazon.awssdk.services.s3.model.S3Exception;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */

public class CopyObject {
    public static void main(String[] args) {
        final String usage = ""

        Usage:
```

See the [complete example](https://github.com) on GitHub.
<objectKey> <fromBucket> <toBucket>

Where:
  objectKey - The name of the object (for example, book.pdf).
  fromBucket - The S3 bucket name that contains the object (for example, bucket1).
  toBucket - The S3 bucket to copy the object to (for example, bucket2).

if (args.length != 3) {
    System.out.println(usage);
    System.exit(1);
}

String objectKey = args[0];
String fromBucket = args[1];
String toBucket = args[2];
System.out.format("Copying object %s from bucket %s to %s\n", objectKey, fromBucket, toBucket);
Region region = Region.US_EAST_1;
S3Client s3 = S3Client.builder()
    .region(region)
    .build();

copyBucketObject(s3, fromBucket, objectKey, toBucket);
s3.close();
}

public static String copyBucketObject(S3Client s3, String fromBucket, String objectKey, String toBucket) {
   CopyObjectRequest copyReq = CopyObjectRequest.builder()
        .sourceBucket(fromBucket)
        .sourceKey(objectKey)
        .destinationBucket(toBucket)
        .destinationKey(objectKey)
        .build();

    try {
        CopyObjectResponse copyRes = s3.copyObject(copyReq);
        return copyRes.copyObjectResult().toString();
    } catch (S3Exception e) {
        System.err.println(e.awsErrorDetails().errorMessage());
    }

    return null;
}
See the complete example on GitHub.

**List objects**

Build a `ListObjectsRequest` and supply the bucket name. Then invoke the S3Client's `listObjects` method and pass the `ListObjectsRequest` object. This method returns a `ListObjectsResponse` that contains all of the objects in the bucket. You can invoke this object's `contents` method to get a list of objects. You can iterate through this list to display the objects, as shown in the following code example.

### Imports

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.model.ListObjectsRequest;
import software.amazon.awssdk.services.s3.model.ListObjectsResponse;
import software.amazon.awssdk.services.s3.model.S3Exception;
import software.amazon.awssdk.services.s3.model.S3Object;
import java.util.List;
```

### Code

```java
/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
```
public class ListObjects {
    public static void main(String[] args) {
        final String usage = """"""""
        Usage:
        
        <bucketName>\s
        
        Where:
        
        bucketName - The Amazon S3 bucket from which objects are read.\s
        """""
        
        if (args.length != 1) {
            System.out.println(usage);
            System.exit(1);
        }
        
        String bucketName = args[0];
        Region region = Region.US_EAST_1;
        S3Client s3 = S3Client.builder()
            .region(region)
            .build();
        
        listBucketObjects(s3, bucketName);
        s3.close();
    }

    public static void listBucketObjects(S3Client s3, String bucketName) {
        try {
            ListObjectsRequest listObjects = ListObjectsRequest
                .builder()
                .bucket(bucketName)
                .build();

            ListObjectsResponse res = s3.listObjects(listObjects);
            List<S3Object> objects = res.contents();
            for (S3Object myValue : objects) {
                System.out.print("\n The name of the key is " + myValue.key());
                System.out.print("\n The object is " + calKb(myValue.size()) + " KBs");
                System.out.print("\n The owner is " + myValue.owner());
            }
        }
    }
}
} catch (S3Exception e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

// convert bytes to kbs.
private static long calKb(Long val) {
    return val / 1024;
}

See the complete example on GitHub.

More examples

The Code examples section of this guide contains more examples of working with Amazon S3 objects including how to download an object.

Work with Amazon S3 pre-signed URLs

Pre-signed URLs provide temporary access to private S3 objects without requiring users to have AWS credentials or permissions.

For example, assume Alice has access to an S3 object, and she wants to temporarily share access to that object with Bob. Alice can generate a pre-signed GET request to share with Bob so that he can download the object without requiring access to Alice's credentials. You can generate pre-signed URLs for HTTP GET and for HTTP PUT requests.

Generate a pre-signed URL for an object, then download it (GET request)

The following example consists of two parts.

- Part 1: Alice generates the pre-signed URL for an object.
- Part 2: Bob downloads the object by using the pre-signed URL.

Part 1: Generate the URL

Alice already has an object in an S3 bucket. She uses the following code to generate a URL string that Bob can use in a subsequent GET request.
/* Create a pre-signed URL to download an object in a subsequent GET request. */
public String createPresignedGetUrl(String bucketName, String keyName) {
    try (S3Presigner presigner = S3Presigner.create()) {
        GetObjectRequest objectRequest = GetObjectRequest.builder()
                .bucket(bucketName)
                .key(keyName)
                .build();

        GetObjectPresignRequest presignRequest = GetObjectPresignRequest.builder()
.signatureDuration(Duration.ofMinutes(10))  // The URL will expire in 10 minutes.
.getObjectName(objectRequest)
.build();

PresignedGetObjectRequest presignedRequest =
presigner.presignGetObject(presignRequest);
logger.info("Presigned URL: [{]}", presignedRequest.url().toString());
logger.info("HTTP method: [{]}", presignedRequest.httpRequest().method());

return presignedRequest.url().toExternalForm();
}
}

Part 2: Download the object

Bob uses one of the following three code options to download the object. Alternatively, he could use a browser to perform the GET request.

Use JDK HttpURLConnection (since v1.1)

/* Use the JDK HttpURLConnection (since v1.1) class to do the download. */
public byte[] useHttpUrlConnectionToGet(String presignedUrlString) {
    ByteArrayOutputStream byteArrayOutputStream = new ByteArrayOutputStream(); // Capture the response body to a byte array.
    try {
        URL presignedUrl = new URL(presignedUrlString);
        HttpURLConnection connection = (HttpURLConnection)
presignedUrl.openConnection();
        connection.setRequestMethod("GET");
        // Download the result of executing the request.
        try (InputStream content = connection.getInputStream()) {
            IoUtils.copy(content, byteArrayOutputStream);
        }
        logger.info("HTTP response code is " + connection.getResponseCode());
    }
    catch (S3Exception | IOException e) {
        logger.error(e.getMessage(), e);
    }
    return byteArrayOutputStream.toByteArray();
}
Use JDK HttpClient (since v11)

/* Use the JDK HttpClient (since v11) class to do the download. */
public byte[] useHttpClientToGet(String presignedUrlString) {
    ByteArrayOutputStream byteArrayOutputStream = new ByteArrayOutputStream(); // Capture the response body to a byte array.

    HttpRequest.Builder requestBuilder = HttpRequest.newBuilder();
    HttpClient httpClient = HttpClient.newHttpClient();
    try {
        URL presignedUrl = new URL(presignedUrlString);
        HttpResponse<InputStream> response = httpClient.send(requestBuilder
            .uri(presignedUrl.toURI())
            .GET()
            .build(),
            HttpResponse.BodyHandlers.ofInputStream());

        IoUtils.copy(response.body(), byteArrayOutputStream);

        logger.info("HTTP response code is " + response.statusCode());
    } catch (URISyntaxException | InterruptedException | IOException e) {
        logger.error(e.getMessage(), e);
    }
    return byteArrayOutputStream.toByteArray();
}

Use SdkHttpClient from the SDK for Java

/* Use the AWS SDK for Java SdkHttpClient class to do the download. */
public byte[] useSdkHttpClientToPut(String presignedUrlString) {

    ByteArrayOutputStream byteArrayOutputStream = new ByteArrayOutputStream(); // Capture the response body to a byte array.
    try {
        URL presignedUrl = new URL(presignedUrlString);
        SdkHttpRequest request = SdkHttpRequest.builder()
            .method(SdkHttpMethod.GET)
            .uri(presignedUrl.toURI())
            .build();

        HttpExecuteRequest executeRequest = HttpExecuteRequest.builder()
            .request(request)

        HttpExecuteResponse response = httpClient.execute(executeRequest);
        return response.getBody().array();
    } catch (SdkClientException e) {
        logger.error(e.getMessage(), e);
    }
    return byteArrayOutputStream.toByteArray();
}
try (SdkHttpClient sdkHttpClient = ApacheHttpClient.create()) {
    HttpResponse response =
    sdkHttpClient.prepareRequest(executeRequest).call();
    responseBody().ifPresentOrElse(
        abortableInputStream -> {
            try {
                IoUtils.copy(abortableInputStream, byteArrayOutputStream);
            } catch (IOException e) {
                throw new RuntimeException(e);
            }
        },
        () -> logger.error("No response body.");

    logger.info("HTTP Response code is {}",
        response.httpResponse().statusCode());
    }
} catch (URISyntaxException | IOException e) {
    logger.error(e.getMessage(), e);
}
return byteArrayOutputStream.toByteArray();

See the [complete example](https://github.com/example) and [test](https://github.com/example) on GitHub.

**Generate a pre-signed URL for an upload, then upload a file (PUT request)**

The following example consists of two parts.

- Part 1: Alice generates the pre-signed URL to upload an object.
- Part 2: Bob uploads a file by using the pre-signed URL.

**Part 1: Generate the URL**

Alice already has an S3 bucket. She uses the following code to generate a URL string that Bob can use in a subsequent PUT request.

**Imports**

```java
import com.example.s3.util.PresignUrlUtils;
```
import org.slf4j.Logger;
import software.amazon.awssdk.core.internal.sync.FileContentStreamProvider;
import software.amazon.awssdk.http.HttpExecuteRequest;
import software.amazon.awssdk.http.HttpExecuteResponse;
import software.amazon.awssdk.http.SdkHttpClient;
import software.amazon.awssdk.http.SdkHttpMethod;
import software.amazon.awssdk.http.SdkHttpRequest;
import software.amazon.awssdk.http.apache.ApacheHttpClient;
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.model.PutObjectRequest;
import software.amazon.awssdk.services.s3.model.S3Exception;
import software.amazon.awssdk.services.s3.presigner.S3Presigner;
import software.amazon.awssdk.services.s3.presigner.model.PresignedPutObjectRequest;
import software.amazon.awssdk.services.s3.presigner.model.PutObjectPresignRequest;

import java.io.File;
import java.io.IOException;
import java.io.OutputStream;
import java.io.RandomAccessFile;
import java.net.HttpURLConnection;
import java.net.URISyntaxException;
import java.net.URL;
import java.net.http.HttpClient;
import java.net.http.HttpRequest;
import java.net.http.HttpResponse;
import java.nio.ByteBuffer;
import java.nio.channels.FileChannel;
import java.nio.file.Path;
import java.nio.file.Paths;
import java.time.Duration;
import java.util.Map;
import java.util.UUID;

/* Create a presigned URL to use in a subsequent PUT request */
public String createPresignedUrl(String bucketName, String keyName, Map<String, String> metadata) {
    try (S3Presigner presigner = S3Presigner.create()) {
        PutObjectRequest objectRequest = PutObjectRequest.builder()
            .bucket(bucketName)
            .key(keyName)
            .metadata(metadata)
            .build();
PutObjectPresignRequest presignRequest = PutObjectPresignRequest.builder()
    .signatureDuration(Duration.ofMinutes(10))  // The URL expires in 10 minutes.
    .putObjectRequest(objectRequest)
    .build();

PresignedPutObjectRequest presignedRequest = presigner.presignPutObject(presignRequest);
String myURL = presignedRequest.url().toString();
logger.info("Presigned URL to upload a file to: [{}]", myURL);
logger.info("HTTP method: [{}]", presignedRequest.httpRequest().method());

return presignedRequest.url().toExternalForm();

Part 2: Upload a file object

Bob uses one of the following three code options to upload a file.

Use JDK HttpURLConnection (since v1.1)

/* Use the JDK HttpURLConnection (since v1.1) class to do the upload. */
public void useHttpUrlConnectionToPut(String presignedUrlString, File fileToPut,
Map<String, String> metadata) {
    logger.info("Begin [{}] upload", fileToPut.toString());
    try {
        URL presignedUrl = new URL(presignedUrlString);
        HttpURLConnection connection = (HttpURLConnection)
        presignedUrl.openConnection();
        connection.setDoOutput(true);
        metadata.forEach((k, v) -> connection.setRequestProperty("x-amz-meta-" + k, v));
        connection.setRequestMethod("PUT");
        OutputStream out = connection.getOutputStream();

        try (RandomAccessFile file = new RandomAccessFile(fileToPut, "r")
            FileChannel inChannel = file.getChannel()) {
            ByteBuffer buffer = ByteBuffer.allocate(8192);  // Buffer size is 8k

            while (inChannel.read(buffer) > 0) {
                buffer.flip();
            }
        }
    }
}
for (int i = 0; i < buffer.limit(); i++) {
    out.write(buffer.get());
}
buffer.clear();
}
}
} catch (IOException e) {
    logger.error(e.getMessage(), e);
}

out.close();
connection.getResponseCode();
logger.info("HTTP response code is " + connection.getResponseCode());

} catch (S3Exception | IOException e) {
    logger.error(e.getMessage(), e);
}

/* Use the JDK HttpClient (since v11) class to do the upload. */
public void useHttpClientToPut(String presignedUrlString, File fileToPut,
Map<String, String> metadata) {
    logger.info("Begin [{}] upload", fileToPut.toString());

    HttpRequest.Builder requestBuilder = HttpRequest.newBuilder();
    metadata.forEach((k, v) -> requestBuilder.header("x-amz-meta-" + k, v));

    HttpClient httpClient = HttpClient.newHttpClient();
    try {
        final HttpResponse<Void> response = httpClient.send(requestBuilder
            .uri(new URL(presignedUrlString).toURI())
            .PUT(HttpRequest.BodyPublishers.ofFile(Path.of(fileToPut.toURI())))
            .build(),
            HttpResponse.BodyHandlers.discard());

        logger.info("HTTP response code is " + response.statusCode());
    } catch (URISyntaxException | InterruptedException | IOException e) {
        logger.error(e.getMessage(), e);
    }
}
Use SdkHttpClient from the SDK for Java

```java
/* Use the AWS SDK for Java V2 SdkHttpClient class to do the upload. */
public void useSdkHttpClientToPut(String presignedUrlString, File fileToPut,
                                Map<String, String> metadata) {
    logger.info("Begin [{}]", fileToPut.toPath().toString());

    try {
        URL presignedUrl = new URL(presignedUrlString);

        SdkHttpRequest.Builder requestBuilder = SdkHttpRequest.builder()
            .method(SdkHttpMethod.PUT)
            .uri(presignedUrl.toURI());
        // Add headers
        metadata.forEach((k, v) -> requestBuilder.putHeader("x-amz-meta-" + k, v));
        // Finish building the request.
        SdkHttpRequest request = requestBuilder.build();

        HttpExecuteRequest executeRequest = HttpExecuteRequest.builder()
            .request(request)
            .contentStreamProvider(new FileContentStreamProvider(fileToPut.toPath()))
            .build();

        try (SdkHttpClient sdkHttpClient = ApacheHttpClient.create()) {
            HttpExecuteResponse response = sdkHttpClient.prepareRequest(executeRequest).call();
        } catch (URISyntaxException | IOException e) {
            logger.error(e.getMessage(), e);
        }
    }
}
```

See the [complete example](https://github.com/aws/aws-sdk-java) and test on GitHub.

### Cross-Region access for Amazon S3

When you work with Amazon Simple Storage Service (Amazon S3) buckets, you usually know the AWS Region for the bucket. The Region you work with is determined when you create the S3 client.

However, sometimes you might need to work with a specific bucket, but you don’t know if it’s located in the same Region that’s set for the S3 client.
Instead of making more calls to determine the bucket Region, you can use the SDK to enable access to S3 buckets across different Regions.

**Setup**

Support for cross-Region access became available with version 2.20.111 of the SDK. Use this version or a later one in your Maven build file for the s3 dependency as shown in the following snippet.

```xml
<dependency>
  <groupId>software.amazon.awssdk</groupId>
  <artifactId>s3</artifactId>
  <version>2.20.111</version>
</dependency>
```

Next, when you create your S3 client, enable cross-Region access as shown in the snippet. By default, access is not enabled.

```java
S3AsyncClient client = S3AsyncClient.builder()
    .crossRegionAccessEnabled(true)
    .build();
```

**How the SDK provides cross-Region access**

When you reference an existing bucket in a request, such as when you use the putObject method, the SDK initiates a request to the Region configured for the client.

If the bucket does not exist in that specific Region, the error response includes the actual Region where the bucket resides. The SDK then uses the correct Region in a second request.

To optimize future requests to the same bucket, the SDK caches this Region mapping in the client.

**Considerations**

When you enable cross-Region bucket access, be aware that the first API call might result in increased latency if the bucket isn't in the client's configured Region. However, subsequent calls benefit from cached Region information, resulting in improved performance.

When you enable cross-Region access, access to the bucket is not affected. The user must be authorized to access the bucket in whatever Region it resides.
Amazon S3 checksums with AWS SDK for Java

Amazon Simple Storage Service (Amazon S3) provides the ability to specify a checksum when you upload an object. When you specify a checksum, it is stored with the object and can be validated when the object is downloaded.

Checksums provide an additional layer of data integrity when you transfer files. With checksums, you can verify data consistency by confirming that the received file matches the original file. For more information about checksums with Amazon S3, see the Amazon Simple Storage Service User Guide.

Amazon S3 currently supports four checksum algorithms: SHA-1, SHA-256, CRC-32, and CRC-32C. You have the flexibility to choose the algorithm that best fits your needs and let the SDK calculate the checksum. Alternatively, you can specify their own pre-computed checksum value by using one of the four supported algorithms.

We discuss checksums in two request phases: uploading an object and downloading an object.

Upload an object

You upload objects to Amazon S3 by using the putObject method of the S3Client. Use the checksumAlgorithm method of the builder for the PutObjectRequest to enable checksum computation and specify the algorithm. Valid values for the algorithm are CRC32, CRC32C, SHA1, and SHA256.

The following code snippet shows a request to upload an object with a CRC-32 checksum. When the SDK sends the request, it calculates the CRC-32 checksum and uploads the object. Amazon S3 stores the checksum with the object.

```java
public void putObjectWithChecksum() {
    s3Client.putObject(b -> b
        .bucket(bucketName)
        .key(key)
        .checksumAlgorithm(ChecksumAlgorithm.CRC32),
    RequestBody.fromString("This is a test");
}
```

If the checksum that the SDK calculates doesn't match the checksum that Amazon S3 calculates when it receives the request, an error is returned.
Use a pre-calculated checksum value

A pre-calculated checksum value provided with the request disables automatic computation by the SDK and uses the provided value instead.

The following example shows a request with a pre-calculated SHA-256 checksum.

```java
public void putObjectWithPrecalculatedChecksum(String filePath) {
    String checksum = calculateChecksum(filePath, "SHA-256");
    s3Client.putObject((b -> b
        .bucket(bucketName)
        .key(key)
        .checksumSHA256(checksum),
        RequestBody.fromFile(Paths.get(filePath)));
}
```

If Amazon S3 determines the checksum value is incorrect for the specified algorithm, the service returns an error response.

Multipart uploads

You can also use checksums with multipart uploads. The SDK for Java 2.x provides two options to use checksums with multipart uploads. The first option uses the S3TransferManager.

The following transfer manager example specifies the SHA1 algorithm for the upload.

```java
public void multipartUploadWithChecksumTm(String filePath) {
    S3TransferManager transferManager = S3TransferManager.create();
    UploadFileRequest uploadFileRequest = UploadFileRequest.builder()
        .putObjectRequest(b -> b
            .bucket(bucketName)
            .key(key)
            .checksumAlgorithm(ChecksumAlgorithm.SHA1)
        .source(Paths.get(filePath))
        .build();
    FileUpload fileUpload = transferManager.uploadFile(uploadFileRequest);
    fileUpload.completionFuture().join();
    transferManager.close();
}
```

The second option uses the S3Client API (or the S3AsyncClient API) to perform the multipart upload. If you specify a checksum with this approach, you must specify the algorithm to use on the...
initiation of the upload. You must also specify the algorithm for each part request and provide the checksum calculated for each part after it is uploaded.

```java
public void multipartUploadWithChecksumS3Client(String filePath) {
    ChecksumAlgorithm algorithm = ChecksumAlgorithm.CRC32;

    // Initiate the multipart upload.
    CreateMultipartUploadResponse createMultipartUploadResponse = 
            s3Client.createMultipartUpload(b -> b
                .bucket(bucketName)
                .key(key)
                .checksumAlgorithm(algorithm)); // Checksum specified on initiation.
    String uploadId = createMultipartUploadResponse.uploadId();

    // Upload the parts of the file.
    int partNumber = 1;
    List<CompletedPart> completedParts = new ArrayList<>();
    ByteBuffer bb = ByteBuffer.allocate(1024 * 1024 * 5); // 5 MB byte buffer

    try (RandomAccessFile file = new RandomAccessFile(filePath, "r")) {
        long fileSize = file.length();
        int position = 0;
        while (position < fileSize) {
            file.seek(position);
            int read = file.getChannel().read(bb);

            bb.flip(); // Swap position and limit before reading from the buffer.
            UploadPartRequest uploadPartRequest = UploadPartRequest.builder()
                .bucket(bucketName)
                .key(key)
                .uploadId(uploadId)
                .checksumAlgorithm(algorithm) // Checksum specified on each part.
                .partNumber(partNumber)
                .build();

            UploadPartResponse partResponse = s3Client.uploadPart(
                    uploadPartRequest,
                    RequestBody.fromByteBuffer(bb));

            CompletedPart part = CompletedPart.builder()
                .partNumber(partNumber)
                .build();

            completedParts.add(part);
            position += read;
        }
    }

    // Finalize the upload.
    CompleteMultipartUploadRequest completeMultipartUploadRequest = CompleteMultipartUploadRequest.builder()
            .bucket(bucketName)
            .key(key)
            .uploadId(uploadId)
            .build();

    CompleteMultipartUploadResponse completeMultipartUploadResponse = 
            s3Client.completeMultipartUpload(completeMultipartUploadRequest);
}
```
.checksumCRC32(partResponse.checksumCRC32()) // Provide the calculated checksum.
    .eTag(partResponse.eTag())
    .build();
    completedParts.add(part);

    bb.clear();
    position += read;
    partNumber++;
}
} catch (IOException e) {
    System.err.println(e.getMessage());
}

// Complete the multipart upload.
s3Client.completeMultipartUpload(b -> b
    .bucket(bucketName)
    .key(key)
    .uploadId(uploadId)

    .multipartUpload(CompletedMultipartUpload.builder().parts(completedParts).build()));
}

**Code for the complete examples** and **tests** are in the GitHub code examples repository.

**Download an object**

When you use the `getObject` method to download an object, the SDK automatically validates the checksum when the `checksumMode` method of the builder for the `GetObjectRequest` is set to `ChecksumMode.ENABLED`.

The request in the following snippet directs the SDK to validate the checksum in the response by calculating the checksum and comparing the values.

```java
public GetObjectResponse getObjectWithChecksum() {
    return s3Client.getObject(b -> b
        .bucket(bucketName)
        .key(key)
        .checksumMode(ChecksumMode.ENABLED))
        .response();
}
```

If the object wasn't uploaded with a checksum, no validation takes place.
An object in Amazon S3 can have multiple checksums, but only one checksum is validated on download. The following precedence—based on the efficiency of the checksum algorithm—determines which checksum the SDK validates:

1. CRC-32C
2. CRC-32
3. SHA-1
4. SHA-256

For example, if a response contains both CRC-32 and SHA-256 checksums, only the CRC-32 checksum is validated.

**Use a performant S3 client: AWS CRT-based S3 client**

The AWS CRT-based S3 client—built on top of the AWS Common Runtime (CRT)—is an alternative S3 asynchronous client. It transfers objects to and from Amazon Simple Storage Service (Amazon S3) with enhanced performance and reliability by automatically using Amazon S3's multipart upload API and byte-range fetches.

The AWS CRT-based S3 client improves transfer reliability in case there is a network failure. Reliability is improved by retrying individual failed parts of a file transfer without restarting the transfer from the beginning.

In addition, the AWS CRT-based S3 client offers enhanced connection pooling and Domain Name System (DNS) load balancing, which also improves throughput.

You can use the AWS CRT-based S3 client in place of the SDK's standard S3 asynchronous client and take advantage of its improved throughput right away.

**AWS CRT-based components in the SDK**

The AWS CRT-based S3 client, described in this topic, and the AWS CRT-based HTTP client are different components in the SDK.

The **AWS CRT-based S3 client** is an implementation of the S3AsyncClient interface and is used for working with the Amazon S3 service. It is an alternative to the Java-based implementation of the S3AsyncClient interface and offers several benefits.
The AWS CRT-based HTTP client is an implementation of the SdkAsyncHttpClient interface and is used for general HTTP communication. It is an alternative to the Netty implementation of the SdkAsyncHttpClient interface and offers several advantages.

Although both components use libraries from the AWS Common Runtime, the AWS CRT-based S3 client uses the aws-c-s3 library and supports the S3 multipart upload API features. Since the AWS CRT-based HTTP client is meant for general purpose use, it does not support the S3 multipart upload API features.

Add dependencies to use the AWS CRT-based S3 client

To use the AWS CRT-based S3 client, add the following two dependencies to your Maven project file. The example shows the minimum versions to use. Search the Maven central repository for the most recent versions of the s3 and aws-crt artifacts.

```xml
<dependency>
  <groupId>software.amazon.awssdk</groupId>
  <artifactId>s3</artifactId>
  <version>2.20.68</version>
</dependency>
<dependency>
  <groupId>software.amazon.awssdk.crt</groupId>
  <artifactId>aws-crt</artifactId>
  <version>0.21.16</version>
</dependency>
```

Create an instance of the AWS CRT-based S3 client

Create an instance of the AWS CRT-based S3 client with default settings as shown in the following code snippet.

```java
S3AsyncClient s3AsyncClient = S3AsyncClient.crtCreate();
```

To configure the client, use the AWS CRT client builder. You can switch from the standard S3 asynchronous client to AWS CRT-based client by changing the builder method.

```java
import software.amazon.awssdk.auth.credentials.DefaultCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.S3AsyncClient;
```
S3AsyncClient s3AsyncClient =
    S3AsyncClient.crtBuilder()
    .credentialsProvider(DefaultCredentialsProvider.create())
    .region(Region.US_WEST_2)
    .targetThroughputInGbps(20.0)
    .minimumPartSizeInBytes(8 * 1025 * 1024L)
    .build();

Note
Some of the settings in the standard builder might not be currently supported in the AWS CRT client builder. Get the standard builder by calling S3AsyncClient#builder().

Use the AWS CRT-based S3 client

Use the AWS CRT-based S3 client to call Amazon S3 API operations. The following example demonstrates the PutObject and GetObject operations available through the AWS SDK for Java.

```java
import software.amazon.awssdk.core.async.AsyncRequestBody;
import software.amazon.awssdk.core.async.AsyncResponseTransformer;
import software.amazon.awssdk.services.s3.S3AsyncClient;
import software.amazon.awssdk.services.s3.model.GetObjectResponse;
import software.amazon.awssdk.services.s3.model.PutObjectResponse;

S3AsyncClient s3Client = S3AsyncClient.crtCreate();

// Upload a local file to Amazon S3.
PutObjectResponse putObjectResponse =
    s3Client.putObject(req -> req.bucket(<BUCKET_NAME>)
                        .key(<KEY_NAME>),
                        AsyncRequestBody.fromFile(Paths.get(<FILE_NAME>))).join();

// Download an object from Amazon S3 to a local file.
GetObjectResponse getObjectResponse =
    s3Client.getObject(req -> req.bucket(<BUCKET_NAME>)
                        .key(<KEY_NAME>),
                        AsyncResponseTransformer.toFile(Paths.get(<FILE_NAME>))).join();
```
Transfer files and directories with the Amazon S3 Transfer Manager

The Amazon S3 Transfer Manager is an open source, high level file transfer utility for the AWS SDK for Java 2.x. Use it to transfer files and directories to and from Amazon Simple Storage Service (Amazon S3).

When built on top of the AWS CRT-based S3 client, the S3 Transfer Manager can take advantage of performance improvements such as the multipart upload API and byte-range fetches.

With the S3 Transfer Manager, you can also monitor a transfer's progress in real time and pause the transfer for later execution.

Get started

Add dependencies to your build file

To use the S3 Transfer Manager with enhanced performance based on the AWS CRT-based S3 client, configure your build file with the following dependencies.

- Use version 2.19.1 or higher of the SDK for Java 2.x.
- Add the s3-transfer-manager artifact as a dependency.
- Add the aws-crt artifact as a dependency at version 0.20.3 or higher.

The following code example shows how to configure your project dependencies for Maven.

```
<project>
  <properties>
    <aws.sdk.version>2.19.1</aws.sdk.version>
  </properties>
  <dependencyManagement>
    <dependencies>
      <dependency>
        <groupId>software.amazon.awssdk</groupId>
        <artifactId>bom</artifactId>
        <version>${aws.sdk.version}</version>
        <type>pom</type>
        <scope>import</scope>
      </dependency>
    </dependencies>
  </dependencyManagement>
  <dependencies>
  </dependencies>
</project>
```
<dependency>
   <groupId>software.amazon.awssdk</groupId>
   <artifactId>s3-transfer-manager</artifactId>
</dependency>
<dependency>
   <groupId>software.amazon.awssdk.crt</groupId>
   <artifactId>aws-crt</artifactId>
   <version>0.20.3</version>
</dependency>
</dependencies>

Search the Maven central repository for the most recent versions of the s3-transfer-manager and aws-crt artifacts.

Create an instance of the S3 Transfer Manager

The following snippet shows how to create a S3TransferManager instance with default settings.

S3TransferManager transferManager = S3TransferManager.create();

The following example shows how to configure a S3 Transfer Manager with custom settings. In this example, a AWS CRT-based S3AsyncClient instance is used as the underlying client for the S3 Transfer Manager.

S3AsyncClient s3AsyncClient = S3AsyncClient.crtBuilder()
   .credentialsProvider(DefaultCredentialsProvider.create())
   .region(Region.US_EAST_1)
   .targetThroughputInGbps(20.0)
   .minimumPartSizeInBytes(8 * MB)
   .build();

S3TransferManager transferManager = S3TransferManager.builder()
   .s3Client(s3AsyncClient)
   .build();

Note

If the aws-crt dependency is not included in the build file, the S3 Transfer Manager is built on top of the standard S3 asynchronous client used in the SDK for Java 2.x.
Upload a file to an S3 bucket

The following example shows a file upload example along with the optional use of a LoggingTransferListener, which logs the progress of the upload.

To upload a file to Amazon S3 using the S3 Transfer Manager, pass an UploadFileRequest object to the S3TransferManager's uploadFile method.

The FileUpload object returned from the uploadFile method represents the upload process. After the request finishes, the CompletedFileUpload object contains information about the upload.

```java
public String uploadFile(S3TransferManager transferManager, String bucketName, String key, URI filePathURI) {
    UploadFileRequest uploadFileRequest = UploadFileRequest.builder()
            .putObjectRequest(b -> b.bucket(bucketName).key(key))
            .addTransferListener(LoggingTransferListener.create())
            .source(Paths.get(filePathURI))
            .build();

    FileUpload fileUpload = transferManager.uploadFile(uploadFileRequest);

    CompletedFileUpload uploadResult = fileUpload.completionFuture().join();
    return uploadResult.response().eTag();
}
```

Imports

```java
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.transfer.s3.S3TransferManager;
import software.amazon.awssdk.transfer.s3.model.CompletedFileUpload;
import software.amazon.awssdk.transfer.s3.model.FileUpload;
import software.amazon.awssdk.transfer.s3.model.UploadFileRequest;
import software.amazon.awssdk.transfer.s3.progress.LoggingTransferListener;
import java.net.URI;
import java.net.URISyntaxException;
import java.net.URL;
import java.nio.file.Paths;
import java.util.UUID;
```
Download a file from an S3 bucket

The following example shows a download example along with the optional use of a LoggingTransferListener, which logs the progress of the download.

To download an object from an S3 bucket using the S3 Transfer Manager, build a DownloadFileRequest object and pass it to the downloadFile method.

The FileDownload object returned by the S3TransferManager's downloadFile method represents the file transfer. After the download completes, the CompletedFileDownload contains access to information about the download.

```java
public Long downloadFile(S3TransferManager transferManager, String bucketName,
                        String key, String downloadedFileWithPath) {
    DownloadFileRequest downloadFileRequest = DownloadFileRequest.builder()
        .getObjectRequest(b -> b.bucket(bucketName).key(key))
        .addTransferListener(LoggingTransferListener.create())
        .destination(Paths.get(downloadedFileWithPath))
        .build();

    FileDownload downloadFile = transferManager.downloadFile(downloadFileRequest);

    CompletedFileDownload downloadResult = downloadFile.completionFuture().join();
    logger.info("Content length ", downloadResult.response().contentLength());
    return downloadResult.response().contentLength();
}
```

**Imports**

```java
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.core.sync.RequestBody;
import software.amazon.awssdk.transfer.s3.S3TransferManager;
import software.amazon.awssdk.transfer.s3.model.CompletedFileDownload;
import software.amazon.awssdk.transfer.s3.model.DownloadFileRequest;
import software.amazon.awssdk.transfer.s3.model.FileDownload;
import software.amazon.awssdk.transfer.s3.progress.LoggingTransferListener;

import java.nio.file.Files;
import java.nio.file.Path;
import java.nio.file.Paths;
```
import java.util.UUID;

**Copy an Amazon S3 object to another bucket**

The following example shows how to copy an object with the S3 Transfer Manager.

To begin the copy of an object from an S3 bucket to another bucket, create a basic `CopyObjectRequest` instance.

Next, wrap the basic `CopyObjectRequest` in a `CopyRequest` that can be used by the S3 Transfer Manager.

The `Copy` object returned by the S3TransferManager's copy method represents the copy process. After the copy process completes, the `CompletedCopy` object contains details about the response.

```java
public String copyObject(S3TransferManager transferManager, String bucketName, String key, String destinationBucket, String destinationKey) {
    CopyObjectRequest copyObjectRequest = CopyObjectRequest.builder()
        .sourceBucket(bucketName)
        .sourceKey(key)
        .destinationBucket(destinationBucket)
        .destinationKey(destinationKey)
        .build();

    CopyRequest copyRequest = CopyRequest.builder()
        .copyObjectRequest(copyObjectRequest)
        .build();

    Copy copy = transferManager.copy(copyRequest);

    CompletedCopy completedCopy = copy.completionFuture().join();
    return completedCopy.response().copyObjectResult().eTag();
}
```

**Note**

To perform a cross-Region copy with the S3 Transfer Manager, enable `crossRegionAccessEnabled` on the AWS CRT-based S3 client builder as shown in the following snippet.

```java
S3AsyncClient s3AsyncClient = S3AsyncClient.crtBuilder()
```
S3TransferManager transferManager = S3TransferManager.builder()  
    .s3Client(s3AsyncClient)  
    .build();

Imports

import org.slf4j.Logger;  
import org.slf4j.LoggerFactory;  
import software.amazon.awssdk.core.sync.RequestBody;  
import software.amazon.awssdk.services.s3.model.CopyObjectRequest;  
import software.amazon.awssdk.transfer.s3.S3TransferManager;  
import software.amazon.awssdk.transfer.s3.model.CompletedCopy;  
import software.amazon.awssdk.transfer.s3.model.Copy;  
import software.amazon.awssdk.transfer.s3.model.CopyRequest;  
import java.util.UUID;

Upload a local directory to an S3 bucket

The following example demonstrates how you can upload a local directory to S3.

Start by calling the uploadDirectory method of the S3TransferManager instance, passing in an UploadDirectoryRequest.

The DirectoryUpload object represents the upload process, which generates a CompletedDirectoryUpload when the request completes. The CompleteDirectoryUpload object contains information about the results of the transfer, including which files failed to transfer.

```java
public Integer uploadDirectory(S3TransferManager transferManager,  
                               URI sourceDirectory, String bucketName) {
    DirectoryUpload directoryUpload =  
        transferManager.uploadDirectory(UploadDirectoryRequest.builder()  
                                        .source(Paths.get(sourceDirectory))  
                                        .bucket(bucketName)  
                                        .build());

    CompletedDirectoryUpload completedDirectoryUpload =  
        directoryUpload.completionFuture().join();
```
completedDirectoryUpload.failedTransfers()
    .forEach(fail -> logger.warn("Object [{},] failed to transfer",
        fail.toString()));
    return completedDirectoryUpload.failedTransfers().size();
}

Imports

import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.services.s3.model.ObjectIdentifier;
import software.amazon.awssdk.transfer.s3.S3TransferManager;
import software.amazon.awssdk.transfer.s3.model.CompletedDirectoryUpload;
import software.amazon.awssdk.transfer.s3.model.DirectoryUpload;
import software.amazon.awssdk.transfer.s3.model.UploadDirectoryRequest;
import java.net.URI;
import java.net.URISyntaxException;
import java.net.URL;
import java.nio.file.Paths;
import java.util.UUID;

Download S3 bucket objects to a local directory

You can download the objects in an S3 bucket to a local directory as shown in the following example.

To download the objects in an S3 bucket to a local directory, begin by calling the downloadDirectory method of the Transfer Manager, passing in a DownloadDirectoryRequest.

The DirectoryDownload object represents the download process, which generates a CompletedDirectoryDownload when the request completes. The CompletedDirectoryDownload object contains information about the results of the transfer, including which files failed to transfer.

```java
public Integer downloadObjectsToDirectory(S3TransferManager transferManager,
    URI destinationPathURI, String bucketName) {
    DirectoryDownload directoryDownload =
        transferManager.downloadDirectory(DownloadDirectoryRequest.builder()
            .destination(Paths.get(destinationPathURI))
            .bucket(bucketName)
            .build());
    return directoryDownload.failedTransfers().size();
}
```
.build();
CompletedDirectoryDownload completedDirectoryDownload =
directoryDownload.completionFuture().join();

completedDirectoryDownload.failedTransfers()
    .forEach(fail -> logger.warn("Object [{}] failed to transfer", fail.toString()));
    return completedDirectoryDownload.failedTransfers().size();
}

Imports

import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.core.sync.RequestBody;
import software.amazon.awssdk.services.s3.model.ObjectIdentifier;
import software.amazon.awssdk.transfer.s3.S3TransferManager;
import software.amazon.awssdk.transfer.s3.model.CompletedDirectoryDownload;
import software.amazon.awssdk.transfer.s3.model.DirectoryDownload;
import software.amazon.awssdk.transfer.s3.model.DownloadDirectoryRequest;
import java.io.IOException;
import java.net.URI;
import java.net.URISyntaxException;
import java.nio.file.Files;
import java.nio.file.Path;
import java.nio.file.Paths;
import java.util.HashSet;
import java.util.Set;
import java.util.UUID;
import java.util.stream.Collectors;

See complete examples

GitHub contains the complete code for all examples on this page.

Work with Amazon Simple Notification Service

With Amazon Simple Notification Service, you can easily push real-time notification messages from your applications to subscribers over multiple communication channels. This topic describes how to perform some of the basic functions of Amazon SNS.
Create a topic

A **topic** is a logical grouping of communication channels that defines which systems to send a message to, for example, fanning out a message to AWS Lambda and an HTTP webhook. You send messages to Amazon SNS, then they're distributed to the channels defined in the topic. This makes the messages available to subscribers.

To create a topic, first build a **CreateTopicRequest** object, with the name of the topic set using the `name()` method in the builder. Then, send the request object to Amazon SNS by using the `createTopic()` method of the **SnsClient**. You can capture the result of this request as a **CreateTopicResponse** object, as demonstrated in the following code snippet.

**Imports**

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sns.SnsClient;
import software.amazon.awssdk.services.sns.model.CreateTopicRequest;
import software.amazon.awssdk.services.sns.model.CreateTopicResponse;
import software.amazon.awssdk.services.sns.model.SnsException;
```

**Code**

```java
public static String createSNSTopic(SnsClient snsClient, String topicName) {
    CreateTopicResponse result = null;
    try {
        CreateTopicRequest request = CreateTopicRequest.builder()
                .name(topicName)
                .build();

        result = snsClient.createTopic(request);
        return result.topicArn();
    } catch (SnsException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
        return "";
    }
}
```

See the [complete example](#) on GitHub.
List your Amazon SNS topics

To retrieve a list of your existing Amazon SNS topics, build a `ListTopicsRequest` object. Then, send the request object to Amazon SNS by using the `listTopics()` method of the `SnsClient`. You can capture the result of this request as a `ListTopicsResponse` object.

The following code snippet prints out the HTTP status code of the request and a list of Amazon Resource Names (ARNs) for your Amazon SNS topics.

**Imports**

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sns.SnsClient;
import software.amazon.awssdk.services.sns.model.ListTopicsRequest;
import software.amazon.awssdk.services.sns.model.ListTopicsResponse;
import software.amazon.awssdk.services.sns.model.SnsException;
```

**Code**

```java
public static void listSNSTopics(SnsClient snsClient) {
    try {
        ListTopicsRequest request = ListTopicsRequest.builder()
            .build();

        ListTopicsResponse result = snsClient.listTopics(request);
        System.out.println("Status was " + result.sdkHttpResponse().statusCode() + 
            "\n\nTopics\n\n" + result.topics());
    } catch (SnsException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

See the [complete example](#) on GitHub.

**Subscribe an endpoint to a topic**

After you create a topic, you can configure which communication channels will be endpoints for that topic. Messages are distributed to these endpoints after Amazon SNS receives them.
To configure a communication channel as an endpoint for a topic, subscribe that endpoint to the topic. To start, build a `SubscribeRequest` object. Specify the communication channel (for example, lambda or email) as the `protocol()`. Set the `endpoint()` to the relevant output location (for example, the ARN of a Lambda function or an email address), and then set the ARN of the topic to which you want to subscribe as the `topicArn()`. Send the request object to Amazon SNS by using the `subscribe()` method of the `SnsClient`. You can capture the result of this request as a `SubscribeResponse` object.

The following code snippet shows how to subscribe an email address to a topic.

**Imports**

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sns.SnsClient;
import software.amazon.awssdk.services.sns.model.SnsException;
import software.amazon.awssdk.services.sns.model.SubscribeRequest;
import software.amazon.awssdk.services.sns.model.SubscribeResponse;
```

**Code**

```java
public static void subEmail(SnsClient snsClient, String topicArn, String email) {
    try {
        SubscribeRequest request = SubscribeRequest.builder()
                .protocol("email")
                .endpoint(email)
                .returnSubscriptionArn(true)
                .topicArn(topicArn)
                .build();

        SubscribeResponse result = snsClient.subscribe(request);
        System.out.println("Subscription ARN: " + result.subscriptionArn() + "\n\nStatus is " + result.sdkHttpResponse().statusCode());
    } catch (SnsException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

See the [complete example](https://github.com/aws/aws-sdk-java) on GitHub.
Publish a message to a topic

After you have a topic and one or more endpoints configured for it, you can publish a message to it. To start, build a `PublishRequest` object. Specify the `message()` to send, and the ARN of the topic (`topicArn()`)) to send it to. Then, send the request object to Amazon SNS by using the `publish()` method of the `SnsClient`. You can capture the result of this request as a `PublishResponse` object.

Imports

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sns.SnsClient;
import software.amazon.awssdk.services.sns.model.PublishRequest;
import software.amazon.awssdk.services.sns.model.PublishResponse;
import software.amazon.awssdk.services.sns.model.SnsException;
```

Code

```java
public static void pubTopic(SnsClient snsClient, String message, String topicArn) {
    try {
        PublishRequest request = PublishRequest.builder()
                        .message(message)
                        .topicArn(topicArn)
                        .build();

        PublishResponse result = snsClient.publish(request);
        System.out.println(result.messageId() + " Message sent. Status is " +
                        result.sdkHttpResponse().statusCode());
    } catch (SnsException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

See the [complete example](https://github.com/aws-amazon-sns-examples/publish-message-to-topic) on GitHub.
Unsubscribe an endpoint from a topic

You can remove the communication channels configured as endpoints for a topic. After doing that, the topic itself continues to exist and distribute messages to any other endpoints configured for that topic.

To remove a communication channel as an endpoint for a topic, unsubscribe that endpoint from the topic. To start, build an `UnsubscribeRequest` object and set the ARN of the topic you want to unsubscribe from as the `subscriptionArn()`. Then send the request object to SNS by using the `unsubscribe()` method of the `SnsClient`. You can capture the result of this request as an `UnsubscribeResponse` object.

### Imports

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sns.SnsClient;
import software.amazon.awssdk.services.sns.model.SnsException;
import software.amazon.awssdk.services.sns.model.UnsubscribeRequest;
import software.amazon.awssdk.services.sns.model.UnsubscribeResponse;
```

### Code

```java
public static void unSub(SnsClient snsClient, String subscriptionArn) {
    try {
        UnsubscribeRequest request = UnsubscribeRequest.builder()
                .subscriptionArn(subscriptionArn)
                .build();

        UnsubscribeResponse result = snsClient.unsubscribe(request);
        System.out.println("Status was " + result.sdkHttpResponse().statusCode()
                + "Subscription was removed for " + request.subscriptionArn());
    } catch (SnsException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

See the [complete example](https://github.com/aws/aws-sdk-java) on GitHub.
Delete a topic

To delete an Amazon SNS topic, first build a `DeleteTopicRequest` object with the ARN of the topic set as the `topicArn()` method in the builder. Then send the request object to Amazon SNS by using the `deleteTopic()` method of the `SnsClient`. You can capture the result of this request as a `DeleteTopicResponse` object, as demonstrated in the following code snippet.

**Imports**

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sns.SnsClient;
import software.amazon.awssdk.services.sns.model.DeleteTopicRequest;
import software.amazon.awssdk.services.sns.model.DeleteTopicResponse;
import software.amazon.awssdk.services.sns.model.SnsException;
```

**Code**

```java
public static void deleteSNSTopic(SnsClient snsClient, String topicArn) {
  try {
    DeleteTopicRequest request = DeleteTopicRequest.builder()
      .topicArn(topicArn)
      .build();

    DeleteTopicResponse result = snsClient.deleteTopic(request);
    System.out.println("\n\nStatus was " +
    result.sdkHttpResponse().statusCode());
  } catch (SnsException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
  }
}
```

See the [complete example](https://github.com/aws/aws-sdk-java) on GitHub.

For more information, see the [Amazon Simple Notification Service Developer Guide](https://docs.aws.amazon.com/sns/latest/dg/).
Work with Amazon Simple Queue Service

This section provides examples of programming Amazon Simple Queue Service using the AWS SDK for Java 2.x.

The following examples include only the code needed to demonstrate each technique. The complete example code is available on GitHub. From there, you can download a single source file or clone the repository locally to get all the examples to build and run.

Topics

- Work with Amazon Simple Queue Service message queues
- Send, receive, and delete Amazon Simple Queue Service messages

Work with Amazon Simple Queue Service message queues

A message queue is the logical container used for sending messages reliably in Amazon Simple Queue Service. There are two types of queues: standard and first-in, first-out (FIFO). To learn more about queues and the differences between these types, see the Amazon Simple Queue Service Developer Guide.

This topic describes how to create, list, delete, and get the URL of an Amazon Simple Queue Service queue by using the AWS SDK for Java.

The sqsClient variable that is used in the following examples can be created from the following snippet.

```java
SqsClient sqsClient = SqsClient.create();
```

When you create an SqsClient by using the static create() method, the SDK configures the Region by using the default region provider chain and the credentials by using the default credentials provider chain.

Create a queue

Use the SqsClient’s createQueue method, and provide a CreateQueueRequest object that describes the queue parameters as shown in the following code snippet.

Imports
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sqs.SqsClient;
import software.amazon.awssdk.services.sqs.model.*;
import java.util.List;

### Code

```java
CreateQueueRequest createQueueRequest = CreateQueueRequest.builder()
  .queueName(queueName)
  .build();

sqsClient.createQueue(createQueueRequest);
```

See the [complete sample](https://github.com/aws/aws-sdk-java) on GitHub.

### List queues

To list the Amazon Simple Queue Service queues for your account, call the SqsClient’s `listQueues` method with a `ListQueuesRequest` object.

When you use the form of the `listQueues` method that takes no parameters, the service returns all queues—up to 1,000 queues.

You can supply a queue name prefix to the `ListQueuesRequest` object to limit the results to queues that match that prefix as shown in the following code.

### Imports

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sqs.SqsClient;
import software.amazon.awssdk.services.sqs.model.*;
import java.util.List;
```

### Code

```java
String prefix = "que";

try {
    ListQueuesRequest listQueuesRequest = ListQueuesRequest.builder()
      .queueNamePrefix(prefix).build();
    ListQueuesResponse listQueuesResponse = sqsClient.listQueues(listQueuesRequest);
}
```
for (String url : listQueuesResponse.queueUrls()) {
    System.out.println(url);
}

} catch (SqsException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

See the [complete sample](https://github.com) on GitHub.

### Get the URL for a queue

The following code shows how to get the URL for a queue by calling the SqsClient’s `getQueueUrl` method with a `GetQueueUrlRequest` object.

**Imports**

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sqs.SqsClient;
import software.amazon.awssdk.services.sqs.model.*;
import java.util.List;
```

**Code**

```java
GetQueueUrlResponse getQueueUrlResponse =
    sqsClient.getQueueUrl(GetQueueUrlRequest.builder().queueName(queueName).build());
String queueUrl = getQueueUrlResponse.queueUrl();
return queueUrl;
```

See the [complete sample](https://github.com) on GitHub.

### Delete a queue

Provide the queue’s [URL](https://github.com) to the `DeleteQueueRequest` object. Then call the SqsClient’s `deleteQueue` method to delete a queue as shown in the following code.

**Imports**

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sqs.SqsClient;
```
import software.amazon.awssdk.services.sqs.model.*;
import java.util.List;

Code

```java
public static void deleteSQSQueue(SqsClient sqsClient, String queueName) {
    try {
        GetQueueUrlRequest getQueueRequest = GetQueueUrlRequest.builder()
            .queueName(queueName)
            .build();

        String queueUrl = sqsClient.getQueueUrl(getQueueRequest).queueUrl();

        DeleteQueueRequest deleteQueueRequest = DeleteQueueRequest.builder()
            .queueUrl(queueUrl)
            .build();

        sqsClient.deleteQueue(deleteQueueRequest);
    } catch (SqsException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

See the [complete sample](https://github.com) on GitHub.

More information

- [CreateQueue](#) in the Amazon Simple Queue Service API Reference
- [GetQueueUrl](#) in the Amazon Simple Queue Service API Reference
- [ListQueues](#) in the Amazon Simple Queue Service API Reference
- [DeleteQueue](#) in the Amazon Simple Queue Service API Reference

Send, receive, and delete Amazon Simple Queue Service messages

A message is a piece of data that can be sent and received by distributed components. Messages are always delivered using an [SQS Queue](#).
The sqsClient variable that is used in the following examples can be created from the following snippet.

```java
SqsClient sqsClient = SqsClient.create();
```

When you create an SqsClient by using the static `create()` method, the SDK configures the Region by using the default region provider chain and the credentials by using the default credentials provider chain.

**Send a message**

Add a single message to an Amazon Simple Queue Service queue by calling the SqsClient client `sendMessage` method. Provide a `SendMessageRequest` object that contains the queue's URL, message body, and optional delay value (in seconds).

**Imports**

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sqs.SqsClient;
import software.amazon.awssdk.services.sqs.model.*;
import java.util.List;
```

**Code**

```java
sqsClient.sendMessage(SendMessageRequest.builder()
  .queueUrl(queueUrl)
  .messageBody("Hello world!")
  .delaySeconds(10)
  .build());

sqsClient.sendMessage(sendMsgRequest);
```

**Send multiple messages in a request**

Send more than one message in a single request by using the SqsClient `sendMessageBatch` method. This method takes a `SendMessageBatchRequest` that contains the queue URL and a list of messages to send. (Each message is a `SendMessageBatchRequestEntry`.) You can also delay sending a specific message by setting a delay value on the message.

**Imports**
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sqs.SqsClient;
import software.amazon.awssdk.services.sqs.model.*;
import java.util.List;

Code

SendMessageBatchRequest sendMessageBatchRequest = 
    SendMessageBatchRequest.builder()
    .queueUrl(queueUrl)
    .entries(SendMessageBatchRequestEntry.builder().id("id1").messageBody("Hello from msg 1").build(),
    SendMessageBatchRequestEntry.builder().id("id2").messageBody("msg 2").delaySeconds(10).build())
    .build();
sqsClient.sendMessageBatch(sendMessageBatchRequest);

See the [complete sample](https://github.com) on GitHub.

Retrieve Messages

Retrieve any messages that are currently in the queue by calling the SqsClient `receiveMessage` method. This method takes a `ReceiveMessageRequest` that contains the queue URL. You can also specify the maximum number of messages to return. Messages are returned as a list of `Message` objects.

Imports

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sqs.SqsClient;
import software.amazon.awssdk.services.sqs.model.*;
import java.util.List;
```

Code

```java
try {
    ReceiveMessageRequest receiveMessageRequest = 
    ReceiveMessageRequest.builder()
```
See the [complete sample](https://github.com/aws-samples/aws-sdk-java-streaming-sqs-example) on GitHub.

### Delete a message after receipt

After receiving a message and processing its contents, delete the message from the queue by sending the message's receipt handle and queue URL to the SqsClient's `deleteMessage` method.

#### Imports

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sqs.SqsClient;
import software.amazon.awssdk.services.sqs.model.*;
import java.util.List;
```

#### Code

```java
try {
    for (Message message : messages) {
        DeleteMessageRequest deleteMessageRequest =
            DeleteMessageRequest.builder()
                .queueUrl(queueUrl)
                .receiptHandle(message.receiptHandle())
                .build();
        sqsClient.deleteMessage(deleteMessageRequest);
    }
}
```

See the [complete sample](https://github.com/aws-samples/aws-sdk-java-streaming-sqs-example) on GitHub.
More Info

• How Amazon Simple Queue Service Queues Work in the Amazon Simple Queue Service Developer Guide
• SendMessage in the Amazon Simple Queue Service API Reference
• SendMessageBatch in the Amazon Simple Queue Service API Reference
• ReceiveMessage in the Amazon Simple Queue Service API Reference
• DeleteMessage in the Amazon Simple Queue Service API Reference

Work with Amazon Transcribe

The following example shows how bidirectional streaming works using Amazon Transcribe. Bidirectional streaming implies that there’s both a stream of data going to the service and being received back in real time. The example uses Amazon Transcribe streaming transcription to send an audio stream and receive a stream of transcribed text back in real time.

See Streaming Transcription in the Amazon Transcribe Developer Guide to learn more about this feature.

See Getting Started in the Amazon Transcribe Developer Guide to get started using Amazon Transcribe.

Set up the microphone

This code uses the javax.sound.sampled package to stream audio from an input device.

Code

```java
import javax.sound.sampled.AudioFormat;
import javax.sound.sampled.AudioSystem;
import javax.sound.sampled.DataLine;
import javax.sound.sampled.TargetDataLine;

public class Microphone {
    public static TargetDataLine get() throws Exception {
        AudioFormat format = new AudioFormat(16000, 16, 1, true, false);
        DataLine.Info datalineInfo = new DataLine.Info(TargetDataLine.class, format);
        TargetDataLine dataLine = (TargetDataLine) AudioSystem.getLine(datalineInfo);
    }
```
dataLine.open(format);
return dataLine;
}
}

See the complete example on GitHub.

Create a publisher

This code implements a publisher that publishes audio data from the Amazon Transcribe audio stream.

Code

```java
package com.amazonaws.transcribe;

import java.io.IOException;
import java.io.InputStream;
import java.io.UncheckedIOException;
import java.nio.ByteBuffer;
import java.util.concurrent.ExecutorService;
import java.util.concurrent.Executors;
import java.util.concurrent.atomic.AtomicLong;
import org.reactivestreams.Publisher;
import org.reactivestreams.Subscriber;
import org.reactivestreams.Subscription;
import software.amazon.awssdk.core.SdkBytes;
import software.amazon.awssdk.services.transcribestreaming.model.AudioEvent;
import software.amazon.awssdk.services.transcribestreaming.model.AudioStream;
import software.amazon.awssdk.services.transcribestreaming.model.TranscribeStreamingException;

public class AudioStreamPublisher implements Publisher<AudioStream> {
    private final InputStream inputStream;

    public AudioStreamPublisher(InputStream inputStream) {
        this.inputStream = inputStream;
    }

    @Override
    public void subscribe(Subscriber<? super AudioStream> s) {
```
s.onSubscribe(new SubscriptionImpl(s, inputStream));

private class SubscriptionImpl implements Subscription {
    private static final int CHUNK_SIZE_IN_BYTES = 1024 * 1;
    private ExecutorService executor = Executors.newFixedThreadPool(1);
    private AtomicLong demand = new AtomicLong(0);

    private final Subscriber<? super AudioStream> subscriber;
    private final InputStream inputStream;

    private SubscriptionImpl(Subscriber<? super AudioStream> s, InputStream inputStream) {
        this.subscriber = s;
        this.inputStream = inputStream;
    }

    @Override
    public void request(long n) {
        if (n <= 0) {
            subscriber.onError(new IllegalArgumentException("Demand must be positive"));
        }

        demand.getAndAdd(n);

        executor.submit(() -> {
            try {
                do {
                    ByteBuffer audioBuffer = getNextEvent();
                    if (audioBuffer.remaining() > 0) {
                        AudioEvent audioEvent = audioEventFromBuffer(audioBuffer);
                        subscriber.onNext(audioEvent);
                    } else {
                        subscriber.onComplete();
                        break;
                    }
                } while (demand.decrementAndGet() > 0);
            } catch (TranscribeStreamingException e) {
                subscriber.onError(e);
            }
        });
    }
}
@Override
public void cancel() {
}

private ByteBuffer getNextEvent() {
    ByteBuffer audioBuffer;
    byte[] audioBytes = new byte[CHUNK_SIZE_IN_BYTES];
    int len = 0;
    try {
        len = inputStream.read(audioBytes);
        if (len <= 0) {
            audioBuffer = ByteBuffer.allocate(0);
        } else {
            audioBuffer = ByteBuffer.wrap(audioBytes, 0, len);
        }
    } catch (IOException e) {
        throw new UncheckedIOException(e);
    }
    return audioBuffer;
}

private AudioEvent audioEventFromBuffer(ByteBuffer bb) {
    return AudioEvent.builder()
        .audioChunk(SdkBytes.fromByteBuffer(bb))
        .build();
}

See the [complete example](https://github.com) on GitHub.

**Create the client and start the stream**

In the main method, create a request object, start the audio input stream and instantiate the publisher with the audio input.

You must also create a [StartStreamTranscriptionResponseHandler](https://github.com) to specify how to handle the response from Amazon Transcribe.
Then, use the TranscribeStreamingAsyncClient's `startStreamTranscription` method to start the bidirectional streaming.

**Imports**

```java
import javax.sound.sampled.AudioFormat;
import javax.sound.sampled.AudioSystem;
import javax.sound.sampled.DataLine;
import javax.sound.sampled.TargetDataLine;
import javax.sound.sampled.AudioInputStream;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.transcribestreaming.TranscribeStreamingAsyncClient;
import software.amazon.awssdk.services.transcribestreaming.model.TranscribeStreamingException;
import software.amazon.awssdk.services.transcribestreaming.model.StartStreamTranscriptionRequest;
import software.amazon.awssdk.services.transcribestreaming.model.MediaEncoding;
import software.amazon.awssdk.services.transcribestreaming.model.LanguageCode;
import software.amazon.awssdk.services.transcribestreaming.model.StartStreamTranscriptionResponseHandler;
import software.amazon.awssdk.services.transcribestreaming.model.TranscriptEvent;
```

**Code**

```java
public static void convertAudio(TranscribeStreamingAsyncClient client) throws Exception {
    try {
        StartStreamTranscriptionRequest request = 
            StartStreamTranscriptionRequest.builder()
                .mediaEncoding(MediaEncoding.PCM)
                .languageCode(LanguageCode.EN_US)
                .mediaSampleRateHertz(16_000).build();

        TargetDataLine mic = Microphone.get();
        mic.start();

        AudioStreamPublisher publisher = new AudioStreamPublisher(new AudioInputStream(mic));

        StartStreamTranscriptionResponseHandler response =
```
StartStreamTranscriptionResponseHandler.builder().subscriber(e -> {
    TranscriptEvent event = (TranscriptEvent) e;
    event.transcript().results().forEach(r ->
        r.alternatives().forEach(a -> System.out.println(a.transcript())));
}).build();

// Keeps Streaming until you end the Java program
client.startStreamTranscription(request, publisher, response);

} catch (TranscribeStreamingException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

See the complete example on GitHub.

SDK for Java 2.x code examples

The code examples in this topic show you how to use the AWS SDK for Java 2.x with AWS.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Cross-service examples are sample applications that work across multiple AWS services.

Examples

- Actions and scenarios using SDK for Java 2.x
- Cross-service examples using SDK for Java 2.x

Actions and scenarios using SDK for Java 2.x

Create a REST API

The following code example shows how to create an API Gateway REST API.

SDK for Java 2.x

```java
public static String createAPI(ApiGatewayClient apiGateway, String restApiId, String restApiName) {
    try {
        CreateRestApiRequest request = CreateRestApiRequest.builder()
            .cloneFrom(restApiId)
            .description("Created using the Gateway Java API")
            .name(restApiName)
            .build();

        CreateRestApiResponse response = apiGateway.createRestApi(request);
        System.out.println("The id of the new api is " + response.id());
        return response.id();
    } catch (ApiGatewayException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/aws/aws-sdk-java).
Delete a REST API

The following code example shows how to delete an API Gateway REST API.

```java
public static void deleteAPI(ApiGatewayClient apiGateway, String restApiId) {
    try {
        DeleteRestApiRequest request = DeleteRestApiRequest.builder()
            .restApiId(restApiId)
            .build();

        apiGateway.deleteRestApi(request);
        System.out.println("The API was successfully deleted");
    } catch (ApiGatewayException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

For API details, see [DeleteRestApi](https://docs.aws.amazon.com/AWSJavaSDK/latest/api/aws/service/ApiGatewayClient.html#deleteRestApi) in *AWS SDK for Java 2.x API Reference*.

Delete a deployment

The following code example shows how to delete a deployment.
Deploy a REST API

The following code example shows how to deploy an API Gateway REST API.

```java
public static void deleteSpecificDeployment(ApiGatewayClient apiGateway, String restApiId, String deploymentId) {
    try {
        DeleteDeploymentRequest request = DeleteDeploymentRequest.builder()
            .restApiId(restApiId)
            .deploymentId(deploymentId)
            .build();

        apiGateway.deleteDeployment(request);
        System.out.println("Deployment was deleted");

    } catch (ApiGatewayException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

For API details, see [DeleteDeployment](https://aws-sdk-java.github.io/aws-sdk-java/) in *AWS SDK for Java 2.x API Reference*.

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/aws/aws-sdk-java).
public static String createNewDeployment(ApiGatewayClient apiGateway, String restApiId, String stageName) {
    try {
        CreateDeploymentRequest request = CreateDeploymentRequest.builder()
            .restApiId(restApiId)
            .description("Created using the AWS API Gateway Java API")
            .stageName(stageName)
            .build();

        CreateDeploymentResponse response =
            apiGateway.createDeployment(request);
        System.out.println("The id of the deployment is " + response.id());
        return response.id();
    } catch (ApiGatewayException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
    return "";
}

• For API details, see CreateDeployment in AWS SDK for Java 2.x API Reference.

Application Auto Scaling examples using SDK for Java 2.x

Application Recovery Controller examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Application Recovery Controller.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Actions

Get the state of a routing control

The following code example shows how to get the state of an Application Recovery Controller routing control.

**SDK for Java 2.x**

```java
public static GetRoutingControlStateResponse getRoutingControlState(List<ClusterEndpoint> clusterEndpoints,
```
String routingControlArn) {
  // As a best practice, we recommend choosing a random cluster endpoint to get or set routing control states.
  // For more information, see https://docs.aws.amazon.com/r53recovery/latest/dg/route53-arc-best-practices.html#route53-arc-best-practices.regional
  Collections.shuffle(clusterEndpoints);
  for (ClusterEndpoint clusterEndpoint : clusterEndpoints) {
    try {
      System.out.println(clusterEndpoint);
      Route53RecoveryClusterClient client = Route53RecoveryClusterClient.builder()
        .endpointOverride(URI.create(clusterEndpoint.endpoint()))
        .region(Region.of(clusterEndpoint.region())).build();
      return client.getRoutingControlState(
        GetRoutingControlStateRequest.builder()
          .routingControlArn(routingControlArn).build());
    } catch (Exception exception) {
      System.out.println(exception);
    }
  }
  return null;
}

• For API details, see GetRoutingControlState in AWS SDK for Java 2.x API Reference.

Update the state of a routing control

The following code example shows how to update the state of an Application Recovery Controller routing control.

SDK for Java 2.x

⚠️ Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
public static UpdateRoutingControlStateResponse
updateRoutingControlState(List<ClusterEndpoint> clusterEndpoints,
   String routingControlArn,
   String routingControlState) {
   // As a best practice, we recommend choosing a random cluster endpoint to
get or
   // set routing control states.
   // For more information, see
   Collections.shuffle(clusterEndpoints);
   for (ClusterEndpoint clusterEndpoint : clusterEndpoints) {
      try {
         System.out.println(clusterEndpoint);
         Route53RecoveryClusterClient client =
            Route53RecoveryClusterClient.builder()
               .endpointOverride(URI.create(clusterEndpoint.endpoint()))
               .region(Region.of(clusterEndpoint.region()))
               .build();
         return client.updateRoutingControlState(
            UpdateRoutingControlStateRequest.builder()
               .routingControlArn(routingControlArn).routingControlState(routingControlState).build());
      } catch (Exception exception) {
         System.out.println(exception);
      }
   }
   return null;
}

Aurora examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios
by using the AWS SDK for Java 2.x with Aurora.

Actions are code excerpts from larger programs and must be run in context. While actions show you
how to call individual service functions, you can see actions in context in their related scenarios and
cross-service examples.
Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Get started

Hello Aurora

The following code examples show how to get started using Aurora.

SDK for Java 2.x

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.rds.RdsClient;
import software.amazon.awssdk.services.rds.paginators.DescribeDBClustersIterable;

public class DescribeDbClusters {
    public static void main(String[] args) {
        Region region = Region.US_EAST_1;
        RdsClient rdsClient = RdsClient.builder()
            .region(region)
            .build();

        describeClusters(rdsClient);
        rdsClient.close();
    }

    public static void describeClusters(RdsClient rdsClient) {
        DescribeDBClustersIterable clustersIterable =
            rdsClient.describeDBClustersPaginator();
        clustersIterable.stream()
            .flatMap(r -> r.dbClusters().stream())
            .forEach(cluster -> System.out
                .println("Database name: " + cluster.databaseName() + " Arn = " + cluster.dbClusterArn()));
    }
}
```
For API details, see DescribeDBClusters in AWS SDK for Java 2.x API Reference.

Actions

Create a DB cluster

The following code example shows how to create an Aurora DB cluster.

SDK for Java 2.x

```java
public static String createDBCluster(RdsClient rdsClient, String dbParameterGroupFamily, String dbName,
        String dbClusterIdentifier, String userName, String password) {
    try {
        CreateDbClusterRequest clusterRequest = CreateDbClusterRequest.builder()
                .databaseName(dbName)
                .dbClusterIdentifier(dbClusterIdentifier)
                .dbClusterParameterGroupName(dbParameterGroupFamily)
                .engine("aurora-mysql")
                .masterUsername(userName)
                .masterUserPassword(password)
                .build();

        CreateDbClusterResponse response = rdsClient.createDBCluster(clusterRequest);
        return response.dbCluster().dbClusterArn();
    }
}
```

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
For API details, see [CreateDBCluster](https://docs.aws.amazon.com/AWSJavaSDK/latest/api/aws/rds/RdsClient.html#createDBCluster) in *AWS SDK for Java 2.x API Reference*.

### Create a DB cluster parameter group

The following code example shows how to create an Aurora DB cluster parameter group.

**SDK for Java 2.x**

```java
public static void createDBClusterParameterGroup(RdsClient rdsClient, String dbClusterGroupName,
                                               String dbParameterGroupFamily) {
    try {
        CreateDbClusterParameterGroupRequest groupRequest =
            CreateDbClusterParameterGroupRequest.builder()
                .dbClusterParameterGroupName(dbClusterGroupName)
                .dbParameterGroupFamily(dbParameterGroupFamily)
                .description("Created by using the AWS SDK for Java")
                .build();

        CreateDbClusterParameterGroupResponse response =
            rdsClient.createDBClusterParameterGroup(groupRequest);
        System.out.println("The group name is "+
                           response.dbClusterParameterGroup().dbClusterParameterGroupName());
    } catch (RdsException e) {
        System.out.println(e.getLocalizedMessage());
        System.exit(1);
    }
}
```

- There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/aws-samples/aws-sdk-java-examples).
• For API details, see CreateDBClusterParameterGroup in AWS SDK for Java 2.x API Reference.

Create a DB cluster snapshot

The following code example shows how to create an Aurora DB cluster snapshot.

SDK for Java 2.x

```java
public static void createDBClusterSnapshot(RdsClient rdsClient, String dbInstanceClusterIdentifier, String dbSnapshotIdentifier) {
    try {
        CreateDbClusterSnapshotRequest snapshotRequest =
                CreateDbClusterSnapshotRequest.builder()
                        .dbClusterIdentifier(dbInstanceClusterIdentifier)
                        .dbClusterSnapshotIdentifier(dbSnapshotIdentifier)
                        .build();

        CreateDbClusterSnapshotResponse response =
                rdsClient.createDBClusterSnapshot(snapshotRequest);
        System.out.println("The Snapshot ARN is " +
                        response.dbClusterSnapshot().dbClusterSnapshotArn());

    } catch (RdsException e) {
        System.out.println(e.getLocalizedMessage());
        System.exit(1);
    }
}
```

• For API details, see CreateDBClusterSnapshot in AWS SDK for Java 2.x API Reference.
Create a DB instance in a DB cluster

The following code example shows how to create a DB instance in an Aurora DB cluster.

SDK for Java 2.x

```java
public static String createDBInstanceCluster(RdsClient rdsClient,
                                           String dbInstanceIdentifier,
                                           String dbInstanceClusterIdentifier,
                                           String instanceClass) {
    try {
        CreateDbInstanceRequest instanceRequest =
            CreateDbInstanceRequest.builder()
                .dbInstanceIdentifier(dbInstanceIdentifier)
                .dbClusterIdentifier(dbInstanceClusterIdentifier)
                .engine("aurora-mysql")
                .dbInstanceClass(instanceClass)
                .build();

        CreateDbInstanceResponse response =
            rdsClient.createDBInstance(instanceRequest);
        System.out.print("The status is " +
                       response.dbInstance().dbInstanceStatus());
        return response.dbInstance().dbInstanceArn();
    } catch (RdsException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
    return "";
}
```

- For API details, see [CreateDBInstance](https://docs.aws.amazon.com/AWSJavaSDK/latest/api/com/amazonaws/services/rds/model/AmazonRDSClient.html#createDBInstance) in [AWS SDK for Java 2.x API Reference](https://docs.aws.amazon.com/AWSJavaSDK/latest/api/com/amazonaws/services/rds/model/AmazonRDSClient.html).

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/aws-samples/aws-code-examples).
Delete a DB cluster

The following code example shows how to delete an Aurora DB cluster.

**SDK for Java 2.x**

```java
public static void deleteCluster(RdsClient rdsClient, String dbInstanceClusterIdentifier) {
    try {
        DeleteDbClusterRequest deleteDbClusterRequest = DeleteDbClusterRequest.builder()
            .dbClusterIdentifier(dbInstanceClusterIdentifier)
            .skipFinalSnapshot(true)
            .build();

        rdsClient.deleteDBCluster(deleteDbClusterRequest);
        System.out.println(dbInstanceClusterIdentifier + " was deleted!");
    } catch (RdsException e) {
        System.out.println(e.getLocalizedMessage());
        System.exit(1);
    }
}
```

- For API details, see [DeleteDBCluster](https://aws-sdk.amazonaws.com/java/latest/api/javaaws/RdsClient.html#deleteDBCluster(DeleteDbClusterRequest)) in AWS SDK for Java 2.x API Reference.

Delete a DB cluster parameter group

The following code example shows how to delete an Aurora DB cluster parameter group.
public static void deleteDBClusterGroup(RdsClient rdsClient, String dbClusterGroupName, String clusterDBARN)
    throws InterruptedException {
    try {
        boolean isDataDel = false;
        boolean didFind;
        String instanceARN;

        // Make sure that the database has been deleted.
        while (!isDataDel) {
            DescribeDbInstancesResponse response =
                rdsClient.describeDBInstances();
            List<DBInstance> instanceList = response.dbInstances();
            int listSize = instanceList.size();
            didFind = false;
            int index = 1;
            for (DBInstance instance : instanceList) {
                instanceARN = instance.dbInstanceArn();
                if (instanceARN.compareTo(clusterDBARN) == 0) {
                    System.out.println(clusterDBARN + " still exists");
                    didFind = true;
                }
                if ((index == listSize) && (!didFind)) {
                    // Went through the entire list and did not find the
                    database ARN.
                    isDataDel = true;
                }
            }
        }
    } catch (InterruptedException e) {
        // wait for DB Cluster to be deleted
        Thread.sleep(sleepTime * 1000);
        index++;
    }

    DeleteDbClusterParameterGroupRequest clusterParameterGroupRequest =
        DeleteDbClusterParameterGroupRequest
Delete a DB instance

The following code example shows how to delete an Aurora DB instance.

SDK for Java 2.x

```java
public static void deleteDatabaseInstance(RdsClient rdsClient, String dbInstanceIdentifier) {
    try {
        DeleteDbInstanceRequest deleteDbInstanceRequest =
            DeleteDbInstanceRequest.builder()
                .dbInstanceIdentifier(dbInstanceIdentifier)
                .deleteAutomatedBackups(true)
                .skipFinalSnapshot(true)
                .build();

        DeleteDbInstanceResponse response =
            rdsClient.deleteDBInstance(deleteDbInstanceRequest);
        System.out.println("The status of the database is " +
            response.dbInstance().dbInstanceStatus());
    } catch (RdsException e) {
        System.out.println(e.getLocalizedMessage());
        System.exit(1);
    }
}
```

Describe DB instances

The following code example shows how to describe Aurora DB instances.
// Waits until the database instance is available.
public static void waitForInstanceReady(RdsClient rdsClient, String dbClusterIdentifier) {
    boolean instanceReady = false;
    String instanceReadyStr;
    System.out.println("Waiting for instance to become available.");
    try {
        DescribeDbClustersRequest instanceRequest =
            DescribeDbClustersRequest.builder()
                .dbClusterIdentifier(dbClusterIdentifier)
                .build();

        while (!instanceReady) {
            DescribeDbClustersResponse response =
                rdsClient.describeDBClusters(instanceRequest);
            List<DBCluster> clusterList = response.dbClusters();
            for (DBCluster cluster : clusterList) {
                instanceReadyStr = cluster.status();
                if (instanceReadyStr.contains("available")) {
                    instanceReady = true;
                } else {
                    System.out.print(".");
                    Thread.sleep(sleepTime * 1000);
                }
            }
        }
        System.out.println("Database cluster is available!");
    }
    } catch (RdsException | InterruptedException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}
● For API details, see DescribeDBInstances in AWS SDK for Java 2.x API Reference.

Describe database engine versions

The following code example shows how to describe Aurora database engine versions.

SDK for Java 2.x

```java
public static void describeDBEngines(RdsClient rdsClient) {
    try {
        DescribeDbEngineVersionsRequest engineVersionsRequest =
            DescribeDbEngineVersionsRequest.builder()

Describe options for DB instances

The following code example shows how to describe options for Aurora DB instances.

```java
public static void describeDBEngines(RdsClient rdsClient) {
    try {
        DescribeDbEngineVersionsRequest engineVersionsRequest =
            DescribeDbEngineVersionsRequest.builder()
                .engine("aurora-mysql")
                .defaultOnly(true)
                .maxRecords(20)
                .build();

        DescribeDbEngineVersionsResponse response =
            rdsClient.describeDBEngineVersions(engineVersionsRequest);
        List<DBEngineVersion> engines = response.dbEngineVersions();

        // Get all DBEngineVersion objects.
        for (DBEngineVersion engineOb : engines) {
            System.out.println("The name of the DB parameter group family for
            the database engine is ",
                + engineOb.dbParameterGroupFamily());
            System.out.println("The name of the database engine " +
                engineOb.engine());
            System.out.println("The version number of the database engine " +
                engineOb.engineVersion());
        }
    } catch (RdsException e) {
        // Handle exception
    }
}
```

**Describe parameters from a DB cluster parameter group**

The following code example shows how to describe parameters from an Aurora DB cluster parameter group.

**SDK for Java 2.x**

```java
public static void describeDbClusterParameters(RdsClient rdsClient, String dbClusterGroupName, int flag) {
    try {
        DescribeDbClusterParametersRequest dbParameterGroupsRequest;
        if (flag == 0) {
            dbParameterGroupsRequest = DescribeDbClusterParametersRequest.builder()
                .dbClusterParameterGroupName(dbClusterGroupName)
                .build();
        } else {
            dbParameterGroupsRequest = DescribeDbClusterParametersRequest.builder()
                .dbClusterParameterGroupName(dbClusterGroupName)
                .source("user")
                .build();
        }

        DescribeDbClusterParametersResponse response = rdsClient.describeDBClusterParameters(dbParameterGroupsRequest);
    }
    catch (RdsException e) {
        System.out.println(e.getLocalizedMessage());
        System.exit(1);
    }
}
```

Update parameters in a DB cluster parameter group

The following code example shows how to update parameters in an Aurora DB cluster parameter group.

SDK for Java 2.x

ℹ️ Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
public static void describeDbClusterParameterGroups(RdsClient rdsClient, String dbClusterGroupName) {
    try {
        DescribeDbClusterParameterGroupsRequest groupsRequest =
            DescribeDbClusterParameterGroupsRequest.builder()
                .dbClusterParameterGroupName(dbClusterGroupName)
                .maxRecords(20)
                .build();

        List<DBClusterParameterGroup> groups =
            rdsClient.describeDBClusterParameterGroups(groupsRequest)
                .dbClusterParameterGroups();
        for (DBClusterParameterGroup group : groups) {
            System.out.println("The group name is "+
                group.dbClusterParameterGroupName());
            System.out.println("The group ARN is "+
                group.dbClusterParameterGroupArn());
        }
    } catch (RdsException e) {
        System.out.println(e.getLocalizedMessage());
        System.exit(1);
    }
}

Scenarios

Get started with DB clusters

The following code example shows how to:

- Create a custom Aurora DB cluster parameter group and set parameter values.
- Create a DB cluster that uses the parameter group.
- Create a DB instance that contains a database.
- Take a snapshot of the DB cluster, then clean up resources.

For API details, see [ModifyDBClusterParameterGroup](#) in [AWS SDK for Java 2.x API Reference](#).
Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```java
/**
 * Before running this Java (v2) code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * This example requires an AWS Secrets Manager secret that contains the
 * database credentials. If you do not create a
 * secret, this example will not work. For details, see:
 *
 * https://docs.aws.amazon.com/secretsmanager/latest/userguide/integrating_how-servers-use-secrets_RS.html
 *
 * This Java example performs the following tasks:
 *
 * 1. Gets available engine families for Amazon Aurora MySQL-Compatible Edition
 * by calling the DescribeDbEngineVersions(Engine='aurora-mysql') method.
 * 2. Selects an engine family and creates a custom DB cluster parameter group
 * by invoking the describeDBClusterParameters method.
 * 3. Gets the parameter groups by invoking the describeDBClusterParameterGroups
 * method.
 * 4. Gets parameters in the group by invoking the describeDBClusterParameters
 * method.
 * 5. Modifies the auto_increment_offset parameter by invoking the
 * modifyDbClusterParameterGroupRequest method.
 * 6. Gets and displays the updated parameters.
 * 7. Gets a list of allowed engine versions by invoking the
 * describeDbEngineVersions method.
 * 8. Creates an Aurora DB cluster database cluster that contains a MySQL
 * database.
 * 9. Waits for DB instance to be ready.
 * 10. Gets a list of instance classes available for the selected engine.
```
11. Creates a database instance in the cluster.
12. Waits for DB instance to be ready.
13. Creates a snapshot.
14. Waits for DB snapshot to be ready.
15. Deletes the DB cluster.
16. Deletes the DB cluster group.

```java
public class AuroraScenario {
    public static long sleepTime = 20;
    public static final String DASHES = new String(new char[80]).replace("\0", "-"uide);

    public static void main(String[] args) throws InterruptedException {
        final String usage = "\n" +
            "Usage:\n" +
            "    <dbClusterGroupName> <dbParameterGroupFamily>
<dbInstanceClusterIdentifier> <dbInstanceIdentifier> <dbName>
<dbSnapshotIdentifier><secretName>"
        +
            "Where:\n" +
            "    dbClusterGroupName - The name of the DB cluster parameter
    
    dbParameterGroupFamily - The DB cluster parameter group family
    name (for example, aurora-mysql5.7). \n" +
            "    dbInstanceClusterIdentifier - The instance cluster identifier
    
    dbInstanceIdentifier - The database instance identifier.\n" +
            "    dbName - The database name.\n" +
            "    dbSnapshotIdentifier - The snapshot identifier.\n" +
            "    secretName - The name of the AWS Secrets Manager secret that
    contains the database credentials"\n";

**Auto Scaling examples using SDK for Java 2.x**

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Auto Scaling.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

**Get started**
Hello Auto Scaling

The following code examples show how to get started using Auto Scaling.

SDK for Java 2.x

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.autoscaling.AutoScalingClient;
import software.amazon.awssdk.services.autoscaling.model.AutoScalingGroup;
import software.amazon.awssdk.services.autoscaling.model.DescribeAutoScalingGroupsResponse;
import java.util.List;

/**
 * Before running this SDK for Java (v2) code example, set up your development environment, including your credentials.
 * For more information, see the following documentation:
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class DescribeAutoScalingGroups {
    public static void main(String[] args) throws InterruptedException {
        AutoScalingClient autoScalingClient = AutoScalingClient.builder()
            .region(Region.US_EAST_1)
            .build();

        describeGroups(autoScalingClient);
    }

    public static void describeGroups(AutoScalingClient autoScalingClient) {
        DescribeAutoScalingGroupsResponse response = autoScalingClient.describeAutoScalingGroups();
        List<AutoScalingGroup> groups = response.autoScalingGroups();
        groups.forEach(group -> {
            System.out.println("Group Name: " + group.autoScalingGroupName());
            System.out.println("Group ARN: " + group.autoScalingGroupARN());
        });
    }
}
```

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/aws/aws-sdk-java/tree/master/code-examples/services/services-service-example).
• For API details, see DescribeAutoScalingGroups in AWS SDK for Java 2.x API Reference.

• Actions
• Scenarios

Actions

Create a group

The following code example shows how to create an Auto Scaling group.

SDK for Java 2.x

```java
import software.amazon.awssdk.core.waiters.WaiterResponse;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.autoscaling.AutoScalingClient;
import software.amazon.awssdk.services.autoscaling.model.AutoScalingException;
import software.amazon.awssdk.services.autoscaling.model.CreateAutoScalingGroupRequest;
import software.amazon.awssdk.services.autoscaling.model.DescribeAutoScalingGroupsRequest;
import software.amazon.awssdk.services.autoscaling.model.DescribeAutoScalingGroupsResponse;
import software.amazon.awssdk.services.autoscaling.model.LaunchTemplateSpecification;
import software.amazon.awssdk.services.autoscaling.waiters.AutoScalingWaiter;
```
Before running this SDK for Java (v2) code example, set up your development environment, including your credentials.

For more information, see the following documentation:

https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html

```java
public class CreateAutoScalingGroup {
    public static void main(String[] args) {
        final String usage = ""

        Usage:
        <groupName> <launchTemplateName> <serviceLinkedRoleARN>
        <vpcZoneId>

        Where:
        groupName - The name of the Auto Scaling group.
        launchTemplateName - The name of the launch template.
        vpcZoneId - A subnet Id for a virtual private cloud (VPC) where instances in the Auto Scaling group can be created.

        if (args.length != 3) {
            System.out.println(usage);
            System.exit(1);
        }

        String groupName = args[0];
        String launchTemplateName = args[1];
        String vpcZoneId = args[2];
        AutoScalingClient autoScalingClient = AutoScalingClient.builder()
            .region(Region.US_EAST_1)
            .build();

        createAutoScalingGroup(autoScalingClient, groupName, launchTemplateName, vpcZoneId);
        autoScalingClient.close();
    }

    public static void createAutoScalingGroup(AutoScalingClient autoScalingClient,
                                              String groupName,
                                              String launchTemplateName,
                                              String vpcZoneId) {
```
try {
    AutoScalingWaiter waiter = autoScalingClient.waiter();
    LaunchTemplateSpecification templateSpecification =
        LaunchTemplateSpecification.builder()
            .launchTemplateName(launchTemplateName)
            .build();

            autoScalingClient.describeAutoScalingInstances(describeAutoScalingInstancesRequest);
    } catch (AutoScalingException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
DescribeAutoScalingInstancesResponse response = autoScalingClient.describeAutoScalingInstances(describeAutoScalingInstancesRequest);
List<AutoScalingInstanceDetails> instances = response.autoScalingInstances();
for (AutoScalingInstanceDetails instance : instances) {
    System.out.println("The instance lifecycle state is: " + instance.lifecycleState());
}
}

} catch (AutoScalingException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

} }

• For API details, see DescribeAutoScalingInstances in AWS SDK for Java 2.x API Reference.

Get information about scaling activities

The following code example shows how to get information about Auto Scaling activities.

SDK for Java 2.x

public static void describeScalingActivities(AutoScalingClient autoScalingClient, String groupName) {
    try {
        DescribeScalingActivitiesRequest scalingActivitiesRequest = DescribeScalingActivitiesRequest.builder() .autoScalingGroupName(groupName) .maxRecords(10) .build();
    
    } catch (AutoScalingException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
DescribeScalingActivitiesResponse response = autoScalingClient.describeScalingActivities(scalingActivitiesRequest);
List<Activity> activities = response.activities();
for (Activity activity : activities) {
    System.out.println("The activity Id is " + activity.activityId());
    System.out.println("The activity details are " +
    activity.details());
}

} catch (AutoScalingException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

• For API details, see DescribeScalingActivities in AWS SDK for Java 2.x API Reference.

Set the desired capacity of a group

The following code example shows how to set the desired capacity of an Auto Scaling group.

SDK for Java 2.x

public static void setDesiredCapacity(AutoScalingClient autoScalingClient, 
String groupName) {
    try {
        SetDesiredCapacityRequest capacityRequest = 
        SetDesiredCapacityRequest.builder()
            .autoScalingGroupName(groupName)
            .desiredCapacity(2)
            .build();

        autoScalingClient.setDesiredCapacity(capacityRequest);
System.out.println("You have set the DesiredCapacity to 2");

} catch (AutoScalingException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

For API details, see `SetDesiredCapacity` in *AWS SDK for Java 2.x API Reference*.

**Terminate an instance in a group**

The following code example shows how to terminate an instance in an Auto Scaling group.

**SDK for Java 2.x**

```
public static void terminateInstanceInAutoScalingGroup(AutoScalingClient autoScalingClient, String instanceId) {
    try {
        TerminateInstanceInAutoScalingGroupRequest request =
            TerminateInstanceInAutoScalingGroupRequest.builder()
                .instanceId(instanceId)
                .shouldDecrementDesiredCapacity(false)
                .build();

        autoScalingClient.terminateInstanceInAutoScalingGroup(request);
        System.out.println("You have terminated instance " + instanceId);
    } catch (AutoScalingException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/aws-samples/aws-code-examples).
• For API details, see TerminateInstanceInAutoScalingGroup in AWS SDK for Java 2.x API Reference.

Update a group

The following code example shows how to update the configuration for an Auto Scaling group.

SDK for Java 2.x

```java
public static void updateAutoScalingGroup(AutoScalingClient autoScalingClient, String groupName, String launchTemplateName) {
    try {
        AutoScalingWaiter waiter = autoScalingClient.waiter();
        LaunchTemplateSpecification templateSpecification = LaunchTemplateSpecification.builder()
            .launchTemplateName(launchTemplateName)
            .build();

        UpdateAutoScalingGroupRequest groupRequest = UpdateAutoScalingGroupRequest.builder()  
            .maxSize(3)  
            .autoScalingGroupName(groupName)  
            .launchTemplate(templateSpecification)  
            .build();

        autoScalingClient.updateAutoScalingGroup(groupRequest);
        DescribeAutoScalingGroupsRequest groupsRequest = DescribeAutoScalingGroupsRequest.builder()  
            .autoScalingGroupNames(groupName)  
            .build();

        WaiterResponse<DescribeAutoScalingGroupsResponse> waiterResponse = waiter
            .waitUntilGroupInService(groupsRequest);
        waiterResponse.matched().response().ifPresent(System.out::println);
```
System.out.println("You successfully updated the auto scaling group " +
groupName);

} catch (AutoScalingException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

- For API details, see [UpdateAutoScalingGroup](#) in *AWS SDK for Java 2.x API Reference*.

### Scenarios

#### Build and manage a resilient service

The following code example shows how to create a load-balanced web service that returns book, movie, and song recommendations. The example shows how the service responds to failures, and how to restructure the service for more resilience when failures occur.

- Use an Amazon EC2 Auto Scaling group to create Amazon Elastic Compute Cloud (Amazon EC2) instances based on a launch template and to keep the number of instances in a specified range.
- Handle and distribute HTTP requests with Elastic Load Balancing.
- Monitor the health of instances in an Auto Scaling group and forward requests only to healthy instances.
- Run a Python web server on each EC2 instance to handle HTTP requests. The web server responds with recommendations and health checks.
- Simulate a recommendation service with an Amazon DynamoDB table.
- Control web server response to requests and health checks by updating AWS Systems Manager parameters.

### SDK for Java 2.x

Creating an Elastic Load Balancing target group and load balancer.
The target group defines how the load balancer connects to instances. The load balancer provides a single endpoint where clients connect and dispatches requests to instances in the group.

```java
String vpcId = autoScaler.getDefaultVPC();
List<Subnet> subnets = autoScaler.getSubnets(vpcId, zones);
System.out.println("You have retrieved a list with " + subnets.size() + " subnets");
String targetGroupArn = loadBalancer.createTargetGroup(protocol, port, vpcId, targetGroupName);
String elbDnsName = loadBalancer.createLoadBalancer(subnets, targetGroupArn, lbName, port, protocol);
autoScaler.attachLoadBalancerTargetGroup(autoScalingGroupName, targetGroupArn);
System.out.println("Verifying access to the load balancer endpoint...");
boolean wasSuccessful = loadBalancer.verifyLoadBalancerEndpoint(elbDnsName);
if (!wasSuccessful) {
    System.out.println("Couldn't connect to the load balancer, verifying that the port is open...");
    CloseableHttpClient httpclient = HttpClients.createDefault();

    // Create an HTTP GET request to "http://checkip.amazonaws.com"
    HttpGet httpGet = new HttpGet("http://checkip.amazonaws.com");
    try {
```
// Execute the request and get the response
HttpResponse response = httpClient.execute(httpGet);

// Read the response content.
String ipAddress =
IOUtils.toString(response.getEntity().getContent(), StandardCharsets.UTF_8).trim();

// Print the public IP address.
System.out.println("Public IP Address: "+ ipAddress);
GroupInfo groupInfo = autoScaler.verifyInboundPort(vpcId, port, ipAddress);

if (!groupInfo.isPortOpen()) {
    System.out.println("For this example to work, the default security group for 
your default VPC must 
automatically from this 
example or add it yourself using the AWS Management 
Console.
    
    ");

    System.out.println( 
        "Do you want to add a rule to security group "+ 
groupInfo.getGroupName() + " to allow");
    System.out.println("inbound traffic on port "+ port + " from 
your computer's IP address (y/n)");
    String ans = in.nextLine();
    if ("y".equalsIgnoreCase(ans)) {
        autoScaler.openInboundPort(groupInfo.getGroupName(), String.valueOf(port), ipAddress);
    } else {
        System.out.println("Security group rule added.");
    }
}

} catch (AutoScalingException e) {
    e.printStackTrace();
} else if (wasSuccessul) {
    System.out.println("Your load balancer is ready. You can access it by 
browsing to:");
    System.out.println("\t http://" + elbDnsName);
} else {
System.out.println("Couldn't get a successful response from the load balancer endpoint. Troubleshoot by");
System.out.println("manually verifying that your VPC and security group are configured correctly and that");

    This part of the demonstration shows how to toggle different parts of the system to create situations where the web service fails, and shows how using a resilient architecture can keep the web service running in spite of these failures.
    """
);
    demoChoices(loadBalancer);

    System.out.println("""
    The web service running on the EC2 instances gets recommendations by querying a DynamoDB table. The table name is contained in a Systems Manager parameter named self.param_helper.table.
    """
);
To simulate a failure of the recommendation service, let's set this parameter to name a non-existent table.

```java
paramHelper.put(paramHelper.tableName, "this-is-not-a-table");

System.out.println("\nNow, sending a GET request to the load balancer endpoint returns a failure code. But, the service reports as healthy to the load balancer because shallow health checks don't check for failure of the recommendation service.\n\n")
demoChoices(loadBalancer);

System.out.println("Instead of failing when the recommendation service fails, the web service can return a static response. While this is not a perfect solution, it presents the customer with a somewhat better experience than failure.\n")
paramHelper.put(paramHelper.failureResponse, "static");

System.out.println("Now, sending a GET request to the load balancer endpoint returns a static response. The service still reports as healthy because health checks are still shallow.\n")
demoChoices(loadBalancer);

System.out.println("Let's reinstate the recommendation service.");
paramHelper.put(paramHelper.tableName, paramHelper.dyntable);

System.out.println("Let's also substitute bad credentials for one of the instances in the target group so that it can't access the DynamoDB recommendation table. We will get an instance id value.\n")
```

LaunchTemplateCreator templateCreator = new LaunchTemplateCreator();
AutoScaler autoScaler = new AutoScaler();
// Create a new instance profile based on badCredsProfileName.
    templateCreator.createInstanceProfile(policyFile, policyName, badCredsProfileName, roleName);
    String badInstanceId = autoScaler.getBadInstance(autoScalingGroupName);
    System.out.println("The bad instance id values used for this demo is " + badInstanceId);

    String profileAssociationId = autoScaler.getInstanceProfile(badInstanceId);
    System.out.println("The association Id value is " + profileAssociationId);
    System.out.println("Replacing the profile for instance " + badInstanceId + " with a profile that contains bad credentials");
    autoScaler.replaceInstanceProfile(badInstanceId, badCredsProfileName, profileAssociationId);

    System.out.println("""Now, sending a GET request to the load balancer endpoint
returns either a recommendation or a static response,
depending on which instance is selected by the load
balancer."""");

demoChoices(loadBalancer);

    System.out.println("""
Let's implement a deep health check. For this demo, a deep health
check tests whether
the web service can access the DynamoDB table that it depends on for
recommendations. Note that
the deep health check is only for ELB routing and not for Auto
Scaling instance health.
This kind of deep health check is not recommended for Auto Scaling
instance health, because it
risks accidental termination of all instances in the Auto Scaling
group when a dependent service fails.
"""");

    System.out.println("""
By implementing deep health checks, the load balancer can detect
when one of the instances is failing
and take that instance out of rotation.
"""");

    paramHelper.put(paramHelper.healthCheck, "deep");
Now, checking target health indicates that the instance with bad credentials is unhealthy. Note that it might take a minute or two for the load balancer to detect the unhealthy instance. Sending a GET request to the load balancer endpoint always returns a recommendation, because the load balancer takes unhealthy instances out of its rotation.

Because the instances in this demo are controlled by an auto scaler, the simplest way to fix an unhealthy instance is to terminate it and let the auto scaler start a new instance to replace it.

Even while the instance is terminating and the new instance is starting, sending a GET request to the web service continues to get a successful recommendation response because the load balancer routes requests to the healthy instances. After the replacement instance starts and reports as healthy, it is included in the load balancing rotation. Note that terminating and replacing an instance typically takes several minutes, during which time you can see the changing health check status until the new instance is running and healthy.

If the recommendation service fails now, deep health checks mean all instances report as unhealthy.

Auto Scaling

Manage groups and instances

The following code example shows how to:

• Create an Amazon EC2 Auto Scaling group with a launch template and Availability Zones, and get information about running instances.

• Enable Amazon CloudWatch metrics collection.

• Update the group's desired capacity and wait for an instance to start.

• Terminate an instance in the group.
• List scaling activities that occur in response to user requests and capacity changes.
• Get statistics for CloudWatch metrics, then clean up resources.

SDK for Java 2.x

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/awslabs/aws-code-examples).

```java
/**
 * Before running this SDK for Java (v2) code example, set up your development environment, including your credentials.
 *
 * For more information, see the following documentation:
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * In addition, create a launch template. For more information, see the following topic:
 *
 * This code example performs the following operations:
 * 1. Creates an Auto Scaling group using an AutoScalingWaiter.
 * 2. Gets a specific Auto Scaling group and returns an instance Id value.
 * 3. Describes Auto Scaling with the Id value.
 * 5. Update an Auto Scaling group.
 * 7. Describe account details" 
 * 8. Updates an Auto Scaling group to use an additional instance.
 * 9. Gets the specific Auto Scaling group and gets the number of instances.
 * 10. List the scaling activities that have occurred for the group.
 * 11. Terminates an instance in the Auto Scaling group.
 * 12. Stops the metrics collection.
 * 13. Deletes the Auto Scaling group.
 */

Amazon Bedrock examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon Bedrock.
Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Get details about an Amazon Bedrock foundation model

The following code example shows how to get details about an Amazon Bedrock foundation model.

SDK for Java 2.x

```java
/**
 * Get details about an Amazon Bedrock foundation model.
 *
 * @param bedrockClient The service client for accessing Amazon Bedrock.
 * @param modelIdentifier The model identifier.
 * @return An object containing the foundation model's details.
 */
public static FoundationModelDetails getFoundationModel(BedrockClient bedrockClient, String modelIdentifier) {
    try {
```
Get details about a foundation model using the asynchronous Amazon Bedrock client.

```java
GetFoundationModelResponse response = bedrockClient.getFoundationModel(
    r -> r.modelIdentifier(modelIdentifier)
);

FoundationModelDetails model = response.modelDetails();

System.out.println(" Model ID: " + model.modelId());
System.out.println(" Model ARN: "+
    model.modelArn());
System.out.println(" Model Name: " +
    model.modelName());
    System.out.println(" Provider Name: " +
    model.providerName());
System.out.println(" Lifecycle status: " +
    model.modelLifecycle().statusAsString());
System.out.println(" Input modalities: " +
    model.inputModalities());
System.out.println(" Output modalities: " +
    model.outputModalities());
System.out.println(" Supported customizations: " +
    model.customizationsSupported());
System.out.println(" Supported inference types: " +
    model.inferenceTypesSupported());
System.out.println(" Response streaming supported: " +
    model.responseStreamingSupported());

return model;

} catch (ValidationException e) {
    throw new IllegalArgumentException(e.getMessage());
} catch (SdkException e) {
    System.err.println(e.getMessage());
    throw new RuntimeException(e);
}
```
* @param modelIdentifier The model identifier.
* @return An object containing the foundation model's details.
*/

public static FoundationModelDetails getFoundationModel(BedrockAsyncClient bedrockClient, String modelIdentifier) {
    try {
        CompletableFuture<GetFoundationModelResponse> future = bedrockClient.getFoundationModel(
            r -> r.modelIdentifier(modelIdentifier)
        );

        FoundationModelDetails model = future.get().modelDetails();

List available Amazon Bedrock foundation models

The following code example shows how to list available Amazon Bedrock foundation models.

SDK for Java 2.x

For API details, see [GetFoundationModel](#) in *AWS SDK for Java 2.x API Reference*.

```
/**
 * Lists Amazon Bedrock foundation models that you can use.
 * You can filter the results with the request parameters.
 * @param bedrockClient The service client for accessing Amazon Bedrock.
 * @return A list of objects containing the foundation models' details
 */
public static List<FoundationModelSummary> listFoundationModels(BedrockClient bedrockClient) {
    try {
        ListFoundationModelsResponse response =
            bedrockClient.listFoundationModels(r -> {});

        List<FoundationModelSummary> models = response.modelSummaries();

        if (models.isEmpty()) {
            System.out.println("No available foundation models in " +
                region.toString());
        }
```

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).
List the available Amazon Bedrock foundation models using the asynchronous Amazon Bedrock client.

```java
/**
 * Lists Amazon Bedrock foundation models that you can use.
 * You can filter the results with the request parameters.
 */

public static List<FoundationModelSummary> listFoundationModels(BedrockAsyncClient bedrockClient) {
    try {
        CompletableFuture<ListFoundationModelsResponse> future =
            bedrockClient.listFoundationModels(r -> {});

        List<FoundationModelSummary> models = future.get().modelSummaries();

        if (models.isEmpty()) {
            System.out.println("No available foundation models in " +
                region.toString());
        } else {
            for (FoundationModelSummary model : models) {
                System.out.println("Model ID: " + model.modelId());
                System.out.println("Provider: " + model.providerName());
                System.out.println("Name: " + model.modelName());
            }
        }
    }
}
```
```java
    System.out.println("Name:     " + model.modelName());
    System.out.println;
    }
    }

    return models;

} catch (InterruptedException e) {

**Amazon Bedrock Runtime examples using SDK for Java 2.x**

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon Bedrock Runtime.

**Actions** are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

**Scenarios** are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Scenarios

Create a playground application to interact with Amazon Bedrock foundation models

The following code example shows how to create playgrounds to interact with Amazon Bedrock foundation models through different modalities.

SDK for Java 2.x

The Java Foundation Model (FM) Playground is a Spring Boot sample application that showcases how to use Amazon Bedrock with Java. This example shows how Java developers can use Amazon Bedrock to build generative AI-enabled applications. You can test and interact with Amazon Bedrock foundation models by using the following three playgrounds:

• A text playground.
• A chat playground.
• An image playground.

The example also lists and displays the foundation models you have access to, along with their characteristics. For source code and deployment instructions, see the project in GitHub.

Services used in this example

• Amazon Bedrock Runtime
CloudFront examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with CloudFront.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Create a function

The following code example shows how to create an Amazon CloudFront function.
import software.amazon.awssdk.core.SdkBytes;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.cloudfront.CloudFrontClient;
import software.amazon.awssdk.services.cloudfront.model.CloudFrontException;
import software.amazon.awssdk.services.cloudfront.model.CreateFunctionRequest;
import software.amazon.awssdk.services.cloudfront.model.CreateFunctionResponse;
import software.amazon.awssdk.services.cloudfront.model.FunctionConfig;
import software.amazon.awssdk.services.cloudfront.model.FunctionRuntime;
import java.io.InputStream;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 * *
 * For more information, see the following documentation topic:
 * *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */

public class CreateFunction {

    public static void main(String[] args) {
        final String usage = """";

        Usage:
        <functionName> <filePath>

        Where:
        functionName - The name of the function to create.\n        filePath - The path to a file that contains the application
        logic for the function.\n        """;

        if (args.length != 2) {
            System.out.println(usage);
        }
System.exit(1);
}

String functionName = args[0];
String filePath = args[1];
CloudFrontClient cloudFrontClient = CloudFrontClient.builder()
    .region(Region.AWS_GLOBAL)
    .build();

String funArn = createNewFunction(cloudFrontClient, functionName, filePath);
System.out.println("The function ARN is " + funArn);
cloudFrontClient.close();
}

public static String createNewFunction(CloudFrontClient cloudFrontClient, String
functionName, String filePath) {
    try {
        InputStream fileIs =
CreateFunction.class.getClassLoader().getResourceAsStream(filePath);
        SdkBytes functionCode = SdkBytes.fromInputStream(fileIs);

        FunctionConfig config = FunctionConfig.builder()
            .comment("Created by using the CloudFront Java API")
            .runtime(FunctionRuntime.CLOUDFRONT_JS_1_0)
            .build();

            .name(functionName)
            .functionCode(functionCode)
            .functionConfig(config)
            .build();

        CreateFunctionResponse response =
cloudFrontClient.createFunction(functionRequest);
        return response.functionSummary().functionMetadata().functionARN();
    } catch (CloudFrontException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
    return "";
}
For API details, see CreateFunction in AWS SDK for Java 2.x API Reference.

Create a key group

The following code example shows how to create a key group that you can use with signed URLs and signed cookies.

SDK for Java 2.x

A key group requires at least one public key that is used to verify signed URLs or cookies.

```java
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.services.cloudfront.CloudFrontClient;
import java.util.UUID;

public class CreateKeyGroup {
    private static final Logger logger = LoggerFactory.getLogger(CreateKeyGroup.class);

    public static String createKeyGroup(CloudFrontClient cloudFrontClient, String publicKeyId) {
        String keyGroupId = cloudFrontClient.createKeyGroup(b -> b.keyGroupConfig(c ->
            c.items(publicKeyId).
                name("JavaKeyGroup" + UUID.randomUUID()).
                keyGroup().id();
        ).keyGroup().id();
        logger.info("KeyGroup created with ID: ", keyGroupId);
        return keyGroupId;
    }
}
```
Delete a distribution

The following code example shows how to delete a CloudFront distribution.

SDK for Java 2.x

```java
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.core.internal.waiters.ResponseOrException;
import software.amazon.awssdk.services.cloudfront.CloudFrontClient;
import software.amazon.awssdk.services.cloudfront.model.DeleteDistributionResponse;
import software.amazon.awssdk.services.cloudfront.model.DistributionConfig;
import software.amazon.awssdk.services.cloudfront.waiters.CloudFrontWaiter;

public class DeleteDistribution {
    private static final Logger logger = LoggerFactory.getLogger(DeleteDistribution.class);

    public static void deleteDistribution(final CloudFrontClient cloudFrontClient, final String distributionId) {
        // First, disable the distribution by updating it.
        GetDistributionResponse response = cloudFrontClient.getDistribution(b -> b
            .id(distributionId));
        String etag = response.eTag();
        DistributionConfig distConfig = response.distribution().distributionConfig();

        cloudFrontClient.updateDistribution(builder -> builder
            .id(distributionId))
```
.distributionConfig(builder1 -> builder1

  .cacheBehaviors(distConfig.cacheBehaviors())

  .defaultCacheBehavior(distConfig.defaultCacheBehavior())
    .enabled(false)
    .origins(distConfig.origins())
    .comment(distConfig.comment())

  .callerReference(distConfig.callerReference())

  .defaultCacheBehavior(distConfig.defaultCacheBehavior())
    .priceClass(distConfig.priceClass())
    .aliases(distConfig.aliases())

  • DeleteOriginAccessControl
  • DeletePublicKey

Update a distribution

The following code example shows how to update an Amazon CloudFront distribution.

SDK for Java 2.x

import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.cloudfront.CloudFrontClient;
import software.amazon.awssdk.services.cloudfront.model.GetDistributionRequest;
import software.amazon.awssdk.services.cloudfront.model.GetDistributionResponse;
import software.amazon.awssdk.services.cloudfront.model.Distribution;
import software.amazon.awssdk.services.cloudfront.model.DistributionConfig;
import software.amazon.awssdk.services.cloudfront.model.UpdateDistributionRequest;
import software.amazon.awssdk.services.cloudfront.model.CloudFrontException;

/**
 * Before running this Java V2 code example, set up your development
public class ModifyDistribution {
    public static void main(String[] args) {
        final String usage = ""
        Usage:
            <id>\s
            Where:
            id - the id value of the distribution.\s
        "";

        if (args.length != 1) {
            System.out.println(usage);
            System.exit(1);
        }

        String id = args[0];
        CloudFrontClient cloudFrontClient = CloudFrontClient.builder()
            .region(Region.AWS_GLOBAL)
            .build();

        modDistribution(cloudFrontClient, id);
        cloudFrontClient.close();
    }

    public static void modDistribution(CloudFrontClient cloudFrontClient, String idVal) {
        try {
            // Get the Distribution to modify.
            GetDistributionRequest disRequest = GetDistributionRequest.builder()
                .id(idVal)
                .build();

            GetDistributionResponse response = cloudFrontClient.getDistribution(disRequest);
            Distribution disObject = response.distribution();
            DistributionConfig config = disObject.distributionConfig();
            CloudFront
// Create a new DistributionConfig object and add new values to comment and aliases

DistributionConfig config1 = DistributionConfig.builder()
    .aliases(config.aliases()) // You can pass in new values here
    .comment("New Comment")
    .cacheBehaviors(config.cacheBehaviors())
    .priceClass(config.priceClass())
    .defaultCacheBehavior(config.defaultCacheBehavior())
    .enabled(config.enabled())
    .callerReference(config.callerReference())
    .logging(config.logging())
    .originGroups(config.originGroups())
    .origins(config.origins())
    .restrictions(config.restrictions())
    .defaultRootObject(config.defaultRootObject())
    .webACLId(config.webACLId())
    .viewerCertificate(config.viewerCertificate())
    .customErrorResponses(config.customErrorResponses())
    .build();

UpdateDistributionRequest updateDistributionRequest =
    UpdateDistributionRequest.builder()
    .distributionConfig(config1)
    .id(disObject.id())
    .ifMatch(response.eTag())
    .build();

cloudFrontClient.updateDistribution(updateDistributionRequest);

} catch (CloudFrontException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

• For API details, see [UpdateDistribution](#) in [AWS SDK for Java 2.x API Reference](#).
Upload a public key

The following code example shows how to upload a public key.

SDK for Java 2.x

The following code example reads in a public key and uploads it to Amazon CloudFront.

```java
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.services.cloudfront.CloudFrontClient;
import software.amazon.awssdk.services.cloudfront.model.CreatePublicKeyResponse;
import software.amazon.awssdk.utils.IoUtils;

import java.io.IOException;
import java.io.InputStream;
import java.util.UUID;

public class CreatePublicKey {
    private static final Logger logger = LoggerFactory.getLogger(CreatePublicKey.class);

    public static String createPublicKey(CloudFrontClient cloudFrontClient, String publicKeyFileName) {
        try (InputStream is = CreatePublicKey.class.getClassLoader().getResourceAsStream(publicKeyFileName)) {
            String publicKeyString = IoUtils.toUtf8String(is);
            CreatePublicKeyResponse createPublicKeyResponse = cloudFrontClient
                .createPublicKey(b -> b.publicKeyConfig(c -> c
                    .name("JavaCreatedPublicKey" + UUID.randomUUID())
                    .encodedKey(publicKeyString)
                    .callerReference(UUID.randomUUID().toString())));
            String createdPublicKeyId = createPublicKeyResponse.publicKey().id();
            logger.info("Public key created with id: [{}]", createdPublicKeyId);
            return createdPublicKeyId;
        } catch (IOException e) {
```

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
Scenarios

Sign URLs and cookies

The following code example shows how to create signed URLs and cookies that allow access to restricted resources.

SDK for Java 2.x

Use the `CannedSignerRequest` class to sign URLs or cookies with a `canned` policy.

```java
import software.amazon.awssdk.services.cloudfront.model.CannedSignerRequest;

import java.net.URL;
import java.nio.file.Path;
import java.nio.file.Paths;
import java.time.Instant;
import java.time.temporal.ChronoUnit;

public class CreateCannedPolicyRequest {
    public static CannedSignerRequest createRequestForCannedPolicy(String distributionDomainName, String fileNameToUpload, String privateKeyFullPath, String publicKeyId) throws Exception {
        String protocol = "https";
        String resourcePath = "/" + fileNameToUpload;
```

• For API details, see [CreatePublicKey](#) in *AWS SDK for Java 2.x API Reference*.

---

CloudFront

580
Use the `CustomSignerRequest` class to sign URLs or cookies with a custom policy. The `activeDate` and `ipRange` are optional methods.

```java
import software.amazon.awssdk.services.cloudfront.model.CustomSignerRequest;
import java.net.URL;
import java.nio.file.Path;
import java.nio.file.Paths;
import java.time.Instant;
import java.time.temporal.ChronoUnit;

public class CreateCustomPolicyRequest {

    public static CustomSignerRequest createRequestForCustomPolicy(String distributionDomainName,
            String fileNameToUpload,
            String privateKeyFullPath, String publicKeyId) throws Exception {
        String protocol = "https";
        String resourcePath = "/" + fileNameToUpload;

        String cloudFrontUrl = new URL(protocol, distributionDomainName,
                resourcePath).toString();
        Instant expireDate = Instant.now().plus(7, ChronoUnit.DAYS);
        Path path = Paths.get(privateKeyFullPath);

        return CannedSignerRequest.builder()
                .resourceUrl(cloudFrontUrl)
                .privateKey(path)
                .keyPairId(publicKeyId)
                .expirationDate(expirationDate)
                .build();
    }
}
```
The following example demonstrates the use of the `CloudFrontUtilities` class to produce signed cookies and URLs. [View](https://github.com/aws/aws-sdk-java) this code example on GitHub.

```java
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.services.cloudfront.CloudFrontUtilities;
import software.amazon.awssdk.services.cloudfront.cookie.CookiesForCannedPolicy;
import software.amazon.awssdk.services.cloudfront.cookie.CookiesForCustomPolicy;
import software.amazon.awssdk.services.cloudfront.model.CannedSignerRequest;
import software.amazon.awssdk.services.cloudfront.model.CustomSignerRequest;
import software.amazon.awssdk.services.cloudfront.url.SignedUrl;

public class SigningUtilities {
    private static final Logger logger =
            LoggerFactory.getLogger(SigningUtilities.class);
    private static final CloudFrontUtilities cloudFrontUtilities =
            CloudFrontUtilities.create();

    public static SignedUrl signUrlForCannedPolicy(CannedSignerRequest cannedSignerRequest) {
        SignedUrl signedUrl =
                cloudFrontUtilities.getSignedUrlWithCannedPolicy(cannedSignerRequest);
        logger.info("Signed URL: [{}]", signedUrl.url());
        return signedUrl;
    }

    public static SignedUrl signUrlForCustomPolicy(CustomSignerRequest customSignerRequest) {
        SignedUrl signedUrl =
                cloudFrontUtilities.getSignedUrlWithCustomPolicy(customSignerRequest);
        logger.info("Signed URL: [{}]", signedUrl.url());
        return signedUrl;
    }
}
```
return signedUrl;
}

public static CookiesForCannedPolicy get_cookies_for_canned_policy(CannedSignerRequest cannedSignerRequest) {
    CookiesForCannedPolicy cookiesForCannedPolicy = cloudFrontUtilities.get_cookies_for_canned_policy(cannedSignerRequest);
    logger.info("Cookie EXPIRES header 
[]",
    cookiesForCannedPolicy.expiresHeaderValue());
    logger.info("Cookie KEYPAIR header 
[]",
    cookiesForCannedPolicy.keyPairIdHeaderValue());
    logger.info("Cookie SIGNATURE header 
[]",
    cookiesForCannedPolicy.signatureHeaderValue());
    return cookiesForCannedPolicy;
}

public static CookiesForCustomPolicy get_cookies_for_custom_policy(CustomSignerRequest customSignerRequest) {
    CookiesForCustomPolicy cookiesForCustomPolicy = cloudFrontUtilities.get_cookies_for_custom_policy(customSignerRequest);
    logger.info("Cookie POLICY header 
[]",
    cookiesForCustomPolicy.policyHeaderValue());
    logger.info("Cookie KEYPAIR header 
[]",
    cookiesForCustomPolicy.keyPairIdHeaderValue());
    logger.info("Cookie SIGNATURE header 
[]",
    cookiesForCustomPolicy.signatureHeaderValue());
    return cookiesForCustomPolicy;
}

• For API details, see CloudFrontUtilities in AWS SDK for Java 2.x API Reference.

CloudWatch examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with CloudWatch.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.
Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Get started

Hello CloudWatch

The following code examples show how to get started using CloudWatch.

SDK for Java 2.x

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.cloudwatch.CloudWatchClient;
import software.amazon.awssdk.services.cloudwatch.model.CloudWatchException;
import software.amazon.awssdk.services.cloudwatch.model.ListMetricsRequest;
import software.amazon.awssdk.services.cloudwatch.paginators.ListMetricsIterable;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */

class HelloService {
    public static void main(String[] args) {
        final String usage = ""

        // Usage:
        // <namespace>

        // Where:
```

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
namespace - The namespace to filter against (for example, AWS/EC2).

if (args.length != 1) {
    System.out.println(usage);
    System.exit(1);
}

String namespace = args[0];
Region region = Region.US_EAST_1;
CloudWatchClient cw = CloudWatchClient.builder()
    .region(region)
    .build();

listMets(cw, namespace);
cw.close();
}

public static void listMets(CloudWatchClient cw, String namespace) {
    try {
        ListMetricsRequest request = ListMetricsRequest.builder()
            .namespace(namespace)
            .build();

        ListMetricsIterable listRes = cw.listMetricsPaginator(request);
        listRes.stream()
            .flatMap(r -> r.metrics().stream())
            .forEach(metrics -> System.out.println(" Retrieved metric is: "
                + metrics.metricName()));
    } catch (CloudWatchException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}

• For API details, see ListMetrics in AWS SDK for Java 2.x API Reference.
Actions

Create a dashboard

The following code example shows how to create an Amazon CloudWatch dashboard.

```java
public static void createDashboardWithMetrics(CloudWatchClient cw, String dashboardName, String fileName) {
    try {
        PutDashboardRequest dashboardRequest = PutDashboardRequest.builder()
            .dashboardName(dashboardName)
            .dashboardBody(readFileAsString(fileName))
            .build();

        PutDashboardResponse response = cw.putDashboard(dashboardRequest);
        System.out.println(dashboardName + " was successfully created.");
        List<DashboardValidationMessage> messages = response.dashboardValidationMessages();
        if (messages.isEmpty()) {
            System.out.println("There are no messages in the new Dashboard");
        } else {
            for (DashboardValidationMessage message : messages) {
                System.out.println("Message is: " + message.message());
            }
        }
    } catch (CloudWatchException | IOException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}
```

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/awslabs/aws-code-examples).
Create a metric alarm

The following code example shows how to create or update an Amazon CloudWatch alarm and associate it with the specified metric, metric math expression, anomaly detection model, or Metrics Insights query.

SDK for Java 2.x

```java
public static String createAlarm(CloudWatchClient cw, String fileName) {
    try {
        // Read values from the JSON file.
        JsonParser parser = new JsonFactory().createParser(new File(fileName));
        com.fasterxml.jackson.databind.JsonNode rootNode = new ObjectMapper().readTree(parser);
        String customMetricNamespace = rootNode.findValue("customMetricNamespace").asText();
        String customMetricName = rootNode.findValue("customMetricName").asText();
        String alarmName = rootNode.findValue("exampleAlarmName").asText();
        String emailTopic = rootNode.findValue("emailTopic").asText();
        String accountId = rootNode.findValue("accountId").asText();
        String region = rootNode.findValue("region").asText();

        // Create a List for alarm actions.
        List<String> alarmActions = new ArrayList<>();
        alarmActions.add("arn:aws:sns:" + region + ":" + accountId + ":" + emailTopic);
        PutMetricAlarmRequest alarmRequest = PutMetricAlarmRequest.builder()
            .alarmActions(alarmActions)
            .alarmDescription("Example metric alarm")
            .cloudWatchClient(cw)
            .build();
    }
}
```

• For API details, see `PutDashboard` in *AWS SDK for Java 2.x API Reference*.

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
The following code example shows how to create an Amazon CloudWatch anomaly detector.

**SDK for Java 2.x**

```java
public static void addAnomalyDetector(CloudWatchClient cw, String fileName) {
    try {
        CloudWatch
        .alarmName(alarmName)
            .comparisonOperator(ComparisonOperator.GREATER_THAN_OR_EQUAL_TO_THRESHOLD)
                .threshold(100.00)
                .metricName(customMetricName)
                .namespace(customMetricNamespace)
                .evaluationPeriods(1)
                .period(10)
                .statistic("Maximum")
                .datapointsToAlarm(1)
                .treatMissingData("ignore")
                .build();

        cw.putMetricAlarm(alarmRequest);
        System.out.println(alarmName + " was successfully created!");
        return alarmName;
    } catch (CloudWatchException | IOException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
    return "";
}
```

- For API details, see [PutMetricAlarm](https://docs.aws.amazon.com/aws-sdk-java/latest/developer-guide/aws-java-sdk-api-cloudwatch.html) in *AWS SDK for Java 2.x API Reference*.

**Create an anomaly detector**

The following code example shows how to create an Amazon CloudWatch anomaly detector.

**SDK for Java 2.x**

```java
public static void addAnomalyDetector(CloudWatchClient cw, String fileName) {
    try {
        CloudWatch
        .alarmName(alarmName)
            .comparisonOperator(ComparisonOperator.GREATER_THAN_OR_EQUAL_TO_THRESHOLD)
                .threshold(100.00)
                .metricName(customMetricName)
                .namespace(customMetricNamespace)
                .evaluationPeriods(1)
                .period(10)
                .statistic("Maximum")
                .datapointsToAlarm(1)
                .treatMissingData("ignore")
                .build();

        cw.putMetricAlarm(alarmRequest);
        System.out.println(alarmName + " was successfully created!");
        return alarmName;
    } catch (CloudWatchException | IOException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
    return "";
}
```
// Read values from the JSON file.
JsonParser parser = new JsonFactory().createParser(new File(fileName));
com.fasterxml.jackson.databind.JsonNode rootNode = new ObjectMapper().readTree(parser);
String customMetricNamespace = rootNode.findValue("customMetricNamespace").asText();
String customMetricName = rootNode.findValue("customMetricName").asText();

SingleMetricAnomalyDetector singleMetricAnomalyDetector =
    SingleMetricAnomalyDetector.builder()
    .metricName(customMetricName)
    .namespace(customMetricNamespace)
    .stat("Maximum")
    .build();

PutAnomalyDetectorRequest anomalyDetectorRequest =
    PutAnomalyDetectorRequest.builder()
    .singleMetricAnomalyDetector(singleMetricAnomalyDetector)
    .build();

cw.putAnomalyDetector(anomalyDetectorRequest);
System.out.println("Added anomaly detector for metric " +
customMetricName + ".");
}
} catch (CloudWatchException | IOException e) {
    System.err.println(e.getMessage());
    System.exit(1);
}

• For API details, see PutAnomalyDetector in AWS SDK for Java 2.x API Reference.

Delete alarms

The following code example shows how to delete Amazon CloudWatch alarms.
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.cloudwatch.CloudWatchClient;
import software.amazon.awssdk.services.cloudwatch.model.CloudWatchException;
import software.amazon.awssdk.services.cloudwatch.model.DeleteAlarmsRequest;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 * 
 * For more information, see the following documentation topic:
 * 
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */

public class DeleteAlarm {
    public static void main(String[] args) {
        final String usage = ""
            "Usage:
                <alarmName>
            
            Where:
                alarmName - An alarm name to delete (for example, MyAlarm).
            ""
        ;

        if (args.length != 1) {
            System.out.println(usage);
            System.exit(1);
        }

        String alarmName = args[0];
        Region region = Region.US_EAST_2;
        CloudWatchClient cw = CloudWatchClient.builder()
            .region(region)
public static void deleteCWAlarm(CloudWatchClient cw, String alarmName) {
    try {
        DeleteAlarmsRequest request = DeleteAlarmsRequest.builder()
                .alarmNames(alarmName)
                .build();

        cw.deleteAlarms(request);
        System.out.printf("Successfully deleted alarm %s", alarmName);
    } catch (CloudWatchException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}

For API details, see DeleteAlarms in AWS SDK for Java 2.x API Reference.

Delete an anomaly detector

The following code example shows how to delete an Amazon CloudWatch anomaly detector.

SDK for Java 2.x

public static void deleteAnomalyDetector(CloudWatchClient cw, String fileName) {
    try {
        // Read values from the JSON file.
        JsonParser parser = new JsonFactory().createParser(new File(fileName));
        CloudWatch
    }
}
com.fasterxml.jackson.databind.JsonNode rootNode = new ObjectMapper().readTree(parser);

String customMetricNamespace = rootNode.findValue("customMetricNamespace").asText();
String customMetricName = rootNode.findValue("customMetricName").asText();

SingleMetricAnomalyDetector singleMetricAnomalyDetector = SingleMetricAnomalyDetector.builder()
    .metricName(customMetricName)
    .namespace(customMetricNamespace)
    .stat("Maximum")
    .build();

DeleteAnomalyDetectorRequest request = DeleteAnomalyDetectorRequest.builder()
    .singleMetricAnomalyDetector(singleMetricAnomalyDetector)
    .build();

cw.deleteAnomalyDetector(request);
System.out.println("Successfully deleted the Anomaly Detector.");

} catch (CloudWatchException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
} catch (IOException e) {
    e.printStackTrace();
}
"

- For API details, see [DeleteAnomalyDetector](#) in *AWS SDK for Java 2.x API Reference*.

### Delete dashboards

The following code example shows how to delete Amazon CloudWatch dashboards.
SDK for Java 2.x

### Delete Dashboard

```java
public static void deleteDashboard(CloudWatchClient cw, String dashboardName) {
    try {
        DeleteDashboardsRequest dashboardsRequest =
            DeleteDashboardsRequest.builder()
                .dashboardNames(dashboardName)
                .build();
        cw.deleteDashboards(dashboardsRequest);
        System.out.println(dashboardName + " was successfully deleted.");
    } catch (CloudWatchException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}
```

- For API details, see [DeleteDashboards](#) in *AWS SDK for Java 2.x API Reference*.

### Describe Alarm History

The following code example shows how to describe an Amazon CloudWatch alarm history.

```java
public static void getAlarmHistory(CloudWatchClient cw, String fileName, String date) {
    CloudWatch
```

### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).
try {
    // Read values from the JSON file.
    JsonParser parser = new JsonFactory().createParser(new File(fileName));
    com.fasterxml.jackson.databind.JsonNode rootNode = new ObjectMapper().readTree(parser);
    String alarmName = rootNode.findValue("exampleAlarmName").asText();

    Instant start = Instant.parse(date);
    Instant endDate = Instant.now();
    DescribeAlarmHistoryRequest historyRequest =
      DescribeAlarmHistoryRequest.builder()
      .startDate(start)
      .endDate(endDate)
      .alarmName(alarmName)
      .historyItemType(HistoryItemType.ACTION)
      .build();

    DescribeAlarmHistoryResponse response =
      cw.describeAlarmHistory(historyRequest);
    List<AlarmHistoryItem> historyItems = response.alarmHistoryItems();
    if (historyItems.isEmpty()) {
        System.out.println("No alarm history data found for " + alarmName + ".");
    } else {
        for (AlarmHistoryItem item : historyItems) {
            System.out.println("History summary: " + item.historySummary());
            System.out.println("Time stamp: " + item.timestamp());
        }
    }
} catch (CloudWatchException | IOException e) {
    System.err.println(e.getMessage());
    System.exit(1);
}

- For API details, see [DescribeAlarmHistory](#) in *AWS SDK for Java 2.x API Reference*.

**Describe alarms**

The following code example shows how to describe Amazon CloudWatch alarms.
public static void describeAlarms(CloudWatchClient cw) {
    try {
        List<AlarmType> typeList = new ArrayList<>();
        typeList.add(AlarmType.METRIC_ALARM);

        DescribeAlarmsRequest alarmsRequest = DescribeAlarmsRequest.builder()
                .alarmTypes(typeList)
                .maxRecords(10)
                .build();

        DescribeAlarmsResponse response = cw.describeAlarms(alarmsRequest);
        List<MetricAlarm> alarmList = response.metricAlarms();
        for (MetricAlarm alarm : alarmList) {
            System.out.println("Alarm name: " + alarm.alarmName());
            System.out.println("Alarm description: " + alarm.alarmDescription());
        }
    } catch (CloudWatchException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}

• For API details, see DescribeAlarms in AWS SDK for Java 2.x API Reference.

Describe alarms for a metric

The following code example shows how to describe Amazon CloudWatch alarms for a metric.
public static void checkForMetricAlarm(CloudWatchClient cw, String fileName) {
    try {
        // Read values from the JSON file.
        JsonParser parser = new JsonFactory().createParser(new File(fileName));
        ObjectMapper().readTree(parser);
        String customMetricNamespace = rootNode.findValue("customMetricNamespace").asText();
        String customMetricName = rootNode.findValue("customMetricName").asText();
        boolean hasAlarm = false;
        int retries = 10;

        DescribeAlarmsForMetricRequest metricRequest =
            DescribeAlarmsForMetricRequest.builder()
                .metricName(customMetricName)
                .namespace(customMetricNamespace)
                .build();

        while (!hasAlarm && retries > 0) {
            DescribeAlarmsForMetricResponse response =
                cw.describeAlarmsForMetric(metricRequest);
            hasAlarm = response.hasMetricAlarms();
            retries--;
            Thread.sleep(20000);
            System.out.println(".");
        }
        if (!hasAlarm)
            System.out.println("No Alarm state found for " + customMetricName + " after 10 retries.");
        else
            System.out.println("Alarm state found for " + customMetricName + ".");
    }
}
Try catching the exception:

```java
} catch (CloudWatchException | IOException | InterruptedException e) {
    System.err.println(e.getMessage());
    System.exit(1);
}
```

- For API details, see [DescribeAlarmsForMetric](https://docs.aws.amazon.com/AWSJavaSDK/latest/api/com/amazonaws/services/cloudwatch/model/DescribeAlarmsForMetric.html) in *AWS SDK for Java 2.x API Reference*.

### Describe anomaly detectors

The following code example shows how to describe Amazon CloudWatch anomaly detectors.

**SDK for Java 2.x**

```java
public static void describeAnomalyDetectors(CloudWatchClient cw, String fileName) {
    try {
        // Read values from the JSON file.
        JsonParser parser = new JsonFactory().createParser(new File(fileName));
        com.fasterxml.jackson.databind.JsonNode rootNode = new ObjectMapper().readTree(parser);
        String customMetricNamespace = rootNode.findValue("customMetricNamespace").asText();
        String customMetricName = rootNode.findValue("customMetricName").asText();
        DescribeAnomalyDetectorsRequest detectorsRequest = DescribeAnomalyDetectorsRequest.builder()
            .maxResults(10)
            .metricName(customMetricName)
            .namespace(customMetricNamespace)
            .build();

        DescribeAnomalyDetectorsResponse response = cw.describeAnomalyDetectors(detectorsRequest);
        List<AnomalyDetector> anomalyDetectorList = response.anomalyDetectors();
    }
    catch (CloudWatchException | IOException | InterruptedException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}
```

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/aws-samples/aws-sdk-java).
for (AnomalyDetector detector : anomalyDetectorList) {
    System.out.println("Metric name: "+
    detector.singleMetricAnomalyDetector().metricName());
    System.out.println("State: "+ detector.stateValue());
}

} catch (CloudWatchException | IOException e) {
    System.err.println(e.getMessage());
    System.exit(1);
}

• For API details, see DescribeAnomalyDetectors in AWS SDK for Java 2.x API Reference.

Disable alarm actions

The following code example shows how to disable Amazon CloudWatch alarm actions.

SDK for Java 2.x

import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.cloudwatch.CloudWatchClient;
import software.amazon.awssdk.services.cloudwatch.model.CloudWatchException;
import software.amazon.awssdk.services.cloudwatch.model.DisableAlarmActionsRequest;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class DisableAlarmActions {
    public static void main(String[] args) {

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
final String usage = ""

Usage:
<alarmName>

Where:
alarmName - An alarm name to disable (for example, MyAlarm).

if (args.length != 1) {
    System.out.println(usage);
    System.exit(1);
}

String alarmName = args[0];
Region region = Region.US_EAST_1;
CloudWatchClient cw = CloudWatchClient.builder()
    .region(region)
    .build();

disableActions(cw, alarmName);
cw.close();
}

public static void disableActions(CloudWatchClient cw, String alarmName) {
    try {
        DisableAlarmActionsRequest request =
            DisableAlarmActionsRequest.builder()
                .alarmNames(alarmName)
                .build();

        cw.disableAlarmActions(request);
        System.out.printf("Successfully disabled actions on alarm %s", alarmName);
    } catch (CloudWatchException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    } 
}

• For API details, see DisableAlarmActions in AWS SDK for Java 2.x API Reference.
Enable alarm actions

The following code example shows how to enable Amazon CloudWatch alarm actions.

SDK for Java 2.x

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.cloudwatch.CloudWatchClient;
import software.amazon.awssdk.services.cloudwatch.model.CloudWatchException;
import software.amazon.awssdk.services.cloudwatch.model.EnableAlarmActionsRequest;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class EnableAlarmActions {
    public static void main(String[] args) {
        final String usage = """";

        Usage:
        <alarmName>

        Where:
        alarmName - An alarm name to enable (for example, MyAlarm).
        """

        if (args.length != 1) {
            System.out.println(usage);
            System.exit(1);
        }

        String alarm = args[0];
        Region region = Region.US_EAST_1;
```
public static void enableActions(CloudWatchClient cw, String alarm) {
    try {
        EnableAlarmActionsRequest request = EnableAlarmActionsRequest.builder()
            .alarmNames(alarm)
            .build();

        cw.enableAlarmActions(request);
        System.out.printf("Successfully enabled actions on alarm %s", alarm);
    } catch (CloudWatchException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}

Get a metric data image

The following code example shows how to get an Amazon CloudWatch metric data image.

SDK for Java 2.x

• For API details, see EnableAlarmActions in AWS SDK for Java 2.x API Reference.

public static void getAndOpenMetricImage(CloudWatchClient cw, String fileName) {
    System.out.println("Getting Image data for custom metric.");
    try {

        CloudWatchClient cw = CloudWatchClient.builder()
            .region(region)
            .build();

        enableActions(cw, alarm);
        cw.close();
    }
}
```java
String myJSON = "{\n  "title": "Example Metric Graph",
  "view": "timeSeries",
  "stacked": false,
  "period": 10,
  "width": 1400,
  "height": 600,
  "metrics": [
    ["AWS/Billing",
     "EstimatedCharges",
     "Currency",
     "USD"
    ]
  ]\n}";

GetMetricWidgetImageRequest imageRequest =
  GetMetricWidgetImageRequest.builder()
    .metricWidget(myJSON)
    .build();

GetMetricWidgetImageResponse response =
  cw.getMetricWidgetImage(imageRequest);
SdkBytes sdkBytes = response.metricWidgetImage();
byte[] bytes = sdkBytes.asByteArray();
File outputFile = new File(fileName);
try (FileOutputStream outputStream = new FileOutputStream(outputFile)) {
  outputStream.write(bytes);
}
}
```
public static void getCustomMetricData(CloudWatchClient cw, String fileName) {
    try {
        // Read values from the JSON file.
        JsonParser parser = new JsonFactory().createParser(new File(fileName));  
        com.fasterxml.jackson.databind.JsonNode rootNode = new ObjectMapper().readTree(parser);
        String customMetricNamespace = rootNode.findValue("customMetricNamespace").asText();
        String customMetricName = rootNode.findValue("customMetricName").asText();

        // Set the date.
        Instant nowDate = Instant.now();

        long hours = 1;
        long minutes = 30;
        Instant date2 = nowDate.plus(hours, ChronoUnit.HOURS).plus(minutes, ChronoUnit.MINUTES);

        Metric met = Metric.builder()
            .metricName(customMetricName)
            .namespace(customMetricNamespace)
            .build();

        MetricStat metStat = MetricStat.builder()
            .stat("Maximum")
            .period(1)
            .metric(met)
            .build();

        MetricDataQuery dataQuery = MetricDataQuery.builder()
            .metricStat(metStat)
            .id("foo2")
            .returnData(true)
    }
}
```java
List<MetricDataQuery> dq = new ArrayList<>();
dq.add(dataQuery);

GetMetricDataRequest getMetReq = GetMetricDataRequest.builder()
    .maxDatapoints(10)
    .scanBy(ScanBy.TIMESTAMP_DESCENDING)
    .startTime(nowDate)
    .endTime(date2)
    .metricDataQueries(dq)
    .build();

GetMetricDataResponse response = cw.getMetricData(getMetReq);
List<MetricDataResult> data = response.metricDataResults();
for (MetricDataResult item : data) {
    System.out.println("The label is " + item.label());
    System.out.println("The status code is " +
        item.statusCode().toString());
}
```

### Get metric statistics

The following code example shows how to get Amazon CloudWatch metric statistics.

**SDK for Java 2.x**

```
Note
There's more on GitHub. Find the complete example and learn how to set up and run in
the [AWS Code Examples Repository](https://github.com/aws-samples/aws-java-sdk-gradle-template).
public static void getAndDisplayMetricStatistics(CloudWatchClient cw, String nameSpace, String metVal, String metricOption, String date, Dimension myDimension) {
    try {
        Instant start = Instant.parse(date);
        Instant endDate = Instant.now();

        GetMetricStatisticsRequest statisticsRequest = GetMetricStatisticsRequest.builder()
            .endTime(endDate)
            .startTime(start)
            .dimensions(myDimension)
            .metricName(metVal)
            .namespace(nameSpace)
            .period(86400)
            .statistics(Statistic.fromValue(metricOption))
            .build();

        GetMetricStatisticsResponse response = cw.getMetricStatistics(statisticsRequest);
        List<Datapoint> data = response.datapoints();
        if (!data.isEmpty()) {
            for (Datapoint datapoint : data) {
                System.out.println("Timestamp: " + datapoint.timestamp() + " Maximum value: " + datapoint.maximum());
            }
        } else {
            System.out.println("The returned data list is empty");
        }
    } catch (CloudWatchException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}

- For API details, see GetMetricStatistics in AWS SDK for Java 2.x API Reference.
List dashboards

The following code example shows how to list Amazon CloudWatch dashboards.

SDK for Java 2.x

```java
public static void listDashboards(CloudWatchClient cw) {
    try {
        ListDashboardsIterable listRes = cw.listDashboardsPage();
        listRes.stream()
            .flatMap(r -> r.dashboardEntries().stream())
            .forEach(entry -> {
                System.out.println("Dashboard name is: " +
                    entry.dashboardName());
                System.out.println("Dashboard ARN is: " +
                    entry.dashboardArn());
            });
    } catch (CloudWatchException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

- For API details, see [ListDashboards](https://aws.amazon.com/api-reference) in *AWS SDK for Java 2.x API Reference*.

List metrics

The following code example shows how to list the metadata for Amazon CloudWatch metrics. To get data for a metric, use the GetMetricData or GetMetricStatistics actions.
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.cloudwatch.CloudWatchClient;
import software.amazon.awssdk.services.cloudwatch.model.CloudWatchException;
import software.amazon.awssdk.services.cloudwatch.model.ListMetricsRequest;
import software.amazon.awssdk.services.cloudwatch.model.ListMetricsResponse;
import software.amazon.awssdk.services.cloudwatch.model.Metric;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.

            }
            for (Metric metric : response.metrics()) {
                System.out.printf("Retrieved metric %s", metric.metricName());
                System.out.println();
            }
            if (response.nextToken() == null) {
                done = true;
            } else {
                nextToken = response.nextToken();
            }
        }
    } catch (CloudWatchException e) {
        CloudWatch
For API details, see [ListMetrics](https://docs.aws.amazon.com/sdk-for-java/v1/developer-guide/aws-java-v2-list-metrics.html) in *AWS SDK for Java 2.x API Reference*.

**Put data into a metric**

The following code example shows how to publish metric data points to Amazon CloudWatch.

**SDK for Java 2.x**

```java
public static void addMetricDataForAlarm(CloudWatchClient cw, String fileName) {
    try {
        // Read values from the JSON file.
        JsonParser parser = new JsonFactory().createParser(new File(fileName));
        com.fasterxml.jackson.databind.JsonNode rootNode = new ObjectMapper().readTree(parser);
        String customMetricNamespace = rootNode.findValue("customMetricNamespace").asText();
        String customMetricName = rootNode.findValue("customMetricName").asText();

        // Set an Instant object.
        String time = ZonedDateTime.now(ZoneOffset.UTC).format(DateTimeFormatter.ISO_INSTANT);
        Instant instant = Instant.parse(time);

        MetricDatum datum = MetricDatum.builder()
            .metricName(customMetricName)
            .unit(StandardUnit.NONE)
            .value(1001.00)
            .timestamp(instant)
            .build();

        // Publish the metric data point.
        cw.putMetricData(Collections.singletonList(datum));
    } catch (Exception e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/aws-samples/aws-java-v2-examples).
MetricDatum datum2 = MetricDatum.builder()
    .metricName(customMetricName)
    .unit(StandardUnit.NONE)
    .value(1002.00)
    .timestamp(instant)
    .build();

List<MetricDatum> metricDataList = new ArrayList<>();
metricDataList.add(datum);
metricDataList.add(datum2);

PutMetricDataRequest request = PutMetricDataRequest.builder()
    .namespace(customMetricNamespace)
    .metricData(metricDataList)
    .build();

cw.putMetricData(request);
    System.out.println("Added metric values for for metric ",
    customMetricName);

} catch (CloudWatchException | IOException e) {
    System.err.println(e.getMessage());
    System.exit(1);
}
}

• For API details, see PutMetricData in AWS SDK for Java 2.x API Reference.

Scenarios

Get started with metrics, dashboards, and alarms

The following code example shows how to:

• List CloudWatch namespaces and metrics.
• Get statistics for a metric and for estimated billing.
• Create and update a dashboard.
• Create and add data to a metric.
• Create and trigger an alarm, then view alarm history.
• Add an anomaly detector.
• Get a metric image, then clean up resources.

**SDK for Java 2.x**

⚠️ **Note**

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * To enable billing metrics and statistics for this example, make sure billing
 * alerts are enabled for your account:
 * https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/
 * monitor_estimated_charges_with_cloudwatch.html#turning_on_billing_metrics
 *
 * This Java code example performs the following tasks:
 *
 * 1. List available namespaces from Amazon CloudWatch.
 * 2. List available metrics within the selected Namespace.
 * 3. Get statistics for the selected metric over the last day.
 * 4. Get CloudWatch estimated billing for the last week.
 * 5. Create a new CloudWatch dashboard with metrics.
 * 7. Create a new custom metric by adding data for it.
 * 8. Add the custom metric to the dashboard.
 * 9. Create an alarm for the custom metric.
 * 10. Describe current alarms.
 * 11. Get current data for the new custom metric.
 * 12. Push data into the custom metric to trigger the alarm.
 * 13. Check the alarm state using the action DescribeAlarmsForMetric.
 * 15. Add an anomaly detector for the custom metric.
 * 16. Describe current anomaly detectors.
 * 17. Get a metric image for the custom metric.
 * 18. Clean up the Amazon CloudWatch resources.
 */

    public static final String DASHES = new String(new char[80]).replace("\0", "-");

    public static void main(String[] args) throws IOException {
        final String usage = ""

        Usage:
<myDate> <costDateWeek> <dashboardName> <dashboardJson>
<dashboardAdd> <settings> <metricImage> \s

Where:
myDate - The start date to use to get metric statistics. (For example, 2023-01-11T18:35:24.00Z.)

costDateWeek - The start date to use to get AWS/Billing statistics. (For example, 2023-01-11T18:35:24.00Z.)
dashboardName - The name of the dashboard to create.
dashboardJson - The location of a JSON file to use to create a dashboard. (See Readme file.)
dashboardAdd - The location of a JSON file to use to update a dashboard. (See Readme file.)
settings - The location of a JSON file from which various values are read. (See Readme file.)
metricImage - The location of a BMP file that is used to create a graph.

CloudWatch Events examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with CloudWatch Events.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Delete a subscription filter

The following code example shows how to delete an Amazon CloudWatch Logs subscription filter.

SDK for Java 2.x

```java
import software.amazon.awssdk.services.cloudwatch.model.CloudWatchException;
import software.amazon.awssdk.services.cloudwatchlogs.CloudWatchLogsClient;
import 
software.amazon.awssdk.services.cloudwatchlogs.model.DeleteSubscriptionFilterRequest;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 */
```
public class DeleteSubscriptionFilter {
    public static void main(String[] args) {
        final String usage = ""

        Usage:
            <filter> <logGroup>

        Where:
            filter - The name of the subscription filter (for example, MyFilter).
            logGroup - The name of the log group. (for example, testgroup).

        if (args.length != 2) {
            System.out.println(usage);
            System.exit(1);
        }

        String filter = args[0];
        String logGroup = args[1];
        CloudWatchLogsClient logs = CloudWatchLogsClient.builder()
            .build();

        deleteSubFilter(logs, filter, logGroup);
        logs.close();
    }

    public static void deleteSubFilter(CloudWatchLogsClient logs, String filter,
        String logGroup) {
        try {
            DeleteSubscriptionFilterRequest request =
                DeleteSubscriptionFilterRequest.builder()
                    .filterName(filter)
                    .logGroupName(logGroup)
                    .build();

            logs.deleteSubscriptionFilter(request);
            System.out.printf("Successfully deleted CloudWatch logs subscription filter %s", filter);
        } catch (Exception e) {
            e.printStackTrace();
        }
    }
}

**Describe existing subscription filters**

The following code example shows how to describe Amazon CloudWatch Logs existing subscription filters.

### SDK for Java 2.x

```java
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.services.cloudwatch.model.CloudWatchException;
import software.amazon.awssdk.services.cloudwatchlogs.CloudWatchLogsClient;
import software.amazon.awssdk.services.cloudwatchlogs.model.DescribeSubscriptionFiltersRequest;
import software.amazon.awssdk.services.cloudwatchlogs.model.DescribeSubscriptionFiltersResponse;
import software.amazon.awssdk.services.cloudwatchlogs.model.SubscriptionFilter;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 * For more information, see the following documentation topic:
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */

public class DescribeSubscriptionFilters {
    public static void main(String[] args) {
```
final String usage = ""

    Usage:
    <logGroup>

    Where:
    logGroup - A log group name (for example, myloggroup).
    "";

    if (args.length != 1) {
        System.out.println(usage);
        System.exit(1);
    }

    String logGroup = args[0];
    CloudWatchLogsClient logs = CloudWatchLogsClient.builder()
        .credentialsProvider(ProfileCredentialsProvider.create())
        .build();

    describeFilters(logs, logGroup);
    logs.close();
}

class DescribeFilters {
    
    public static void describeFilters(CloudWatchLogsClient logs, String logGroup) {
        try {
            boolean done = false;
            String newToken = null;

            while (!done) {
                DescribeSubscriptionFiltersResponse response;
                if (newToken == null) {
                    DescribeSubscriptionFiltersRequest request = DescribeSubscriptionFiltersRequest.builder()
                        .logGroupName(logGroup)
                        .limit(1).build();

                    response = logs.describeSubscriptionFilters(request);
                } else {
                    DescribeSubscriptionFiltersRequest request = DescribeSubscriptionFiltersRequest.builder()
                        .nextToken(newToken)
                        .logGroupName(logGroup)
                        .limit(1).build();

                    response = logs.describeSubscriptionFilters(request);
                }

                done = response.nextToken().isPresent();
                newToken = response.nextToken();
            }

            // Process the filters...
        }
    }

    // Other methods and logic...
}

// Example usage:

DescribeFilters.describeFilters(logs, "myloggroup");
response = logs.describeSubscriptionFilters(request);
}

for (SubscriptionFilter filter : response.subscriptionFilters()) {
    System.out.printf("Retrieved filter with name %s, " + "pattern %s " + "and destination arn %s", 
        filter.filterName(),
        filter.filterPattern(),
        filter.destinationArn());
}

if (response.nextToken() == null) {
    done = true;
} else {
    newToken = response.nextToken();
}
}

catch (CloudWatchException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

System.out.printf("Done");
}

• For API details, see DescribeSubscriptionFilters in AWS SDK for Java 2.x API Reference.

Start a Live Tail session

The following code example shows how to start a Live Tail session for an existing log group/log stream.

SDK for Java 2.x

Include the required files.

import io.reactivex.FlowableSubscriber;
import io.reactivex.annotations.NonNull;
import org.reactivestreams.Subscription;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.services.cloudwatchlogs.CloudWatchLogsAsyncClient;
import software.amazon.awssdk.services.cloudwatchlogs.model.LiveTailSessionLogEvent;
import software.amazon.awssdk.services.cloudwatchlogs.model.LiveTailSessionStart;
import software.amazon.awssdk.services.cloudwatchlogs.model.LiveTailSessionUpdate;
import software.amazon.awssdk.services.cloudwatchlogs.model.StartLiveTailRequest;
import
software.amazon.awssdk.services.cloudwatchlogs.model.StartLiveTailResponseHandler;
import software.amazon.awssdk.services.cloudwatchlogs.model.CloudWatchLogsException;
import
software.amazon.awssdk.services.cloudwatchlogs.model.StartLiveTailResponseStream;

import java.util.Date;
import java.util.List;
import java.util.concurrent.atomic.AtomicReference;

Handle the events from the Live Tail session.

private static StartLiveTailResponseHandler
getStartLiveTailResponseStreamHandler(
   AtomicReference<Subscription> subscriptionAtomicReference) {
   return StartLiveTailResponseHandler.builder()
      .onResponse(r -> System.out.println("Received initial response"))
      .onError(throwable -> {
         CloudWatchLogsException e = (CloudWatchLogsException)
            throwable.getCause();
         System.err.println(e.awsErrorDetails().errorMessage());
         System.exit(1);
      })
      .subscriber(() -> new FlowableSubscriber<>(){
         @Override
         public void onSubscribe(@NonNull Subscription s) {
            subscriptionAtomicReference.set(s);
            s.request(Long.MAX_VALUE);
         }

         @Override
         public void onNext(StartLiveTailResponseStream event) {
            if (event instanceof LiveTailSessionStart) {
               LiveTailSessionStart sessionStart = (LiveTailSessionStart)
                  event;
               System.out.println(sessionStart);
            } else if (event instanceof LiveTailSessionUpdate) {

CloudWatch Logs
LiveTailSessionUpdate sessionUpdate =
(LiveTailSessionUpdate) event;
List<LiveTailSessionLogEvent> logEvents =
sessionUpdate.sessionResults();
    logEvents.forEach(e -> {
        long timestamp = e.timestamp();
        Date date = new Date(timestamp);
        System.out.println("[" + date + "] " + e.message());
    });
} else {
    throw CloudWatchLogsException.builder().message("Unknown event type").build();
}

@override
public void onError(Throwable throwable) {
    System.out.println(throwable.getMessage());
    System.exit(1);
}

@override
public void onComplete() {
    System.out.println("Completed Streaming Session");
}
})
.build();

Start the Live Tail session.

CloudWatchLogsAsyncClient cloudWatchLogsAsyncClient =
CloudWatchLogsAsyncClient.builder()
    .credentialsProvider(ProfileCredentialsProvider.create())
    .build();

StartLiveTailRequest request =
StartLiveTailRequest.builder()
    .logGroupIdentifiers(logGroupIdentifiers)
    .logStreamNames(logStreamNames)
    .logEventFilterPattern(logEventFilterPattern)
    .build();
/* Create a reference to store the subscription */
final AtomicReference<Subscription> subscriptionAtomicReference = new AtomicReference<>(null);

cloudWatchLogsAsyncClient.startLiveTail(request, 
    getStartLiveTailResponseStreamHandler(subscriptionAtomicReference));

Stop the Live Tail session after a period of time has elapsed.

/* Set a timeout for the session and cancel the subscription. This will:
  * 1). Close the stream
  * 2). Stop the Live Tail session
  */
try {
    Thread.sleep(10000);
} catch (InterruptedException e) {
    throw new RuntimeException(e);
}
if (subscriptionAtomicReference.get() != null) {
    subscriptionAtomicReference.get().cancel();
    System.out.println("Subscription to stream closed");
}

• For API details, see StartLiveTail in AWS SDK for Java 2.x API Reference.

Amazon Cognito Identity examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon Cognito Identity.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.
Actions

Create an identity pool

The following code example shows how to create an Amazon Cognito identity pool.

SDK for Java 2.x

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.cognitoidentity.CognitoIdentityClient;
import software.amazon.awssdk.services.cognitoidentity.model.CreateIdentityPoolRequest;
import software.amazon.awssdk.services.cognitoidentity.model.CreateIdentityPoolResponse;
import software.amazon.awssdk.services.cognitoidentityprovider.model.CognitoIdentityProviderException;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 * For more information, see the following documentation topic:
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class CreateIdentityPool {
    public static void main(String[] args) {
        final String usage = """;
        Usage:
            <identityPoolName>

        Where:
```

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
identityPoolName - The name to give your identity pool.

if (args.length != 1) {
    System.out.println(usage);
    System.exit(1);
}

String identityPoolName = args[0];
CognitoIdentityClient cognitoClient = CognitoIdentityClient.builder()

Amazon Cognito Identity Provider examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon Cognito Identity Provider.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Get started

Hello Amazon Cognito

The following code examples show how to get started using Amazon Cognito.
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.cognitoidentityprovider.CognitoIdentityProviderClient;
import software.amazon.awssdk.services.cognitoidentityprovider.model.CognitoIdentityProviderException;
import software.amazon.awssdk.services.cognitoidentityprovider.model.ListUserPoolsResponse;
import software.amazon.awssdk.services.cognitoidentityprovider.model.ListUserPoolsRequest;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class ListUserPools {
    public static void main(String[] args) {
        CognitoIdentityProviderClient cognitoClient =
        CognitoIdentityProviderClient.builder()
            .region(Region.US_EAST_1)
            .build();

        listAllUserPools(cognitoClient);
        cognitoClient.close();
    }

    public static void listAllUserPools(CognitoIdentityProviderClient cognitoClient) {
        try {
            ListUserPoolsRequest request = ListUserPoolsRequest.builder()
                .maxResults(10)
                .build();
        }
    }
}
ListUserPoolsResponse response = cognitoClient.listUserPools(request);
response.userPools().forEach(userpool -> {
    System.out.println("User pool " + userpool.name() + ", User ID " +
    userpool.id());
});

} catch (CognitoIdentityProviderException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
}

Confirm a user

The following code example shows how to confirm an Amazon Cognito user.

SDK for Java 2.x

```
public static void confirmSignUp(CognitoIdentityProviderClient
    identityProviderClient, String clientId, String code,
    String userName) {
    try {
```
ConfirmSignUpRequest signUpRequest = ConfirmSignUpRequest.builder()
        .clientId(clientId)
        .confirmationCode(code)
        .username(userName)
        .build();

        identityProviderClient.confirmSignUp(signUpRequest);
        System.out.println(userName + " was confirmed");

    } catch (CognitoIdentityProviderException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}

• For API details, see ConfirmSignUp in AWS SDK for Java 2.x API Reference.

Create a user pool

The following code example shows how to create an Amazon Cognito user pool.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.cognitoidentityprovider.CognitoIdentityProviderClient;
import software.amazon.awssdk.services.cognitoidentityprovider.model.CognitoIdentityProviderException;
import software.amazon.awssdk.services.cognitoidentityprovider.model.CreateUserPoolRequest;
import software.amazon.awssdk.services.cognitoidentityprovider.model.CreateUserPoolResponse;

/**
 * Before running this Java V2 code example, set up your development

public static void main(String[] args) {
    final String usage = ""
    Usages:
    <userPoolName>\s
    Where:
    userPoolName - The name to give your user pool when it's created.
    ""
    if (args.length != 1) {
        System.out.println(usage);
        System.exit(1);
    }
    String userPoolName = args[0];
    CognitoIdentityProviderClient cognitoClient =
    CognitoIdentityProviderClient.builder()
        .region(Region.US_EAST_1)
        .build();
    String id = createPool(cognitoClient, userPoolName);
    System.out.println("User pool ID: " + id);
    cognitoClient.close();
}

public static String createUserPool(CognitoIdentityProviderClient cognitoClient, String userPoolName) {
    try {
        CreateUserPoolRequest request = CreateUserPoolRequest.builder()
            .poolName(userPoolName)
            .build();
        CreateUserPoolResponse response = cognitoClient.createUserPool(request);
        return response.userPool().id();
}
For API details, see CreateUserPool in AWS SDK for Java 2.x API Reference.

Create an app client

The following code example shows how to create an Amazon Cognito user pool client app.

SDK for Java 2.x

```
import software.amazon.awssdk.regions.Region;
import
software.amazon.awssdk.services.cognitoidentityprovider.CognitoIdentityProviderClient;
import
software.amazon.awssdk.services.cognitoidentityprovider.model.CognitoIdentityProviderException;
import
software.amazon.awssdk.services.cognitoidentityprovider.model.CreateUserPoolClientRequest;
import
software.amazon.awssdk.services.cognitoidentityprovider.model.CreateUserPoolClientResponse;

/**
 * A user pool client app is an application that authenticates with Amazon
 * Cognito user pools.
 * When you create a user pool, you can configure app clients that allow mobile
 * or web applications
 * to call API operations to authenticate users, manage user attributes and
 * profiles,
 * and implement sign-up and sign-in flows.
*/
```
Before running this Java V2 code example, set up your development environment, including your credentials.

For more information, see the following documentation topic:
https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html

```java
public class CreateUserPoolClient {
    public static void main(String[] args) {
        final String usage = ""
        Usage:
            <clientName> <userPoolId>\s
        Where:
            clientName - The name for the user pool client to create.
            userPoolId - The ID for the user pool.
        "";

        if (args.length != 2) {
            System.out.println(usage);
            System.exit(1);
        }

        String clientName = args[0];
        String userPoolId = args[1];
        CognitoIdentityProviderClient cognitoClient = CognitoIdentityProviderClient.builder()
            .region(Region.US_EAST_1)
            .build();

        createPoolClient(cognitoClient, clientName, userPoolId);
        cognitoClient.close();
    }

    public static void createPoolClient(CognitoIdentityProviderClient cognitoClient,
            String clientName, String userPoolId) {
        try {
            CreateUserPoolClientRequest request =
                CreateUserPoolClientRequest.builder()
                    .clientName(clientName)
                    .userPoolId(userPoolId)
                    .build();
```
CreateUserPoolClientResponse response =
cognitoClient.createUserPoolClient(request);
    System.out.println("User pool " + response.userPoolClient().clientName()
+ " created. ID: "
    + response.userPoolClient().clientId());

} catch (CognitoIdentityProviderException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

• For API details, see CreateUserPoolClient in AWS SDK for Java 2.x API Reference.

Get a token to associate an MFA application with a user

The following code example shows how to get a token to associate an MFA application with an
Amazon Cognito user.

SDK for Java 2.x

public static String getSecretForAppMFA(CognitoIdentityProviderClient
identityProviderClient, String session) {
    AssociateSoftwareTokenRequest softwareTokenRequest =
AssociateSoftwareTokenRequest.builder()
        .session(session)
        .build();

    AssociateSoftwareTokenResponse tokenResponse = identityProviderClient
        .associateSoftwareToken(softwareTokenRequest);
    String secretCode = tokenResponse.secretCode();
    System.out.println("Enter this token into Google Authenticator");
System.out.println(secretCode);
return tokenResponse.session();
}

- For API details, see `AssociateSoftwareToken` in `AWS SDK for Java 2.x API Reference`.

Get information about a user

The following code example shows how to get information about an Amazon Cognito user.

**SDK for Java 2.x**

```
public static void getAdminUser(CognitoIdentityProviderClient identityProviderClient, String userName, String poolId) {
    try {
        AdminGetUserRequest userRequest = AdminGetUserRequest.builder()
            .username(userName)
            .userPoolId(poolId)
            .build();

        AdminGetUserResponse response = identityProviderClient.adminGetUser(userRequest);
        System.out.println("User status " + response.userStatusAsString());
    } catch (CognitoIdentityProviderException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

- For API details, see `AdminGetUser` in `AWS SDK for Java 2.x API Reference`.

### Note

        System.exit(1);
    }
}

• For API details, see ListUsers in AWS SDK for Java 2.x API Reference.
Resend a confirmation code

The following code example shows how to resend an Amazon Cognito confirmation code.

SDK for Java 2.x

```
public static void resendConfirmationCode(CognitoIdentityProviderClient identityProviderClient, String clientId, String userName) {
    try {
        ResendConfirmationCodeRequest codeRequest = ResendConfirmationCodeRequest.builder()
            .clientId(clientId)
            .username(userName)
            .build();

        ResendConfirmationCodeResponse response = identityProviderClient.resendConfirmationCode(codeRequest);
        System.out.println("Method of delivery is "+
            response.codeDeliveryDetails().deliveryMediumAsString());
    } catch (CognitoIdentityProviderException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

Respond to an authentication challenge

The following code example shows how to respond to an Amazon Cognito authentication challenge.
Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/aws-samples/awsc-em-cognito).

```java
// Respond to an authentication challenge.
public static void adminRespondToAuthChallenge(CognitoIdentityProviderClient identityProviderClient,
        String userName, String clientId, String mfaCode, String session) {
    System.out.println("SOFTWARE_TOKEN_MFA challenge is generated");
    Map<String, String> challengeResponses = new HashMap<>();

    challengeResponses.put("USERNAME", userName);
    challengeResponses.put("SOFTWARE_TOKEN_MFA_CODE", mfaCode);

    AdminRespondToAuthChallengeRequest respondToAuthChallengeRequest =
        AdminRespondToAuthChallengeRequest.builder()
            .challengeName(ChallengeNameType.SOFTWARE_TOKEN_MFA)
            .clientId(clientId)
            .challengeResponses(challengeResponses)
            .session(session)
            .build();

    AdminRespondToAuthChallengeResponse respondToAuthChallengeResult =
        identityProviderClient
            .adminRespondToAuthChallenge(respondToAuthChallengeRequest);
    System.out.println("respondToAuthChallengeResult.getAuthenticationResult()" +
        respondToAuthChallengeResult.authenticationResult());
}
```

- For API details, see [AdminRespondToAuthChallenge](https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/javadoc/com.amazonaws.services.cognitoidentityprovider.model.AdminRespondToAuthChallengeRequest.html) in AWS SDK for Java 2.x API Reference.

**Sign up a user**

The following code example shows how to sign up a user with Amazon Cognito.
public static void signUp(CognitoIdentityProviderClient identityProviderClient,
String clientId, String userName,
String password, String email) {
    AttributeType userAttrs = AttributeType.builder()
         .name("email")
         .value(email)
         .build();

    List<AttributeType> userAttrsList = new ArrayList<>();
    userAttrsList.add(userAttrs);
    try {
        SignUpRequest signUpRequest = SignUpRequest.builder()
            .userAttributes(userAttrsList)
            .username(userName)
            .clientId(clientId)
            .password(password)
            .build();

        identityProviderClient.signUp(signUpRequest);
        System.out.println("User has been signed up ");
    }
    catch (CognitoIdentityProviderException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }

}

• For API details, see [SignUp](https://aws.amazon.com/documentation/sdk-for-java/2.x/guides/api-reference/) in *AWS SDK for Java 2.x API Reference*. 

---

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://aws.amazon.com/code-examples/).
Start authentication with administrator credentials

The following code example shows how to start authentication with Amazon Cognito and administrator credentials.

SDK for Java 2.x

```java
public static AdminInitiateAuthResponse initiateAuth(CognitoIdentityProviderClient identityProviderClient,
String clientId, String userName, String password, String userPoolId) {
    try {
        Map<String, String> authParameters = new HashMap<>();
        authParameters.put("USERNAME", userName);
        authParameters.put("PASSWORD", password);

        AdminInitiateAuthRequest authRequest =
            AdminInitiateAuthRequest.builder()
                .clientId(clientId)
                .userPoolId(userPoolId)
                .authParameters(authParameters)
                .authFlow(AuthFlowType.ADMIN_USER_PASSWORD_AUTH)
                .build();

        AdminInitiateAuthResponse response = identityProviderClient.adminInitiateAuth(authRequest);
        System.out.println("Result Challenge is : " + response.challengeName());
        return response;
    } catch (CognitoIdentityProviderException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }

    return null;
}
```

Note
---
There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://aws.amazon.com/code-examples/).
• For API details, see AdminInitiateAuth in AWS SDK for Java 2.x API Reference.

Verify an MFA application with a user

The following code example shows how to verify an MFA application with an Amazon Cognito user.

SDK for Java 2.x

```
// Verify the TOTP and register for MFA.
public static void verifyTOTP(CognitoIdentityProviderClient identityProviderClient, String session, String code) {
    try {
        VerifySoftwareTokenRequest tokenRequest = VerifySoftwareTokenRequest.builder()
            .userCode(code)
            .session(session)
            .build();

        VerifySoftwareTokenResponse verifyResponse = identityProviderClient.verifySoftwareToken(tokenRequest);
        System.out.println("The status of the token is " + verifyResponse.statusAsString());
    } catch (CognitoIdentityProviderException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

• For API details, see VerifySoftwareToken in AWS SDK for Java 2.x API Reference.
Scenarios

Sign up a user with a user pool that requires MFA

The following code example shows how to:

- Sign up and confirm a user with a username, password, and email address.
- Set up multi-factor authentication by associating an MFA application with the user.
- Sign in by using a password and an MFA code.

SDK for Java 2.x

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.cognitoidentityprovider.CognitoIdentityProviderClient;
import software.amazon.awssdk.services.cognitoidentityprovider.model.AdminGetUserRequest;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * TIP: To set up the required user pool, run the AWS Cloud Development Kit (AWS
 * CDK) script provided in this GitHub repo at
 * resources/cdk/cognito_scenario_user_pool_with_mfa.
 *
 * This code example performs the following operations:
 *
 * 1. Invokes the signUp method to sign up a user.
 * 2. Invokes the adminGetUser method to get the user's confirmation status.
 * 3. Invokes the ResendConfirmationCode method if the user requested another
 *    code.
 * 4. Invokes the confirmSignUp method.
 * 5. Invokes the AdminInitiateAuth to sign in. This results in being prompted
 *    to set up TOTP (time-based one-time password). (The response is
 *    “ChallengeName”: “MFA_SETUP”).
 * 6. Invokes the AssociateSoftwareToken method to generate a TOTP MFA private
* key. This can be used with Google Authenticator.
* 7. Invokes the VerifySoftwareToken method to verify the TOTP and register for
* MFA.
* 8. Invokes the AdminInitiateAuth to sign in again. This results in being
* prompted to submit a TOTP (Response: “ChallengeName”: “SOFTWARE_TOKEN_MFA”).
* 9. Invokes the AdminRespondToAuthChallenge to get back a token.
*/

**Amazon Comprehend examples using SDK for Java 2.x**

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon Comprehend.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Actions

Create a document classifier

The following code example shows how to create an Amazon Comprehend document classifier.

SDK for Java 2.x

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.comprehend.ComprehendClient;
import software.amazon.awssdk.services.comprehend.model.ComprehendException;
import 
software.amazon.awssdk.services.comprehend.model.CreateDocumentClassifierRequest;
import 
software.amazon.awssdk.services.comprehend.model.CreateDocumentClassifierResponse;
import 
software.amazon.awssdk.services.comprehend.model.DocumentClassifierInputDataConfig;

/**
 * Before running this code example, you can setup the necessary resources, such
 * as the CSV file and IAM Roles, by following this document:
 * https://aws.amazon.com/blogs/machine-learning/building-a-custom-classifier-using-
 * amazon-comprehend/
 * 
 * Also, set up your development environment, including your credentials.
 * 
 * For more information, see the following documentation topic:
 * 
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class DocumentClassifierDemo {
    public static void main(String[] args) {
        final String usage = ""
        
            Usage: <dataAccessRoleArn> <s3Uri> <documentClassifierName>

            Where:
```
dataAccessRoleArn - The ARN value of the role used for this operation.
s3Uri - The Amazon S3 bucket that contains the CSV file.
documentClassifierName - The name of the document classifier.

if (args.length != 3) {
    System.out.println(usage);
    System.exit(1);
}

  }
}

For API details, see [DetectSentiment](DynamoDB) in [AWS SDK for Java 2.x API Reference](DynamoDB).

**DynamoDB examples using SDK for Java 2.x**

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with DynamoDB.

**Actions** are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

**Scenarios** are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

**Get started**
Hello DynamoDB

The following code examples show how to get started using DynamoDB.

SDK for Java 2.x

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.model.ListTablesRequest;
import software.amazon.awssdk.services.dynamodb.model.ListTablesResponse;
import java.util.List;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class ListTables {
    public static void main(String[] args) {
        System.out.println("Listing your Amazon DynamoDB tables:\n");
        Region region = Region.US_EAST_1;
        DynamoDbClient ddb = DynamoDbClient.builder()
            .region(region)
            .build();
        listAllTables(ddb);
        ddb.close();
    }

    public static void listAllTables(DynamoDbClient ddb) {
        boolean moreTables = true;
        String lastName = null;

        while (moreTables) {
            // Code for listing all tables
        }
    }
}
```

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
try {
    ListTablesResponse response = null;
    if (lastName == null) {
        ListTablesRequest request = ListTablesRequest.builder().build();
        response = ddb.listTables(request);
    } else {
        ListTablesRequest request = ListTablesRequest.builder()
            .exclusiveStartTableName(lastName).build();
        response = ddb.listTables(request);
    }

    List<String> tableNames = response.tableNames();
    if (tableNames.size() > 0) {
        for (String curName : tableNames) {
            System.out.format("* %s\n", curName);
        }
    } else {
        System.out.println("No tables found!");
        System.exit(0);
    }

    lastName = response.lastEvaluatedTableName();
    if (lastName == null) { 
        moreTables = false;
    }

} catch (DynamoDbException e) {
    System.err.println(e.getMessage());
    System.exit(1);
}
System.out.println("\nDone!");
Actions

Create a table

The following code example shows how to create a DynamoDB table.

SDK for Java 2.x

```java
import software.amazon.awssdk.core.waiters.WaiterResponse;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.AttributeDefinition;
import software.amazon.awssdk.services.dynamodb.model.CreateTableRequest;
import software.amazon.awssdk.services.dynamodb.model.CreateTableResponse;
import software.amazon.awssdk.services.dynamodb.model.DescribeTableRequest;
import software.amazon.awssdk.services.dynamodb.model.DescribeTableResponse;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.model.KeySchemaElement;
import software.amazon.awssdk.services.dynamodb.model.KeyType;
import software.amazon.awssdk.services.dynamodb.model.ProvisionedThroughput;
import software.amazon.awssdk.services.dynamodb.model.ScalarAttributeType;
import software.amazon.awssdk.services.dynamodb.waiters.DynamoDbWaiter;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class CreateTable {
    public static void main(String[] args) {
        final String usage = ""
            Usage:
                <tableName> <key>
```

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
Where:

- **tableName** - The Amazon DynamoDB table to create (for example, `Music3`).
- **key** - The key for the Amazon DynamoDB table (for example, `Artist`).

```java
String tableName = args[0];
String key = args[1];
System.out.println("Creating an Amazon DynamoDB table " + tableName + " with a simple primary key: " + key);
Region region = Region.US_EAST_1;
DynamoDbClient ddb = DynamoDbClient.builder()
    .region(region)
    .build();

String result = createTable(ddb, tableName, key);
System.out.println("New table is " + result);
```

```java
public static String createTable(DynamoDbClient ddb, String tableName, String key) {
    DynamoDbWaiter dbWaiter = ddb.waiter();
    CreateTableRequest request = CreateTableRequest.builder()
        .attributeDefinitions(AttributeDefinition.builder()
            .attributeName(key)
            .attributeType(ScalarAttributeType.S)
            .build())
        .keySchema(KeySchemaElement.builder()
            .attributeName(key)
            .keyType(KeyType.HASH)
            .build())
        .provisionedThroughput(ProvisionedThroughput.builder()
            .readCapacityUnits(10L)
            .writeCapacityUnits(10L)
            .build())
        .tableName(tableName)
```

```java
    .build();
```

```java
ddb.close();
}
```

**Get a batch of items**

The following code example shows how to get a batch of DynamoDB items.

**SDK for Java 2.x**

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.AttributeValue;
import software.amazon.awssdk.services.dynamodb.model.BatchGetItemRequest;
import software.amazon.awssdk.services.dynamodb.model.BatchGetItemResponse;
import software.amazon.awssdk.services.dynamodb.model.KeysAndAttributes;
import java.util.HashMap;
import java.util.List;
import java.util.Map;

/**
 * Before running this Java V2 code example, set up your development environment,
 * including your credentials.
 */
```

* Note

There's more on GitHub. Find the complete example and learn how to set up and run in the *AWS Code Examples Repository*. 

shows how to get batch items using the service client.
public class BatchReadItems {
    public static void main(String[] args) {
        final String usage = ""
        Usage:
            <tableName>
        Where:
            tableName - The Amazon DynamoDB table (for example, Music).\s "";

        String tableName = "Music";
        Region region = Region.US_EAST_1;
        DynamoDbClient dynamoDbClient = DynamoDbClient.builder()
            .region(region)
            .build();

        getBatchItems(dynamoDbClient, tableName);
    }

    public static void getBatchItems(DynamoDbClient dynamoDbClient, String tableName) {
        // Define the primary key values for the items you want to retrieve.
        Map<String, AttributeValue> key1 = new HashMap<>();
        key1.put("Artist", AttributeValue.builder().s("Artist1").build();

        Map<String, AttributeValue> key2 = new HashMap<>();
        key2.put("Artist", AttributeValue.builder().s("Artist2").build();

        // Construct the batchGetItem request.
        Map<String, KeysAndAttributes> requestItems = new HashMap<>();
        requestItems.put(tableName, KeysAndAttributes.builder()
            .keys(List.of(key1, key2))
            .projectionExpression("Artist, SongTitle")
            .build();

        BatchGetItemRequest batchGetItemRequest = BatchGetItemRequest.builder()
            .requestItems(requestItems)
            .build();
shows how to get batch items using the service client and a paginator.

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.AttributeValue;
import software.amazon.awssdk.services.dynamodb.model.BatchGetItemRequest;
import software.amazon.awssdk.services.dynamodb.model.KeysAndAttributes;
import java.util.Collections;
import java.util.HashMap;
import java.util.List;
import java.util.Map;

public class BatchGetItemsPaginator {

    public static void main(String[] args){
        final String usage = "">
    }
}
```
String tableName = "Music";
Region region = Region.US_EAST_1;

Put an item in a table

The following code example shows how to put an item in a DynamoDB table.
Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Puts an item into a table using DynamoDbClient.

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.AttributeValue;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.model.PutItemRequest;
import software.amazon.awssdk.services.dynamodb.model.PutItemResponse;
import software.amazon.awssdk.services.dynamodb.model.ResourceNotFoundException;
import java.util.HashMap;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * To place items into an Amazon DynamoDB table using the AWS SDK for Java V2, its better practice to use the Enhanced Client. See the EnhancedPutItem example.
 */

public class PutItem {
    public static void main(String[] args) {
        final String usage = ""

        Usage:
        <tableName> <key> <keyVal> <albumtitle> <albumtitleval> <awards>
        <awardsval> <Songtitle> <songtitleval>

        Where:
        tableName - The Amazon DynamoDB table in which an item is placed (for example, Music3).
```
key - The key used in the Amazon DynamoDB table (for example, Artist).
keyval - The key value that represents the item to get (for example, Famous Band).
albumTitle - The Album title (for example, AlbumTitle).
AlbumTitleValue - The name of the album (for example, Songs About Life).
Awards - The awards column (for example, Awards).
AwardVal - The value of the awards (for example, 10).
SongTitle - The song title (for example, SongTitle).
SongTitleVal - The value of the song title (for example, Happy Day).

**Warning** This program will place an item that you specify into a table!

```java
    if (args.length != 9) {
        System.out.println(usage);
        System.exit(1);
    }

Query a table

The following code example shows how to query a DynamoDB table.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://aws.amazon.com/code-examples/).

Queries a table by using `DynamoDbClient`.

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.AttributeValue;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.model.QueryRequest;
import software.amazon.awssdk.services.dynamodb.model.QueryResponse;
import java.util.HashMap;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 * For more information, see the following documentation topic:
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 * To query items from an Amazon DynamoDB table using the AWS SDK for Java V2, its better practice to use the Enhanced Client. See the EnhancedQueryRecords example.
 */
public class Query {
    public static void main(String[] args) {
        final String usage = ""
        Usage:
        <tableName> <partitionKeyName> <partitionKeyVal>
        Where:
```
tableName - The Amazon DynamoDB table to put the item in (for example, Music3).

partitionKeyName - The partition key name of the Amazon DynamoDB table (for example, Artist).

partitionKeyVal - The value of the partition key that should match (for example, Famous Band).

if (args.length != 3) {
    System.out.println(usage);
    System.exit(1);
}

String tableName = args[0];
String partitionKeyName = args[1];
String partitionKeyVal = args[2];

// For more information about an alias, see:
// https://docs.aws.amazon.com/amazondynamodb/latest/developerguide/
Expressions.ExpressionAttributeNames.html

String partitionAlias = "#a";

System.out.format("Querying %s", tableName);
System.out.println("\n");
Region region = Region.US_EAST_1;
DynamoDbClient ddb = DynamoDbClient.builder()
    .region(region)
    .build();

int count = queryTable(ddb, tableName, partitionKeyName, partitionKeyVal, partitionAlias);
System.out.println("There were " + count + " record(s) returned");
ddb.close();
}

public static int queryTable(DynamoDbClient ddb, String tableName, String partitionKeyName, String partitionKeyVal, String partitionAlias) {
    // Set up an alias for the partition key name in case it's a reserved word.
    HashMap<String, String> attrNameAlias = new HashMap<String, String>();
    attrNameAlias.put(partitionAlias, partitionKeyName);

    // Set up mapping of the partition name with the value.
    HashMap<String, AttributeValue> attrValues = new HashMap<>();

attrValues.put(":", partitionKeyName, AttributeValue.builder()
    .s(partitionKeyVal)
    .build());

QueryRequest queryReq = QueryRequest.builder()
    .tableName(tableName)
    .keyConditionExpression(partitionAlias + " = " + partitionKeyName)
    .expressionAttributeNames(attrNameAlias)

    return response.count();
}

} catch (DynamoDbException e) {
    System.err.println(e.getMessage());
    System.exit(1);
}
return -1;

}

Queries a table by using DynamoDbClient and a secondary index.

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
* Create the Movies table by running the Scenario example and loading the Movie data from the JSON file. Next create a secondary index for the Movies table that uses only the year column. Name the index **year-index**. For more information, see:
* https://docs.aws.amazon.com/amazondynamodb/latest/developerguide/GSI.html
*/

```java
public class QueryItemsUsingIndex {
    public static void main(String[] args) {
        String tableName = "Movies";
        Region region = Region.US_EAST_1;
        DynamoDbClient ddb = DynamoDbClient.builder()
            .region(region)
            .build();

        queryIndex(ddb, tableName);
        ddb.close();
    }

    public static void queryIndex(DynamoDbClient ddb, String tableName) {
        try {
            Map<String, String> expressionAttributesNames = new HashMap<>();
            expressionAttributesNames.put("#year", "year");
            Map<String, AttributeValue> expressionAttributeValues = new HashMap<>();
            expressionAttributeValues.put(":yearValue", AttributeValue.builder().n("2013").build());

            QueryRequest request = QueryRequest.builder()
                .tableName(tableName)
                .indexName("year-index")
                .keyConditionExpression("#year = :yearValue")
                .expressionAttributeNames(expressionAttributesNames)
                .expressionAttributeValues(expressionAttributeValues)
                .build();

            System.out.println("=== Movie Titles ===");
            QueryResponse response = ddb.query(request);
            response.items().
                forEach(movie -> System.out.println(movie.get("title").s()));
        } catch (DynamoDbException e) {
            System.err.println(e.getMessage());
            System.exit(1);
        }
    }
}
```
Scan a table

The following code example shows how to scan a DynamoDB table.

SDK for Java 2.x

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.AttributeValue;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.model.ScanRequest;
import software.amazon.awssdk.services.dynamodb.model.ScanResponse;
import java.util.Map;
import java.util.Set;

/**************************
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.

  System.exit(1);
}
}
For API details, see `BatchWriteItem` in *AWS SDK for Java 2.x API Reference*.

### Scenarios

**Get started with tables, items, and queries**

The following code example shows how to:

- Create a table that can hold movie data.
- Put, get, and update a single movie in the table.
- Write movie data to the table from a sample JSON file.
- Query for movies that were released in a given year.
- Scan for movies that were released in a range of years.
- Delete a movie from the table, then delete the table.

### SDK for Java 2.x

#### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/aws/aws-sdk-java-examples).

Create a DynamoDB table.

```java
// Create a table with a Sort key.
public static void createTable(DynamoDbClient ddb, String tableName) {
    DynamoDbWaiter dbWaiter = ddb.waiter();
    ArrayList<AttributeDefinition> attributeDefinitions = new ArrayList<>();

    // Define attributes.
    attributeDefinitions.add(AttributeDefinition.builder()
    .attributeName("year")
    .attributeType("N")
    .build());

    attributeDefinitions.add(AttributeDefinition.builder()
    .attributeName("title")
    .attributeType("S")
    .build());

    CreateTableRequest request = CreateTableRequest.builder()
    .tableName(tableName)
    .attributeDefinitions(attributeDefinitions)
    .build();

    ddb.createTable(request);
    dbWaiter.tableCreated(tableName);
}
```
```java
attributeName("title")
.attributeType("S")
.build();

ArrayList<KeySchemaElement> tableKey = new ArrayList<>();
KeySchemaElement key = KeySchemaElement.builder()
    .attributeName("year")
    .keyType(KeyType.HASH)
    .build();

KeySchemaElement key2 = KeySchemaElement.builder()
    .attributeName("title")
    .keyType(KeyType.RANGE)
    .build();

// Add KeySchemaElement objects to the list.
tableKey.add(key);
tableKey.add(key2);

CreateTableRequest request = CreateTableRequest.builder()
    .keySchema(tableKey)
    .provisionedThroughput(ProvisionedThroughput.builder()
        .readCapacityUnits(10L)
        .writeCapacityUnits(10L)
        .build())
    .attributeDefinitions(attributeDefinitions)
    .tableName(tableName)
    .build();

try {
    CreateTableResponse response = ddb.createTable(request);
    DescribeTableRequest tableRequest = DescribeTableRequest.builder()
        .tableName(tableName)
        .build();

    // Wait until the Amazon DynamoDB table is created.
    WaiterResponse<DescribeTableResponse> waiterResponse =
        dbWaiter.waitUntilTableExists(tableRequest);
    waiterResponse.matched().response().ifPresent(System.out::println);
    String newTable = response.tableDescription().tableName();
    System.out.println("The " + newTable + " was successfully created.");
}

} catch (DynamoDbException e) {
    System.err.println(e.getMessage());
```
Create a helper function to download and extract the sample JSON file.

```java
// Load data into the table.
public static void loadData(DynamoDbClient ddb, String tableName, String fileName) throws IOException {
    DynamoDbEnhancedClient enhancedClient = DynamoDbEnhancedClient.builder()
        .dynamoDbClient(ddb)
        .build();

    DynamoDbTable<Movies> mappedTable = enhancedClient.table("Movies",
        TableSchema.fromBean(Movies.class));
    JsonParser parser = new JsonFactory().createParser(new File(fileName));
    com.fasterxml.jackson.databind.JsonNode rootNode = new ObjectMapper().readTree(parser);
    Iterator<JsonNode> iter = rootNode.iterator();
    ObjectNode currentNode;
    int t = 0;
    while (iter.hasNext()) {
        // Only add 200 Movies to the table.
        if (t == 200)
            break;
        currentNode = (ObjectNode) iter.next();

        int year = currentNode.path("year").asInt();
        String title = currentNode.path("title").asText();
        String info = currentNode.path("info").toString();

        Movies movies = new Movies();
        movies.setYear(year);
        movies.setTitle(title);
        movies.setInfo(info);

        // Put the data into the Amazon DynamoDB Movie table.
        mappedTable.putItem(movies);
        t++;
    }
}
```
Get an item from a table.

```java
public static void getItem(DynamoDbClient ddb) {

    HashMap<String, AttributeValue> keyToGet = new HashMap<>();
    keyToGet.put("year", AttributeValue.builder()
        .n("1933")
        .build());

    keyToGet.put("title", AttributeValue.builder()
        .s("King Kong")
        .build());

    GetItemRequest request = GetItemRequest.builder()
        .key(keyToGet)
        .tableName("Movies")
        .build();

    try {
        Map<String, AttributeValue> returnedItem = ddb.getItem(request).item();

        if (returnedItem != null) {
            Set<String> keys = returnedItem.keySet();
            System.out.println("Amazon DynamoDB table attributes: \n");

            for (String key1 : keys) {
                System.out.format("%s: %s\n", key1,
                    returnedItem.get(key1).toString());
            }
        } else {
            System.out.format("No item found with the key %s!\n", "year");
        }

    } catch (DynamoDbException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}
```

Full example.
Before running this Java V2 code example, set up your development environment, including your credentials.

For more information, see the following documentation topic:

https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html

This Java example performs these tasks:

1. Creates the Amazon DynamoDB Movie table with partition and sort key.
2. Puts data into the Amazon DynamoDB table from a JSON document using the Enhanced client.
4. Adds a new item.
5. Updates an item.
6. Uses a Scan to query items using the Enhanced client.
7. Queries all items where the year is 2013 using the Enhanced Client.
8. Deletes the table.

```java
public class Scenario {
    public static final String DASHES = new String(new char[80]).replace("\0", "-");

    public static void main(String[] args) throws IOException {
        final String usage = "
        Usage:
            <fileName>
        Where:
            fileName - The path to the moviedata.json file that you can download from the Amazon DynamoDB Developer Guide.
        ""

        if (args.length != 1) {
            System.out.println(usage);
            System.exit(1);
        }

        String tableName = "Movies";
        String fileName = args[0];
        Region region = Region.US_EAST_1;

### Query a table by using batches of PartiQL statements

The following code example shows how to:

- Get a batch of items by running multiple SELECT statements.
- Add a batch of items by running multiple INSERT statements.
- Update a batch of items by running multiple UPDATE statements.
- Delete a batch of items by running multiple DELETE statements.

#### SDK for Java 2.x

```java
public class ScenarioPartiQLBatch {
    public static void main(String[] args) throws IOException {
        // Code snippet...
    }
}
```

---

**Query a table using PartiQL**

The following code example shows how to:

- Get an item by running a SELECT statement.
- Add an item by running an INSERT statement.
- Update an item by running an UPDATE statement.
- Delete an item by running a DELETE statement.

**SDK for Java 2.x**

```java
public class ScenarioPartiQ {
    public static void main(String[] args) throws IOException {
        final String usage = "Usage:
            <fileName>
            Where:
            fileName - The path to the moviedata.json file that you can
download from the Amazon DynamoDB Developer Guide.
            "

        if (args.length != 1) {
            System.out.println(usage);
            System.exit(1);
        }

        String fileName = args[0];
        String tableName = "MoviesPartiQ";
```
Region region = Region.US_EAST_1;
DynamoDbClient ddb = DynamoDbClient.builder()
  .region(region)
  .build();

System.out.println("******* Creating an Amazon DynamoDB table named MoviesPartiQ with a
key named year and a sort key named title.");
createTable(ddb, tableName);

System.out.println("******* Loading data into the MoviesPartiQ table.");
loadData(ddb, fileName);

System.out.println("******* Getting data from the MoviesPartiQ table.");
getItem(ddb);

System.out.println("******* Putting a record into the MoviesPartiQ table.");

Amazon EC2 examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon EC2.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Get started

Hello Amazon EC2

The following code examples show how to get started using Amazon EC2.
public static void describeSecurityGroups(Ec2Client ec2, String groupId) {
    try {
        DescribeSecurityGroupsRequest request =
            DescribeSecurityGroupsRequest.builder()
                .groupIds(groupId)
                .build();

        // Use a paginator.
        DescribeSecurityGroupsIterable listGroups =
            ec2.describeSecurityGroupsPaginator(request);
        listGroups.stream()
            .flatMap(r -> r.securityGroups().stream())
            .forEach(group -> System.out
                .println(" Group id: " +group.groupId() + " group name = " +
                    group.groupName()));

    } catch (Ec2Exception e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}

• For API details, see DescribeSecurityGroups in AWS SDK for Java 2.x API Reference.

Allocate an Elastic IP address

The following code example shows how to allocate an Elastic IP address for Amazon EC2.

SDK for Java 2.x

```java
public static String allocateAddress(Ec2Client ec2) {
    try {
        AllocateAddressRequest allocateRequest =
            AllocateAddressRequest.builder()
            .domain(DomainType.VPC)
            .build();

        AllocateAddressResponse allocateResponse =
            ec2.allocateAddress(allocateRequest);
        return allocateResponse.allocationId();
    } catch (Ec2Exception e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
    return "";
}
```

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

• For API details, see AllocateAddress in AWS SDK for Java 2.x API Reference.

Associate an Elastic IP address with an instance

The following code example shows how to associate an Elastic IP address with an Amazon EC2 instance.
public static String associateAddress(Ec2Client ec2, String instanceId, String allocationId) {
    try {
        AssociateAddressRequest associateRequest = 
              AssociateAddressRequest.builder()
            .instanceId(instanceId)
            .allocationId(allocationId)
            .build();

        AssociateAddressResponse associateResponse = 
              ec2.associateAddress(associateRequest);
        return associateResponse.associationId();
    } catch (Ec2Exception e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
    return "";
}

• For API details, see AssociateAddress in AWS SDK for Java 2.x API Reference.

Create a security group

The following code example shows how to create an Amazon EC2 security group.
SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```java
public static String createSecurityGroup(Ec2Client ec2, String groupName, String groupDesc, String vpcId, String myIpAddress) {
    try {
        CreateSecurityGroupRequest createRequest =
            CreateSecurityGroupRequest.builder()
            .groupName(groupName)
            .description(groupDesc)
            .vpcId(vpcId)
            .build();

        CreateSecurityGroupResponse resp =
            ec2.createSecurityGroup(createRequest);
        IpRange ipRange = IpRange.builder()
            .cidrIp(myIpAddress + "/0")
            .build();

        IpPermission ipPerm = IpPermission.builder()
            .ipProtocol("tcp")
            .toPort(80)
            .fromPort(80)
            .ipRanges(ipRange)
            .build();

        IpPermission ipPerm2 = IpPermission.builder()
            .ipProtocol("tcp")
            .toPort(22)
            .fromPort(22)
            .ipRanges(ipRange)
            .build();

        AuthorizeSecurityGroupIngressRequest authRequest =
            AuthorizeSecurityGroupIngressRequest.builder()
            .groupName(groupName)
```
public static void createKeyPair(Ec2Client ec2, String keyName, String fileName) {
    try {
        CreateKeyPairRequest request = CreateKeyPairRequest.builder()
            .keyName(keyName)
            .build();

        CreateKeyPairResponse response = ec2.createKeyPair(request);
        String content = response.keyMaterial();
        BufferedWriter writer = new BufferedWriter(new FileWriter(fileName));
        writer.write(content);
        writer.close();
    } catch (Ec2Exception e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
    return "";
}
System.out.println("Successfully created key pair named " + keyName);

} catch (Ec2Exception | IOException e) {
    System.err.println(e.getMessage());
    System.exit(1);
}

• For API details, see CreateKeyPair in AWS SDK for Java 2.x API Reference.

Create and run an instance

The following code example shows how to create and run an Amazon EC2 instance.

SDK for Java 2.x

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.ec2.Ec2Client;
import software.amazon.awssdk.services.ec2.model.InstanceType;
import software.amazon.awssdk.services.ec2.model.RunInstancesRequest;
import software.amazon.awssdk.services.ec2.model.RunInstancesResponse;
import software.amazon.awssdk.services.ec2.model.Tag;
import software.amazon.awssdk.services.ec2.model.CreateTagsRequest;
import software.amazon.awssdk.services.ec2.model.Ec2Exception;

/**

Describe instances

The following code example shows how to describe Amazon EC2 instances.

SDK for Java 2.x

> Note
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
public static void describeEC2Instances(Ec2Client ec2) {
    try {
        DescribeInstancesRequest request = DescribeInstancesRequest.builder()
            .maxResults(10)
            .build();

        DescribeInstancesIterable instancesIterable = ec2.describeInstancesPaginator(request);
        instancesIterable.stream()
            .flatMap(r -> r.reservations().stream())
            .flatMap(reservation -> reservation.instances().stream())
            .forEach(instance -> {
                System.out.println("Instance Id is " + instance.instanceId());
                System.out.println("Image id is " + instance.imageId());
                System.out.println("Instance type is " + instance.instanceType());
                System.out.println("Instance state name is " + instance.state().name());
                System.out.println("Monitoring information is " + instance.monitoring().state());
            });
    } catch (Ec2Exception e) {
        System.err.println(e.awsErrorDetails().errorCode());
        System.exit(1);
    }
}

• For API details, see DescribeInstances in AWS SDK for Java 2.x API Reference.

Disassociate an Elastic IP address from an instance

The following code example shows how to disassociate an Elastic IP address from an Amazon EC2 instance.
public static void disassociateAddress(Ec2Client ec2, String associationId) {
    try {
        DisassociateAddressRequest addressRequest =
            DisassociateAddressRequest.builder()
                .associationId(associationId)
                .build();

        ec2.disassociateAddress(addressRequest);
        System.out.println("You successfully disassociated the address!");
    } catch (Ec2Exception e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}

For API details, see DisassociateAddress in AWS SDK for Java 2.x API Reference.

Get data about a security group

The following code example shows how to get data about an Amazon EC2 security group.

SDK for Java 2.x

public static void describeSecurityGroups(Ec2Client ec2, String groupId) {
    
    
}
try {
    DescribeSecurityGroupsRequest request =
    DescribeSecurityGroupsRequest.builder()
        .groupIds(groupId)
        .build();

    // Use a paginator.
    DescribeSecurityGroupsIterable listGroups =
    ec2.describeSecurityGroupsPaginator(request);
    listGroups.stream()
        .flatMap(r -> r.securityGroups().stream())
        .forEach(group -> System.out
            .println(" Group id: " +group.groupId() + " group name = " +
            group.groupName()));

} catch (Ec2Exception e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

• For API details, see DescribeSecurityGroups in AWS SDK for Java 2.x API Reference.

Get data about instance types
The following code example shows how to get data about Amazon EC2 instance types.

SDK for Java 2.x

**Note**
There's more on GitHub. Find the complete example and learn how to set up and run in
the AWS Code Examples Repository.

// Get a list of instance types.
public static String getInstanceTypes(Ec2Client ec2) {
    String instanceType;
    try {
        DescribeInstanceTypesRequest typesRequest =
        DescribeInstanceTypesRequest.builder()
For API details, see [DescribeInstanceTypes](https://docs.aws.amazon.com/sdk-for-java/latest/api/com/amazonaws/services/ec2/model/DescribeInstanceTypes.html) in AWS SDK for Java 2.x API Reference.

### List security key pairs

The following code example shows how to list Amazon EC2 security key pairs.

```java
public static void describeKeys(Ec2Client ec2) {
    // Code snippet...
}
```

**SDK for Java 2.x**

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/aws-samples/aws-sdk-java-examples).
try {
    DescribeKeyPairsResponse response = ec2.describeKeyPairs();
    response.keyPairs().forEach(keyPair -> System.out.printf(
        "Found key pair with name %s and fingerprint %s",
        keyPair.keyName(),
        keyPair.keyFingerprint()));
}

For API details, see DescribeKeyPairs in AWS SDK for Java 2.x API Reference.

Release an Elastic IP address

The following code example shows how to release an Elastic IP address.

SDK for Java 2.x

```java
public static void releaseEC2Address(Ec2Client ec2, String allocId) {
    try {
        ReleaseAddressRequest request = ReleaseAddressRequest.builder()
            .allocationId(allocId)
            .build();

        ec2.releaseAddress(request);
        System.out.println("Successfully released Elastic IP address "+
            allocId);
    } catch (Ec2Exception e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
• For API details, see ReleaseAddress in AWS SDK for Java 2.x API Reference.

Set inbound rules for a security group

The following code example shows how to set inbound rules for an Amazon EC2 security group.

SDK for Java 2.x

```java
public static String createSecurityGroup(Ec2Client ec2, String groupName, String groupDesc, String vpcId, String myIpAddress) {
    try {
        CreateSecurityGroupRequest createRequest =
            CreateSecurityGroupRequest.builder()
                .groupName(groupName)
                .description(groupDesc)
                .vpcId(vpcId)
                .build();

        CreateSecurityGroupResponse resp =
            ec2.createSecurityGroup(createRequest);
        IpRange ipRange = IpRange.builder()
            .cidrIp(myIpAddress + "/0")
            .build();

        IpPermission ipPerm = IpPermission.builder()
            .ipProtocol("tcp")
            .toPort(80)
            .fromPort(80)
            .ipRanges(ipRange)
            .build();

        IpPermission ipPerm2 = IpPermission.builder()
```
AuthorizeSecurityGroupIngressRequest authRequest =
    AuthorizeSecurityGroupIngressRequest.builder()
    .groupName(groupName)
    .ipPermissions(ipPerm, ipPerm2)
    .build();

e2.authorizeSecurityGroupIngress(authRequest);
    System.out.println("Successfully added ingress policy to security group " + groupName);
    return resp.groupId();
}

} catch (Ec2Exception e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
return "";

• For API details, see AuthorizeSecurityGroupIngress in AWS SDK for Java 2.x API Reference.

Start an instance

The following code example shows how to start an Amazon EC2 instance.

SDK for Java 2.x

public static void startInstance(Ec2Client ec2, String instanceId) {
    Ec2Waiter ec2Waiter = Ec2Waiter.builder()
        .overrideConfiguration(b -> b.maxAttempts(100))
Start an instance

The following code example shows how to start an Amazon EC2 instance.

```java
public void startInstance(String instanceId) {
    client(ec2)
    .build();

    StartInstancesRequest request = StartInstancesRequest.builder()
        .instanceIds(instanceId)
        .build();

    System.out.println("Use an Ec2Waiter to wait for the instance to run. This will take a few minutes.");
    ec2.startInstances(request);
    DescribeInstancesRequest instanceRequest =
        DescribeInstancesRequest.builder()
        .instanceIds(instanceId)
        .build();

    WaiterResponse<DescribeInstancesResponse> waiterResponse =
        ec2Waiter.waitUntilInstanceRunning(instanceRequest);
    waiterResponse.matched().response().ifPresent(System.out::println);
    System.out.println("Successfully started instance " + instanceId);
}
```

For API details, see `StartInstances` in *AWS SDK for Java 2.x API Reference*.

Stop an instance

The following code example shows how to stop an Amazon EC2 instance.

```java
public static void stopInstance(Ec2Client ec2, String instanceId) {
    Ec2Waiter ec2Waiter = Ec2Waiter.builder()
        .overrideConfiguration(b -> b.maxAttempts(100))
        .client(ec2)
        .build();
    StopInstancesRequest request = StopInstancesRequest.builder()
```
.instanceIds(instanceId)
 .build();

 System.out.println("Use an Ec2Waiter to wait for the instance to stop. This will take a few minutes.");
 ec2.stopInstances(request);
 DescribeInstancesRequest instanceRequest =
 DescribeInstancesRequest.builder()
 .instanceIds(instanceId)
 .build();

 WaiterResponse<DescribeInstancesResponse> waiterResponse =
 ec2Waiter.waitUntilInstanceStopped(instanceRequest);
 waiterResponse.matched().response().ifPresent(System.out::println);
 System.out.println("Successfully stopped instance " + instanceId);
}

- For API details, see StopInstances in AWS SDK for Java 2.x API Reference.

**Terminate an instance**

The following code example shows how to terminate an Amazon EC2 instance.

**SDK for Java 2.x**

```java
public static void terminateEC2(Ec2Client ec2, String instanceId) {
    try {
        Ec2Waiter ec2Waiter = Ec2Waiter.builder()
            .overrideConfiguration(b -> b.maxAttempts(100))
            .client(ec2)
            .build();

        TerminateInstancesRequest ti = TerminateInstancesRequest.builder()
            .instanceIds(instanceId)
            .build();
```
System.out.println("Use an Ec2Waiter to wait for the instance to terminate. This will take a few minutes.");
ec2.terminateInstances(ti);
DescribeInstancesRequest instanceRequest =
DescribeInstancesRequest.builder()
    .instanceIds(instanceId)
    .build();

WaiterResponse<DescribeInstancesResponse> waiterResponse = ec2Waiter
    .waitUntilInstanceTerminated(instanceRequest);
waiterResponse.matched().response().ifPresent(System.out::println);
System.out.println("Successfully started instance " + instanceId);
System.out.println(instanceId + " is terminated!");

} catch (Ec2Exception e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

• For API details, see TerminateInstances in AWS SDK for Java 2.x API Reference.

Scenarios

Build and manage a resilient service

The following code example shows how to create a load-balanced web service that returns book, movie, and song recommendations. The example shows how the service responds to failures, and how to restructure the service for more resilience when failures occur.

• Use an Amazon EC2 Auto Scaling group to create Amazon Elastic Compute Cloud (Amazon EC2) instances based on a launch template and to keep the number of instances in a specified range.
• Handle and distribute HTTP requests with Elastic Load Balancing.
• Monitor the health of instances in an Auto Scaling group and forward requests only to healthy instances.
• Run a Python web server on each EC2 instance to handle HTTP requests. The web server responds with recommendations and health checks.
• Simulate a recommendation service with an Amazon DynamoDB table.
- Control web server response to requests and health checks by updating AWS Systems Manager parameters.

**SDK for Java 2.x**

> Note
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/aws-samples/aws-sdk-java-2).

Run the interactive scenario at a command prompt.

```java
public class Main {

    public static final String fileName = "C:\AWS\resworkflow\recommendations.json"; // Modify file location.
    public static final String tableName = "doc-example-recommendation-service";
    public static final String startScript = "C:\AWS\resworkflow\server_startup_script.sh"; // Modify file location.
    public static final String policyFile = "C:\AWS\resworkflow\instance_policy.json"; // Modify file location.
    public static final String ssmJSON = "C:\AWS\resworkflow\ssm_only_policy.json"; // Modify file location.
    public static final String failureResponse = "doc-example-resilient-architecture-failure-response";
    public static final String healthCheck = "doc-example-resilient-architecture-health-check";
    public static final String templateName = "doc-example-resilience-template";
    public static final String roleName = "doc-example-resilience-role";
    public static final String policyName = "doc-example-resilience-pol";
    public static final String profileName = "doc-example-resilience-prof";
    public static final String badCredsProfileName = "doc-example-resilience-prof-bc";

    public static final String targetGroupName = "doc-example-resilience-tg";
    public static final String autoScalingGroupName = "doc-example-resilience-group";
    public static final String lbName = "doc-example-resilience-lb";
    public static final String protocol = "HTTP";
    public static final int port = 80;
```
public static final String DASHES = new String(new char[80]).replace("\0", "-" صفحة 784

public static void main(String[] args) throws IOException, InterruptedException {
    Scanner in = new Scanner(System.in);
    Database database = new Database();
    AutoScaler autoScaler = new AutoScaler();
    LoadBalancer loadBalancer = new LoadBalancer();

    System.out.println(DASHES);
    System.out.println("Welcome to the demonstration of How to Build and Manage a Resilient Service!");
    System.out.println(DASHES);
    System.out.println(DASHES);
    System.out.println("A - SETUP THE RESOURCES");
    System.out.println("Press Enter when you're ready to start deploying resources.");
    in.nextLine();
    deploy(loadBalancer);
    System.out.println(DASHES);
    System.out.println(DASHES);
    System.out.println("B - DEMO THE RESILIENCE FUNCTIONALITY");
    System.out.println("Press Enter when you're ready.");
    in.nextLine();
    demo(loadBalancer);
    System.out.println(DASHES);
    System.out.println(DASHES);
    System.out.println("C - DELETE THE RESOURCES");
    System.out.println("This concludes the demo of how to build and manage a resilient service.
    To keep things tidy and to avoid unwanted charges on your account, we can clean up all AWS resources
    that were created for this demo.
    ")
    System.out.println("\n Do you want to delete the resources (y/n)? ");
    String userInput = in.nextLine().trim().toLowerCase(); // Capture user input
    if (userInput.equals("y")) {
        // Delete resources here
// Deletes the AWS resources used in this example.
 private static void deleteResources(LoadBalancer loadBalancer, AutoScaler autoScaler, Database database)
 
 throws IOException, InterruptedException {
 loadBalancer.deleteLoadBalancer(lbName);
 System.out.println("*** Wait 30 secs for resource to be deleted");
 TimeUnit.SECONDS.sleep(30);
 loadBalancer.deleteTargetGroup(targetGroupName);
 autoScaler.deleteAutoScaleGroup(autoScalingGroupName);
 autoScaler.deleteRolesPolicies(policyName, roleName, profileName);
 autoScaler.deleteTemplate(templateName);
 database.deleteTable(tableName);
 }

deploy
 private static void deploy(LoadBalancer loadBalancer) throws InterruptedException, IOException {
 Scanner in = new Scanner(System.in);
 System.out.println(""");

 For this demo, we'll use the AWS SDK for Java (v2) to create several AWS resources
 to set up a load-balanced web service endpoint and explore some ways to make it resilient
 against various kinds of failures.

 Some of the resources create by this demo are:
* A DynamoDB table that the web service depends on to provide book, movie, and song recommendations.
* An EC2 launch template that defines EC2 instances that each contain a Python web server.
* An EC2 Auto Scaling group that manages EC2 instances across several Availability Zones.
* An Elastic Load Balancing (ELB) load balancer that targets the Auto Scaling group to distribute requests.

```java
System.out.println("Press Enter when you're ready.");
in.nextLine();
System.out.println(DASHES);
System.out.println(DASHES);
System.out.println("Creating and populating a DynamoDB table named " + tableName);
Database database = new Database();
database.createTable(tableName, fileName);
System.out.println(DASHES);
System.out.println(DASHES);
System.out.println("Creating an EC2 launch template that runs '{startup_script}' when an instance starts.
This script starts a Python web server defined in the `server.py` script. The web server
listens to HTTP requests on port 80 and responds to requests to '/'
and to '/healthcheck'.
For demo purposes, this server is run as the root user. In production, the best practice is to
run a web server, such as Apache, with least-privileged credentials.
The template also defines an IAM policy that each instance uses to assume a role that grants
permissions to access the DynamoDB recommendation table and Systems Manager parameters
that control the flow of the demo.
""");

LaunchTemplateCreator templateCreator = new LaunchTemplateCreator();
templateCreator.createTemplate(policyFile, policyName, profileName,
startScript, templateName, roleName);
System.out.println(DASHES);"
Creating an EC2 Auto Scaling group that maintains three EC2 instances, each in a different Availability Zone.

*** Wait 30 secs for the VPC to be created

AutoScaler autoScaler = new AutoScaler();
String[] zones = autoScaler.createGroup(3, templateName, autoScalingGroupName);

At this point, you have EC2 instances created. Once each instance starts, it listens for HTTP requests. You can see these instances in the console or continue with the demo.

Press Enter when you're ready to continue.

Creating variables that control the flow of the demo.

Creating an Elastic Load Balancing target group and load balancer. The target group defines how the load balancer connects to instances. The load balancer provides a single endpoint where clients connect and dispatches requests to instances in the group.

System.out.println("Let's reinstate the recommendation service.");
paramHelper.put(paramHelper.tableName, paramHelper.dyntable);

System.out.println(""
    Let's also substitute bad credentials for one of the instances in
    the target group so that it can't
    access the DynamoDB recommendation table. We will get an instance id
    value.
    "");

LaunchTemplateCreator templateCreator = new LaunchTemplateCreator();
AutoScaler autoScaler = new AutoScaler();

// Create a new instance profile based on badCredsProfileName.
templateCreator.createInstanceProfile(policyFile, policyName,
    badCredsProfileName, roleName);
String badInstanceId = autoScaler.getBadInstance(autoScalingGroupName);
System.out.println("The bad instance id values used for this demo is " +
    badInstanceId);

String profileAssociationId = autoScaler.getInstanceProfile(badInstanceId);
System.out.println("The association Id value is " + profileAssociationId);
System.out.println("Replacing the profile for instance " + badInstanceId +
    " with a profile that contains bad credentials");
autoScaler.replaceInstanceProfile(badInstanceId, badCredsProfileName,
    profileAssociationId);

System.out.println("
    Now, sending a GET request to the load balancer endpoint
returns either a recommendation or a static response,
    depending on which instance is selected by the load
balancer.
    "");

demoChoices(loadBalancer);

System.out.println(""
    Let's implement a deep health check. For this demo, a deep health
check tests whether
    the web service can access the DynamoDB table that it depends on for
recommendations. Note that
the deep health check is only for ELB routing and not for Auto
Scaling instance health.

This kind of deep health check is not recommended for Auto Scaling
instance health, because it
risks accidental termination of all instances in the Auto Scaling
group when a dependent service fails.

```java
System.out.println(""
By implementing deep health checks, the load balancer can detect
when one of the instances is failing
and take that instance out of rotation.
"");

paramHelper.put(paramHelper.healthCheck, "deep");

System.out.println(""
Now, checking target health indicates that the instance with bad
credentials
is unhealthy. Note that it might take a minute or two for the load
balancer to detect the unhealthy
instance. Sending a GET request to the load balancer endpoint always
returns a recommendation, because
the load balancer takes unhealthy instances out of its rotation.
"");

demoChoices(loadBalancer);

System.out.println(""
Because the instances in this demo are controlled by an auto
scaler, the simplest way to fix an unhealthy
instance is to terminate it and let the auto scaler start a
new instance to replace it.
"");

autoScaler.terminateInstance(badInstanceId);

System.out.println(""
Even while the instance is terminating and the new instance is
starting, sending a GET
request to the web service continues to get a successful
recommendation response because
the load balancer routes requests to the healthy instances. After
the replacement instance
starts and reports as healthy, it is included in the load balancing rotation.

Note that terminating and replacing an instance typically takes several minutes, during which time you can see the changing health check status until the new instance is running and healthy.

""

demoChoices(loadBalancer);
System.out.println("If the recommendation service fails now, deep health checks mean all instances report as unhealthy.");
paramHelper.put(paramHelper.tableName, "this-is-not-a-table");

demoChoices(loadBalancer);
paramHelper.reset();

Get started with instances

The following code example shows how to:

- Create a key pair and security group.
- Select an Amazon Machine Image (AMI) and compatible instance type, then create an instance.
- Stop and restart the instance.
- Associate an Elastic IP address with your instance.
- Connect to your instance with SSH, then clean up resources.

SDK for Java 2.x

```java
/**
 * Before running this Java (v2) code example, set up your development environment, including your credentials.
 * For more information, see the following documentation topic:
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 * This Java example performs the following tasks:
 * 1. Creates an RSA key pair and saves the private key data as a .pem file.
 * 2. Lists key pairs.
 * 3. Creates a security group for the default VPC.
 * 4. Displays security group information.
 * 5. Gets a list of Amazon Linux 2 AMIs and selects one.
 * 6. Gets more information about the image.
 */
```
7. Gets a list of instance types that are compatible with the selected AMI’s architecture.
8. Creates an instance with the key pair, security group, AMI, and an instance type.
9. Displays information about the instance.
10. Stops the instance and waits for it to stop.
11. Starts the instance and waits for it to start.
12. Allocates an Elastic IP address and associates it with the instance.
13. Displays SSH connection info for the instance.
14. Disassociates and deletes the Elastic IP address.
15. Terminates the instance and waits for it to terminate.
16. Deletes the security group.
17. Deletes the key pair.

```
public class EC2Scenario {
    public static final String DASHES = new String(new char[80]).replace("\0", "-");

    public static void main(String[] args) throws InterruptedException {
        final String usage = ""
        Usage:
            <keyName> <fileName> <groupName> <groupDesc> <vpcId>
        Where:
            keyName - A key pair name (for example, TestKeyPair).
            fileName - A file name where the key information is written to.
            groupName - The name of the security group.
            groupDesc - The description of the security group.
            vpcId - A VPC Id value. You can get this value from the AWS Management Console.
            myIpAddress - The IP address of your development machine.

**Amazon ECS examples using SDK for Java 2.x**

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon ECS.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.
Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

**Topics**

- **Actions**

**Actions**

**Create a cluster**

The following code example shows how to create an Amazon ECS cluster.

**SDK for Java 2.x**

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.ecs.EcsClient;
import software.amazon.awssdk.services.ecs.model.ExecuteCommandConfiguration;
import software.amazon.awssdk.services.ecs.model.ExecuteCommandLogging;
import software.amazon.awssdk.services.ecs.model.ClusterConfiguration;
import software.amazon.awssdk.services.ecs.model.CreateClusterResponse;
import software.amazon.awssdk.services.ecs.model.EcsException;
import software.amazon.awssdk.services.ecs.model.CreateClusterRequest;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 * For more information, see the following documentation topic:
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class CreateCluster {
    public static void main(String[] args) {

    UpdateServiceRequest serviceRequest = UpdateServiceRequest.builder()
        .cluster(clusterName)
        .service(serviceArn)
        .desiredCount(0)
        .build();

    ecsClient.updateService(serviceRequest);
    System.out.println("The service was modified");

} catch (EcsException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

For API details, see UpdateService in AWS SDK for Java 2.x API Reference.

Elastic Load Balancing examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Elastic Load Balancing.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

**Get started**

**Hello Elastic Load Balancing**

The following code examples show how to get started using Elastic Load Balancing.
Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```java
public class HelloLoadBalancer {
    public static void main(String[] args) {
        ElasticLoadBalancingV2Client loadBalancingV2Client = ElasticLoadBalancingV2Client.builder()
            .region(Region.US_EAST_1)
            .build();

        DescribeLoadBalancersResponse loadBalancersResponse = loadBalancingV2Client.describeLoadBalancers(r -> r.pageSize(10));
        List<LoadBalancer> loadBalancerList = loadBalancersResponse.loadBalancers();
        for (LoadBalancer lb : loadBalancerList) {
            System.out.println("Load Balancer DNS name = " + lb.dnsName());
        }
    }
}
```

- For API details, see [DescribeLoadBalancers](#) in AWS SDK for Java 2.x API Reference.

Topics

- **Scenarios**

Actions

Create a listener for a load balancer

The following code example shows how to create a listener that forwards requests from an ELB load balancer to a target group.
SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```java
/*
 * Creates an Elastic Load Balancing load balancer that uses the specified
 * subnets
 * and forwards requests to the specified target group.
 */
public String createLoadBalancer(List<Subnet> subnetIds, String targetGroupARN,
String lbName, int port,
    String protocol) {
    try {
        List<String> subnetIdStrings = subnetIds.stream()
            .map(Subnet::subnetId)
            .collect(Collectors.toList());

        CreateLoadBalancerRequest balancerRequest =
            CreateLoadBalancerRequest.builder()
                .subnets(subnetIdStrings)
                .name(lbName)
                .scheme("internet-facing")
                .build();

        // Create and wait for the load balancer to become available.
        CreateLoadBalancerResponse lsResponse =
            getLoadBalancerClient().createLoadBalancer(balancerRequest);
        String lbARN = lsResponse.loadBalancers().get(0).loadBalancerArn();

        ElasticLoadBalancingV2Waiter loadBalancerWaiter =
            getLoadBalancerClient().waiter();
        DescribeLoadBalancersRequest request =
            DescribeLoadBalancersRequest.builder()
                .loadBalancerArns(lbARN)
                .build();

        System.out.println("Waiting for Load Balancer " + lbName + " to become
available.");
```
WaiterResponse<DescribeLoadBalancersResponse> waiterResponse = loadBalancerWaiter
       .waitUntilLoadBalancerAvailable(request);
waiterResponse.matched().response().ifPresent(System.out::println);
System.out.println("Load Balancer " + lbName + " is available.");

// Get the DNS name (endpoint) of the load balancer.
String lbDNSName = lsResponse.loadBalancers().get(0).dnsName();
System.out.println("*** Load Balancer DNS Name: " + lbDNSName);

// Create a listener for the load balance.
Action action = Action.builder()
       .targetGroupArn(targetGroupARN)
       .type("forward")
       .build();

CreateListenerRequest listenerRequest = CreateListenerRequest.builder()
       .loadBalancerArn(lsResponse.loadBalancers().get(0).loadBalancerArn())
       .defaultActions(action)
       .port(port)
       .protocol(protocol)
       .defaultActions(action)
       .build();

getLoadBalancerClient().createListener(listenerRequest); System.out.println("Created listener to forward traffic from load
balancer " + lbName + " to target group "
              + targetGroupARN);

// Return the load balancer DNS name.
return lbDNSName;

} catch (ElasticLoadBalancingV2Exception e) {
    e.printStackTrace();
}
return "";
}

- For API details, see [CreateListener](https://docs.aws.amazon.com/sdk-for-java/latest/awssdk.reference/api/com.amazonaws.services.elasticloadbalancingv2/aws-java2/com.amazonaws.services.elasticloadbalancingv2.model/CreateListenerRequest.html) in *AWS SDK for Java 2.x API Reference*.  

---

**Elastic Load Balancing**

850
Create a target group

The following code example shows how to create an ELB target group.

SDK for Java 2.x

```java
/**
 * Creates an Elastic Load Balancing target group. The target group specifies
 * how
 * the load balancer forward requests to instances in the group and how instance
 * health is checked.
 */

public String createTargetGroup(String protocol, int port, String vpcId, String targetGroupName) {
    CreateTargetGroupRequest targetGroupRequest =
            CreateTargetGroupRequest.builder()
                    .healthCheckPath("/healthcheck")
                    .healthCheckTimeoutSeconds(5)
                    .port(port)
                    .vpcId(vpcId)
                    .name(targetGroupName)
                    .protocol(protocol)
                    .build();

    CreateTargetGroupResponse targetGroupResponse =
            getLoadBalancerClient().createTargetGroup(targetGroupRequest);
    String targetGroupArn =
            targetGroupResponse.targetGroups().get(0).targetGroupArn();
    String targetGroup =
            targetGroupResponse.targetGroups().get(0).targetGroupName();
    System.out.println("The " + targetGroup + " was created with ARN" + targetGroupArn);
    return targetGroupArn;
}
```
Create an Application Load Balancer

The following code example shows how to create an ELB Application Load Balancer.

SDK for Java 2.x

```java
/*
 * Creates an Elastic Load Balancing load balancer that uses the specified
 * subnets
 * and forwards requests to the specified target group.
 */
public String createLoadBalancer(List<Subnet> subnetIds, String targetGroupARN,
String lbName, int port,
String protocol) {
try {
List<String> subnetIdStrings = subnetIds.stream()
.map(Subnet::subnetId)
.collect(Collectors.toList());

CreateLoadBalancerRequest balancerRequest =
CreateLoadBalancerRequest.builder()
.subnets(subnetIdStrings)
.name(lbName)
.scheme("internet-facing")
.build();

// Create and wait for the load balancer to become available.
CreateLoadBalancerResponse lsResponse =
getLoadBalancerClient().createLoadBalancer(balancerRequest);
String lbARN = lsResponse.loadBalancers().get(0).loadBalancerArn();

ElasticLoadBalancingV2Waiter loadBalancerWaiter =
getLoadBalancerClient().waiter();
```
DescribeLoadBalancersRequest request =
    DescribeLoadBalancersRequest.builder()
    .loadBalancerArns(lbARN)
    .build();

System.out.println("Waiting for Load Balancer " + lbName + " to become available.");
WaiterResponse<DescribeLoadBalancersResponse> waiterResponse =
    loadBalancerWaiter
    .waitUntilLoadBalancerAvailable(request);
waiterResponse.matched().response().ifPresent(System.out::println);
System.out.println("Load Balancer " + lbName + " is available.");

// Get the DNS name (endpoint) of the load balancer.
String lbDNSName = lsResponse.loadBalancers().get(0).dnsName();
System.out.println("*** Load Balancer DNS Name: " + lbDNSName);

// Create a listener for the load balance.
Action action = Action.builder()
    .targetGroupArn(targetGroupARN)
    .type("forward")
    .build();

CreateListenerRequest listenerRequest = CreateListenerRequest.builder()
    .loadBalancerArn(lsResponse.loadBalancers().get(0).loadBalancerArn())
    .defaultActions(action)
    .port(port)
    .protocol(protocol)
    .defaultActions(action)
    .build();

getLoadBalancerClient().createListener(listenerRequest);
System.out.println("Created listener to forward traffic from load balancer " + lbName + " to target group "
    + targetGroupARN);

// Return the load balancer DNS name.
return lbDNSName;

} catch (ElasticLoadBalancingV2Exception e) {
    e.printStackTrace();
}
return "";
For API details, see `CreateLoadBalancer` in *AWS SDK for Java 2.x API Reference*.

**Delete a load balancer**

The following code example shows how to delete an ELB load balancer.

**SDK for Java 2.x**

```java
// Deletes a load balancer.
public void deleteLoadBalancer(String lbName) {
    try {
        // Use a waiter to delete the Load Balancer.
        DescribeLoadBalancersResponse res = getLoadBalancerClient()
            .describeLoadBalancers(describe -> describe.names(lbName));
        ElasticLoadBalancingV2Waiter loadBalancerWaiter =
            getLoadBalancerClient().waiter();
        DescribeLoadBalancersRequest request =
            DescribeLoadBalancersRequest.builder()
                .loadBalancerArns(res.loadBalancers().get(0).loadBalancerArn())
                .build();
        getLoadBalancerClient().deleteLoadBalancer(
            builder ->
                builder.loadBalancerArn(res.loadBalancers().get(0).loadBalancerArn()));
        WaiterResponse<DescribeLoadBalancersResponse> waiterResponse =
            loadBalancerWaiter
                .waitUntilLoadBalancersDeleted(request);
        waiterResponse.matched().response().ifPresent(System.out::println);
    } catch (ElasticLoadBalancingV2Exception e) {
        System.err.println(e.awsErrorDetails().errorMessage());
    }
}
```

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/aws-samples/aws-sdk-java).
System.out.println(lbName + " was deleted.");
}

- For API details, see [DeleteLoadBalancer](#) in *AWS SDK for Java 2.x API Reference*.

### Delete a target group

The following code example shows how to delete an ELB target group.

**SDK for Java 2.x**

```java
// Deletes the target group.
public void deleteTargetGroup(String targetGroupName) {
    try {
        DescribeTargetGroupsResponse res = getLoadBalancerClient()
            .describeTargetGroups(describe ->
                describe.names(targetGroupName));
        getLoadBalancerClient()
            .deleteTargetGroup(builder ->
                builder.targetGroupArn(res.targetGroups().get(0).targetGroupArn()));
    } catch (ElasticLoadBalancingV2Exception e) {
        System.err.println(e.awsErrorDetails().errorMessage());
    }
    System.out.println(targetGroupName + " was deleted.");
}
```

- For API details, see [DeleteTargetGroup](#) in *AWS SDK for Java 2.x API Reference*.

### Get the health of a target group

The following code example shows how to get the health of instances in an ELB target group.

**SDK for Java 2.x**

```java
// Deletes the target group.
public void deleteTargetGroup(String targetGroupName) {
    try {
        DescribeTargetGroupsResponse res = getLoadBalancerClient()
            .describeTargetGroups(describe ->
                describe.names(targetGroupName));
        getLoadBalancerClient()
            .deleteTargetGroup(builder ->
                builder.targetGroupArn(res.targetGroups().get(0).targetGroupArn()));
    } catch (ElasticLoadBalancingV2Exception e) {
        System.err.println(e.awsErrorDetails().errorMessage());
    }
    System.out.println(targetGroupName + " was deleted.");
}
```
// Checks the health of the instances in the target group.
public List<TargetHealthDescription> checkTargetHealth(String targetGroupName) {
    DescribeTargetGroupsRequest targetGroupsRequest =
        DescribeTargetGroupsRequest.builder()
            .names(targetGroupName)
            .build();

    DescribeTargetGroupsResponse tgResponse =
        getLoadBalancerClient().describeTargetGroups(targetGroupsRequest);

    DescribeTargetHealthRequest healthRequest =
        DescribeTargetHealthRequest.builder()
            .targetGroupArn(tgResponse.targetGroups().get(0).targetGroupArn())
            .build();

    DescribeTargetHealthResponse healthResponse =
        getLoadBalancerClient().describeTargetHealth(healthRequest);

    return healthResponse.targetHealthDescriptions();
}

• For API details, see DescribeTargetHealth in AWS SDK for Java 2.x API Reference.

Scenarios

Build and manage a resilient service

The following code example shows how to create a load-balanced web service that returns book, movie, and song recommendations. The example shows how the service responds to failures, and how to restructure the service for more resilience when failures occur.

• Use an Amazon EC2 Auto Scaling group to create Amazon Elastic Compute Cloud (Amazon EC2) instances based on a launch template and to keep the number of instances in a specified range.
- Handle and distribute HTTP requests with Elastic Load Balancing.
- Monitor the health of instances in an Auto Scaling group and forward requests only to healthy instances.
- Run a Python web server on each EC2 instance to handle HTTP requests. The web server responds with recommendations and health checks.
- Simulate a recommendation service with an Amazon DynamoDB table.
- Control web server response to requests and health checks by updating AWS Systems Manager parameters.

SDK for Java 2.x

⚠️ Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run the interactive scenario at a command prompt.

```java
public class Main {
    public static final String fileName = "C:\AWS\resworkflow\recommendations.json"; // Modify file location.

    database.deleteTable(tableName);
}
```

```
private static void deploy(LoadBalancer loadBalancer) throws InterruptedException, IOException {
    Scanner in = new Scanner(System.in);
```
For this demo, we'll use the AWS SDK for Java (v2) to create several AWS resources to set up a load-balanced web service endpoint and explore some ways to make it resilient against various kinds of failures.

Some of the resources create by this demo are:
- A DynamoDB table that the web service depends on to provide book, movie, and song recommendations.
- An EC2 launch template that defines EC2 instances that each contain a Python web server.
- An EC2 Auto Scaling group that manages EC2 instances across several Availability Zones.
- An Elastic Load Balancing (ELB) load balancer that targets the Auto Scaling group to distribute requests.

System.out.println("Press Enter when you're ready.");
in.nextLine();
System.out.println(DASHES);
System.out.println(DASHES);
System.out.println("Creating and populating a DynamoDB table named "+
tableName);
    Database database = new Database();
    database.createTable(tableName, fileName);
    System.out.println(DASHES);
    System.out.println(DASHES);
    System.out.println("Creating an EC2 launch template that runs '{startup_script}' when an instance starts.
    This script starts a Python web server defined in the `server.py` script. The web server
    listens to HTTP requests on port 80 and responds to requests to '/'
    and to '/healthcheck'.
    For demo purposes, this server is run as the root user. In production, the best practice is to
    run a web server, such as Apache, with least-privileged credentials.
    The template also defines an IAM policy that each instance uses to assume a role that grants
    Elastic Load Balancing
    860
permissions to access the DynamoDB recommendation table and Systems Manager parameters

LaunchTemplateCreator templateCreator = new LaunchTemplateCreator();
templateCreator.createTemplate(policyFile, policyName, profileName,
startScript, templateName, roleName);
System.out.println(DASHES);
System.out.println(DASHES);

System.out.println(DASHES);
System.out.println("Creating an EC2 Auto Scaling group that maintains three EC2
instances, each in a different Availability Zone.");
System.out.println("*** Wait 30 secs for the VPC to be created");

recommendations by querying a DynamoDB table.
The table name is contained in a Systems Manager parameter
named self.param_helper.table.
To simulate a failure of the recommendation service, let's
set this parameter to name a non-existent table.
");
paramHelper.put(paramHelper.tableName, "this-is-not-a-table");

System.out.println("\nNow, sending a GET request to the load balancer endpoint
returns a failure code. But, the service reports as
healthy to the load balancer because shallow health checks
don't check for failure of the recommendation service.
");
demoChoices(loadBalancer);

System.out.println("Instead of failing when the recommendation service fails,
the web service can return a static response.
While this is not a perfect solution, it presents the
customer with a somewhat better experience than failure.
");
paramHelper.put(paramHelper.failureResponse, "static");

System.out.println(""
   Now, sending a GET request to the load balancer endpoint returns a
   static response.
   The service still reports as healthy because health checks are still shallow.
   "");
demoChoices(loadBalancer);

System.out.println("Let's reinstate the recommendation service.");
paramHelper.put(paramHelper.tableName, paramHelper.dyntable);

System.out.println(""
   Let's also substitute bad credentials for one of the instances in
   the target group so that it can't
   access the DynamoDB recommendation table. We will get an instance id
   value.
   "");

LaunchTemplateCreator templateCreator = new LaunchTemplateCreator();
AutoScaler autoScaler = new AutoScaler();

// Create a new instance profile based on badCredsProfileName.
templateCreator.createInstanceProfile(policyFile, policyName,
badCredsProfileName, roleName);
String badInstanceId = autoScaler.getBadInstance(autoScalingGroupName);
System.out.println("The bad instance id values used for this demo is " +
badInstanceId);

String profileAssociationId = autoScaler.getInstanceProfile(badInstanceId);
System.out.println("The association Id value is " + profileAssociationId);
System.out.println("Replacing the profile for instance " + badInstanceId
   + " with a profile that contains bad credentials");
autoScaler.replaceInstanceProfile(badInstanceId, badCredsProfileName,
profileAssociationId);

System.out.println(""
   Now, sending a GET request to the load balancer endpoint
   returns either a recommendation or a static response,
   depending on which instance is selected by the load
   balancer.
   "");
demoChoices(loadBalancer);

System.out.println(""
    Let's implement a deep health check. For this demo, a deep health check tests whether
    the web service can access the DynamoDB table that it depends on for recommendations. Note that
    the deep health check is only for ELB routing and not for Auto Scaling instance health.
    This kind of deep health check is not recommended for Auto Scaling instance health, because it
    risks accidental termination of all instances in the Auto Scaling group when a dependent service fails.
"");

System.out.println(""
    By implementing deep health checks, the load balancer can detect when one of the instances is failing
    and take that instance out of rotation.
"");

paramHelper.put(paramHelper.healthCheck, "deep");

System.out.println(""
    Now, checking target health indicates that the instance with bad credentials
    is unhealthy. Note that it might take a minute or two for the load balancer to detect the unhealthy
    instance. Sending a GET request to the load balancer endpoint always returns a recommendation, because
    the load balancer takes unhealthy instances out of its rotation.
"");

demoChoices(loadBalancer);

System.out.println(""
    Because the instances in this demo are controlled by an auto scaler, the simplest way to fix an unhealthy
    instance is to terminate it and let the auto scaler start a new instance to replace it.
"");
autoScaler.terminateInstance(badInstanceId);
Even while the instance is terminating and the new instance is starting, sending a GET request to the web service continues to get a successful recommendation response because the load balancer routes requests to the healthy instances. After the replacement instance starts and reports as healthy, it is included in the load balancing rotation. Note that terminating and replacing an instance typically takes several minutes, during which time you can see the changing health check status until the new instance is running and healthy.

```java
System.out.println(""");
demoChoices(loadBalancer);
System.out.println(
    "If the recommendation service fails now, deep health checks mean all instances report as unhealthy.");
paramHelper.put(paramHelper.tableName, "this-is-not-a-table");
demoChoices(loadBalancer);
paramHelper.reset();
```

**MediaStore examples using SDK for Java 2.x**

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with MediaStore.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

        PutObjectRequest objectRequest = PutObjectRequest.builder()
            .path(completePath)
            .contentType("video/mp4")
            .build();

        PutObjectResponse response = mediaStoreData.putObject(objectRequest, requestBody);
        System.out.println("The saved object is " +
               response.storageClass().toString());
    } catch (MediaStoreDataException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
public static String getEndpoint(String containerName) {
    Region region = Region.US_EAST_1;
    MediaStoreClient mediaStoreClient = MediaStoreClient.builder()
        .region(region)
        .build();

    DescribeContainerRequest containerRequest =
        DescribeContainerRequest.builder()
        .containerName(containerName)
        .build();

    DescribeContainerResponse response =
        mediaStoreClient.describeContainer(containerRequest);
    return response.container().endpoint();
}

For API details, see PutObject in AWS SDK for Java 2.x API Reference.

OpenSearch Service examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with OpenSearch Service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Actions

Create a domain

The following code example shows how to create an OpenSearch Service domain.

SDK for Java 2.x

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.opensearch.OpenSearchClient;
import software.amazon.awssdk.services.opensearch.model.ClusterConfig;
import software.amazon.awssdk.services.opensearch.model.EBSOptions;
import software.amazon.awssdk.services.opensearch.model.VolumeType;
import software.amazon.awssdk.services.opensearch.model.NodeToNodeEncryptionOptions;
import software.amazon.awssdk.services.opensearch.model.CreateDomainRequest;
import software.amazon.awssdk.services.opensearch.model.CreateDomainResponse;
import software.amazon.awssdk.services.opensearch.model.OpenSearchException;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 *

        Region region = Region.US_EAST_1;
        OpenSearchClient searchClient = OpenSearchClient.builder()
            .region(region)
            .build();

        deleteSpecificDomain(searchClient, domainName);
        System.out.println("Done");
    }

    public static void deleteSpecificDomain(OpenSearchClient searchClient, String domainName) {
        try {
            DeleteDomainRequest domainRequest = DeleteDomainRequest.builder()
                .domainName(domainName)
                .build();

            searchClient.deleteDomain(domainRequest);
            System.out.println(domainName + " was successfully deleted.");
        } catch (OpenSearchException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
}
For API details, see **DeleteDomain** in *AWS SDK for Java 2.x API Reference*.

## List domains

The following code example shows how to list OpenSearch Service domains.

### SDK for Java 2.x

```java
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.opensearch.OpenSearchClient;
import software.amazon.awssdk.services.opensearch.model.DomainInfo;
import software.amazon.awssdk.services.opensearch.model.ListDomainNamesRequest;
import software.amazon.awssdk.services.opensearch.model.ListDomainNamesResponse;
import software.amazon.awssdk.services.opensearch.model.OpenSearchException;
import java.util.List;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class ListDomainNames {
    public static void main(String[] args) {
        Region region = Region.US_EAST_1;
        OpenSearchClient searchClient = OpenSearchClient.builder()
            .region(region)
            .credentialsProvider(ProfileCredentialsProvider.create())
            .build();
        listAllDomains(searchClient);
    }
}
```

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/aws/aws-sdk-java).
public static void listAllDomains(OpenSearchClient searchClient) {
    try {
        ListDomainNamesRequest namesRequest = ListDomainNamesRequest.builder()
            .engineType("OpenSearch")
            .build();

        ListDomainNamesResponse response = searchClient.listDomainNames(namesRequest);
        List<DomainInfo> domainInfoList = response.domainNames();
        for (DomainInfo domain : domainInfoList)
            System.out.println("Domain name is " + domain.domainName());
    } catch (OpenSearchException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}

• For API details, see ListDomainNames in AWS SDK for Java 2.x API Reference.

Modify a cluster configuration

The following code example shows how to modify a cluster configuration of an OpenSearch Service domain.

SDK for Java 2.x

import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.opensearch.OpenSearchClient;
import software.amazon.awssdk.services.opensearch.model.ClusterConfig;
import software.amazon.awssdk.services.opensearch.model.OpenSearchException;

Note
There’s more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
import software.amazon.awssdk.services.opensearch.model.UpdateDomainConfigRequest;
import software.amazon.awssdk.services.opensearch.model.UpdateDomainConfigResponse;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 * For more information, see the following documentation topic:
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */

public class UpdateDomain {
    public static void main(String[] args) {
        final String usage = ""
        
        Usage:
            <domainName>

        Where:
            domainName - The name of the domain to update.

        "";

        if (args.length != 1) {
            System.out.println(usage);
            System.exit(1);
        }

        String domainName = args[0];
        Region region = Region.US_EAST_1;
        OpenSearchClient searchClient = OpenSearchClient.builder()
            .region(region)
            .build();

        updateSpecificDomain(searchClient, domainName);
        System.out.println("Done");
    }

    public static void updateSpecificDomain(OpenSearchClient searchClient, String domainName) {
        try {
            ClusterConfig clusterConfig = ClusterConfig.builder()
                .instanceCount(3)
                .build();
UpdateDomainConfigRequest updateDomainConfigRequest =
UpdateDomainConfigRequest.builder()
  .domainName(domainName)
  .clusterConfig(clusterConfig)
  .build();

System.out.println("Sending domain update request...");
UpdateDomainConfigResponse updateResponse =
searchClient.updateDomainConfig(updateDomainConfigRequest);
System.out.println("Domain update response from Amazon OpenSearch Service:");
System.out.println(updateResponse.toString());

} catch (OpenSearchException e) {
  System.err.println(e.awsErrorDetails().errorMessage());
  System.exit(1);
}

• For API details, see UpdateDomainConfig in AWS SDK for Java 2.x API Reference.

EventBridge examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with EventBridge.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Get started
Hello EventBridge

The following code examples show how to get started using EventBridge.

SDK for Java 2.x

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 */
public class HelloEventBridge {
    public static void main(String[] args) {
        Region region = Region.US_WEST_2;
        EventBridgeClient eventBrClient = EventBridgeClient.builder()
            .region(region)
            .build();

        listBuses(eventBrClient);
        eventBrClient.close();
    }

    public static void listBuses(EventBridgeClient eventBrClient) {
        try {
            ListEventBusesRequest busesRequest = ListEventBusesRequest.builder()
                .limit(10)
                .build();

            ListEventBusesResponse response =
                eventBrClient.listEventBuses(busesRequest);
            List<EventBus> buses = response.eventBuses();
            for (EventBus bus : buses) {
                System.out.println("The name of the event bus is: " + bus.name());
            }
        } catch (Exception e) {
            e.printStackTrace();
        }
    }
}

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
System.out.println("The ARN of the event bus is: " + bus.arn());
}
} catch (EventBridgeException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
}

• For API details, see ListEventBuses in AWS SDK for Java 2.x API Reference.

Actions

Add a target

The following code example shows how to add a target to an Amazon EventBridge event.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Add an Amazon SNS topic as a target for a rule.

```java
// Add a rule which triggers an SNS target when a file is uploaded to an S3 bucket.
public static void addSnsEventRule(EventBridgeClient eventBrClient, String ruleName, String topicArn,
                                   String topicName, String eventRuleName, String bucketName) {
    String targetID = java.util.UUID.randomUUID().toString();
    Target myTarget = Target.builder().withArn(topicArn).build();
    eventBrClient.putRuleTarget(ruleName, myTarget);
}
```
```java
List<Target> targets = new ArrayList<>();
targets.add(myTarget);
PutTargetsRequest request = PutTargetsRequest.builder()
    .eventBusName(null)
    .targets(targets)
    .rule(ruleName)
    .build();

eventBrClient.putTargets(request);
System.out.println("Added event rule " + eventRuleName + " with Amazon SNS target " + topicName + " for bucket "
    + bucketName + ".");
```

Add an input transformer to a target for a rule.

```java
public static void updateCustomRuleTargetWithTransform(EventBridgeClient eventBrClient, String topicArn,
            String ruleName) {
    String targetId = java.util.UUID.randomUUID().toString();
    InputTransformer inputTransformer = InputTransformer.builder()
        .inputTemplate(""Notification: sample event was received."")
        .build();
    Target target = Target.builder()
        .id(targetId)
        .arn(topicArn)
        .inputTransformer(inputTransformer)
        .build();
    try {
        PutTargetsRequest targetsRequest = PutTargetsRequest.builder()
            .rule(ruleName)
            .targets(target)
            .eventBusName(null)
            .build();
        eventBrClient.putTargets(targetsRequest);
    }
```
For API details, see **PutTargets** in *AWS SDK for Java 2.x API Reference*.

**Create a rule**

The following code example shows how to create an Amazon EventBridge rule.

**SDK for Java 2.x**

```java
public static void createEBRule(EventBridgeClient eventBrClient, String ruleName, String cronExpression) {
    try {
        PutRuleRequest ruleRequest = PutRuleRequest.builder()
            .name(ruleName)
            .eventBusName("default")
            .scheduleExpression(cronExpression)
            .state("ENABLED")
            .description("A test rule that runs on a schedule created by the Java API")
            .build();

        PutRuleResponse ruleResponse = eventBrClient.putRule(ruleRequest);
        System.out.println("The ARN of the new rule is " + ruleResponse.ruleArn());
    } catch (EventBridgeException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

- Note
  There's more on GitHub. Find the complete example and learn how to set up and run in the **AWS Code Examples Repository**.

**Create a scheduled rule.**

```java
public static void createEBRule(EventBridgeClient eventBrClient, String ruleName, String cronExpression) {
    try {
        PutRuleRequest ruleRequest = PutRuleRequest.builder()
            .name(ruleName)
            .eventBusName("default")
            .scheduleExpression(cronExpression)
            .state("ENABLED")
            .description("A test rule that runs on a schedule created by the Java API")
            .build();

        PutRuleResponse ruleResponse = eventBrClient.putRule(ruleRequest);
        System.out.println("The ARN of the new rule is " + ruleResponse.ruleArn());
    } catch (EventBridgeException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
    }
}
```
Create a rule that triggers when an object is added to an Amazon Simple Storage Service bucket.

```java
// Create a new event rule that triggers when an Amazon S3 object is created in a bucket.
public static void addEventRule(EventBridgeClient eventBrClient, String roleArn,
                                 String bucketName,
                                 String eventRuleName) {
    String eventPattern = "{
        "source": ["aws.s3"],
        "detail-type": ["Object Created"],
        "detail": {
            "bucket": {
                "name": ["{\"bucket\"}"
            }
        }
    }";

    try {
        PutRuleRequest ruleRequest = PutRuleRequest.builder()
            .description("Created by using the AWS SDK for Java v2")
            .name(eventRuleName)
            .eventPattern(eventPattern)
            .roleArn(roleArn)
            .build();

        PutRuleResponse ruleResponse = eventBrClient.putRule(ruleRequest);
        System.out.println("The ARN of the new rule is " +
                           ruleResponse.ruleArn());
    } catch (EventBridgeException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

- For API details, see [PutRule](https://docs.aws.amazon.com/sdk-for-java/latest/api/index.html?method=PutRule) in *AWS SDK for Java 2.x API Reference*. 

Delete a rule

The following code example shows how to delete an Amazon EventBridge rule.

SDK for Java 2.x

```java
public static void deleteRuleByName(EventBridgeClient eventBrClient, String ruleName) {
    DeleteRuleRequest ruleRequest = DeleteRuleRequest.builder()
        .name(ruleName)
        .build();

    eventBrClient.deleteRule(ruleRequest);
    System.out.println("Successfully deleted the rule");
}
```

For API details, see DeleteRule in AWS SDK for Java 2.x API Reference.

Describe a rule

The following code example shows how to describe an Amazon EventBridge rule.

SDK for Java 2.x

```java
public static void checkRule(EventBridgeClient eventBrClient, String eventRuleName) {

}
```

For API details, see DescribeRule in AWS SDK for Java 2.x API Reference.
try {
    DescribeRuleRequest ruleRequest = DescribeRuleRequest.builder()
        .name(eventRuleName)
        .build();

    DescribeRuleResponse response = eventBrClient.describeRule(ruleRequest);
    System.out.println("The state of the rule is " + response.stateAsString());

} catch (EventBridgeException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

• For API details, see DescribeRule in AWS SDK for Java 2.x API Reference.

Disable a rule

The following code example shows how to disable an Amazon EventBridge rule.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Disable a rule by using its rule name.

    public static void changeRuleState(EventBridgeClient eventBrClient, String eventRuleName, Boolean isEnabled) {
        try {
            if (!isEnabled) {
                System.out.println("Disabling the rule: " + eventRuleName);
                DisableRuleRequest ruleRequest = DisableRuleRequest.builder()
                    .name(eventRuleName)
                    .build();

            }
        } catch (EventBridgeException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
eventBrClient.disableRule(ruleRequest);
} else {
    System.out.println("Enabling the rule: " + eventRuleName);
    EnableRuleRequest ruleRequest = EnableRuleRequest.builder()
        .name(eventRuleName)
        .build();
    eventBrClient.enableRule(ruleRequest);
}

} catch (EventBridgeException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

• For API details, see DisableRule in AWS SDK for Java 2.x API Reference.

Enable a rule

The following code example shows how to enable an Amazon EventBridge rule.

SDK for Java 2.x

Enable a rule by using its rule name.

public static void changeRuleState(EventBridgeClient eventBrClient, String eventRuleName, Boolean isEnabled) {
    try {
        if (!isEnabled) {
            System.out.println("Disabling the rule: " + eventRuleName);
            DisableRuleRequest ruleRequest = DisableRuleRequest.builder()
                .name(eventRuleName)
                .build();
            eventBrClient.disableRule(ruleRequest);
        }
    } catch (EventBridgeException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
eventBrClient.disableRule(ruleRequest);
} else {
    System.out.println("Enabling the rule: " + eventRuleName);
    EnableRuleRequest ruleRequest = EnableRuleRequest.builder()
        .name(eventRuleName)
        .build();
    eventBrClient.enableRule(ruleRequest);
}

} catch (EventBridgeException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

• For API details, see EnableRule in AWS SDK for Java 2.x API Reference.

List rule names for a target

The following code example shows how to list Amazon EventBridge rule names for a target.

SDK for Java 2.x

```java
public static void listTargetRules(EventBridgeClient eventBrClient, String topicArn) {
    ListRuleNamesByTargetRequest ruleNamesByTargetRequest =
        ListRuleNamesByTargetRequest.builder()
            .targetArn(topicArn)
            .build();

    ListRuleNamesByTargetResponse response =
        eventBrClient.listRuleNamesByTarget(ruleNamesByTargetRequest);
    List<String> rules = response.ruleNames();
}
```

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/aws-samples/amazon-eventbridge-java-sdk-getting-started).
List rules

The following code example shows how to list Amazon EventBridge rules.

SDK for Java 2.x

```java
public static void listRules(EventBridgeClient eventBrClient) {
    try {
        ListRulesRequest rulesRequest = ListRulesRequest.builder()
            .eventBusName("default")
            .limit(10)
            .build();

        ListRulesResponse response = eventBrClient.listRules(rulesRequest);
        List<Rule> rules = response.rules();
        for (Rule rule : rules) {
            System.out.println("The rule name is : " + rule.name());
            System.out.println("The rule description is : " + rule.description());
            System.out.println("The rule state is : " + rule.stateAsString());
        }
    } catch (EventBridgeException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

For API details, see [ListRuleNamesByTarget](https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/aws-sdk-for-java-2x-api-reference.html#amazon-eventbridge-api-list-rule-names) in *AWS SDK for Java 2.x API Reference*.

Enable a rule by using its rule name.

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/aws-samples/aws-sdk-for-java).
List targets for a rule

The following code example shows how to list Amazon EventBridge targets for a rule.

SDK for Java 2.x

```
public static void listTargets(EventBridgeClient eventBrClient, String ruleName)
{
    ListTargetsByRuleRequest ruleRequest = ListTargetsByRuleRequest.builder()
        .rule(ruleName)
        .build();

    ListTargetsByRuleResponse res =
        eventBrClient.listTargetsByRule(ruleRequest);
    List<Target> targetsList = res.targets();
    for (Target target: targetsList) {
        System.out.println("Target ARN: "+target.arn());
    }
}
```

• For API details, see ListTargetsByRule in AWS SDK for Java 2.x API Reference.

Remove targets from a rule

The following code example shows how to remove Amazon EventBridge targets from a rule.

SDK for Java 2.x

```
public static void removeTargets(EventBridgeClient eventBrClient, String ruleName, String targetArn)
{
    RemoveTargetsFromRuleRequest ruleRequest = RemoveTargetsFromRuleRequest.builder()
        .rule(ruleName)
        .targetArn(targetArn)
        .build();

    eventBrClient.removeTargetsFromRule(ruleRequest);
}
```

• For API details, see RemoveTargetsFromRule in AWS SDK for Java 2.x API Reference.
Remove all of the targets for a rule by using the rule name.

```java
public static void deleteTargetsFromRule(EventBridgeClient eventBrClient, String eventRuleName) {
    // First, get all targets that will be deleted.
    ListTargetsByRuleRequest request = ListTargetsByRuleRequest.builder()
        .rule(eventRuleName)
        .build();

    ListTargetsByRuleResponse response = eventBrClient.listTargetsByRule(request);
    List<Target> allTargets = response.targets();

    // Get all targets and delete them.
    for (Target myTarget : allTargets) {
        RemoveTargetsRequest removeTargetsRequest = RemoveTargetsRequest.builder()
            .rule(eventRuleName)
            .ids(myTarget.id())
            .build();

        eventBrClient.removeTargets(removeTargetsRequest);
        System.out.println("Successfully removed the target");
    }
}
```

- For API details, see [RemoveTargets](https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/aws-java-sdk-core-ref.html#aws-java-sdk-core) in **AWS SDK for Java 2.x API Reference**.

### Send events

The following code example shows how to send Amazon EventBridge events.
Note
There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://aws.github.io/aws-code-examples/).

```java
public static void triggerCustomRule(EventBridgeClient eventBrClient, String email) {
    String json = "{" + "\"UserEmail\": \"" + email + \"\"," + "\"Message\": \"This event was generated by example code.\"," + "\"UtcTime\": \"Now.\"" + "\"\"};

    PutEventsRequestEntry entry = PutEventsRequestEntry.builder()
            .source("ExampleSource")
            .detail(json)
            .detailType("ExampleType")
            .build();

    PutEventsRequest eventsRequest = PutEventsRequest.builder()
            .entries(entry)
            .build();

    eventBrClient.putEvents(eventsRequest);
}
```

- For API details, see [PutEvents](https://docs.aws.amazon.com/AmazonEventBridge/latest/APIReferenceROUPutEvents.html) in *AWS SDK for Java 2.x API Reference*.

**Scenarios**

**Get started with rules and targets**

The following code example shows how to:

- Create a rule and add a target to it.
- Enable and disable rules.
- List and update rules and targets.
• Send events, then clean up resources.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```java
/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * This Java code example performs the following tasks:
 *
 * This Java V2 example performs the following tasks with Amazon EventBridge:
 *
 * 1. Creates an AWS Identity and Access Management (IAM) role to use with Amazon EventBridge.
 * 2. Amazon Simple Storage Service (Amazon S3) bucket with EventBridge events enabled.
 * 3. Creates a rule that triggers when an object is uploaded to Amazon S3.
 * 4. Lists rules on the event bus.
 * 5. Creates a new Amazon Simple Notification Service (Amazon SNS) topic and lets the user subscribe to it.
 * 6. Adds a target to the rule that sends an email to the specified topic.
 * 7. Creates an EventBridge event that sends an email when an Amazon S3 object is created.
 * 8. Lists Targets.
 * 9. Lists the rules for the same target.
 * 10. Triggers the rule by uploading a file to the Amazon S3 bucket.
 * 11. Disables a specific rule.
 * 12. Checks and print the state of the rule.
 * 13. Adds a transform to the rule to change the text of the email.
 * 14. Enables a specific rule.
 * 15. Triggers the updated rule by uploading a file to the Amazon S3 bucket.
 * 16. Updates the rule to be a custom rule pattern.
```
public class EventbridgeMVP {
    public static final String DASHES = new String(new char[80]).replace("\0", "-"); 

    public static void main(String[] args) throws InterruptedException, IOException 
    {
        final String usage = ""

        Usage:
        <roleName> <bucketName> <topicName> <eventRuleName>

        Where:
        roleName - The name of the role to create.
        bucketName - The Amazon Simple Storage Service (Amazon S3) bucket name to create.
        topicName - The name of the Amazon Simple Notification Service (Amazon SNS) topic to create.
        eventRuleName - The Amazon EventBridge rule name to create.
        ""

        if (args.length != 5) {

**Forecast examples using SDK for Java 2.x**

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Forecast.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

AWS Glue examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with AWS Glue.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Get started
Hello AWS Glue

The following code examples show how to get started using AWS Glue.

SDK for Java 2.x

```java
package com.example.glue;

import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.glue.GlueClient;
import software.amazon.awssdk.services.glue.model.ListJobsRequest;
import software.amazon.awssdk.services.glue.model.ListJobsResponse;
import java.util.List;

public class HelloGlue {
    public static void main(String[] args) {
        GlueClient glueClient = GlueClient.builder()
            .region(Region.US_EAST_1)
            .build();

        listJobs(glueClient);
    }

    public static void listJobs(GlueClient glueClient) {
        ListJobsRequest request = ListJobsRequest.builder()
            .maxResults(10)
            .build();
        ListJobsResponse response = glueClient.listJobs(request);
        List<String> jobList = response.jobNames();
        jobList.forEach(job -> {
            System.out.println("Job Name: " + job);
        });
    }
}
```

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
For API details, see ListJobs in AWS SDK for Java 2.x API Reference.

Actions

Create a crawler

The following code example shows how to create an AWS Glue crawler.

SDK for Java 2.x

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.glue.GlueClient;
import software.amazon.awssdk.services.glue.model.CreateCrawlerRequest;
import software.amazon.awssdk.services.glue.model.CrawlerTargets;
import software.amazon.awssdk.services.glue.model.GlueException;
import software.amazon.awssdk.services.glue.model.S3Target;
import java.util.ArrayList;
import java.util.List;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class CreateCrawler {
    public static void main(String[] args) {
        final String usage = "";
```
Usage:

```java
<IAM> <s3Path> <cron> <dbName> <crawlerName>
```

Where:

- **IAM** - The ARN of the IAM role that has AWS Glue and S3 permissions.
- **s3Path** - The Amazon Simple Storage Service (Amazon S3) target that contains data (for example, CSV data).
- **cron** - A cron expression used to specify the schedule (i.e., `cron(15 12 * * ? *)`).
- **dbName** - The database name.
- **crawlerName** - The name of the crawler.

```
if (args.length != 5) {
    System.out.println(usage);
    System.exit(1);
}

String iam = args[0];
String s3Path = args[1];
String cron = args[2];
String dbName = args[3];
String crawlerName = args[4];
String region = Region.US_EAST_1;
GlueClient glueClient = GlueClient.builder()
    .region(region)
    .build();

createGlueCrawler(glueClient, iam, s3Path, cron, dbName, crawlerName);
glueClient.close();
```

```java
public static void createGlueCrawler(GlueClient glueClient,
    String iam,
    String s3Path,
    String cron,
    String dbName,
    String crawlerName) {

    try {
        S3Target s3Target = S3Target.builder()
            .path(s3Path)
            .build();
```
.build();

// Add the S3Target to a list.
List<S3Target> targetList = new ArrayList<>();
targetList.add(s3Target);

CrawlerTargets targets = CrawlerTargets.builder()
    .s3Targets(targetList)
    .build();

CreateCrawlerRequest crawlerRequest = CreateCrawlerRequest.builder()
    .databaseName(dbName)
    .name(crawlerName)
    .description("Created by the AWS Glue Java API")
    .targets(targets)
    .role(iam)
    .schedule(cron)
    .build();

glueClient.createCrawler(crawlerRequest);
System.out.println(crawlerName + " was successfully created");

} catch (GlueException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
}

- For API details, see [CreateCrawler](https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/aws-java-sdk-core-api.html) in *AWS SDK for Java 2.x API Reference*.

        System.exit(1);
    }
}

• For API details, see GetDatabase in AWS SDK for Java 2.x API Reference.

Get tables from a database

The following code example shows how to get tables from a database in the AWS Glue Data Catalog.
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.glue.GlueClient;
import software.amazon.awssdk.services.glue.model.GetTableRequest;
import software.amazon.awssdk.services.glue.model.GetTableResponse;
import software.amazon.awssdk.services.glue.model.GlueException;
import java.time.Instant;
import java.time.ZoneId;
import java.time.format.DateTimeFormatter;
import java.time.format.FormatStyle;
import java.util.Locale;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class GetTable {
    public static void main(String[] args) {
        final String usage = ""

        Usage:
        <dbName> <tableName>

        Where:
        dbName - The database name.
        tableName - The name of the table.

        "";

        if (args.length != 2) {
            System.out.println(usage);
            System.exit(1);
        }
String dbName = args[0];
String tableName = args[1];
Region region = Region.US_EAST_1;
GlueClient glueClient = GlueClient.builder()
   .region(region)
   .build();

getGlueTable(glueClient, dbName, tableName);
glueClient.close();
}

public static void getGlueTable(GlueClient glueClient, String dbName, String tableName) {
    try {
        GetTableRequest tableRequest = GetTableRequest.builder()
            .databaseName(dbName)
            .name(tableName)
            .build();

        GetTableResponse tableResponse = glueClient.getTable(tableRequest);
        Instant createDate = tableResponse.table().createTime();

        // Convert the Instant to readable date.
        DateTimeFormatter formatter =
            DateTimeFormatter.ofLocalizedDateTime(FormatStyle.SHORT)
            .withLocale(Locale.US)
            .withZone(ZoneId.systemDefault());

        formatter.format(createDate);
        System.out.println("The create date of the table is " + createDate);
    } catch (GlueException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}

• For API details, see GetTables in AWS SDK for Java 2.x API Reference.
Start a crawler

The following code example shows how to start an AWS Glue crawler.

SDK for Java 2.x

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.glue.GlueClient;
import software.amazon.awssdk.services.glue.model.GlueException;
import software.amazon.awssdk.services.glue.model.StartCrawlerRequest;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class StartCrawler {
    public static void main(String[] args) {
        final String usage = "";

        Usage:
        <crawlerName>

        Where:
        crawlerName - The name of the crawler.

        if (args.length != 1) {
            System.out.println(usage);
            System.exit(1);
        }

        String crawlerName = args[0];
        Region region = Region.US_EAST_1;
```
GlueClient glueClient = GlueClient.builder()
    .region(region)
    .build();

startSpecificCrawler(glueClient, crawlerName);
    glueClient.close();
}

public static void startSpecificCrawler(GlueClient glueClient, String
crawlerName) {
    try {
        StartCrawlerRequest crawlerRequest = StartCrawlerRequest.builder()
            .name(crawlerName)
            .build();

        glueClient.startCrawler(crawlerRequest);
    } catch (GlueException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}

For API details, see StartCrawler in AWS SDK for Java 2.x API Reference.

Scenarios

Get started with crawlers and jobs

The following code example shows how to:

• Create a crawler that crawls a public Amazon S3 bucket and generates a database of CSV-
  formatted metadata.

• List information about databases and tables in your AWS Glue Data Catalog.

• Create a job to extract CSV data from the S3 bucket, transform the data, and load JSON-
  formatted output into another S3 bucket.

• List information about job runs, view transformed data, and clean up resources.
For more information, see Tutorial: Getting started with AWS Glue Studio.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```java
/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * To set up the resources, see this documentation topic:
 *
 * https://docs.aws.amazon.com/glue/latest/ug/tutorial-add-crawler.html
 *
 * This example performs the following tasks:
 *
 * 1. Create a database.
 * 2. Create a crawler.
 * 3. Get a crawler.
 * 4. Start a crawler.
 * 5. Get a database.
 * 7. Create a job.
 * 8. Start a job run.
 * 9. List all jobs.
 * 11. Delete a job.
 * 12. Delete a database.
 * 13. Delete a crawler.
 */

HealthImaging examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with HealthImaging.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

**Topics**

- CreateCrawler
- CreateJob
- DeleteCrawler
- DeleteDatabase
- DeleteJob
- DeleteTable
- GetCrawler
- GetDatabase
- GetDatabases
- GetJob
- GetJobRun
- GetJobRuns
- GetTables
- ListJobs
- StartCrawler
- StartJobRun
• **Scenarios**

**Actions**

**Add a tag to a resource**

The following code example shows how to add a tag to a HealthImaging resource.

**SDK for Java 2.x**

```java
public static void tagMedicalImagingResource(MedicalImagingClient medicalImagingClient,
                                              String resourceArn,
                                              Map<String, String> tags) {
    try {
        TagResourceRequest tagResourceRequest = TagResourceRequest.builder()
            .resourceArn(resourceArn)
            .tags(tags)
            .build();

        medicalImagingClient.tagResource(tagResourceRequest);

        System.out.println("Tags have been added to the resource.");
    } catch (MedicalImagingException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

• For API details, see [TagResource](#) in *AWS SDK for Java 2.x API Reference*.

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

**Copy an image set**

The following code example shows how to copy a HealthImaging image set.
public static String copyMedicalImageSet(MedicalImagingClient medicalImagingClient,
        String datastoreId,
        String imageSetId,
        String latestVersionId,
        String destinationImageSetId,
        String destinationVersionId) {

        try {
            CopySourceImageSetInformation copySourceImageSetInformation =
                    CopySourceImageSetInformation.builder()
                    .latestVersionId(latestVersionId)
                    .build();

            CopyImageSetInformation.Builder copyImageSetBuilder =
                    CopyImageSetInformation.builder()
                    .sourceImageSet(copySourceImageSetInformation);

            if (destinationImageSetId != null) {
                copyImageSetBuilder =
                        copyImageSetBuilder.destinationImageSet(CopyDestinationImageSet.builder()
                                .imageSetId(destinationImageSetId)
                                .latestVersionId(destinationVersionId)
                                .build());
            }

            CopyImageSetRequest copyImageSetRequest = CopyImageSetRequest.builder()
                    .datastoreId(datastoreId)
                    .sourceImageSetId(imageSetId)
                    .copyImageSetInformation(copyImageSetBuilder.build())
                    .build();

            CopyImageSetResponse response =
                    medicalImagingClient.copyImageSet(copyImageSetRequest);

            return response.destinationImageSetProperties().imageSetId();
        } catch (MedicalImagingException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }

        return "";
Create a data store

The following code example shows how to create a HealthImaging data store.

SDK for Java 2.x

```java
public static String createMedicalImageDatastore(MedicalImagingClient medicalImagingClient,
        String datastoreName) {
    try {
        CreateDatastoreRequest datastoreRequest =
            CreateDatastoreRequest.builder()
                .datastoreName(datastoreName)
                .build();
        CreateDatastoreResponse response =
            medicalImagingClient.createDatastore(datastoreRequest);
        return response.datastoreId();
    } catch (MedicalImagingException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
    return "";
}
```

- For API details, see `CopyImageSet` in `AWS SDK for Java 2.x API Reference`.

- For API details, see `CreateDatastore` in `AWS SDK for Java 2.x API Reference`.

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
Delete a data store

The following code example shows how to delete a HealthImaging data store.

SDK for Java 2.x

```java
public static void deleteMedicalImagingDatastore(MedicalImagingClient medicalImagingClient,
        String datastoreID) {
    try {
        DeleteDatastoreRequest datastoreRequest =
            DeleteDatastoreRequest.builder()
            .datastoreId(datastoreID)
            .build();
        medicalImagingClient.deleteDatastore(datastoreRequest);
    } catch (MedicalImagingException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

For API details, see [DeleteDatastore](#) in *AWS SDK for Java 2.x API Reference*.

Delete an image set

The following code example shows how to delete a HealthImaging image set.
public static void deleteMedicalImageSet(MedicalImagingClient medicalImagingClient,
   String datastoreId,
   String imagesetId) {
   try {
      DeleteImageSetRequest deleteImageSetRequest =
         DeleteImageSetRequest.builder()
         .datastoreId(datastoreId)
         .imageSetId(imagesetId)
         .build();

      medicalImagingClient.deleteImageSet(deleteImageSetRequest);

      System.out.println("The image set was deleted.");
   } catch (MedicalImagingException e) {
      System.err.println(e.awsErrorDetails().errorMessage());
      System.exit(1);
   }
}

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/aws-samples/aws-code-examples).

Get an image frame

The following code example shows how to get an image frame.

SDK for Java 2.x

```java
public static void getMedicalImageSetFrame(MedicalImagingClient medicalImagingClient,
   String destinationPath,
   String datastoreId,
   String imagesetId,
   HealthImaging
```
String imageFrameId) {
    try {
        GetImageFrameRequest getImageSetMetadataRequest =
            GetImageFrameRequest.builder()
                .datastoreId(datastoreId)
                .imageSetId(imagesetId)
                .imageFrameInformation(ImageFrameInformation.builder()
                    .imageFrameId(imageFrameId)
                    .build())
                .build();

        medicalImagingClient.getImageFrame(getImageSetMetadataRequest,
            FileSystems.getDefault().getPath(destinationPath));
        System.out.println("Image frame downloaded to " +
            destinationPath);
    } catch (MedicalImagingException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}

• For API details, see GetImageFrame in AWS SDK for Java 2.x API Reference.

Note
There's more on GitHub. Find the complete example and learn how to set up and run in

Get data store properties

The following code example shows how to get HealthImaging data store properties.

SDK for Java 2.x

    public static DatastoreProperties getMedicalImageDatastore(MedicalImagingClient
        medicalImagingClient,
        String datastoreID) {

try {
    GetDatastoreRequest datastoreRequest = GetDatastoreRequest.builder()
        .datastoreId(datastoreID)
        .build();
    GetDatastoreResponse response =
        medicalImagingClient.getDatastore(datastoreRequest);
    return response.datastoreProperties();
} catch (MedicalImagingException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

return null;
}

• For API details, see **GetDatastore** in *AWS SDK for Java 2.x API Reference*.

---

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/aws/aws-Developer-Guide/tree/master/demos/medical-image-processing).

---

**Get image set properties**

The following code example shows how to get HealthImaging image set properties.

---

**SDK for Java 2.x**

```java
public static GetImageSetResponse getMedicalImageSet(MedicalImagingClient medicalImagingClient,
    String datastoreId,
    String imagesetId,
    String versionId) {
    try {
        GetImageSetRequest.Builder getImageSetRequestBuilder =
            GetImageSetRequest.builder()
                .datastoreId(datastoreId)
                .imageSetId(imagesetId);
        if (versionId != null) {
```
getImageSetRequestBuilder = getImageSetRequestBuilder.versionId(versionId);
}
return medicalImagingClient.getImageSet(getImageSetRequestBuilder.build());
} catch (MedicalImagingException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
return null;
}

For API details, see [GetImageSet](#) in *AWS SDK for Java 2.x API Reference*.

### Note

---

**Get import job properties**

The following code example shows how to get the import job properties.

### SDK for Java 2.x

```java
public static DICOMImportJobProperties getDicomImportJob(MedicalImagingClient medicalImagingClient,
    String datastoreId,
    String jobId) {
    try {
        GetDicomImportJobRequest getDicomImportJobRequest =
            GetDicomImportJobRequest.builder()
                .datastoreId(datastoreId)
                .jobId(jobId)
                .build();
        GetDicomImportJobResponse response =
            medicalImagingClient.getDICOMImportJob(getDicomImportJobRequest);
        return response.getDicomImportJobProperties();
    } catch (MedicalImagingException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
    return null;
}
```
For API details, see [GetDICOMImportJob](#) in AWS SDK for Java 2.x API Reference.

### Note
There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

### Get metadata for an image set

The following code example shows how to get metadata for a HealthImaging image set.

**SDK for Java 2.x**

```java
public static void getMedicalImageSetMetadata(MedicalImagingClient medicalImagingClient,
                                            String destinationPath,
                                            String datastoreId,
                                            String imagesetId,
                                            String versionId) {

    try {
        GetImageSetMetadataRequest.Builder getImageSetMetadataRequestBuilder =
            GetImageSetMetadataRequest.builder()
                .datastoreId(datastoreId)
                .imageSetId(imagesetId);

        if (versionId != null) {
            getImageSetMetadataRequestBuilder =
                getImageSetMetadataRequestBuilder.versionId(versionId);
        }

        GetImageSetMetadataResponse response = medicalImagingClient.getMedicalImageSetMetadata(
            GetImageSetMetadataRequest.builder()
                .datastoreId(datastoreId)
                .imageSetId(imagesetId)
                .versionId(versionId)
                .build());

        return response.jobProperties();
    } catch (MedicalImagingException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }

    return null;
}
```
For API details, see [GetImageSetMetadata](#) in [AWS SDK for Java 2.x API Reference](#).

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

### Import bulk data into a data store

The following code example shows how to import bulk data into a HealthImaging data store.

#### SDK for Java 2.x

```java
public static String startDicomImportJob(MedicalImagingClient medicalImagingClient,
                                          String jobName,
                                          String datastoreId,
                                          String dataAccessRoleArn,
                                          String inputS3Uri,
                                          String outputS3Uri) {

    try {
        StartDicomImportJobRequest startDicomImportJobRequest =
            StartDicomImportJobRequest.builder()
                .jobName(jobName)
                .datastoreId(datastoreId)
                .dataAccessRoleArn(dataAccessRoleArn)
                .inputS3Uri(inputS3Uri)
                .outputS3Uri(outputS3Uri)
                .build();

        medicalImagingClient.startDicomImportJob(startDicomImportJobRequest);
        System.out.println("Job started.");

    } catch (MedicalImagingException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }

    return "Job started.";
}
```
For API details, see [StartDICOMImportJob](https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/aws-java-sdk-code-reference.html#aws-java-sdk-medicalimaging.StartDICOMImportJob) in *AWS SDK for Java 2.x API Reference*.

### Note

**List data stores**

The following code example shows how to list HealthImaging data stores.

```java
public static List<DatastoreSummary> listMedicalImagingDatastores(MedicalImagingClient medicalImagingClient) {
  try {
    ListDatastoresRequest datastoreRequest = ListDatastoresRequest.builder()
        .build();
    ListDatastoresIterable responses = medicalImagingClient.listDatastoresPaginator(datastoreRequest);
    List<DatastoreSummary> datastoreSummaries = new ArrayList<>();
    responses.stream().forEach(response ->
        datastoreSummaries.addAll(response.datastoreSummaries()));
    return datastoreSummaries;
  } catch (MedicalImagingException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
  }
  return new ArrayList<>();
}
```
For API details, see ListDatastores in AWS SDK for Java 2.x API Reference.

Note

List image set versions

The following code example shows how to list HealthImaging image set versions.

SDK for Java 2.x

```java
public static List<ImageSetProperties>
listMedicalImageSetVersions(MedicalImagingClient medicalImagingClient,
    String datastoreId,
    String imagesetId) {
try {
    ListImageSetVersionsRequest getImageSetRequest =
    ListImageSetVersionsRequest.builder()
        .datastoreId(datastoreId)
        .imageSetId(imagesetId)
        .build();

    ListImageSetVersionsIterable responses = medicalImagingClient
        .listImageSetVersionsPaginator(getImageSetRequest);
    List<ImageSetProperties> imageSetProperties = new ArrayList<>();
    responses.stream().forEach(response ->
        imageSetProperties.addAll(response.imageSetPropertiesList()));

    return imageSetProperties;
} catch (MedicalImagingException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
```
List import jobs for a data store

The following code example shows how to list import jobs for a HealthImaging data store.

SDK for Java 2.x

```java
public static List<DICOMImportJobSummary> listDicomImportJobs(MedicalImagingClient medicalImagingClient, String datastoreId) {
    try {
        ListDicomImportJobsRequest listDicomImportJobsRequest = ListDicomImportJobsRequest.builder()
            .datastoreId(datastoreId)
            .build();
        ListDicomImportJobsResponse response = medicalImagingClient.listDICOMImportJobs(listDicomImportJobsRequest);
        return response.jobSummaries();
    } catch (MedicalImagingException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }

    return new ArrayList<>();
}
```

- For API details, see ListDicomImportJobs in AWS SDK for Java 2.x API Reference.

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

- For API details, see ListImageSetVersions in AWS SDK for Java 2.x API Reference.
### List tags for a resource

The following code example shows how to list tags for a HealthImaging resource.

**SDK for Java 2.x**

```java
public static ListTagsForResourceResponse listMedicalImagingResourceTags(MedicalImagingClient medicalImagingClient,
    String resourceArn) {
    try {
        ListTagsForResourceRequest listTagsForResourceRequest =
            ListTagsForResourceRequest.builder()
                .resourceArn(resourceArn)
                .build();

        return
            medicalImagingClient.listTagsForResource(listTagsForResourceRequest);
    } catch (MedicalImagingException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }

    return null;
}
```

- For API details, see [ListTagsForResource](https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/java-api-listtagsforresource.html) in *AWS SDK for Java 2.x API Reference*.

---

Remove a tag from a resource

The following code example shows how to remove a tag from a HealthImaging resource.

SDK for Java 2.x

```java
public static void untagMedicalImagingResource(MedicalImagingClient medicalImagingClient, 
        String resourceArn, 
        Collection<String> tagKeys) {
    try {
        UntagResourceRequest untagResourceRequest = 
                UntagResourceRequest.builder() 
                .resourceArn(resourceArn) 
                .tagKeys(tagKeys) 
                .build();

        medicalImagingClient.untagResource(untagResourceRequest);

        System.out.println("Tags have been removed from the resource.");
    } catch (MedicalImagingException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

- For API details, see [UntagResource](https://docs.aws.amazon.com/sdk-for-java/latest/api/aws/AmazonMedicalImaging.html#AmazonMedicalImaging.untagResource) in *AWS SDK for Java 2.x API Reference*.

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/awsdocs/aws-sdk-java-examples/tree/master/medical-imaging).

Search image sets

The following code example shows how to search HealthImaging image sets.

SDK for Java 2.x

The utility function for searching image sets.
public static List<ImageSetsMetadataSummary> searchMedicalImagingImageSets(
    MedicalImagingClient medicalImagingClient,
    String datastoreId, List<SearchFilter> searchFilters) {
  try {
    SearchImageSetsRequest datastoreRequest =
        SearchImageSetsRequest.builder()
            .datastoreId(datastoreId)
            .searchCriteria(SearchCriteria.builder().filters(searchFilters).build())
            .build();
    SearchImageSetsIterable responses = medicalImagingClient
        .searchImageSetsPaginator(datastoreRequest);
    List<ImageSetsMetadataSummary> imageSetsMetadataSummaries =
        new ArrayList<>();
    responses.stream().forEach(response ->
        imageSetsMetadataSummaries
            .addAll(response.imageSetsMetadataSummaries()));
    return imageSetsMetadataSummaries;
  } catch (MedicalImagingException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
  }
  return null;
}

Use case #1: EQUAL operator.

List<SearchFilter> searchFilters =
    Collections.singletonList(SearchFilter.builder()
        .operator(Operator.EQUAL)
        .values(SearchByAttributeValue.builder()
            .dicomPatientId(patientId)
            .build());
List<ImageSetsMetadataSummary> imageSetsMetadataSummaries =
    searchMedicalImagingImageSets(
        medicalImagingClient,
Use case #2: BETWEEN operator using DICOMStudyDate and DICOMStudyTime.

```
DateTimeFormatter formatter =
    DateTimeFormatter.ofPattern("yyyyMMdd");
searchFilters = Collections.singletonList(SearchFilter.builder()
    .operator(Operator.BETWEEN)
    .values(SearchByAttributeValue.builder()
        .dicomStudyDateAndTime(DICOMStudyDateAndTime.builder()
            .dicomStudyDate("19990101")
            .dicomStudyTime("000000.000")
            .build())
        .dicomStudyDateAndTime(DICOMStudyDateAndTime.builder()
            .dicomStudyDate((LocalDate.now().format(formatter)))
            .dicomStudyTime("000000.000")
            .build(),
        SearchByAttributeValue.builder()
            .dicomStudyDateAndTime(DICOMStudyDateAndTime.builder()
            .build(),
        SearchByAttributeValue.builder()
            .build())
    .build());
imageSetsMetadataSummaries =
    searchMedicalImagingImageSets(medicalImagingClient,
        datastoreId, searchFilters);
if (imageSetsMetadataSummaries != null) {
    System.out.println(
        "The image sets for patient " + patientId
        + " are:\n" + imageSetsMetadataSummaries);
    System.out.println();
}
```
"The image sets searched with BETWEEN operator using DICOMStudyDate and DICOMStudyTime are:
+ imageSetsMetadataSummaries);

System.out.println();
} }

Use case #3: BETWEEN operator using createdAt. Time studies were previously persisted.

    searchFilters = Collections.singletonList(SearchFilter.builder()
      .operator(Operator.BETWEEN)
      .values(SearchByAttributeValue.builder()
        .createdAt(Instant.parse("1985-04-12T23:20:50.52Z"))
          .build(),
        SearchByAttributeValue.builder()
          .createdAt(Instant.now())
            .build())
      .build());

    imageSetsMetadataSummaries = searchMedicalImagingImageSets(medicalImagingClient,
      datastoreId, searchFilters);
  if (imageSetsMetadataSummaries != null) {
    System.out.println("The image sets searched with BETWEEN operator using createdAt are:
 "
     + imageSetsMetadataSummaries);
    System.out.println();
  }

• For API details, see SearchImageSets in AWS SDK for Java 2.x API Reference.

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
Update image set metadata

The following code example shows how to update HealthImaging image set metadata.

SDK for Java 2.x

```java
public static void updateMedicalImageSetMetadata(MedicalImagingClient medicalImagingClient,
                                                 String datastoreId,
                                                 String imagesetId,
                                                 String versionId,
                                                 MetadataUpdates metadataUpdates) {
  try {
    UpdateImageSetMetadataRequest updateImageSetMetadataRequest =
                                  UpdateImageSetMetadataRequest
                                                                 .builder()
                                                                 .datastoreId(datastoreId)
                                                                 .imageSetId(imagesetId)
                                                                 .latestVersionId(versionId)
                                                                 .updateImageSetMetadataUpdates(metadataUpdates)
                                                                 .build();

    medicalImagingClient.updateImageSetMetadata(updateImageSetMetadataRequest);

    System.out.println("The image set metadata was updated");
  } catch (MedicalImagingException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
  }
}
```

- For API details, see [UpdateImageSetMetadata](#) in *AWS SDK for Java 2.x API Reference*.

Scenarios

Tagging a data store

The following code example shows how to tag a HealthImaging data store.

SDK for Java 2.x

To tag a data store.

```java
final String datastoreArn = "arn:aws:medical-imaging:us-east-1:123456789012:datastore/12345678901234567890123456789012";
TagResource.tagMedicalImagingResource(medicalImagingClient,
   datastoreArn,
   ImmutableMap.of("Deployment", "Development"));
```

The utility function for tagging a resource.

```java
public static void tagMedicalImagingResource(MedicalImagingClient medicalImagingClient,
   String resourceArn,
   Map<String, String> tags) {
   try {
      TagResourceRequest tagResourceRequest = TagResourceRequest.builder()
         .resourceArn(resourceArn)
         .tags(tags)
         .build();

      medicalImagingClient.tagResource(tagResourceRequest);

      System.out.println("Tags have been added to the resource.");
   } catch (MedicalImagingException e) {
      System.err.println(e.awsErrorDetails().errorMessage());
      System.exit(1);
   }
}
```

To list tags for a data store.
final String datastoreArn = "arn:aws:medical-imaging:us-east-1:123456789012:datastore/12345678901234567890123456789012";

ListTagsForResourceResponse result =
ListTagsForResource.listMedicalImagingResourceTags(
medicalImagingClient,
datastoreArn);
if (result != null) {
    System.out.println("Tags for resource: " + result.tags());
}

The utility function for listing a resource's tags.

public static ListTagsForResourceResponse
listMedicalImagingResourceTags(MedicalImagingClient medicalImagingClient,
String resourceArn) {
    try {
        ListTagsForResourceRequest listTagsForResourceRequest =
ListTagsForResourceRequest.builder()
            .resourceArn(resourceArn)
            .build();

        return
medicalImagingClient.listTagsForResource(listTagsForResourceRequest);
    } catch (MedicalImagingException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }

    return null;
}

To untag a data store.

final String datastoreArn = "arn:aws:medical-imaging:us-east-1:123456789012:datastore/12345678901234567890123456789012";

UntagResource.untagMedicalImagingResource(medicalImagingClient,
datastoreArn,
Collections.singletonList("Deployment"));
The utility function for untagging a resource.

```java
public static void untagMedicalImagingResource(MedicalImagingClient medicalImagingClient,
                                               String resourceArn,
                                               Collection<String> tagKeys) {
    try {
        UntagResourceRequest untagResourceRequest =
            UntagResourceRequest.builder()
            .resourceArn(resourceArn)
            .tagKeys(tagKeys)
            .build();

        medicalImagingClient.untagResource(untagResourceRequest);

        System.out.println("Tags have been removed from the resource.");
    } catch (MedicalImagingException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

- For API details, see the following topics in *AWS SDK for Java 2.x API Reference*.
  - ListTagsForResource
  - TagResource
  - UntagResource

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/aws/aws-sdk-java).

**Tagging an image set**

The following code example shows how to tag a HealthImaging image set.
SDK for Java 2.x

To tag an image set.

```java
final String imageSetArn = "arn:aws:medical-imaging:us-east-1:123456789012345678901234567890123456789012/";

TagResource.tagMedicalImagingResource(medicalImagingClient, imageSetArn, ImmutableMap.of("Deployment", "Development"));
```

The utility function for tagging a resource.

```java
public static void tagMedicalImagingResource(MedicalImagingClient medicalImagingClient, String resourceArn, Map<String, String> tags) {
    try {
        TagResourceRequest tagResourceRequest = TagResourceRequest.builder()
            .resourceArn(resourceArn)
            .tags(tags)
            .build();

        medicalImagingClient.tagResource(tagResourceRequest);

        System.out.println("Tags have been added to the resource.");
    } catch (MedicalImagingException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

To list tags for an image set.

```java
final String imageSetArn = "arn:aws:medical-imaging:us-east-1:123456789012345678901234567890123456789012/";

ListTagsForResourceResponse result = ListTagsForResource.listMedicalImagingResourceTags(healthImagingClient, imageSetArn);
```
The utility function for listing a resource's tags.

```java
public static ListTagsForResourceResponse
listMedicalImagingResourceTags(MedicalImagingClient medicalImagingClient,
String resourceArn) {
try {
ListTagsForResourceRequest listTagsForResourceRequest =
ListTagsForResourceRequest.builder()
    .resourceArn(resourceArn)
    .build();

return
medicalImagingClient.listTagsForResource(listTagsForResourceRequest);
} catch (MedicalImagingException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

return null;
}
```

To untag an image set.

```java
final String imageSetArn = "arn:aws:medical-imaging:us-east-1:123456789012:datastore/12345678901234567890123456789012/datastore/12345678901234567890123456789012/imageset/12345678901234567890123456789012";

UntagResource.untagMedicalImagingResource(medicalImagingClient,
imageSetArn,
    Collections.singletonList("Deployment"));
```

The utility function for untagging a resource.
public static void untagMedicalImagingResource(MedicalImagingClient medicalImagingClient,
    String resourceArn,
    Collection<String> tagKeys) {
  try {
    UntagResourceRequest untagResourceRequest =
        UntagResourceRequest.builder()
        .resourceArn(resourceArn)
        .tagKeys(tagKeys)
        .build();

    medicalImagingClient.untagResource(untagResourceRequest);
    System.out.println("Tags have been removed from the resource.");
  } catch (MedicalImagingException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
  }
}

**IAM examples using SDK for Java 2.x**

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with IAM.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.
Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Get started

Hello IAM

The following code examples show how to get started using IAM.

SDK for Java 2.x

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
import software.amazon.awssdk.services.iam.model.ListPoliciesResponse;
import software.amazon.awssdk.services.iam.model.Policy;
import java.util.List;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 * For more information, see the following documentation topic:
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class HelloIAM {
    public static void main(String[] args) {
        Region region = Region.AWS_GLOBAL;
        IamClient iam = IamClient.builder()
            .region(region)
            .build();

        listPolicies(iam);
    }
}
```

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
public static void listPolicies(IamClient iam) {
    ListPoliciesResponse response = iam.listPolicies();
    List<Policy> polList = response.policies();
    polList.forEach(policy -> {
            System.out.println("Policy Name: " + policy.policyName());
    });
}

• For API details, see ListPolicies in AWS SDK for Java 2.x API Reference.

Actions

Attach a policy to a role

The following code example shows how to attach an IAM policy to a role.

SDK for Java 2.x

import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
import software.amazon.awssdk.services.iam.model.IamException;
import software.amazon.awssdk.services.iam.model.AttachRolePolicyRequest;
import software.amazon.awssdk.services.iam.model.AttachedPolicy;
import software.amazon.awssdk.services.iam.model.ListAttachedRolePoliciesRequest;
import software.amazon.awssdk.services.iam.model.ListAttachedRolePoliciesResponse;
import java.util.List;

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
public class AttachRolePolicy {
    public static void main(String[] args) {
        final String usage =
            "Usage:
              <roleName> <policyArn>
             Where:
              roleName - A role name that you can obtain from the AWS Management Console.
              policyArn - A policy ARN that you can obtain from the AWS Management Console."
        
        if (args.length != 2) {
            System.out.println(usage);
            System.exit(1);
        }

        String roleName = args[0];
        String policyArn = args[1];

        Region region = Region.AWS_GLOBAL;
        IamClient iam = IamClient.builder()
            .region(region)
            .build();

        attachIAMRolePolicy(iam, roleName, policyArn);
        iam.close();
    }

    public static void attachIAMRolePolicy(IamClient iam, String roleName, String policyArn) {
        try {
            ListAttachedRolePoliciesRequest request = ListAttachedRolePoliciesRequest.builder()
.roleName(roleName)
.build();

ListAttachedRolePoliciesResponse response =
iam.listAttachedRolePolicies(request);
List<AttachedPolicy> attachedPolicies = response.attachedPolicies();

// Ensure that the policy is not attached to this role
String polArn = "";
for (AttachedPolicy policy : attachedPolicies) {
polArn = policy.policyArn();
if (polArn.compareTo(policyArn) == 0) {
    System.out.println(roleName + " policy is already attached to this role.");
    return;
}
}

AttachRolePolicyRequest attachRequest =
AttachRolePolicyRequest.builder()
    .roleName(roleName)
    .policyArn(policyArn)
    .build();

iam.attachRolePolicy(attachRequest);

System.out.println("Successfully attached policy " + policyArn + " to role " + roleName);

} catch (IamException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
System.out.println("Done");
}

• For API details, see AttachRolePolicy in AWS SDK for Java 2.x API Reference.

Create a policy

The following code example shows how to create an IAM policy.
import software.amazon.awssdk.core.waiters.WaiterResponse;
import software.amazon.awssdk.services.iam.model.CreatePolicyRequest;
import software.amazon.awssdk.services.iam.model.CreatePolicyResponse;
import software.amazon.awssdk.services.iam.model.GetPolicyRequest;
import software.amazon.awssdk.services.iam.model.GetPolicyResponse;
import software.amazon.awssdk.services.iam.model.IamException;

Create a role

The following code example shows how to create an IAM role.

SDK for Java 2.x

```java
import org.json.simple.JSONObject;
import org.json.simple.parser.JSONParser;
import software.amazon.awssdk.services.iam.model.CreateRoleRequest;
import software.amazon.awssdk.services.iam.model.CreateRoleResponse;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
import java.io.FileReader;

/*

For API details, see CreatePolicy in AWS SDK for Java 2.x API Reference.

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
*/
This example requires a trust policy document. For more information, see:

In addition, set up your development environment, including your credentials.

For information, see this documentation topic:
https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html

```
public class CreateRole {
    public static void main(String[] args) throws Exception {
        final String usage = "
            Usage:
                <rolename> <fileLocation>
            
            Where:
                rolename - The name of the role to create.
                fileLocation - The location of the JSON document that represents
                the trust policy.
        "
        
        if (args.length != 2) {
            System.out.println(usage);
            System.exit(1);
        }

        String rolename = args[0];
        String fileLocation = args[1];
        Region region = Region.AWS_GLOBAL;
        IamClient iam = IamClient.builder()
            .region(region)
            .build();

        String result = createIAMRole(iam, rolename, fileLocation);
        System.out.println("Successfully created user: " + result);
        iam.close();
    }

### List users

The following code example shows how to list IAM users.

```java
import software.amazon.awssdk.services.iam.model.AttachedPermissionsBoundary;
import software.amazon.awssdk.services.iam.model.IamException;
import software.amazon.awssdk.services.iam.model.ListUsersRequest;
import software.amazon.awssdk.services.iam.model.ListUsersResponse;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
import software.amazon.awssdk.services.iam.model.User;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 */
```

**Warning**

To avoid security risks, don't use IAM users for authentication when developing purpose-built software or working with real data. Instead, use federation with an identity provider such as [AWS IAM Identity Center](https://aws.amazon.com/identity-center/).

**Scenarios**

**Build and manage a resilient service**

The following code example shows how to create a load-balanced web service that returns book, movie, and song recommendations. The example shows how the service responds to failures, and how to restructure the service for more resilience when failures occur.

• Use an Amazon EC2 Auto Scaling group to create Amazon Elastic Compute Cloud (Amazon EC2) instances based on a launch template and to keep the number of instances in a specified range.

• Handle and distribute HTTP requests with Elastic Load Balancing.
Monitor the health of instances in an Auto Scaling group and forward requests only to healthy instances.

Run a Python web server on each EC2 instance to handle HTTP requests. The web server responds with recommendations and health checks.

Simulate a recommendation service with an Amazon DynamoDB table.

Control web server response to requests and health checks by updating AWS Systems Manager parameters.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run the interactive scenario at a command prompt.

```java
public class Main {

    ParameterHelper paramHelper = new ParameterHelper();
    System.out.println("Read the ssm_only_policy.json file");
    String ssmOnlyPolicy = readFileAsString(ssmJSON);
    System.out.println("Resetting parameters to starting values for demo.");
    paramHelper.reset();
System.out.println(
    ""
    This part of the demonstration shows how to toggle
different parts of the system
to create situations where the web service fails, and shows
how using a resilient
architecture can keep the web service running in spite of
these failures.

    At the start, the load balancer endpoint returns
recommendations and reports that all targets are healthy.
    ");
demoChoices(loadBalancer);

System.out.println(
    ""
    The web service running on the EC2 instances gets
recommendations by querying a DynamoDB table.
The table name is contained in a Systems Manager parameter
named self.param_helper.table.
To simulate a failure of the recommendation service, let's
set this parameter to name a non-existent table.
    ");
paramHelper.put(paramHelper.tableName, "this-is-not-a-table");

System.out.println(
    ""
    \nNow, sending a GET request to the load balancer endpoint
returns a failure code. But, the service reports as
healthy to the load balancer because shallow health checks
don't check for failure of the recommendation service.
    ");
demoChoices(loadBalancer);

System.out.println(
    ""
    Instead of failing when the recommendation service fails,
the web service can return a static response.
    While this is not a perfect solution, it presents the
customer with a somewhat better experience than failure.
    ");
paramHelper.put(paramHelper.failureResponse, "static");
System.out.println(""");

Now, sending a GET request to the load balancer endpoint returns a static response.

The service still reports as healthy because health checks are still shallow.

""\n
demoChoices(loadBalancer);

System.out.println("Let's reinstate the recommendation service.");
paramHelper.put(paramHelper.tableName, paramHelper.dyntable);

System.out.println(""");

Let's also substitute bad credentials for one of the instances in the target group so that it can't access the DynamoDB recommendation table. We will get an instance id value.

""\n
LaunchTemplateCreator templateCreator = new LaunchTemplateCreator();
AutoScaler autoScaler = new AutoScaler();

// Create a new instance profile based on badCredsProfileName.
templateCreator.createInstanceProfile(policyFile, policyName, badCredsProfileName, roleName);
String badInstanceId = autoScaler.getBadInstance(autoScalingGroupName);
System.out.println("The bad instance id values used for this demo is " + badInstanceId);

String profileAssociationId = autoScaler.getInstanceProfile(badInstanceId);
System.out.println("The association Id value is " + profileAssociationId);
System.out.println("Replacing the profile for instance " + badInstanceId + " with a profile that contains bad credentials");
autoScaler.replaceInstanceProfile(badInstanceId, badCredsProfileName, profileAssociationId);

System.out.println(""");

Now, sending a GET request to the load balancer endpoint returns either a recommendation or a static response, depending on which instance is selected by the load balancer.

""\n
demoChoices(loadBalancer);
Let's implement a deep health check. For this demo, a deep health check tests whether the web service can access the DynamoDB table that it depends on for recommendations. Note that the deep health check is only for ELB routing and not for Auto Scaling instance health. This kind of deep health check is not recommended for Auto Scaling instance health, because it risks accidental termination of all instances in the Auto Scaling group when a dependent service fails.

By implementing deep health checks, the load balancer can detect when one of the instances is failing and take that instance out of rotation.

Now, checking target health indicates that the instance with bad credentials is unhealthy. Note that it might take a minute or two for the load balancer to detect the unhealthy instance. Sending a GET request to the load balancer endpoint always returns a recommendation, because the load balancer takes unhealthy instances out of its rotation.

demoChoices(loadBalancer);

Because the instances in this demo are controlled by an auto scaler, the simplest way to fix an unhealthy instance is to terminate it and let the auto scaler start a new instance to replace it.

autoScaler.terminateInstance(badInstanceId);

System.out.println(""
Even while the instance is terminating and the new instance is starting, sending a GET request to the web service continues to get a successful recommendation response because the load balancer routes requests to the healthy instances. After the replacement instance starts and reports as healthy, it is included in the load balancing rotation.

Note that terminating and replacing an instance typically takes several minutes, during which time you can see the changing health check status until the new instance is running and healthy.

```java
demoChoices(loadBalancer);
System.out.println("If the recommendation service fails now, deep health checks mean all instances report as unhealthy.");
paramHelper.put(paramHelper.tableName, "this-is-not-a-table");
demoChoices(loadBalancer);
paramHelper.reset();
}

Create a user and assume a role

The following code example shows how to create a user and assume a role.

⚠️ **Warning**

To avoid security risks, don't use IAM users for authentication when developing purpose-built software or working with real data. Instead, use federation with an identity provider such as [AWS IAM Identity Center](https://aws.amazon.com/iam/).

- Create a user with no permissions.
- Create a role that grants permission to list Amazon S3 buckets for the account.
- Add a policy to let the user assume the role.
- Assume the role and list S3 buckets using temporary credentials, then clean up resources.

**SDK for Java 2.x**

ℹ️ **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/aws-sdk-java/aws-sdk-java/tree/master/code-examples/iidc/iam/example-iam)

Create functions that wrap IAM user actions.

```java
/*
IAM
*/
To run this Java V2 code example, set up your development environment, including your credentials.

For information, see this documentation topic:

https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html

This example performs these operations:

1. Creates a user that has no permissions.
2. Creates a role and policy that grants Amazon S3 permissions.
3. Creates a role.
4. Grants the user permissions.
5. Gets temporary credentials by assuming the role. Creates an Amazon S3 Service client object with the temporary credentials.
6. Deletes the resources.

```java
public class IAMScenario {
    public static final String DASHES = new String(new char[80]).replace("\0", "-" nga="
    public static final String PolicyDocument = "{" +
        " "Version": "2012-10-17"", " +

**Work with the IAM Policy Builder API**

The following code example shows how to:

- Create IAM policies by using the object-oriented API.
- Use the IAM Policy Builder API with the IAM service.

**SDK for Java 2.x**

```java
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.policybuilder.iam.IamConditionOperator;
import software.amazon.awssdk.policybuilder.iam.IamEffect;
import software.amazon.awssdk.policybuilder.iam.IamPolicy;
import software.amazon.awssdk.policybuilder.iam.IamPolicyWriter;
import software.amazon.awssdk.policybuilder.iam.IamPrincipal;
import software.amazon.awssdk.policybuilder.iam.IamPrincipalType;
import software.amazon.awssdk.policybuilder.iam.IamResource;
import software.amazon.awssdk.policybuilder.iam.IamStatement;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
import software.amazon.awssdk.services.iam.model.GetPolicyResponse;
```

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://aws.amazon.com/code-examples/).
import software.amazon.awssdk.services.iam.model.GetPolicyVersionResponse;
import software.amazon.awssdk.services.sts.StsClient;

import java.net.URLDecoder;
import java.nio.charset.StandardCharsets;
import java.util.Arrays;
import java.util.List;

Create a time-based policy.

```java
public String timeBasedPolicyExample() {
    IamPolicy policy = IamPolicy.builder()
        .addStatement(b -> b
            .effect(IamEffect.ALLOW)
            .addAction("dynamodb:GetItem")
            .addResource(IamResource.ALL)
            .addCondition(b1 -> b1
                .operator(IamConditionOperator.DATE_GREATER_THAN)
                .key("aws:CurrentTime")
                .value("2020-04-01T00:00:00Z")(b1)
            .addCondition(b1 -> b1
                .operator(IamConditionOperator.DATE_LESS_THAN)
                .key("aws:CurrentTime")
                .value("2020-06-30T23:59:59Z")
            .build();

    // Use an IamPolicyWriter to write out the JSON string to a more
    // readable
    return policy.toJson(IamPolicyWriter.builder()
        .prettyPrint(true)
        .build());
}
```

Create a policy with multiple conditions.
public String multipleConditionsExample() {
    IamPolicy policy = IamPolicy.builder()
        .addStatement(b -> b
            .effect(IamEffect.ALLOW)
            .addAction("dynamodb:GetItem")
            .addAction("dynamodb:BatchGetItem")
            .addAction("dynamodb:Query")
            .addAction("dynamodb:PutItem")
            .addAction("dynamodb:UpdateItem")
            .addAction("dynamodb:DeleteItem")
            .addAction("dynamodb:BatchWriteItem")
        .addResource("arn:aws:dynamodb:::table/table-name")
        .addConditions(IamConditionOperator.STRING_EQUALS
            .addPrefix("ForAllValues:"),
            "dynamodb:Attributes",
            List.of("column-name1", "column-name2", "column-name3")
          .addCondition(b1 -> b1
            .operator(IamConditionOperator.STRING_EQUALS
            .addSuffix("IfExists"))
            .key("dynamodb:Select")
            .value("SPECIFIC_ATTRIBUTES"))
        .build();
    return policy.toJson(IamPolicyWriter.builder()
        .prettyPrint(true).build());
}

Use principals in a policy.

public String specifyPrincipalsExample() {
    IamPolicy policy = IamPolicy.builder()
        .addStatement(b -> b
            .addAction("iam:PassRole")
        .addPrincipal("arn:aws:iam:::user/user-name")
        .build();
    return policy.toJson(IamPolicyWriter.builder()
        .prettyPrint(true).build());
}
Allow cross-account access.

```java
public String allowCrossAccountAccessExample() {
    IamPolicy policy = IamPolicy.builder()
        .addStatement(b -> b
            .effect(IamEffect.ALLOW)
            .addPrincipal(IamPrincipalType.AWS, "111122223333")
            .addAction("s3:PutObject")
            .addResource("arn:aws:s3:::DOC-EXAMPLE-BUCKET/*")
            .addCondition(b1 -> b1
                .operator(IamConditionOperator.STRING_EQUALS)
                .key("s3:x-amz-acl")
                .value("bucket-owner-full-control")))
        .build();
    return policy.toJson(IamPolicyWriter.builder()
        .prettyPrint(true).build());
}
```
Build and upload an IamPolicy.

```java
public String createAndUploadPolicyExample(IamClient iam, String accountID, String policyName) {
    // Build the policy.
    IamPolicy policy = IamPolicy.builder() // 'version' defaults to "2012-10-17".
        .addStatement(IamStatement.builder()
            .effect(IamEffect.ALLOW)
            .addAction("dynamodb:PutItem")
            .addResource("arn:aws:dynamodb:us-east-1:" + accountID + ":table/exampleTableName")
        .build())
        .build();
    // Upload the policy.
    iam.createPolicy(r -> r.policyName(policyName).policyDocument(policy.toJson()));
    return policy.toJson(IamPolicyWriter.builder().prettyPrint(true).build());
}
```

Download and work with an IamPolicy.

```java
public String createNewBasedOnExistingPolicyExample(IamClient iam, String accountID, String policyName, String newPolicyName) {
    String policyArn = "arn:aws:iam::" + accountID + ":policy/" + policyName;
    GetPolicyResponse getPolicyResponse = iam.getPolicy(r -> r.policyArn(policyArn));

    String policyVersion = getPolicyResponse.policy().defaultVersionId();

    // Create an IamPolicy instance from the JSON string returned from IAM.
```
String decodedPolicy =
URLDecoder.decode(getPolicyVersionResponse.policyVersion().document(),
    StandardCharsets.UTF_8);
IamPolicy policy = IamPolicy.fromJson(decodedPolicy);

/*
 * All IamPolicy components are immutable, so use the copy method that creates a
 * new instance that
 * can be altered in the same method call.
 * *
 * Add the ability to get an item from DynamoDB as an additional action.
 */
IamStatement newStatement = policy.statements().get(0).copy(s ->
    s.addAction("dynamodb:GetItem");

    // Create a new statement that replaces the original statement.
    IamPolicy newPolicy = policy.copy(p ->
        p.statements(Arrays.asList(newStatement)));

    // Upload the new policy. IAM now has both policies.
    iam.createPolicy(r -> r.policyName(newPolicyName)
        .policyDocument(newPolicy.toJson()));

    return
    newPolicy.toJson(IamPolicyWriter.builder().prettyPrint(true).build());
}
Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Get started

Hello AWS IoT

The following code examples show how to get started using AWS IoT.

SDK for Java 2.x

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iot.IotClient;
import software.amazon.awssdk.services.iot.model.ListThingsRequest;
import software.amazon.awssdk.services.iot.model.ListThingsResponse;
import software.amazon.awssdk.services.iot.model.ThingAttribute;
import java.util.List;

public class HelloIoT {
    public static void main(String[] args) {
        System.out.println("Hello AWS IoT. Here is a listing of your AWS IoT Things:");
        IotClient iotClient = IotClient.builder()
            .region(Region.US_EAST_1)
            .build();

        listAllThings(iotClient);
    }
```
public static void listAllThings(IotClient iotClient) {
    ListThingsRequest thingsRequest = ListThingsRequest.builder()
        .maxResults(10)
        .build();

    ListThingsResponse response = iotClient.listThings(thingsRequest);
    List<ThingAttribute> thingList = response.things();
    for (ThingAttribute attribute : thingList) {
        System.out.println("Thing name: "+attribute.thingName());
        System.out.println("Thing ARN: "+attribute.thingArn());
    }
}

For API details, see listThings in AWS SDK for Java 2.x API Reference.

Actions

Attach a certificate

The following code example shows how to attach an AWS IoT certificate.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

public static void attachCertificateToThing(IotClient iotClient, String thingName, String certificateArn) {
    // Attach the certificate to the thing.
    AttachThingPrincipalRequest principalRequest = AttachThingPrincipalRequest.builder()
AttachThingPrincipalResponse attachResponse =
    iotClient.attachThingPrincipal(principalRequest);

    // Verify the attachment was successful.
    if (attachResponse.sdkHttpResponse().isSuccessful()) {
        System.out.println("Certificate attached to Thing successfully.");

        // Print additional information about the Thing.
        describeThing(iotClient, thingName);
    } else {
        System.err.println("Failed to attach certificate to Thing. HTTP Status Code: " +
            attachResponse.sdkHttpResponse().statusCode());
    }
}

- For API details, see AttachThingPrincipal in AWS SDK for Java 2.x API Reference.

Create a certificate

The following code example shows how to create an AWS IoT certificate.

SDK for Java 2.x

```java
public static String createCertificate(IotClient iotClient) {
    try {
        CreateKeysAndCertificateResponse response =
            iotClient.createKeysAndCertificate();
        String certificatePem = response.certificatePem();
        String certificateArn = response.certificateArn();
    }
```
// Print the details.
System.out.println("Certificate:");
System.out.println(certificatePem);
System.out.println("Certificate ARN:"ed); System.out.println(certificateArn);
return certificateArn;

} catch (IotException e) {
  System.err.println(e.awsErrorDetails().errorMessage());
  System.exit(1);
}

return "";
}

• For API details, see CreateKeysAndCertificate in AWS SDK for Java 2.x API Reference.

Create a rule

The following code example shows how to create an AWS IoT rule.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```java
public static void createIoTRule(IotClient iotClient, String roleARN, String ruleName, String action) {
  try {
    String sql = "SELECT * FROM ", TOPIC, ";
    SnsAction action1 = SnsAction.builder()
      .targetArn(action)
      .roleArn(roleARN)
      .build();

    // Create the action.
    Action myAction = Action.builder()
      .sns(action1)
```
// Create the topic rule payload.
TopicRulePayload topicRulePayload = TopicRulePayload.builder()
    .sql(sql)
    .actions(myAction)
    .build();

// Create the topic rule request.
CreateTopicRuleRequest topicRuleRequest =
    CreateTopicRuleRequest.builder()
    .ruleName(ruleName)
    .topicRulePayload(topicRulePayload)
    .build();

// Create the rule.
    iotClient.createTopicRule(topicRuleRequest);
    System.out.println("IoT Rule created successfully.");

} catch (IotException e) {
    System.err.println(e.getMessage());
    System.exit(1);
}

• For API details, see [CreateTopicRule](https://aws.amazon.com/sdk-for-java/developer-guide/) in [AWS SDK for Java 2.x API Reference](https://aws.amazon.com/sdk-for-java/developer-guide/).

Create a thing

The following code example shows how to create an AWS IoT thing.

SDK for Java 2.x

```java
public static void createIoTThing(IotClient iotClient, String thingName) {
    try {
```
CreateThingRequest createThingRequest = CreateThingRequest.builder()
    .thingName(thingName)
    .build();

CreateThingResponse createThingResponse =
    iotClient.createThing(createThingRequest);
    System.out.println(thingName +" was successfully created. The ARN value is " + createThingResponse.thingArn());

} catch (IotException e) {
   System.err.println(e.awsErrorDetails().errorMessage());
   System.exit(1);
}

• For API details, see CreateThing in AWS SDK for Java 2.x API Reference.

Delete a certificate

The following code example shows how to delete an AWS IoT certificate.

SDK for Java 2.x

```
public static void deleteCertificate(IotClient iotClient, String certificateArn ) {
    DeleteCertificateRequest certificateProviderRequest =
        DeleteCertificateRequest.builder()
            .certificateId(extractCertificateId(certificateArn))
            .build();

    iotClient.deleteCertificate(certificateProviderRequest);
    System.out.println(certificateArn +" was successfully deleted.");
}
```

Note

Delete a thing

The following code example shows how to delete an AWS IoT thing.

SDK for Java 2.x

```java
public static void deleteIoTThing(IotClient iotClient, String thingName) {
    try {
        DeleteThingRequest deleteThingRequest = DeleteThingRequest.builder()
            .thingName(thingName)
            .build();

        iotClient.deleteThing(deleteThingRequest);
        System.out.println("Deleted Thing " + thingName);
    } catch (IotException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

Describe a thing

The following code example shows how to describe an AWS IoT thing.

```java
public static void describeIoTThing(IotClient iotClient, String thingName) {
    DescribeThingRequest describeThingRequest = DescribeThingRequest.builder()
        .thingName(thingName)
        .build();

    DescribeThingResponse describeThingResponse = iotClient.describeThing(describeThingRequest);
    System.out.println("Description of Thing "+ thingName); 
}
```
SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```java
private static void describeThing(IotClient iotClient, String thingName) {
    try {
        DescribeThingRequest thingRequest = DescribeThingRequest.builder()
                            .thingName(thingName)
                            .build();

        // Print Thing details.
        DescribeThingResponse describeResponse =
            iotClient.describeThing(thingRequest);
        System.out.println("Thing Details:");
        System.out.println("Thing Name: " + describeResponse.thingName());
        System.out.println("Thing ARN: " + describeResponse.thingArn());
    } catch (IotException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

- For API details, see DescribeThing in AWS SDK for Java 2.x API Reference.

Detach a certificate

The following code example shows how to detach an AWS IoT certificate.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
public static void detachThingPrincipal(IotClient iotClient, String thingName, 
String certificateArn){
    try {
        DetachThingPrincipalRequest thingPrincipalRequest = 
        DetachThingPrincipalRequest.builder()
            .principal(certificateArn)
            .thingName(thingName)
            .build();

        iotClient.detachThingPrincipal(thingPrincipalRequest);
        System.out.println(certificateArn +" was successfully removed from " +thingName);
    } catch (IotException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}

• For API details, see DetachThingPrincipal in AWS SDK for Java 2.x API Reference.

Get endpoint information

The following code example shows how to get AWS IoT endpoint information.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

public static String describeEndpoint(IotClient iotClient) {
    try {
        DescribeEndpointResponse endpointResponse = 
        iotClient.describeEndpoint(DescribeEndpointRequest.builder().build());

        // Get the endpoint URL.
        String endpointUrl = endpointResponse.endpointAddress();
String exString = getValue(endpointUrl);
String fullEndpoint = "https://"+exString+-ats.iot.us-
  east-1.amazonaws.com";

   System.out.println("Full Endpoint URL: "+fullEndpoint);
   return fullEndpoint;

} catch (IotException e) {
   System.err.println(e.awsErrorDetails().errorMessage());
   System.exit(1);
} 

return "" ;

• For API details, see DescribeEndpoint in AWS SDK for Java 2.x API Reference.

List your certificates

The following code example shows how to list your AWS IoT certificates.

SDK for Java 2.x

public static void listCertificates(IotClient iotClient) {
   ListCertificatesResponse response = iotClient.listCertificates();
   List<Certificate> certList = response.certificates();
   for (Certificate cert : certList) {
      System.out.println("Cert id: " + cert.certificateId());
      System.out.println("Cert Arn: " + cert.certificateArn());
   }
}

• For API details, see ListCertificates in AWS SDK for Java 2.x API Reference.

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
Query the search index

The following code example shows how to query the AWS IoT search index.

SDK for Java 2.x

```java
public static void searchThings(IotClient iotClient, String queryString){
    SearchIndexRequest searchIndexRequest = SearchIndexRequest.builder()
        .queryString(queryString)
        .build();

    try {
        // Perform the search and get the result.
        SearchIndexResponse searchIndexResponse = iotClient.searchIndex(searchIndexRequest);

        // Process the result.
        if (searchIndexResponse.things().isEmpty()) {
            System.out.println("No things found.");
        } else {
            searchIndexResponse.things().forEach(thing ->
                System.out.println("Thing id found using search is " + thing.thingId()));
        }
    } catch (IotException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

- For API details, see [SearchIndex](https://aws.amazon.com) in [AWS SDK for Java 2.x API Reference](https://aws.amazon.com).

Update a thing

The following code example shows how to update an AWS IoT thing.
public static void updateThing(IotClient iotClient, String thingName) {
    // Specify the new attribute values.
    String newLocation = "Office";
    String newFirmwareVersion = "v2.0";

    Map<String, String> attMap = new HashMap<>();
    attMap.put("location", newLocation);
    attMap.put("firmwareVersion", newFirmwareVersion);

    AttributePayload attributePayload = AttributePayload.builder()
        .attributes(attMap)
        .build();

    UpdateThingRequest updateThingRequest = UpdateThingRequest.builder()
        .thingName(thingName)
        .attributePayload(attributePayload)
        .build();

    try {
        // Update the IoT Thing attributes.
        iotClient.updateThing(updateThingRequest);
        System.out.println("Thing attributes updated successfully.");
    } catch (IotException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}

• For API details, see UpdateThing in AWS SDK for Java 2.x API Reference.
Scenarios

Work with device management use cases

The following code example shows how to work with AWS IoT device management use cases using AWS IoT SDK

SDK for Java 2.x

```java
import software.amazon.awssdk.core.SdkBytes;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * This Java example performs these tasks:
 *
 * 1. Creates an AWS IoT Thing.
 * 2. Generate and attach a device certificate.
 * 3. Update an AWS IoT Thing with Attributes.
 * 5. List your certificates.
 * 6. Updates the shadow for the specified thing..
 * 7. Write out the state information, in JSON format
 * 8. Creates a rule
 * 9. List rules
 * 10. Search things
 * 11. Detach amd delete the certificate.
 * 12. Delete Thing.
 */

**AWS IoT data examples using SDK for Java 2.x**

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with AWS IoT data.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

**Topics**

- **Actions**
Actions

Get the shadow

The following code example shows how to get the shadow for an AWS IoT thing.

SDK for Java 2.x

```java
public static void getPayload(IotDataPlaneClient iotPlaneClient, String thingName) {
    try {
        GetThingShadowRequest getThingShadowRequest =
            GetThingShadowRequest.builder()
                .thingName(thingName)
                .build();

        GetThingShadowResponse getThingShadowResponse =
            iotPlaneClient.getThingShadow(getThingShadowRequest);

        // Extracting payload from response.
        SdkBytes payload = getThingShadowResponse.payload();
        String payloadString = payload.asUtf8String();
        System.out.println("Received Shadow Data: " + payloadString);
    } catch (IotException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}
```

- For API details, see `GetThingShadow` in `AWS SDK for Java 2.x API Reference`.

Update the shadow

The following code example shows how to update the shadow for an AWS IoT thing.
public static void updateShadowThing(IotDataPlaneClient iotPlaneClient, String thingName) {
    try {
        // Create Thing Shadow State Document.
        String stateDocument = "{"state":{"reported":{"temperature":25,"humidity":50}}}");
        SdkBytes data = SdkBytes.fromString(stateDocument, StandardCharsets.UTF_8);
        UpdateThingShadowRequest updateThingShadowRequest = UpdateThingShadowRequest.builder()
            .thingName(thingName)
            .payload(data)
            .build();

        // Update Thing Shadow.
        iotPlaneClient.updateThingShadow(updateThingShadowRequest);
        System.out.println("Thing Shadow updated successfully.");
    } catch (IotException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}

• For API details, see UpdateThingShadow in AWS SDK for Java 2.x API Reference.

Amazon Keypaces examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon Keypaces.
*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

**Get started**

**Hello Amazon Keyspaces**

The following code examples show how to get started using Amazon Keyspaces.

**SDK for Java 2.x**

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.keyspaces.KeyspacesClient;
import software.amazon.awssdk.services.keyspaces.model.KeyspaceSummary;
import software.amazon.awssdk.services.keyspaces.model.KeyspacesException;
import software.amazon.awssdk.services.keyspaces.model.ListKeyspacesRequest;
import software.amazon.awssdk.services.keyspaces.model.ListKeyspacesResponse;
import java.util.List;

/**
 * Before running this Java (v2) code example, set up your development environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class HelloKeyspaces {
  public static void main(String[] args) {
```

>Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://aws.amazon.com/developer/code-examples/).
Region region = Region.US_EAST_1;
KeyspacesClient keyClient = KeyspacesClient.builder()
  .region(region)
  .build();

listKeyspaces(keyClient);
}

public static void listKeyspaces(KeyspacesClient keyClient) {
  try {
    ListKeyspacesRequest keyspaceRequest = ListKeyspacesRequest.builder()
      .maxResults(10)
      .build();

    ListKeyspacesResponse response = keyClient.listKeyspaces(keyspaceRequest);
    List<KeyspaceSummary> keyspaces = response.keyspaces();
    for (KeyspaceSummary keyspace : keyspaces) {
      System.out.println("The name of the keyspace is "+
        keyspace.keyspaceName());
    }
  }
  catch (KeyspacesException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
  }
}

• For API details, see ListKeyspaces in AWS SDK for Java 2.x API Reference.

Actions

Create a keyspace

The following code example shows how to create an Amazon Keyspaces keyspace.
public static void createKeySpace(KeyspacesClient keyClient, String keyspaceName) {
    try {
        CreateKeyspaceRequest keyspaceRequest = CreateKeyspaceRequest.builder()
            .keyspaceName(keyspaceName)
            .build();

        CreateKeyspaceResponse response = keyClient.createKeyspace(keyspaceRequest);
        System.out.println("The ARN of the KeySpace is " +
            response.resourceArn());
    } catch (KeyspacesException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}

• For API details, see CreateKeyspace in AWS SDK for Java 2.x API Reference.

Create a table

The following code example shows how to create an Amazon Keyspaces table.

SDK for Java 2.x

● Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
public static void createTable(KeyspacesClient keyClient, String keySpace, String tableName) {
    try {
        // Set the columns.
        ColumnDefinition defTitle = ColumnDefinition.builder()
            .name("title")
            .type("text")
            .build();

        ColumnDefinition defYear = ColumnDefinition.builder()
            .name("year")
            .type("int")
            .build();

        ColumnDefinition defReleaseDate = ColumnDefinition.builder()
            .name("release_date")
            .type("timestamp")
            .build();

        ColumnDefinition defPlot = ColumnDefinition.builder()
            .name("plot")
            .type("text")
            .build();

        List<ColumnDefinition> colList = new ArrayList<>();
        colList.add(defTitle);
        colList.add(defYear);
        colList.add(defReleaseDate);
        colList.add(defPlot);

        // Set the keys.
        PartitionKey yearKey = PartitionKey.builder()
            .name("year")
            .build();

        PartitionKey titleKey = PartitionKey.builder()
            .name("title")
            .build();

        List<PartitionKey> keyList = new ArrayList<>();
        keyList.add(yearKey);
        keyList.add(titleKey);
    }
}
SchemaDefinition schemaDefinition = SchemaDefinition.builder()
    .partitionKeys(keyList)
    .allColumns(colList)
    .build();

PointInTimeRecovery timeRecovery = PointInTimeRecovery.builder()
    .status(PointInTimeRecoveryStatus.ENABLED)
    .build();

CreateTableRequest tableRequest = CreateTableRequest.builder()
    .keyspaceName(keySpace)
    .tableName(tableName)
    .schemaDefinition(schemaDefinition)
    .pointInTimeRecovery(timeRecovery)
    .build();

CreateTableResponse response = keyClient.createTable(tableRequest);
System.out.println("The table ARN is " + response.resourceArn());

} catch (KeyspacesException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

• For API details, see CreateTable in AWS SDK for Java 2.x API Reference.

Delete a keyspace

The following code example shows how to delete an Amazon Keyspaces keyspace.

SDK for Java 2.x

```java
public static void deleteKeyspace(KeyspacesClient keyClient, String
keyspaceName) {
```

Note
There's more on GitHub. Find the complete example and learn how to set up and run in
the AWS Code Examples Repository.
try {
    DeleteKeyspaceRequest deleteKeyspaceRequest =
    DeleteKeyspaceRequest.builder()
        .keyspaceName(keyspaceName)
        .build();

    keyClient.deleteKeyspace(deleteKeyspaceRequest);
}

} catch (KeyspacesException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

• For API details, see DeleteKeyspace in AWS SDK for Java 2.x API Reference.

Delete a table

The following code example shows how to delete an Amazon Keyspaces table.

SDK for Java 2.x

public static void deleteTable(KeyspacesClient keyClient, String keyspaceName, String tableName) {
    try {
        DeleteTableRequest tableRequest = DeleteTableRequest.builder()
            .keyspaceName(keyspaceName)
            .tableName(tableName)
            .build();

        keyClient.deleteTable(tableRequest);
    } catch (KeyspacesException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
Get data about a keyspace

The following code example shows how to get data about an Amazon Keyspaces keyspace.

SDK for Java 2.x

```java
public static void checkKeyspaceExistence(KeyspacesClient keyClient, String keyspaceName) {
    try {
        GetKeyspaceRequest keyspaceRequest = GetKeyspaceRequest.builder()
            .keyspaceName(keyspaceName)
            .build();

        GetKeyspaceResponse response = keyClient.getKeyspace(keyspaceRequest);
        String name = response.keyspaceName();
        System.out.println("The " + name + " KeySpace is ready");
    } catch (KeyspacesException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

Get data about a table

The following code example shows how to get data about an Amazon Keyspaces table.
public static void checkTable(KeyspacesClient keyClient, String keyspaceName, String tableName)
    throws InterruptedException {
    try {
        boolean tableStatus = false;
        String status;
        GetTableResponse response = null;
        GetTableRequest tableRequest = GetTableRequest.builder()
            .keyspaceName(keyspaceName)
            .tableName(tableName)
            .build();

        while (!tableStatus) {
            response = keyClient.getTable(tableRequest);
            status = response.statusAsString();
            System.out.println("The table status is " + status);
            if (status.compareTo("ACTIVE") == 0) {
                tableStatus = true;
            }
            Thread.sleep(500);
        } List<ColumnDefinition> cols = response.schemaDefinition().allColumns();
        for (ColumnDefinition def : cols) {
            System.out.println("The column name is " + def.name());
            System.out.println("The column type is " + def.type());
        }
    } catch (KeyspacesException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
List keyspaces

The following code example shows how to list Amazon Keyspaces keyspaces.

SDK for Java 2.x

```java
public static void listKeyspacesPaginator(KeyspacesClient keyClient) {
    try {
        ListKeyspacesRequest keyspacesRequest = ListKeyspacesRequest.builder()
            .maxResults(10)
            .build();

        ListKeyspacesIterable listRes = keyClient.listKeyspacesPaginator(keyspacesRequest);
        listRes.stream()
            .flatMap(r -> r.keyspaces().stream())
            .forEach(content -> System.out.println(" Name: " + content.keyspaceName()));
    } catch (KeyspacesException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

List tables in a keyspace

The following code example shows how to list Amazon Keyspaces tables in a keyspace.

```java
• For API details, see ListKeyspaces in AWS SDK for Java 2.x API Reference.
```
public static void listTables(KeyspacesClient keyClient, String keyspaceName) {
    try {
        ListTablesRequest tablesRequest = ListTablesRequest.builder()
            .keyspaceName(keyspaceName)
            .build();

        ListTablesIterable listRes =
            keyClient.listTablesPaginator(tablesRequest);
        listRes.stream()
            .flatMap(r -> r.tables().stream())
            .forEach(content -> System.out.println(" ARN: " +
                content.resourceArn() +
                " Table name: " + content.tableName()));
    } catch (KeyspacesException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}

• For API details, see ListTables in AWS SDK for Java 2.x API Reference.

### Restore a table to a point in time

The following code example shows how to restore an Amazon Keyspaces table to a point in time.
SDK for Java 2.x

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```java
public static void restoreTable(KeyspacesClient keyClient, String keyspaceName, ZonedDateTime utc) {
    try {
        Instant myTime = utc.toInstant();
        RestoreTableRequest restoreTableRequest = RestoreTableRequest.builder()
            .restoreTimestamp(myTime)
            .sourceTableName("Movie")
            .targetKeyspaceName(keyspaceName)
            .targetTableName("MovieRestore")
            .sourceKeyspaceName(keyspaceName)
            .build();

        RestoreTableResponse response =
            keyClient.restoreTable(restoreTableRequest);
        System.out.println("The ARN of the restored table is "+
            response.restoredTableARN());
    } catch (KeyspacesException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

- For API details, see [RestoreTable](https://aws-sdk-java.amazonaws.com/documentation/api-reference) in AWS SDK for Java 2.x API Reference.

Update a table

The following code example shows how to update an Amazon Keyspaces table.
SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```java
public static void updateTable(KeyspacesClient keyClient, String keySpace, String tableName) {
    try {
        ColumnDefinition def = ColumnDefinition.builder()
            .name("watched")
            .type("boolean")
            .build();

        UpdateTableRequest tableRequest = UpdateTableRequest.builder()
            .keyspaceName(keySpace)
            .tableName(tableName)
            .addColumn(def)
            .build();

        keyClient.updateTable(tableRequest);
    } catch (KeyspacesException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

- For API details, see UpdateTable in AWS SDK for Java 2.x API Reference.

Scenarios

Get started with keyspaces and tables

The following code example shows how to:

- Create a keyspace and table. The table schema holds movie data and has point-in-time recovery enabled.
- Connect to the keyspace using a secure TLS connection with SigV4 authentication.
- Query the table. Add, retrieve, and update movie data.
- Update the table. Add a column to track watched movies.
- Restore the table to its previous state and clean up resources.

SDK for Java 2.x

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/aws/aws-sdk-java).

```java
/**
 * Before running this Java (v2) code example, set up your development environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * Before running this Java code example, you must create a Java keystore (JKS) file and place it in your project's resources folder.
 *
 * This file is a secure file format used to hold certificate information for Java applications. This is required to make a connection to Amazon Keyspaces.
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/keyspaces/latest/devguide/using-java-driver.html
 *
 * This Java example performs the following tasks:
 *
 * 1. Create a keyspace.
 * 2. Check for keyspace existence.
 * 3. List keyspaces using a paginator.
 * 4. Create a table with a simple movie data schema and enable point-in-time recovery.
 * 5. Check for the table to be in an Active state.
 * 6. List all tables in the keyspace.
 * 7. Use a Cassandra driver to insert some records into the Movie table.
 */
```
8. Get all records from the Movie table.
9. Get a specific Movie.
10. Get a UTC timestamp for the current time.
11. Update the table schema to add a 'watched' Boolean column.
12. Update an item as watched.
13. Query for items with watched = True.
14. Restore the table back to the previous state using the timestamp.
15. Check for completion of the restore action.
16. Delete the table.
17. Confirm that both tables are deleted.
18. Delete the keyspace.

public class ScenarioKeyspaces {
    public static final String DASHES = new String(new char[80]).replace("\0", "-");

    /*
    * Usage:
    * fileName - The name of the JSON file that contains movie data. (Get this file
    * from the GitHub repo at resources/sample_file.)
    * keyspaceName - The name of the keyspace to create.
    */

Kinesis examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Kinesis.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

**Topics**
- Actions
- Serverless examples

**Actions**

**Create a stream**

The following code example shows how to create a Kinesis stream.
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.kinesis.KinesisClient;
import software.amazon.awssdk.services.kinesis.model.CreateStreamRequest;
import software.amazon.awssdk.services.kinesis.model.KinesisException;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */

public class CreateDataStream {
    public static void main(String[] args) {

        final String usage = """
            Usage:
            <streamName>
            Where:
            streamName - The Amazon Kinesis data stream (for example, StockTradeStream).
        """;

        if (args.length != 1) {
            System.out.println(usage);
            System.exit(1);
        }

        String streamName = args[0];

### Serverless examples

#### Invoke a Lambda function from a Kinesis trigger

The following code example shows how to implement a Lambda function that receives an event triggered by receiving records from a Kinesis stream. The function retrieves the Kinesis payload, decodes from Base64, and logs the record contents.

SDK for Java 2.x

```java
package example;

import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.lambda.runtime.LambdaLogger;
import com.amazonaws.services.lambda.runtime.RequestHandler;
import com.amazonaws.services.lambda.runtime.events.KinesisEvent;

public class Handler implements RequestHandler<KinesisEvent, Void> {

    Kinesis

```

```java
    ```

### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Serverless examples](http://aws.amazon.com/sdk-for-java) repository.

Consuming a Kinesis event with Lambda using Java.

```java
package example;

```
@Override
public Void handleRequest(final KinesisEvent event, final Context context) {
    LambdaLogger logger = context.getLogger();
    if (event.getRecords().isEmpty()) {
        logger.log("Empty Kinesis Event received");
        return null;
    }
    for (KinesisEvent.KinesisEventRecord record : event.getRecords()) {
        try {
            logger.log("Processed Event with EventId: "+record.getEventID());
            String data = new String(record.getKinesis().getData().array());
            logger.log("Data:"+ data);
            // TODO: Do interesting work based on the new data
        }
        catch (Exception ex) {
            logger.log("An error occurred:"+ex.getMessage());
            throw ex;
        }
    }
    logger.log("Successfully processed:"+event.getRecords().size()+" records");
    return null;
}

Reporting batch item failures for Lambda functions with a Kinesis trigger

The following code example shows how to implement partial batch response for Lambda functions that receive events from a Kinesis stream. The function reports the batch item failures in the response, signaling to Lambda to retry those messages later.

SDK for Java 2.x

>Note
There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Reporting Kinesis batch item failures with Lambda using Java.
import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.lambda.runtime.RequestHandler;
import com.amazonaws.services.lambda.runtime.events.KinesisEvent;
import com.amazonaws.services.lambda.runtime.eventsStreamsEventResponse;

import java.io.Serializable;
import java.util.ArrayList;
import java.util.List;

public class ProcessKinesisRecords implements RequestHandler<KinesisEvent,
StreamsEventResponse> {

    @Override
    public StreamsEventResponse handleRequest(KinesisEvent input, Context context) {

        List<StreamsEventResponse.BatchItemFailure> batchItemFailures = new
        ArrayList<>();
        String curRecordSequenceNumber = "";

        for (KinesisEvent.KinesisEventRecord kinesisEventRecord :
        input.getRecords()) {
            try {
                //Process your record
                KinesisEvent.Record kinesisRecord = kinesisEventRecord.getKinesis();
                curRecordSequenceNumber = kinesisRecord.getSequenceNumber();

            } catch (Exception e) {
                /* Since we are working with streams, we can return the failed item
                immediately. */
                Lambda will immediately begin to retry processing from this
                failed item onwards. */
                batchItemFailures.add(new
                StreamsEventResponse.BatchItemFailure(curRecordSequenceNumber));
                return new StreamsEventResponse(batchItemFailures);
            }
        }

        return new StreamsEventResponse(batchItemFailures);
    }
}
AWS KMS examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with AWS KMS.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Create a grant for a key

The following code example shows how to create a grant for a KMS key.

SDK for Java 2.x

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.kms.KmsClient;
import software.amazon.awssdk.services.kms.model.CreateGrantRequest;
import software.amazon.awssdk.services.kms.model.CreateGrantResponse;
import software.amazon.awssdk.services.kms.model.KmsException;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 */
```
public class CreateGrant {
    public static void main(String[] args) {
        final String usage = """;
            Usage:
                <keyId> <granteePrincipal> <operation>\s

            Where:
                keyId - The unique identifier for the customer master key (CMK) that the grant applies to.\s
                granteePrincipal - The principal that is given permission to perform the operations that the grant permits.\s
                operation - An operation (for example, Encrypt).\s
        """;

        if (args.length != 3) {
            System.out.println(usage);
            System.exit(1);
        }

        String keyId = args[0];
        String granteePrincipal = args[1];
        String operation = args[2];
        Region region = Region.US_WEST_2;
        KmsClient kmsClient = KmsClient.builder()
            .region(region)
            .build();

        String grantId = createGrant(kmsClient, keyId, granteePrincipal, operation);
        System.out.printf("Successfully created a grant with ID %s%n", grantId);
        kmsClient.close();
    }

    public static String createGrant(KmsClient kmsClient, String keyId, String granteePrincipal, String operation) {
        try {
            CreateGrantRequest grantRequest = CreateGrantRequest.builder()
                .keyId(keyId)
                .granteePrincipal(granteePrincipal)
Create a key

The following code example shows how to create an AWS KMS key.

SDK for Java 2.x

• For API details, see CreateGrant in AWS SDK for Java 2.x API Reference.

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.kms.KmsClient;
import software.amazon.awssdk.services.kms.model.CreateKeyRequest;
import software.amazon.awssdk.services.kms.model.CustomerMasterKeySpec;
import software.amazon.awssdk.services.kms.model.CreateKeyResponse;
import software.amazon.awssdk.services.kms.model.KmsException;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 */
```

(Note: There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.)

### Create an alias for a key

The following code example shows how to create an alias for a KMS key key.
This code example demonstrates how to create an alias for an AWS KMS key using the AWS SDK for Java 2.x. The example includes a usage message and checks if the correct number of arguments are provided.

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.kms.KmsClient;
import software.amazon.awssdk.services.kms.model.CreateAliasRequest;
import software.amazon.awssdk.services.kms.model.KmsException;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 * For more information, see the following documentation topic:
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class CreateAlias {
    public static void main(String[] args) {

        final String usage = "";
        Usage: 
            <targetKeyId> <aliasName>\n
        Where:
            targetKeyId - The key ID or the Amazon Resource Name (ARN) of the customer master key (CMK).\n            aliasName - An alias name (for example, alias/myAlias).\n        "";

        if (args.length != 2) {
            System.out.println(usage);
            System.exit(1);
        }

        String targetKeyId = args[0];
        String aliasName = args[1];
    }
}
```
Region region = Region.US_WEST_2;
KmsClient kmsClient = KmsClient.builder()
    .region(region)
    .build();

createCustomAlias(kmsClient, targetKeyId, aliasName);
kmsClient.close();
}

public static void createCustomAlias(KmsClient kmsClient, String targetKeyId, String aliasName) {
    try {
        CreateAliasRequest aliasRequest = CreateAliasRequest.builder()
            .aliasName(aliasName)
            .targetKeyId(targetKeyId)
            .build();

        kmsClient.createAlias(aliasRequest);
    } catch (KmsException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}

- For API details, see CreateAlias in AWS SDK for Java 2.x API Reference.

Decrypt ciphertext

The following code example shows how to decrypt ciphertext that was encrypted by a KMS key.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
public static void decryptData(KmsClient kmsClient, SdkBytes encryptedData, String keyId) {
    try {
        DecryptRequest decryptRequest = DecryptRequest.builder()
            .ciphertextBlob(encryptedData)
            .keyId(keyId)
            .build();

        DecryptResponse decryptResponse = kmsClient.decrypt(decryptRequest);
        decryptResponse.plaintext();
    } catch (KmsException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}

• For API details, see Decrypt in AWS SDK for Java 2.x API Reference.

Describe a key

The following code example shows how to describe a KMS key.

SDK for Java 2.x

import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.kms.KmsClient;
import software.amazon.awssdk.services.kms.model.DescribeKeyRequest;
import software.amazon.awssdk.services.kms.model.DescribeKeyResponse;
import software.amazon.awssdk.services.kms.model.KmsException;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 */
public class DescribeKey {
    public static void main(String[] args) {
        final String usage = ""
        
            Usage:
            <keyId>
            
            Where:
            keyId - A key id value to describe (for example, xxxxxxxbcd-12ab-34cd-56ef-1234567890ab)."
        
        if (args.length != 1) {
            System.out.println(usage);
            System.exit(1);
        }
        
        String keyId = args[0];
        Region region = Region.US_WEST_2;
        KmsClient kmsClient = KmsClient.builder()
                .region(region)
                .build();

        describeSpecificKey(kmsClient, keyId);
        kmsClient.close();
    }

    public static void describeSpecificKey(KmsClient kmsClient, String keyId) {
        try {
            DescribeKeyRequest keyRequest = DescribeKeyRequest.builder()
                    .keyId(keyId)
                    .build();

            DescribeKeyResponse response = kmsClient.describeKey(keyRequest);
            System.out.println("The key description is " +
                    response.keyMetadata().description());
            System.out.println("The key ARN is " + response.keyMetadata().arn());
        } catch (KmsException e) {
            
        }
    }
}
System.err.println(e.getMessage());
System.exit(1);
}
}

• For API details, see DescribeKey in AWS SDK for Java 2.x API Reference.

Disable a key

The following code example shows how to disable a KMS key.

SDK for Java 2.x

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.kms.KmsClient;
import software.amazon.awssdk.services.kms.model.DisableKeyRequest;
import software.amazon.awssdk.services.kms.model.KmsException;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 * For more information, see the following documentation topic:
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class DisableCustomerKey {
    public static void main(String[] args) {
        final String usage = ""

        Usage:
        <keyId>\s
```

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
Where:
   keyId - A key id value to disable (for example, xxxxxxxbcd-12ab-34cd-56ef-1234567890ab).

```java
if (args.length != 1) {
    System.out.println(usage);
    System.exit(1);
}

String keyId = args[0];
Region region = Region.US_WEST_2;
KmsClient kmsClient = KmsClient.builder()
    .region(region)
    .build();

disableKey(kmsClient, keyId);
kmsClient.close();
}

public static void disableKey(KmsClient kmsClient, String keyId) {
    try {
        DisableKeyRequest keyRequest = DisableKeyRequest.builder()
            .KeyId(keyId)
            .build();

        kmsClient.disableKey(keyRequest);
    } catch (KmsException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}
```

- For API details, see [DisableKey](https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/aws-java-kms-disable-key.html) in *AWS SDK for Java 2.x API Reference*.

### Enable a key

The following code example shows how to enable a KMS key.
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.kms.KmsClient;
import software.amazon.awssdk.services.kms.model.KmsException;
import software.amazon.awssdk.services.kms.model.EnableKeyRequest;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class EnableCustomerKey {
    public static void main(String[] args) {
        final String usage = ""
        Usage:
            <keyId>
        Where:
            keyId - A key id value to enable (for example,
        xxxxxxxbcd-12ab-34cd-56ef-1234567890ab).
        ""

        if (args.length != 1) {
            System.out.println(usage);
            System.exit(1);
        }

        String keyId = args[0];
        Region region = Region.US_WEST_2;
        KmsClient kmsClient = KmsClient.builder()
            .region(region)
Encrypt text using a key

The following code example shows how to encrypt text using a KMS key.

```
import software.amazon.awssdk.core.SdkBytes;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.kms.KmsClient;
import software.amazon.awssdk.services.kms.model.EncryptRequest;
import software.amazon.awssdk.services.kms.model.EncryptResponse;
import software.amazon.awssdk.services.kms.model.KmsException;
```

For API details, see `EnableKey` in *AWS SDK for Java 2.x API Reference*.
import software.amazon.awssdk.services.kms.model.DecryptRequest;

      List<KeyListEntry> keyListEntries = keysResponse.keys();
      for (KeyListEntry key : keyListEntries) {
         System.out.println("The key ARN is: " + key.keyArn());
         System.out.println("The key Id is: " + key.keyId());
      }
   } catch (KmsException e) {
      System.err.println(e.getMessage());
      System.exit(1);
   }
}

• For API details, see ListKeys in AWS SDK for Java 2.x API Reference.

Lambda examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Lambda.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.
Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Get started

Hello Lambda

The following code examples show how to get started using Lambda.

SDK for Java 2.x

```
package com.example.lambda;

import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.lambda.LambdaClient;
import software.amazon.awssdk.services.lambda.model.LambdaException;
import software.amazon.awssdk.services.lambda.model.ListFunctionsResponse;
import software.amazon.awssdk.services.lambda.model.FunctionConfiguration;
import java.util.List;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 * For more information, see the following documentation topic:
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class ListLambdaFunctions {
    public static void main(String[] args) {
        Region region = Region.US_WEST_2;
        LambdaClient awsLambda = LambdaClient.builder()
            .region(region)
            .build();

        listFunctions(awsLambda);
        awsLambda.close();
    }
}
```

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
public static void listFunctions(LambdaClient awsLambda) {
    try {
        ListFunctionsResponse functionResult = awsLambda.listFunctions();
        List<FunctionConfiguration> list = functionResult.functions();
        for (FunctionConfiguration config : list) {
            System.out.println("The function name is " + config.functionName());
        }
    } catch (LambdaException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}

For API details, see ListFunctions in AWS SDK for Java 2.x API Reference.

Delete a function

The following code example shows how to delete a Lambda function.

SDK for Java 2.x

import software.amazon.awssdk.services.lambda.LambdaClient;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.lambda.model.DeleteFunctionRequest;
import software.amazon.awssdk.services.lambda.model.LambdaException;

/**
* There's more on GitHub. Find the complete example and learn how to set up and run in
the AWS Code Examples Repository.
*/

Lambda
Before running this Java V2 code example, set up your development environment, including your credentials.

For more information, see the following documentation topic:

https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html

```java
public class DeleteFunction {
    public static void main(String[] args) {
        final String usage = ""
            Usage: 
                <functionName>
            Where: 
                functionName - The name of the Lambda function.
            
        if (args.length != 1) {
            System.out.println(usage);
            System.exit(1);
        }

        String functionName = args[0];
        Region region = Region.US_EAST_1;
        LambdaClient awsLambda = LambdaClient.builder()
            .region(region)
            .build();

        deleteLambdaFunction(awsLambda, functionName);
        awsLambda.close();
    }

    public static void deleteLambdaFunction(LambdaClient awsLambda, String functionName) {
        try {
            DeleteFunctionRequest request = DeleteFunctionRequest.builder()
                .functionName(functionName)
                .build();

            awsLambda.deleteFunction(request);
            System.out.println("The " + functionName + " function was deleted");
        } catch (LambdaException e) {
            
        }
    }
}
```
For API details, see [DeleteFunction](https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/aws-sdk-for-java-deletefunction.html) in *AWS SDK for Java 2.x API Reference*.

**Invoke a function**

The following code example shows how to invoke a Lambda function.

**SDK for Java 2.x**

```java
import org.json.JSONObject;
import software.amazon.awssdk.auth.credentials.ProfileCredentialsProvider;
import software.amazon.awssdk.services.lambda.LambdaClient;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.lambda.model.InvokeRequest;
import software.amazon.awssdk.core.SdkBytes;
import software.amazon.awssdk.services.lambda.model.InvokeResponse;
import software.amazon.awssdk.services.lambda.model.LambdaException;

public class LambdaInvoke {

    /*
     * Function names appear as
     * you can retrieve the value by looking at the function in the AWS Console
     * 
     * Also, set up your development environment, including your credentials.
     * 
     * For information, see this documentation topic:
     * 
    */
```
public static void main(String[] args) {
    final String usage = ""

    Usage:
    <functionName>

    Where:
    functionName - The name of the Lambda function
    "";

    if (args.length != 1) {
        System.out.println(usage);
        System.exit(1);
    }

    String functionName = args[0];
    Region region = Region.US_WEST_2;
    LambdaClient awsLambda = LambdaClient.builder()
        .region(region)
        .build();

    invokeFunction(awsLambda, functionName);
    awsLambda.close();
}

public static void invokeFunction(LambdaClient awsLambda, String functionName) {

    InvokeResponse res = null;
    try {
        // Need a SdkBytes instance for the payload.
        JSONObject jsonObj = new JSONObject();
        jsonObj.put("inputValue", "2000");
        String json = jsonObj.toString();
        SdkBytes payload = SdkBytes.fromUtf8String(json);

        // Setup an InvokeRequest.
        InvokeRequest request = InvokeRequest.builder()
            .functionName(functionName)
            .payload(payload)
            .build();
res = awsLambda.invoke(request);
String value = res.payload().asUtf8String();
System.out.println(value);
}

} catch (LambdaException e) {
    System.err.println(e.getMessage());
    System.exit(1);
}

• For API details, see Invoke in AWS SDK for Java 2.x API Reference.

Scenarios

Get started with functions

The following code example shows how to:

• Create an IAM role and Lambda function, then upload handler code.
• Invoke the function with a single parameter and get results.
• Update the function code and configure with an environment variable.
• Invoke the function with new parameters and get results. Display the returned execution log.
• List the functions for your account, then clean up resources.

For more information, see Create a Lambda function with the console.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

**Serverless examples**

**Invoke a Lambda function from a Kinesis trigger**

The following code example shows how to implement a Lambda function that receives an event triggered by receiving records from a Kinesis stream. The function retrieves the Kinesis payload, decodes from Base64, and logs the record contents.
Consuming a Kinesis event with Lambda using Java.

```java
package example;

import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.lambda.runtime.LambdaLogger;
import com.amazonaws.services.lambda.runtime.RequestHandler;
import com.amazonaws.services.lambda.runtime.events.KinesisEvent;

public class Handler implements RequestHandler<KinesisEvent, Void> {
    @Override
    public Void handleRequest(final KinesisEvent event, final Context context) {
        LambdaLogger logger = context.getLogger();
        if (event.getRecords().isEmpty()) {
            logger.log("Empty Kinesis Event received");
            return null;
        }
        for (KinesisEvent.KinesisEventRecord record : event.getRecords()) {
            try {
                logger.log("Processed Event with EventId: "+record.getEventID());
                String data = new String(record.getKinesis().getData().array());
                logger.log("Data:"+ data);
                // TODO: Do interesting work based on the new data
            } catch (Exception ex) {
                logger.log("An error occurred:"+ex.getMessage());
                throw ex;
            }
        }
        logger.log("Successfully processed:"+event.getRecords().size()+" records");
        return null;
    }
}
```
Invoke a Lambda function from an Amazon S3 trigger

The following code example shows how to implement a Lambda function that receives an event triggered by uploading an object to an S3 bucket. The function retrieves the S3 bucket name and object key from the event parameter and calls the Amazon S3 API to retrieve and log the content type of the object.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Consuming an S3 event with Lambda using Java.

```java
package example;

import software.amazon.awssdk.services.s3.model.HeadObjectRequest;
import software.amazon.awssdk.services.s3.model.HeadObjectResponse;
import software.amazon.awssdk.services.s3.S3Client;
import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.lambda.runtime.RequestHandler;
import com.amazonaws.services.lambda.runtime.events.S3Event;
import com.amazonaws.services.lambda.runtime.events.models.s3.S3EventNotification.S3EventNotificationRecord;
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;

public class Handler implements RequestHandler<S3Event, String> {
    private static final Logger logger = LoggerFactory.getLogger(Handler.class);

    @Override
    public String handleRequest(S3Event s3event, Context context) {
        try {
            S3EventNotificationRecord record = s3event.getRecords().get(0);
            String srcBucket = record.getS3().getBucket().getName();
            String srcObjectKey = record.getS3().getObject().getKey();

            S3Client s3Client = S3Client.builder().build();
            HeadObjectRequest headObjectRequest = HeadObjectRequest.builder().bucket(srcBucket).key(srcObjectKey).build();
            HeadObjectResponse headObjectResponse = s3Client.headObject(headObjectRequest);
            String contentType = headObjectResponse.getContentType();

            logger.info("Content type from S3: ", contentType);
            // Log the object content type
        } catch (Exception e) {
            logger.error("Error getting S3 object content type: ", e.getMessage());
        }
        return "Hello, World!";
    }
}
```
String srcKey = record.getS3().getObject().getUrlDecodedKey();

S3Client s3Client = S3Client.builder().build();
HeadObjectResponse headObject = getHeadObject(s3Client, srcBucket, srcKey);

logger.info("Successfully retrieved " + srcBucket + "/" + srcKey + " of type " + headObject.contentType());

return "Ok";
} catch (Exception e) {
    throw new RuntimeException(e);
}

private HeadObjectResponse getHeadObject(S3Client s3Client, String bucket, String key) {
    HeadObjectRequest headObjectRequest = HeadObjectRequest.builder()
        .bucket(bucket)
        .key(key)
        .build();
    return s3Client.headObject(headObjectRequest);
}

Invoke a Lambda function from an Amazon SNS trigger

The following code example shows how to implement a Lambda function that receives an event triggered by receiving messages from an SNS topic. The function retrieves the messages from the event parameter and logs the content of each message.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Consuming an SNS event with Lambda using Java.
package example;

import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.lambda.runtime.LambdaLogger;
import com.amazonaws.services.lambda.runtime.RequestHandler;
import com.amazonaws.services.lambda.runtime.events.SNSEvent;
import com.amazonaws.services.lambda.runtime.events.SNSEvent.SNSRecord;

import java.util.Iterator;
import java.util.List;

public class SNSEventHandler implements RequestHandler<SNSEvent, Boolean> {
    LambdaLogger logger;

    @Override
    public Boolean handleRequest(SNSEvent event, Context context) {
        logger = context.getLogger();
        List<SNSRecord> records = event.getRecords();
        if (!records.isEmpty()) {
            Iterator<SNSRecord> recordsIter = records.iterator();
            while (recordsIter.hasNext()) {
                processRecord(recordsIter.next());
            }
        }
        return Boolean.TRUE;
    }

    public void processRecord(SNSRecord record) {
        try {
            String message = record.getSNS().getMessage();
            logger.log("message: " + message);
        } catch (Exception e) {
            throw new RuntimeException(e);
        }
    }
}

Invoke a Lambda function from an Amazon SQS trigger

The following code example shows how to implement a Lambda function that receives an event triggered by receiving messages from an SQS queue. The function retrieves the messages from the event parameter and logs the content of each message.

SDK for Java 2.x

### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Serverless examples](https://github.com/aws-samples/serverless-examples) repository.

Consuming an SQS event with Lambda using Java.

```java
import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.lambda.runtime.RequestHandler;
import com.amazonaws.services.lambda.runtime.events.SQSEvent;
import com.amazonaws.services.lambda.runtime.events.SQSEvent.SQSMessage;

public class Function implements RequestHandler<SQSEvent, Void> {
    @Override
    public Void handleRequest(SQSEvent sqsEvent, Context context) {
        for (SQSMessage msg : sqsEvent.getRecords()) {
            processMessage(msg, context);
        }
        context.getLogger().log("done");
        return null;
    }

    private void processMessage(SQSEvent msg, Context context) {
        try {
            context.getLogger().log("Processed message "+ msg.getBody());
        } catch (Exception e) {
            context.getLogger().log("An error occurred");
            throw e;
        }
    }
```
Reporting batch item failures for Lambda functions with a Kinesis trigger

The following code example shows how to implement partial batch response for Lambda functions that receive events from a Kinesis stream. The function reports the batch item failures in the response, signaling to Lambda to retry those messages later.

SDK for Java 2.x

```java
import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.lambda.runtime.RequestHandler;
import com.amazonaws.services.lambda.runtime.events.KinesisEvent;
import com.amazonaws.services.lambda.runtime.events.StreamsEventResponse;

import java.io.Serializable;
import java.util.ArrayList;
import java.util.List;

public class ProcessKinesisRecords implements RequestHandler<KinesisEvent, StreamsEventResponse> {
    @Override
    public StreamsEventResponse handleRequest(KinesisEvent input, Context context) {
        List<StreamsEventResponse.BatchItemFailure> batchItemFailures = new ArrayList<>();
        String curRecordSequenceNumber = "";
        for (KinesisEvent.KinesisEventRecord kinesisEventRecord : input.getRecords()) {
            try {
                // Process the record...
            } catch (Exception e) {
                batchItemFailures.add(new StreamsEventResponse.BatchItemFailure(
                    kinesisEventRecord.getSequenceNumber(),
                    kinesisEventRecord.getMessageId(),
                    curRecordSequenceNumber));
                curRecordSequenceNumber = kinesisEventRecord.getSequenceNumber();
            }
        }

        // Return the response with batch item failures...
    }
}
```

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Serverless examples](#) repository.

Reporting Kinesis batch item failures with Lambda using Java.

```java
import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.lambda.runtime.RequestHandler;
import com.amazonaws.services.lambda.runtime.events.KinesisEvent;
import com.amazonaws.services.lambda.runtime.events.StreamsEventResponse;

import java.io.Serializable;
import java.util.ArrayList;
import java.util.List;

public class ProcessKinesisRecords implements RequestHandler<KinesisEvent, StreamsEventResponse> {
    @Override
    public StreamsEventResponse handleRequest(KinesisEvent input, Context context) {
        List<StreamsEventResponse.BatchItemFailure> batchItemFailures = new ArrayList<>();
        String curRecordSequenceNumber = "";
        for (KinesisEvent.KinesisEventRecord kinesisEventRecord : input.getRecords()) {
            try {
                // Process the record...
            } catch (Exception e) {
                batchItemFailures.add(new StreamsEventResponse.BatchItemFailure(
                    kinesisEventRecord.getSequenceNumber(),
                    kinesisEventRecord.getMessageId(),
                    curRecordSequenceNumber));
                curRecordSequenceNumber = kinesisEventRecord.getSequenceNumber();
            }
        }

        // Return the response with batch item failures...
    }
```
//Process your record
KinesisEvent.Record kinesisRecord = kinesisEventRecord.getKinesis();
curRecordSequenceNumber = kinesisRecord.getSequenceNumber();

} catch (Exception e) {
    /* Since we are working with streams, we can return the failed item immediately. Lambda will immediately begin to retry processing from this failed item onwards. */
    batchItemFailures.add(new StreamsEventResponse.BatchItemFailure(curRecordSequenceNumber));
    return new StreamsEventResponse(batchItemFailures);
}

return new StreamsEventResponse(batchItemFailures);

Reporting batch item failures for Lambda functions with an Amazon SQS trigger

The following code example shows how to implement partial batch response for Lambda functions that receive events from an SQS queue. The function reports the batch item failures in the response, signaling to Lambda to retry those messages later.

SDK for Java 2.x

Note

Reporting SQS batch item failures with Lambda using Java.

```java
import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.lambda.runtime.RequestHandler;
import com.amazonaws.services.lambda.runtime.events.SQSEvent;
import com.amazonaws.services.lambda.runtime.events.SQSBatchResponse;
```
import java.util.ArrayList;
import java.util.List;

public class ProcessSQSMessageBatch implements RequestHandler<SQSEvent, SQSBatchResponse> {
    @Override
    public SQSBatchResponse handleRequest(SQSEvent sqsEvent, Context context) {
        List<SQSBatchResponse.BatchItemFailure> batchItemFailures = new ArrayList<SQSBatchResponse.BatchItemFailure>();
        String messageId = "";
        for (SQSEvent.SQSMessage message : sqsEvent.getRecords()) {
            try {
                //process your message
                messageId = message.getMessageId();
            } catch (Exception e) {
                //Add failed message identifier to the batchItemFailures list
                batchItemFailures.add(new SQSBatchResponse.BatchItemFailure(messageId));
            }
        }
        return new SQSBatchResponse(batchItemFailures);
    }
}

MediaConvert examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with MediaConvert.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

    .build();

listCompleteJobs(mc);
mc.close();
}

class MediaConvert {
    // Constructor
}

Migration Hub examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Migration Hub.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

        migrationClient.close();
    }

    public static void deleteStream(MigrationHubClient migrationClient, String streamName) {
        try {
            DeleteProgressUpdateStreamRequest deleteProgressUpdateStreamRequest =
                DeleteProgressUpdateStreamRequest.builder()

migrationClient.deleteProgressUpdateStream(deleteProgressUpdateStreamRequest);
    System.out.println(streamName + " is deleted");

} catch (MigrationHubException e) {
    System.out.println(e.getMessage());
    System.exit(1);
}
}

• For API details, see DeleteProgressUpdateStream in AWS SDK for Java 2.x API Reference.

Describe migration status

The following code example shows how to describe migration status.

SDK for Java 2.x

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.migrationhub.MigrationHubClient;
import software.amazon.awssdk.services.migrationhub.model.DescribeApplicationStateRequest;
import software.amazon.awssdk.services.migrationhub.model.DescribeApplicationStateResponse;
import software.amazon.awssdk.services.migrationhub.model.MigrationHubException;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 * *
 * For more information, see the following documentation topic:
 */
```
public class DescribeAppState {
    public static void main(String[] args) {
        final String usage = ""

        Usage:
            DescribeAppState <appId>

        Where:
            appId - the application id value.
"

        if (args.length != 1) {
            System.out.println(usage);
            System.exit(1);
        }

        String appId = args[0];
        Region region = Region.US_WEST_2;
        MigrationHubClient migrationClient = MigrationHubClient.builder()
            .region(region)
            .build();

        describeApplicationState(migrationClient, appId);
        migrationClient.close();
    }

    public static void describeApplicationState(MigrationHubClient migrationClient,
        String appId) {
        try {
            DescribeApplicationStateRequest applicationStateRequest =
                DescribeApplicationStateRequest.builder()
                    .applicationId(appId)
                    .build();

            DescribeApplicationStateResponse applicationStateResponse =
                migrationClient
e            .describeApplicationState(applicationStateRequest);
            System.out.println("The application status is " +
                applicationStateResponse.applicationStatusAsString());
        } catch (MigrationHubException e) {

Get list of attributes associated with a migration

The following code example shows how to get list of attributes that are associated with a migration.

**SDK for Java 2.x**

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.migrationhub.MigrationHubClient;
import software.amazon.awssdk.services.migrationhub.model.DescribeMigrationTaskRequest;
import software.amazon.awssdk.services.migrationhub.model.DescribeMigrationTaskResponse;
import software.amazon.awssdk.services.migrationhub.model.MigrationHubException;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 * For more information, see the following documentation topic:
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class DescribeMigrationTask {

    public static void main(String[] args) {
        final String usage = ""
```
Usage:
    DescribeMigrationTask <migrationTask> <progressStream>\n
Where:
    migrationTask - the name of a migration task.\n    progressStream - the name of a progress stream.\n
if (args.length < 2) {
    System.out.println(usage);
    System.exit(1);
}

String migrationTask = args[0];
String progressStream = args[1];
Region region = Region.US_WEST_2;
MigrationHubClient migrationClient = MigrationHubClient.builder()
    .region(region)
    .build();

describeMigTask(migrationClient, migrationTask, progressStream);
migrationClient.close();

public static void describeMigTask(MigrationHubClient migrationClient, String migrationTask,
    String progressStream) {
try {
    DescribeMigrationTaskRequest migrationTaskRequestRequest =
        DescribeMigrationTaskRequest.builder()
            .progressUpdateStream(progressStream)
            .migrationTaskName(migrationTask)
            .build();

    DescribeMigrationTaskResponse migrationTaskResponse = migrationClient
        .describeMigrationTask(migrationTaskRequestRequest);
    System.out.println("The name is " +
        migrationTaskResponse.migrationTask().migrationTaskName());
} catch (MigrationHubException e) {
    System.out.println(e.getMessage());
    System.exit(1);
}
For API details, see `DescribeMigrationTask` in *AWS SDK for Java 2.x API Reference*.

### List applications

The following code example shows how to list applications.

**SDK for Java 2.x**

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.migrationhub.MigrationHubClient;
import software.amazon.awssdk.services.migrationhub.model.ApplicationState;
import software.amazon.awssdk.services.migrationhub.model.ListApplicationStatesRequest;
import software.amazon.awssdk.services.migrationhub.model.ListApplicationStatesResponse;
import software.amazon.awssdk.services.migrationhub.model.MigrationHubException;
import java.util.List;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 * For more information, see the following documentation topic:
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class ListApplications {
    public static void main(String[] args) {
        Region region = Region.US_WEST_2;
        MigrationHubClient migrationClient = MigrationHubClient.builder()
            .region(region)
            .build();
```
```java
public static void listApps(MigrationHubClient migrationClient) {
    try {
        ListApplicationStatesRequest applicationStatesRequest = 
            ListApplicationStatesRequest.builder()
                .maxResults(10)
                .build();

        ListApplicationStatesResponse response = 
            migrationClient.listApplicationStates(applicationStatesRequest);
        List<ApplicationState> apps = response.applicationStateList();
        for (ApplicationState appState : apps) {
            System.out.println("App Id is " + appState.applicationId());
            System.out.println("The status is " + 
                appState.applicationStatus().toString());
        }
    } catch (MigrationHubException e) {
        System.out.println(e.getMessage());
        System.exit(1);
    }
}
```

- For API details, see ListApplications in AWS SDK for Java 2.x API Reference.

**List created artifacts**

Amazon Personalize examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon Personalize.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

• Actions

Actions

Create a batch interface job

The following code example shows how to create a Amazon Personalize batch interface job.

SDK for Java 2.x

```
public static String createPersonalizeBatchInferenceJob(PersonalizeClient personalizeClient,
    String solutionVersionArn,
    String jobName,
    String s3InputDataSourcePath,
    String s3DataDestinationPath,
    String roleArn,
    String explorationWeight,
    String explorationItemAgeCutOff) {
```

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/aws-samples/aws-code-examples).
long waitInMilliseconds = 60 * 1000;
String status;
String batchInferenceJobArn;

try {

    // Set up data input and output parameters.
    S3DataConfig inputSource = S3DataConfig.builder()
        .path(s3InputDataSourcePath)
        .build();

    S3DataConfig outputDestination = S3DataConfig.builder()
        .path(s3DataDestinationPath)
        .build();

    BatchInferenceJobInput jobInput =
        BatchInferenceJobInput.builder()
        .s3DataSource(inputSource)
        .build();

    BatchInferenceJobOutput jobOutputLocation =
        BatchInferenceJobOutput.builder()
        .s3DataDestination(outputDestination)
        .build();

    // Optional code to build the User-Personalization specific
    // config.
    HashMap<String, String> explorationConfig = new HashMap<>();
    explorationConfig.put("explorationWeight",
        explorationWeight);
    explorationConfig.put("explorationItemAgeCutOff",
        explorationItemAgeCutOff);

    BatchInferenceJobConfig jobConfig =
        BatchInferenceJobConfig.builder()
        .itemExplorationConfig(explorationConfig)
        .build();

    // End optional User-Personalization recipe specific code.
CreateBatchInferenceJobRequest
createBatchInferenceJobRequest = CreateBatchInferenceJobRequest
    .builder()
    .solutionVersionArn(solutionVersionArn)
    .jobInput(jobInput)
    .jobOutput(jobOutputLocation)
    .jobName(jobName)
    .roleArn(roleArn)
    .batchInferenceJobConfig(jobConfig) // Optional
    .build();

batchInferenceJobArn = personalizeClient.createBatchInferenceJob(createBatchInferenceJobRequest)
    .batchInferenceJobArn();

DescribeBatchInferenceJobRequest
describeBatchInferenceJobRequest = DescribeBatchInferenceJobRequest
    .builder()
    .batchInferenceJobArn(batchInferenceJobArn)
    .build();

long maxTime = Instant.now().getEpochSecond() + 3 * 60 * 60;
while (Instant.now().getEpochSecond() < maxTime) {
    BatchInferenceJob batchInferenceJob = personalizeClient
        .describeBatchInferenceJob(describeBatchInferenceJobRequest)
        .batchInferenceJob();

    status = batchInferenceJob.status();
    System.out.println("Batch inference job status: " + status);

    if (status.equals("ACTIVE") || status.equals("CREATE FAILED")) {
        break;
    }
    try {
        Thread.sleep(waitInMilliseconds);
    } catch (InterruptedException e) {
        System.out.println(e.getMessage());
    }
}
return batchInferenceJobArn;

} catch (PersonalizeException e) {
    System.out.println(e.awsErrorDetails().errorMessage());
}
return "";

• For API details, see CreateBatchInferenceJob in AWS SDK for Java 2.x API Reference.

Create a campaign

The following code example shows how to create a Amazon Personalize campaign.

SDK for Java 2.x

public static void createPersonalCampaign(PersonalizeClient personalizeClient,
    String solutionVersionArn,
    String name) {

    try {
        CreateCampaignRequest createCampaignRequest =
            CreateCampaignRequest.builder()
                .minProvisionedTPS(1)
                .solutionVersionArn(solutionVersionArn)
                .name(name)
                .build();

        CreateCampaignResponse campaignResponse =
            personalizeClient.createCampaign(createCampaignRequest);
        System.out.println("The campaign ARN is " +
            campaignResponse.campaignArn());

}
For API details, see [CreateCampaign](#) in *AWS SDK for Java 2.x API Reference*.

### Create a dataset

The following code example shows how to create a Amazon Personalize dataset.

#### SDK for Java 2.x

```java
public static String createDataset(PersonalizeClient personalizeClient,
                                    String datasetName,
                                    String datasetGroupArn,
                                    String datasetType,
                                    String schemaArn) {
    try {
        CreateDatasetRequest request = CreateDatasetRequest.builder()
            .name(datasetName)
            .datasetGroupArn(datasetGroupArn)
            .datasetType(datasetType)
            .schemaArn(schemaArn)
            .build();

        String datasetArn = personalizeClient.createDataset(request)
            .datasetArn();
        System.out.println("Dataset " + datasetName + " created.");
        return datasetArn;
    } catch (PersonalizeException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
    }
}
```

---

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).
System.exit(1);
} return "";
}

- For API details, see CreateDataset in AWS SDK for Java 2.x API Reference.

Create a dataset export job

The following code example shows how to create a Amazon Personalize dataset export job.

SDK for Java 2.x

```java
public static String createDatasetExportJob(PersonalizeClient personalizeClient,
                              String jobName,
                              String datasetArn,
                              IngestionMode ingestionMode,
                              String roleArn,
                              String s3BucketPath,
                              String kmsKeyArn) {

    long waitInMilliseconds = 30 * 1000; // 30 seconds
    String status = null;

    try {

        S3DataConfig exportS3DataConfig =
        S3DataConfig.builder().path(s3BucketPath).kmsKeyArn(kmsKeyArn).build();
        DatasetExportJobOutput jobOutput =
        DatasetExportJobOutput.builder().s3DataDestination(exportS3DataConfig)
        .build();

        CreateDatasetExportJobRequest createRequest =
        CreateDatasetExportJobRequest.builder()
```
String datasetExportJobArn = personalizeClient.createDatasetExportJob(createRequest).datasetExportJobArn();

DescribeDatasetExportJobRequest describeDatasetExportJobRequest = DescribeDatasetExportJobRequest.builder()
    .datasetExportJobArn(datasetExportJobArn)
    .build();

long maxTime = Instant.now().getEpochSecond() + 3 * 60 * 60;

while (Instant.now().getEpochSecond() < maxTime) {
    DatasetExportJob datasetExportJob = personalizeClient
        .describeDatasetExportJob(describeDatasetExportJobRequest)
        .datasetExportJob();

    status = datasetExportJob.status();
    System.out.println("Export job status: " + status);

    if (status.equals("ACTIVE") || status.equals("CREATE FAILED")) {
        return status;
    }
    try {
        Thread.sleep(waitInMilliseconds);
    } catch (InterruptedException e) {
        System.out.println(e.getMessage());
    }
}
}
}
}

return "";
}
Create a dataset group

The following code example shows how to create a Amazon Personalize dataset group.

SDK for Java 2.x

```java
public static String createDatasetGroup(PersonalizeClient personalizeClient,
        String datasetGroupName) {
    try {
        CreateDatasetGroupRequest createDatasetGroupRequest =
            CreateDatasetGroupRequest.builder()
                .name(datasetGroupName)
                .build();
        return
            personalizeClient.createDatasetGroup(createDatasetGroupRequest).datasetGroupArn();
    } catch (PersonalizeException e) {
        System.out.println(e.awsErrorDetails().errorMessage());
    }
    return "";
}
```

Create a domain dataset group.

```java
public static String createDomainDatasetGroup(PersonalizeClient personalizeClient,
        String datasetGroupName, String domain) {
    try {
        CreateDatasetGroupRequest createDatasetGroupRequest =
            CreateDatasetGroupRequest.builder()
                .name(datasetGroupName)
                .domain(domain)
                .build();
    ```
Create a dataset import job

The following code example shows how to create a Amazon Personalize dataset import job.

**SDK for Java 2.x**

```java
public static String createPersonalizeDatasetImportJob(PersonalizeClient personalizeClient,
        String jobName,
        String datasetArn,
        String s3BucketPath,
        String roleArn) {

    long waitInMilliseconds = 60 * 1000;
    String status;
    String datasetImportJobArn;

    try {
        DataSource importDataSource = DataSource.builder()
                .dataLocation(s3BucketPath)
                .build();

        CreateDatasetImportJobRequest createDatasetImportJobRequest =
                CreateDatasetImportJobRequest.builder()
"}

```
```java
.datasetArn(datasetArn)
.dataSource(importDataSource)
.jobName(jobName)
.roleArn(roleArn)
.build();

datasetImportJobArn = personalizeClient.createDatasetImportJob(createDatasetImportJobRequest)
    .datasetImportJobArn();
DescribeDatasetImportJobRequest describeDatasetImportJobRequest = DescribeDatasetImportJobRequest.builder()
    .datasetImportJobArn(datasetImportJobArn)
    .build();

long maxTime = Instant.now().getEpochSecond() + 3 * 60 * 60;

while (Instant.now().getEpochSecond() < maxTime) {
    DatasetImportJob datasetImportJob = personalizeClient
        .describeDatasetImportJob(describeDatasetImportJobRequest)
        .datasetImportJob();

    status = datasetImportJob.status();
    System.out.println("Dataset import job status: " + status);

    if (status.equals("ACTIVE") || status.equals("CREATE FAILED")) {
        break;
    }
    try {
        Thread.sleep(waitInMilliseconds);
    } catch (InterruptedException e) {
        System.out.println(e.getMessage());
    }
}
return datasetImportJobArn;
}
```

- For API details, see [CreateDatasetImportJob](#) in *AWS SDK for Java 2.x API Reference.*
Create a domain schema

The following code example shows how to create a Amazon Personalize domain schema.

SDK for Java 2.x

```java
public static String createDomainSchema(PersonalizeClient personalizeClient,
String schemaName, String domain,
String filePath) {

String schema = null;
try {
    schema = new String(Files.readAllBytes(Paths.get(filePath)));
} catch (IOException e) {
    System.out.println(e.getMessage());
}

try {
    CreateSchemaRequest createSchemaRequest = CreateSchemaRequest.builder()
        .name(schemaName)
        .domain(domain)
        .schema(schema)
        .build();

    String schemaArn = personalizeClient.createSchema(createSchemaRequest).schemaArn();

    System.out.println("Schema arn: " + schemaArn);

    return schemaArn;
} catch (PersonalizeException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

return "";
}
```

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
Create a filter

The following code example shows how to create a Amazon Personalize filter.

SDK for Java 2.x

```java
public static String createFilter(PersonalizeClient personalizeClient,
                 String filterName,
                 String datasetGroupArn,
                 String filterExpression) {
  try {
    CreateFilterRequest request = CreateFilterRequest.builder()
      .name(filterName)
      .datasetGroupArn(datasetGroupArn)
      .filterExpression(filterExpression)
      .build();

    return personalizeClient.createFilter(request).filterArn();
  } catch (PersonalizeException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
  }
  return "";
}
```

Create a recommender

The following code example shows how to create a Amazon Personalize recommender.

• For API details, see CreateFilter in AWS SDK for Java 2.x API Reference.
public static String createRecommender(PersonalizeClient personalizeClient,
        String name,
        String datasetGroupArn,
        String recipeArn) {

    long maxTime = 0;
    long waitInMilliseconds = 30 * 1000; // 30 seconds
    String recommenderStatus = "";

    try {
        CreateRecommenderRequest createRecommenderRequest = CreateRecommenderRequest.builder()
            .datasetGroupArn(datasetGroupArn)
            .name(name)
            .recipeArn(recipeArn)
            .build();

        CreateRecommenderResponse recommenderResponse = personalizeClient
            .createRecommender(createRecommenderRequest);
        String recommenderArn = recommenderResponse.recommenderArn();
        System.out.println("The recommender ARN is " + recommenderArn);

        DescribeRecommenderRequest describeRecommenderRequest = DescribeRecommenderRequest.builder()
            .recommenderArn(recommenderArn)
            .build();

        maxTime = Instant.now().getEpochSecond() + 3 * 60 * 60;

        while (Instant.now().getEpochSecond() < maxTime) {
            recommenderStatus = personalizeClient.describeRecommender(describeRecommenderRequest).recommender()
                .status();
        }
    } catch (Exception e) {
        String message = String.format("Exception: %s", e.getMessage());
        System.out.println(message);
    }

    return recommenderArn;
}
System.out.println("Recommender status: " + recommenderStatus);

if (recommenderStatus.equals("ACTIVE") ||
    recommenderStatus.equals("CREATE FAILED")) {
    break;
}
try {
    Thread.sleep(waitInMilliseconds);
} catch (InterruptedException e) {
    System.out.println(e.getMessage());
}
return recommenderArn;

} catch (PersonalizeException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
} return "";

• For API details, see CreateRecommender in AWS SDK for Java 2.x API Reference.

Create a schema

The following code example shows how to create a Amazon Personalize schema.

SDK for Java 2.x

public static String createSchema(PersonalizeClient personalizeClient, String schemaName, String filePath) {
    String schema = null;
    try {
        schema = new String(Files.readAllBytes(Paths.get(filePath)));
        personalizeClient.createSchema(schemaName, schema);
    } catch (ApiException e) {
        System.out.println(e.getMessage());
        return "";
    }
    return schema;
}
```java
try {
    CreateSchemaRequest createSchemaRequest = CreateSchemaRequest.builder()
        .name(schemaName)
        .schema(schema)
        .build();

    String schemaArn = personalizeClient.createSchema(createSchemaRequest).schemaArn();

    System.out.println("Schema arn: " + schemaArn);

    return schemaArn;
} catch (PersonalizeException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
} return ";
```

- For API details, see [CreateSchema](https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/aws-java-sdk-error-location.html) in *AWS SDK for Java 2.x API Reference*.

**Create a solution**

The following code example shows how to create a Amazon Personalize solution.

**SDK for Java 2.x**

```java
public static String createPersonalizeSolution(PersonalizeClient personalizeClient,
                                               String datasetGroupArn,
```
public static String createPersonalizeSolutionVersion(PersonalizeClient personalizeClient, String solutionArn) {
    long maxTime = 0;
    long waitInMilliseconds = 30 * 1000; // 30 seconds
    String solutionStatus = "";
    String solutionVersionStatus = "";

    try {
        CreateSolutionRequest solutionRequest = CreateSolutionRequest.builder()
            .name(solutionName)
            .datasetGroupArn(datasetGroupArn)
            .recipeArn(recipeArn)
            .build();

        CreateSolutionResponse solutionResponse = personalizeClient.createSolution(solutionRequest);
        return solutionResponse.solutionArn();
    }
    catch (PersonalizeException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
    return "";
}

- For API details, see [CreateSolution](https://aws.amazon.com) in [AWS SDK for Java 2.x API Reference](https://aws.amazon.com).

**Create a solution version**

The following code example shows how to create a Amazon Personalize solution.

**SDK for Java 2.x**

> Note
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://aws.amazon.com).
String solutionVersionArn = "";

try {
    DescribeSolutionRequest describeSolutionRequest =
    DescribeSolutionRequest.builder()
        .solutionArn(solutionArn)
        .build();

    maxTime = Instant.now().getEpochSecond() + 3 * 60 * 60;

    // Wait until solution is active.
    while (Instant.now().getEpochSecond() < maxTime) {

        solutionStatus =
        personalizeClient.describeSolution(describeSolutionRequest).solution().status();
        System.out.println("Solution status: " + solutionStatus);

        if (solutionStatus.equals("ACTIVE") || solutionStatus.equals("CREATE FAILED")) {
            break;
        }
        try {
            Thread.sleep(waitInMilliseconds);
        } catch (InterruptedException e) {
            System.out.println(e.getMessage());
        }
    }

    if (solutionStatus.equals("ACTIVE")) {

        CreateSolutionVersionRequest createSolutionVersionRequest =
        CreateSolutionVersionRequest.builder()
            .solutionArn(solutionArn)
            .build();

        CreateSolutionVersionResponse createSolutionVersionResponse =
        personalizeClient
            .createSolutionVersion(createSolutionVersionRequest);

        solutionVersionArn =
        createSolutionVersionResponse.solutionVersionArn();

        System.out.println("Solution version ARN: " + solutionVersionArn);
    }
}
```java
DescribeSolutionVersionRequest describeSolutionVersionRequest =
    DescribeSolutionVersionRequest.builder()
    .solutionVersionArn(solutionVersionArn)
    .build();

while (Instant.now().getEpochSecond() < maxTime) {
    solutionVersionStatus =
        personalizeClient.describeSolutionVersion(describeSolutionVersionRequest)
            .solutionVersion().status();
    System.out.println("Solution version status: " +
        solutionVersionStatus);

    if (solutionVersionStatus.equals("ACTIVE") ||
            solutionVersionStatus.equals("CREATE FAILED")) {
        break;
    }
    try {
        Thread.sleep(waitInMilliseconds);
    } catch (InterruptedException e) {
        System.out.println(e.getMessage());
    }
}
return solutionVersionArn;
}
```

For API details, see [CreateSolutionVersion](#) in *[AWS SDK for Java 2.x API Reference](#)*.

### Create an event tracker

The following code example shows how to create a Amazon Personalize event tracker.
Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```java
public static String createEventTracker(PersonalizeClient personalizeClient,
                                      String eventTrackerName,
                                      String datasetGroupArn) {

    String eventTrackerId = "";
    String eventTrackerArn;
    long maxTime = 3 * 60 * 60; // 3 hours
    long waitInMilliseconds = 20 * 1000; // 20 seconds
    String status;
    
    try {

        CreateEventTrackerRequest createEventTrackerRequest =
            CreateEventTrackerRequest.builder()
                .name(eventTrackerName)
                .datasetGroupArn(datasetGroupArn)
                .build();

        CreateEventTrackerResponse createEventTrackerResponse =
            personalizeClient
                .createEventTracker(createEventTrackerRequest);

        eventTrackerArn = createEventTrackerResponse.eventTrackerArn();
        eventTrackerId = createEventTrackerResponse.trackingId();
        System.out.println("Event tracker ARN: " + eventTrackerArn);
        System.out.println("Event tracker ID: " + eventTrackerId);

        maxTime = Instant.now().getEpochSecond() + maxTime;

        DescribeEventTrackerRequest describeRequest =
            DescribeEventTrackerRequest.builder()
                .eventTrackerArn(eventTrackerArn)
                .build();

```
while (Instant.now().getEpochSecond() < maxTime) {

    status = personalizeClient.describeEventTracker(describeRequest).eventTracker().status();
    System.out.println("EventTracker status: "+ status);

    if (status.equals("ACTIVE") || status.equals("CREATE FAILED")) {
        break;
    }
    try {
        Thread.sleep(waitInMilliseconds);
    } catch (InterruptedException e) {
        System.out.println(e.getMessage());
    }
    return eventTrackerId;
} catch (PersonalizeException e) {
    System.out.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
return eventTrackerId;
}

• For API details, see CreateEventTracker in AWS SDK for Java 2.x API Reference.

Delete a campaign

The following code example shows how to delete a campaign in Amazon Personalize.

SDK for Java 2.x

public static void deleteSpecificCampaign(PersonalizeClient personalizeClient, String campaignArn) {

    System.out.println("Deleting campaign: "+ campaignArn);
    personalizeClient.deleteCampaign(deleteRequest);
    System.out.println("Campaign deleted");

    System.out.println("Exiting");
    System.exit(0);
}
try {
    DeleteCampaignRequest campaignRequest = DeleteCampaignRequest.builder()
        .campaignArn(campaignArn)
        .build();

    personalizeClient.deleteCampaign(campaignRequest);
}

} catch (PersonalizeException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

- For API details, see [DeleteCampaign](#) in [AWS SDK for Java 2.x API Reference](#).

### Delete a solution

The following code example shows how to delete a solution in Amazon Personalize.

**SDK for Java 2.x**

```java
public static void deleteGivenSolution(PersonalizeClient personalizeClient, String solutionArn) {
    try {
        DeleteSolutionRequest solutionRequest = DeleteSolutionRequest.builder()
            .solutionArn(solutionArn)
            .build();

        personalizeClient.deleteSolution(solutionRequest);
        System.out.println("Done");
    } catch (PersonalizeException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
    }
}
```

- For API details, see [DeleteSolution](#) in [AWS SDK for Java 2.x API Reference](#).

---

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).
Delete an event tracker

The following code example shows how to delete an event tracker in Amazon Personalize.

**SDK for Java 2.x**

```java
public static void deleteEventTracker(PersonalizeClient personalizeClient, String eventTrackerArn) {
    try {
        DeleteEventTrackerRequest deleteEventTrackerRequest =
            DeleteEventTrackerRequest.builder()
                .eventTrackerArn(eventTrackerArn)
                .build();

        int status =
            personalizeClient.deleteEventTracker(deleteEventTrackerRequest).sdkHttpResponse().statusCode();

        System.out.println("Status code:" + status);
    } catch (PersonalizeException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

• For API details, see [DeleteEventTracker](#) in **AWS SDK for Java 2.x API Reference**.

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).
Describe a campaign

The following code example shows how to describe a campaign in Amazon Personalize.

SDK for Java 2.x

```java
    public static void describeSpecificCampaign(PersonalizeClient personalizeClient, String campaignArn) {
        try {
            DescribeCampaignRequest campaignRequest =
            DescribeCampaignRequest.builder()
                .campaignArn(campaignArn)
                .build();

            DescribeCampaignResponse campaignResponse =
            personalizeClient.describeCampaign(campaignRequest);
            Campaign myCampaign = campaignResponse.campaign();
            System.out.println("The Campaign name is " + myCampaign.name());
            System.out.println("The Campaign status is " + myCampaign.status());
        } catch (PersonalizeException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
```

- For API details, see DescribeCampaign in AWS SDK for Java 2.x API Reference.

Describe a recipe

The following code example shows how to describe a recipe in Amazon Personalize.
public static void describeSpecificRecipe(PersonalizeClient personalizeClient, String recipeArn) {
    try {
        DescribeRecipeRequest recipeRequest = DescribeRecipeRequest.builder()
            .recipeArn(recipeArn)
            .build();

        DescribeRecipeResponse recipeResponse = personalizeClient.describeRecipe(recipeRequest);
        System.out.println("The recipe name is "+
            recipeResponse.recipe().name());
    } catch (PersonalizeException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}

• For API details, see DescribeRecipe in AWS SDK for Java 2.x API Reference.

Describe a solution

The following code example shows how to describe a solution in Amazon Personalize.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
public static void describeSpecificSolution(PersonalizeClient personalizeClient, String solutionArn) {
    try {
        DescribeSolutionRequest solutionRequest =
                DescribeSolutionRequest.builder()
                .solutionArn(solutionArn)
                .build();

        DescribeSolutionResponse response =
                personalizeClient.describeSolution(solutionRequest);
        System.out.println("The Solution name is " +
                response.solution().name());
    } catch (PersonalizeException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}

- For API details, see DescribeSolution in AWS SDK for Java 2.x API Reference.

List campaigns

The following code example shows how to list campaigns in Amazon Personalize.

SDK for Java 2.x

```
public static void listAllCampaigns(PersonalizeClient personalizeClient, String solutionArn) {
    try {
        ListCampaignsRequest campaignsRequest =
                ListCampaignsRequest.builder()
                .maxResults(10)
                .build();

        ListCampaignsResponse response =
                personalizeClient.listCampaigns(campaignsRequest);
        System.out.println("The Campaigns are " +
                response.campaigns().stream().map(
                campaign -> campaign.name()).collect(Collectors.toList()));
    } catch (PersonalizeException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
ListCampaignsResponse response =
personalizeClient.listCampaigns(campaignsRequest);
List<CampaignSummary> campaigns = response.campaigns();
for (CampaignSummary campaign : campaigns) {
    System.out.println("Campaign name is : " + campaign.name());
    System.out.println("Campaign ARN is : " + campaign.campaignArn());
}
} catch (PersonalizeException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
}

- For API details, see ListCampaigns in AWS SDK for Java 2.x API Reference.

**List dataset groups**

The following code example shows how to list dataset groups in Amazon Personalize.

**SDK for Java 2.x**

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```java
public static void listDSGroups(PersonalizeClient personalizeClient) {
    try {
        ListDatasetGroupsRequest groupsRequest =
        ListDatasetGroupsRequest.builder()
            .maxResults(15)
            .build();

        ListDatasetGroupsResponse groupsResponse =
        personalizeClient.listDatasetGroups(groupsRequest);
    }
```
List<DatasetGroupSummary> groups = groupsResponse.datasetGroups();
for (DatasetGroupSummary group : groups) {
    System.out.println("The DataSet name is : " + group.name());
    System.out.println("The DataSet ARN is : " + group.datasetGroupArn());
}
}

} catch (PersonalizeException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

}  

• For API details, see ListDatasetGroups in AWS SDK for Java 2.x API Reference.

List recipes

The following code example shows how to list recipes in Amazon Personalize.

SDK for Java 2.x

public static void listAllRecipes(PersonalizeClient personalizeClient) {

    try {
        ListRecipesRequest recipesRequest = ListRecipesRequest.builder()
            .maxResults(15)
            .build();

        ListRecipesResponse response = personalizeClient.listRecipes(recipesRequest);
        List<RecipeSummary> recipes = response.recipes();
        for (RecipeSummary recipe : recipes) {
            System.out.println("The recipe ARN is: " + recipe.recipeArn());
            System.out.println("The recipe name is: " + recipe.name());
        }
    }
}
For API details, see ListRecipes in AWS SDK for Java 2.x API Reference.

**List solutions**

The following code example shows how to list solutions in Amazon Personalize.

**SDK for Java 2.x**

```java
import com.amazonaws.services.personalize.model.SolutionSummary;
import com.amazonaws.services.personalize.model.ListSolutionsRequest;
import com.amazonaws.services.personalize.model.ListSolutionsResponse;
import com.amazonaws.services.personalize.AWSPersonalizeClient;

public static void listAllSolutions(PersonalizeClient personalizeClient, String datasetGroupArn) {
    try {
        ListSolutionsRequest solutionsRequest = ListSolutionsRequest.builder()
            .maxResults(10)
            .datasetGroupArn(datasetGroupArn)
            .build();

        ListSolutionsResponse response = personalizeClient.listSolutions(solutionsRequest);
        List<SolutionSummary> solutions = response.solutions();
        for (SolutionSummary solution : solutions) {
            System.out.println("The solution ARN is: " + solution.solutionArn());
            System.out.println("The solution name is: " + solution.name());
        }
    } catch (PersonalizeException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

---

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
Update a campaign

The following code example shows how to update a campaign Amazon Personalize.

SDK for Java 2.x

```java
public static String updateCampaign(PersonalizeClient personalizeClient,
        String campaignArn,
        String solutionVersionArn,
        Integer minProvisionedTPS) {

    try {
        // build the updateCampaignRequest
        UpdateCampaignRequest updateCampaignRequest =
                UpdateCampaignRequest.builder()
                        .campaignArn(campaignArn)
                        .solutionVersionArn(solutionVersionArn)
                        .minProvisionedTPS(minProvisionedTPS)
                        .build();

        // update the campaign
        personalizeClient.updateCampaign(updateCampaignRequest);

        DescribeCampaignRequest campaignRequest =
                DescribeCampaignRequest.builder()
                        .campaignArn(campaignArn)
                        .build();

```
DescribeCampaignResponse campaignResponse = personalizeClient.describeCampaign(campaignRequest);
   Campaign updatedCampaign = campaignResponse.campaign();

   System.out.println("The Campaign status is " +
   updatedCampaign.status());
   return updatedCampaign.status();

} catch (PersonalizeException e) {
   System.err.println(e.awsErrorDetails().errorMessage());
   System.exit(1);
}
return ";

Amazon Personalize Events examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon Personalize Events.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Import real-time interaction event data

The following code example shows how to import real-time interaction event data into Amazon Personalize Events.

SDK for Java 2.x

```java
public static int putItems(PersonalizeEventsClient personalizeEventsClient,
   String datasetArn,
   String item1Id,
   String item1PropertyName,
   String item1PropertyValue,
   String item2Id,
   String item2PropertyName,
   String item2PropertyValue) {

   int responseCode = 0;
   ArrayList<Item> items = new ArrayList<>();

   try {
      Item item1 = Item.builder()
               .itemId(item1Id)
               .properties(String.format("{%1$s": "%2$s",
               item1PropertyName,
               item1PropertyValue))
               .build();

      items.add(item1);

      Item item2 = Item.builder()
               .itemId(item2Id)
               .properties(String.format("{%1$s": "%2$s",
               item2PropertyName,
               item2PropertyValue))
               .build();

      items.add(item2);

      return personalizeEventsClient.putItems(datasetArn, items);
   }

   catch (Exception e) {
      // Handle exception
      return -1;
   }

   return responseCode;
}
```

Note

Get recommendations (custom dataset group)

The following code example shows how to get Amazon Personalize Runtime Runtime ranked recommendations.

SDK for Java 2.x

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

    public static List<PredictedItem> getRankedRecs(PersonalizeRuntimeClient personalizeRuntimeClient,
```java
String campaignArn,
String userId,
ArrayList<String> items) {

    try {
        GetPersonalizedRankingRequest rankingRecommendationsRequest =
            GetPersonalizedRankingRequest.builder()
                .campaignArn(campaignArn)
                .userId(userId)
                .inputList(items)
                .build();

        GetPersonalizedRankingResponse recommendationsResponse =
            personalizeRuntimeClient
                .getPersonalizedRanking(rankingRecommendationsRequest);

        List<PredictedItem> rankedItems =
            recommendationsResponse.personalizedRanking();

        int rank = 1;
        for (PredictedItem item : rankedItems) {
            System.out.println("Item ranked at position " + rank + " details");
            System.out.println("Item Id is : " + item.itemId());
            System.out.println("Item score is : " + item.score());
            System.out.println("---------------------------------------------");
            rank++;
        }
        return rankedItems;
    }
    catch (PersonalizeRuntimeException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }

    return null;
}
```

- For API details, see [GetPersonalizedRanking](https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/aws-java-sdk-lambda-get-started.html) in *AWS SDK for Java 2.x API Reference*.

**Get recommendations from a recommender (domain dataset group)**

The following code example shows how to get Amazon Personalize Runtime Runtime recommendations.
Get a list of recommended items.

```java
public static void getRecs(PersonalizeRuntimeClient personalizeRuntimeClient,
String campaignArn, String userId) {
    try {
        GetRecommendationsRequest recommendationsRequest =
            GetRecommendationsRequest.builder()
                .campaignArn(campaignArn)
                .numResults(20)
                .userId(userId)
                .build();

        GetRecommendationsResponse recommendationsResponse =
            personalizeRuntimeClient
                .getRecommendations(recommendationsRequest);
        List<PredictedItem> items = recommendationsResponse.itemList();
        for (PredictedItem item : items) {
            System.out.println("Item Id is : " + item.itemId());
            System.out.println("Item score is : " + item.score());
        }
    } catch (AwsServiceException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

Get a list of recommended items from a recommender created in a domain dataset group.

```java
public static void getRecs(PersonalizeRuntimeClient personalizeRuntimeClient,
String recommenderArn,
String userId) {
```
try {
    GetRecommendationsRequest recommendationsRequest =
    GetRecommendationsRequest.builder()
        .recommenderArn(recommenderArn)
        .numResults(20)
        .userId(userId)
        .build();

    GetRecommendationsResponse recommendationsResponse =
    personalizeRuntimeClient
        .getRecommendations(recommendationsRequest);
    List<PredictedItem> items = recommendationsResponse.itemList();

    for (PredictedItem item : items) {
        System.out.println("Item Id is : " + item.itemId());
        System.out.println("Item score is : " + item.score());
    }
} catch (AwsServiceException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

Use a filter when requesting recommendations.

public static void getFilteredRecs(PersonalizeRuntimeClient personalizeRuntimeClient,
    String campaignArn,
    String userId,
    String filterArn,
    String parameter1Name,
    String parameter1Value1,
    String parameter1Value2,
    String parameter2Name,
    String parameter2Value) {

    try {

        Map<String, String> filterValues = new HashMap<>();

        filterValues.put(parameter1Name, String.format("\%1$s","\%2$s"));

    } catch (AwsServiceException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
parameter1Value1, parameter1Value2));
    filterValues.put(parameter2Name, String.format("\"%1$s\"", parameter2Value));

    GetRecommendationsRequest recommendationsRequest =
    GetRecommendationsRequest.builder()
      .campaignArn(campaignArn)
      .numResults(20)
      .userId(userId)
      .filterArn(filterArn)
      .filterValues(filterValues)
      .build();

    GetRecommendationsResponse recommendationsResponse =
    personalizeRuntimeClient
      .getRecommendations(recommendationsRequest);
    List<PredictedItem> items = recommendationsResponse.itemList();

    for (PredictedItem item : items) {
      System.out.println("Item Id is : " + item.itemId());
      System.out.println("Item score is : " + item.score());
    }
  } catch (PersonalizeRuntimeException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
  }
}

• For API details, see [GetRecommendations](https://docs.aws.amazon.com/sdk-for-java/latest/APIReference/API_GetRecommendations.html) in *AWS SDK for Java 2.x API Reference*.

### Amazon Pinpoint examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon Pinpoint.

**Actions** are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

**Scenarios** are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.
Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

 */

public class ExportEndpoints {
    public static void main(String[] args) {
        final String usage = """;

        This program performs the following steps:

        1. Exports the endpoints to an Amazon S3 bucket.
        2. Downloads the exported endpoints files from Amazon S3.
        3. Parses the endpoints files to obtain the endpoint IDs and prints
           them.
    }
}
Usage: ExportEndpoints <applicationId> <s3BucketName> <iamExportRoleArn> <path>

Where:
applicationId - The ID of the Amazon Pinpoint application that has the endpoint.
s3BucketName - The name of the Amazon S3 bucket to export the JSON file to.
iamExportRoleArn - The ARN of an IAM role that grants Amazon Pinpoint write permissions to the S3 bucket.
path - The path where the files downloaded from the Amazon S3 bucket are written (for example, C:/AWS/).

if (args.length != 4) {
    System.out.println(usage);
    System.exit(1);
}

Amazon Pinpoint SMS and Voice API examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon Pinpoint SMS and Voice API.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

**Topics**

- **Actions**

**Actions**

*Send a voice message with Amazon Pinpoint SMS and Voice API*

The following code example shows how to send a voice message with Amazon Pinpoint SMS and Voice API.

**SDK for Java 2.x**

```java
import software.amazon.awssdk.core.client.config.ClientOverrideConfiguration;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.pinpointsmsvoice.PinpointSmsVoiceClient;
import software.amazon.awssdk.services.pinpointsmsvoice.model.SSMLMessageType;
import software.amazon.awssdk.services.pinpointsmsvoice.model.VoiceMessageContent;
import software.amazon.awssdk.services.pinpointsmsvoice.model.SendVoiceMessageRequest;
```

Amazon Polly examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon Polly.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Create a snapshot of a DB instance

The following code example shows how to create a snapshot of an Amazon RDS DB instance.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in
the AWS Code Examples Repository.

// Create an Amazon RDS snapshot.
public static void createSnapshot(RdsClient rdsClient, String dbInstanceIdentifier, String dbSnapshotIdentifier) {
    try {

CreateDbSnapshotRequest snapshotRequest =
CreateDbSnapshotRequest.builder()
    .dbInstanceIdentifier(dbInstanceIdentifier)
    .dbSnapshotIdentifier(dbSnapshotIdentifier)
    .build();

CreateDbSnapshotResponse response =
rdsClient.createDBSnapshot(snapshotRequest);  
    System.out.println("The Snapshot id is " +
response.dbSnapshot().dbiResourceId());

} catch (RdsException e) {  
    System.out.println(e.getLocalizedMessage());
    System.exit(1);
}

• For API details, see CreateDBSnapshot in AWS SDK for Java 2.x API Reference.

Create an authentication token

The following code example shows how to create an authentication token for IAM authentication.

SDK for Java 2.x

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Use the RdsUtilities class to generate an authentication token.

public class GenerateRDSAuthToken {
    public static void main(String[] args) {
        final String usage = ""

        Usage:
        <dbInstanceIdentifier> <masterUsername>

        Where:
```java
String dbInstanceIdentifier = args[0];
String masterUsername = args[1];
Region region = Region.US_WEST_2;
RdsClient rdsClient = RdsClient.builder()
    .region(region)
    .build();

String token = getAuthToken(rdsClient, dbInstanceIdentifier, masterUsername);
System.out.println("The token response is " + token);

public static String getAuthToken(RdsClient rdsClient, String dbInstanceIdentifier, String masterUsername) {
    RdsUtilities utilities = rdsClient.utilities();
    try {
        GenerateAuthenticationTokenRequest tokenRequest = GenerateAuthenticationTokenRequest.builder()
            .credentialsProvider(ProfileCredentialsProvider.create())
            .username(masterUsername)
            .port(3306)
            .hostname(dbInstanceIdentifier)
            .build();

        return utilities.generateAuthenticationToken(tokenRequest);
    } catch (RdsException e) {
        System.out.println(e.getLocalizedMessage());
        System.exit(1);
    }
    return "";
}
```
Delete a DB instance

The following code example shows how to delete an Amazon RDS DB instance.

SDK for Java 2.x

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.rds.RdsClient;
import software.amazon.awssdk.services.rds.model.DeleteDbInstanceRequest;
import software.amazon.awssdk.services.rds.model.DeleteDbInstanceResponse;
import software.amazon.awssdk.services.rds.model.RdsException;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class DeleteDBInstance {
    public static void main(String[] args) {
        final String usage = ""
        
        Usage:
        <dbInstanceIdentifier>

        Where:
        dbInstanceIdentifier - The database instance identifier
    }
```
if (args.length != 1) {
    System.out.println(usage);
    System.exit(1);
}

### Delete a DB parameter group

The following code example shows how to delete an Amazon RDS DB parameter group.
Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```java
// Delete the parameter group after database has been deleted.
// An exception is thrown if you attempt to delete the para group while database
// exists.
public static void deleteParaGroup(RdsClient rdsClient, String dbGroupName,
String dbARN)
    throws InterruptedException {
    try {
        boolean isDataDel = false;
        boolean didFind;
        String instanceARN;

        // Make sure that the database has been deleted.
        while (!isDataDel) {
            DescribeDbInstancesResponse response =
                rdsClient.describeDBInstances();
            List<DBInstance> instanceList = response.dbInstances();
            int listSize = instanceList.size();
            didFind = false;
            int index = 1;
            for (DBInstance instance : instanceList) {
                instanceARN = instance.dbInstanceArn();
                if (instanceARN.compareTo(dbARN) == 0) {
                    System.out.println(dbARN + " still exists");
                    didFind = true;
                }
                if ((index == listSize) && (!didFind)) {
                    // Went through the entire list and did not find the
                    // database ARN.
                    isDataDel = true;
                }
                Thread.sleep(sleepTime * 1000);
                index++;
            }
        }
    }
```
// Delete the para group.
DeleteDbParameterGroupRequest parameterGroupRequest =
    DeleteDbParameterGroupRequest.builder()
    .dbParameterGroupName(dbGroupName)
    .build();

    rdsClient.deleteDBParameterGroup(parameterGroupRequest);
    System.out.println(dbGroupName + " was deleted.");

} catch (RdsException e) {
    System.out.println(e.getLocalizedMessage());
    System.exit(1);
}

For API details, see [DeleteDBParameterGroup](https://aws.amazon.com/documentation/sdk-for-java/api-reference/) in AWS SDK for Java 2.x API Reference.

### Describe DB instances

The following code example shows how to describe Amazon RDS DB instances.

**SDK for Java 2.x**

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.rds.RdsClient;
import software.amazon.awssdk.services.rds.model.DescribeDbInstancesResponse;
import software.amazon.awssdk.services.rds.model.DBInstance;
import software.amazon.awssdk.services.rds.model.RdsException;
import java.util.List;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 */
```
public class DescribeDBInstances {

    public static void main(String[] args) {
        Region region = Region.US_EAST_1;
        RdsClient rdsClient = RdsClient.builder()
                .region(region)
                .build();

        describeInstances(rdsClient);
        rdsClient.close();
    }

    public static void describeInstances(RdsClient rdsClient) {
        try {
            DescribeDbInstancesResponse response = rdsClient.describeDBInstances();
            List<DBInstance> instanceList = response.dbInstances();
            for (DBInstance instance : instanceList) {
                System.out.println("Instance ARN is: " + instance.dbInstanceArn());
                System.out.println("The Engine is " + instance.engine);
                System.out.println("Connection endpoint is" + instance.endpoint().address());
            }
        } catch (RdsException e) {
            System.out.println(e.getLocalizedMessage());
            System.exit(1);
        }
    }
}

• For API details, see DescribeDBInstances in AWS SDK for Java 2.x API Reference.

Describe DB parameter groups

The following code example shows how to describe Amazon RDS DB parameter groups.
SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```java
public static void describeDbParameterGroups(RdsClient rdsClient, String dbGroupName) {
    try {
        DescribeDbParameterGroupsRequest groupsRequest =
                DescribeDbParameterGroupsRequest.builder()
                        .dbParameterGroupName(dbGroupName)
                        .maxRecords(20)
                        .build();

        DescribeDbParameterGroupsResponse response =
                rdsClient.describeDBParameterGroups(groupsRequest);
        List<DBParameterGroup> groups = response.dbParameterGroups();
        for (DBParameterGroup group : groups) {
            System.out.println("The group name is "+
                    group.dbParameterGroupName());
            System.out.println("The group description is "+
                    group.description());
        }
    } catch (RdsException e) {
        System.out.println(e.getLocalizedMessage());
        System.exit(1);
    }
}
```

- For API details, see DescribeDBParameterGroups in AWS SDK for Java 2.x API Reference.

Describe database engine versions

The following code example shows how to describe Amazon RDS database engine versions.
Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```java
public static void describeDBEngines(RdsClient rdsClient) {
    try {
        DescribeDbEngineVersionsRequest engineVersionsRequest =
            DescribeDbEngineVersionsRequest.builder()
                .defaultOnly(true)
                .engine("mysql")
                .maxRecords(20)
                .build();

        DescribeDbEngineVersionsResponse response =
            rdsClient.describeDBEngineVersions(engineVersionsRequest);
        List<DBEngineVersion> engines = response.dbEngineVersions();

        // Get all DBEngineVersion objects.
        for (DBEngineVersion engineOb : engines) {
            System.out.println("The name of the DB parameter group family for
            the database engine is " +
                engineOb.dbParameterGroupFamily());
            System.out.println("The name of the database engine " +
                engineOb.engine());
            System.out.println("The version number of the database engine " +
                engineOb.engineVersion());
        }
    } catch (RdsException e) {
        System.out.println(e.getLocalizedMessage());
        System.exit(1);
    }
}
```

- For API details, see [DescribeDBEngineVersions](https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/api-index.html) in AWS SDK for Java 2.x API Reference.
Describe options for DB instances

The following code example shows how to describe options for Amazon RDS DB instances.

SDK for Java 2.x

```java
// Get a list of allowed engine versions.
public static void getAllowedEngines(RdsClient rdsClient, String
dbParameterGroupFamily) {
    try {
        DescribeDbEngineVersionsRequest versionsRequest =
            DescribeDbEngineVersionsRequest.builder()
                .dbParameterGroupFamily(dbParameterGroupFamily)
                .engine("mysql")
                .build();

        DescribeDbEngineVersionsResponse response =
            rdsClient.describeDbEngineVersions(versionsRequest);
        List<DBEngineVersion> dbEngines = response.dbEngineVersions();
        for (DBEngineVersion dbEngine : dbEngines) {
            System.out.println("The engine version is "+
                dbEngine.engineVersion());
            System.out.println("The engine description is "+
                dbEngine.dbEngineDescription());
        }
    } catch (RdsException e) {
        System.out.println(e.getLocalizedMessage());
        System.exit(1);
    }
}
```

- For API details, see [DescribeOrderableDBInstanceOptions](https://aws.amazon.com) in *AWS SDK for Java 2.x API Reference*. 

---

*Note*
There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://aws.amazon.com).
Describe parameters in a DB parameter group

The following code example shows how to describe parameters in an Amazon RDS DB parameter group.

SDK for Java 2.x

```
// Retrieve parameters in the group.
public static void describeDbParameters(RdsClient rdsClient, String dbGroupName, int flag) {
    try {
        DescribeDbParametersRequest dbParameterGroupsRequest;
        if (flag == 0) {
            dbParameterGroupsRequest = DescribeDbParametersRequest.builder()
                .dbParameterGroupName(dbGroupName)
                .build();
        } else {
            dbParameterGroupsRequest = DescribeDbParametersRequest.builder()
                .dbParameterGroupName(dbGroupName)
                .source("user")
                .build();
        }
    }

    DescribeDbParametersResponse response =
        rdsClient.describeDBParameters(dbParameterGroupsRequest);

    List<Parameter> dbParameters = response.parameters();
    String paraName;
    for (Parameter para : dbParameters) {
        // Only print out information about either auto_increment_offset or
        // auto_increment_increment.
        paraName = para.parameterName();
        if ((paraName.compareTo("auto_increment_offset") == 0)
            || (paraName.compareTo("auto_increment_increment") == 0)) {
            System.out.println("*** The parameter name is " + paraName);
            System.out.println("*** The parameter value is " +
                para.parameterValue());
        }
    }
```

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
For API details, see DescribeDBParameters in AWS SDK for Java 2.x API Reference.

Modify a DB instance

The following code example shows how to modify an Amazon RDS DB instance.

SDK for Java 2.x

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.rds.RdsClient;
import software.amazon.awssdk.services.rds.model.ModifyDbInstanceRequest;
import software.amazon.awssdk.services.rds.model.ModifyDbInstanceResponse;
import software.amazon.awssdk.services.rds.model.RdsException;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 */
```
public class ModifyDBInstance {
    public static void main(String[] args) {
        final String usage = """";

        Usage:
            <dbInstanceIdentifier> <dbSnapshotIdentifier>\n        Where:
            dbInstanceIdentifier - The database instance identifier.\n            masterUserPassword - The updated password that corresponds to
            the master user name.\n        """;

        if (args.length != 2) {

Reboot a DB instance

The following code example shows how to reboot an Amazon RDS DB instance.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
Usage:
   <dbInstanceIdentifier>\s

Where:
   dbInstanceIdentifier - The database instance identifier\s
   "";

if (args.length != 1) {
   System.out.println(usage);
   System.exit(1);
}

String dbInstanceIdentifier = args[0];
Region region = Region.US_WEST_2;
RdsClient rdsClient = RdsClient.builder()
   .region(region)
   .build();

rebootInstance(rdsClient, dbInstanceIdentifier);
rdsClient.close();
}

public static void rebootInstance(RdsClient rdsClient, String dbInstanceIdentifier) {
   try {
      RebootDbInstanceRequest rebootDbInstanceRequest =
         RebootDbInstanceRequest.builder()
            .dbInstanceIdentifier(dbInstanceIdentifier)
            .build();

      RebootDbInstanceResponse instanceResponse =
         rdsClient.rebootDBInstance(rebootDbInstanceRequest);
      System.out.print("The database " +
         instanceResponse.dbInstance().dbInstanceArn() + " was rebooted");

   } catch (RdsException e) {
      System.out.println(e.getLocalizedMessage());
      System.exit(1);
   }
}
}
Retrieve attributes

The following code example shows how to retrieve attributes that belong to an Amazon RDS account.

SDK for Java 2.x

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.rds.RdsClient;
import software.amazon.awssdk.services.rds.model.AccountQuota;
import software.amazon.awssdk.services.rds.model.RdsException;
import software.amazon.awssdk.services.rds.model.DescribeAccountAttributesResponse;
import java.util.List;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 * For more information, see the following documentation topic:
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class DescribeAccountAttributes {
    public static void main(String[] args) {
        Region region = Region.US_WEST_2;
        RdsClient rdsClient = RdsClient.builder()
                .region(region)
                .build();

        getAccountAttributes(rdsClient);
        rdsClient.close();
    }

    public static void getAccountAttributes(RdsClient rdsClient) {
```
try {
    DescribeAccountAttributesResponse response = 
        rdsClient.describeAccountAttributes();
    List<AccountQuota> quotasList = response.accountQuotas();
    for (AccountQuota quotas : quotasList) {
        System.out.println("Name is: " + quotas.accountQuotaName());
        System.out.println("Max value is " + quotas.max());
    } 
} catch (RdsException e) {
    System.out.println(e.getLocalizedMessage());
    System.exit(1);
} 

• For API details, see DescribeAccountAttributes in AWS SDK for Java 2.x API Reference.

Update parameters in a DB parameter group

The following code example shows how to update parameters in an Amazon RDS DB parameter group.

SDK for Java 2.x

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

// Modify auto_increment_offset and auto_increment_increment parameters.
public static void modifyDBParas(RdsClient rdsClient, String dbGroupName) {
    try {
        Parameter parameter1 = Parameter.builder()
            .parameterName("auto_increment_offset")
            .applyMethod("immediate")
            .parameterValue("5")
            .build();

        List<Parameter> paraList = new ArrayList<>();

```java
paraList.add(parameter1);
ModifyDbParameterGroupRequest groupRequest =
    ModifyDbParameterGroupRequest.builder()
    .dbParameterGroupName(dbGroupName)
    .parameters(paraList)
    .build();

ModifyDbParameterGroupResponse response =
rdsClient.modifyDBParameterGroup(groupRequest);
    System.out.println("The parameter group " +
    response.dbParameterGroupName() + " was successfully modified");

} catch (RdsException e) {
    System.out.println(e.getLocalizedMessage());
    System.exit(1);
}
```

- For API details, see [ModifyDBParameterGroup](https://aws.amazon.com/sdk-for-java/api-reference) in *AWS SDK for Java 2.x API Reference*.

**Scenarios**

**Get started with DB instances**

The following code example shows how to:

- Create a custom DB parameter group and set parameter values.
- Create a DB instance that's configured to use the parameter group. The DB instance also contains a database.
- Take a snapshot of the instance.
- Delete the instance and parameter group.

**SDK for Java 2.x**

 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * This example requires an AWS Secrets Manager secret that contains the
 * database credentials. If you do not create a
 * secret, this example will not work. For details, see:
 *
 * https://docs.aws.amazon.com/secretsmanager/latest/userguide/integrating_how-services-use-secrets_RS.html
 *
 * This Java example performs these tasks:
 *
 * 1. Returns a list of the available DB engines.
 * 2. Selects an engine family and create a custom DB parameter group.
 * 3. Gets the parameter groups.
 * 4. Gets parameters in the group.
 * 5. Modifies the auto_increment_offset parameter.
 * 6. Gets and displays the updated parameters.
 * 7. Gets a list of allowed engine versions.
 * 8. Gets a list of micro instance classes available for the selected engine.
 * 9. Creates an RDS database instance that contains a MySql database and uses
 * the parameter group.
 * 10. Waits for the DB instance to be ready and prints out the connection
 * endpoint value.
 * 11. Creates a snapshot of the DB instance.
 * 12. Waits for an RDS DB snapshot to be ready.
 * 13. Deletes the RDS DB instance.
 * 14. Deletes the parameter group.
 */

Amazon Redshift examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon Redshift.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Get started

Hello Amazon Redshift

The following code example shows how to get started using Amazon Redshift.

SDK for Java 2.x

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.redshift.RedshiftClient;
import software.amazon.awssdk.services.redshift.paginators.DescribeClustersIterable;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *

Actions

Create a cluster

The following code example shows how to create an Amazon Redshift cluster.

SDK for Java 2.x

⚠️ Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
Create the cluster.

```java
public static void createCluster(RedshiftClient redshiftClient, String clusterId, String masterUsername, String masterUserPassword) {
    try {
        CreateClusterRequest clusterRequest = CreateClusterRequest.builder()
            .clusterIdentifier(clusterId)
            .masterUsername(masterUsername)
            .masterUserPassword(masterUserPassword)
            .nodeType("ra3.4xlarge")
            .publiclyAccessible(true)
            .numberOfNodes(2)
            .build();

        CreateClusterResponse clusterResponse = redshiftClient.createCluster(clusterRequest);
        System.out.println("Created cluster " + clusterResponse.cluster().clusterIdentifier());
    } catch (RedshiftException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}
```

- For API details, see [CreateCluster](https://aws.amazon.com/sdk-for-java/developer-guide/redshift-api-reference/) in *AWS SDK for Java 2.x API Reference*.

Create a table

The following code example shows how to create an Amazon Redshift table.

**SDK for Java 2.x**

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://aws.amazon.com/code-examples/).
public static void createTable(RedshiftDataClient redshiftDataClient, String clusterId, String databaseName, String userName) {
    try {
        ExecuteStatementRequest createTableRequest =
        ExecuteStatementRequest.builder()
            .clusterIdentifier(clusterId)
            .dbUser(userName)
            .database(databaseName)
            .sql("CREATE TABLE Movies (" + "+ "id INT PRIMARY KEY, " + "+ "title VARCHAR(100), " + "+ "year INT")")
            .build();

        redshiftDataClient.executeStatement(createTableRequest);
        System.out.println("Table created: Movies");
    } catch (RedshiftDataException e) {
        System.err.println("Error creating table: " + e.getMessage());
        System.exit(1);
    }
}

- For API details, see CreateTable in AWS SDK for Java 2.x API Reference.

Delete a cluster

The following code example shows how to delete an Amazon Redshift cluster.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Delete the cluster.
public static void deleteRedshiftCluster(RedshiftClient redshiftClient, String clusterId) {
    try {
        DeleteClusterRequest deleteClusterRequest =
            DeleteClusterRequest.builder()
            .clusterIdentifier(clusterId)
            .skipFinalClusterSnapshot(true)
            .build();

        DeleteClusterResponse response =
            redshiftClient.deleteCluster(deleteClusterRequest);
        System.out.println("The status is " +
            response.cluster().clusterStatus());
    } catch (RedshiftException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}

For API details, see DeleteCluster in AWS SDK for Java 2.x API Reference.

Describe a query statement

The following code example shows how to describe an Amazon Redshift query statement.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

public static void checkStatement(RedshiftDataClient redshiftDataClient, String sqlId) {
    try {
        DescribeStatementRequest statementRequest =
            DescribeStatementRequest.builder()
            .id(sqlId)
String status;
while (true) {
    DescribeStatementResponse response =
        redshiftDataClient.describeStatement(statementRequest);
    status = response.statusAsString();
    System.out.println("..." + status);

    if (status.compareTo("FAILED") == 0) {
        System.out.println("The Query Failed. Ending program");
        System.exit(1);
    } else if (status.compareTo("FINISHED") == 0) {
        break;
    }
    TimeUnit.SECONDS.sleep(1);
}

System.out.println("The statement is finished!");

} catch (RedshiftDataException | InterruptedException e) {
    System.err.println(e.getMessage());
    System.exit(1);
}

For API details, see DescribeStatement in AWS SDK for Java 2.x API Reference.

Describe clusters

The following code example shows how to describe Amazon Redshift clusters.

SDK for Java 2.x

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
public static void waitForClusterReady(RedshiftClient redshiftClient, String clusterId) {
    boolean clusterReady = false;
    String clusterReadyStr;
    System.out.println("Waiting for cluster to become available. This may take a few mins.");
    try {
        DescribeClustersRequest clustersRequest =
            DescribeClustersRequest.builder()
                .clusterIdentifier(clusterId)
                .build();
        long startTime = System.currentTimeMillis();

        // Loop until the cluster is ready.
        while (!clusterReady) {
            DescribeClustersResponse clusterResponse =
                redshiftClient.describeClusters(clustersRequest);
            List<Cluster> clusterList = clusterResponse.clusters();
            for (Cluster cluster : clusterList) {
                clusterReadyStr = cluster.clusterStatus();
                if (clusterReadyStr.contains("available"))
                    clusterReady = true;
                else {
                    long elapsedTimeMillis = System.currentTimeMillis() - startTime;
                    long elapsedTimeSeconds = elapsedTimeMillis / 1000;
                    long minutes = elapsedTimeSeconds / 60;
                    long seconds = elapsedTimeSeconds % 60;
                    System.out.printf("Elapsed Time: %02d:%02d - Waiting for
cluster... 
%n", minutes, seconds);
                    TimeUnit.SECONDS.sleep(5);
                }
            }
        }
    }
}

long elapsedTimeMillis = System.currentTimeMillis() - startTime;
long elapsedTimeSeconds = elapsedTimeMillis / 1000;
long minutes = elapsedTimeSeconds / 60;
long seconds = elapsedTimeSeconds % 60;
System.out.println(String.format("Cluster is available! Total Elapsed Time: %02d:%02d", minutes, seconds));

} catch (RedshiftException | InterruptedException e) {
    System.err.println(e.getMessage());
    System.exit(1);
}

• For API details, see DescribeClusters in AWS SDK for Java 2.x API Reference.

Get the statement result

The following code example shows how to get the statement result.

**SDK for Java 2.x**

```java
public static void getResults(RedshiftDataClient redshiftDataClient, String statementId) {
    try {
        GetStatementResultRequest resultRequest = GetStatementResultRequest.builder()
            .id(statementId)
            .build();

        // Extract and print the field values using streams.
        GetStatementResultResponse response = redshiftDataClient.getStatementResult(resultRequest);
        response.records().stream()
            .flatMap(List::stream)
            .map(Field::stringValue)
            .filter(value -> value != null)
```
The following code example shows how to insert data into an Amazon Redshift table.

SDK for Java 2.x

```
public static void popTable(RedshiftDataClient redshiftDataClient, String clusterId, String databaseName, String userName, String fileName, int number) throws IOException {
    JsonParser parser = new JsonFactory().createParser(new File(fileName));
    com.fasterxml.jackson.databind.JsonNode rootNode = new ObjectMapper().readTree(parser);
    Iterator<JsonNode> iter = rootNode.iterator();
    ObjectNode currentNode;
    int t = 0;
    while (iter.hasNext()) {
        if (t == number)
            break;
        currentNode = (ObjectNode) iter.next();
        int year = currentNode.get("year").asInt();
        String title = currentNode.get("title").asText();
        // Use SqlParameter to avoid SQL injection.
        List<SqlParameter> parameterList = new ArrayList<>();
        
        // Insert data into table
        parameterList.add(new SqlParameter("year", Integer.valueOf(year)));  
        parameterList.add(new SqlParameter("title", title));
        List<SqlRow> rows = redshiftDataClient.insertTableData("moviedata", parameterList);
    }
}
```

• For API details, see GetStatementResult in AWS SDK for Java 2.x API Reference.

Insert data into a table

The following code example shows how to insert data into an Amazon Redshift table.
String sqlStatement = "INSERT INTO Movies
VALUES( :id , :title, :year);";

// Create the parameters.
SqlParameter idParam = SqlParameter.builder()
    .name("id")
    .value(String.valueOf(t))
    .build();

SqlParameter titleParam= SqlParameter.builder()
    .name("title")
    .value(title)
    .build();

SqlParameter yearParam = SqlParameter.builder()
    .name("year")
    .value(String.valueOf(year))
    .build();
parameterList.add(idParam);
parameterList.add(titleParam);
parameterList.add(yearParam);

try {
    ExecuteStatementRequest insertStatementRequest =
    ExecuteStatementRequest.builder()
        .clusterIdentifier(clusterId)
        .sql(sqlStatement)
        .database(databaseName)
        .dbUser(userName)
        .parameters(parameterList)
        .build();

    redshiftDataClient.executeStatement(insertStatementRequest);
    System.out.println("Inserted: " + title + " (" + year + ")");
t++;
} catch (RedshiftDataException e) {
    System.err.println("Error inserting data: " + e.getMessage());
    System.exit(1);
}
System.out.println(t + " records were added to the Movies table. ");
For API details, see Insert in AWS SDK for Java 2.x API Reference.

Modify a cluster

The following code example shows how to modify an Amazon Redshift cluster.

SDK for Java 2.x

```
public static void modifyCluster(RedshiftClient redshiftClient, String clusterId) {
    try {
        ModifyClusterRequest modifyClusterRequest =
            ModifyClusterRequest.builder()
                .clusterIdentifier(clusterId)
                .preferredMaintenanceWindow("wed:07:30-wed:08:00")
                .build();

        ModifyClusterResponse clusterResponse =
            redshiftClient.modifyCluster(modifyClusterRequest);
        System.out.println("The modified cluster was successfully modified and has " +
            clusterResponse.cluster().preferredMaintenanceWindow() + " as the maintenance window");
    }
    catch (RedshiftException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}
```

For API details, see ModifyCluster in AWS SDK for Java 2.x API Reference.
Query a table

The following code example shows how to query an Amazon Redshift table.

SDK for Java 2.x

```java
public static String queryMoviesByYear(RedshiftDataClient redshiftDataClient,
                                        String database,
                                        String dbUser,
                                        int year,
                                        String clusterId) {

    try {
        String sqlStatement = "SELECT * FROM Movies WHERE year = :year";
        SqlParameter yearParam = SqlParameter.builder()
                                        .name("year")
                                        .value(String.valueOf(year))
                                        .build();

        ExecuteStatementRequest statementRequest =
                ExecuteStatementRequest.builder()
                .clusterIdentifier(clusterId)
                .database(database)
                .dbUser(dbUser)
                .parameters(yearParam)
                .sql(sqlStatement)
                .build();

        ExecuteStatementResponse response =
                redshiftDataClient.executeStatement(statementRequest);
        return response.id();
    } catch (RedshiftDataException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }

    return null;
}
```

Note

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * This Java example performs these tasks:
 *
 * 1. Prompts the user for a unique cluster ID or use the default value.
 * 2. Creates a Redshift cluster with the specified or default cluster Id value.
 * 3. Waits until the Redshift cluster is available for use.
 * 4. Lists all databases using a pagination API call.
 * 5. Creates a table named "Movies" with fields ID, title, and year.
 * 6. Inserts a specified number of records into the "Movies" table by reading the
Movies JSON file.
 * 7. Prompts the user for a movie release year.
 * 8. Runs a SQL query to retrieve movies released in the specified year.
 * 10. Prompts the user for confirmation to delete the Redshift cluster.
 * 11. If confirmed, deletes the specified Redshift cluster.
 */

Amazon Rekognition examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon Rekognition.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

### Route 53 domain registration examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Route 53 domain registration.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

#### Get started

**Hello Route 53 domain registration**

The following code examples show how to get started using Route 53 domain registration.
AWS SDK for Java 2.x

Developer Guide for version 2.x

SDK for Java 2.x

Note
There's more on GitHub. Find the complete example and learn how to set up and run in
the AWS Code Examples Repository.

- Scenarios

Actions

Check domain availability

The following code example shows how to check the availability of a domain.

SDK for Java 2.x

```java
public static void checkDomainAvailability(Route53DomainsClient route53DomainsClient, String domainSuggestion) {
    try {
        CheckDomainAvailabilityRequest availabilityRequest = CheckDomainAvailabilityRequest.builder()
            .domainName(domainSuggestion)
            .build();

        CheckDomainAvailabilityResponse response = route53DomainsClient
```
For API details, see CheckDomainAvailability in AWS SDK for Java 2.x API Reference.

Check domain transferability

The following code example shows how to check the transferability of a domain.

SDK for Java 2.x

```java
public static void checkDomainTransferability(Route53DomainsClient route53DomainsClient, String domainSuggestion) {
    try {
        CheckDomainTransferabilityRequest transferabilityRequest = 
            CheckDomainTransferabilityRequest.builder()
                .domainName(domainSuggestion)
                .build();

        CheckDomainTransferabilityResponse response = route53DomainsClient
            .checkDomainTransferability(transferabilityRequest);
        System.out.println("Transferability: "+ response.transferability().transferable().toString());
    } catch (Route53Exception e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}
```

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
For API details, see [CheckDomainTransferability](https://aws-sdk官网) in *AWS SDK for Java 2.x API Reference*.

### Get domain details

The following code example shows how to get the details for a domain.

**SDK for Java 2.x**

```java
public static void getDomainDetails(Route53DomainsClient route53DomainsClient, String domainSuggestion) {
    try {
        GetDomainDetailRequest detailRequest = GetDomainDetailRequest.builder()
            .domainName(domainSuggestion)
            .build();

        GetDomainDetailResponse response = route53DomainsClient.getDomainDetail(detailRequest);
        System.out.println("The contact first name is " + response.registrantContact().firstName());
        System.out.println("The contact last name is " + response.registrantContact().lastName());
        System.out.println("The contact org name is " + response.registrantContact().organizationName());
    } catch (Route53Exception e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}
```

For API details, see [GetDomainDetail](https://aws-sdk官网) in *AWS SDK for Java 2.x API Reference*.
Get operation details

The following code example shows how to get details on an operation.

SDK for Java 2.x

```java
public static void getOperationalDetail(Route53DomainsClient route53DomainsClient, String operationId) {
    try {
        GetOperationDetailRequest detailRequest = GetOperationDetailRequest.builder()
            .operationId(operationId)
            .build();

        GetOperationDetailResponse response = route53DomainsClient.getOperationDetail(detailRequest);
        System.out.println("Operation detail message is " + response.message());

    } catch (Route53Exception e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}
```

- For API details, see [GetOperationDetail](https://aws.amazon.com/sdk-for-java) in *AWS SDK for Java 2.x API Reference*.

Get suggested domain names

The following code example shows how to get domain name suggestions.
public static void listDomainSuggestions(Route53DomainsClient route53DomainsClient, String domainSuggestion) {
    try {
        GetDomainSuggestionsRequest suggestionsRequest = GetDomainSuggestionsRequest.builder()
            .domainName(domainSuggestion)
            .suggestionCount(5)
            .onlyAvailable(true)
            .build();

        GetDomainSuggestionsResponse response = route53DomainsClient.getDomainSuggestions(suggestionsRequest);
        List<DomainSuggestion> suggestions = response.suggestionsList();
        for (DomainSuggestion suggestion : suggestions) {
            System.out.println("Suggestion Name: " + suggestion.domainName());
            System.out.println("Availability: " + suggestion.availability());
            System.out.println(" ");
        }
    } catch (Route53Exception e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}

For API details, see [GetDomainSuggestions](#) in AWS SDK for Java 2.x API Reference.

**List domain prices**

The following code example shows how to list domain prices.
public static void listPrices(Route53DomainsClient route53DomainsClient, String domainType) {
    try {
        ListPricesRequest pricesRequest = ListPricesRequest.builder()
            .tld(domainType)
            .build();

        ListPricesIterable listRes = route53DomainsClient.listPricesPaginator(pricesRequest);
        listRes.stream()
            .flatMap(r -> r.prices().stream())
            .forEach(content -> System.out.println(" Name: " +
                " Registration: " + content.registrationPrice().price() + " "
                + content.registrationPrice().currency() +
                " Renewal: " + content.renewalPrice().price() + " " +
                content.renewalPrice().currency()));

    } catch (Route53Exception e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}

• For API details, see ListPrices in AWS SDK for Java 2.x API Reference.

List domains

The following code example shows how to list the registered domains.
public static void listDomains(Route53DomainsClient route53DomainsClient) {
    try {
        ListDomainsIterable listRes = route53DomainsClient.listDomainsPaginator();
        listRes.stream()
            .flatMap(r -> r.domains().stream())
            .forEach(content -> System.out.println("The domain name is " +
            content.domainName()));

List operations

The following code example shows how to list operations.

SDK for Java 2.x

public static void listOperations(Route53DomainsClient route53DomainsClient) {
try {
    Date currentDate = new Date();
    LocalDateTime localDateTime = currentDate.toInstant().atZone(ZoneId.systemDefault()).toLocalDate();
    ZoneOffset zoneOffset = ZoneOffset.of("+01:00");
    localDateTime = localDateTime.minusYears(1);
    Instant myTime = localDateTime.toInstant(zoneOffset);

    ListOperationsRequest operationsRequest =
        ListOperationsRequest.builder()
            .submittedSince(myTime)
            .build();

    ListOperationsIterable listRes =
        route53DomainsClient.listOperationsPaginator(operationsRequest);
    listRes.stream()
        .flatMap(r -> r.operations().stream())
        .forEach(content -> System.out.println(" Operation Id: " +
        " Status: " + content.statusAsString() +
        " Date: " + content.submittedDate()));
}

} catch (Route53Exception e) {
    System.err.println(e.getMessage());
    System.exit(1); }

• For API details, see ListOperations in AWS SDK for Java 2.x API Reference.

Register a domain

The following code example shows how to register a domain.

SDK for Java 2.x

Note

**Scenarios**

**Get started with domains**

The following code example shows how to:

- List current domains, and list operations in the past year.
- View billing for the past year, and view prices for domain types.
- Get domain suggestions.
- Check domain availability and transferability.
- Optionally, request a domain registration.
- Get an operation detail.
- Optionally, get a domain detail.

**SDK for Java 2.x**

**Note**

There’s more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```plaintext
/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 * For more information, see the following documentation topic:
 * ...
 */
```
* This example uses pagination methods where applicable. For example, to list domains, the listDomainsPaginator method is used. For more information about pagination, see the following documentation topic:

* https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/pagination.html

* This Java code example performs the following operations:

* 1. List current domains.
* 2. List operations in the past year.
* 3. View billing for the account in the past year.
* 4. View prices for domain types.
* 5. Get domain suggestions.
* 6. Check domain availability.
* 7. Check domain transferability.
* 8. Request a domain registration.
* 10. Optionally, get domain details.

Amazon S3 examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon S3.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Get started

Hello Amazon S3

The following code examples show how to get started using Amazon S3.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.model.Bucket;
import software.amazon.awssdk.services.s3.model.ListBucketsResponse;
import software.amazon.awssdk.services.s3.model.S3Exception;
import java.util.List;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 * *
 * For more information, see the following documentation topic:
 * *
```
public class HelloS3 {
    public static void main(String[] args) {
        Region region = Region.US_EAST_1;
        S3Client s3 = S3Client.builder()
            .region(region)
            .build();

        listBuckets(s3);
    }

    public static void listBuckets(S3Client s3) {
        try {
            ListBucketsResponse response = s3.listBuckets();
            List<Bucket> bucketList = response.buckets();
            bucketList.forEach(bucket -> {
                System.out.println("Bucket Name: " + bucket.name());
            });
        } catch (S3Exception e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
}

## Add a lifecycle configuration to a bucket

The following code example shows how to add a lifecycle configuration to an S3 bucket.

### SDK for Java 2.x

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.model.LifecycleRuleFilter;
import software.amazon.awssdk.services.s3.model.Transition;
import software.amazon.awssdk.services.s3.model.GetBucketLifecycleConfigurationRequest;
import software.amazon.awssdk.services.s3.model.GetBucketLifecycleConfigurationResponse;
import software.amazon.awssdk.services.s3.model.DeleteBucketLifecycleRequest;
import software.amazon.awssdk.services.s3.model.TransitionStorageClass;
import software.amazon.awssdk.services.s3.model.LifecycleRule;
import software.amazon.awssdk.services.s3.model.ExpirationStatus;
import software.amazon.awssdk.services.s3.model.BucketLifecycleConfiguration;
import software.amazon.awssdk.services.s3.model.PutBucketLifecycleConfigurationRequest;
import software.amazon.awssdk.services.s3.model.S3Exception;
import java.util.ArrayList;
import java.util.List;

For API details, see ListBuckets in AWS SDK for Java 2.x API Reference.

List in-progress multipart uploads

The following code example shows how to list in-progress multipart uploads to an S3 bucket.

SDK for Java 2.x

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.model.ListMultipartUploadsRequest;
import software.amazon.awssdk.services.s3.model.ListMultipartUploadsResponse;
import software.amazon.awssdk.services.s3.model.MultipartUpload;
import software.amazon.awssdk.services.s3.model.S3Exception;
import java.util.List;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */

public class ListMultipartUploads {
    public static void main(String[] args) {
        final String usage = """";

        Usage:
        <bucketName>\s
```
bucketName - The name of the Amazon S3 bucket where an in-progress multipart upload is occurring.

```java
if (args.length != 1) {
    System.out.println(usage);
    System.exit(1);
}

String bucketName = args[0];
Region region = Region.US_EAST_1;
S3Client s3 = S3Client.builder()
    .region(region)
    .build();
listUploads(s3, bucketName);
s3.close();
```

```java
public static void listUploads(S3Client s3, String bucketName) {
    try {
        ListMultipartUploadsRequest listMultipartUploadsRequest =
            ListMultipartUploadsRequest.builder()
                .bucket(bucketName)
                .build();

        ListMultipartUploadsResponse response =
            s3.listMultipartUploads(listMultipartUploadsRequest);
        List<MultipartUpload> uploads = response.uploads();
        for (MultipartUpload upload : uploads) {
            System.out.println("Upload in progress: Key = "+ upload.key() + ", id = " + upload.uploadId());
        }
    } catch (S3Exception e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}
```

Upload an object to a bucket

The following code example shows how to upload an object to an S3 bucket.

SDK for Java 2.x

⚠️ Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Upload a file to a bucket using an S3Client.
import software.amazon.awssdk.core.sync.RequestBody;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.model.PutObjectRequest;
import software.amazon.awssdk.services.s3.model.S3Exception;
import java.io.File;
import java.util.HashMap;
import java.util.Map;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */

public class PutObject {
    public static void main(String[] args) {
        final String usage = ""

        Usage:
        <bucketName> <objectKey> <objectPath>

        Where:
        bucketName - The Amazon S3 bucket to upload an object into.
        objectKey - The object to upload (for example, book.pdf).
        objectPath - The path where the file is located (for example, C:/AWS/book2.pdf).

        "";

        if (args.length != 3) {
            System.out.println(usage);
            System.exit(1);
        }

        String bucketName = args[0];
        String objectKey = args[1];
        String objectPath = args[2];
        Region region = Region.US_EAST_1;
        S3Client s3 = S3Client.builder()
            .region(region)
Use an `S3TransferManager` to upload a file to a bucket. View the complete file and test.

```java
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.transfer.s3.S3TransferManager;
import software.amazon.awssdk.transfer.s3.model.CompletedFileUpload;
import software.amazon.awssdk.transfer.s3.model.FileUpload;
import software.amazon.awssdk.transfer.s3.model.UploadFileRequest;
import software.amazon.awssdk.transfer.s3.progress.LoggingTransferListener;
import java.net.URI;
import java.net.URISyntaxException;
import java.net.URL;
```
import java.nio.file.Paths;
import java.util.UUID;

public String uploadFile(S3TransferManager transferManager, String bucketName,
    String key, URI filePathURI) {
    UploadFileRequest uploadFileRequest = UploadFileRequest.builder()
        .putObjectRequest(b -> b.bucket(bucketName).key(key))
        .addTransferListener(LoggingTransferListener.create())
        .source(Paths.get(filePathURI))
        .build();

    FileUpload fileUpload = transferManager.uploadFile(uploadFileRequest);

    CompletedFileUpload uploadResult = fileUpload.completionFuture().join();
    return uploadResult.response().eTag();
}

Upload an object to a bucket and set tags using an S3Client.

public static void putS3ObjectTags(S3Client s3, String bucketName, String
    objectKey, String objectPath) {
    try {
        Tag tag1 = Tag.builder()
            .key("Tag 1")

        s3.putObject(putOb, RequestBody.fromFile(new File(objectPath)));
        System.out.println("Successfully placed " + objectKey + " into bucket " + bucketName);
    } catch (S3Exception e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}
Upload an object to a bucket and set an object retention value using an S3Client.

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.model.PutObjectRetentionRequest;
import software.amazon.awssdk.services.s3.model.ObjectLockRetention;
import software.amazon.awssdk.services.s3.model.S3Exception;
import java.time.Instant;
import java.time.LocalDate;
import java.time.LocalDateTime;
import java.time.ZoneOffset;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */

public class PutObjectRetention {
    public static void main(String[] args) {
        final String usage = ""

        Usage:
            <key> <bucketName>

        Where:
            key - The name of the object (for example, book.pdf).
            bucketName - The Amazon S3 bucket name that contains the object
        (for example, bucket1).

        if (args.length != 2) {
            System.out.println(usage);
            System.exit(1);
        }

        String key = args[0];
    }
}
```
String bucketName = args[1];
Region region = Region.US_EAST_1;
S3Client s3 = S3Client.builder()
    .region(region)
    .build();

setRentionPeriod(s3, key, bucketName);
s3.close();
}

public static void setRentionPeriod(S3Client s3, String key, String bucket) {
    try {
        LocalDate localDate = LocalDate.parse("2020-07-17");
        LocalDateTime localDateTime = localDate.atStartOfDay();
        Instant instant = localDateTime.toInstant(ZoneOffset.UTC);

        ObjectLockRetention lockRetention = ObjectLockRetention.builder()
            .mode("COMPLIANCE")
            .retainUntilDate(instant)
            .build();

        PutObjectRetentionRequest retentionRequest =
            PutObjectRetentionRequest.builder()
                .bucket(bucket)
                .key(key)
                .bypassGovernanceRetention(true)
                .retention(lockRetention)
                .build();

        // To set Retention on an object, the Amazon S3 bucket must support
        // locking, otherwise an exception is thrown.
        s3.putObjectRetention(retentionRequest);
        System.out.print("An object retention configuration was successfully
            placed on the object");
    } catch (S3Exception e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
For API details, see PutObject in AWS SDK for Java 2.x API Reference.

Upload directory to a bucket

The following code example shows how to upload a local directory recursively to an Amazon Simple Storage Service (Amazon S3) bucket.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Use an S3TransferManager to upload a local directory. View the complete file and test.

```java
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.services.s3.model.ObjectIdentifier;
import software.amazon.awssdk.transfer.s3.S3TransferManager;
import software.amazon.awssdk.transfer.s3.model.CompletedDirectoryUpload;
import software.amazon.awssdk.transfer.s3.model.DirectoryUpload;
import software.amazon.awssdk.transfer.s3.model.UploadDirectoryRequest;
import java.net.URI;
import java.net.URISyntaxException;
import java.net.URL;
import java.nio.file.Paths;
import java.util.UUID;

public Integer uploadDirectory(S3TransferManager transferManager,
        URI sourceDirectory, String bucketName) {
    DirectoryUpload directoryUpload =
            transferManager.uploadDirectory(UploadDirectoryRequest.builder()
                    .source(Paths.get(sourceDirectory))
                    .bucket(bucketName)
                    .build());

    CompletedDirectoryUpload completedDirectoryUpload =
            directoryUpload.completionFuture().join();
    completedDirectoryUpload.failedTransfers();
```
For API details, see `UploadDirectory` in *AWS SDK for Java 2.x API Reference*.

**Use SQL with Amazon S3 Select**

The following code example shows how to retrieve a subset of data using SQL.

**SDK for Java 2.x**

```java
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.core.async.AsyncRequestBody;
import software.amazon.awssdk.core.async.BlockingInputStreamAsyncRequestBody;
import software.amazon.awssdk.core.exception.SdkException;
import software.amazon.awssdk.services.s3.S3AsyncClient;
import software.amazon.awssdk.services.s3.model.CSVInput;
import software.amazon.awssdk.services.s3.model.CSVOutput;
import software.amazon.awssdk.services.s3.model.CompressionType;
import software.amazon.awssdk.services.s3.model.ExpressionType;
import software.amazon.awssdk.services.s3.model.FileHeaderInfo;
import software.amazon.awssdk.services.s3.model.InputSerialization;
import software.amazon.awssdk.services.s3.model.JSONInput;
import software.amazon.awssdk.services.s3.model.JSONOutput;
import software.amazon.awssdk.services.s3.model.JSONType;
import software.amazon.awssdk.services.s3.model.ObjectIdentifier;
import software.amazon.awssdk.services.s3.model.OutputSerialization;
import software.amazon.awssdk.services.s3.model.Progress;
```

The following example shows a query using a JSON object. The [complete example](#) also shows the use of a CSV object.

Scenarios

Create a presigned URL

The following code example shows how to create a presigned URL for Amazon S3 and upload an object.
Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Generate a pre-signed URL for an object, then download it (GET request).

Imports.

```java
import com.example.s3.util.PresignUrlUtils;
import org.slf4j.Logger;
import software.amazon.awssdk.http.HttpExecuteRequest;
import software.amazon.awssdk.http.HttpExecuteResponse;
import software.amazon.awssdk.http.SdkHttpClient;
import software.amazon.awssdk.http.SdkHttpMethod;
import software.amazon.awssdk.http.SdkHttpRequest;
import software.amazon.awssdk.http.apache.ApacheHttpClient;
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.model.GetObjectRequest;
import software.amazon.awssdk.services.s3.model.S3Exception;
import software.amazon.awssdk.services.s3.presigner.S3Presigner;
import software.amazon.awssdk.services.s3.presigner.model.GetObjectPresignRequest;
import software.amazon.awssdk.services.s3.presigner.model.PresignedGetObjectRequest;
import software.amazon.awssdk.utils.IoUtils;

import java.io.ByteArrayOutputStream;
import java.io.File;
import java.io.IOException;
import java.io.InputStream;
import java.net.HttpURLConnection;
import java.net.URI;
import java.net.URIConnection;
import java.net.URISyntaxException;
import java.net.URL;
import java.net.http.HttpClient;
import java.net.http.HttpRequest;
import java.net.http.HttpResponse;
import java.nio.file.Paths;
import java.time.Duration;
import java.util.UUID;
```
AWS SDK for Java 2.x

Generate the URL.

```java
/* Create a pre-signed URL to download an object in a subsequent GET request. */
public String createPresignedGetUrl(String bucketName, String keyName) {
    try (S3Presigner presigner = S3Presigner.create()) {

        GetObjectRequest objectRequest = GetObjectRequest.builder()
            .bucket(bucketName)
            .key(keyName)
            .build();

        GetObjectPresignRequest presignRequest =
            GetObjectPresignRequest.builder()
            .signatureDuration(Duration.ofMinutes(10))  // The URL will expire in 10 minutes.
            .getObjectRequest(objectRequest)
            .build();

        PresignedGetObjectRequest presignedRequest =
            presigner.presignGetObject(presignRequest);
        logger.info("Presigned URL: [{]", presignedRequest.url().toString());
        logger.info("HTTP method: [{]", presignedRequest.httpRequest().method());

        return presignedRequest.url().toExternalForm();
    }
}
```

Download the object by using any one of the following three approaches.

Use JDK HttpURLConnection (since v1.1) class to do the download.

```java
/* Use the JDK HttpURLConnection (since v1.1) class to do the download. */
public byte[] useHttpUrlConnectionToGet(String presignedUrlString) {
    ByteArrayOutputStream byteArrayOutputStream = new ByteArrayOutputStream(); // Capture the response body to a byte array.
    try {
        URL presignedUrl = new URL(presignedUrlString);
        HttpURLConnection connection = (HttpURLConnection)
            presignedUrl.openConnection();
        connection.setRequestMethod("GET");
        return byteArrayOutputStream.toByteArray();
    }
}
```
// Download the result of executing the request.
try (InputStream content = connection.getInputStream()) {
    IoUtils.copy(content, byteArrayOutputStream);
}
logger.info("HTTP response code is " + connection.getResponseCode());

} catch (S3Exception | IOException e) {
    logger.error(e.getMessage(), e);
}
return byteArrayOutputStream.toByteArray();

Use JDK HttpClient (since v11) class to do the download.

/* Use the JDK HttpClient (since v11) class to do the download. */
public byte[] useHttpClientToGet(String presignedUrlString) {
    ByteArrayOutputStream byteArrayOutputStream = new
    ByteArrayOutputStream(); // Capture the response body to a byte array.
    HttpRequest.Builder requestBuilder = HttpRequest.newBuilder();
    HttpClient httpClient = HttpClient.newHttpClient();
    try {
        URL presignedUrl = new URL(presignedUrlString);
        HttpResponse<InputStream> response = httpClient.send(requestBuilder
            .uri(presignedUrl.toURI())
            .GET()
            .build(),
            HttpResponse.BodyHandlers.ofInputStream());
        IoUtils.copy(response.body(), byteArrayOutputStream);
        logger.info("HTTP response code is " + response.statusCode());
    } catch (URISyntaxException | InterruptedException | IOException e) {
        logger.error(e.getMessage(), e);
    }
    return byteArrayOutputStream.toByteArray();
}

Use the AWS SDK for Java SdkHttpClient class to do the download.
/* Use the AWS SDK for Java SdkHttpClient class to do the download. */
public byte[] useSdkHttpClientToPut(String presignedUrlString) {
  ByteArrayOutputStream byteArrayOutputStream = new
  ByteArrayOutputStream(); // Capture the response body to a byte array.
  try {
    URL presignedUrl = new URL(presignedUrlString);
    SdkHttpRequest request = SdkHttpRequest.builder()
      .method(SdkHttpMethod.GET)
      .uri(presignedUrl.toURI())
      .build();

    HttpExecuteRequest executeRequest = HttpExecuteRequest.builder()
      .request(request)
      .build();

    try (SdkHttpClient sdkHttpClient = ApacheHttpClient.create()) {
      HttpExecuteResponse response =
        sdkHttpClient.prepareRequest(executeRequest).call();
      response.responseBody().ifPresentOrElse(
        abortableInputStream -> {
          try {
            IoUtils.copy(abortableInputStream,
            byteArrayOutputStream);
          } catch (IOException e) {
            throw new RuntimeException(e);
          }
        },
        () -> logger.error("No response body.")
      );
      logger.info("HTTP Response code is {}",
        response.httpResponse().statusCode());
    } catch (URISyntaxException | IOException e) {
      logger.error(e.getMessage(), e);
    }
    return byteArrayOutputStream.toByteArray();
  }
}

Generate a pre-signed URL for an upload, then upload a file (PUT request).

Generate the URL.

/* Create a presigned URL to use in a subsequent PUT request */
public String createPresignedUrl(String bucketName, String keyName, Map<String, String> metadata) {
    try (S3Presigner presigner = S3Presigner.create()) {
        PutObjectRequest objectRequest = PutObjectRequest.builder()
Upload a file object by using any one of the following three approaches.

Use the JDK HttpURLConnection (since v1.1) class to do the upload.

```java
/* Use the JDK HttpURLConnection (since v1.1) class to do the upload. */
public void useHttpUrlConnectionToPut(String presignedUrlString, File fileToPut,
Map<String, String> metadata) {
    logger.info("Begin [{] upload", fileToPut.toString());
    try {
        URL presignedUrl = new URL(presignedUrlString);
        HttpURLConnection connection = (HttpURLConnection)
        presignedUrl.openConnection();
        connection.setDoOutput(true);
        metadata.forEach((k, v) -> connection.setRequestProperty("x-amz-meta-" + k, v));
        connection.setRequestMethod("PUT");
        OutputStream out = connection.getOutputStream();
        try (RandomAccessFile file = new RandomAccessFile(fileToPut, "r")
```

```java
        .bucket(bucketName)
        .key(keyName)
        .metadata(metadata)
        .build();

        PutObjectPresignRequest presignRequest =
        PutObjectPresignRequest.builder()
        .signatureDuration(Duration.ofMinutes(10))  // The URL expires
        in 10 minutes.
        .putObjectRequest(objectRequest)
        .build();

        PresignedPutObjectRequest presignedRequest =
        presigner.presignPutObject(presignRequest);
        String myURL = presignedRequest.url().toString();
        logger.info("Presigned URL to upload a file to: [{]", myURL);
        logger.info("HTTP method: [{]",
        presignedRequest.httpRequest().method());

        return presignedRequest.url().toExternalForm();
    }
}
```
FileChannel inChannel = file.getChannel();
ByteBuffer buffer = ByteBuffer.allocate(8192); // Buffer size is 8k

while (inChannel.read(buffer) > 0) {
    buffer.flip();
    for (int i = 0; i < buffer.limit(); i++) {
        out.write(buffer.get());
    }
    buffer.clear();
}
} catch (IOException e) {
    logger.error(e.getMessage(), e);
}

out.close();
connection.getResponseCode();
logger.info("HTTP response code is " + connection.getResponseCode());

} catch (S3Exception | IOException e) {
    logger.error(e.getMessage(), e);
}

Use the JDK HttpClient (since v11) class to do the upload.

// Use the JDK HttpClient (since v11) class to do the upload. */
public void useHttpClientToPut(String presignedUrlString, File fileToPut,
Map<String, String> metadata) {
    logger.info("Begin [{}] upload", fileToPut.toString());

    HttpRequest.Builder requestBuilder = HttpRequest.newBuilder();
    metadata.forEach((k, v) -> requestBuilder.header("x-amz-meta-" + k, v));

    HttpClient httpClient = HttpClient.newHttpClient();
    try {
        final HttpResponse<Void> response = httpClient.send(requestBuilder
            .uri(new URL(presignedUrlString).toURI())
            .PUT(HttpRequest.BodyPublishers.ofFile(Path.of(fileToPut.toURI())))
            .build(),
            HttpResponse.BodyHandlers.discard());
        .PUT(HttpRequest.BodyPublishers.ofFile(Path.of(fileToPut.toURI())))
        .build(),
        HttpResponse.BodyHandlers.discard());
Use the AWS for Java V2 SdkHttpClient class to do the upload.

```java
/* Use the AWS SDK for Java V2 SdkHttpClient class to do the upload. */
public void useSdkHttpClientToPut(String presignedUrlString, File fileToPut,
        Map<String, String> metadata) {
    logger.info("Begin [\{}\] upload", fileToPut.toString());

    try {
        URL presignedUrl = new URL(presignedUrlString);

        SdkHttpRequest.Builder requestBuilder = SdkHttpRequest.builder()
                .method(SdkHttpMethod.PUT)
                .uri(presignedUrl.toURI());
        // Add headers
        metadata.forEach((k, v) -> requestBuilder.putHeader("x-amz-meta-" + k, v));

        // Finish building the request.
        SdkHttpRequest request = requestBuilder.build();

        HttpExecuteRequest executeRequest = HttpExecuteRequest.builder()
                .request(request)
                .contentStreamProvider(new FileContentStreamProvider(fileToPut.toPath()))
                .build();

        try (SdkHttpClient sdkHttpClient = ApacheHttpClient.create()) {
            HttpExecuteResponse response = sdkHttpClient.prepareRequest(executeRequest).call();
        }
    } catch (URISyntaxException | IOException e) {
        logger.error(e.getMessage(), e);
    }
}
```

Use the AWS for Java V2 SdkHttpClient class to do the upload.
Get started with buckets and objects

The following code example shows how to:

- Create a bucket and upload a file to it.
- Download an object from a bucket.
- Copy an object to a subfolder in a bucket.
- List the objects in a bucket.
- Delete the bucket objects and the bucket.

SDK for Java 2.x

```java
/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * This Java code example performs the following tasks:
 *
 * 1. Creates an Amazon S3 bucket.
 * 2. Uploads an object to the bucket.
 * 3. Downloads the object to another local file.
 * 4. Uploads an object using multipart upload.
 * 5. List all objects located in the Amazon S3 bucket.
 * 6. Copies the object to another Amazon S3 bucket.
 * 7. Deletes the object from the Amazon S3 bucket.
 * 8. Deletes the Amazon S3 bucket.
 */
```
public class S3Scenario {
    public static final String DASHES = new String(new char[80]).replace("\0", "-");

    public static void main(String[] args) throws IOException {
        final String usage = """
        Usage:
        <bucketName> <key> <objectPath> <savePath> <toBucket>

        Where:
        bucketName - The Amazon S3 bucket to create.
        key - The key to use.
        objectPath - The path where the file is located (for example, C:/AWS/book2.pdf).
        savePath - The path where the file is saved after it's downloaded (for example, C:/AWS/book2.pdf).
        toBucket - An Amazon S3 bucket to where an object is copied to (for example, C:/AWS/book2.pdf).
        """

        System.exit(1);
    }
}
```
For API details, see the following topics in *AWS SDK for Java 2.x API Reference*.

- **CopyObject**
- **CreateBucket**
- **DeleteBucket**
- **DeleteObjects**
- **GetObject**
- **ListObjectsV2**
- **PutObject**

### Parse URIs

The following code example shows how to parse Amazon S3 URIs to extract important components like the bucket name and object key.

#### SDK for Java 2.x

```java
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.S3Utilities;
import java.net.URI;
import java.util.List;
import java.util.Map;
```

Parse an Amazon S3 URI by using the **S3Uri** class.
```java
/**
 * @param s3Client - An S3Client through which you acquire an S3Uri instance.
 * @param s3ObjectUrl - A complex URL (String) that is used to demonstrate S3Uri capabilities.
 */
public static void parseS3UriExample(S3Client s3Client, String s3ObjectUrl) {
    logger.info(s3ObjectUrl);
    // Console output:
    // 'https://s3.us-west-1.amazonaws.com/myBucket/resources/doc.txt?versionId=abc123&partNumber=77&partNumber=88'.

    // Create an S3Utilities object using the configuration of the s3Client.
    S3Utilities s3Utilities = s3Client.utilities();
    // From a String URL create a URI object to pass to the parseUri() method.
    URI uri = URI.create(s3ObjectUrl);
    S3Uri s3Uri = s3Utilities.parseUri(uri);

    // If the URI contains no value for the Region, bucket or key, the SDK returns
    // an empty Optional.
    // The SDK returns decoded URI values.
    Region region = s3Uri.region().orElse(null);
    log("region", region);
    // Console output: 'region: us-west-1'.

    String bucket = s3Uri.bucket().orElse(null);
    log("bucket", bucket);
    // Console output: 'bucket: myBucket'.

    String key = s3Uri.key().orElse(null);
    log("key", key);
    // Console output: 'key: resources/doc.txt'.

    Boolean isPathStyle = s3Uri.isPathStyle();
    log("isPathStyle", isPathStyle);
    // Console output: 'isPathStyle: true'.

    // If the URI contains no query parameters, the SDK returns an empty map.
    Map<String, List<String>> queryParams = s3Uri.rawQueryParameters();
    log("rawQueryParameters", queryParams);
```
// Console output: 'rawQueryParameters: {versionId=[abc123], partNumber=[77, // 88]}'.

// Retrieve the first or all values for a query parameter as shown in the
// following code.
String versionId =
s3Uri.firstMatchingRawQueryParameter("versionId").orElse(null);
log("firstMatchingRawQueryParameter-versionId", versionId);
// Console output: 'firstMatchingRawQueryParameter-versionId: abc123'.

String partNumber =
s3Uri.firstMatchingRawQueryParameter("partNumber").orElse(null);
log("firstMatchingRawQueryParameter-partNumber", partNumber);
// Console output: 'firstMatchingRawQueryParameter-partNumber: 77'.

List<String> partNumbers =
s3Uri.firstMatchingRawQueryParameters("partNumber");
log("firstMatchingRawQueryParameter", partNumbers);
// Console output: 'firstMatchingRawQueryParameter: [77, 88]'.

/
* Object keys and query parameters with reserved or unsafe characters, must
be
* URL-encoded.
* For example replace whitespace " " with "%20".
* Valid:
* "https://s3.us-west-1.amazonaws.com/myBucket/object%20key?query=
%5Bbrackets%5D"
* Invalid:
* "https://s3.us-west-1.amazonaws.com/myBucket/object key?query=[brackets]"
* Virtual-hosted-style URIs with bucket names that contain a dot, ".", the
dot
* must not be URL-encoded.
* Invalid: "https://my%2EBucket.s3.us-west-1.amazonaws.com/key"
*/

private static void log(String s3UriElement, Object element) {
if (element == null) {
    logger.info("{}: \0x2026", s3UriElement, "null");
} else {
    logger.info("{}: \{\}\", s3UriElement, element.toString());
}
Perform a multipart upload

The following code example shows how to perform a multipart upload to an Amazon S3 object.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

The code examples use the following imports.

```java
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.core.exception.SdkException;
import software.amazon.awssdk.core.sync.RequestBody;
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.model.CompletedMultipartUpload;
import software.amazon.awssdk.services.s3.model.CompletedPart;
import software.amazon.awssdk.services.s3.model.CreateMultipartUploadResponse;
import software.amazon.awssdk.services.s3.model.UploadPartRequest;
import software.amazon.awssdk.services.s3.model.UploadPartResponse;
import software.amazon.awssdk.services.s3.waiters.S3Waiter;
import software.amazon.awssdk.transfer.s3.S3TransferManager;
import software.amazon.awssdk.transfer.s3.model.FileUpload;
import software.amazon.awssdk.transfer.s3.model.UploadFileRequest;

import java.io.IOException;
import java.io.RandomAccessFile;
import java.net.URISyntaxException;
import java.net.URL;
import java.nio.ByteBuffer;
import java.nio.file.Paths;
import java.util.ArrayList;
import java.util.List;
```
Use the S3 Transfer Manager on top of the AWS CRT-based S3 client to transparently perform a multipart upload when the size of the content exceeds a threshold. The default threshold size is 8 MB.

```java
import java.util.Objects;
import java.util.UUID;

public void multipartUploadWithTransferManager(String filePath) {
    S3TransferManager transferManager = S3TransferManager.create();
    UploadFileRequest uploadFileRequest = UploadFileRequest.builder()
        .putObjectRequest(b -> b
            .bucket(bucketName)
            .key(key))
        .source(Paths.get(filePath))
        .build();
    FileUpload fileUpload = transferManager.uploadFile(uploadFileRequest);
    fileUpload.completionFuture().join();
    transferManager.close();
}
```

Use the S3Client API or (S3AsyncClient API) to perform a multipart upload.

```java
public void multipartUploadWithS3Client(String filePath) {
    // Initiate the multipart upload.
    CreateMultipartUploadResponse createMultipartUploadResponse =
        s3Client.createMultipartUpload(b -> b
            .bucket(bucketName)
            .key(key));
    String uploadId = createMultipartUploadResponse.uploadId();

    // Upload the parts of the file.
    int partNumber = 1;
    List<CompletedPart> completedParts = new ArrayList<>();
    ByteBuffer bb = ByteBuffer.allocate(1024 * 1024 * 5); // 5 MB byte buffer
    try (RandomAccessFile file = new RandomAccessFile(filePath, "r") { 
        long fileSize = file.length();
        int position = 0;
        while (position < fileSize) {
```
file.seek(position);
int read = file.getChannel().read(bb);

bb.flip(); // Swap position and limit before reading from the buffer.

UploadPartRequest uploadPartRequest = UploadPartRequest.builder()
    .bucket(bucketName)
    .key(key)
    .uploadId(uploadId)
    .partNumber(partNumber)
    .build();

UploadPartResponse partResponse = s3Client.uploadPart(
    uploadPartRequest,
    RequestBody.fromByteBuffer(bb));

CompletedPart part = CompletedPart.builder()
    .partNumber(partNumber)
    .eTag(partResponse.eTag())
    .build();
completedParts.add(part);

bb.clear();
position += read;
partNumber++;
}
} catch (IOException e) {
    logger.error(e.getMessage());
}

// Complete the multipart upload.
s3Client.completeMultipartUpload(b -> b
    .bucket(bucketName)
    .key(key)
    .uploadId(uploadId)
    .multipartUpload(CompletedMultipartUpload.builder().parts(completedParts).build()));

- For API details, see the following topics in AWS SDK for Java 2.x API Reference.
  - CompleteMultipartUpload
  - CreateMultipartUpload
Upload or download large files

The following code example shows how to upload or download large files to and from Amazon S3.

For more information, see [Uploading an object using multipart upload](#).

Call functions that transfer files to and from an S3 bucket using the S3TransferManager.

```java
public Integer downloadObjectsToDirectory(S3TransferManager transferManager,
                                          URI destinationPathURI, String bucketName) {
    DirectoryDownload directoryDownload =
        transferManager.downloadDirectory(DownloadDirectoryRequest.builder()        
            .destination(Paths.get(destinationPathURI))        
            .bucket(bucketName)        
            .build());
    CompletedDirectoryDownload completedDirectoryDownload =
        directoryDownload.completionFuture().join();
    completedDirectoryDownload.failedTransfers().
        forEach(fail -> logger.warn("Object {} failed to transfer",        
            fail.toString()));
    return completedDirectoryDownload.failedTransfers().size();
}
```

Upload an entire local directory.

```java
public Integer uploadDirectory(S3TransferManager transferManager,
                               URI sourceDirectory, String bucketName) {
    DirectoryUpload directoryUpload =
        transferManager.uploadDirectory(UploadDirectoryRequest.builder()        
```
Upload a single file.

```java
public String uploadFile(S3TransferManager transferManager, String bucketName, String key, URI filePathURI) {
    UploadFileRequest uploadFileRequest = UploadFileRequest.builder()
        .putObjectRequest(b -> b.bucket(bucketName).key(key))
        .addTransferListener(LoggingTransferListener.create())
        .source(Paths.get(filePathURI))
        .build();

    FileUpload fileUpload = transferManager.uploadFile(uploadFileRequest);
    CompletedFileUpload uploadResult = fileUpload.completionFuture().join();
    return uploadResult.response().eTag();
}
```

Upload stream of unknown size

The following code example shows how to upload a stream of unknown size to an Amazon S3 object.

 SDK for Java 2.x

ℹ️ Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/aws/aws-sdk-java-examples).
Use the **AWS CRT-based S3 Client**.

```java
import com.example.s3.util.AsyncExampleUtils;
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.core.async.AsyncRequestBody;
import software.amazon.awssdk.core.async.BlockingInputStreamAsyncRequestBody;
import software.amazon.awssdk.core.exception.SdkException;
import software.amazon.awssdk.services.s3.S3AsyncClient;
import software.amazon.awssdk.services.s3.model.PutObjectResponse;

import java.io.ByteArrayInputStream;
import java.util.UUID;
import java.util.concurrent.CompletableFuture;

/**
 * @param s3CrtAsyncClient - To upload content from a stream of unknown size, use the AWS CRT-based S3 client. For more information, see https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/crt-based-s3-client.html.
 * @param bucketName - The name of the bucket.
 * @param key - The name of the object.
 * @return software.amazon.awssdk.services.s3.model.PutObjectResponse - Returns metadata pertaining to the put object operation.
 */
public PutObjectResponse putObjectFromStream(S3AsyncClient s3CrtAsyncClient, String bucketName, String key) {

    BlockingInputStreamAsyncRequestBody body =
        AsyncRequestBody.forBlockingInputStream(null); // 'null' indicates a stream will be provided later.

    CompletableFuture<PutObjectResponse> responseFuture =
        s3CrtAsyncClient.putObject(r -> r.bucket(bucketName).key(key), body);

    // AsyncExampleUtils.randomString() returns a random string up to 100 characters.
    String randomString = AsyncExampleUtils.randomString();
    logger.info("random string to upload: {}\: length={}", randomString, randomString.length());

    // Provide the stream of data to be uploaded.
    body.writeInputStream(new ByteArrayInputStream(randomString.getBytes()));
}
```
    logger.info("Object {} uploaded to bucket {}.", key, bucketName);
    return response;
}
Use checksums

The following code example shows how to use checksums to work with an Amazon S3 object.

SDK for Java 2.x

```java
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.core.exception.SdkException;
import software.amazon.awssdk.core.sync.RequestBody;
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.model.ChecksumAlgorithm;
import software.amazon.awssdk.services.s3.model.ChecksumMode;
import software.amazon.awssdk.services.s3.model.CompletedMultipartUpload;
import software.amazon.awssdk.services.s3.model.CompletedPart;

// AsyncExampleUtils.randomString() returns a random string up to 100 characters.
String randomString = AsyncExampleUtils.randomString();
logger.info("random string to upload: {}, length={}", randomString,
randomString.length);

// Provide the stream of data to be uploaded.
body.writeInputStream(new ByteArrayInputStream(randomString.getBytes()));
return upload.completionFuture().join();
```

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

The code examples use a subset of the following imports.
Specify a checksum algorithm for the `putObject` method when you build the `PutObjectRequest`.

```java
public void putObjectWithChecksum() {
    s3Client.putObject(b -> b
        .bucket(bucketName)
        .key(key)
        .checksumAlgorithm(ChecksumAlgorithm.CRC32),
    RequestBody.fromString("This is a test"));
}
```

Verify the checksum for the `getObject` method when you build the `GetObjectRequest`.

```java
public GetObjectResponse getObjectWithChecksum() {
    return s3Client.getObject(b -> b
```
Pre-calculate a checksum for the `putObject` method when you build the `PutObjectRequest`.

```java
public void putObjectWithPrecalculatedChecksum(String filePath) {
    String checksum = calculateChecksum(filePath, "SHA-256");

    s3Client.putObject((b -> b
        .bucket(bucketName)
        .key(key)
        .checksumSHA256(checksum),
    RequestBody.fromFile(Paths.get(filePath)));
}
```

Use the [S3 Transfer Manager](https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/transfer-manager.html) on top of the [AWS CRT-based S3 client](https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/awscrt-s3-client.html) to transparently perform a multipart upload when the size of the content exceeds a threshold. The default threshold size is 8 MB.

You can specify a checksum algorithm for the SDK to use. By default, the SDK uses the CRC32 algorithm.

```java
public void multipartUploadWithChecksumTm(String filePath) {
    S3TransferManager transferManager = S3TransferManager.create();
    UploadFileRequest uploadFileRequest = UploadFileRequest.builder()
        .putObjectRequest(b -> b
            .bucket(bucketName)
            .key(key)
            .checksumAlgorithm(ChecksumAlgorithm.SHA1)
        .source(Paths.get(filePath))
        .build();
    FileUpload fileUpload = transferManager.uploadFile(uploadFileRequest);
    fileUpload.completionFuture().join();
    transferManager.close();
}
```
Use the **S3Client API** or (S3AsyncClient API) to perform a multipart upload. If you specify an additional checksum, you must specify the algorithm to use on the initiation of the upload. You must also specify the algorithm for each part request and provide the checksum calculated for each part after it is uploaded.

```java
public void multipartUploadWithChecksumS3Client(String filePath) {
    ChecksumAlgorithm algorithm = ChecksumAlgorithm.CRC32;

    // Initiate the multipart upload.
    CreateMultipartUploadResponse createMultipartUploadResponse = 
        s3Client.createMultipartUpload(b -> b
            .bucket(bucketName)
            .key(key)
            .checksumAlgorithm(algorithm)); // Checksum specified on initiation.
    String uploadId = createMultipartUploadResponse.uploadId();

    // Upload the parts of the file.
    int partNumber = 1;
    List<CompletedPart> completedParts = new ArrayList<>();
    ByteBuffer bb = ByteBuffer.allocate(1024 * 1024 * 5); // 5 MB byte buffer

    try (RandomAccessFile file = new RandomAccessFile(filePath, "r")) {
        long fileSize = file.length();
        int position = 0;
        while (position < fileSize) {
            file.seek(position);
            int read = file.getChannel().read(bb);

            bb.flip(); // Swap position and limit before reading from the buffer.

            UploadPartRequest uploadPartRequest = UploadPartRequest.builder()
                .bucket(bucketName)
                .key(key)
                .uploadId(uploadId)
                .checksumAlgorithm(algorithm) // Checksum specified on each part.
                .partNumber(partNumber)
                .build();

            UploadPartResponse partResponse = s3Client.uploadPart(
                uploadPartRequest,
                RequestBody.fromByteBuffer(bb));
        }
    }
}
```
CompletedPart part = CompletedPart.builder().partNumber(partNumber)
    .checksumCRC32(partResponse.checksumCRC32()) // Provide the calculated checksum.
    .eTag(partResponse.eTag())
    .build();
completedParts.add(part);

bb.clear();
position += read;
partNumber++;
}
} catch (IOException e) {
    System.err.println(e.getMessage());
}

// Complete the multipart upload.
S3Client.completeMultipartUpload(b -> b
    .bucket(bucketName)
    .key(key)
    .uploadId(uploadId)

    .multipartUpload(CompletedMultipartUpload.builder().parts(completedParts).build()));
}

- For API details, see the following topics in AWS SDK for Java 2.x API Reference.
  - CompleteMultipartUpload
  - CreateMultipartUpload
  - UploadPart

Serverless examples

Invoke a Lambda function from an Amazon S3 trigger

The following code example shows how to implement a Lambda function that receives an event triggered by uploading an object to an S3 bucket. The function retrieves the S3 bucket name and object key from the event parameter and calls the Amazon S3 API to retrieve and log the content type of the object.
Consuming an S3 event with Lambda using Java.

```java
package example;

import software.amazon.awssdk.services.s3.model.HeadObjectRequest;
import software.amazon.awssdk.services.s3.model.HeadObjectResponse;
import software.amazon.awssdk.services.s3.S3Client;

import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.lambda.runtime.RequestHandler;
import com.amazonaws.services.lambda.runtime.events.S3Event;
import com.amazonaws.services.lambda.runtime.events.models.s3.S3EventNotification.S3EventNotificationRecord;
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;

public class Handler implements RequestHandler<S3Event, String> {
    private static final Logger logger = LoggerFactory.getLogger(Handler.class);

    @Override
    public String handleRequest(S3Event s3event, Context context) {
        try {
            S3EventNotificationRecord record = s3event.getRecords().get(0);
            String srcBucket = record.getS3().getBucket().getName();
            String srcKey = record.getS3().getObject().getUrlDecodedKey();

            S3Client s3Client = S3Client.builder().build();
            HeadObjectResponse headObject = getHeadObject(s3Client, srcBucket, srcKey);

            logger.info("Successfully retrieved " + srcBucket + "/" + srcKey + " of type " + headObject.contentType());
            return "Ok";
        } catch (Exception e) {
            return "Error: " + e.getMessage();
        }
    }
}
```
throw new RuntimeException(e);
}

private HeadObjectResponse getHeadObject(S3Client s3Client, String bucket, String key) {
    HeadObjectRequest headObjectRequest = HeadObjectRequest.builder()
        .bucket(bucket)
        .key(key)
        .build();
    return s3Client.headObject(headObjectRequest);
}

S3 Glacier examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with S3 Glacier.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

### SageMaker examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with SageMaker.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

**Get started**

**Hello SageMaker**

The following code examples show how to get started using SageMaker.
/*
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */

public class HelloSageMaker {
    public static void main(String[] args) {
        Region region = Region.US_WEST_2;
        SageMakerClient sageMakerClient = SageMakerClient.builder()
                .region(region)
                .build();

        listBooks(sageMakerClient);
        sageMakerClient.close();
    }

    public static void listBooks(SageMakerClient sageMakerClient) {
        try {
            ListNotebookInstancesResponse notebookInstancesResponse =
                    sageMakerClient.listNotebookInstances();
            List<NotebookInstanceSummary> items =
                    notebookInstancesResponse.notebookInstances();
            for (NotebookInstanceSummary item : items) {
                System.out.println("The notebook name is: "+
                        item.notebookInstanceName());
                }
        } catch (SageMakerException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
}
Actions

Create a pipeline

The following code example shows how to create or update a pipeline in SageMaker.

```
// Create a pipeline from the example pipeline JSON.
public static void setupPipeline(SageMakerClient sageMakerClient, String filePath, String roleArn, String functionArn, String pipelineName) {
    System.out.println("Setting up the pipeline.");
    JSONParser parser = new JSONParser();

    // Read JSON and get pipeline definition.
    try (FileReader reader = new FileReader(filePath)) {
        Object obj = parser.parse(reader);
        JSONObject jsonObject = (JSONObject) obj;
        JSONArray stepsArray = (JSONArray) jsonObject.get("Steps");
        for (Object stepObj : stepsArray) {
            JSONObject step = (JSONObject) stepObj;
            if (step.containsKey("FunctionArn")) {
```

**Topics**

- **Scenarios**

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/aws-samples/aws-code-examples).
% step.put("FunctionArn", functionArn);
%
} System.out.println(jsonObject);
%
// Create the pipeline.
CreatePipelineRequest pipelineRequest = CreatePipelineRequest.builder()
  .pipelineDescription("Java SDK example pipeline")
  .roleArn(roleArn)
  .pipelineName(pipelineName)
  .pipelineDefinition(jsonObject.toString())
  .build();
%
sagemakerClient.createPipeline(pipelineRequest);
%
} catch (IamException e) {
  System.err.println(e.awsErrorDetails().errorMessage());
  System.exit(1);
} catch (IOException | ParseException e) {
  throw new RuntimeException(e);
%
%

  • CreatePipeline
  • UpdatePipeline

Delete a pipeline

The following code example shows how to delete a pipeline in SageMaker.

SDK for Java 2.x

![Note]

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/aws-samples/aws-sdk-java-examples).

// Delete a SageMaker pipeline by name.
public static void deletePipeline(SageMakerClient sageMakerClient, String pipelineName) {
    DeletePipelineRequest pipelineRequest = DeletePipelineRequest.builder()
        .pipelineName(pipelineName)
        .build();

    sageMakerClient.deletePipeline(pipelineRequest);
    System.out.println("*** Successfully deleted " + pipelineName);
}

• For API details, see DeletePipeline in AWS SDK for Java 2.x API Reference.

Describe a pipeline execution

The following code example shows how to describe a pipeline execution in SageMaker.

SDK for Java 2.x

// Check the status of a pipeline execution.
public static void waitForPipelineExecution(SageMakerClient sageMakerClient, String executionArn)
    throws InterruptedException {
    String status;
    int index = 0;
    do {
        DescribePipelineExecutionRequest pipelineExecutionRequest = DescribePipelineExecutionRequest.builder()
            .pipelineExecutionArn(executionArn)
            .build();

        DescribePipelineExecutionResponse response = sageMakerClient.describePipelineExecution(pipelineExecutionRequest);
        status = response.pipelineExecutionStatusAsString();
        System.out.println(index + ". The Status of the pipeline is "+ status);
        TimeUnit.SECONDS.sleep(4);
    } while (!status.equals("Success"));
}
Execute a pipeline

The following code example shows how to start a pipeline execution in SageMaker.

SDK for Java 2.x

```java
// Start a pipeline run with job configurations.
public static String executePipeline(SageMakerClient sageMakerClient, String bucketName, String queueUrl,
                                     String roleArn, String pipelineName) {
    System.out.println("Starting pipeline execution.");
    String inputBucketLocation = "s3://" + bucketName + "/samplefiles/latlongtest.csv";
    String output = "s3://" + bucketName + "/outputfiles/";
    Gson gson = new GsonBuilder()
        .setFieldNamingPolicy(FieldNamingPolicy.UPPER_CAMEL_CASE)
        .setPrettyPrinting().create();

    // Set up all parameters required to start the pipeline.
    List<Parameter> parameters = new ArrayList<>();
    Parameter para1 = Parameter.builder()
        .name("parameter_execution_role")
        .value(roleArn)
        .build();

    Parameter para2 = Parameter.builder()
        .name("parameter_queue_url")
        .value(queueUrl)
```

- For API details, see [DescribePipelineExecution](#) in *AWS SDK for Java 2.x API Reference*.
.build();

String inputJSON = "{\n" +
  "\"DataSourceConfig\": {\n" +
    "\"S3Data\": {\n" +
      "\"S3Uri\": "s3://" + bucketName + "/samplefiles/latlongtest.csv\"\n" +
    },\n" +

sageMakerClient.startPipelineExecution(pipelineExecutionRequest);
return response.pipelineExecutionArn();
}

- For API details, see StartPipelineExecution in AWS SDK for Java 2.x API Reference.

Scenarios

Get started with geospatial jobs and pipelines

The following code example shows how to:

- Set up resources for a pipeline.
• Set up a pipeline that executes a geospatial job.
• Start a pipeline execution.
• Monitor the status of the execution.
• View the output of the pipeline.
• Clean up resources.

For more information, see Create and run SageMaker pipelines using AWS SDKs on Community.aws.

SDK for Java 2.x

⚠️ Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```java
public class SagemakerWorkflow {
    public static final String DASHES = new String(new char[80]).replace("\0", "-"),
    private static String eventSourceMapping = "";

    public static void main(String[] args) throws InterruptedException {
        final String usage = "\n" +
            "Usage:\n" + " <sageMakerRoleName> <lambdaRoleName> <functionFileLocation>
            <functionName> <queueName> <bucketName> <lnglatData> <spatialPipelinePath>
            <pipelineName>\n" +
            "Where:\n" + " sageMakerRoleName - The name of the Amazon SageMaker role.\n" +
            " lambdaRoleName - The name of the AWS Lambda role.\n" +
            " functionFileLocation - The file location where the JAR file that represents the AWS Lambda function is located.\n" +
            " functionName - The name of the AWS Lambda function (for example,SageMakerExampleFunction).\n" +
            " queueName - The name of the Amazon Simple Queue Service (Amazon SQS) queue.\n" +
    }
```
bucketName - The name of the Amazon Simple Storage Service (Amazon S3) bucket.
lnglatData - The file location of the latlongtest.csv file required for this use case.
spatialPipelinePath - The file location of the GeoSpatialPipeline.json file required for this use case.
pipelineName - The name of the pipeline to create (for example, sagemaker-sdk-example-pipeline).

if (args.length != 9) {
    System.out.println(usage);
    System.exit(1);
}

String sageMakerRoleName = args[0];
String lambdaRoleName = args[1];
String functionFileLocation = args[2];
String functionName = args[3];
String queueName = args[4];
String bucketName = args[5];
String lnglatData = args[6];
String spatialPipelinePath = args[7];
String pipelineName = args[8];
String handlerName = "org.example.SageMakerLambdaFunction::handleRequest";

Region region = Region.US_WEST_2;
SageMakerClient sageMakerClient = SageMakerClient.builder()
    .region(region)
    .build();

IamClient iam = IamClient.builder()
    .region(region)
    .build();

LambdaClient lambdaClient = LambdaClient.builder()
    .region(region)
    .build();

SqsClient sqsClient = SqsClient.builder()
    .region(region)
    .build();

S3Client s3Client = S3Client.builder()
Set up the roles, functions, and queue needed by the SageMaker pipeline.

String lambdaRoleArn = checkLambdaRole(iam, lambdaRoleName);
String sageMakerRoleArn = checkSageMakerRole(iam, sageMakerRoleName);

String functionArn = checkFunction(lambdaClient, functionName,
handlerName);

**Secrets Manager examples using SDK for Java 2.x**

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Secrets Manager.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

List email templates

The following code example shows how to list Amazon SES email templates.

SDK for Java 2.x

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sesv2.SesV2Client;
import software.amazon.awssdk.services.sesv2.model.ListEmailTemplatesRequest;
import software.amazon.awssdk.services.sesv2.model.ListEmailTemplatesResponse;
import software.amazon.awssdk.services.sesv2.model.SesV2Exception;

public class ListTemplates {

    public static void main(String[] args) {
        Region region = Region.US_EAST_1;
        SesV2Client sesv2Client = SesV2Client.builder()
            .region(region)
            .build();

        listAllTemplates(sesv2Client);
    }

    public static void listAllTemplates(SesV2Client sesv2Client) {
        try {
            ListEmailTemplatesRequest templatesRequest =
                ListEmailTemplatesRequest.builder()
                    .pageSize(1)
                    .build();

            ListEmailTemplatesResponse response =
                sesv2Client.listEmailTemplates(templatesRequest);
            response.templatesMetadata().
                forEach(template -> System.out.println("Template name: " +
                    template.templateName()));
        } catch (SesV2Exception e) {
            System.err.println(e.getMessage());
        }
    }
}
```

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Amazon SNS examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon SNS.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Get started

Hello Amazon SNS

The following code examples show how to get started using Amazon SNS.
package com.example.sns;

import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sns.SnsClient;
import software.amazon.awssdk.services.sns.model.SnsException;
import software.amazon.awssdk.services.sns.paginators.ListTopicsIterable;

public class HelloSNS {
    public static void main(String[] args) {
        SnsClient snsClient = SnsClient.builder()
            .region(Region.US_EAST_1)
            .build();

        listSNSTopics(snsClient);
        snsClient.close();
    }

    public static void listSNSTopics(SnsClient snsClient) {
        try {
            ListTopicsIterable listTopics = snsClient.listTopicsPaginator();
            listTopics.stream()
                .flatMap(r -> r.topics().stream())
                .forEach(content -> System.out.println(" Topic ARN: " +
                    content.topicArn()));
        } catch (SnsException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
}

- For API details, see [ListTopics](#) in AWS SDK for Java 2.x API Reference.
Actions

Add tags to a topic

The following code example shows how to add tags to an Amazon SNS topic.

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sns.SnsClient;
import software.amazon.awssdk.services.sns.model.SnsException;
import software.amazon.awssdk.services.sns.model.Tag;
import software.amazon.awssdk.services.sns.model.TagResourceRequest;
import java.util.ArrayList;
import java.util.List;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class AddTags {
    public static void main(String[] args) {
        final String usage = "Usage: <topicArn>"
        final String usage = "Usage: <topicArn>"
    }
}
```

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://aws.amazon.com/code-examples/).
Where:
  topicArn - The ARN of the topic to which tags are added.

"""

if (args.length != 1) {
    System.out.println(usage);
    System.exit(1);
}

String topicArn = args[0];
SnsClient snsClient = SnsClient.builder()
    .region(Region.US_EAST_1)
    .build();

addTopicTags(snsClient, topicArn);
snsClient.close();
}

public static void addTopicTags(SnsClient snsClient, String topicArn) {
    try {
        Tag tag = Tag.builder()
            .key("Team")
            .value("Development")
            .build();

        Tag tag2 = Tag.builder()
            .key("Environment")
            .value("Gamma")
            .build();

        List<Tag> tagList = new ArrayList<>();
tagList.add(tag);
tagList.add(tag2);

        TagResourceRequest tagResourceRequest = TagResourceRequest.builder()
            .resourceArn(topicArn)
            .tags(tagList)
            .build();

        snsClient.tagResource(tagResourceRequest);
        System.out.println("Tags have been added to " + topicArn);
For API details, see [TagResource](#) in [AWS SDK for Java 2.x API Reference](#).

**Check whether a phone number is opted out**

The following code example shows how to check whether a phone number is opted out of receiving Amazon SNS messages.

### SDK for Java 2.x

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sns.SnsClient;
import software.amazon.awssdk.services.sns.model.CheckIfPhoneNumberIsOptedOutRequest;
import software.amazon.awssdk.services.sns.model.CheckIfPhoneNumberIsOptedOutResponse;
import software.amazon.awssdk.services.sns.model.SnsException;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 * For more information, see the following documentation topic:
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class CheckOptOut {
    public static void main(String[] args) {
```

[Note](#) There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).
final String usage = """";

Usage:  <phoneNumber>
Where:
    phoneNumber - The mobile phone number to look up (for example, +1XXX5550100).
""";

if (args.length != 1) {
    System.out.println(usage);
    System.exit(1);
}

String phoneNumber = args[0];
SnsClient snsClient = SnsClient.builder()
    .region(Region.US_EAST_1)
    .build();

checkPhone(snsClient, phoneNumber);
snsClient.close();
}

public static void checkPhone(SnsClient snsClient, String phoneNumber) {
    try {
        CheckIfPhoneNumberIsOptedOutRequest request =
            CheckIfPhoneNumberIsOptedOutRequest.builder()
                .phoneNumber(phoneNumber)
                .build();

        CheckIfPhoneNumberIsOptedOutResponse result =
            snsClient.checkIfPhoneNumberIsOptedOut(request);
        System.out.println(
            result.isOptedOut() + "Phone Number " + phoneNumber + " has
            Opted Out of receiving sns messages." +
            "\n\nStatus was " +
            result.sdkHttpResponse().statusCode());
    } catch (SnsException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
Confirm an endpoint owner wants to receive messages

The following code example shows how to confirm the owner of an endpoint wants to receive Amazon SNS messages by validating the token sent to the endpoint by an earlier Subscribe action.

SDK for Java 2.x

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sns.SnsClient;
import software.amazon.awssdk.services.sns.model.ConfirmSubscriptionRequest;
import software.amazon.awssdk.services.sns.model.ConfirmSubscriptionResponse;
import software.amazon.awssdk.services.sns.model.SnsException;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 * For more information, see the following documentation topic:
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class ConfirmSubscription {
    public static void main(String[] args) {
        final String usage = ""
        Usage: <subscriptionToken> <topicArn>

        Where:
        subscriptionToken - A short-lived token sent to an endpoint during the Subscribe action.
```
topicArn - The ARN of the topic.

if (args.length != 2) {
    System.out.println(usage);
    System.exit(1);
}

String subscriptionToken = args[0];
String topicArn = args[1];
SnsClient snsClient = SnsClient.builder().region(Region.US_EAST_1).build();

confirmSub(snsClient, subscriptionToken, topicArn);
snsClient.close();
}

public static void confirmSub(SnsClient snsClient, String subscriptionToken, String topicArn) {
    try {
      ConfirmSubscriptionRequest request =
        ConfirmSubscriptionRequest.builder()
        .token(subscriptionToken)
        .topicArn(topicArn)
        .build();

      ConfirmSubscriptionResponse result =
        snsClient.confirmSubscription(request);
      System.out.println("\n\nStatus was " +
        result.sdkHttpResponse().statusCode() + "\n\nSubscription Arn: \n\n" + result.subscriptionArn());
}

    catch (SnsException e) {
      System.err.println(e.awsErrorDetails().errorMessage());
      System.exit(1);
    }
}

• For API details, see ConfirmSubscription in AWS SDK for Java 2.x API Reference.
Create a topic

The following code example shows how to create an Amazon SNS topic.

SDK for Java 2.x

import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sns.SnsClient;
import software.amazon.awssdk.services.sns.model.CreateTopicRequest;
import software.amazon.awssdk.services.sns.model.CreateTopicResponse;
import software.amazon.awssdk.services.sns.model.SnsException;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 * 
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class CreateTopic {
    public static void main(String[] args) {
        final String usage = ""
        Usage: <topicName>

        Where:
        topicName - The name of the topic to create (for example, mytopic).

        "";

        if (args.length != 1) {
            System.out.println(usage);
            System.out.println(usage);
            System.exit(1);
        }
    }
}
String topicName = args[0];
System.out.println("Creating a topic with name: " + topicName);
SnsClient snsClient = SnsClient.builder()
  .region(Region.US_EAST_1)
  .build();

String arnVal = createSNSTopic(snsClient, topicName);
System.out.println("The topic ARN is" + arnVal);
snsClient.close();
}

public static String createSNSTopic(SnsClient snsClient, String topicName) {
  CreateTopicResponse result;
  try {
    CreateTopicRequest request = CreateTopicRequest.builder()
      .name(topicName)
      .build();

    result = snsClient.createTopic(request);
    return result.topicArn();
  }
  catch (SnsException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
  }
  return "";
}

• For API details, see CreateTopic in AWS SDK for Java 2.x API Reference.

Delete a subscription

The following code example shows how to delete an Amazon SNS subscription.

SDK for Java 2.x

ℹ️ Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
import software.amazon.awssdk.regions.Region;

 */
public class DeleteTopic {
    public static void main(String[] args) {
        final String usage = """";

        Usage: <topicArn>

        Where:
        topicArn - The ARN of the topic to delete.
        """

        if (args.length != 1) {
            System.out.println(usage);
            System.exit(1);
        }

        String topicArn = args[0];
        SnsClient snsClient = SnsClient.builder()
            .region(Region.US_EAST_1)
            .build();

        System.out.println("Deleting a topic with name: " + topicArn);
        deleteSNSTopic(snsClient, topicArn);
        snsClient.close();
    }

    public static void deleteSNSTopic(SnsClient snsClient, String topicArn) {
        try {
            DeleteTopicRequest request = DeleteTopicRequest.builder()
                .topicArn(topicArn)
                .build();

            DeleteTopicResponse result = snsClient.deleteTopic(request);
            System.out.println("\n\nStatus was " + result.sdkHttpResponse().statusCode());
        } catch (SnsException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
}
For API details, see DeleteTopic in AWS SDK for Java 2.x API Reference.

Get the properties of a topic

The following code example shows how to get the properties of an Amazon SNS topic.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sns.SnsClient;
import software.amazon.awssdk.services.sns.model.GetTopicAttributesRequest;
import software.amazon.awssdk.services.sns.model.GetTopicAttributesResponse;
import software.amazon.awssdk.services.sns.model.SnsException;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 * For more information, see the following documentation topic:
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class GetTopicAttributes {
    public static void main(String[] args) {
        final String usage = ""
        Usage:    <topicArn>
        Where:
            topicArn - The ARN of the topic to look up.
        "";
        if (args.length != 1) {
```
For API details, see [GetTopicAttributes](https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/aws-java-sdk-api.html) in AWS SDK for Java 2.x API Reference.

Get the settings for sending SMS messages

The following code example shows how to get the settings for sending Amazon SNS SMS messages.
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sns.SnsClient;
import software.amazon.awssdk.services.sns.model.GetSubscriptionAttributesRequest;
import software.amazon.awssdk.services.sns.model.GetSubscriptionAttributesResponse;
import software.amazon.awssdk.services.sns.model.SnsException;
import java.util.Iterator;
import java.util.Map;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 * For more information, see the following documentation topic:
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class GetSmsAttributes {
    public static void main(String[] args) {
        final String usage = """ Usage: <topicArn>

Where:
    topicArn - The ARN of the topic from which to retrieve attributes.
"""

        if (args.length != 1) {
            System.out.println(usage);
            System.exit(1);
        }

        String topicArn = args[0];
        SnsClient snsClient = SnsClient.builder().build();

        GetSubscriptionAttributesRequest request = GetSubscriptionAttributesRequest.builder().topicArn(topicArn).build();
        GetSubscriptionAttributesResponse response = snsClient.getSubscriptionAttributes(request);

        if (response.errors.isPresent()) {
            System.out.println("Error: ", response.errors.get().toString());
            System.exit(1);
        } else {
            Map<String, String> attributes = response.attributes();
            System.out.println(attributes.toString());
        }
    }
}
For API details, see [GetSMSSAttributes](#) in [AWS SDK for Java 2.x API Reference](#).

### List opted out phone numbers

The following code example shows how to list phone numbers that are opted out of receiving Amazon SNS messages.
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sns.SnsClient;
import software.amazon.awssdk.services.sns.model.ListPhoneNumbersOptedOutRequest;
import software.amazon.awssdk.services.sns.model.ListPhoneNumbersOptedOutResponse;
import software.amazon.awssdk.services.sns.model.SnsException;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 * For more information, see the following documentation topic:
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class ListOptOut {
    public static void main(String[] args) {
        SnsClient snsClient = SnsClient.builder()
                .region(Region.US_EAST_1)
                .build();

        listOpts(snsClient);
        snsClient.close();
    }

    public static void listOpts(SnsClient snsClient) {
        try {
            ListPhoneNumbersOptedOutRequest request =
                    ListPhoneNumbersOptedOutRequest.builder().build();
            ListPhoneNumbersOptedOutResponse result =
                    snsClient.listPhoneNumbersOptedOut(request);
            System.out.println("Status is " + result.sdkHttpResponse().statusCode() + "\n\nPhone Numbers: \n\n" + result.phoneNumbers());
        } catch (SnsException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
}
For API details, see [ListPhoneNumbersOptedOut](#) in *AWS SDK for Java 2.x API Reference*.

### List the subscribers of a topic

The following code example shows how to retrieve the list of subscribers of an Amazon SNS topic.

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sns.SnsClient;
import software.amazon.awssdk.services.sns.model.ListSubscriptionsRequest;
import software.amazon.awssdk.services.sns.model.ListSubscriptionsResponse;
import software.amazon.awssdk.services.sns.model.SnsException;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 * For more information, see the following documentation topic:
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class ListSubscriptions {
    public static void main(String[] args) {
        SnsClient snsClient = SnsClient.builder()
            .region(Region.US_EAST_1)
            .build();
```
listSNSSubscriptions(snsClient);
snsClient.close();
}

public static void listSNSSubscriptions(SnsClient snsClient) {
  try {
    ListSubscriptionsRequest request = ListSubscriptionsRequest.builder()
        .build();

    ListSubscriptionsResponse result = snsClient.listSubscriptions(request);
    System.out.println(result.subscriptions());
  } catch (SnsException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
  }
}

• For API details, see ListSubscriptions in AWS SDK for Java 2.x API Reference.

List topics

The following code example shows how to list Amazon SNS topics.

SDK for Java 2.x

import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sns.SnsClient;
import software.amazon.awssdk.services.sns.model.ListTopicsRequest;
import software.amazon.awssdk.services.sns.model.ListTopicsResponse;
import software.amazon.awssdk.services.sns.model.SnsException;

Note

        String topicArn = args[1];
        SnsClient snsClient = SnsClient.builder()
            .region(Region.US_EAST_1)
            .build();
        pubTopic(snsClient, message, topicArn);
        snsClient.close();
    }

    public static void pubTopic(SnsClient snsClient, String message, String topicArn) {
        try {
            PublishRequest request = PublishRequest.builder()
                .message(message)
                .topicArn(topicArn)
For API details, see Publish in AWS SDK for Java 2.x API Reference.

Set a filter policy

The following code example shows how to set an Amazon SNS filter policy.

SDK for Java 2.x

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sns.SnsClient;
import software.amazon.awssdk.services.sns.model.SnsException;
import java.util.ArrayList;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 * For more information, see the following documentation topic:
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
```
public class UseMessageFilterPolicy {
    public static void main(String[] args) {
        final String usage = ""

        Usage:    <subscriptionArn>

        Where:
        subscriptionArn - The ARN of a subscription.

        "";

        if (args.length != 1) {
            System.out.println(usage);
            System.exit(1);
        }

        String subscriptionArn = args[0];
        SnsClient snsClient = SnsClient.builder()
            .region(Region.US_EAST_1)
            .build();

        usePolicy(snsClient, subscriptionArn);
        snsClient.close();
    }

    public static void usePolicy(SnsClient snsClient, String subscriptionArn) {
        try {
            SNSMessageFilterPolicy fp = new SNSMessageFilterPolicy();
            // Add a filter policy attribute with a single value
            fp.addAttribute("store", "example_corp");
            fp.addAttribute("event", "order_placed");
            // Add a prefix attribute
            fp.addAttributePrefix("customer_interests", "bas");
            // Add an anything-but attribute
            fp.addAttributeAnythingBut("customer_interests", "baseball");

            // Add a filter policy attribute with a list of values
            ArrayList<String> attributeValues = new ArrayList<>();
            attributeValues.add("rugby");
            attributeValues.add("soccer");
            attributeValues.add("hockey");
            fp.addAttribute("customer_interests", attributeValues);
        }
    }
}

Amazon SNS
// Add a numeric attribute
fp.addAttribute("price_usd", "," , 0);

// Add a numeric attribute with a range
fp.addAttributeRange("price_usd", "," , 0 , "," , 100);

// Apply the filter policy attributes to an Amazon SNS subscription
fp.apply(snsClient, subscriptionArn);

} catch (SnsException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

• For API details, see SetSubscriptionAttributes in AWS SDK for Java 2.x API Reference.

Set the default settings for sending SMS messages

The following code example shows how to set the default settings for sending SMS messages using Amazon SNS.

SDK for Java 2.x

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sns.SnsClient;
import software.amazon.awssdk.services.sns.model.SetSmsAttributesRequest;
import software.amazon.awssdk.services.sns.model.SetSmsAttributesResponse;
import software.amazon.awssdk.services.sns.model.SnsException;
import java.util.HashMap;

/**
 * Note
 * There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
 */
```
Before running this Java V2 code example, set up your development environment, including your credentials.  
* For more information, see the following documentation topic:  
* https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html */

```java
public class SetSMSAttributes {
    public static void main(String[] args) {
        HashMap<String, String> attributes = new HashMap<>(1);
        attributes.put("DefaultSMSType", "Transactional");
        attributes.put("UsageReportS3Bucket", "janbucket");

        SnsClient snsClient = SnsClient.builder()
            .region(Region.US_EAST_1)
            .build();
        setSNSAttributes(snsClient, attributes);
        snsClient.close();
    }

    public static void setSNSAttributes(SnsClient snsClient, HashMap<String, String> attributes) {
        try {
            SetSmsAttributesRequest request = SetSmsAttributesRequest.builder()
                .attributes(attributes)
                .build();

            SetSmsAttributesResponse result = snsClient.setSMSAttributes(request);
            System.out.println("Set default Attributes to " + attributes + ". Status was "+ result.sdkHttpResponse().statusCode());
        } catch (SnsException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
}
```

- For API details, see [SetSMSAttributes](https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html) in *AWS SDK for Java 2.x API Reference.*
Set topic attributes

The following code example shows how to set Amazon SNS topic attributes.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/awslabs/aws-code-examples).

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sns.SnsClient;
import software.amazon.awssdk.services.sns.model.SetTopicAttributesRequest;
import software.amazon.awssdk.services.sns.model.SetTopicAttributesResponse;
import software.amazon.awssdk.services.sns.model.SnsException;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 * For more information, see the following documentation topic:
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class SetTopicAttributes {
    public static void main(String[] args) {
        final String usage = ""
        final String usage = ""
            Usage: <attribute> <topicArn> <value>
            Where:
            attribute - The attribute action to use. Valid parameters are: Policy | DisplayName | DeliveryPolicy .
            topicArn - The ARN of the topic.
            value - The value for the attribute.
            ""
            if (args.length < 3) {
                System.out.println(usage);
                System.out.println(usage);
                System.exit(1);
            }
```
String attribute = args[0];
String topicArn = args[1];

        System.exit(1);
    }
}

• For API details, see SetTopicAttributes in AWS SDK for Java 2.x API Reference.
Subscribe a Lambda function to a topic

The following code example shows how to subscribe a Lambda function so it receives notifications from an Amazon SNS topic.

SDK for Java 2.x

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sns.SnsClient;
import software.amazon.awssdk.services.sns.model.SnsException;
import software.amazon.awssdk.services.sns.model.SubscribeRequest;
import software.amazon.awssdk.services.sns.model.SubscribeResponse;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 * For more information, see the following documentation topic:
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class SubscribeLambda {

    public static void main(String[] args) {

        final String usage = ""
        Usage:    <topicArn> <lambdaArn>

        Where:
            topicArn - The ARN of the topic to subscribe.
            lambdaArn - The ARN of an AWS Lambda function.
            "";

        if (args.length != 2) {
            System.out.println(usage);
        }
```

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
System.exit(1);
}

String topicArn = args[0];
String lambdaArn = args[1];
SnsClient snsClient = SnsClient.builder()
    .region(Region.US_EAST_1)
    .build();

String arnValue = subLambda(snsClient, topicArn, lambdaArn);
System.out.println("Subscription ARN: " + arnValue);
snsClient.close();
}

public static String subLambda(SnsClient snsClient, String topicArn, String lambdaArn) {
    try {
        SubscribeRequest request = SubscribeRequest.builder()
            .protocol("lambda")
            .endpoint(lambdaArn)
            .returnSubscriptionArn(true)
            .topicArn(topicArn)
            .build();

        SubscribeResponse result = snsClient.subscribe(request);
        return result.subscriptionArn();
    } catch (SnsException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
    return "";
}

Subscribe an HTTP endpoint to a topic

The following code example shows how to subscribe an HTTP or HTTPS endpoint so it receives notifications from an Amazon SNS topic.
SDK for Java 2.x

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sns.SnsClient;
import software.amazon.awssdk.services.sns.model.SnsException;
import software.amazon.awssdk.services.sns.model.SubscribeRequest;
import software.amazon.awssdk.services.sns.model.SubscribeResponse;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 * For more information, see the following documentation topic:
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class SubscribeHTTPS {

    public static void main(String[] args) {
        final String usage = "Usage: <topicArn> <url>
Where:
    topicArn - The ARN of the topic to subscribe.
    url - The HTTPS endpoint that you want to receive notifications."

        if (args.length < 2) {
            System.out.println(usage);
            System.exit(1);
        }

        String topicArn = args[0];
        String url = args[1];
        SnsClient snsClient = SnsClient.builder()
            .region(Region.US_EAST_1)
```

Amazon SNS
```java
    build();

    subHTTPS(snsClient, topicArn, url);
    snsClient.close();
}

public static void subHTTPS(SnsClient snsClient, String topicArn, String url) {
    try {
        SubscribeRequest request = SubscribeRequest.builder()
            .protocol("https")
            .endpoint(url)
            .returnSubscriptionArn(true)
            .topicArn(topicArn)
            .build();

        SubscribeResponse result = snsClient.subscribe(request);
        System.out.println("Subscription ARN is " + result.subscriptionArn() +
            "\n\n    Status is "
            + result.sdkHttpResponse().statusCode());
    } catch (SnsException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

        }
    }
}
For API details, see Subscribe in AWS SDK for Java 2.x API Reference.

Scenarios

Create a platform endpoint for push notifications

The following code example shows how to create a platform endpoint for Amazon SNS push notifications.

SDK for Java 2.x

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sns.SnsClient;
import software.amazon.awssdk.services.sns.model.CreatePlatformEndpointRequest;
import software.amazon.awssdk.services.sns.model.CreatePlatformEndpointResponse;
import software.amazon.awssdk.services.sns.model.SnsException;
```
/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 * For more information, see the following documentation topic:
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 * In addition, create a platform application using the AWS Management Console.
 * See this doc topic:
 * https://docs.aws.amazon.com/sns/latest/dg/mobile-push-send-register.html
 * Without the values created by following the previous link, this code examples does not work.
 */

public class RegistrationExample {
    public static void main(String[] args) {
        String usage = """";
        usage += "Usage: <token> <platformApplicationArn>
            Where:
            token - The name of the FIFO topic.
            platformApplicationArn - The ARN value of platform application.
            You can get this value from the AWS Management Console.
        ""
        
        if (args.length != 2) {
            System.out.println(usage);
            System.exit(1);
        }

        String token = args[0];
        String platformApplicationArn = args[1];
        SnsClient snsClient = SnsClient.builder()
            .region(Region.US_EAST_1)
            .build();

        createEndpoint(snsClient, token, platformApplicationArn);
    }
}
public static void createEndpoint(SnsClient snsClient, String token, String platformApplicationArn) {
    System.out.println("Creating platform endpoint with token " + token);
    try {
        CreatePlatformEndpointRequest endpointRequest =
            CreatePlatformEndpointRequest.builder()
                .token(token)
                .platformApplicationArn(platformApplicationArn)
                .build();

        CreatePlatformEndpointResponse response =
            snsClient.createPlatformEndpoint(endpointRequest);
        System.out.println("The ARN of the endpoint is " +
        response.endpointArn());
    } catch (SnsException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}

Create and publish to a FIFO topic

The following code example shows how to create and publish to a FIFO Amazon SNS topic.

SDK for Java 2.x

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

This example
- creates an Amazon SNS FIFO topic, two Amazon SQS FIFO queues, and one Standard queue.
- subscribes the queues to the topic and publishes a message to the topic.

The test verifies the receipt of the message to each queue. The complete example also shows the addition of access policies and deletes the resources at the end.
public class PriceUpdateExample {
    public final static SnsClient snsClient = SnsClient.create();
    public final static SqsClient sqsClient = SqsClient.create();

    public static void main(String[] args) {
        final String usage = "\n" +
            "Usage: " +
            "<topicName> <wholesaleQueueFifoName> <retailQueueFifoName>
<analyticsQueueName>\n\n" +
            "Where:\n\n" +
            " fifoTopicName - The name of the FIFO topic that you want to create. \n\n" +
            " wholesaleQueueARN - The name of a SQS FIFO queue that will be created for the wholesale consumer. \n\n" +
            " retailQueueARN - The name of a SQS FIFO queue that will created for the retail consumer. \n\n" +
            " analyticsQueueARN - The name of a SQS standard queue that will be created for the analytics consumer. \n\n";
        if (args.length != 4) {
            System.out.println(usage);
            System.exit(1);
        }

        final String fifoTopicName = args[0];
        final String wholeSaleQueueName = args[1];
        final String retailQueueName = args[2];
        final String analyticsQueueName = args[3];

        // For convenience, the QueueData class holds metadata about a queue: ARN, URL,
        // name and type.
        List<QueueData> queues = List.of(
            new QueueData(wholeSaleQueueName, QueueType.FIFO),
            new QueueData(retailQueueName, QueueType.FIFO),
            new QueueData(analyticsQueueName, QueueType.Standard));

        // Create queues.
        createQueues(queues);

        // Create a topic.
        String topicARN = createFIFOTopic(fifoTopicName);
// Subscribe each queue to the topic.

System.out.println(response.sequenceNumber());
System.out.println("Message was published to " + topicArn);
}
} catch (SnsException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

- For API details, see the following topics in AWS SDK for Java 2.x API Reference.
  - CreateTopic
  - Publish
  - Subscribe

Publish SMS messages to a topic

The following code example shows how to:

- Create an Amazon SNS topic.
- Subscribe phone numbers to the topic.
- Publish SMS messages to the topic so that all subscribed phone numbers receive the message at once.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

}

Serverless examples

Invoke a Lambda function from an Amazon SNS trigger

The following code example shows how to implement a Lambda function that receives an event triggered by receiving messages from an SNS topic. The function retrieves the messages from the event parameter and logs the content of each message.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Consuming an SNS event with Lambda using Java.

package example;
public class SNSEventHandler implements RequestHandler<SNSEvent, Boolean> { 
    LambdaLogger logger;

    @Override
    public Boolean handleRequest(SNSEvent event, Context context) {
        logger = context.getLogger();
        List<SNSRecord> records = event.getRecords();
        if (!records.isEmpty()) {
            Iterator<SNSRecord> recordsIter = records.iterator();
            while (recordsIter.hasNext()) {
                processRecord(recordsIter.next());
            }
        }
        return Boolean.TRUE;
    }

    public void processRecord(SNSRecord record) {
        try {
            String message = record.getSNS().getMessage();
            logger.log("message: "+ message);
        } catch (Exception e) {
            throw new RuntimeException(e);
        }
    }
}
Amazon SQS examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon SQS.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Get started

Hello Amazon SQS

The following code examples show how to get started using Amazon SQS.

SDK for Java 2.x

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sqs.SqsClient;
import software.amazon.awssdk.services.sqs.model.SqsException;
import software.amazon.awssdk.services.sqs.paginators.ListQueuesIterable;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 * For more information, see the following documentation topic:
 */
```

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/aws/aws-code-examples).
public class HelloSQS {
    public static void main(String[] args) {
        SqsClient sqsClient = SqsClient.builder()
            .region(Region.US_WEST_2)
            .build();

        listQueues(sqsClient);
        sqsClient.close();
    }

    public static void listQueues(SqsClient sqsClient) {
        try {
            ListQueuesIterable listQueues = sqsClient.listQueuesPaginator();
            listQueues.stream()
                .flatMap(r -> r.queueUrls().stream())
                .forEach(content -> System.out.println(" Queue URL: "+
                    content.toLowerCase()));
        } catch (SqsException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
}

- For API details, see [ListQueues](https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/list-queues.html) in *AWS SDK for Java 2.x API Reference*.

                .queueUrl(queueUrl)
                .receiptHandle(message.receiptHandle())
                .build();
            sqsClient.deleteMessage(deleteMessageRequest);
        }
    } catch (SqsException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

For API details, see [CreateQueue](https://aws.amazon.com/documentation/sqs/api-reference/) in AWS SDK for Java 2.x API Reference.
try {
    for (Message message : messages) {
        DeleteMessageRequest deleteMessageRequest =
            DeleteMessageRequest.builder()
                .queueUrl(queueUrl)
                .receiptHandle(message.receiptHandle())
                .build();
        sqsClient.deleteMessage(deleteMessageRequest);
    }
} catch (SqsException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

• For API details, see DeleteMessage in AWS SDK for Java 2.x API Reference.

Delete a queue

The following code example shows how to delete an Amazon SQS queue.
```java
import software.amazon.awssdk.services.sqs.model.DeleteQueueRequest;
import software.amazon.awssdk.services.sqs.model.SqsException;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */

public class DeleteQueue {
    public static void main(String[] args) {
        final String usage = ""

            Usage: <queueName>

            Where:
                queueName - The name of the Amazon SQS queue to delete.

            "";

        if (args.length != 1) {
            System.out.println(usage);
            System.exit(1);
        }

        String queueName = args[0];
        SqsClient sqs = SqsClient.builder()
            .region(Region.US_WEST_2)
            .build();

        deleteSQSQueue(sqs, queueName);
        sqs.close();
    }

    public static void deleteSQSQueue(SqsClient sqsClient, String queueName) {
        try {
            GetQueueUrlRequest getQueueRequest = GetQueueUrlRequest.builder()
                .queueName(queueName)
                .build();

            String queueUrl = sqsClient.getQueueUrl(getQueueRequest).queueUrl();
            DeleteQueueRequest deleteQueueRequest = DeleteQueueRequest.builder()
The following code example shows how to get the URL of an Amazon SQS queue.

```java
GetQueueUrlResponse getQueueUrlResponse = sqsClient
    .getQueueUrl(GetQueueUrlRequest.builder().queueName(queueName).build());
return getQueueUrlResponse.queueUrl();
```

**List queues**

The following code example shows how to list Amazon SQS queues.
Receive messages from a queue

The following code example shows how to receive messages from an Amazon SQS queue.

```java
String prefix = "que";

try {
    ListQueuesRequest listQueuesRequest =
        ListQueuesRequest.builder().queueNamePrefix(prefix).build();
    ListQueuesResponse listQueuesResponse =
        sqsClient.listQueues(listQueuesRequest);
    for (String url : listQueuesResponse.queueUrls()) {
        System.out.println(url);
    }
} catch (SqsException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
```

- For API details, see [ListQueues](https://aws-sdk-java-developer-guide.s3.amazonaws.com/AWS-SQS.html#ListQueues) in AWS SDK for Java 2.x API Reference.

Scenarios

Create and publish to a FIFO topic

The following code example shows how to create and publish to a FIFO Amazon SNS topic.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

This example

- creates an Amazon SNS FIFO topic, two Amazon SQS FIFO queues, and one Standard queue.
- subscribes the queues to the topic and publishes a message to the topic.

The test verifies the receipt of the message to each queue. The complete example also shows the addition of access policies and deletes the resources at the end.

```java
public class PriceUpdateExample {
    public final static SnsClient snsClient = SnsClient.create();
    public final static SqsClient sqsClient = SqsClient.create();

    public static void main(String[] args) {
        final String usage = "\n" +
            "Usage: " +
            "    <topicName> <wholesaleQueueFifoName> <retailQueueFifoName>
            <analyticsQueueName>\n\n" +
            "Where:\n" +
            "    fifoTopicName - The name of the FIFO topic that you want to
            create. \n\n" +
            "    wholesaleQueueARN - The name of a SQS FIFO queue that will be
            created for the wholesale consumer. \n\n" +
            "    retailQueueARN - The name of a SQS FIFO queue that will created
            for the retail consumer. \n\n" +
            "    analyticsQueueARN - The name of a SQS standard queue that will
            be created for the analytics consumer. \n\n";
        if (args.length != 4) {
```

Amazon SQS
final String fifoTopicName = args[0];
final String wholeSaleQueueName = args[1];
final String retailQueueName = args[2];
final String analyticsQueueName = args[3];

// For convenience, the QueueData class holds metadata about a queue: ARN, URL,
// name and type.
List<QueueData> queues = List.of(
    new QueueData(wholeSaleQueueName, QueueType.FIFO),
    new QueueData(retailQueueName, QueueType.FIFO),
    new QueueData(analyticsQueueName, QueueType.Standard));

// Create queues.

Serverless examples

Invoke a Lambda function from an Amazon SQS trigger

The following code example shows how to implement a Lambda function that receives an event triggered by receiving messages from an SQS queue. The function retrieves the messages from the event parameter and logs the content of each message.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Consuming an SQS event with Lambda using Java.

```java
import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.lambda.runtime.RequestHandler;
import com.amazonaws.services.lambda.runtime.events.SQSEvent;
import com.amazonaws.services.lambda.runtime.events.SQSEvent.SQSMessage;

public class Function implements RequestHandler<SQSEvent, Void> {
    @Override
    public Void handleRequest(SQSEvent sqsEvent, Context context) {
        for (SQSMessage msg : sqsEvent.getRecords()) {
            processMessage(msg, context);
        }
        context.getLogger().log("done");
        return null;
    }

    private void processMessage(SQSEMessage msg, Context context) {
        try {
            context.getLogger().log("Processed message " + msg.getBody());
            // TODO: Do interesting work based on the new message
        } catch (Exception e) {
            context.getLogger().log("An error occurred");
            throw e;
        }
    }
}
Reporting batch item failures for Lambda functions with an Amazon SQS trigger

The following code example shows how to implement partial batch response for Lambda functions that receive events from an SQS queue. The function reports the batch item failures in the response, signaling to Lambda to retry those messages later.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Importing necessary packages:

```java
import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.lambda.runtime.RequestHandler;
import com.amazonaws.services.lambda.runtime.events.SQSEvent;
import com.amazonaws.services.lambda.runtime.events.SQSBatchResponse;
import java.util.ArrayList;
import java.util.List;
```

Creating a class to handle SQS batch messages:

```java
public class ProcessSQSMessageBatch implements RequestHandler<SQSEvent, SQSBatchResponse> {
    @Override
    public SQSBatchResponse handleRequest(SQSEvent sqsEvent, Context context) {
        List<SQSBatchResponse.BatchItemFailure> batchItemFailures = new ArrayList<SQSBatchResponse.BatchItemFailure>();
        String messageId = "";
        for (SQSEvent.SQSMessage message : sqsEvent.getRecords()) {
            try {
                //process your message
                messageId = message.getMessageId();
            } catch (Exception e) {
                batchItemFailures.add(new SQSBatchResponse.BatchItemFailure(messageId, e.getMessage()));
            }
        }
        return new SQSBatchResponse(batchItemFailures);
    }
}
```
Step Functions examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Step Functions.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Get started

Hello Step Functions

The following code examples show how to get started using Step Functions.

SDK for Java 2.x

Note

There’s more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Java version of Hello.
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sfn.SfnClient;
import software.amazon.awssdk.services.sfn.model.ListStateMachinesResponse;
import software.amazon.awssdk.services.sfn.model.SfnException;
import software.amazon.awssdk.services.sfn.model.StateMachineListItem;
import java.util.List;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.

Actions

Create a state machine

The following code example shows how to create a Step Functions state machine.

SDK for Java 2.x

```java
public static String createMachine(SfnClient sfnClient, String roleARN, String stateMachineName, String json) {
    try {
        CreateStateMachineRequest machineRequest = CreateStateMachineRequest.builder()
            .definition(json)
            .name(stateMachineName)
            .roleArn(roleARN)
            .type(StateMachineType.STANDARD)
            .build();

        CreateStateMachineResponse response = sfnClient.createStateMachine(machineRequest);
        return response.stateMachineArn();
    } catch (SfnException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
    }
}
```

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
Create an activity

The following code example shows how to create a Step Functions activity.

SDK for Java 2.x

```java
public static String createActivity(SfnClient sfnClient, String activityName) {
    try {
        CreateActivityRequest activityRequest = CreateActivityRequest.builder()
            .name(activityName)
            .build();

        CreateActivityResponse response = sfnClient.createActivity(activityRequest);
        return response.activityArn();
    } catch (SfnException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
    return "";
}
```

- For API details, see [CreateActivity](https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/stepfunctions-createactivity.html) in *AWS SDK for Java 2.x API Reference*.
Delete a state machine

The following code example shows how to delete a Step Functions state machine.

SDK for Java 2.x

```java
public static void deleteMachine(SfnClient sfnClient, String stateMachineArn) {
    try {
        DeleteStateMachineRequest deleteStateMachineRequest = DeleteStateMachineRequest.builder()
            .stateMachineArn(stateMachineArn)
            .build();

        sfnClient.deleteStateMachine(deleteStateMachineRequest);
        DescribeStateMachineRequest describeStateMachine = DescribeStateMachineRequest.builder()
            .stateMachineArn(stateMachineArn)
            .build();

        while (true) {
            DescribeStateMachineResponse response = sfnClient.describeStateMachine(describeStateMachine);
            System.out.println("The state machine is not deleted yet. The status is " + response.status());
            Thread.sleep(3000);
        }
    } catch (SfnException | InterruptedException e) {
        System.err.println(e.getMessage());
    }
    System.out.println(stateMachineArn + " was successfully deleted.");
}
```

- For API details, see [DeleteStateMachine](https://aws.amazon.com/sdk-for-java) in AWS SDK for Java 2.x API Reference.
Delete an activity

The following code example shows how to delete a Step Functions activity.

SDK for Java 2.x

```java
public static void deleteActivity(SfnClient sfnClient, String actArn) {
    try {
        DeleteActivityRequest activityRequest = DeleteActivityRequest.builder()
            .activityArn(actArn)
            .build();

        sfnClient.deleteActivity(activityRequest);
        System.out.println("You have deleted " + actArn);
    } catch (SfnException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

Note

Describe a state machine

The following code example shows how to describe a Step Functions state machine.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/awsdocs/aws-sdk-java/tree/master/code-examples/stepfunctions).
public static void describeStateMachine(SfnClient sfnClient, String stateMachineArn) {
    try {
        DescribeStateMachineRequest stateMachineRequest = DescribeStateMachineRequest.builder()
            .stateMachineArn(stateMachineArn)
            .build();

        DescribeStateMachineResponse response = sfnClient.describeStateMachine(stateMachineRequest);
        System.out.println("The name of the State machine is " + response.name());
        System.out.println("The status of the State machine is " + response.status());
        System.out.println("The ARN value of the State machine is " + response.stateMachineArn());
        System.out.println("The role ARN value is " + response.roleArn());
    } catch (SfnException e) {
        System.err.println(e.getMessage());
    }
}

- For API details, see `DescribeStateMachine` in AWS SDK for Java 2.x API Reference.

Describe a state machine run

The following code example shows how to describe a Step Functions state machine run.

SDK for Java 2.x

public static void describeExe(SfnClient sfnClient, String executionArn) {
    try {
        
        
    } catch (SfnException e) {
        System.err.println(e.getMessage());
    }
}
DescribeExecutionRequest executionRequest =
DescribeExecutionRequest.builder()
    .executionArn(executionArn)
    .build();

String status = "";
boolean hasSucceeded = false;
while (!hasSucceeded) {
    DescribeExecutionResponse response =
        sfnClient.describeExecution(executionRequest);
    status = response.statusAsString();
    if (status.compareTo("RUNNING") == 0) {
        System.out.println("The state machine is still running, let's
wait for it to finish.");
        Thread.sleep(2000);
    } else if (status.compareTo("SUCCEEDED") == 0) {
        System.out.println("The Step Function workflow has succeeded");
        hasSucceeded = true;
    } else {
        System.out.println("The Status is neither running or
succeeded");
    }
} System.out.println("The Status is " + status);

} catch (SfnException | InterruptedException e) {
    System.err.println(e.getMessage());
    System.exit(1);
}

• For API details, see DescribeExecution in AWS SDK for Java 2.x API Reference.

Get task data for an activity

The following code example shows how to get task data for a Step Functions activity.
null public static List<String> getActivityTask(SfnClient sfnClient, String actArn) {
    List<String> myList = new ArrayList<>();
    GetActivityTaskRequest getActivityTaskRequest =
        GetActivityTaskRequest.builder()
            .activityArn(actArn)
            .build();

    GetActivityTaskResponse response =
        sfnClient.getActivityTask(getActivityTaskRequest);
    myList.add(response.taskToken());
    myList.add(response.input());
    return myList;
}

/// <summary>
/// Stop execution of a Step Functions workflow.
/// </summary>
/// <param name="executionArn">The Amazon Resource Name (ARN) of
/// the Step Functions execution to stop.</param>
/// <returns>A Boolean value indicating the success of the action.</returns>
public async Task<bool> StopExecution(string executionArn)
{
    var response =
        await _amazonStepFunctions.StopExecutionAsync(new StopExecutionRequest
        { ExecutionArn = executionArn });
}

• For API details, see GetActivityTask in AWS SDK for Java 2.x API Reference.
List activities

The following code example shows how to list Step Functions activities.

SDK for Java 2.x

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.sfn.SfnClient;
import software.amazon.awssdk.services.sfn.model.ListActivitiesRequest;
import software.amazon.awssdk.services.sfn.model.ListActivitiesResponse;
import software.amazon.awssdk.services.sfn.model.SfnException;
import software.amazon.awssdk.services.sfn.model.ActivityListItem;
import java.util.List;

/**
 * Before running this Java V2 code example, set up your development environment, including your credentials.
 * For more information, see the following documentation topic:
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class ListActivities {
    public static void main(String[] args) {
        Region region = Region.US_EAST_1;
        SfnClient sfnClient = SfnClient.builder()
            .region(region)
            .build();

        listAllActivites(sfnClient);
        sfnClient.close();
    }

    public static void listAllActivites(SfnClient sfnClient) {
        try {
            ListActivitiesRequest activitiesRequest = ListActivitiesRequest.builder()
                .build();
```
List Activities Response

```java
ListActivitiesResponse response = sfnClient.listActivities(activitiesRequest);
List<ActivityListItem> items = response.activities();
for (ActivityListItem item : items) {
    System.out.println("The activity ARN is " + item.activityArn() + " and name is " + item.name());
}
```

```java
catch (SfnException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}
```

For API details, see ListActivities in AWS SDK for Java 2.x API Reference.

### List state machine runs

The following code example shows how to list Step Functions state machine runs.

### SDK for Java 2.x

```java
public static void getExeHistory(SfnClient sfnClient, String exeARN) {
    try {
        GetExecutionHistoryRequest historyRequest =
            GetExecutionHistoryRequest.builder()
            .executionArn(exeARN)
            .maxResults(10)
            .build();
```
GetExecutionHistoryResponse historyResponse =
    sfnClient.getExecutionHistory(historyRequest);
List<HistoryEvent> events = historyResponse.events();
for (HistoryEvent event : events) {
    System.out.println("The event type is "+ event.type().toString());
}
} catch (SfnException e) {
    System.err.println(e.awsErrorDetails().errorMessage());
    System.exit(1);
}

• For API details, see ListExecutions in AWS SDK for Java 2.x API Reference.

List state machines

The following code example shows how to list Step Functions state machines.

SDK for Java 2.x

    }

    public static void listMachines(SfnClient sfnClient) {
        try {
            ListStateMachinesResponse response = sfnClient.listStateMachines();
            List<StateMachineListItem> machines = response.stateMachines();
            for (StateMachineListItem machine : machines) {
                System.out.println("The name of the state machine is: " +
                    machine.name());
                System.out.println("The ARN value is : " +
                    machine.stateMachineArn());
            }
        } catch (SfnException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
}

For API details, see [ListStateMachines](https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html) in AWS SDK for Java 2.x API Reference.

Send a success response to a task

The following code example shows how to send a success response to a Step Functions task.
public static void sendTaskSuccess(SfnClient sfnClient, String token, String json) {
    try {
        SendTaskSuccessRequest successRequest = SendTaskSuccessRequest.builder()
            .taskToken(token)
            .output(json)
            .build();

        sfnClient.sendTaskSuccess(successRequest);
    } catch (SfnException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
public static String startWorkflow(SfnClient sfnClient, String stateMachineArn, String jsonEx) {
    UUID uuid = UUID.randomUUID();
    String uuidValue = uuid.toString();
    try {
        StartExecutionRequest executionRequest = StartExecutionRequest.builder()
            .input(jsonEx)
            .stateMachineArn(stateMachineArn)
            .name(uuidValue)
            .build();

        StartExecutionResponse response =
            sfnClient.startExecution(executionRequest);
        return response.executionArn();
    } catch (SfnException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
    return "";
}

- For API details, see StartExecution in AWS SDK for Java 2.x API Reference.

Scenarios

Get started with state machines

The following code example shows how to:

- Create an activity.
- Create a state machine from an Amazon States Language definition that contains the previously created activity as a step.
- Run the state machine and respond to the activity with user input.
- Get the final status and output after the run completes, then clean up resources.
Note

There's more on GitHub. Find the complete example and learn how to set up and run in
the AWS Code Examples Repository.

/ *
* You can obtain the JSON file to create a state machine in the following
* GitHub location.
* *
* *
* To run this code example, place the chat_sfn_state_machine.json file into
* your project's resources folder.
* *
* Also, set up your development environment, including your credentials.
* *
* For information, see this documentation topic:
* *
* https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
* *
* This Java code example performs the following tasks:
* *
* 1. Creates an activity.
* 2. Creates a state machine.
* 3. Describes the state machine.
* 4. Starts execution of the state machine and interacts with it.
* 5. Describes the execution.
* 6. Delete the activity.
* 7. Deletes the state machine.
*/

AWS STS examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with AWS STS.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Actions

Add a communication to a case

The following code example shows how to add an AWS Support communication with an attachment to a support case.

SDK for Java 2.x

```java
public static void addAttachSupportCase(SupportClient supportClient, String caseId, String attachmentSetId) {
    try {
        AddCommunicationToCaseRequest caseRequest =
            AddCommunicationToCaseRequest.builder()
                .caseId(caseId)
                .attachmentSetId(attachmentSetId)
                .communicationBody("Please refer to attachment for details.")
                .build();

        AddCommunicationToCaseResponse response =
            supportClient.addCommunicationToCase(caseRequest);
        if (response.result())
            System.out.println("You have successfully added a communication to an AWS Support case");
        else
            System.out.println("There was an error adding the communication to an AWS Support case");
    }
```
For API details, see AddCommunicationToCase in AWS SDK for Java 2.x API Reference.

Add an attachment to a set

The following code example shows how to add an AWS Support attachment to an attachment set.

SDK for Java 2.x

```java
public static String addAttachment(SupportClient supportClient, String fileAttachment) {
    try {
        File myFile = new File(fileAttachment);
        InputStream sourceStream = new FileInputStream(myFile);
        SdkBytes sourceBytes = SdkBytes.fromInputStream(sourceStream);

        Attachment attachment = Attachment.builder()
                .fileName(myFile.getName())
                .data(sourceBytes)
                .build();

        AddAttachmentsToSetRequest setRequest =
                AddAttachmentsToSetRequest.builder()
                .attachments(attachment)
                .build();

        AddAttachmentsToSetResponse response =
                supportClient.addAttachmentsToSet(setRequest);
        return response.attachmentSetId();
    } catch (SupportException e) {
        System.out.println(e.getLocalizedMessage());
        System.exit(1);
    }
}
```

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
### Create a case

The following code example shows how to create a new AWS Support case.

```java
public static String createSupportCase(SupportClient supportClient, List<String> sevCatList, String sevLevel) {
    try {
        String serviceCode = sevCatList.get(0);
        String caseCat = sevCatList.get(1);
        CreateCaseRequest caseRequest = CreateCaseRequest.builder()
            .categoryCode(caseCat.toLowerCase())
            .serviceCode(serviceCode.toLowerCase())
            .severityCode(sevLevel.toLowerCase())
            .communicationBody("Test issue with " + serviceCode.toLowerCase())
            .subject("Test case, please ignore")
            .language("en")
            .issueType("technical")
            .build();
        CreateCaseResponse response = supportClient.createCase(caseRequest);
        return response.caseId();
    }
}
```

Describe an attachment

The following code example shows how to describe an attachment for an AWS Support case.

```java
public static void describeAttachment(SupportClient supportClient, String attachId) {
    try {
        DescribeAttachmentRequest attachmentRequest =
            DescribeAttachmentRequest.builder()
                .attachmentId(attachId)
                .build();

        DescribeAttachmentResponse response =
            supportClient.describeAttachment(attachmentRequest);
        System.out.println("The name of the file is " +
            response.attachment().fileName());
    } catch (SupportException e) {
        System.out.println(e.getLocalizedMessage());
        System.exit(1);
    }
    return "";
}
```

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).
Describe cases

The following code example shows how to describe AWS Support cases.

SDK for Java 2.x

```java
public static void getOpenCase(SupportClient supportClient) {
    try {
        // Specify the start and end time.
        Instant now = Instant.now();
        java.time.LocalDate.now();
        Instant yesterday = now.minus(1, ChronoUnit.DAYS);

        DescribeCasesRequest describeCasesRequest =
            DescribeCasesRequest.builder()
            .maxResults(20)
            .afterTime(yesterday.toString())
            .beforeTime(now.toString())
            .build();

        DescribeCasesResponse response =
            supportClient.describeCases(describeCasesRequest);
        List<CaseDetails> cases = response.cases();
        for (CaseDetails sinCase : cases) {
            System.out.println("The case status is " + sinCase.status());
            System.out.println("The case Id is " + sinCase.caseId());
            System.out.println("The case subject is " + sinCase.subject());
        }
    } catch (SupportException e) {
        System.out.println(e.getLocalizedMessage());
        System.exit(1);
    }
}
```

For API details, see `DescribeAttachment` in *AWS SDK for Java 2.x API Reference*.

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/aws-samples/aws-sdk-java-examples).
• For API details, see DescribeCases in AWS SDK for Java 2.x API Reference.

Describe communications

The following code example shows how to describe AWS Support communications for a case.

SDK for Java 2.x

```java
public static String listCommunications(SupportClient supportClient, String caseId) {
    try {
        String attachId = null;
        DescribeCommunicationsRequest communicationsRequest =
                DescribeCommunicationsRequest.builder()
                .caseId(caseId)
                .maxResults(10)
                .build();

        DescribeCommunicationsResponse response =
                supportClient.describeCommunications(communicationsRequest);
        List<Communication> communications = response.communications();
        for (Communication comm : communications) {
            System.out.println("the body is: " + comm.body());

            // Get the attachment id value.
            List<AttachmentDetails> attachments = comm.attachmentSet();
            for (AttachmentDetails detail : attachments) {
                attachId = detail.attachmentId();
            }
        }
        return attachId;
    } catch (SupportException e) {
        System.out.println(e.getLocalizedMessage());
    }
}
```
System.exit(1);
}
return "";
}

- For API details, see DescribeCommunications in AWS SDK for Java 2.x API Reference.

Describe services

The following code example shows how to describe the list of AWS services.

SDK for Java 2.x

```java
// Return a List that contains a Service name and Category name.
public static List<String> displayServices(SupportClient supportClient) {
    try {
        DescribeServicesRequest servicesRequest =
            DescribeServicesRequest.builder()
                .language("en")
                .build();

        DescribeServicesResponse response =
            supportClient.describeServices(servicesRequest);
        String serviceCode = null;
        String catName = null;
        List<String> sevCatList = new ArrayList<>();
        List<Service> services = response.services();

        System.out.println("Get the first 10 services");
        int index = 1;
        for (Service service : services) {
            if (index == 11)
                break;

            System.out.println("The Service name is: " + service.name());
        }
    }
    catch (Exception e) {
        System.out.println(e.getMessage());
    }
}
```

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
public static String displaySevLevels(SupportClient supportClient) {
    try {
        if (service.name().compareTo("Account") == 0)
            serviceCode = service.code();

        // Get the Categories for this service.
        List<Category> categories = service.categories();
        for (Category cat : categories) {
            System.out.println("The category name is: " + cat.name());
            if (cat.name().compareTo("Security") == 0)
                catName = cat.name();
        }
        index++;
    }

    // Push the two values to the list.
    sevCatList.add(serviceCode);
    sevCatList.add(catName);
    return sevCatList;

    } catch (SupportException e) {
        System.out.println(e.getLocalizedMessage());
        System.exit(1);
    }
    return null;
}

- For API details, see [DescribeServices](https://docs.aws.amazon.com/sdk-for-java/v1/developer-guide/java-api.html#aws-java-sdk-support.DescribeServices) in *AWS SDK for Java 2.x API Reference*.

**Describe severity levels**

The following code example shows how to describe AWS Support severity levels.

### SDK for Java 2.x

- Note

  There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/aws-samples/aws-sdk-java-support).
DescribeSeverityLevelsRequest severityLevelsRequest =
   DescribeSeverityLevelsRequest.builder()
   .language("en")
   .build();

DescribeSeverityLevelsResponse response =
supportClient.describeSeverityLevels(severityLevelsRequest);
List<SeverityLevel> severityLevels = response.severityLevels();
String levelName = null;
for (SeverityLevel sevLevel : severityLevels) {
   System.out.println("The severity level name is: " + sevLevel.name());
   if (sevLevel.name().compareTo("High") == 0)
      levelName = sevLevel.name();
}
return levelName;

} catch (SupportException e) {
   System.out.println(e.getLocalizedMessage());
   System.exit(1);
}
return "";

• For API details, see DescribeSeverityLevels in AWS SDK for Java 2.x API Reference.

Resolve case

The following code example shows how to resolve an AWS Support case.

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
ResolveCaseRequest caseRequest = ResolveCaseRequest.builder()
    .caseId(caseId)
    .build();

ResolveCaseResponse response = supportClient.resolveCase(caseRequest);
System.out.println("The status of case " + caseId + " is " +
    response.finalCaseStatus());
}

} catch (SupportException e) {
    System.out.println(e.getLocalizedMessage());
    System.exit(1);
}

• For API details, see ResolveCase in AWS SDK for Java 2.x API Reference.

Scenarios

Get started with cases

The following code example shows how to:

• Get and display available services and severity levels for cases.
• Create a support case using a selected service, category, and severity level.
• Get and display a list of open cases for the current day.
• Add an attachment set and a communication to the new case.
• Describe the new attachment and communication for the case.
• Resolve the case.
• Get and display a list of resolved cases for the current day.

 */
```
For more information, see the following documentation topic:

https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html

In addition, you must have the AWS Business Support Plan to use the AWS Support Java API. For more information, see:

https://aws.amazon.com/premiumsupport/plans/

This Java example performs the following tasks:

1. Gets and displays available services.
2. Gets and displays severity levels.
3. Creates a support case by using the selected service, category, and severity level.
4. Gets a list of open cases for the current day.
5. Creates an attachment set with a generated file.
6. Adds a communication with the attachment to the support case.
7. Lists the communications of the support case.
8. Describes the attachment set included with the communication.
9. Resolves the support case.
10. Gets a list of resolved cases for the current day.

Add a parameter

The following code example shows how to add a Systems Manager parameter.

SDK for Java 2.x

```java
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.ssm.SsmClient;
import software.amazon.awssdk.services.ssm.model.ParameterType;
import software.amazon.awssdk.services.ssm.model.PutParameterRequest;
import software.amazon.awssdk.services.ssm.model.SsmException;

public class PutParameter {
    public static void main(String[] args) {
        final String usage = ""
            Usage:
                <paraName>
            Where:
                paraName - The name of the parameter.
                paraValue - The value of the parameter.
            "";

        if (args.length != 2) {
            System.out.println(usage);
            System.exit(1);
        }

        String paraName = args[0];
        String paraValue = args[1];
        Region region = Region.US_EAST_1;
        SsmClient ssmClient = SsmClient.builder()
            .region(region)
```
```java
public static void putParaValue(SsmClient ssmClient, String paraName, String paraValue) {
    try {
        PutParameterRequest parameterRequest = PutParameterRequest.builder()
            .name(paraName)
            .type(ParameterType.STRING)
            .value(paraValue)
            .build();

        ssmClient.putParameter(parameterRequest);
        System.out.println("The parameter was successfully added.");
    }
    catch (SsmException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
}
```

Amazon Transcribe examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon Transcribe.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Each example includes a link to GitHub, where you can find instructions on how to set up and run the code in context.

Topics
• Actions
• Scenarios
Actions

List transcription jobs

The following code example shows how to list Amazon Transcribe transcription jobs.

SDK for Java 2.x

```java
public class ListTranscriptionJobs {
    public static void main(String[] args) {
        TranscribeClient transcribeClient = TranscribeClient.builder()
                .region(Region.US_EAST_1)
                .build();

        listTranscriptionJobs(transcribeClient);
    }

    public static void listTranscriptionJobs(TranscribeClient transcribeClient) {
        ListTranscriptionJobsRequest listJobsRequest = 
            ListTranscriptionJobsRequest.builder()
                .build();

        transcribeClient.listTranscriptionJobsPaginator(listJobsRequest).stream()
            .flatMap(response -> response.transcriptionJobSummaries().stream())
            .forEach(jobSummary -> {
                System.out.println("Job Name: " + jobSummary.transcriptionJobName());
                System.out.println("Job Status: " + jobSummary.transcriptionJobStatus());
                System.out.println("Output Location: " + jobSummary.outputLocationType());
                // Add more information as needed
                // Retrieve additional details for the job if necessary
            });
    }
}
```

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/aws-samples/aws-sdk-for-java/tree/main/examples/).
GetTranscriptionJobResponse jobDetails =
    transcribeClient.getTranscriptionJob(
        GetTranscriptionJobRequest.builder()
            .transcriptionJobName(jobSummary.transcriptionJobName())
            .build());

    // Display additional details
    System.out.println("Language Code: " +
        jobDetails.transcriptionJob().languageCode());
    System.out.println("Media Format: " +
        jobDetails.transcriptionJob().mediaFormat());
    // Add more details as needed
    System.out.println("-----------------");
}]
}

- For API details, see ListTranscriptionJobs in AWS SDK for Java 2.x API Reference.

Start a transcription job

For API details, see `StartTranscriptionJob` in *AWS SDK for Java 2.x API Reference*.

**Scenarios**

**Transcribe audio and get job data**

The following code example shows how to:

- Start a transcription job with Amazon Transcribe.
- Wait for the job to complete.
- Get the URI where the transcript is stored.

For more information, see *Getting started with Amazon Transcribe*.

**SDK for Java 2.x**

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the *AWS Code Examples Repository*.

Transcribes a PCM file.

Cross-service examples using SDK for Java 2.x

The following sample applications use the AWS SDK for Java 2.x to work across multiple AWS services.

Cross-service examples target an advanced level of experience to help you start building applications.

Examples
  
  • Build an application to submit data to a DynamoDB table
  • Create an Amazon Lex chatbot to engage your website visitors
  • Build a publish and subscription application that translates messages
  • Create a web application that sends and retrieves messages by using Amazon SQS
  • Create a photo asset management application that lets users manage photos using labels
  • Create a web application to track DynamoDB data
  • Create an Amazon Redshift item tracker
• Create an Aurora Serverless work item tracker
• Create an application that analyzes customer feedback and synthesizes audio
• Detect PPE in images with Amazon Rekognition using an AWS SDK
• Detect objects in images with Amazon Rekognition using an AWS SDK
• Detect people and objects in a video with Amazon Rekognition using an AWS SDK
• Publish Amazon SNS messages to Amazon SQS queues using an AWS SDK
• Use API Gateway to invoke a Lambda function
• Use Step Functions to invoke Lambda functions
• Use scheduled events to invoke a Lambda function

Build an application to submit data to a DynamoDB table

SDK for Java 2.x

Shows how to create a dynamic web application that submits data using the Amazon DynamoDB Java API and sends a text message using the Amazon Simple Notification Service Java API.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

• DynamoDB
• Amazon SNS

Create an Amazon Lex chatbot to engage your website visitors

SDK for Java 2.x

Shows how to use the Amazon Lex API to create a Chatbot within a web application to engage your website visitors.

For complete source code and instructions on how to set up and run, see the full example on GitHub.
Services used in this example

- Amazon Comprehend
- Amazon Lex
- Amazon Translate

Build a publish and subscription application that translates messages

SDK for Java 2.x

Shows how to use the Amazon Simple Notification Service Java API to create a web application that has subscription and publish functionality. In addition, this example application also translates messages.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

For complete source code and instructions on how to set up and run the example that uses the Java Async API, see the full example on GitHub.

Services used in this example

- Amazon SNS
- Amazon Translate

Create a web application that sends and retrieves messages by using Amazon SQS

SDK for Java 2.x

Shows how to use the Amazon SQS API to develop a Spring REST API that sends and retrieves messages.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- Amazon Comprehend
Create a photo asset management application that lets users manage photos using labels

**SDK for Java 2.x**

Shows how to develop a photo asset management application that detects labels in images using Amazon Rekognition and stores them for later retrieval.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](https://github.com). For a deep dive into the origin of this example see the post on [AWS Community](https://aws.amazon.com/community).

**Services used in this example**

- API Gateway
- DynamoDB
- Lambda
- Amazon Rekognition
- Amazon S3
- Amazon SNS

Create a web application to track DynamoDB data

**SDK for Java 2.x**

Shows how to use the Amazon DynamoDB API to create a dynamic web application that tracks DynamoDB work data.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](https://github.com).

**Services used in this example**

- DynamoDB
- Amazon SES
Create an Amazon Redshift item tracker

SDK for Java 2.x

Shows how to create a web application that tracks and reports on work items stored in an Amazon Redshift database.

For complete source code and instructions on how to set up a Spring REST API that queries Amazon Redshift data and for use by a React application, see the full example on GitHub.

Services used in this example

- Amazon Redshift
- Amazon SES

Create an Aurora Serverless work item tracker

SDK for Java 2.x

Shows how to create a web application that tracks and reports on work items stored in an Amazon RDS database.

For complete source code and instructions on how to set up a Spring REST API that queries Amazon Aurora Serverless data and for use by a React application, see the full example on GitHub.

For complete source code and instructions on how to set up and run an example that uses the JDBC API, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES
Create an application that analyzes customer feedback and synthesizes audio

SDK for Java 2.x

This example application analyzes and stores customer feedback cards. Specifically, it fulfills the need of a fictitious hotel in New York City. The hotel receives feedback from guests in various languages in the form of physical comment cards. That feedback is uploaded into the app through a web client. After an image of a comment card is uploaded, the following steps occur:

- Text is extracted from the image using Amazon Textract.
- Amazon Comprehend determines the sentiment of the extracted text and its language.
- The extracted text is translated to English using Amazon Translate.
- Amazon Polly synthesizes an audio file from the extracted text.

The full app can be deployed with the AWS CDK. For source code and deployment instructions, see the project in GitHub.

Services used in this example

- Amazon Comprehend
- Lambda
- Amazon Polly
- Amazon Textract
- Amazon Translate

Detect PPE in images with Amazon Rekognition using an AWS SDK

SDK for Java 2.x

Shows how to create an AWS Lambda function that detects images with Personal Protective Equipment.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- DynamoDB
Detect objects in images with Amazon Rekognition using an AWS SDK

SDK for Java 2.x

Shows how to use Amazon Rekognition Java API to create an app that uses Amazon Rekognition to identify objects by category in images located in an Amazon Simple Storage Service (Amazon S3) bucket. The app sends the admin an email notification with the results using Amazon Simple Email Service (Amazon SES).

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- Amazon Rekognition
- Amazon S3
- Amazon SES

Detect people and objects in a video with Amazon Rekognition using an AWS SDK

SDK for Java 2.x

Shows how to use Amazon Rekognition Java API to create an app to detect faces and objects in videos located in an Amazon Simple Storage Service (Amazon S3) bucket. The app sends the admin an email notification with the results using Amazon Simple Email Service (Amazon SES).

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- Amazon Rekognition
- Amazon S3
• Amazon SES

Publish Amazon SNS messages to Amazon SQS queues using an AWS SDK

SDK for Java 2.x

Demonstrates messaging with topics and queues using Amazon Simple Notification Service (Amazon SNS) and Amazon Simple Queue Service (Amazon SQS).

For complete source code and instructions that demonstrate messaging with topics and queues in Amazon SNS and Amazon SQS, see the full example on GitHub.

Services used in this example

• Amazon SNS
• Amazon SQS

Use API Gateway to invoke a Lambda function

SDK for Java 2.x

Shows how to create an AWS Lambda function by using the Lambda Java runtime API. This example invokes different AWS services to perform a specific use case. This example demonstrates how to create a Lambda function invoked by Amazon API Gateway that scans an Amazon DynamoDB table for work anniversaries and uses Amazon Simple Notification Service (Amazon SNS) to send a text message to your employees that congratulates them at their one year anniversary date.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

• API Gateway
• DynamoDB
• Lambda
• Amazon SNS
Use Step Functions to invoke Lambda functions

SDK for Java 2.x

Shows how to create an AWS serverless workflow by using AWS Step Functions and the AWS SDK for Java 2.x. Each workflow step is implemented using an AWS Lambda function.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- DynamoDB
- Lambda
- Amazon SES
- Step Functions

Use scheduled events to invoke a Lambda function

SDK for Java 2.x

Shows how to create an Amazon EventBridge scheduled event that invokes an AWS Lambda function. Configure EventBridge to use a cron expression to schedule when the Lambda function is invoked. In this example, you create a Lambda function by using the Lambda Java runtime API. This example invokes different AWS services to perform a specific use case. This example demonstrates how to create an app that sends a mobile text message to your employees that congratulates them at the one year anniversary date.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- DynamoDB
- EventBridge
- Lambda
- Amazon SNS
Security for the AWS SDK for Java

Cloud security at Amazon Web Services (AWS) is the highest priority. As an AWS customer, you benefit from a data center and network architecture that is built to meet the requirements of the most security-sensitive organizations. Security is a shared responsibility between AWS and you. The **Shared Responsibility Model** describes this as Security of the Cloud and Security in the Cloud.

**Security of the Cloud** – AWS is responsible for protecting the infrastructure that runs all of the services offered in the AWS Cloud and providing you with services that you can use securely. Our security responsibility is the highest priority at AWS, and the effectiveness of our security is regularly tested and verified by third-party auditors as part of the **AWS Compliance Programs**.

**Security in the Cloud** – Your responsibility is determined by the AWS service you are using, and other factors including the sensitivity of your data, your organization's requirements, and applicable laws and regulations.

This AWS product or service follows the **shared responsibility model** through the specific Amazon Web Services (AWS) services it supports. For AWS service security information, see the **AWS service security documentation page** and **AWS services that are in scope of AWS compliance efforts by compliance program**.

**Topics**
- [Data protection in AWS SDK for Java 2.x](#)
- [Working with TLS in the SDK for Java](#)
- [Identity and Access Management](#)
- [Compliance Validation for this AWS Product or Service](#)
- [Resilience for this AWS Product or Service](#)
- [Infrastructure Security for this AWS Product or Service](#)

**Data protection in AWS SDK for Java 2.x**

The AWS **shared responsibility model** applies to data protection in AWS SDK for Java. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. You are also responsible for the security configuration and management tasks for
the AWS services that you use. For more information about data privacy, see the Data Privacy FAQ. For information about data protection in Europe, see the AWS Shared Responsibility Model and GDPR blog post on the AWS Security Blog.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual users with AWS IAM Identity Center or AWS Identity and Access Management (IAM). That way, each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We require TLS 1.2 and recommend TLS 1.3.
- Set up API and user activity logging with AWS CloudTrail.
- Use AWS encryption solutions, along with all default security controls within AWS services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
- If you require FIPS 140-2 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-2.

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form text fields such as a Name field. This includes when you work with SDK for Java or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into tags or free-form text fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

**Working with TLS in the SDK for Java**

The AWS SDK for Java uses the TLS capabilities of its underlying Java platform. In this topic, we show examples using the OpenJDK implementation used by Amazon Corretto 17.

To work with AWS services, the underlying JDK must support a minimum version of TLS 1.2, but TLS 1.3 is recommended.

Users should consult the documentation of the the Java platform they are using with the SDK to find out which TLS versions are enabled by default as well as how to enable and disable specific TLS versions.
How to check TLS version information

Using OpenJDK, the following code shows the use of \texttt{SSLContext} to print which TLS/SSL versions are supported.

\begin{verbatim}
System.out.println(Arrays.toString(SSLContext.getDefault().getSupportedSSLParameters().getProtocols()));
\end{verbatim}

For example, Amazon Corretto 17 (OpenJDK) produces the following output.

\begin{verbatim}
[TLSv1.3, TLSv1.2, TLSv1.1, TLSv1, SSLv3, SSLv2Hello]
\end{verbatim}

To see the SSL handshake in action and what version of TLS is used, you can use the system property \texttt{javax.net.debug}.

For example, run a Java application that uses TLS.

\begin{verbatim}
java app.jar -Djavax.net.debug=ssl:handshake
\end{verbatim}

The application logs the SSL handshake similar to the following.

\begin{verbatim}
... 
javax.net.ssl|DEBUG|10|main|2022-12-23 13:53:12.221 EST|ClientHello.java:641|Produced 
    ClientHello handshake message ( 
    "ClientHello": { 
        "client version"      : "TLSv1.2", 
    }, 
... 
javax.net.ssl|DEBUG|10|main|2022-12-23 13:53:12.295 EST|ServerHello.java:888|Consuming 
    ServerHello handshake message ( 
    "ServerHello": { 
        "server version"      : "TLSv1.2", 
    }, 
... 
\end{verbatim}

Enforce a minimum TLS version

The SDK for Java always prefers the latest TLS version supported by the platform and service. If you wish to enforce a specific minimum TLS version, consult your Java platform's documentation.

For OpenJDK-based JVMs, you can use the system property \texttt{jdk.tls.client.protocols}. 

Check TLS versions
For example, if you want SDK service clients in your application to use TLS 1.2, even though TLS 1.3 is available, provide the following system property.

```java
java app.jar -Djdk.tls.client.protocols=TLSv1.2
```

**AWS API endpoints upgrade to TLS 1.2**

See this blog post for information about AWS API endpoints moving to TLS 1.2 for the minimum version.

**Identity and Access Management**

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use AWS resources. IAM is an AWS service that you can use with no additional charge.

**Topics**

- Audience
- Authenticating with identities
- Managing access using policies
- How AWS services work with IAM
- Troubleshooting AWS identity and access

**Audience**

How you use AWS Identity and Access Management (IAM) differs, depending on the work that you do in AWS.

**Service user** – If you use AWS services to do your job, then your administrator provides you with the credentials and permissions that you need. As you use more AWS features to do your work, you might need additional permissions. Understanding how access is managed can help you request the right permissions from your administrator. If you cannot access a feature in AWS, see Troubleshooting AWS identity and access or the user guide of the AWS service you are using.

**Service administrator** – If you're in charge of AWS resources at your company, you probably have full access to AWS. It's your job to determine which AWS features and resources your service users
should access. You must then submit requests to your IAM administrator to change the permissions of your service users. Review the information on this page to understand the basic concepts of IAM. To learn more about how your company can use IAM with AWS, see the user guide of the AWS service you are using.

**IAM administrator** – If you’re an IAM administrator, you might want to learn details about how you can write policies to manage access to AWS. To view example AWS identity-based policies that you can use in IAM, see the user guide of the AWS service you are using.

### Authenticating with identities

Authenticating is how you sign in to AWS using your identity credentials. You must be authenticated (signed in to AWS) as the AWS account root user, as an IAM user, or by assuming an IAM role.

You can sign in to AWS as a federated identity by using credentials provided through an identity source. AWS IAM Identity Center (IAM Identity Center) users, your company's single sign-on authentication, and your Google or Facebook credentials are examples of federated identities. When you sign in as a federated identity, your administrator previously set up identity federation using IAM roles. When you access AWS by using federation, you are indirectly assuming a role.

Depending on the type of user you are, you can sign in to the AWS Management Console or the AWS access portal. For more information about signing in to AWS, see [How to sign in to your AWS account](https://docs.aws.amazon.com/iam/latest/userguide/signin.html) in the AWS Sign-In User Guide.

If you access AWS programmatically, AWS provides a software development kit (SDK) and a command line interface (CLI) to cryptographically sign your requests by using your credentials. If you don’t use AWS tools, you must sign requests yourself. For more information about using the recommended method to sign requests yourself, see [Signing AWS API requests](https://docs.aws.amazon.com/IAM/latest/userguide/sigv4.html) in the IAM User Guide.

Regardless of the authentication method that you use, you might be required to provide additional security information. For example, AWS recommends that you use multi-factor authentication (MFA) to increase the security of your account. To learn more, see [Multi-factor authentication](https://docs.aws.amazon.com/IAM/latest/userguide/mfa.html) in the AWS IAM Identity Center User Guide and [Using multi-factor authentication (MFA) in AWS](https://docs.aws.amazon.com/IAM/latest/userguide/using-mfa.html) in the IAM User Guide.
AWS account root user

When you create an AWS account, you begin with one sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account root user and is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you don't use the root user for your everyday tasks. Safeguard your root user credentials and use them to perform the tasks that only the root user can perform. For the complete list of tasks that require you to sign in as the root user, see Tasks that require root user credentials in the IAM User Guide.

Federated identity

As a best practice, require human users, including users that require administrator access, to use federation with an identity provider to access AWS services by using temporary credentials.

A federated identity is a user from your enterprise user directory, a web identity provider, the AWS Directory Service, the Identity Center directory, or any user that accesses AWS services by using credentials provided through an identity source. When federated identities access AWS accounts, they assume roles, and the roles provide temporary credentials.

For centralized access management, we recommend that you use AWS IAM Identity Center. You can create users and groups in IAM Identity Center, or you can connect and synchronize to a set of users and groups in your own identity source for use across all your AWS accounts and applications. For information about IAM Identity Center, see What is IAM Identity Center? in the AWS IAM Identity Center User Guide.

IAM users and groups

An IAM user is an identity within your AWS account that has specific permissions for a single person or application. Where possible, we recommend relying on temporary credentials instead of creating IAM users who have long-term credentials such as passwords and access keys. However, if you have specific use cases that require long-term credentials with IAM users, we recommend that you rotate access keys. For more information, see Rotate access keys regularly for use cases that require long-term credentials in the IAM User Guide.

An IAM group is an identity that specifies a collection of IAM users. You can't sign in as a group. You can use groups to specify permissions for multiple users at a time. Groups make permissions easier to manage for large sets of users. For example, you could have a group named IAMAdmins and give that group permissions to administer IAM resources.
Users are different from roles. A user is uniquely associated with one person or application, but a role is intended to be assumable by anyone who needs it. Users have permanent long-term credentials, but roles provide temporary credentials. To learn more, see When to create an IAM user (instead of a role) in the IAM User Guide.

**IAM roles**

An IAM role is an identity within your AWS account that has specific permissions. It is similar to an IAM user, but is not associated with a specific person. You can temporarily assume an IAM role in the AWS Management Console by switching roles. You can assume a role by calling an AWS CLI or AWS API operation or by using a custom URL. For more information about methods for using roles, see Using IAM roles in the IAM User Guide.

IAM roles with temporary credentials are useful in the following situations:

- **Federated user access** – To assign permissions to a federated identity, you create a role and define permissions for the role. When a federated identity authenticates, the identity is associated with the role and is granted the permissions that are defined by the role. For information about roles for federation, see Creating a role for a third-party Identity Provider in the IAM User Guide. If you use IAM Identity Center, you configure a permission set. To control what your identities can access after they authenticate, IAM Identity Center correlates the permission set to a role in IAM. For information about permissions sets, see Permission sets in the AWS IAM Identity Center User Guide.

- **Temporary IAM user permissions** – An IAM user or role can assume an IAM role to temporarily take on different permissions for a specific task.

- **Cross-account access** – You can use an IAM role to allow someone (a trusted principal) in a different account to access resources in your account. Roles are the primary way to grant cross-account access. However, with some AWS services, you can attach a policy directly to a resource (instead of using a role as a proxy). To learn the difference between roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the IAM User Guide.

- **Cross-service access** – Some AWS services use features in other AWS services. For example, when you make a call in a service, it's common for that service to run applications in Amazon EC2 or store objects in Amazon S3. A service might do this using the calling principal's permissions, using a service role, or using a service-linked role.

- **Forward access sessions (FAS)** – When you use an IAM user or role to perform actions in AWS, you are considered a principal. When you use some services, you might perform an
action that then initiates another action in a different service. FAS uses the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. FAS requests are only made when a service receives a request that requires interactions with other AWS services or resources to complete. In this case, you must have permissions to perform both actions. For policy details when making FAS requests, see Forward access sessions.

• **Service role** – A service role is an [IAM role](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_roles-service.html) that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.

• **Service-linked role** – A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

• **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see Using an IAM role to grant permissions to applications running on Amazon EC2 instances in the IAM User Guide.

To learn whether to use IAM roles or IAM users, see When to create an IAM role (instead of a user) in the IAM User Guide.

### Managing access using policies

You control access in AWS by creating policies and attaching them to AWS identities or resources. A policy is an object in AWS that, when associated with an identity or resource, defines their permissions. AWS evaluates these policies when a principal (user, root user, or role session) makes a request. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in AWS as JSON documents. For more information about the structure and contents of JSON policy documents, see Overview of JSON policies in the IAM User Guide.

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.
By default, users and roles have no permissions. To grant users permission to perform actions on the resources that they need, an IAM administrator can create IAM policies. The administrator can then add the IAM policies to roles, and users can assume the roles.

IAM policies define permissions for an action regardless of the method that you use to perform the operation. For example, suppose that you have a policy that allows the `iam:GetRole` action. A user with that policy can get role information from the AWS Management Console, the AWS CLI, or the AWS API.

### Identity-based policies

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see [Creating IAM policies](https://docs.aws.amazon.com/IAM/latest/userguide/creating-identity-based-policies.html) in the IAM User Guide.

Identity-based policies can be further categorized as *inline policies* or *managed policies*. Inline policies are embedded directly into a single user, group, or role. Managed policies are standalone policies that you can attach to multiple users, groups, and roles in your AWS account. Managed policies include AWS managed policies and customer managed policies. To learn how to choose between a managed policy or an inline policy, see [Choosing between managed policies and inline policies](https://docs.aws.amazon.com/IAM/latest/userguide/choosing-between-managed-policies-and-inline-policies.html) in the IAM User Guide.

### Resource-based policies

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM `role trust policies` and Amazon S3 `bucket policies`. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must [specify a principal](https://docs.aws.amazon.com/IAM/latest/userguide/using-policy-syntax.html#using-policy-syntax-principal) in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

Resource-based policies are inline policies that are located in that service. You can't use AWS managed policies from IAM in a resource-based policy.
Access control lists (ACLs)

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

Amazon S3, AWS WAF, and Amazon VPC are examples of services that support ACLs. To learn more about ACLs, see Access control list (ACL) overview in the Amazon Simple Storage Service Developer Guide.

Other policy types

AWS supports additional, less-common policy types. These policy types can set the maximum permissions granted to you by the more common policy types.

- **Permissions boundaries** – A permissions boundary is an advanced feature in which you set the maximum permissions that an identity-based policy can grant to an IAM entity (IAM user or role). You can set a permissions boundary for an entity. The resulting permissions are the intersection of an entity's identity-based policies and its permissions boundaries. Resource-based policies that specify the user or role in the Principal field are not limited by the permissions boundary. An explicit deny in any of these policies overrides the allow. For more information about permissions boundaries, see Permissions boundaries for IAM entities in the IAM User Guide.

- **Service control policies (SCPs)** – SCPs are JSON policies that specify the maximum permissions for an organization or organizational unit (OU) in AWS Organizations. AWS Organizations is a service for grouping and centrally managing multiple AWS accounts that your business owns. If you enable all features in an organization, then you can apply service control policies (SCPs) to any or all of your accounts. The SCP limits permissions for entities in member accounts, including each AWS account root user. For more information about Organizations and SCPs, see How SCPs work in the AWS Organizations User Guide.

- **Session policies** – Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary session for a role or federated user. The resulting session's permissions are the intersection of the user or role's identity-based policies and the session policies. Permissions can also come from a resource-based policy. An explicit deny in any of these policies overrides the allow. For more information, see Session policies in the IAM User Guide.
Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see Policy evaluation logic in the IAM User Guide.

How AWS services work with IAM

To get a high-level view of how AWS services work with most IAM features, see AWS services that work with IAM in the IAM User Guide.

To learn how to use a specific AWS service with IAM, see the security section of the relevant service's User Guide.

Troubleshooting AWS identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with AWS and IAM.

Topics

- I am not authorized to perform an action in AWS
- I am not authorized to perform iam:PassRole
- I want to allow people outside of my AWS account to access my AWS resources

I am not authorized to perform an action in AWS

If you receive an error that you're not authorized to perform an action, your policies must be updated to allow you to perform the action.

The following example error occurs when the mateojackson IAM user tries to use the console to view details about a fictional my-example-widget resource but doesn't have the fictional awes:GetWidget permissions.

User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform: awes:GetWidget on resource: my-example-widget

In this case, the policy for the mateojackson user must be updated to allow access to the my-example-widget resource by using the awes:GetWidget action.
If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

I am not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the iam:PassRole action, your policies must be updated to allow you to pass a role to AWS.

Some AWS services allow you to pass an existing role to that service instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named marymajor tries to use the console to perform an action in AWS. However, the action requires the service to have permissions that are granted by a service role. Mary does not have permissions to pass the role to the service.

User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform: iam:PassRole

In this case, Mary's policies must be updated to allow her to perform the iam:PassRole action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

I want to allow people outside of my AWS account to access my AWS resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether AWS supports these features, see How AWS services work with IAM.
- To learn how to provide access to your resources across AWS accounts that you own, see Providing access to an IAM user in another AWS account that you own in the IAM User Guide.
- To learn how to provide access to your resources to third-party AWS accounts, see Providing access to AWS accounts owned by third parties in the IAM User Guide.
- To learn how to provide access through identity federation, see Providing access to externally authenticated users (identity federation) in the IAM User Guide.
• To learn the difference between using roles and resource-based policies for cross-account access, see [How IAM roles differ from resource-based policies](#) in the [IAM User Guide](#).

**Compliance Validation for this AWS Product or Service**

To learn whether an AWS service is within the scope of specific compliance programs, see [AWS services in Scope by Compliance Program](#) and choose the compliance program that you are interested in. For general information, see [AWS Compliance Programs](#).

You can download third-party audit reports using AWS Artifact. For more information, see [Downloading Reports in AWS Artifact](#).

Your compliance responsibility when using AWS services is determined by the sensitivity of your data, your company's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

• **Security and Compliance Quick Start Guides** – These deployment guides discuss architectural considerations and provide steps for deploying baseline environments on AWS that are security and compliance focused.

• **Architecting for HIPAA Security and Compliance on Amazon Web Services** – This whitepaper describes how companies can use AWS to create HIPAA-eligible applications.

---

**Note**

Not all AWS services are HIPAA eligible. For more information, see the [HIPAA Eligible Services Reference](#).

• **AWS Compliance Resources** – This collection of workbooks and guides might apply to your industry and location.

• **AWS Customer Compliance Guides** – Understand the shared responsibility model through the lens of compliance. The guides summarize the best practices for securing AWS services and map the guidance to security controls across multiple frameworks (including National Institute of Standards and Technology (NIST), Payment Card Industry Security Standards Council (PCI), and International Organization for Standardization (ISO)).

• **Evaluating Resources with Rules** in the [AWS Config Developer Guide](#) – The AWS Config service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
• **AWS Security Hub** – This AWS service provides a comprehensive view of your security state within AWS. Security Hub uses security controls to evaluate your AWS resources and to check your compliance against security industry standards and best practices. For a list of supported services and controls, see [Security Hub controls reference](https://docs.aws.amazon.com/securityhub/latest/userguide/security-hub-reference.html).

• **AWS Audit Manager** – This AWS service helps you continuously audit your AWS usage to simplify how you manage risk and compliance with regulations and industry standards.

This AWS product or service follows the [shared responsibility model](https://aws.amazon.com/sharedResponsibility/) through the specific Amazon Web Services (AWS) services it supports. For AWS service security information, see the [AWS service security documentation page](https://docs.aws.amazon.com/service-authorization/latest/reference/list_services.html) and [AWS services that are in scope of AWS compliance efforts by compliance program](https://aws.amazon.com/compliance/service-authorization/).

### Resilience for this AWS Product or Service

The AWS global infrastructure is built around AWS Regions and Availability Zones.

AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking.

With Availability Zones, you can design and operate applications and databases that automatically fail over between zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about AWS Regions and Availability Zones, see [AWS Global Infrastructure](https://aws.amazon.com/global-infrastructure/).

This AWS product or service follows the [shared responsibility model](https://aws.amazon.com/sharedResponsibility/) through the specific Amazon Web Services (AWS) services it supports. For AWS service security information, see the [AWS service security documentation page](https://docs.aws.amazon.com/service-authorization/latest/reference/list_services.html) and [AWS services that are in scope of AWS compliance efforts by compliance program](https://aws.amazon.com/compliance/service-authorization/).

### Infrastructure Security for this AWS Product or Service

This AWS product or service uses managed services, and therefore is protected by the AWS global network security. For information about AWS security services and how AWS protects infrastructure, see [AWS Cloud Security](https://aws.amazon.com/security/). To design your AWS environment using the best practices for infrastructure security, see [Infrastructure Protection](https://aws.amazon.com/architecture/security-pillar/) in [Security Pillar AWS Well-Architected Framework](https://aws.amazon.com/wellarchitected/).
You use AWS published API calls to access this AWS Product or Service through the network. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.
- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

This AWS product or service follows the shared responsibility model through the specific Amazon Web Services (AWS) services it supports. For AWS service security information, see the AWS service security documentation page and AWS services that are in scope of AWS compliance efforts by compliance program.
Migrate from version 1.x to 2.x of the AWS SDK for Java

The AWS SDK for Java 2.x is a major rewrite of the 1.x code base built on top of Java 8+. It includes many updates, such as improved consistency, ease of use, and strongly enforced immutability. This section describes the major features that are new in version 2.x, and provides guidance on how to migrate your code to version 2.x from 1.x.

Topics

• **What’s new in version 2**
• **Migration step-by-step instructions with example**
• **What’s different between the AWS SDK for Java 1.x and 2.x**
• **Use the SDK for Java 1.x and 2.x side-by-side**

What’s new in version 2

• You can configure your own HTTP clients. See [HTTP transport configuration](#).
• Async clients feature non-blocking I/O support and return `CompletableFuture` objects. See [Asynchronous programming](#).
• Operations that return multiple pages have autopaginated responses. This way, you can focus your code on what to do with the response, without the need to check for and get subsequent pages. See [Pagination](#).
• SDK start time performance for AWS Lambda functions is improved. See [SDK start time performance improvements](#).
• Version 2.x supports a new shorthand method for creating requests.

Example

dynamoDbClient.putItem(request -> request.tableName(TABLE))

For more details about the new features and to see specific code examples, refer to the other sections of this guide.

• **Quick Start**
• **Setting up**
Migration step-by-step instructions with example

This section provides a step-by-step guide to migrate your application that currently uses the SDK for Java v1.x to the SDK for Java 2.x. The first part presents an overview of the steps followed by a detailed example of a migration.

The steps that are covered here describe a migration of a normal use case, where the application calls AWS services using model-driven service clients. If you need to migrate code that uses higher level APIs such as S3 Transfer Manager or CloudFront presigning, refer to the section under the section called “What's different between 1.x and 2.x” table of contents.

The approach described here is a suggestion. You may use other techniques and leverage your IDE's code editing features to reach the same result.

Overview of steps

1. Begin by adding the SDK for Java 2.x BOM

By adding the Maven BOM (Bill of Materials) element for the SDK for Java 2.x to your POM file, you ensure that all of the v2 dependency you need are from the same version. Your POM can contain both v1 and v2 dependencies. This allows you to incrementally migrate your code rather than change it all at once.

SDK for Java 2.x BOM

```xml
<dependencyManagement>
    <dependencies>
        <dependency>
            <groupId>software.amazon.awssdk</groupId>
            <artifactId>bom</artifactId>
            <version>2.24.3</version>
            <type>pom</type>
            <scope>import</scope>
        </dependency>
    </dependencies>
</dependencyManagement>
```
You can find the latest version on the Maven Central Repository.

2. Search files for v1 class import statements

By scanning the files in your application for v1 imports, you'll find v2 dependencies to add to your Maven POM file.

3. Determine the v2 Maven dependencies from the v1 import statements

After you find all unique v1 import statements, you can determine the corresponding Maven artifact for the v2 dependency by referring to the Package name to dependency mapping table.

4. Add v2 dependency elements to the POM file

Update the Maven POM file with dependency elements determined in step 3.

5. In the Java files, incrementally change over the v1 classes to v2 classes

As you do this make the necessary changes to support the v2 API such as using builders instead of constructors and using fluent getters and setters.

6. Remove v1 Maven dependencies from the POM and v1 imports from files

As you do this make the necessary changes to support the v2 API such as using builders instead of constructors and using the fluent getters and setters.

7. Refactor the code to use v2 API enhancements

After the code successfully compiles as passes tests, you can take advantage of v2 enhancements such as using a different HTTP client or paginators to simplify code. This is an optional step.

Example migration

In this example, we migrate an application that uses the SDK for Java v1 and accesses several AWS services. We work through the following v1 method in detail in step 5. This is one method in a class that contains eight methods and there are 32 classes in the application.
v1 method to migrate

Only the v1 SDK imports are listed below from the Java file.

```java
import com.amazonaws.ClientConfiguration;
import com.amazonaws.regions.Region;
import com.amazonaws.regions.RegionUtils;
import com.amazonaws.services.ec2.AmazonEC2Client;
import com.amazonaws.services.ec2.model.AmazonEC2Exception;
import com.amazonaws.services.ec2.model.CreateTagsRequest;
import com.amazonaws.services.ec2.model.DescribeInstancesRequest;
import com.amazonaws.services.ec2.model.DescribeInstancesResult;
import com.amazonaws.services.ec2.model.TerminateInstancesRequest;

private static List<Instance> getRunningInstances(AmazonEC2Client ec2, List<String> instanceIds) {
    List<Instance> runningInstances = new ArrayList<>();
    try {
        DescribeInstancesRequest request = new DescribeInstancesRequest()
                .withInstanceIds(instanceIds);
        DescribeInstancesResult result;
        do {
            // DescribeInstancesResponse is a paginated response, so use tokens with
            // multiple requests.
            result = ec2.describeInstances(request);
            request.setNextToken(result.getNextToken());   // Prepare request for next
            page.
            for (final Reservation r : result.getReservations()) {
                for (final Instance instance : r.getInstances()) {
                    LOGGER.info("Examining instanceId: "+ instance.getInstanceId());
                    // if instance is in a running state, add it to runningInstances
                    list.
                    if (RUNNING_STATES.contains(instance.getState().getName())) {
                        runningInstances.add(instance);
                    }
                }
            }
        } while (result.getNextToken() != null);
    } catch (final AmazonEC2Exception exception) {
        // if instance isn't found, assume its terminated and continue.
    }
}
```

Example migration
if (exception.getErrorCode().equals(NOT_FOUND_ERROR_CODE)) {
    LOGGER.info("Instance probably terminated; moving on.");
} else {
    throw exception;
}
return runningInstances;

1. Add v2 Maven BOM

Add the Maven BOM for the SDK for Java 2.x to the POM along side any other dependencies in the dependencyManagement section. If your POM file has the BOM for v1 of the SDK, leave it for now. It will be removed at a later step.

POM Dependency management at outset

```xml
<dependencyManagement>
    <dependencies>
        <dependency>
            <groupId>org.example</groupId> <!--Existing dependency in POM. -->
            <artifactId>bom</artifactId>
            <version>1.3.4</version>
            <type>pom</type>
            <scope>import</scope>
        </dependency>
        ...
        <dependency>
            <groupId>com.amazonaws</groupId> <!--Existing v1 BOM dependency. -->
            <artifactId>aws-java-sdk-bom</artifactId>
            <version>1.11.1000</version>
            <type>pom</type>
            <scope>import</scope>
        </dependency>
        ...
        <dependency>
            <groupId>software.amazon.awssdk</groupId> <!--Add v2 BOM dependency. -->
            <artifactId>bom</artifactId>
            <version>2.24.3</version>
            <type>pom</type>
            <scope>import</scope>
        </dependency>
    </dependencies>
</dependencyManagement>
```
2. Search files for v1 class import statements

Search the application's code for unique occurrences of `import com.amazonaws.services`. This helps us determine the v1 dependencies used by the project. If your application has a Maven POM file with v1 dependencies listed, you can use this information instead.

For this example we use the `ripgrep (rg)` command to search the code base.

From the root of your code base, execute the following `ripgrep` command. After `ripgrep` finds the import statements, they are piped to the `cut`, `sort`, and `uniq` commands to isolate the service names.

```
rg --no-filename 'import\s+com\..amazonaws\..services' | cut -d '.' -f 4 | sort | uniq
```

For this application, the following is logged to the console.

```
autoscaling
cloudformation
ce2
identitymanagement
```

This indicates that there was at least one occurrence of each of the following package names used in import statements. For our purposes, the individual class names don't matter. We just need to find the services that are used.

```
com.amazonaws.services.autoscaling.*
com.amazonaws.services.cloudformation.*
com.amazonaws.services.ec2.*
com.amazonaws.services.identitymanagement.*
```

3. Determine the v2 Maven dependencies from the v1 import statements

The service names for v1 that we isolated from Step 2—for example autoscaling and cloudformation—can be mapped to the same v2 service name for the most part. Since the v2 Maven artifactId matches the service name in most cases, you have the information you need to add dependency blocks to your POM file.

The following table shows how we can determine the v2 dependencies.
### AWS SDK for Java 2.x

#### Developer Guide for version 2.x

<table>
<thead>
<tr>
<th>v1 service name</th>
<th>maps to ...</th>
<th>v2 service name</th>
<th>maps to ...</th>
<th>v2 Maven dependency</th>
</tr>
</thead>
<tbody>
<tr>

|                  |             |                 |             | &lt;groupId&gt;software.amazon.awssdk&lt;/groupId&gt;  
|                  |             |                 |             | &lt;artifactId&gt; autoscaling &lt;/artifactId&gt;  
|                  |             |                 |             | &lt;/dependency&gt; |
| **cloudformation** |             | **cloudformation** |             |                     |
| com.amazonaws.services. cloudformation.* | | software.amazon.awssdk.cloudformation.* | | &lt;dependency&gt;  
|                  |             |                 |             | &lt;groupId&gt;software.amazon.awssdk&lt;/groupId&gt;  
|                  |             |                 |             | &lt;artifactId&gt; cloudformation &lt;/artifactId&gt;  
|                  |             |                 |             | &lt;/dependency&gt; |
| **identitymanagement*** |             | **iam** |             |                     |
| com.amazonaws.services. identitymanagement.* | | software.amazon.awssdk.iam.* | | &lt;dependency&gt;  
|                  |             |                 |             | &lt;groupId&gt;software.amazon.awssdk&lt;/groupId&gt;  
|                  |             |                 |             | &lt;artifactId&gt; iam&lt;/artifactId&gt;  
|                  |             |                 |             | &lt;/dependency&gt; |

* The identitymanagement to iam mapping is an exception where the service name used in the package name differs between versions.
4. Add v2 dependency elements to the POM file

In step 3, we determined the four dependency blocks that need to be added to the POM file. We don't need to add a version because we have specified the BOM in step 1. After the imports are added, our POM file has the following dependency elements.

```xml
...<dependencies>...
  <dependency>
    <groupId>software.amazon.awssdk</groupId>
    <artifactId>autoscaling</artifactId>
  </dependency>
  <dependency>
    <groupId>software.amazon.awssdk</groupId>
    <artifactId>iam</artifactId>
  </dependency>
  <dependency>
    <groupId>software.amazon.awssdk</groupId>
    <artifactId>cloudformation</artifactId>
  </dependency>
  <dependency>
    <groupId>software.amazon.awssdk</groupId>
    <artifactId>ec2</artifactId>
  </dependency>
...</dependencies>...
```

5. In the Java files, incrementally change over the v1 classes to v2 classes

In the method that we are migrating, we see

- An EC2 service client from `com.amazonaws.services.ec2.AmazonEC2Client`.
- Several EC2 model classes used. For example `DescribeInstancesRequest` and `DescribeInstancesResult`.

```java
import com.amazonaws.ClientConfiguration;
import com.amazonaws.regions.Region;
import com.amazonaws.regions.RegionUtils;
import com.amazonaws.services.ec2.AmazonEC2Client;
```
import com.amazonaws.services.ec2.model.AmazonEC2Exception;
import com.amazonaws.services.ec2.model.CreateTagsRequest;
import com.amazonaws.services.ec2.model.DescribeInstancesRequest;
import com.amazonaws.services.ec2.model.DescribeInstancesResult;
import com.amazonaws.services.ec2.model.Instance;
import com.amazonaws.services.ec2.model.InstanceStateName;
import com.amazonaws.services.ec2.model.Reservation;
import com.amazonaws.services.ec2.model.Tag;
import com.amazonaws.services.ec2.model.TerminateInstancesRequest;
...
private static List<Instance> getRunningInstances(AmazonEC2Client ec2, List<String> instanceIds)
    List<Instance> runningInstances = new ArrayList<>();
    try {
        DescribeInstancesRequest request = new DescribeInstancesRequest()
            .withInstanceIds(instanceIds);
        DescribeInstancesResult result;
        do {
            // DescribeInstancesResponse is a paginated response, so use tokens with multiple re
            result = ec2.describeInstances(request);
            request.setNextToken(result.getNextToken());   // Prepare request for next
            page.
            for (final Reservation r : result.getReservations()) {
                for (final Instance instance : r.getInstances()) {
                    LOGGER.info("Examining instanceId: "+ instance.getInstanceId());
                    // if instance is in a running state, add it to runningInstances
                    list.
                    if (RUNNING_STATES.contains(instance.getState().getName())) {
                        runningInstances.add(instance);
                    }
                }
            }
        } while (result.getNextToken() != null);
    } catch (final AmazonEC2Exception exception) {
        // if instance isn't found, assume its terminated and continue.
        if (exception.getErrorCode().equals(NOT_FOUND_ERROR_CODE)) {
            LOGGER.info("Instance probably terminated; moving on.");
        } else {
            throw exception;
        }
    }
    return runningInstances;
Our goal is to replace all v1 imports with v2 imports. We proceed one class at a time.

a. Replace import statement or class name

We see that the first parameter to the describeRunningInstances method is a v1 AmazonEC2Client instance. Do one of the following:

- Replace the import for com.amazonaws.services.ec2.AmazonEC2Client with software.amazon.awssdk.services.ec2.Ec2Client and change AmazonEC2Client to Ec2Client.
- Change the parameter type to Ec2Client and let the IDE prompt us for the correct import. Our IDE will prompt us to import the v2 class because the client names differ—AmazonEC2Client and Ec2Client. This approach does not work if the class name is the same in both versions.

b. Replace v1 model classes with v2 equivalents

After the change to the v2 Ec2Client, if we use an IDE, we see compilation errors in the following statement.

```java
result = ec2.describeInstances(request);
```

The compilation error results from using an instance of v1’s DescribeInstancesRequest as a parameter to the v2 Ec2Client describeInstances method. To fix, make the following replacement or import statements.

<table>
<thead>
<tr>
<th>replace</th>
<th>with</th>
</tr>
</thead>
<tbody>
<tr>
<td>import com.amazonaws.services.ec2.model.DescribeInstancesRequest</td>
<td>import software.amazon.awssdk.services.ec2.model.DescribeInstancesRequest</td>
</tr>
</tbody>
</table>

c. Change v1 constructors to v2 builders.

We still see compilation errors because there are **no constructors on v2 classes**. To fix, make the following change.
**d. Replace v1 *Result response objects with v2 *Response equivalents**

A consistent difference between v1 and v2 is that all response objects in v2 end with *Response instead of *Result. Replace the v1 DescribeInstancesResult import to the v2 import, DescribeInstancesResponse.

**d. Make API changes**

The following statement needs a few changes.

```java
request.setNextToken(result.getNextToken());
```

In v2, **setter methods** do not use the set or with prefix. Getter methods prefixed with get are also gone in the SDK for Java 2.x

Model classes, such as the request instance, are immutable in v2, so we need to create a new DescribeInstancesRequest with a builder.

In v2, the statement becomes the following.

```java
request = DescribeInstancesRequest.builder()
  .nextToken(result.nextToken())
  .build();
```

d. Repeat until method compiles with v2 classes

Continue with the rest of the code. Replace v1 imports with v2 imports and fix the compilation errors. Refer to the v2 API Reference and What's different reference as needed.
After we migrate this single method, we have the following v2 code.

```java
import com.amazonaws.ClientConfiguration;
import com.amazonaws.regions.Region;
import com.amazonaws.regions.RegionUtils;
import com.amazonaws.services.ec2.AmazonEC2Client;
import com.amazonaws.services.ec2.model.AmazonEC2Exception;
import com.amazonaws.services.ec2.model.CreateTagsRequest;
import com.amazonaws.services.ec2.model.InstanceStateName;
import com.amazonaws.services.ec2.model.Tag;
import com.amazonaws.services.ec2.model.TerminateInstancesRequest;
import software.amazon.awssdk.services.ec2.Ec2Client;
import software.amazon.awssdk.services.ec2.model.DescribeInstancesRequest;
import software.amazon.awssdk.services.ec2.model.DescribeInstancesResponse;
import software.amazon.awssdk.services.ec2.model.Ec2Exception;
import software.amazon.awssdk.services.ec2.model.Instance;
import software.amazon.awssdk.services.ec2.model.Reservation;
...
private static List<Instance> getRunningInstances(Ec2Client ec2, List<String> instanceIds) {
    List<Instance> runningInstances = new ArrayList<>();
    try {
        DescribeInstancesRequest request = DescribeInstancesRequest.builder()
            .instanceIds(instanceIds)
            .build();
        DescribeInstancesResponse result;
        do {
            // DescribeInstancesResponse is a paginated response, so use tokens
            result = ec2.describeInstances(request);
            request = DescribeInstancesRequest.builder()   // Prepare request for
                .nextToken(result.nextToken())
            .build();
            for (final Reservation r : result.reservations()) {
                for (final Instance instance : r.instances()) {
                    // if instance is in a running state, add it to
                    runningInstances list.
                    if (RUNNING_STATES.contains(instance.state().nameAsString())) {
                        runningInstances.add(instance);
                    }
                }
            }
        } while (result.nextToken() != null);
    }
    return runningInstances;
}
```
Because we are migrating a single method in a Java file with eight methods, we have a mix of v1 and v2 imports as we work through the file. We added the last six import statements as we performed the steps.

After we migrate all the code, there will be no more v1 import statements.

6. Remove v1 Maven dependencies from the POM and v1 imports from files

After we migrate all v1 code in the file, we have the following v2 SDK import statements.

```java
import software.amazon.awssdk.core.client.config.ClientOverrideConfiguration;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.regions.ServiceMetadata;
import software.amazon.awssdk.services.ec2.Ec2Client;
import software.amazon.awssdk.services.ec2.model.CreateTagsRequest;
import software.amazon.awssdk.services.ec2.model.DescribeInstancesRequest;
import software.amazon.awssdk.services.ec2.model.DescribeInstancesResponse;
import software.amazon.awssdk.services.ec2.model.Ec2Exception;
import software.amazon.awssdk.services.ec2.model.Instance;
import software.amazon.awssdk.services.ec2.model.InstanceStateName;
import software.amazon.awssdk.services.ec2.model.Reservation;
import software.amazon.awssdk.services.ec2.model.Tag;
import software.amazon.awssdk.services.ec2.model.TerminateInstancesRequest;
```

After we migrate all files in our application, we no longer need the v1 dependencies in our POM file. Remove the v1 BOM from the dependencyManagement section, if using, and all v1 dependency blocks.
7. Refactor the code to use v2 API enhancements

For the snippet we have been migrating, we can optionally use a v2 paginator and let the SDK manage the token-based requests for more data.

We can replace the entire do clause with the following.

```java
DescribeInstancesIterable responses =
ec2.describeInstancesPaginator(request);

responses.reservations().stream()
    .forEach(reservation -> reservation.instances()
        .forEach(instance -> {
            if (RUNNING_STATES.contains(instance.state().nameAsString())) {
                runningInstances.put(instance.instanceId(),
                instance);
            }
        })
    )
```

What's different between the AWS SDK for Java 1.x and 2.x

This section describes the main changes to be aware of when converting an application from using the AWS SDK for Java version 1.x to version 2.x.

**Package name change**

A noticeable change from the SDK for Java 1.x to the SDK for Java 2.x is the package name change. Package names begin with `software.amazon.awssdk` in SDK 2.x, whereas the SDK 1.x uses `com.amazonaws`.

These same names differentiate Maven artifacts from SDK 1.x to SDK 2.x. Maven artifacts for the SDK 2.x use the `software.amazon.awssdk` groupId, whereas the SDK 1.x uses the `com.amazonaws` groupId.

There are a few times when your code requires a `com.amazonaws` dependency for a project that otherwise uses only SDK 2.x artifacts. One example of this is when you work with server-side AWS Lambda. This was shown in the Set up an Apache Maven project section earlier in this guide.
Note

Several package names in the SDK 1.x contain v2. The use of v2 in this case usually means that code in the package is targeted to work with version 2 of the service. Since the full package name begins with com.amazonaws, these are SDK 1.x components. Examples of these package names in the SDK 1.x are:

- com.amazonaws.services.dynamodbv2
- com.amazonaws.retry.v2
- com.amazonaws.services.apigatewayv2
- com.amazonaws.services.simpleemailv2

Adding version 2.x to your project

Maven is the recommended way to manage dependencies when using the AWS SDK for Java 2.x. To add version 2.x components to your project, update your pom.xml file with a dependency on the SDK.

Example

```xml
<dependencyManagement>
  <dependencies>
    <dependency>
      <groupId>software.amazon.awssdk</groupId>
      <artifactId>bom</artifactId>
      <version>2.16.1</version>
      <type>pom</type>
      <scope>import</scope>
    </dependency>
  </dependencies>
</dependencyManagement>

<dependencies>
  <dependency>
    <groupId>software.amazon.awssdk</groupId>
    <artifactId>dynamodb</artifactId>
  </dependency>
</dependencies>
```
You can also use version 1.x and 2.x side-by-side as you migrate your project to version 2.x.

**Immutable POJOs**

Clients and operation request and response objects are now immutable and cannot be changed after creation. To reuse a request or response variable, you must build a new object to assign to it.

**Example of updating a request object in 1.x**

```java
DescribeAlarmsRequest request = new DescribeAlarmsRequest();
DescribeAlarmsResult response = cw.describeAlarms(request);
request.setNextToken(response.getNextToken());
```

**Example of updating a request object in 2.x**

```java
DescribeAlarmsRequest request = DescribeAlarmsRequest.builder().build();
DescribeAlarmsResponse response = cw.describeAlarms(request);
request = DescribeAlarmsRequest.builder()
    .nextToken(response.nextToken())
    .build();
```

**Setter and getter methods**

In the AWS SDK for Java 2.x, setter method names don't include the set or with prefix. For example, *.withEndpoint() is now *.endpoint().

Getter method names do not use the get prefix.

**Example of using setter methods in 1.x**

```java
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard()
    .withRegion("us-east-1")
    .build();
```

**Example of using setter methods in 2.x**

```java
DynamoDbClient client = DynamoDbClient.builder()
    .region(Region.US_EAST_1)
```
Example of using getter methods in 1.x

```java
String token = request.getNextToken();
```

Example of using getter methods in 2.x

```java
String token = request.nextToken();
```

### Model class names

Model class names that represent service responses end with `Response` in v2 instead of `Result` that v1 uses.

**Example of class names that represent a response in v1**

- `CreateApiKeyResult`
- `AllocateAddressResult`

**Example of class names that represent a response in v2**

- `CreateApiKeyResponse`
- `AllocateAddressResponse`

### Migration status of libraries and utilities

**SDK for Java libraries and utilities**

The following table lists the migration status of libraries and utilities for the SDK for Java.

<table>
<thead>
<tr>
<th>Version 1.12.x name</th>
<th>Version 2.x name</th>
<th>Since version in 2.x</th>
</tr>
</thead>
<tbody>
<tr>
<td>DynamoDBMapper</td>
<td><strong>DynamoDbEnhancedClient</strong></td>
<td>2.12.0</td>
</tr>
<tr>
<td>Waiters</td>
<td><strong>Waiters</strong></td>
<td>2.15.0</td>
</tr>
<tr>
<td>CloudFrontUrlSigner, CloudFrontCookieSigner</td>
<td><strong>CloudFrontUtilities</strong></td>
<td>2.18.33</td>
</tr>
</tbody>
</table>
### Version 1.12.x name

<table>
<thead>
<tr>
<th>Name used with version 2.x of the SDK for Java</th>
<th>Since version</th>
</tr>
</thead>
<tbody>
<tr>
<td>TransferManager</td>
<td>2.19.0</td>
</tr>
<tr>
<td>EC2 Metadata client</td>
<td>2.19.29</td>
</tr>
<tr>
<td>S3 URI parser</td>
<td>2.20.41</td>
</tr>
<tr>
<td>IAM Policy Builder</td>
<td>2.20.126</td>
</tr>
<tr>
<td>Amazon SQS Client-side Buffering</td>
<td></td>
</tr>
<tr>
<td>Progress Listeners</td>
<td></td>
</tr>
<tr>
<td>S3TransferManager</td>
<td></td>
</tr>
<tr>
<td>EC2 Metadata client</td>
<td></td>
</tr>
<tr>
<td>S3 URI parser</td>
<td></td>
</tr>
<tr>
<td>IAM Policy Builder</td>
<td></td>
</tr>
<tr>
<td>Automatic Request Batching</td>
<td></td>
</tr>
<tr>
<td>Progress Listeners</td>
<td></td>
</tr>
<tr>
<td>not yet released</td>
<td></td>
</tr>
<tr>
<td>not yet released</td>
<td></td>
</tr>
</tbody>
</table>

### Related libraries

The following table lists libraries that are released separately but work with the SDK for Java 2.x.

<table>
<thead>
<tr>
<th>Name used with version 2.x of the SDK for Java</th>
<th>Since version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon S3 Encryption Client</td>
<td>3.0.0¹</td>
</tr>
<tr>
<td>AWS Database Encryption Client for DynamoDB</td>
<td>3.0.0²</td>
</tr>
</tbody>
</table>

¹The encryption client for Amazon S3 is available by using the following Maven dependency.

```xml
<dependency>
  <groupId>software.amazon.encryption.s3</groupId>
  <artifactId>amazon-s3-encryption-client-java</artifactId>
  <version>3.x</version>
</dependency>
```

²The AWS Database Encryption Client for DynamoDB is available by using the following Maven dependency.

```xml
<dependency>
</dependency>
```
Migration details for libraries and utilities

- S3 Transfer Manager
- EC2 metadata utility
- CloudFront presigning
- S3 URI parsing

Client changes

Client builders

You must create all clients using the client builder method. Constructors are no longer available.

Example of creating a client in version 1.x

```java
AmazonDynamoDB ddbClient = AmazonDynamoDBClientBuilder.defaultClient();
AmazonDynamoDBClient ddbClient = new AmazonDynamoDBClient();
```

Example of creating a client in version 2.x

```java
DynamoDbClient ddbClient = DynamoDbClient.create();
DynamoDbClient ddbClient = DynamoDbClient.builder().build();
```

Client class names

All client class names are now fully camel cased and no longer prefixed by Amazon. These changes are aligned with names used in the AWS CLI.

Example of class names in 1.x

```java
AmazonDynamoDB
AWSACMPCAAsyncClient
```
# Example of class names in 2.x

</tbody>
</table>

**Client creation defaults**

In version 2.x, the following changes have been made to the default client creation logic.
• The default credential provider chain for S3 no longer includes anonymous credentials. You must manually specify anonymous access to S3 by using the AnonymousCredentialsProvider.

• The following environment variables related to default client creation are different.

<table>
<thead>
<tr>
<th>1.x</th>
<th>2.x</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS_CBOR_DISABLED</td>
<td>CBOR_ENABLED</td>
</tr>
<tr>
<td>AWS_ION_BINARY_DISABLE</td>
<td>BINARY_ION_ENABLED</td>
</tr>
</tbody>
</table>

• The following system properties related to default client creation are different.

<table>
<thead>
<tr>
<th>1.x</th>
<th>2.x</th>
</tr>
</thead>
<tbody>
<tr>
<td>com.amazonaws.sdk.disableEc2Metadata</td>
<td>aws.disableEc2Metadata</td>
</tr>
<tr>
<td>com.amazonaws.sdk.ec2MetadataServiceEndpointOverride</td>
<td>aws.ec2MetadataServiceEndpoint</td>
</tr>
<tr>
<td>com.amazonaws.sdk.disableCbor</td>
<td>aws.cborEnabled</td>
</tr>
<tr>
<td>com.amazonaws.sdk.disableIonBinary</td>
<td>aws.binaryIonEnabled</td>
</tr>
</tbody>
</table>

• Version 2.x does not support the following system properties.

<table>
<thead>
<tr>
<th>1.x</th>
</tr>
</thead>
<tbody>
<tr>
<td>com.amazonaws.sdk.disableCertChecking</td>
</tr>
<tr>
<td>com.amazonaws.sdk.enableDefaultMetrics</td>
</tr>
<tr>
<td>com.amazonaws.sdk.enableThrottledRetry</td>
</tr>
<tr>
<td>com.amazonaws.regions.RegionUtils.fileOverride</td>
</tr>
<tr>
<td>com.amazonaws.regions.RegionUtils.disableRemote</td>
</tr>
<tr>
<td>com.amazonaws.services.s3.disableImplicitGlobalClients</td>
</tr>
</tbody>
</table>
com.amazonaws.sdk.enableInRegionOptimizedMode

- Loading Region configuration from a custom endpoints.json file is no longer supported.

**Client configuration**

In 1.x, SDK client configuration was modified by setting a ClientConfiguration instance on the client or client builder. In version 2.x, the client configuration is split into separate configuration classes. With the separate configuration classes, you can configure different HTTP clients for async versus synchronous clients but still use the same ClientOverrideConfiguration class.

**Example of client configuration in version 1.x**

```java
AmazonDynamoDBClientBuilder.standard()
    .withClientConfiguration(clientConfiguration)
    .build()
```

**Example of synchronous client configuration in version 2.x**

```java
ProxyConfiguration.Builder proxyConfig = ProxyConfiguration.builder();

ApacheHttpClient.Builder httpClientBuilder =
    ApacheHttpClient.builder()
    .proxyConfiguration(proxyConfig.build());

ClientOverrideConfiguration.Builder overrideConfig =
    ClientOverrideConfiguration.builder();

DynamoDbClient client =
    DynamoDbClient.builder()
    .httpClientBuilder(httpClientBuilder)
    .overrideConfiguration(overrideConfig.build())
    .build();
```

**Example of asynchronous client configuration in version 2.x**

```java
NettyNioAsyncHttpClient.Builder httpClientBuilder =
    NettyNioAsyncHttpClient.builder();
```
ClientOverrideConfiguration.Builder overrideConfig =
    ClientOverrideConfiguration.builder();

ClientAsyncConfiguration.Builder asyncConfig =
    ClientAsyncConfiguration.builder();

DynamoDbAsyncClient client =
    DynamoDbAsyncClient.builder()
    .httpClientBuilder(httpClientBuilder)
    .overrideConfiguration(overrideConfig.build())
    .asyncConfiguration(asyncConfig.build())
    .build();

### HTTP clients

#### Notable changes

- In version 2.x, you can change which HTTP client to use at runtime by specifying an implementation using `clientBuilder.httpClientBuilder`.

- When you pass an HTTP client by using `clientBuilder.httpClient` to a service client builder, the HTTP client is not closed by default if the service client closes. This allows you to share HTTP clients between service clients.

- Asynchronous HTTP clients now use non-blocking IO.

- Some operations now use HTTP/2 for improved performance.

<td>--------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>clientBuilder.endpointOverride(URI.create(&quot;http:///...&quot;))</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Credentials provider changes**

This section provides a mapping of the name changes of credentials provider classes and methods between versions 1.x and 2.x of the AWS SDK for Java.

**Notable differences**

- The default credentials provider loads system properties before environment variables in version 2.x. For more information, see Using credentials.

- The constructor method is replaced with the `create` or `builder` methods.

**Example**

```
DefaultCredentialsProvider.create();
```

- Asynchronous refresh is no longer set by default. You must specify it with the `builder` of the credentials provider.

**Example**

```
ContainerCredentialsProvider provider = ContainerCredentialsProvider.builder()
    .asyncCredentialUpdateEnabled(true)
    .build();
```

- You can specify a path to a custom profile file using the `ProfileCredentialsProvider.builder()`.

**Example**

```
ProfileCredentialsProvider profile = ProfileCredentialsProvider.builder()
    .profileFile(ProfileFile.builder().content(Paths.get("myProfileFile.file"))).build();
```
- Profile file format has changed to more closely match the AWS CLI. For details, see Configuring the AWS CLI in the AWS Command Line Interface User Guide.

</tbody>
</table>
Region changes

This section describes the changes implemented in the AWS SDK for Java 2.x for using the Region and Regions classes.

Region configuration

- Some AWS services don't have Region specific endpoints. When using those services, you must set the Region as Region.AWS_GLOBAL or Region.AWS_CN_GLOBAL.

Example

```java
Region region = Region.AWS_GLOBAL;
```

- com.amazonaws.regions.Regions and com.amazonaws.regions.Region classes are now combined into one class, software.amazon.awssdk.regions.Region.

Method and class name mappings

The following tables map Region related classes between versions 1.x and 2.x of the AWS SDK for Java. You can create an instance of these classes using the of() method.

Example

```java
RegionMetadata regionMetadata = RegionMetadata.of(Region.US_EAST_1);
```

1.x Regions class method changes

<table>
<thead>
<tr>
<th>1.x</th>
<th>2.x</th>
</tr>
</thead>
<tbody>
<tr>
<td>Regions.fromName</td>
<td>Region.of</td>
</tr>
<tr>

<td>Region.getServiceEndpoint</td>
<td>ServiceMetadata.endpointFor(Region)</td>
</tr>
<tr>
<td>Region.isServiceSupported</td>
<td>ServiceMetadata.regions().contains(Region)</td>
</tr>
</tbody>
</table>
Operations, requests and responses changes

In v2.x of the SDK for Java, requests are passed to a client operation. For example, `DynamoDbClient's PutItemRequest` is passed to `DynamoDbClient.putItem` operation. These operations return a response from the AWS service, such as a `PutItemResponse`.

Version 2.x of the SDK for Java has the following changes from 1.x.

- Operations with multiple response pages now have a `Paginator` method for automatically iterating over all items in the response.
- You cannot mutate requests and responses.
- You must create requests and responses with a static builder method instead of a constructor. For example, 1.x's `new PutItemRequest().withTableName(...)` is now `PutItemRequest.builder().tableName(...).build()`.
- Operations support a short-hand way to create requests: `dynamoDbClient.putItem(request -> request.tableName(...)).`

Streaming operations

Streaming operations such as Amazon S3 `getObject` and `putObject` methods now support non-blocking I/O. As a result, the request and response POJOs no longer take an `InputStream` as a parameter. Instead, for synchronous requests the request object accepts `RequestBody`, which is a stream of bytes. The asynchronous equivalent accepts an `AsyncRequestBody`.

Example of Amazon S3 `putObject` operation in 1.x

```java
s3client.putObject(BUCKET, KEY, new File(file_path));
```

Example of Amazon S3 `putObject` operation in 2.x

```java
s3client.putObject(PutObjectRequest.builder()
    .bucket(BUCKET)
    .key(KEY)
    .build(),
    RequestBody.of(Paths.get("myfile.in")));
```

In parallel, a streaming response object accepts a `ResponseTransformer` for synchronous clients and an `AsyncResponseTransformer` for asynchronous clients.
Example of Amazon S3 getObject operation in 1.x

```java
S3Object o = s3.getObject(bucket, key);
S3ObjectInputStream s3is = o.getObjectContent();
FileOutputStream fos = new FileOutputStream(new File(key));
```

Example of Amazon S3 getObject operation in 2.x

```java
s3client.getObject(GetObjectRequest.builder().bucket(bucket).key(key).build(),
            ResponseTransformer.toFile(Paths.get("key")));
```

In the SDK for Java 2.x, streaming response operations have an AsBytes method to load the response into memory and simplify common in-memory type conversions.

**Exception changes**

Exception class names, their structures, and their relationships have changed. `software.amazon.awssdk.core.exception.SdkException` is the new base `Exception` class that all the other exceptions extend.

This table maps the exception class name changes.

<table>
<thead>
<tr>
<th>1.x</th>
<th>2.x</th>
</tr>
</thead>
<tbody>
<tr>
<td>com.amazonaws.SdkBaseException</td>
<td>software.amazon.awssdk.core.exception.SdkException</td>
</tr>
<tr>
<td>com.amazonaws.AmazonClientException</td>
<td></td>
</tr>
<tr>
<td>com.amazonaws.SdkClientException</td>
<td>software.amazon.awssdk.core.exception.SdkClientException</td>
</tr>
<tr>
<td>com.amazonaws.AmazonServiceException</td>
<td>software.amazon.awssdk.awscore.exception.AwsServiceException</td>
</tr>
</tbody>
</table>

The following table maps the methods on exception classes between version 1.x and 2.x.
<table>
<thead>
<tr>
<th>1.x</th>
<th>2.x</th>
</tr>
</thead>
<tbody>
<tr>
<td>AmazonServiceException.getRequestId</td>
<td>SdkServiceException.requestId</td>
</tr>
<tr>
<td>AmazonServiceException.getServiceName</td>
<td>AwsServiceException.awsErrorDetails().serviceName</td>
</tr>
<tr>
<td>AmazonServiceException.getErrorCode</td>
<td>AwsServiceException.awsErrorDetails().errorCode</td>
</tr>
<tr>
<td>AmazonServiceException.getErrorMessage</td>
<td>AwsServiceException.awsErrorDetails().errorMessage</td>
</tr>
<tr>
<td>AmazonServiceException.getStatusCode</td>
<td>AwsServiceException.awsErrorDetails().sdkHttpResponse().statusCode</td>
</tr>
<tr>
<td>AmazonServiceException.getHttpHeaders</td>
<td>AwsServiceException.awsErrorDetails().sdkHttpResponse().headers</td>
</tr>
<tr>
<td>AmazonServiceException.rawResponse</td>
<td>AwsServiceException.awsErrorDetails().rawResponse</td>
</tr>
</tbody>
</table>

### Serialization changes

The SDK for Java v1.x and v2.x differ in how they serialize List objects to request parameters.

The SDK for Java 1.x does not serialize an empty list, whereas the SDK for Java 2.x serializes an empty list as an empty parameter.

For example, consider a service with a SampleOperation that takes a SampleRequest. The SampleRequest accepts two parameters—a String type `str1` and List type `listParam`—as shown in the following examples.

**Example of SampleOperation in 1.x**

```java
SampleRequest v1Request = new SampleRequest()
```
Wire-level logging shows that the listParam parameter is not serialized.

```
Action=SampleOperation&Version=2011-01-01&str1=TestName
```

**Example of SampleOperation in 2.x**

```
sampleServiceV2Client.sampleOperation(b -> b
    .str1("TestName"));
```

Wire-level logging shows that the listParam parameter is serialized with no value.

```
Action=SampleOperation&Version=2011-01-01&str1=TestName&listParam=
```

**Service-specific changes**

**Amazon S3 changes**

SDK for Java 2.x disables anonymous access by default. As a result, you must enable anonymous access by using the AnonymousCredentialsProvider.

**Operation name changes**

Many of the operation names for the Amazon S3 client have changed in the AWS SDK for Java 2.x. In version 1.x, the Amazon S3 client is not generated directly from the service API. This results in inconsistency between the SDK operations and the service API. In version 2.x, we now generate the Amazon S3 client to be more consistent with the service API.

The following table shows the operation names in the two versions.

**Amazon S3 Operation names**

### Amazon SNS changes

An SNS client can no longer access SNS topics in Regions other than the Region that it is configured to access.
Amazon SQS changes

An SQS client can no longer access SQS queues in Regions other than the Region that it is configured to access.

Amazon RDS changes

The SDK for Java 2.x uses RdsUtilities#generateAuthenticationToken in place of the class RdsIamAuthTokenGenerator in 1.x.

Profile file changes

The AWS SDK for Java 2.x parses the profile definitions in ~/.aws/config and ~/.aws/credentials to more closely emulate the way the AWS CLI parses the files.

The SDK for Java 2.x:

- Resolves a ~/ or ~ followed by the file system's default path separator at the start of the path by checking, in order, $HOME, $USERPROFILE (Windows only), $HOMEDRIVE, $HOMEPATH (Windows only), and then the user.home system property.
- Looks for the AWS_SHARED_CREDENTIALS_FILE environment variable instead of AWS_CREDENTIAL_PROFILES_FILE.
- Silently drops profile definitions in configuration files without the word profile at the beginning of the profile name.
- Silently drops profile definitions that do not consist of alphanumeric, underscore or dash characters (after the leading profile word has been removed for configuration files).
- Merges settings of profile definitions duplicated within the same file.
- Merges settings of profile definitions duplicated in both the configuration and credentials files.
- Does NOT merge settings if both [profile foo] and [foo] are found in the same file.
- Uses settings in [profile foo] if both [profile foo] and [foo] are found in the configuration file.
- Uses the value of the last duplicated setting in the same file and profile.
- Recognizes both ; and # for defining a comment.
- Recognizes ; and # in profile definitions to define a comment, even if the characters are adjacent to the closing bracket.
• Recognizes ; and # to define a comment only in setting values only if they are preceded by whitespace.

• Recognizes ; and # and all following content in setting values if they are not preceded by whitespace.

• Considers role-based credentials the highest-priority credentials. The 2.x SDK always uses role-based credentials if the user specifies the role_arn property.

• Considers session-based credentials the second-highest-priority credentials. The 2.x SDK always uses session-based credentials if role-based credentials were not used and the user specifies the aws_access_key_id and aws_session_token properties.

• Uses basic credentials if role-based and session-based credentials are not used and the user specified the aws_access_key_id property.

### Changes in Waiters from version 1 to version 2

This topic details the changes in the functionality of Waiters from version 1 (v1) to version 2 (v2).

The following tables demonstrate the difference for DynamoDB waiters specifically. Waiters for other services follow the same pattern.

#### High-level changes

Waiters classes are in the same Maven artifact as the service.

**Behavior changes**

**Parallel transfer requires AWS CRT-based S3 client**

In the SDK for Java 2.x, the automatic parallel transfer feature (multipart upload/download) is available through the [AWS CRT-based S3 client](https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/javadoc/index.html#s3-transfer-manager). To enable the parallel transfer feature, you must explicitly add the [AWS Common Runtime (CRT) library](https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/javadoc/index.html#aws-crt-runtime) dependency for the maximized performance.

The AWS CRT-based S3 client alone—without using `S3TransferManager`—provides maximized performance of parallel transfers. `S3TransferManager v2` provides additional APIs that make it easier to transfer files and directories.

The ability for the `S3TransferManager` to perform parallel transfers depends on the how `S3TransferManager` is initiated and if the AWS Common Runtime (CRT) library has been declared as a dependency.

The following table describes three initialization scenarios for an `S3TransferManager v2` with and without the AWS CRT declared as a dependency.

<table>
<thead>
<tr>
<th><code>S3TransferManager v2 initialization approach</code></th>
<th>Is AWS CRT declared as a dependency?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Initialize the <code>S3TransferManager</code> without passing an <code>S3AsyncClient</code> instance</td>
<td>yes</td>
</tr>
</tbody>
</table>

*Static create method:*
### S3TransferManager v2 initialization approach

<table>
<thead>
<tr>
<th>Method</th>
<th>Is AWS CRT declared as a dependency?</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>S3TransferManager.create();</code></td>
<td>automatic parallel transfer enabled</td>
</tr>
<tr>
<td><strong>- OR -</strong></td>
<td>automatic parallel transfer disabled</td>
</tr>
<tr>
<td><strong>Builder method:</strong></td>
<td></td>
</tr>
<tr>
<td><code>S3TransferManager.builder().build();</code></td>
<td></td>
</tr>
</tbody>
</table>

#### Pass an S3AsyncClient instance that is built with one of the `crt*()` builder methods

- OR -

```java
S3AsyncClient s3AsyncClient = S3AsyncClient.crtBuilder().build();
S3TransferManager.builder().s3AsyncClient(s3AsyncClient).build();
```

- OR -

```java
S3AsyncClient s3AsyncClient = S3AsyncClient.crtCreate();
S3TransferManager.builder().s3AsyncClient(s3AsyncClient).build();
```
Pass an `S3AsyncClient` instance that is built with one of the standard builder methods so that the transfer manager has no reference to the CRT

```
S3AsyncClient s3AsyncClient = S3AsyncClient.builder().build();
S3TransferManager.builder().s3AsyncClient(s3AsyncClient).build();
```

- OR -

```
S3AsyncClient s3AsyncClient = S3AsyncClient.create();
S3TransferManager.builder().s3AsyncClient(s3AsyncClient).build();
```

Automatic parallel transfer disabled

Parallel download via byte-range fetches

When the automatic parallel transfer feature is enabled, the S3 Transfer Manager v2 uses byte-range fetches to retrieve specific portions of the object in parallel (multipart download). The way an object is downloaded with v2 does not depend on how the object was originally uploaded. All downloads can benefit from high throughput and concurrency.

In contrast, with S3 Transfer Manager v1, it does matter how the object was originally uploaded. The S3 Transfer Manager v1 retrieves the parts of the object the same way that the parts were uploaded. If an object was originally uploaded as a single object, the S3 Transfer Manager v1 is not able to accelerate the downloading process by using sub-requests.

Failure behavior

With S3 Transfer Manager v1, a directory transfer request fails if any sub-request fails. Unlike v1, the future returned from S3 Transfer Manager v2 completes successfully even if some sub-requests fail.

As a result, you should check for errors in the response by using the `CompletedDirectoryDownload.failedTransfers()` method or
CompletedDirectoryUpload.failedTransfers() method even when the future completes successfully.

Changes in the EC2 metadata utility from version 1 to version 2

This topic details the changes in the SDK for Java Amazon Elastic Compute Cloud (EC2) metadata utility from version 1 (v1) to version 2 (v2).

| Types of clients | Synchronous only utility methods: EC2MetadataUtils | Synchronous: Ec2MetadataClient  
|          |                                                                       | Asynchronous: Ec2MetadataAsyncClient |

¹ Latest version.  ² Latest version.

³ Notice the declaration of the apache-client module for v2. V2 of the EC2 metadata utility requires an implementation of the SdkHttpClient interface for the synchronous metadata client,
or the SdkAsyncHttpClient interface for the asynchronous metadata client. The ??? section shows the list of HTTP clients that you can use.

**Requesting metadata**

In v1, you use static methods that accept no parameters to request metadata for an EC2 resource. In contrast, you need to specify the path to the EC2 resource as a parameter in v2. The following table shows the different approaches.

<table>
<thead>
<tr>
<th>v1</th>
<th>v2</th>
</tr>
</thead>
<tbody>
<tr>
<td>String userMetaData = EC2MetadataUtils.getUserData();</td>
<td>Ec2MetadataClient client = Ec2MetadataClient.create();</td>
</tr>
<tr>
<td></td>
<td>Ec2MetadataResponse response = client.get(&quot;/latest/user-data&quot;);</td>
</tr>
<tr>
<td></td>
<td>String userMetaData = response.asString();</td>
</tr>
</tbody>
</table>

Refer to the [instance metadata categories](#) to find the path you need to supply to request a piece of metadata.

**Note**

When you use an instance metadata client in v2, you should aim to use the same client for all request to retrieve metadata.

**Behavior changes**

**JSON data**

On EC2, the locally running Instance Metadata Service (IMDS) returns some metadata as JSON formatted strings. One such example is the dynamic metadata of an [instance identity document](#).

The v1 API contains separate methods for each piece of instance identity metadata, whereas the v2 API directly returns the JSON string. To work with the JSON string, you can use the [Document API](#) to parse the response and navigate the JSON structure.
The following table compares how you retrieve metadata of an instance identity document in v1 and v2.

<table>
<thead>
<tr>
<th>Use case</th>
<th>v1</th>
<th>v2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Retrieve the Region</td>
<td><img src="example1" alt="v1 code" /></td>
<td><img src="example2" alt="v2 code" /></td>
</tr>
<tr>
<td>Retrieve the instance id</td>
<td><img src="example3" alt="v1 code" /></td>
<td><img src="example4" alt="v2 code" /></td>
</tr>
<tr>
<td>Retrieve the instance type</td>
<td><img src="example5" alt="v1 code" /></td>
<td><img src="example6" alt="v2 code" /></td>
</tr>
</tbody>
</table>
### Endpoint resolution differences

The following table shows the locations that the SDK checks to resolve the endpoint to IMDS. The locations are listed in descending priority.

<table>
<thead>
<tr>
<th>v1</th>
<th>v2</th>
</tr>
</thead>
<tbody>
<tr>
<td>System property: com.amazonaws.sdk.ec2MetadataServiceEndpoint0verride</td>
<td>Client builder configuration method: endpoint(...)</td>
</tr>
<tr>
<td>Environment variable: AWS_EC2_METADATA_SERVICE_ENDPOINT</td>
<td>System property: aws.ec2MetadataServiceEndpoint</td>
</tr>
<tr>
<td>Default Value: <a href="http://169.254.169.254">http://169.254.169.254</a></td>
<td>Config file: ~.aws/config with the ec2_metadata_service_endpoint setting</td>
</tr>
<tr>
<td></td>
<td>Value associated with resolved endpoint-mode</td>
</tr>
<tr>
<td></td>
<td>Default value: <a href="http://169.254.169.254">http://169.254.169.254</a></td>
</tr>
</tbody>
</table>

### Endpoint resolution in v2

When you explicitly set an endpoint by using the builder, that endpoint value takes priority over all other settings. When the following code executes, the aws.ec2MetadataServiceEndpoint system property and config file ec2_metadata_service_endpoint setting are ignored if they exist.

```java
Ec2MetadataClient client = Ec2MetadataClient
    .builder()
    .endpoint(URI.create("endpoint.to.use"))
```
**Endpoint-mode**

With v2, you can specify an endpoint-mode to configure the metadata client to use the default endpoint values for IPv4 or IPv6. Endpoint-mode is not available for v1. The default value used for IPv4 is **http://169.254.169.254** and **http://[fd00:ec2::254]** for IPv6.

The following table shows the different ways that you can set the endpoint mode in order of descending priority.

<table>
<thead>
<tr>
<th>Client builder configuration method: endpointMode(...)</th>
<th>Possible values</th>
</tr>
</thead>
<tbody>
<tr>
<td>EndpointMode.IPV4, EndpointMode.IPV6</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>System property</th>
<th>Possible values</th>
</tr>
</thead>
<tbody>
<tr>
<td>aws.ec2MetadataServiceEndpointMode</td>
<td>IPv4, IPv6 (case does not matter)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Config file: ~/.aws/config</th>
<th>Possible values</th>
</tr>
</thead>
<tbody>
<tr>
<td>ec2_metadata_service_endpoint setting</td>
<td>IPv4, IPv6 (case does not matter)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Not specified in the previous ways</th>
<th>Possible values</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPv4 is used</td>
<td></td>
</tr>
</tbody>
</table>

**How the SDK resolves endpoint or endpoint-mode in v2**

1. The SDK uses the value that you set in code on the client builder and ignores any external settings. Because the SDK throws an exception if both endpoint and endpointMode are called on the client builder, the SDK uses the endpoint value from whichever method you use.

2. If you do not set a value in code, the SDK looks to external configuration—first for system properties and then for a setting in the config file.
   a. The SDK first checks for an endpoint value. If a value is found, it is used.
b. If the SDK still hasn't found a value, the SDK looks for endpoint mode settings.

3. Finally, if the SDK finds no external settings and you have not configured the metadata client in code, the SDK uses the IPv4 value of http://169.254.169.254.

**IMDSv2**

Amazon EC2 defines two approaches to access instance metadata:

- Instance Metadata Service Version 1 (IMDSv1) – Request/response approach
- Instance Metadata Service Version 2 (IMDSv2) – Session-oriented approach

The following table compares how the Java SDKs work with IMDS.

<table>
<thead>
<tr>
<th></th>
<th>v1</th>
<th>v2</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMDSv2 is used by default</td>
<td>Always uses IMDSv2</td>
<td></td>
</tr>
<tr>
<td>Attempts to fetch a session token for each request and falls back to IMDSv1 if it fails to fetch a session token</td>
<td>Keeps a session token in an internal cache that is reused for multiple requests</td>
<td></td>
</tr>
</tbody>
</table>

The SDK for Java 2.x supports only IMDSv2 and does not fall back to IMDSv1.

**Configuration differences**

The following table lists the differing configuration options.

<table>
<thead>
<tr>
<th>Configuration</th>
<th>v1</th>
<th>v2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Retries</td>
<td>Configuration not available</td>
<td>Configurable through builder method retryPolicy(...)</td>
</tr>
<tr>
<td>HTTP</td>
<td>Connection timeout configurable through the AWS_METADATA_SERVICE_TIMEOUT</td>
<td>Configuration available by passing an HTTP client to the builder method httpClient(...) . The default</td>
</tr>
</tbody>
</table>
Configuration | v1 | v2
---|---|---
T environment variable. The default is 1 second. | connection timeout for HTTP clients is 2 seconds.

Example v2 HTTP configuration

The following example shows how you can configure the metadata client. This example configures the connection timeout and uses the Apache HTTP client.

```java
SdkHttpClient httpClient = ApacheHttpClient.builder()
    .connectionTimeout(Duration.ofSeconds(1))
    .build();

Ec2MetadataClient imdsClient = Ec2MetadataClient.builder()
    .httpClient(httpClient)
    .build();
```

### Refactored cookie headers in v2

In Java v1, the Java SDK delivers cookie headers as a `Map.Entry<String, String>`.

```java
Map.Entry<String, String> signatureMap = cookies.getSignature();
String signatureKey = signatureMap.getKey();  // "CloudFront-Signature"
String signatureValue = signatureMap.getValue();  // "[SIGNATURE_VALUE]"
```

The Java v2 SDK delivers the entire header as a single `String`. 
Changes in parsing Amazon S3 URIs from version 1 to version 2

This topic details the changes in parsing Amazon S3 URIs from version 1 (v1) to version 2 (v2).

High-level changes

To begin parsing an S3 URI in v1, you instantiate an AmazonS3URI by using a constructor. In v2 you call parseUri() on an instance of S3Utilities, to return an S3URI.

### Package name

|     | com.amazonaws.services.s3                                        | software.amazon.awssdk.services.s3                                |

### Class names

|     | AmazonS3URI                                                     | S3URI                                                             |

---

**1 Latest version.  2 Latest version.**
Behavior changes

URL encoding

v1 provides the option to pass in a flag to specify whether the URI should be URL encoded. The default value is `true`.

In v2, URL encoding is not supported. If you work with object keys or query parameters that have reserved or unsafe characters, you must URL encode them. For example you need to replace a whitespace " " with `%20`.

Use the SDK for Java 1.x and 2.x side-by-side

You can use both versions of the AWS SDK for Java in your projects.

The following shows an example of the `pom.xml` file for a project that uses Amazon S3 from version 1.x and DynamoDB from version 2.16.1.
Example Example of POM

This example shows a pom.xml file entry for a project that uses both 1.x and 2.x versions of the SDK.

```xml
<dependencyManagement>
  <dependencies>
    <dependency>
      <groupId>com.amazonaws</groupId>
      <artifactId>aws-java-sdk-bom</artifactId>
      <version>1.12.1</version>
      <type>pom</type>
      <scope>import</scope>
    </dependency>
    <dependency>
      <groupId>software.amazon.awssdk</groupId>
      <artifactId>bom</artifactId>
      <version>2.16.1</version>
      <type>pom</type>
      <scope>import</scope>
    </dependency>
  </dependencies>
</dependencyManagement>

<dependencies>
  <dependency>
    <groupId>com.amazonaws</groupId>
    <artifactId>aws-java-sdk-s3</artifactId>
  </dependency>
  <dependency>
    <groupId>software.amazon.awssdk</groupId>
    <artifactId>dynamodb</artifactId>
  </dependency>
</dependencies>
```
OpenPGP key for the AWS SDK for Java

All publicly available Maven artifacts for the AWS SDK for Java are signed using the OpenPGP standard. The public key that you need to verify the signature of an artifact is available in the following section.

Current key

The following table shows OpenPGP key information for the current releases of the SDK for Java 1x and SDK for Java 2.x.

<table>
<thead>
<tr>
<th>Key ID</th>

<tr>
<td>the section called “Get started”</td>
<td>Correct several snippets in the Get Started section of the DynamoDB Enhanced Client topic.</td>
<td>July 24, 2023</td>
</tr>
<tr>
<td>the section called “Proxy support”</td>
<td>Add HTTP proxy support information and examples for each HTTP client.</td>
<td>June 2, 2023</td>
</tr>
<tr>
<td>Reorganize the table of contents</td>
<td>Promote <a href="#">Code examples</a> section and <a href="#">Work with AWS services</a> to top-level TOC entries.</td>
<td>May 24, 2023</td>
</tr>
<tr>
<td>the section called “Add logging dependency”</td>
<td>Show Gradle dependencies in logging section.</td>
<td>May 23, 2023</td>
</tr>
<tr>
<td>the section called “Work with paginated results”</td>
<td>Update pagination topic.</td>
<td>May 18, 2023</td>
</tr>
<tr>
<td>the section called “Set up a Gradle project”</td>
<td>Update Gradle project setup.</td>
<td>May 3, 2023</td>
</tr>
<tr>
<td>DynamoDB Enhanced Client API</td>
<td>Rewritten DynamoDB Enhanced Client API topic released.</td>
<td>April 28, 2023</td>
</tr>
<tr>
<td>Update get started tutorial instructions</td>
<td>Maven archetype modified to include option for credentialsProvider; instructions modified accordingly.</td>
<td>April 11, 2023</td>
</tr>
<tr>
<td>the section called “Client recommendations”</td>
<td>Add HTTP client decision guidance</td>
<td>March 30, 2023</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date</td>
</tr>
<tr>
<td>---------------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------</td>
</tr>
<tr>
<td>IAM best practices updates</td>
<td>Updated guide to align with the IAM best practices. For more information, see Security best practices in IAM.</td>
<td>March 14, 2023</td>
</tr>
<tr>
<td>the section called “Reload profile credentials”</td>
<td>Add section on reloading profile credentials.</td>
<td>February 9, 2023</td>
</tr>
<tr>
<td>the section called “Configure AWS CRT-based HTTP clients”</td>
<td>Update topic for GA release.</td>
<td>February 8, 2023</td>
</tr>
<tr>
<td>the section called “Work with Amazon EC2 instance metadata”</td>
<td>Add guided example for Java SDK client for Amazon S3 instance metadata service.</td>
<td>February 1, 2023</td>
</tr>
<tr>
<td>the section called “Use a performant S3 client”</td>
<td>Add section for the AWS CRT-based S3 Client.</td>
<td>December 19, 2022</td>
</tr>
<tr>
<td>the section called “Transfer files and directories”</td>
<td>Update Amazon S3 Transfer Manager examples for GA release.</td>
<td>December 19, 2022</td>
</tr>
<tr>
<td>the section called “Best practices”</td>
<td>Added best practices section.</td>
<td>November 18, 2022</td>
</tr>
<tr>
<td>the section called “Load temporary credentials from an external process”</td>
<td>Added section on loading credentials from an external process.</td>
<td>November 15, 2022</td>
</tr>
<tr>
<td>the section called “Service client metrics”</td>
<td>Updated metric listing with HTTP client usage requirement.</td>
<td>November 9, 2022</td>
</tr>
<tr>
<td>the section called “Transfer files and directories”</td>
<td>Example code corrected.</td>
<td>November 2, 2022</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date</td>
</tr>
<tr>
<td>-----------------------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-------------------------</td>
</tr>
<tr>
<td>the section called “Reduce SDK startup time for AWS Lambda”</td>
<td>Updated section with additional options to reduce Lambda startup time.</td>
<td>November 1, 2022</td>
</tr>
<tr>
<td>the section called “HTTP clients”</td>
<td>Added configuration information to cover all HTTP clients in the SDK.</td>
<td>October 26, 2022</td>
</tr>
<tr>
<td>the section called “Logging”</td>
<td>Updated logging topic to include wire logging details for all HTTP clients.</td>
<td>October 4, 2022</td>
</tr>
<tr>
<td>the section called “AWS database services”</td>
<td>Added overview section of AWS database services and the SDK for Java 2.x.</td>
<td>September 13, 2022</td>
</tr>
<tr>
<td>EC2-Classic Networking is Retiring</td>
<td>EC2-Classic is retiring on August 15, 2022.</td>
<td>July 28, 2022</td>
</tr>
<tr>
<td>the section called “Additional authentication options”</td>
<td>Update to dependency required for single sign-on authentication.</td>
<td>July 18, 2022</td>
</tr>
<tr>
<td>the section called “Transport Layer Security (TLS)”</td>
<td>Update TLS security information.</td>
<td>April 8, 2022</td>
</tr>
<tr>
<td>the section called “Additional authentication options”</td>
<td>Added more information about setting up and using credentials.</td>
<td>February 22, 2021</td>
</tr>
<tr>
<td>the section called “Set up a GraalVM Native Image project”</td>
<td>New topic for setting up a GraalVM Native Image project.</td>
<td>February 18, 2021</td>
</tr>
<tr>
<td>the section called “Poll for resource states”</td>
<td>Waiters released; added topic for the new feature.</td>
<td>September 30, 2020</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date</td>
</tr>
<tr>
<td>-----------------------------------------------------------------------</td>
<td>-------------------------------------------------------</td>

<tr>
<td>the section called “Use SDK metrics”</td>
<td>Metrics released; added topic for the new feature.</td>
<td>August 17, 2020</td>
</tr>
<tr>
<td>the section called “Amazon SNS”</td>
<td>Added example topics for Amazon SNS.</td>
<td>May 30, 2020</td>
</tr>
<tr>
<td>the section called “Reduce SDK startup time for AWS Lambda”</td>
<td>Added AWS Lambda function performance topic.</td>
<td>May 29, 2020</td>
</tr>
<tr>
<td>the section called “Set the JVM TTL for DNS name lookups”</td>
<td>Added JVM TTL DNS caching topic.</td>
<td>April 27, 2020</td>
</tr>
<tr>
<td>the section called “Set up an Apache Maven project”, the section called “Set up a Gradle project”</td>
<td>New Maven and Gradle set up topics.</td>
<td>April 21, 2020</td>
</tr>
<tr>
<td>the section called “Transport Layer Security (TLS)”</td>
<td>Added TLS 1.2 to security section.</td>
<td>March 19, 2020</td>
</tr>
<tr>
<td>the section called “Subscribe to Amazon Kinesis Data Streams”</td>
<td>Added Kinesis stream examples.</td>
<td>August 2, 2018</td>
</tr>
<tr>
<td>the section called “Work with paginated results”</td>
<td>Added auto pagination topic.</td>
<td>April 5, 2018</td>
</tr>
<tr>
<td>???</td>
<td>Added example topics for IAM, Amazon EC2, CloudWatch and DynamoDB.</td>
<td>December 29, 2017</td>
</tr>
<tr>
<td>the section called “Amazon S3”</td>
<td>Added getobjects example for Amazon S3.</td>
<td>August 7, 2017</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date</td>
</tr>
<tr>
<td>---------------------------------------------</td>
<td>------------------------------------</td>
<td>---------------</td>
</tr>
<tr>
<td>the section called “Use asynchronous programming”</td>
<td>Added async topic.</td>
<td>August 4, 2017</td>
</tr>
<tr>
<td>GA release of the AWS SDK for Java 2.x</td>
<td>AWS SDK for Java version 2 (v2) released.</td>
<td>June 28, 2017</td>
</tr>
